Executive Summary

The Kiski Valley Water Pollution Control Authority (KVWPCA) operates a wastewater treatment plant in Leechburg, Pennsylvania approximately 25 miles (40 kilometers [km]) northeast of Pittsburgh. The facility separates solids from raw sewage, which are then dewatered using a belt filtration press. From 1976 to 1993, the dewatered sludge was incinerated, sterilized, and converted to ash. This ash was mixed with water, forming a slurry, and transferred to an on-site lagoon for storage. The ash lagoon is located in the east end of the KVWPCA property and covers approximately 4,000 square meters. Currently, as dewatered sludge is generated, it is accumulated and disposed of in a municipal landfill on a batch-type basis.

The lagoon is underlain by native clay, is 2 to 3 meters deep at the center, and currently contains approximately 9,000 cubic meters of ash. The lagoon is surrounded by a berm which is 2 to 3 meters high on the north, west, and south sides, diminishing to ground level at the east end.

In August 1993, the Pennsylvania Department of Environmental Resources (PADER) notified the United States Nuclear Regulatory Commission (USNRC) that they had measured elevated uranium activity in a sludge ash sample obtained from the ash lagoon. In September 1994, PADER provided the USNRC a "split" sample for independent analysis. The sample was analyzed by the Oak Ridge Institute for Science and Education (ORISE) and results confirmed PADER's analysis. In September 1994, the USNRC conducted surface and subsurface sampling in the ash lagoon. Analysis of the samples from the ash lagoon indicated that some of the samples contained concentrations of enriched uranium exceeding 900 picocuries per gram (pCi/g) which is higher than unrestricted use guidelines typically used by the USNRC for uranium in soil (30 pCi/g).

ORISE also conducted a radiological characterization survey of the ash lagoon and adjacent property. This included groundwater, surface water, soil, and sediment sampling. Releases of radioactive material from the ash lagoon were nondetectable. This indicates that past and current radiation doses are negligibly low at points of potential exposure both within and beyond the area in which access by the public is controlled. B. Koh & Associates, Inc. (Koh), completed radiological characterization of the contents of the lagoon in 1998.

1.0 Introduction

The Kiski Valley Water Pollution Control Authority (KVWPCA) operates a wastewater treatment plant in Leechburg, Pennsylvania. The facility separates solids from raw sewage, which are then dewatered using a belt filtration press. The dewatered sludge is sent to a municipal landfill. From 1976 to 1993, this ash was mixed with water, forming a slurry, and transferred to an on-site lagoon for storage. Currently, as ash is generated, it is accumulated and disposed of in a municipal landfill on a batch-type basis.

The KVWPCA is located on Pine Camp Road in Leechburg, Allegheny Township, Westmoreland County, Pennsylvania. The site is approximately 23 miles (40 kilometers [km]) northeast of Pittsburgh in southwestern Pennsylvania near the border of Westmoreland and Armstrong counties (Figure 1-1). The site is situated on gently rolling to flat topography that slopes eastward along the southern bank of the Kiskiminetas River below and west of the Norfolk and Southern railroad tracks.

In August 1993, the Pennsylvania Department of Environmental Resources (PADER) notified the United States Nuclear Regulatory Commission (USNRC) that they had measured elevated uranium activity in a sludge ash sample obtained from the ash lagoon. In September 1994, PADER provided the USNRC a "split" sample for independent analysis. The sample was analyzed by the Oak Ridge Institute for Science and Education (ORISE) and results confirmed PADER's analysis. In September 1994, the USNRC conducted surface and subsurface sampling in the ash lagoon. Analysis of the samples from the ash lagoon indicated that some of the samples contained concentrations of enriched uranium exceeding 900 picocuries per gram (pCi/g) which is higher than the unrestricted use guidelines of 30 pCi/g typically used by the USNRC for enriched uranium in soil (USNRC, 1996).

1.1 Purpose and Scope of Remedial Investigation

The purpose of this Remedial Investigation (RI) report is to support the Feasibility Study (FS) by providing site characterization information and assessment of the no-response radiation dose from the resident farmer future use of the site. This report will establish a baseline for assessment of various remedial action alternatives and assessment of the compliance of those projected doses with 10 CFR Part 20, Subpart E limits. The projected doses are those that might

be expected from activities on the site consistent with successful implementation of remedial actions.

1.2 Program Objectives

The objective of this RI is to:

- Provide information concerning the physical characterization of the environmental setting and waste characterization for later use in the FS report.
- Draw conclusions concerning the types and quantities of waste present at the site, the potential for migration of contamination from the site, and the potential for adverse human health and environmental effects if no action is taken at the site and exposure occurs. This goal is achieved by evaluating (a) historical and operational information about the site, (b) potential contaminants of concern, (c) potential migration pathways, (d) potential receptors, (e) exposure, and (f) contaminant toxicity. The result of this evaluation is a characterization of the risks posed by the site through a baseline dose assessment if no action is taken at the site.
- Provide information concerning the preliminary screening of alternatives.
- Identify contaminant-specific and location-specific applicable or relevant and appropriate requirements (ARAR) for the contaminants of concern as identified by the dose assessment.

1.3 Report Organization

The remainder of this report is organized into the following sections. Section 2.0 discusses the characterization of environmental setting, includes the location of the site, and describes its characteristics on a regional and site-specific basis using available geographic, demographic, climate, topographic, geologic, and biological data. Section 3.0 describes the site history and current conditions and includes the results of the site investigations to date. Section 4.0 discusses the baseline dose assessment and the methodology used. Section 5.0 identifies the Preliminary Remedial Action Goals (PRAG). Section 6.0 presents the conclusions and recommendations of this report. References are included in Section 7.0.

2.0 Characterization of Environmental Setting

2.1 Geography

KVWPCA is located in Leechburg, Allegheny Township, Westmoreland County, Pennsylvania. The site is approximately 23 miles (40 km) northeast of Pittsburgh located in southwestern Pennsylvania near the border of Westmoreland and Armstrong counties. The site is situated on gently rolling to flat topography that slopes eastward along the southern bank of the Kiskiminetas River and is west of the Northern and Southern railroad tracks.

2.2 Demography

Land use within the vicinity of the site is mixed, consisting of medium-sized residential communities and individual rural residences, small farms with croplands and pastures, idle farmland, forestlands, and light industrial areas. Allegheny Township has a population of 8,002 people. The borough of Leechburg has a total of 1,193 housing units and Westmoreland County has seen a growth of 10 percent (152,200 to 167,700) from the 1990 to 2000 census count. There are expected to be three new housing developments and a commercial development within the next few years in Allegheny Township. The closest housing development and existing community are in Pine Run Camp, just west of KVWPCA. Some residences within this community are located within 600 feet (200 meters) west of the site. Several industrial buildings and a shopping complex are located within 1.5 miles (2 km) southwest of the site.

2.3 Current/Future Land Use

The site is currently used as a wastewater treatment facility and has an incinerator ash lagoon constructed in 1975. The treatment plant services thirteen participating municipalities from the surrounding area. Residential, commercial, and industrial wastewater is piped to the plant through a network of interceptor pipes and eight remote pumping stations. The system presently is designed to serve an equivalent population of 50,000 people. The treatment facility includes primary settling tanks for solids separation, fine bubble diffuser aeration tanks to sustain the activated sludge process, and final solids settling and chlorine application tanks for sterilization of treated wastewater prior to discharge.

The settled solids withdrawn from the primary tanks and the waste-activated sludge solids generated by the biological process are thickened, then aerobically digested prior to mechanical

dewatering by a belt filter press. From 1976 to 1993, the thickened and dewatered sludge plus grits and screenings were incinerated in a seven-hearth furnace. Prior to installation of the pneumatic dry ash handling system, ash from the incinerator collected in a hopper where it was mixed with water to form slurry. The slurry was then pumped to the ash lagoon via a discharge pipe. Use of the impoundment was discontinued in July 1993 with the installation of a dry ash handling system. Currently, as dewatered sludge is generated, it is accumulated and disposed of in a municipal landfill on a batch-type basis.

2.4 Meteorology and Climatology

Westmoreland County has a humid, continental-type climate, with temperatures ranging from an average of 14 degrees Fahrenheit (°F) to 82 °F. The predominant air mass influencing the climate is a polar, continental mass from Canada. It moves into the region from almost due south from the Hudson Bay region or the Canadian Rockies. In the summer, there are frequent invasions of air from the Gulf of Mexico, with resulting spells of warm, humid weather. The last spring temperature of 32 °F usually occurs in late April and the first in late October. There is a wide variation in the time of the first and last frosts over a radius of 25 miles (40 km) from the center of Pittsburgh due to terrain differences.

The average annual precipitation is about 37 inches and the distribution of precipitation is relatively even throughout the year. During the winter, approximately one-fourth of the precipitation occurs as snow. Measurable snow covers the ground an average of 33 days per year. The wettest weather at most of the climatologic stations in western Pennsylvania occurs in June and July.

Seven months of the year, April through October, have sunshine more than 50 percent of the possible time. During the remaining five months cloudiness is heavier because the track of migratory storms from west to east is closer to the area and because of the frequent periods of cloudy, showery weather associated with northwest winds from across the Great Lakes. Cold air drainage induced by the hills leads to the frequent formation of fog which can persist in the river valleys during the colder months.

2.5 Local and Regional Topography

The site is located in the central portion of the Appalachian Plateau physiographic province. This province is characterized by rounded hills and steep-sided valleys. The site is approximately 780 feet above mean seal level (MSL). The site latitude is 40 degrees 36 minutes north, and the longitude is 79 degrees 35 minutes west. The majority of the region is drained by the Allegheny River and tributaries, such as the Kiskiminetas River. The ground surface in the region is maturely dissected by large river valleys and tributaries in the areas between the large valleys. This regional drainage system features many and varied slopes, with small areas of nearly flat land along valley bottoms and in uplands.

The upland flats represent remnants of old erosional surfaces or peneplains. The Harrisburg peneplain, which has been identified in this region was formed in the Tertiary period, some time between 2 million and 60 million years ago. This peneplain occurs at an elevation of approximately 1,250 feet above MSL in northern Westmoreland County. Late Tertiary time was characterized by periods of relative quiet with gradual periods of uplift. These periods of uplift entrenched most of the major streams in the bedrock. The topography along the southwest side of the river has point bar deposits which is an indication of where the meandering river once flowed. These deposits consist of lower terrace deposits of gravel and sand with pebbles of igneous rocks.

2.6 Local and Regional Geology and Seismology

Soils in the site vicinity were developed on alluvial deposits in the stream valleys. Soil types found on the site are Philo silt loam (Ph) and Sequatchie silt loam (SeA). The Philo Series soils are located along the floodplain of the Kiskiminetas River and consist of deep, moderately well drained soils. The Sequatchie silt loam soils are low terrace deposits that are located along the banks of the Kiskiminetas River. The KVWPCA is located approximately mid-center on a bench terrace of the Kiskiminetas River.

Overburden deposits in the site vicinity consist of valley fill deposits, Pleistocene-aged sand and gravel deposits of glacio-fluvial origin, and clay deposits of Pleistocene and Recent age. Stratigraphically, the sand and gravel outwash deposits form the base of the alluvial sequence and overlie relatively flat-lying bedrock. The sand and gravel deposits are overlain by Recent alluvial fill.

The geological units in this region are Pennsylvanian Age, Allegheny Group. The Allegheny Group is composed of the Freeport Formation, Kittanning Formation, Vanport Limestone, and Clarion Formation and consists of cyclic sequences of sandstone, shale, limestone, clay, and coal. Above the Pennsylvanian units are Quaternary terrace deposits of clay, sand, and gravel.

The site lies on the western limb of a small anticlinal fold between the Duquesne-Fairmont Syncline and the eastern limb of the Leechburg-McHaddon Anticline. This small fold creates a slight dip of from 1 to 2 degrees to the southwest. The axial trace of this fold curves near the southwest portion of the site and plunges southward.

No active faults or other active tectonism has been reported within 30 miles (50 km) of the site. Historically, large earthquakes in eastern North America generally have occurred in three regions: the Mississippi Valley, the St. Lawrence Valley, and near Charleston, South Carolina. Pennsylvania is relatively free of seismic activity, although seismic events have been documented in the southeastern and northwestern parts of the state. By far the most active seismic zone in the state is the Lancaster seismic zone, approximately 200 miles southeast of the site. Since 1738, about 24 earthquakes have been reported in the Lancaster zone, with magnitudes ranging from 2.6 to 4.1 on the Richter scale. The northwest part of the state is the next most active, on a line from Erie southward along the Ohio border. Six earthquakes have been reported in this area between 1852 and 1985. One of them, with an epicenter at Conneaut Lake, approximately 75 miles from the site, had a reported magnitude of 3.2. No earthquake epicenters have been documented within 60 miles of the site.

The site area is believed to be relatively aseismic. It is in the interior of a stable cratonic plate, far from any plate boundaries, which are the focus of nearly all damaging earthquakes. The maximum credible earthquake for this region would be minor.

2.7 Groundwater Hydrology

The site generally drains into the Kiskiminetas River. Localized groundwater flows in an easterly direction towards the Kiskiminetas River. The bedrock of the Allegheny Group is a reliable source of small to moderate supplies of groundwater for domestic use. Groundwater occurs principally in the fractures and pore spaces of the sandstones and along the joints and

bedding planes in the shales. The alluvium in the site vicinity is generally permeable; however, well yields vary considerably depending upon the thickness and permeability of the deposits. The average well yield for the Allegheny Group is 5 gallons per minute, although higher yields have been reported for wells drilled into the sandstones.

Test boring logs for the four site monitoring wells (MW-1 through MW-4) indicate that the subsurface beneath the lagoon consists of alluvial fill comprised of clay, silty clay in the unsaturated zone, and sand and gravel deposits in the saturated zone. Groundwater was encountered in the test borings at depths ranging from 15 feet below ground surface at MW-1 to 26 feet below ground surface at MW-2 and MW-3. Site monitoring wells are screened above bedrock in alluvial fill and intercept the sand and gravel deposits. Test boring logs and well installation logs are provided in Appendix A.

Well yields seen in the site monitoring wells were less than 1 gallon per minute. Because sand and gravel deposits were only encountered at the bottom of the test boring for monitoring well MW-2, well yields in this well were insufficient for sampling during the most recent sampling event in October 2001.

2.8 Surface Water Hydrology

There are no surface impoundments or wetlands on site. The surface drainage from the site predominantly flows northeast directly into the Kiskiminetas River. According to the National Wetland Inventory Map for Northwest Vandergrift Quadrangle, the Kiskiminetas River is defined as a palustrine [P], unconsolidated bottom [UB], and intermittently exposed/permanent [Z] (Figure 2-1). There are two nearby tributaries of the Kiskiminetas River north and south of the site. Pine Run flows into the Kiskiminetas River south of the site and just north of the town of West Vandergrift. The other tributary is unnamed and is north of the site and the residential area of Pine Run Camp.

The Kiskiminetas River flows into the Allegheny River about 8 miles from the site and is a navigable river as defined by the United States Army Corps of Engineers. The river borders the site along the northeast side, and it flows in a northwest direction. Yellow Creek Lake, Conemaugh River, Loyalhanna Lake, and several other smaller reservoirs regulate the flow regime of the river. The highest daily mean flow for the Kiskiminetas River near Vandergrift

during the year 2000 was 9,890 ft^3/s and the lowest mean flow was 253 ft^3/s. The surface elevation of the site is 785 feet above MSL near the Kiskiminetas River and only varies slightly across the site.

According to the Federal Emergency Management Agency (FEMA) Flood Insurance Rate Map for the area (FEMA, 1997) most of the site falls within the 100-year and 500-year floodplains. Although no base flood elevation is given for the site, a flood elevation of 789 feet (National Geodetic Vertical Datum [NGVD]) is given for the lower reach of Pine Run above the site. The top of the ash lagoon is given as 793.0 feet.

2.9 Natural Resources

There are two economic natural resources in the immediate area, coal and natural gas. Locally the Upper Freeport Coal has been deep mined in the outcrop areas surrounding the site. The deep-mined area surrounding the site is west of the Kiskiminetas River from the town of Oklahoma to the town of Bagdad.

A natural gas well is located on the site property. The gas well is owned by Apollo Gas Company and is identified as well No. 736.

2.10 Ecology

The terrestrial ecosystem of the area is characterized by the presence of deciduous wooded areas, croplands, orchards, and an old field located on the site itself. Kiskiminetas River borders the site on the northeastern side.

Western Pennsylvania, including Pittsburgh and surrounding areas, is considered part of the Western Allegheny Plateau. The region is characterized by hilly terrain. Omernik (1986) defines the natural vegetation type as mixed mesophytic forest which typically contains maple (Acer), buckeye (Aesculus), beech (Fagus), tuliptree (Liriodendron tulipifera), oak (Quercus), and linden (Tilia).

A vegetative community typical of disturbed areas is found on the site. These communities characteristically contain a large proportion of herbaceous biennial and perennial species including:

- Queen Anne's lace (Daucus carota)
- Teasal (Dipsacus sylvestris)
- White sweet clover (Melilotus alba)
- Yellow sweet clover (M. officinalis)
- Dandelion (Tavaxacum officinale)
- Milkweed (Aselepias syriaca)
- Chickory (Chicorium intybus)
- Crown vetch (Caronilla varia)
- Goldenrod (Solidago sp.)
- Common ragweed (Ambrosia artemisiifolia)
- Evening primrose (Oenothera biennis)
- Yarrow (Achillea millefolium)
- Pigweed (Amoranthus retroflex)
- Purslane (Portulaca olevacea)
- Black-eyed susan (Rudbeckia hirta)
- Spring beauty (Claytonia virginica)
- Trillium (Trillium sp.).

The presence of wooded areas, open fields, croplands, orchards, and small streams presents a diversity of habitat types, which could potentially support a wide diversity of wildlife. Mammal species found in western Pennsylvania which inhabit such areas include:

- Opossum (Didelphis marsupialis)
- Raccoon (Procyon lotor)
- Masked shrew (Sorex cinereus)
- Least shrew (Cryptotis parua)
- Hairytail mole (Parascalops breweri)
- Striped skunk (Mephitis mephitis)
- Woodchuck (Marmota monax)
- Red fox (Vulpes fulva)
- Gray fox (Urocyon cinereoargentcus)
- Eastern chipmunk (Tamias striatus)
- Eastern gray squirrel (Sciurus carolinensis)
- Fox squirrel (S. niger)
- Southern flying squirrel (Glaucomys volans)
- White-footed mouse (Peromyscus leucopus)
- Deer mouse (P. maniculatus)

- Meadow vole (Microtus pennsylvanicus)
- Pine vole (Pitymys pinetorum)
- Eastern cottontail (Sylvilaqus floridanus)
- Whitetail deer (Odocoileus virginianus)
- Long-tailed weasel (Mustela frenata)
- Black bear (Ursus americanus).

Bird species commonly found in this area of Pennsylvania include:

- Eeastern screech owl (Otus asia)
- Great horned owl (Bubo virginianus)
- Ruffed grouse (Bonasa umbellus)
- American crow (Corvus brachyrhynchos)
- Mourning dove (Zenaida macroura)
- Pileated woodpecker (Dryocopus pileatus)
- Red-headed woodpecker (Melanerpes erythrocephalus)
- Hairy woodpecker (Picoides villosus)
- Eastern wood pewee (Contopus virens)
- Red-eyed vireo (Vireo olivaceus)
- Yellow-throated vireo (V. flavifrons)
- American robin (Turdus migratorius)
- Northern oriole (Icterus galbula)
- Northern cardinal (Cardinalis cardinalis)
- Blue jay (Cyanocitta cristata)
- White-breasted nuthatch (Sitta carolinensis)
- Red-winged blackbird (Agelaius phoeniceus)
- European starling (Sturnus vulgaris).

Common fish species, which would be expected to inhabit the small streams near the site include:

- Fathead minnow (Pimephales promelas)
- Common shiner (Notropis carnatus)
- White sucker (Catostomus commersoni)
- Black bullhead (Ictalurus melas).

Common fish in the Kiskiminetas River include:

- Smallmouth bass (Micropterus dolomieu)
- Channel catfish (Ictalurus punctatus)

- Walleye (Stizostedion vitreum)
- Northern pike (Esox lucius)
- White bass (Morone chrysops)
- Muskellunge (Esox masquinongy)
- Comon carp (Cyprinus carpio)
- Common shiner (Notropis carnatus)
- Fathead minnow (Pimephales promelas).

3.0 Site History and Current Conditions

3.1 Site Description

3.1.1 Location and Description of KVWPCA Site

The KVWPCA facility is bounded on the north and east by the Kiskiminetas River and on the south and west by Norfolk and Southern railroad tracks (Figure 3-1). The Kiskiminetas River also forms the boundary of Armstrong County, immediately east of the plant. The treatment plant and the incinerator ash lagoon were constructed in 1975 on thirty-six acres of land owned by the KVWPCA. The KVWPCA purchased the property in 1972 to construct a wastewater treatment facility. Prior to its purchase, the land was used for farming.

The treatment plant services thirteen participating municipalities from the surrounding area. Residential, industrial, and commercial wastewater is piped to the plant through a network of interceptor pipes and eight remote pumping stations. The system, as presently built, is designed to serve an equivalent population of 50,000. The treatment facility includes primary settling tanks for solids separation, fine bubble diffuser aeration tanks to sustain the activated sludge process, and final solids settling and chlorine contact tanks for disinfection of the treated wastewater prior to discharge.

The settled solids withdrawn from the primary tanks and the waste-activated sludge solids generated by the biological process were concentrated and thickened prior to mechanical dewatering by a belt filter press. From 1976 to 1993, the dewatered sludge plus grits and screenings were incinerated in a seven-hearth furnace. This ash was mixed with water, forming slurry, and transferred via a discharge pipe to an on-site lagoon for storage.

3.1.2 Location and Description of Ash Lagoon

The ash lagoon occupies an area of approximately 2 acres on the KVWPCA property south of the treatment plant. The bottom of the ash lagoon basin was excavated into the native silty clay of the bench terrace of the Kiskiminetas River. The base of the lagoon is at approximately 783 feet MSL. The embankments are constructed of the same material and provided approximately 10 feet of free board prior to the deposition of ash. Elevation at the top of the embankments is 793 feet MSL. Figure 3-2 presents a representative cross section of the ash lagoon and

subsurface. In 1991, measurements by Chester Engineers (Chester) placed the thickness of ash as 0.5 meter (1.57 feet) at the outlet tower to 2.5 meters (8.42 feet) in the center of the lagoon. Chester estimated the total volume to be approximately 9,000 cubic meters (12,000 cubic yards). Use of the impoundment was discontinued in July 1993 with the installation of a dry ash handling system. Currently, as ash is generated, it is accumulated and disposed of in a municipal landfill as required.

In 1999, USNRC developed a 3-dimensional geospatial model of the ash lagoon using all data collected up to that time. The total volume of ash calculated from the 3-dimensional geospatial model was 8,953 cubic meters (11,711 cubic yards).

3.2 Summary of Existing Data

Chester performed initial characterization of the ash lagoon's contents in September 1991. Activities included the collection of composite samples of the entire thickness of the ash from four locations in the lagoon on September 13, 1991. Toxicity Characteristic Leaching Procedure (TCLP) analyses confirmed that the ash is not a hazardous waste. Results of the analyses are included in Appendix B.

In August 1994, PADER notified USNRC that they had measured elevated uranium activity in a sludge ash sample obtained from the ash lagoon. The following month, PADER provided the USNRC a "split" sample for independent analysis. ORISE analyzed this sample and results confirmed PADER's analysis. The USNRC subsequently conducted surface and subsurface sampling in the ash lagoon. Analysis of the samples from the ash lagoon indicated that some of the samples contained concentrations of enriched uranium exceeding 900 pCi/g, which is higher than unrestricted use guidelines typically used by the USNRC for enriched uranium in soil (30 pCi/g).

Two extensive sampling programs have been performed at the site. During the period of December 13 through December 15, 1994, the Environmental Survey and Site Assessment Program (ESSAP) of ORISE conducted a radiological characterization survey of the ash lagoon and adjacent property at the KVWPCA. A 70-meter by 95-meter sampling grid of the ash lagoon was established at 10-meter centers (Figure 3-3). Soil/ash samples were obtained from both surface and subsurface locations. Surface water and groundwater samples were also collected. Following the completion of the radiological characterization, the USNRC notified

the KVWPCA that they were not to release the ash from the site without prior authorization from the USNRC.

In June 1998, B. Koh & Associates (Koh) conducted additional surface and subsurface soil/ash sampling that extended into the top of the clay beneath the bottom of the ash lagoon. Koh used the same sampling grid plan as ORISE.

3.2.1 Lagoon Soil/Ash

3.2.1.1 USNRC Sampling

In December 1994, ESSAP conducted a radiological characterization of the ash lagoon and surrounding area that included a gamma surface scan over the entire lagoon as well as surface and subsurface soil/ash sampling. The surface scan utilized sodium iodide scintillation detectors coupled to rate meters with audible indicators. A total of 71 exposure rate measurements were performed, using the scintillation detectors, in the ash lagoon area. Results of the surface scan did not identify any locations of elevated direct radiation. Exposure rates ranged from 8 to 10 μR/h and averaged 9 μR/h, which are comparable to the background exposure rate range of 8 to 12 μR/h from the Apollo, Pennsylvania area.

Surface soil/ash samples were collected from 50 grid line intersections in the ash lagoon (Figure 3-3). Subsurface soil/ash samples were collected from 25 hand-augured boreholes in the ash lagoon. Borehole locations were selected based on the results of previous sampling performed by the USNRC, the predicted ash dispersal pattern from the influent point, and downhole scan results of previous boreholes closer to the influent point.

Samples were collected at the surface (0-15 centimeters deep), at approximately 1 meter (100 to 115 centimeters deep), at the interval of contamination as identified by the scintillation detector, and at the layer in contact with the underlying in-place clay. Borehole locations are indicated on Figure 3-3.

Samples and data were returned to the ESSAP laboratory in Oak Ridge, Tennessee for analysis and interpretation. A total of 136 soil/ash samples were analyzed by solid state gamma spectrometry and results reported in units of pCi/g. The radionuclides of interest were Uranium-

235 (U-235) and Uranium-238 (U-238); however, spectra were also reviewed for other identifiable photopeaks. Selected soil/ash samples were also analyzed by alpha spectrometry to determine the uranium ratios necessary for isotopic determination.

Concentration ranges for U-235, U-238, and total uranium from the surface (0 to 15 centimeters [cm]), from 100 to 115 cm, from 100 to 115 cm, and from 115 cm to the underlying clay are as follows:

U-235:

0-15 cm:	<0.37 to 1.19 pCi/g
100-115 cm:	<0.39 to 20.93 pCi/g
115 cm to clay:	0.89 to 33.85 pCi/g

U-238:

0-15 cm:	<4.00 to 7.69 pCi/g
100-115 cm:	6.16 to 94.81 pCi/g
115 cm to clay:	3.99 to 144.30 pCi/g

Total U:

0-15 cm:	<13.09 to 34.00 pCi/g
100-115 cm:	<15.23 to 576.20 pCi/g
115 cm to clay:	24.49 to 922.85 pCi/g

Adding the U-234, U-235, and U-238 concentrations determined total uranium concentration in soil/ash samples. Because U-234 concentrations cannot be determined by gamma spectrometry, alpha spectrometry analysis was used to determine the ratio of U-234 to U-235. Five soil/ash samples were selected for this analysis on the basis of gamma spectrometry results. Ratios ranged from 21:1 to 26:1 and averaged 22:1. Therefore, total uranium concentrations, as determined by gamma spectrometry analyses, were calculated by multiplying the U-235 concentration by a factor of 22 and then adding the U-235 and U-238 concentrations. Sample results for U-235, U-238, and total uranium are summarized in Table 3-1.

Concentrations of other radionuclides are listed below.

- For surface ash and soils (0 to 15 cm): Co-60, <0.45 to 0.81 pCi/g; Cs-137, <0.39 pCi/g; Ra-226, <0.94 to 2.25 pCi/g; Am-241, <0.43 to 3.05 pCi/g; Th-228, 0.83 to 2.56 pCi/g; Th-232, <1.80 to 2.63 pCi/g; and total thorium, <4.32 to 4.70 pCi/g.

- For subsurface ash: Co-60, <0.33 to 22.97 pCi/g; Cs-137, <0.37 to 2.27 pCi/g; Ra-226, <0.61 to 2.41 pCi/g; Am-241, <0.80 to 1.92 pCi/g; Th-228, 0.97 to 2.29 pCi/g; Th-232, <2.07 to 2.52 pCi/g; and total thorium, <4.06 to 4.49 pCi/g.

3.2.1.2B. Koh Associates, Inc., Sampling

In June 1998, Koh of Owings Mills, Maryland, collected surface and/or subsurface samples using Geoprobe from 108 locations within the limits of the ash lagoon (Figure 3-4). A total of 155 soil/ash samples from 40 of the sampled locations were submitted for gamma spectrometry analysis to Outreach Laboratory of Broken Arrow, Oklahoma. Results were reported in units of pCi/g. The radionuclides of interest were U-235 and U-238; however, spectra were also reviewed for Cobalt-60. Selected soil/ash samples were also analyzed by alpha spectrometry to confirm the isotopic ratio of U-238, U-235, and U-234 reported by ORISE.

Concentration ranges for U-235, U-238, and total uranium from the surface and at one-foot intervals to the underlying clay at a depth of approximately 8 feet are as follows:

U-235:

0-1 ft:	<0.6 to 4.9 pCi/g
1-2 ft:	<1.0 to 3.1 pCi/g
2-3 ft:	<0.6 to 4.1 pCi/g
3-4 ft:	<0.8 to 20.0 pCi/g
4-5 ft:	1.1 to 11.0 pCi/g
5-6 ft:	1.3 to 11.9 pCi/g
6-7 ft:	<0.8 to 7.4 pCi/g
7-8 ft:	<0.5 to 25.7 pCi/g

U-238:

0-1 ft:	<1.3 to 9.3 pCi/g
1-2 ft:	<1.7 to 9.8 pCi/g
2-3 ft:	<1.4 to 17.3 pCi/g
3-4 ft:	<1.6 to 73.9 pCi/g
4-5 ft:	<3.0 to 43.5 pCi/g
5-6 ft:	5.7 to 33.5 pCi/g
6-7 ft:	<1.6 to 26.1 pCi/g
7-8 ft:	<1.1 to 95.5 pCi/g

Total U:

0-1 ft:	<8.8 to 122.0 pCi/g
1-2 ft:	<11.2 to 62.7 pCi/g
2-3 ft:	<15.2 to 107.1 pCi/g
3-4 ft:	<9.1 to 533.9 pCi/g
4-5 ft:	<22.4 to 296.5 pCi/g
5-6 ft:	<22.4 to 306.6 pCi/g
6-7 ft:	<14.9 to 196.3 pCi/g
7-8 ft:	<11.0 to 686.6 pCi/g

Adding the U-234, U-235, and U-238 concentrations determined concentrations of total uranium. Total uranium concentrations, as determined by gamma spectrometry analyses, were calculated by multiplying the U-235 concentration by a factor of 22, as determined by ORISE earlier, in order to calculate a concentration for U-234 and then adding the U-235 and U-238 concentrations. Sample results for U-235, U-238 and total uranium are summarized in Table 3-2.

3.2.2 Miscellaneous Soil/Sediment Sampling

In December 1994, ESSAP conducted a radiological characterization of the area outside of the ash lagoon. Five surface soil samples were collected from two areas outside the ash lagoon security fence. Both areas, one south of the fence adjacent to the ash lagoon, and one north of the lagoon, adjacent to Manhole No. 1, were reportedly previously landscaped with ash from the lagoon. One borehole (approximately 1 meter in depth) was hand augered at the outside bottom of the north berm and sampled from the bottom of the boring. Two sediment samples were collected from the Kiskiminetas River, one at the plant outfall and one from approximately 50 meters downstream of the outfall. One sample of newly generated ash was collected from the incinerator. Miscellaneous soil and sediment sampling locations are shown in Figure 3-5.

Concentration of uranium in miscellaneous soil, sediment, and newly generated ash samples are presented in Table 3-3. Concentrations of U-235 were all less than the minimum detectable limits. Concentrations of U-238 in soil and sediment ranged from 1.02 to 2.14 pCi/g. The concentration of U-238 in newly generated ash was <4.08 pCi/g. Total uranium for all miscellaneous samples ranged from <2.13 to <8.41 pCi/g.

3.2.3 Surface Water

Two surface water samples were collected as part of the ESSAP investigation. One water sample was collected from the Kiskiminetas River at the plant outfall, and one surface water sample was collected from the standing water in the depression in the eastern end of the ash lagoon. Sample locations are shown in Figure 3-5.

Samples were submitted to the ESSAP laboratory in Oak Ridge, Tennessee for analysis of gross alpha and gross beta parameters. Analytical results indicated that the standing water in the ash lagoon had alpha activity of <2.4 picocuries per liter (pCi/L) and beta activity of 8.4 pCi/L. Surface water taken from the Kiskiminetas River measured alpha activity of <1.5 pCi/L and beta activity at 2.8 pCi/L. Both samples were below the United States Environmental Protection Agency's (USEPA) drinking water limits (maximum contaminant level [MCL]) of 15 pCi/L for gross alpha and 50 pCi/L for gross beta. Surface water concentrations are presented in Table 3-4.

3.2.4 Groundwater

Chester conducted the initial groundwater investigation in 1992 (Chester, 1992). Four groundwater monitoring wells (MW-1, MW-2, MW-3, and MW-4) were installed around the perimeter of the ash lagoon during May 5 through 7, 1992. The locations of the monitoring wells are presented in Figure 3-6. The wells were developed and sampled on May 18, 1992. A second sampling event occurred on June 17, 1992.

Groundwater samples from the May 18th event were analyzed for volatile organics, inorganic parameters, and metals. No organic constituents were identified in concentrations exceeding the detection limit in these samples. However, slightly elevated concentrations of chromium, lead, and nickel were present in some of the monitoring wells.

Because of the slightly elevated metal concentrations detected during the first sampling event, the monitoring wells were resampled on June 17, 1992. Monitoring well MW-2 did not recover sufficiently to yield a representative sample. Therefore, only samples from monitoring wells MW-1, MW-3, and MW-4 were submitted for analysis of metals and inorganic parameters. Analytical results for this sample set indicated that the concentrations of chromium, lead, and

nickel were substantially reduced from the initial sampling event. Chester did not collect samples for radiological parameters during either sampling event.

All four monitoring wells were sampled as part of the ESSAP investigation. Samples were submitted to the ESSAP laboratory in Oak Ridge, Tennessee for analysis of gross alpha and gross beta parameters. Analytical results indicated that groundwater in MW-1, MW-2, MW-3, and MW-4 had alpha activities of <1.6 pCi/L, 3.5 pCi/L, <1.5 pCi/L, and <1.3 pCi/L, respectively, and had beta activities of 3.0 pCi/L, 4.9 pCi/L, 2.5 pCi/L, and <1.6 pCi/L, respectively. All groundwater samples were below the USEPA's drinking water limits (MCL) of 15 pCi/L for gross alpha and 50 pCi/L for gross beta. Groundwater concentrations are presented in Table 3-4.

On October 9, 2001, IT Corporation (IT) resampled the monitoring wells. All four wells were purged of a minimum of three volumes prior to sampling. With the exception of MW-2, which did not recover sufficiently for sample collection, samples were field filtered following collection and sent to BWXT Services, Inc., of Lynchburg, Virginia for analysis of gross alpha, gross beta, and isotopic uranium. Total uranium analytical results indicate that there have been no radiological impacts to groundwater from the ash lagoon. Complete analytical results are presented in Table 3-5 and laboratory reports are included in Appendix C.

3.2.5 Groundwater Elevations Response to River Stage

Beginning in October 2001, IT began measuring and recording groundwater and surface water elevations at the site. Measurements are taken at all four monitoring wells and at the Kiskiminetas River adjacent to the site.

The purpose of measuring these elevations is to evaluate the effects of changing surface water levels in the Kiskiminetas River to groundwater levels beneath the ash lagoon. In general, groundwater flow is easterly towards the Kiskiminetas River (Figures 3-6 and 3-7). As of this writing, no or only minor seasonal fluctuations in elevation have been observed.

4.0 Dose Assessment

Although KVWPCA is not a USNRC licensee, the regulatory framework under which a remediation plan would be reviewed and approved is 10 CFR Part 20, specifically Subpart E and §20.2002. The purpose of this RI report is to support the FS by providing assessment of the no response radiation dose from the "resident farmer" is future use of the site. This report will establish a baseline for assessment of possible remedial action alternatives and assessment of the compliance of those projected doses with 10 CFR Part 20, Subpart E limits. The projected doses are those that might be expected from activities on the site consistent with successful implementation of remedial actions.

Potential future radiation doses are computed from estimates of potential intake rates and exposure rates. Radiation doses from internal exposure (inhalation or ingestion) are computed using dose factors developed using current methodology, specifically those in Federal Guidance Report 11. In conformance with this guidance, the term "dose," as it is used in this report, means "committed effective dose equivalent" (CEDE) in reference to doses from internal exposure, "deep dose" in reference to external exposure, and "total effective dose equivalent" (TEDE) in reference to combined internal and external exposure. Doses totaled over all applicable exposure pathways are computed as a function of time after unrestricted release of the site (over a period up to 1,000 years) for each potentially important receptor. The peak value for each receptor is retained for comparison to dose limits. In probabilistic assessments, a distribution of doses is calculated for each time period, and a corresponding mean dose is derived for each time period. The maximum value of the computed mean doses (termed "peak-of-the-means" in USNRC guidance) is selected for comparison to dose limits.

This assessment is focused on the estimation of radiation doses that might be received by a person as far as 1,000 years into the future. Thus, this assessment considers not only the current conditions at the site, but also considers projected conditions in the distant future as well. The assessment evaluates the most conservative use of the site and potential migration of radioactive materials through the environment over time, taking account of both natural processes and human activities that could be expected to alter the patterns or rates of nuclide movement.

The methodological approach used in this assessment is designed to comply with current Nuclear Regulatory Commission Guidance (USNRC, 1998a, USNRC, 1998b, USNRC, 2000a, USNRC, 2000b, Thomas, 2000). In general, the dose assessment process consists of the following steps:

- Development of a conceptual model of the physical site in its current state
- Identification of potential uses of the site by the resident farmer
- Modification of conceptual representations of the physical site, as appropriate
- Identification of potential exposure pathways
- Development of conceptual integrated exposure scenarios
- Selection of a computer model that reasonably represents the site conceptual model and the conceptual exposure scenarios
- Selection of appropriate input data for use in the computer model
- Use of the computer model to estimate projected radiation doses
- Interpretation of results, comparison of results to regulatory limits, and development of assessment conclusions.

4.1 Identification of Receptors

Residential farming was identified as the land use plausible in some circumstances likely to lead to the highest radiation doses, and is the basis for identification of potential exposure pathways. Consideration of any other potential use of the site would not add to the list of potential exposure pathways derived based on resident farming. Exposure scenarios for virtually any other use of the site can be constructed using a subset of the list of potential exposure pathways for resident farming.

4.2 Pathway Analysis

A comprehensive set of potential exposure pathways for consideration in defining dose assessment exposure scenarios has been developed based on the nuclides of interest, the distribution of the nuclides on the site, potential uses of the site, and potential environmental migration pathways. This list of potential exposure pathways is used below to construct site-

specific exposure scenarios for dose assessment. The potential exposure pathways are as follows:

1. Direct radiation from material in ash.

2. Resuspension of surface particulate material in air; inhalation.

3. Ingestion of ash.

4. Resuspension of surface particulate material in air; deposition or uptake in edible plant tissue; ingestion.

5. Uptake of material in ash through roots of edible plants; ingestion.

6. Resuspension of surface particulate material in air; deposition or uptake in edible plant tissue; ingestion by animal; ingestion of animal products.

7. Uptake of material in ash through roots of edible plants; ingestion by animal; ingestion of animal products.

8. Release of materials in ash to water flowing through the site; runoff to surface water; ingestion.

9. Release of materials in ash to water flowing through the site; runoff to surface water; uptake in water life; ingestion.

10. Release of materials in ash to infiltrating water; presence in groundwater; ingestion.

11. Release of materials in ash to infiltrating water; presence in groundwater; transport to surface water; ingestion by animal; ingestion of animal products.

12. Release of materials in ash to infiltrating water; presence in groundwater; transport to surface water; ingestion.

13. Release of materials in ash to infiltrating water; presence in groundwater; transport to surface as irrigation water; deposition or uptake in edible plant tissue; ingestion.

14. Release of materials in ash to infiltrating water; presence in groundwater; transport to surface as irrigation water; deposition or uptake in edible plant tissue; ingestion by animal; ingestion of animal products.

4.2.1 Source analysis

The source of radionuclides is the sludge ash contained within the ash lagoon. Total volume of ash in the lagoon (approximately 9,000 cubic meters) was calculated by USNRC using a 3-dimensional geospatial model of the KVWPCA ash lagoon (USNRC 1999) and by IT using the Groundwater Modeling System (GMS) 3-Dimensional Scatter Point Module from Boss International (Appendix D).

Radionuclides that were disposed in sufficient quantity to warrant evaluation of their potential contribution to dose include U-234, U-235, and U-238 and their short-lived progeny, which can be assumed to be present at equilibrium with parents. Long-lived products in the decay chains of these nuclides are also included in the assessment because they could become important contributors to radiation dose within the time period of interest. However, these nuclides are unlikely to be significant contributors in the first few hundred years. Typically present at near-equilibrium levels (i.e., activity levels roughly equivalent to activity levels of their U-238 or U-234 parents) in naturally occurring uranium deposits, these nuclides are separated from uranium in the conversion and enrichment processes.

Sampling results from the ORISE and Koh investigations indicate that concentration of total uranium in the ash ranges from less than 2.6 pCi/g to 923 pCi/g. IT calculated the average concentration for total uranium in the lagoon to be 78.7 pCi/g. Average concentrations of individual radionuclides were calculated as follows:

- U-238 at 12.6 pCi/g
- U-235 at 3.2 pCi/g
- U-234 at 62.8 pCi/g

Average concentrations were calculated through the use of geostatistical kriging as a means of interpolating values between sampled points. This was done in conjunction with the calculation of total volume. Kriging is based on a regionalized variable theory and is superior to other means of interpolation because it provides an optimal interpolation estimate for a given coordinate location, as well as a variance estimate for the interpolation value. A total of 291 sample data points, which were scattered over the lagoon and sampled at varying depths, were used in the data set to generate this value (Appendix D).

Mass determinations of uranium were made based on a mass of ash equal to 10,800 metric tons (using an ash density of 1.2 g/cm^3) and the average uranium concentrations identified above. Calculated total mass for each radionuclide is as follows:

- U-238 mass = 280,026 grams
- U-235 mass = 11,084 grams
- U-234 mass = 75.5 grams
- Total U mass = 291,186 grams

The USNRC definition of "source material" in 10 CFR § 20.1003 is "Uranium or thorium, or any combination thereof, in any physical or chemical form; or ores that contain by weight 0.05% or more of uranium, thorium, or any combination thereof." Total uranium makes only 0.0027 percent by weight of the lagoon mass and is therefore not considered source material (Appendix E).

4.2.2 Environmental Transport Analysis

The KVWPCA property discharges into drainage system, which flows into the Kiskiminetas River after a short run. The Kiskiminetas River is not currently used for drinking water supply or irrigation. The nearest downgradient municipal drinking water intake is in Freeport, on the Allegheny River, about 18 miles downstream of the ash lagoon.

No radionuclides traceable to the ash lagoon have been detected in groundwater or surface water outside the lagoon. Reducing conditions and strong retardation of the radionuclides in the underlying clay during site characterization have essentially confined the radioactive material inventory within a zone not beyond or below the physical boundaries of the ash lagoon. This is consistent with the results of batch leaching tests of the ash material conducted by the Oak Ridge National Laboratory (ORNL). These tests were conducted on ash samples collected by ESSAP that ranged in total uranium concentration from 659.36 to 922.85 pCi/g (USNRC, 1996).

The location of nearby perimeter groundwater monitoring wells is shown in Figure 3-1 and selected information on these wells has been provided in Table 4-1. Depth to groundwater beneath the base of the lagoon ranges from approximately 10 feet (3 meters) in the western corner of the lagoon to approximately 13 feet (4 meters) beneath the eastern edge of the lagoon.

4.2.3 Dose/Exposure Analysis

A comprehensive set of potential exposure pathways for consideration in defining dose assessment exposure scenarios has been developed based on the nuclides of interest, the distribution of the nuclides on the site, potential uses of the site, and potential environmental migration pathways. The list of potential exposure pathways presented above is used to construct site-specific exposure scenarios for dose assessment.

Exposure to residual radioactive material in soils on the site could occur through one or more of four terrestrial pathways, depending on the location of soils containing residual radioactive material with respect to the ground surface. If residual radioactive material were contained within soils near the ground surface, exposure could occur from radiation emitted directly from radioactive material in place in the soil, from dusts, or from food products containing radioactive material taken up from soils. In addition, to the extent that groundwater and surface water in the vicinity of the site could be sources of site radioactive materials, radiation exposure could result from use of these resources for consumption, irrigation, stock watering, or some combination of these uses.

4.2.4 Scenario Analysis

Potential uses of the site are identified in this section and are used to define site conceptual models (which can be affected by site uses) and exposure scenarios for dose assessment purposes.

Future potential radiation doses from radioactive materials at the site will depend to a considerable extent on how the site is used in the future. The potential uses of the site depend upon development of the broader area surrounding the site, site characteristics, and, to a considerable extent, the remedial actions implemented. Modifications of site conditions resulting from use of the site and from natural processes occurring over the passage of long periods of time also need to be considered in developing site conceptual models for dose assessment purposes. This section describes the development of site conceptual models and exposure scenarios used for the radiation dose assessment.

Land use within the vicinity of the ash lagoon has been identified as mixed, consisting of medium-sized residential communities and individual rural residences, small industrial facilities,

small farms with croplands and pastures, and idle farmland. Farmland in the site vicinity is largely used for cultivation of corn, wheat, and hay. However, no farms are located within a mile of the site. The closest residential community is Pine Run Camp. Some residences within this community are located within several hundred feet of the ash lagoon. Many residents in the area have small gardens. Projections of future local land use indicate no great changes from present usage. Thus, based only on area development trends, the most probable future land use for the site is residential development or light industry. Resident farming, while not likely, would be plausible.

Based on development trends in the area, use of the site for light industrial or residential development would seem most likely if there were no restrictions on use of the site. Residential use would most likely result in higher doses because of the relatively higher likelihood of exposure (by redistribution of lagoon contents through basement excavation, for example), and the relatively longer duration of exposure that would be experienced by a resident as opposed to a worker. But radiation doses would likely be highest for residential use coupled with agricultural and groundwater use that might be expected for a resident farmer, for example. Of all plausible site uses, resident farming would result in the greatest opportunity for exposure to site radioactive material by providing the largest number of potential exposure pathways and by providing near-maximum exposure duration. Evaluation of the available land area and land quality at the site suggests that such use is unlikely, but plausible, for situations in which use restrictions are not applied.

Resident farming would be plausible for the site if released without restrictions. Resident farming is the land use likely to result in the highest radiation doses from use of the site and resident farmers are likely to represent the critical population group from the annual radiation dose standpoint.

USNRC guidance specifies that exposure scenarios defined for dose assessment be defined in such a way that they are the most conservative (highest dose) scenarios plausible at the site (Thomas, 2000, USNRC, 2000a). In addition, 10 CFR 20, Subpart E, imposes separate limits for different situations:

- License termination with no restrictions on use—25 mrem per year
- License termination with restrictions on use—institutional controls imposing restrictions in place—25 mrem per year
- License termination with restrictions on use—institutional controls imposing restrictions lost—100 mrem per year

For license terminations with restrictions on use, compliance with both dose limits must be demonstrated. These factors are considered in the identification of future uses of the site.

The resident farmer exposure is the only scenario to be evaluated in the dose assessment. USNRC guidance was used to define resident farmer exposure scenario for radiation dose assessment (Thomas, 2000; USNRC, 1998a, 2000a, and 2000b). In this scenario, because the concentration of ash lagoon radionuclides in the surface layer is minimal, the average concentration of radionuclides is considered in order to achieve the most conservative exposure scenario requirements of the USNRC. This is done in order to maximize the dosage through direct contact to the resident farmer.

The process of identifying other potential site uses was not evaluated in this report. Individual exposure pathways associated with other potential exposure scenario will be evaluated in the FS of anticipated remedial alternatives. Once the outlines of the exposure scenario to be used in the dose assessment was established, values for RESRAD Rev. 6.1 computer code input parameters were selected.

4.3 RESRAD Dose Assessment

The computation of nuclide concentrations in media and radiation doses associated with exposure to those media is complex, and is usually performed using computer codes designed for the purpose. The RESRAD code (Gilbert, 1989; Yu, 1993,) was selected as suitable for evaluation of all pathways for the resident farmer exposure scenario in the KVWPCA ash lagoon case. Version 6.1 was used because it is the latest version with the capabilities necessary to implement current USNRC guidance for dose assessment.

Modifications of site conditions resulting from natural processes occurring over the passage of long periods of time need to be considered in developing site conceptual models for dose

assessment purposes. Residential land use might imply excavation of lagoon material, for example, in basement construction for residential use. Time-related changes of potential importance would include erosion, biointrusion, and the effects of changes in lagoon geochemistry on concentration of lagoon nuclides in leachate. Because of limitations with analyzing variable areas of contamination with the RESRAD code, an average value of uranium concentration for each radionuclide was calculated for the entire lagoon.

USNRC guidance (USNRC, 1998a, 2000a, and 2000b) was followed in the selection of input parameter values for the dose assessment. Conservative values were used for single-valued parameters where use of conservative single values would not invalidate the outcome. The most sensitive parameters were treated probabilistically, using distributions developed for the purpose (Cheng, 2000; Biwer, 2000; Beyeler, 1998).

4.3.1 Radiation Exposure Scenario Definition

The resident farmer exposure is the only scenario to be evaluated in the dose assessment.

The average concentration of ash lagoon radionuclides is considered.

4.3.2 Computer Code and Parameter Value Selection

Definition of the outlines of a radiation exposure scenario tends to fix the values of some important parameters in the dose assessment process. However, because models and parameters vary between codes, selection of a code to use for dose assessment is necessary to allow compilation of a list of input parameters and selection of appropriate values for exposure scenarios to be evaluated. The RESRAD code (Gilbert, 1989; Yu, 1993) was selected as suitable for evaluation of all pathways for all exposure scenarios in the ash lagoon case. The RESRAD code groups some of the exposure pathways identified in Section 4.2. The code also assigns shorthand names to pathways.

Input parameters specific to the lagoon contents were derived from measured values, analytical results, and referenced literature. All pathways were left open with the exception of Radon, which is normally not included in USNRC dose assessment. Measured input parameters include the area and thickness of the ash. Input parameters from analytical results include the uranium concentration and leaching data for the ash. Leaching data were used by the USNRC in order to

calculate a distribution coefficient for the uranium in the ash of 1,400. This value was used by the USNRC in the 1996 draft doze assessment (USNRC, 1996). Referenced literature was used to derive a value for the density of the ash (U.S. DOT, 1998).

The unsaturated zone is 3.5 meters feet thick beneath the lagoon. Additional data from boring logs (Chester Engineers, 1992 and American Geotechnical & Environmental Services, 2001) describe the material as clay and silty clay and the United States Department of Agriculture (USDA) soil survey describes it as silty clay loam. Table E.2 of the RESRAD Manual for Rev. 6.0 gives Saturated Hydraulic Conductivity (K) values of 32.6 m/yr for clay and 53.6 m/yr for silty clay. For the unsaturated zone, RESRAD generally uses one tenth of the saturated K value or 3.26 and 5.36. For the purposes of this assessment, 4.31 m/year was used. For the effective porosity value (Table E.8 of the RESRAD Manual for Rev.6.0), the mean value (0.13) of clay (0.06) and silt (0.20) was used. For the soil-specific exponential b parameter, the mean value (9.09) for silty clay (10.40) and silty clay loam (7.75) were used. The distribution coefficient for uranium radionuclides in the unsaturated zone (1,600) was selected for clay from Table E.3.

The saturated zone, based on boring log data from on-site monitoring wells MW-1, MW-2, MW-3, and MW-4, is composed of sand and gravel. The K value for sand in Table E.2 of 5,550 m/yr was used. Sand for the saturated zone b parameter at a value of 4.05 was also used. For the total porosity and effective porosity, the value for coarse sand in Table E.8 of 0.39 and 0.30, respectively, was used.

A complete list of site-specific inputs used for this assessment is included in Table 4-1.

A sensitivity analysis using the RESRAD code examined the most uncertain parameters. Input parameters of ash density and the distribution coefficient of the unsaturated zone were treated probabilistically. These parameters were selected because they were not directly determined through analysis or direct measurement of site conditions. For density, truncated normal distribution of parameters ranging from an upper range of 2.4 to a lower range of 0.6 was used. For the distribution coefficient of the unsaturated zone, triangular distributions of parameters was used with ranges with an upper, middle, and lower range of 51,200 cm^3/g, 1,600 cm^3/g, and 50 cm^3/g, respectively. Results of this sensitivity analysis are presented in Appendix F.

4.4 Dose Assessment Results

Results of RESRAD modeling indicate that in the resident farmer scenario, calculated annual doses are highest at the beginning and diminish slowly with time. Annual doses at the end of the first year reach a peak level of 8.43 mrem per year. At the end of 1,000 years, dose levels drop to 7.93 mrem per year. Results of the dose modeling for all nuclides and with all pathways summed are presented graphically in Figure 4-1. Summary input and output files for the RESRAD run are provided in Appendix G.

External radiation, inhalation, and plant ingestion were all-important pathways for the resident farmer scenario. Pathways that present the greatest dose exposure to the resident are the water-independent pathways. Water-dependent pathways (those associated with groundwater and surface water) do not present any significant dose exposure. Figure 4-2 presents the summed dosage of the water-dependent and independent pathways.

Results of the sensitivity analyses for ash density and the distribution coefficient for the unsaturated zone indicate that changes to either have no significant effects on the dose assessment results.

5.0 Preliminary Remedial Action Goals

PRAGs are normally set for each constituent of concern and for each medium of concern. The PRAG is set at whichever of the following values is the lowest: (1) health-based criteria for carcinogenic effects or for systemic toxic effects, (2) the lowest chemical-specific ARARs, or (3) ecologically based criteria.

Media of concern include soils, sediments, groundwater, and surface water. Constituents of concern at the KVWPCA site include the uranium radionuclides of U-234, U-235, and U-238. No other radionuclides were detected at levels in excess of any established Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) soil cleanup criteria and no radionuclides were detected in any groundwater or surface water samples at or above the MCLs. Therefore, the PRAGs will be based on either a risk-based criteria or an ARAR. The only identified ARAR is the dosage limit established by USNRC's implementation of the rule for License Termination. The dosage limit is also a health-based criteria of 25 mrem per year.

Alternative remedial actions under consideration for the ash lagoon but not evaluated in this assessment will be described in detail in the FS, but are described briefly below:

1. No further action; the KVWPCA ash lagoon would remain in its current configuration with no monitoring, maintenance, or institutional controls.
2. Stabilization and capping on-site.
3. Disposal at a municipal landfill.
4. Disposal at licensed LLW disposal facility.
5. Partial separation and disposal at LLW disposal facility and on site.

6.0 Conclusions and Recommendations

The KVWPCA plant is located approximately mid-center on a bench terrace adjacent to the Kiskiminetas River. The site is within 100- and 500-year floodplains; however, the top of berm surrounding the ash lagoon is above both. Geologically the site is considered to be aseismic and low permeability silty clays underlie the lagoon.

USNRC's leaching data of the ash material indicates that the radionuclides contained in the ash are not mobile. This is consistent with the sampling data, which indicates that no migration of radionuclides beyond the limits of the ash lagoon has occurred.

RESRAD modeling evaluated the existing site conditions in order to assess baseline conditions. This is the equivalent of the no-action alternative. Since a no-action alternative assumes the site is released for unrestricted use, the resident farmer scenario was reasonable for the dose assessment. Doses were evaluated over a period of 1,000 years using all migration pathways available in the RESRAD computer code. The analysis shows a maximum peak dose to be below USNRC's unrestricted release criteria of 25 mrem per year. Results indicated a maximum dose of 8.43 mrem per year occurring at the end of the first year.

The RESRAD model indicates that only the water independent pathways contribute to the dose. Water-dependent pathways are not a factor in the dose assessment due to the immobile conditions of the uranium in the sewage sludge ash. In 1996, USNRC performed RESRAD modeling of the ash lagoon that indicated the water-dependent and independent pathways both contributed to the resulting dose. The results are different from those obtained by the USNRC in the May 1996 report for the following reasons:

- Site-specific input parameters are different for the unsaturated zone. USNRC used a thickness of less than 1 meter compared to the measured thickness of approximately 3.5 meters. USNRC also used a default distribution coefficient of 50 for the unsaturated zone compared to the recommended value of 1,600 for clay in the RESRAD manual. The increased thickness and increase in the distribution coefficient both contribute to the elimination of the water-dependant pathways.

- The concentration of uranium (367 pCi/g) used by USNRC in the ash lagoon was an arithmetic average of concentrations taken from 36 samples in the lower part of the lagoon. At that time, USNRC's estimated volume of ash with concentrations over 200 pCi/g was 3,200 cubic meters or approximately one third of the total volume of the lagoon.

- USNRC's dose assessment assumed that only the bottom third of the lagoon was left in place and that the remaining material had the concentration of 367 pCi/g.

In 1999, additional sampling by KOH allowed USNRC to create a 3-dimensional geospatial model of the lagoon. This model calculated the overall volume of ash in the lagoon to be approximately 9,000 cubic meters of which only 1,100 cubic meters was comprised of uranium concentrations in excess of 200 pCi/g. The model also indicated that these concentrations were not limited to the bottom depths in the lagoon. Using the current data set of 291 analytical data points, IT also generated a 3-dimensional geospatial model of the ash lagoon's contents. The result corresponded with USNRC's estimated volume of 9,000 cubic meters. In addition, IT used the model to calculate an average uranium concentration for the entire lagoon of 78.7 pCi/g for use in the RESRAD model.

Current conditions indicate that conditions inside and surrounding the lagoon do not promote migration of radionuclides beyond the limits of the lagoon. The geologic stability of the site combined with the height of the berm indicates that the existing lagoon can contain radionuclides in the event of a naturally occurring catastrophic event.

The overall stability of the ash lagoon combined with the low dosage attributed to the lagoon indicates that the lagoon, in its present condition, presents little threat to human health and the environment.

Note:

ORISE determined by alpha spectrometry analysis that the ratio of U-234 to U-235 averaged 22:1. Therefore, total uranium was calculated by multiplying the U-235 concentrations by a factor of 23 and then adding the U-238 concentrations. in the total uranium concentration was calculated by propagating the errors in the U-238 and U-235 concentrations.

KISKI VALLEY WATER POLLUTION CONTROL AUTHORITY
LEECHBURG, PENNSYLVANIA

Location	Sample Depth	Radionuclide Concentration (pCi/g)					
		Total Uranium [a]	+/-	U-238	+/-	U-235	+/-
5 m south of Manhole No. 1	surface	<2.13		1.02	1.12	<0.09	
2 m north of Manhole No. 1	surface	<3.67		1.76	1.69	<0.15	
1 m east of gate	surface	<3.05		1.48	1.53	<0.09	
3 m south of south fence	surface	<2.44		1.17	0.97	<0.10	
Perimeter north of berm @foot of berm	1 meter	<4.08		1.99	1.55	<0.10	
Current ash sample [c]	grab	<8.41		<4.08		<0.25	
At plant outfall	sediment	<4.39		2.14	1.72	<0.11	
50 m downstream from outfall	sediment	<2.86		1.39	0.92	<0.08	

[a] Total uranium was calculated by multiplying the U-238 concentration by a factor of 2 and adding the U-235 concentration.

[b] Uncertainties represent the 95% confidence level, based only on counting statistics.

[c] Sample collected from ash furnace.

TABLE 3-4
ORISE GROSS ALPHA AND GROSS BETA ACTIVITY IN WATER SAMPLES
KISKI VALLEY WATER POLLUTION CONTROL AUTHORITY
LEECHBURG, PENNSYLVANIA

Location	Concentration (pCi/L)			
	Alpha Activity	+/-	Beta Activity	+/-
Standing water in lagoon	<2.4		8.4	1.4*
Monitoring well No. 1	<1.6		3.0	1.1
Monitoring well No. 2	3.5	1.1	4.9	1.1
Monitoring well No. 3	<1.5		2.5	1.0
Monitoring well No. 4	<1.3		<1.6	
Kiski River 10 m below outfall	<1.5		2.8	1.0
Purge water from monitoring well Nos. 1 and 2	<2.4		4.1	1.4
Purge water from monitoring well Nos. 3 and 4	<1.9		3.5	1.1

* Uncertainties represent the 95 percent confidence level, based only on counting statistics.

Notes:

ORISE monitoring well locations listed above are labeled incorrectly from the Chester Engineers locations. IT is using monitoring well location numbers identified by Chester Engineers in Figure 3-1.

TABLE 3-5
IT CORPORATION GROUNDWATER SAMPLING RESULTS
KISKI VALLEY WATER POLLUTION CONTROL AUTHORITY
LEECHBURG, PENNSYLVANIA

Location	Concentration (pCi/L)					
	Gross Alpha[a]	Gross Beta[a]	U-234[b]	U-235[b]	U-238[b]	Total Uranium[b]
MW-1	0.60	2.20	0.10	0.09	0.10	0.15
MW-3	0.71	1.78	0.10	0.10	0.10	0.16
MW-4	0.92	2.04	0.09	0.09	0.09	0.14
MW-4 Duplicate	0.73	1.89	0.09	0.10	0.10	0.15
Rinsate	0.46	1.82	0.15	0.12	0.10	0.22

[a] Gross alpha and gross beta were analyzed using EPA Method SW846-9310.

[b] U-234, U-235, U-236, and total uranium were analyzed using Alpha Spectrometry.

Table 4-1
Site Specific Input Parameters for Dose Modeling of Ash Lagoon
Kiski Valley Water Pollution Control Authority
Leechburg, Pennsylvania

Input Parameter	Input Value	Reference
Area of Contaminated Zone (m^2)	4,000	Measured Value
Thickness of Contaminated Zone (m)	2	Measured Value
Length parallel to aquifer flow (m)	100	Approximate length under lagoon and berms
Basic radiation dose limit (mrem/yr)	25	Default
Initial concentration U-234 (pCi/g)	62.9	Avg. concentration
Initial concentration U-235 (pCi/g)	3.2	Avg. concentration
Initial concentration U-238 (pCi/g)	12.6	Avg. concentration
Density of contaminated zone (g/cm^3)	1.2	U.S. DOT Turner-Fairbank Highway Research Center, Sewage Sludge Ash Material Description -http://www.tfhrc.gov/hnr20/recycle/waste/ss1.htm
Contaminated zone erosion rate (m/yr)	0.001	Default
Contaminated zone total porosity	0.4	Default
Contaminated zone field capacity	0.2	Default
Contaminated zone hydraulic conductivity (m/yr)	10	Default
Contaminated zone b parameter	5.3	Default
Average annual wind speed (m/sec)	2	Default
Evapotranspiratin coefficient	0.5	Default
Precipitation (m/yr)	1	Default
Irrigation (m/yr)	0.76	Draft - Dose Assessment for KVWPCA, USNRC, May 1996
Watershed area for nearby stream or pond (m^2)	743,200	U.S.G.S. 7.5' Vandergrift Quandrangle
Density of saturated zone (g/cm^3)	1.63	Draft - Dose Assessment for KVWPCA, USNRC, May 1996
Saturated zone total porosity	0.39	Table E.3; RESRAD Version 6.0 Manual
Saturated zone effective porosity	0.3	Table E.3; RESRAD Version 6.0 Manual
Saturated zone field capacity	0.2	Default
Saturated zone hydraulic conductivity (m/yr)	5,500	Table E.2; RESRAD Version 6.0 Manual
Saturated zone hydraulic gradient	0.02	Measured Value (5/18/92, 6/17/92, 11/8/01) (same value as default)
Saturated zone b parameter	4.05	Table E.2; RESRAD Version 6.0 Manual
Water table drop rate (m/yr)	0.001	Default
Well Pump intake depth (m below water table)	10	Default
Model: Nondispersion (ND) or Mass-Balance (MB)	ND	selection criteria for lagoon size over 1000 m^2 (RESRAD Ver. 6.0 manual)
Well pumping rate (m^3/yr)	250	Default
Number of unsaturated zone strata	1	Site specific field conditions
Unsaturated zone thickness (m)	3.5	Ground Water Investigation, August 1992, Chester Engineers
Unsaturated zone density (g/cm^3)	1.63	Draft - Dose Assessment for KVWPCA, USNRC, May 1996
Unsaturated zone total porosity	0.4	Table E.8; RESRAD Version 6.0 Manual (same value as default)
Unsaturated zone effective porosity	0.2	Table E.8; RESRAD Version 6.0 Manual (same value as default)
Unsaturated zone field capacity	0.2	Default
Unsaturated zone soil specific b parameter	9.08	Table E.2; RESRAD Version 6.0 Manual (avg. of silty clay & silty clay loam)
Unsaturated zone hydraulic conductivity (m/yr)	4.31	Table E.2; RESRAD Version 6.0 Manual (avg. of silty clay & silty clay loam)
Distribution coefficients for U-234:		
Contaminated zone (cm^3/g)	1,400	leaching data from Draft - Dose Assessment for KVWPCA, USNRC, May 1996
Unsaturated zone (cm^3/g)	1,600	Table E.3; RESRAD Version 6.0 Manual (geometric mean for clay)
Saturated zone (cm^3/g)	35	Table E.3; RESRAD Version 6.0 Manual (geometric mean for sand)
Distribution coefficients for U-235:		
Contaminated zone (cm^3/g)	1,400	leaching data from Draft - Dose Assessment for KVWPCA, USNRC, May 1996
Unsaturated zone (cm^3/g)	1,600	Table E.3; RESRAD Version 6.0 Manual (geometric mean for clay)
Saturated zone (cm^3/g)	35	Table E.3; RESRAD Version 6.0 Manual (geometric mean for sand)
Distribution coefficients for U-238:		
Contaminated zone (cm^3/g)	1,400	leaching data from Draft - Dose Assessment for KVWPCA, USNRC, May 1996
Unsaturated zone (cm^3/g)	1,600	Table E.3; RESRAD Version 6.0 Manual (geometric mean for clay)
Saturated zone (cm^3/g)	35	Table E.3; RESRAD Version 6.0 Manual (geometric mean for sand)

APPENDIX D

GMS 3-DIMENSIONAL SCATTER MODULE REPRESENTATION OF ASH LAGOON

The three-dimensional distribution of radioactivity of Uranium in Kiski Ash Lagoon was mapped using geostatistical capabilities provided by computer software package GMS. The Groundwater Modeling System (GMS) is a comprehensive package which provides tools for every phase of a groundwater simulation including site characterization, model development, postprocessing, calibration, and visualization. The GMS 3D Scatter Point Module is a tool to interpolate from groups of 3D scatter points to any of the other data types (meshes, grids). The following interpolation schemes are supported.

- *Inverse Distance Weighted (IDW)* - Includes constant, gradient hyperplane, and quadratic nodal functions. Several subset search options.
- *Natural Neighbor* - Technique based on natural neighbors computed from Thiessen polyhedral. Works well with clustered data.
- *Kriging* - Ordinary and universal kriging routines from the GSLIB software package. Graphical variogram editing. Anisotropy.
- *Log Interpolation*

Three-dimensional interpolation is useful for setting up input data for analysis codes. Three-dimensional interpolation can be used to generate a data set to be used for initial conditions such as groundwater heads and chemical concentrations from a limited set of measured scatter points. Three-dimensional interpolation is also useful for site characterization.

A total of 291 sampling data points were used in the calculations. These data points were obtained from soil sampling scattered over the lagoon area at different depths. The volume of ashes were divided into 35x45x12 uniform blocks. The dimension of the blocks are 2 meter long, 2 meter wide and 0.2 meter thick. Radioactivity of Uranium within each block was assumed to be constant, and was calculated through interpolation from measured scattering data points. Kriging method was used to for interpolation calculations. Some blocks next to the lagoon dikes were eliminated from the ash domain to implement lagoon's 3:1 slope. There are total of 11273 active blocks represent the entire ash domain, and average radioactivity values were calculated from these active blocks for Uranium and its isotopes (attached tables). The attached color coded contours represent the distributions of radioactivity of total Uranium in plane and cross section views.

The calculated average radioactivity

chmical	volume (m3)	average concentration (pCi/g)
U-235	9018.4	3.236187163
U-238	9018.4	12.63874124
U-total	9018.4	78.67514769

Input data - scattering data points.

APPENDIX E

CALCULATION OF URANIUM MASS IN ASH LAGOON

Calculation of Uranium Mass in Ash Lagoon
Kiski Valley Water Pollution Control Authority
Leechburg, Pennsylvania

By activities:

	[1]Volume of Lagoon (m^3)	[2]Avg. Conc. (pCi/g)	[3]Bulk density of Ash	Total Mass of ash (grams)	[4]Total pCi (lagoon)	Total Ci (lagoon)	[5]Decay-rate in entire lagoon (d/s)	[7]Total Mass of Individual Isotopes (grams)
U-238	9000	12.6	1.2	1.08E+10	1.36E+11	0.13608	5.03E+09	**280,026.4**
U-235	9000	3.2	1.2	1.08E+10	3.46E+10	0.03456	1.28E+09	**11,084.3**
U-234	9000	62.9	1.2	1.08E+10	6.79E+11	0.67932	2.51E+10	**75.5**

	Half Life (years)	Half Life (sec)	grams/mole	[6]decay rate (d/s) per gram
U-238	4.46E+09	1.41E+17	238	1.80E+04
U-235	7.04E+08	2.22E+16	235	1.15E+05
U-234	2.45E+05	7.73E+12	234	3.33E+08

Total U in lagoon (grams): **291,186.1**

Percent Lagoon Mass as Total U: **2.70E-05**

Notes:

[1] Value determined by Chester Engineers, NRC and IT Corporation

[2] Value determine by IT Corporation

[3] Estimated value from U.S. DOT Turner-Fairbank Highway Research Center

[4] Total ash mass (g) multiplied by average radionuclude concentrations (pCi/g)

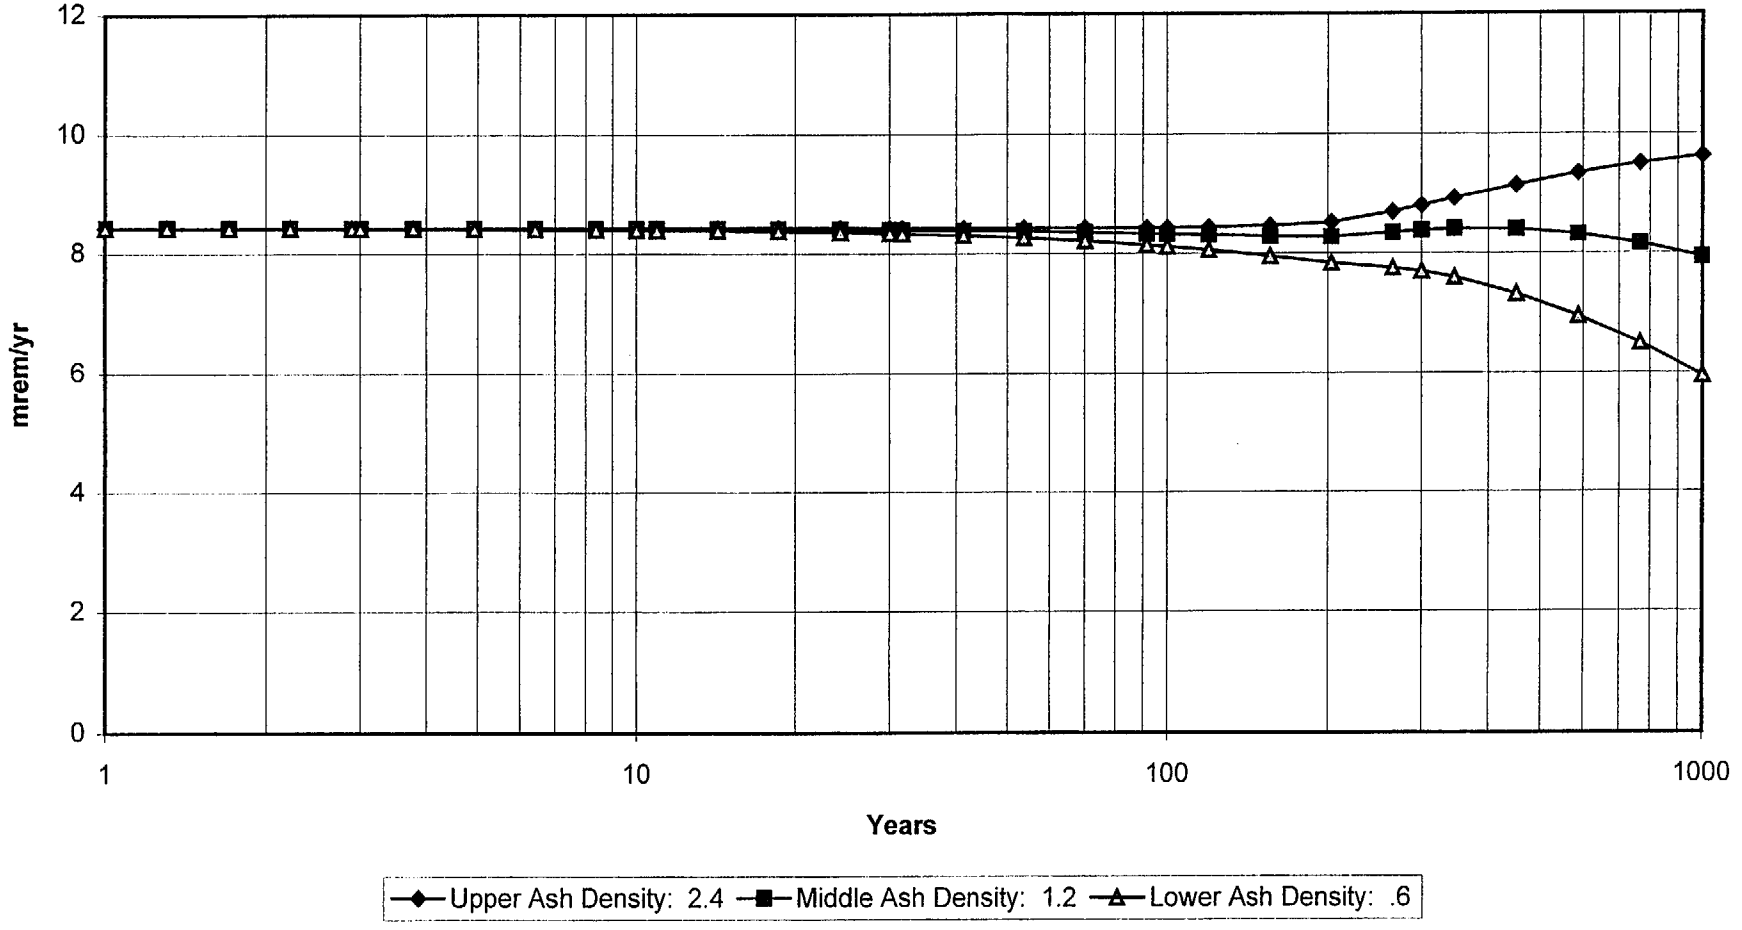
[5] Total curies in lagoon multiplied by decay rate per curie (d/s)

[6] Avagadro's number multiplied by grams per mole of radionuclide divided by half life (s) of radionucllide

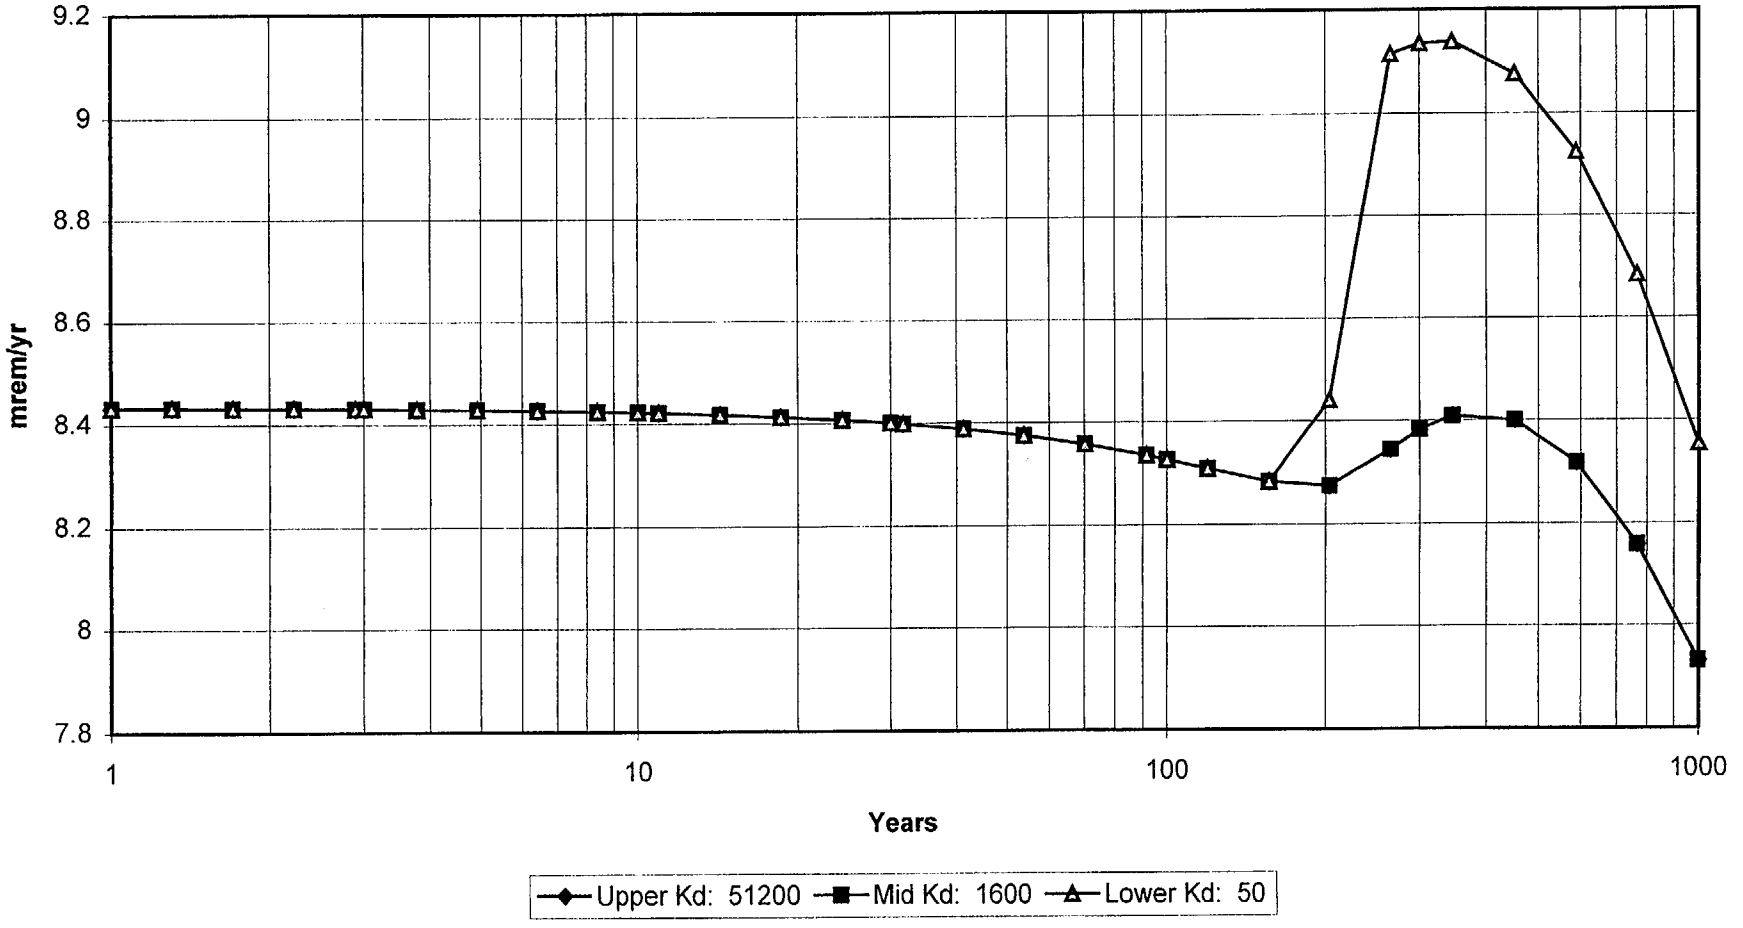
APPENDIX F

RESRAD SENSITIVITY ANALYSIS RESULTS

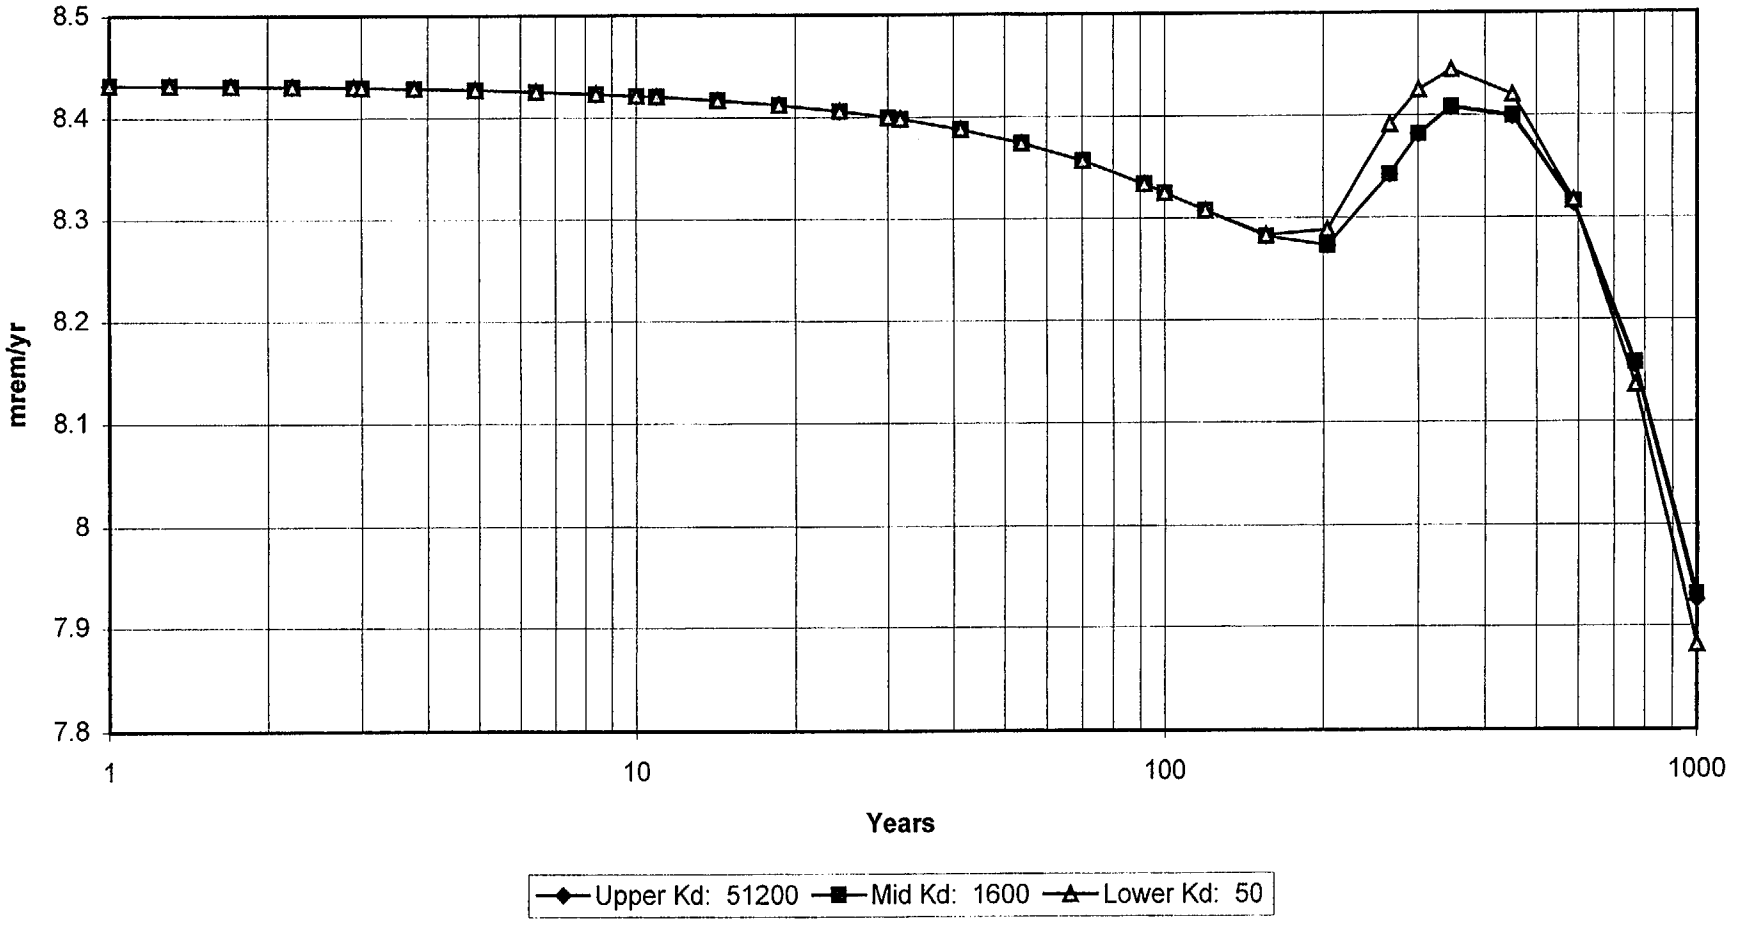
RESRAD Sensitivity Analysis on Density of Contaminated Zone
Avg. Conc. of Total U at 78.6 pCi/g
All Nuclides Summed and all Pathways Summed
KVWPCA Ash Lagoon
Leechburg, Pennsylvania



RESRAD Sensitivity Analysis on Unsaturated Zone Distribution Coefficient for U-234
Avg. Conc. of Total U at 78.6 pCi/g
All Pathways Summed
KVWPCA Ash Lagoon
Leechburg, Pennsylvania



RESRAD Sensitivity Analysis on Unsaturated Zone Distribution Coefficient for U-235
Avg. Conc. of Total U at 78.6 pCi/g
All Pathways Summed
KVWPCA Ash Lagoon
Leechburg, Pennsylvania



RESRAD Sensitivity Analysis on Unsaturated Zone Distribution Coefficient for U-238 Avg.
Conc. of Total U at 78.6 pCi/g
All Pathways Summed
KVWPCA Ash Lagoon
Leechburg, Pennsylvania

R-SQUARE		0.77		0.77		0.87		0.87

-Rank is set to zero if the dose is zero or the correlation matrix is singular.
-R-SQUARE varies between 0 and 1 and is called the coefficient of determination; it provides a measure of the variation in the dependent variable (Dose) explained by regression on the independent variables.

*Branch Fraction is the cumulative factor for the j't principal radionuclide daughter: CUMBRF(j) = BRF(1)*BRF(2)* ... BRF(j).
The DSR includes contributions from associated (half-life ≤ 0.5 yr) daughters.
