Subject: Sample size

What was the approximate sample size of Row 2 U-bend tubes that we looked at? What I am trying to determine is how much actual independent verification of Con Ed did we actually do. (i.e., how much did we rely on them to provide the tubes that they thought were defective). I know that we looked at the four that are discussed in the IR before the High frequency +point, and then the additional four. after the high frequency probe, but how many other U-bends (1997 data) were reviewed by Caius and found not to have defects?

Does this question make make sense?
