The Reliability and PRA and Plant Operations  
Subcommittees met at the Nuclear Regulatory  
Commission, Two White Flint North, Room T-2B1, 11545  
Rockville Pike, at 1:00 p.m., Mario V. Bonaca,  
Acting Chairman, presiding.

SUBCOMMITTEE MEMBERS:

GEORGE APOSTALAKIS, Subcommittee Co-Chairman

JOHN D. SIEBER, Subcommittee Co-Chairman

MARIO V. BONACA, Acting Chairman

GRAHAM M. LEITCH, Member

STEPHEN L. ROSEN, Member

WILLIAM J. SHACK, Member

Donald Dube . . . . . 44

## P-R-O-C-E-E-D-I-N-G-S

1:00 p.m.

MR. BONACA: This meeting will now come to order. This is the meeting of the Reliability and PRA Subcommittee. I'm Mario Bonaca acting as Chair of the Reliability and PRA Subcommittee for George Apostalakis who has been delayed.

Jack Sieber, Chair of the Plant Operations Subcommittee is the Co-Chair. He is not here but will be back I'm sure on time. ACRS members also in attendance are Graham Leitch, Stephen Rosen, who will come up, too, I guess. I didn't see his name listed there. And William Shack. Hopefully George Apostalakis will be here within the hour.

The purpose of this meeting is to discuss the progress of the mitigating systems performance index and to respond to questions raised in the main ACRS subcommittee briefing.

The subcommittee will gather information, analyze relevant issues and facts, and formulate proposed positions and actions as appropriate for deliberation by the full committee. Maggalean Weston is the staff engineer for this meeting.

1           The rules of prospective participation  
2           in today's meeting have been announced in the  
3           Federal Register on June 25, 2003. A transcript of  
4           the meeting is being kept and will be made available  
5           as stated in the Federal Register notice.

6           It is requested the speakers use one of  
7           the microphones available, identify themselves, and  
8           speak with sufficient clarity and volume so that you  
9           may be readily heard.

10           We have received no written comments  
11           from members of the public regarding today's  
12           meeting. We will now proceed with the meeting. Pat  
13           Baranowsky of the Office of Nuclear Research will  
14           begin.

15           MR. BARANOWSKY: Thank you. I'm the  
16           Chief of the Operating Experience Risk Analysis  
17           Branch and with me is Senior Risk and Reliability  
18           Analyst in the branch, Don Dube, and we're going to  
19           make a presentation today.

20           I would like to thank the subcommittee  
21           for giving us this opportunity to present the  
22           progress on this project. We found that airing the  
23           technical issues and getting input from the  
24           subcommittee has been quite valuable in the past and  
25           we would like to continue to do so.

1           Let me go to the first viewgraph here  
2           which pretty much states the purpose and objective  
3           that we had for coming to this meeting. First of  
4           all, as you had mentioned, we want to update you on  
5           the progress we've made on the mitigating systems  
6           performance index which is a performance indicator  
7           set that we've been working on for the past year or  
8           so.

9           We think we've addressed and will  
10          discuss how we have addressed the ACRS comments.  
11          Then ultimately, not after this meeting but perhaps  
12          a future meeting, we would be looking toward getting  
13          an ACRS letter on this particular developmental  
14          activity. Today --

15                 MR. LEITCH: As I looked at the White  
16          Paper I guess I had not particularly focused on the  
17          difference between the word indicator and index. It  
18          seems to me there's a pretty significant difference  
19          there.

20                 MR. BARANOWSKY: I'll explain why we  
21          chose that terminology when I get to my overview.

22                 MR. LEITCH: Okay.

23                 MR. BARANOWSKY: That's coming right up.  
24          The first thing I'm going to cover is some  
25          background on the MSPI. Then we'll identify what we

1 pulled out from the transcript as ACR's comments  
2 from our briefing about a year ago.

3 I'll cover the White Paper that we sent  
4 to you previously and then give a briefing on the  
5 status of the pilot program that we have been  
6 conducting and is coming to a close now.

7 Then really some of the meat of this  
8 presentation is to go over key technical issues that  
9 evolved as a result of comments received and the  
10 pilot program. Then summarize and get to an  
11 implementation time line that we are working toward.

12 Just for some background, the mitigating  
13 systems performance index, that approach evolved  
14 from a feasibility study that we did a couple of  
15 years ago on risk based performance indicators.

16 Basically it's a highly risk informed  
17 simplification to the risk based performance  
18 indicators. It was designed to address some  
19 recognized issues with the current performance  
20 indicators which are somewhat risk informed,  
21 simplified, generic, and so forth.

22 In particular, the MSPI addresses  
23 treatment of demand failures and fault exposure time  
24 which is causing problems in the implementation of  
25 the current set of performance indicators.

1           We addressed issues associated with the  
2 definition of availability and, in particular, spent  
3 a fair amount of time early on discussing  
4 inconsistencies with maintenance rule applications  
5 of unavailability and availability.

6           For the most part I think we have made  
7 as much progress as we can. We are pretty  
8 consistent now in terms of the way we define  
9 unavailability for at-power conditions, safety  
10 systems at-power conditions.

11           The other issue that was raised that was  
12 causing some problems was the lack of plant specific  
13 risk informed performance thresholds. In fact, the  
14 ACRS had brought that up quite some time ago in  
15 reviewing the current set of performance indicators.

16           There had been some problems with  
17 respect to the cascade failure treatment of cooling  
18 water systems where one cooling water system failure  
19 could cascade its impact as a dependent type system  
20 on to other front line systems and produce multiple  
21 hits on performance indicators in a way that they  
22 weren't designed to have multiple hits.

23           Now, the MSPI monitors risk impact of  
24 changes in performance for selected systems. That's  
25 why we call it the MSPI. That identifies a segment

1 of risk impact and it is not a risk indicator per se  
2 so it's like a conditional risk indicator with  
3 certain limitations.

4 It doesn't address shutdown, it doesn't  
5 address external events, and it doesn't address  
6 certain relatively rare events that don't have an  
7 occurrence interval -- recurrence interval that  
8 allows us to get a statistically valid analysis of  
9 performance implications.

10 We coined the phrase "index" even though  
11 we relate the indicator to CDF in trying to make it  
12 risk informed and plant specific. It's called an  
13 index to reflect the fact that it has a limited  
14 scope that it's trying to look at performance issues  
15 on.

16 MR. LEITCH: And that scope is basically  
17 at power?

18 MR. BARANOWSKY: That's basically the at  
19 power, on demand reliability and availability of the  
20 specified set of safety systems.

21 MR. LEITCH: It is by definition then  
22 plant specific?

23 MR. BARANOWSKY: It's plant specific,  
24 yes. It incorporates the plant specific -- well,  
25 that's sort of my next bullet there. It calls for

1 plant specific design, configuration, and plant  
2 specific data to assess the performance with respect  
3 to those six systems per plant.

4 The scope of the PIs -- I think this is  
5 an important point, too -- is consistent with the  
6 current PIs. It's meant to be a replacement for the  
7 current PIs. It's not meant to come up with new  
8 optimal ways of treating the whole oversight process  
9 scheme of PIs. It's meant to specifically address  
10 the mitigating system performance indicators for  
11 which there had been some problems identified by  
12 both the ACRS industry and NRR folks.

13 It does cover unavailability and  
14 unreliability and is consistent with PRA modeling  
15 which is why it's highly risk informed. The process  
16 uses a detailed definition of the scope and  
17 calculation specifics for the PIs in order to get  
18 consistency, reproducibility if you will, of the PI  
19 calculations.

20 The threshold bases are consistent with  
21 the current PI thresholds. Even more so, in fact,  
22 then when we first came here as you'll hear as we go  
23 through this. We've moved toward some performance  
24 thresholds which are consistent with PIs at the so-  
25 called green/white interface and more risk informed

1 thresholds at other threshold interfaces in the  
2 reactor oversight process threshold scheme.

3 MR. LEITCH: So what are the units of  
4 MSPIs, delta CDF?

5 MR. BARANOWSKY: Fundamentally delta  
6 CDF, yeah. Just to summarize some of the points --

7 MR. SIEBER: Maybe I could. In the list  
8 on the preceding slide, you don't talk about the  
9 treatment of common cause failure. Hopefully that  
10 will be discussed as we go.

11 MR. BARANOWSKY: Okay.

12 MR. SIEBER: That's already been dealt  
13 with.

14 MR. BARANOWSKY: I think I'll mention  
15 exactly how we handle that here and then there will  
16 be some additional information that Don will  
17 present.

18 Common cause failure is pretty much  
19 handled in two parts. One is an actual common cause  
20 failure incident which is quite rare and has  
21 significant risk impact on the plant is not  
22 something that we believe this indicator is capable  
23 of trending, if you will. Therefore, our proposal  
24 is that one would use a risk significance process  
25 like the significance determination process to look

1 at any real common cause failures.

2 At the same time the importance of  
3 common cause failure in the risk significance of the  
4 systems that we're monitoring is captured through  
5 the performance indicator. I don't know if that's  
6 clear enough.

7 MR. SIEBER: Well, let me ask a  
8 question. If you've got a non-green mitigating  
9 system performance index, you would get into the SDP  
10 as part of the ROP process. You wouldn't just go  
11 with the indicator.

12 MR. BARANOWSKY: What we would do is we  
13 have a scope split where we think the indicator can  
14 provide valid indication.

15 MR. SIEBER: Regardless of SDP?

16 MR. BARANOWSKY: Yes, because this  
17 indicator is designed to measure accumulated  
18 performance, if you will. Changes in performance  
19 over some period of time.

20 MR. DUBE: Three years.

21 MR. SIEBER: Three years.

22 MR. BARANOWSKY: Three years and then  
23 accumulation of data basically. Whereas the SDP is  
24 a one time, one episode incident.

25 MR. DUBE: Exactly. We have a slide,

1 too.

2 MR. BARANOWSKY: We'll cover that. So  
3 what we've tried to do is identify where we think  
4 this PI works best and where we think a risk  
5 determination type of activity works best. Either  
6 one of those can feed into the matrix.

7 MR. SIEBER: The question is let's say  
8 you've got a non-green index and say you went to the  
9 licensee and you said, "You are the ROP. You get  
10 some special attention."

11 MR. DUBE: It would be no different than  
12 we have now.

13 MR. SIEBER: Yeah. On the other hand,  
14 he would say, "Well, I don't think this is risk  
15 significant." They would then pick out the  
16 instruments that drove them over the edge. Perhaps  
17 it would be a green and now you have a conflict. I  
18 think if you use this, you have to clarify what  
19 takes precedence and why there's a difference  
20 because there will be instances where there will be  
21 differences.

22 MR. DUBE: That's a good point.

23 MR. BARANOWSKY: That's an important  
24 point and we also will cover that in a little more  
25 detail. Then if we don't satisfy you, I'm sure

1 you'll ask us more questions.

2 MR. SIEBER: Well, yeah. I think it's  
3 more understanding and writing down what these  
4 things mean as opposed to an argument as to whether  
5 it's valid or invalid.

6 MR. BARANOWSKY: Yeah, and we're trying  
7 to detail in the guidance documentation where one  
8 uses the mitigating system performance index and  
9 where one uses the significance determination  
10 process. We try to address, at least to some extent  
11 in the White Paper, some points as to why one might  
12 be preferable to the other in general.

13 MR. DUBE: Your point is well taken.  
14 Addressing of technical issues is kind of leading in  
15 those kinds of implementation issues but they are  
16 very important.

17 MR. SIEBER: You've run a couple of  
18 workshops with the industry. In fact, you rely on  
19 an NEI document for part of the development of this.  
20 I would presume that during those workshops -- I  
21 didn't go to the workshops and I haven't read about  
22 them but other than the fact that they occurred you  
23 accomplished something.

24 I would presume that part of those  
25 workshops the industry understands what it is doing

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 here and probably will need in the process of  
2 implementation something in writing that says here's  
3 the policy and how we're going to employ it.

4 MR. BARANOWSKY: I think we actually  
5 have that.

6 MR. SIEBER: Okay.

7 MR. DUBE: You want to say anything,  
8 Mark or John?

9 MR. SATORIUS: What was the question?

10 MR. BARANOWSKY: Well, whether or not we  
11 have documented for the purpose of what we're doing  
12 with the MSPI pilot, for instance, the use of SDP  
13 versus the PI so it's clear for everybody. I think  
14 we've done that.

15 MR. HOUGHTON: Tom Houghton, NEI. Yes,  
16 we have. In the draft guidance document, I think  
17 right up in the very front of it, we list about five  
18 instances when you would use the SDP as opposed to  
19 the MSPI itself. We will be looking as we go  
20 through them with your advice if there are any  
21 others that we need to. Basically it's things that  
22 the indicator can't really measure very well or  
23 aren't included in the indicator's capability.

24 MR. SIEBER: This is in the NEI  
25 document?

1 MR. HOUGHTON: It is. And the  
2 inspection guidance, I think, would follow that.

3 MR. THOMPSON: This is John Thompson,  
4 Inspection Program Branch. Tom is exactly right,  
5 but the point that you were making earlier is an  
6 important point that where the indicator is valid  
7 and gets ahead and crosses a threshold, we have said  
8 in the working group meetings that will suffice as  
9 the input into the action matrix and we will not  
10 also do an SDP on it even if there is a performance  
11 issue.

12 MR. SIEBER: Well, I can see where you  
13 would get two different answers. You need to avoid  
14 that conflict by saying this is the one we will use.

15 MR. THOMPSON: So the challenge for us  
16 as NOR is to assure ourselves that this is at least  
17 as good an indicator of risk as it is what we have  
18 now where we currently do an SDP along with a PI and  
19 then take the higher color input into the occupation  
20 maker.

21 MR. SIEBER: Thank you.

22 MR. BARANOWSKY: Slide 5 identifies the  
23 points, comments, and questions that were identified  
24 from the May 2002 ACRS subcommittee briefing. Just  
25 to mention these bullets, the subcommittee did

1 indicate that we were moving in the right direction  
2 to solve many of the problems with the current  
3 mitigation system performance indicators.

4 They did want to know what we had  
5 learned from any pilot activities. At that time we  
6 were only formulating them but we said we would get  
7 back to you on that.

8 There was a question raised about should  
9 the PI that we are developing deal with risk in  
10 terms of thresholds. An issue was raised regarding  
11 some of the large numbers of SCRAMS that are needed  
12 to cross certain thresholds in the reactor oversight  
13 program.

14 We have looked at this and made some  
15 adjustments based on dealing with issues of validity  
16 of indicators where we have either two few hits that  
17 causes an indicator to cross a threshold, or so many  
18 hits that it's not really indicating anything. Don  
19 Dube will describe that a little later.

20 MR. ROSEN: You would be requiring so  
21 many hits that you would never get there?

22 MR. DUBE: Correct.

23 MR. BARANOWSKY: Basically. So-called  
24 ever-green indicator.

25 A question was raised and we think we

1 answered it but we put it here anyhow about whether  
2 we should be using a plant's own historical  
3 performance in a baseline or some industry  
4 performance. I think we discussed it at the last  
5 meeting but we have also concluded since then that  
6 we would like to use historical industry performance  
7 since.

8 If we were to use a plant specific  
9 performance for the baseline for plants that had --  
10 then they would be rewarded by allowing to have a  
11 delta that goes even more in the core direction.  
12 The plants that have had a very good performance  
13 would be highly penalized. It seems to be more  
14 reasonable in light of what we are trying to  
15 achieve. Sort of a pragmatic as opposed to --

16 MR. ROSEN: This is the difference from  
17 the typical PRA approach where you would update the  
18 performance. It seems perfectly appropriate because  
19 you would tend to use this for a different reason.  
20 I think that is why I'm comfortable with that.

21 When you get done with talking about all  
22 these points, are you going to tell us -- is the  
23 industry, for instance, going to tell us what they  
24 have learned from the pilot and how they feel about  
25 it?

1 MR. BARANOWSKY: We're going to talk  
2 about the pilot. Tom Houghton is here from NEI and  
3 we would be more than happy to have him step up and  
4 say what he thinks.

5 The last point was there is sufficient  
6 data in EPIX. Even though the data currently isn't  
7 sufficient, there have been a number of interactions  
8 with INPO to get EPIX design and capable of handling  
9 this information.

10 It seems to be on track with respect to  
11 the time frame that we are talking about potentially  
12 implementing this indicator so that we would be able  
13 through INPO and their own so-called consolidated  
14 data entry system which is meant to be an efficient  
15 way of collecting various types of data to get the  
16 data that one needs in order to perform the  
17 calculations.

18 Okay. The next chart identifies some  
19 points regarding the White Paper that we sent, I  
20 believe, over a month ago. That's the one, dated  
21 April 28th. Let's make sure we understand what the  
22 White Paper is.

23 It's meant to provide the fundamental  
24 concepts and some related issues that give us a  
25 belief that we should pursue the development of the

1 mitigating system performance indicator. It's not  
2 an analysis of all the possible technical and  
3 implementation issues. It's pretty much a  
4 understanding that this looks like it has some  
5 merit.

6 It also gives the fundamental concept of  
7 how we would make some simplifications in doing these  
8 risk informed calculations to keep the analytical  
9 part as simple as possible but no simpler than need  
10 be in order to get a reasonable indication.

11 We provide the mathematical formulation  
12 with the importance measure relationships, which I  
13 don't plan on going through anymore. We show how we  
14 treat unreliability, unavailability in such a way  
15 that we can combine them together and looking at  
16 both at the same time get an indication of the  
17 impact on the risk index.

18 This is about the simplest calculation,  
19 pretty straightforward algebra. It requires some  
20 bookkeeping but the equations are not really too  
21 complex. There's a parameter here, parameter there.

22 A lot of them are given by like the  
23 Bayesian update parameters, for instance, As, Bs,  
24 and things from analyses that we have done of  
25 industry data to come up with prior distributions

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 and that we have explored to understand how those  
2 parameters impact the calculations in the mitigating  
3 system performance index.

4 MR. ROSEN: The paper says that although  
5 the calculations in the paper can get complicated,  
6 the simplifications that you have proposed, that are  
7 being proposed, don't affect the results greatly.  
8 They are simplifications that have a limited impact  
9 except in some unusual cases.

10 MR. BARANOWSKY: We think we have  
11 identified just about all the little places where  
12 things can be unusual. The basis for some of the  
13 things that we're doing required some complicated  
14 analyses and Don is going to cover that. But then  
15 we believe we are able to boil it down into  
16 relatively simple and straightforward sets of  
17 parameters with these algebraic equations.

18 MR. ROSEN: That can be handled without  
19 a CRAY computer.

20 MR. BARANOWSKY: Yeah. This is just  
21 spreadsheet work.

22 MR. DUBE: This is not on a spreadsheet  
23 now.

24 MR. BARANOWSKY: If you can't track  
25 things that keep you honest with your tech specs,

1 then you wouldn't be able to do this. I would say  
2 vice versa is also true.

3 The benefits, of course, are identified  
4 in terms of some of the issues that we mentioned  
5 earlier; properly accounting for demand reliability  
6 and including plant specific designing data.

7 The limitations are called out to some  
8 extent in the paper. I think the interface is with  
9 where the significance determination process is  
10 proposed to be the appropriate methodology for  
11 evaluating the significance of performance issues is  
12 more detailed out in the NEI guidance document.

13 One thing that specifically needs to be  
14 recognized, that there are a lot of conditions that  
15 get discovered either by design reviews or by  
16 special tests that are not done routinely.

17 Those kinds of issues are also outside  
18 of the scope of this PI because they, in essence,  
19 are the discovery of conditions in which the plant  
20 would have been in a potentially significant risk  
21 state for a long period of time while all the  
22 indications can't possibly detect this because the  
23 data that forms the basis of the indicators is not  
24 being collective in those areas. That also goes  
25 into significance determination.

1 MR. SIEBER: But that does not include  
2 what you refer to as type two test results which is  
3 the 18 months as opposed to a correct test. So even  
4 though you may not discover something until you run  
5 the at-refueling 18-month test, that period where  
6 the deficiency is assumed to occur could be nine  
7 months under the old SDP process.

8 MR. BARANOWSKY: Actually, I think the  
9 main thing that would be discovered on those 18-  
10 month tests are running reliability issues. We have  
11 a way of dealing with those. The answer is yes and  
12 no.

13 If there was an issue that was  
14 identified that was, say, starting reliability on a  
15 diesel generator, for instance, that could not be  
16 detected for some reason during the normal monthly  
17 or quarterly test. We would have to take that into  
18 account. We couldn't just assume that the monthly  
19 or quarterly test provided valid numbers of demands.  
20 We haven't seen anything like that, by the way.

21 MR. LEITCH: For example, the recent --  
22 at least a year ago or so red finding at Point Beach  
23 where they have daily mops. Under some conditions  
24 recirculation were correctly availed and the pumps  
25 would be run again and shut off. No amount of

1 testing would have revealed that after three months  
2 or 18 months or anything. I mean, it was just a  
3 recognition of the problem.

4 MR. BARANOWSKY: That's hopefully a rare  
5 event but it's a longstanding one that is not  
6 amenable to this type of indicator. There might be  
7 other types but not this one.

8 We mentioned issues that are related to  
9 differences between the mitigating system of  
10 performance index and a significant determination  
11 process which we have looked at and are continuing  
12 to look at.

13 There was a lot of discussion related to  
14 false negatives and false positives which we believe  
15 we have pretty good solutions for and validation  
16 issues which we are also addressing and have a  
17 pretty good handle on. Those are just highlighting  
18 the paper. I don't think we have solutions  
19 identified today. We can talk to you about some of  
20 the solutions that are in progress.

21 Of course, also since the last time we  
22 talked to you we did have an actual pilot program in  
23 which some 10 sites with 20 nuclear plants  
24 participated in testing out the guidance for  
25 identifying the scope of equipment within the

1 mitigating system including boundary and component  
2 identification. A data collection was done and  
3 computation using the original formulation that was  
4 put together about a year ago.

5 Another element of doing that pilot was  
6 to go through various validation and verification  
7 issues as we went along. Some of these involve  
8 special so-called table top studies with actually a  
9 significant amount of the pilot activity, for us at  
10 least, and that is the bulk of many of the things  
11 that we are going to talk about here today.

12 They included issues related to our own  
13 SPAR comparisons, SPAR being the standardized plant  
14 analysis risk models which the NRC used for our own  
15 risk analysis. We'll talk more about that. We  
16 wanted to look at a number of issues regarding  
17 differences between what the mitigating system  
18 performance index got and the significance  
19 determination process.

20 The other thing I want to point out is  
21 that the regions performed their temporary  
22 inspections per guidance and we got quite a bit of  
23 feedback on issues regarding burden and problems in  
24 following the guidance and that kind of stuff needs  
25 to be feed back into the updated guidance in order

1 to be more efficient if there is to be an  
2 implementation.

3 MR. LEITCH: One of the things that I  
4 don't quite understand is what the industry gives  
5 you versus what the industry does themselves. In  
6 other words, in these pilots do they just provide --  
7 let's say we're talking about the diesel generators.  
8 Do they just provide reliability or, I should say,  
9 unreliability and unavailability data? Then the  
10 expectation is that the NRC does the number  
11 scrunching to come up with the index?

12 MR. BARANOWSKY: Actually, that's a  
13 really good point. The original idea was that we  
14 would do a 100 percent parallel analysis of the data  
15 even though the licensees are responsible for it.  
16 They would use their PRAs and we would use ours.  
17 But that we would make sure that we did some PRA  
18 benchmarking so that we didn't have things like our  
19 models including designer operational features that  
20 were faulty based on understanding of incomplete  
21 information.

22 So the idea was to benchmark the SPAR  
23 models and then go off and do our own calculations  
24 because, as you will see when Don shows you, a  
25 number of technical issues came up for which we

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

(202) 234-4433

[www.nealgross.com](http://www.nealgross.com)

1 needed to have a consistent set of models to look at  
2 these things across numerous plants. If we couldn't  
3 do that, I don't see anyway we could have done this  
4 project.

5 We would be working on this for years.  
6 Now we've got basically a set of, I guess,  
7 simulation models set up so we can look at a number  
8 of issues separately or together and look at the  
9 impact after we have benchmarked them against the  
10 licensee's models.

11 MR. DUBE: But, in answer to your  
12 question, the licensees submit historical  
13 performance, the number of demands for a particular  
14 quarter, all the importance measures, totaling the  
15 spreadsheet and automatically calculated what the  
16 equivalent delta CDF, core damage frequency, and  
17 what color designation is projected. It's been done  
18 for about six months. It was done monthly but if it  
19 were implemented the data would be submitted only  
20 every three months, every quarter.

21 MR. LEITCH: For example, in the diesels  
22 there's many, many different configurations so the  
23 impact of diesel unreliability and unavailability is  
24 factored into the model for that particular plant.

25 MR. DUBE: Exactly.

1 MR. LEITCH: Be it the smaller models  
2 or --

3 MR. DUBE: The importance measure. If  
4 you would find, for example, that a particular plant  
5 was, let's say, just two diesel generators where  
6 loss of off-site power or station blackout was a  
7 dominant sequence, the importance measures for those  
8 would be reflected in the high importance measures  
9 for that particular component for that plant.

10 Whereas another plant that had more  
11 diesel generators and station blackout or loss of  
12 off-site power was not an important contributor to  
13 core damage frequency might have importance measures  
14 that were lower for that particular plant.

15 MR. ROSEN: this was ACRS' specific  
16 point, that the new system had to account for these  
17 site specific differences in order to be fully  
18 robust.

19 MR. DUBE: Exactly, and that's what it  
20 does.

21 MR. ROSEN: And that's what it does.

22 MR. BARANOWSKY: So it's expected even  
23 if we implement this the licensees will make the  
24 calculations but they will make the data available  
25 for us once we have enough confidence in the

1 calculations and whatever because this is very  
2 different from the current set of indicators and  
3 does use plant specific PRAs so it's a step up in  
4 terms of what we've been doing in the past.

5 MR. SHACK: And he'll be calculating the  
6 importance measure with his PRA rather than you  
7 supplying him an importance measure.

8 MR. BARANOWSKY: That's right.

9 MR. DUBE: I'll talk a little bit about  
10 that when we get there.

11 MR. BARANOWSKY: Let me talk a little  
12 bit about the status of the pilot program and then  
13 if others have some points they want to mention,  
14 that might be a good time to.

15 We did hold a workshop in July of 2002  
16 in which we went over the draft proposed guidance  
17 and we made some changes as a result of that  
18 workshop. Then finally we issued guidelines for the  
19 pilot as modification NEI 9902 in September.

20 Then from September through February the  
21 licensees collected and submitted the data. We  
22 performed the temporary instruction at the pilot  
23 plants basically from -- I don't know exactly. I  
24 think it was September because didn't we start in  
25 September?

1 MR. DUBE: Yeah.

2 MR. BARANOWSKY: It went at least all  
3 the way through March. We had another workshop in  
4 January for sort of mid-course assessment. Then we  
5 identified a number of technical issues regarding  
6 temporary instructions and details of calculations  
7 and anomalies and results and things like that. We  
8 redirected our efforts to look at the issues that  
9 Don is going to talk about shortly.

10 One of the things that we found that we  
11 had to spend a fair amount of time on in order to do  
12 all this was to bring the SPAR models up to a state  
13 where they could be used to give a pretty good  
14 reproduction of the licensee's risk down to a fairly  
15 low level.

16 Normally when we use the SPAR models we  
17 use them for the absence sequence precursor program  
18 and it pictured generic issues. We try to get our  
19 total risk of core damage pretty close, say a factor  
20 two or three on the total core damage frequency.

21 We think if we get that close and most  
22 of the top 10 or 20 dominant contributors are in  
23 there, we're happy because we're going to work with  
24 this on a case-by-case basis if it's a special issue  
25 or an accident sequence precursor.

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 MR. ROSEN: You mean close to the plant  
2 CDF?

3 MR. BARANOWSKY: Right. Or, as a  
4 minimum if we don't get it that close, we're going  
5 to say it's not there because we don't believe the  
6 plant CDF. That's a possibility, too. I might as  
7 well be fair about it.

8 In this case we had to understand  
9 differences that took us into the second and third  
10 decimal place because we are measuring delta CDF  
11 impacts on the order of 10 to the -6 or less and the  
12 total CDF at the plant is about five times 10 to the  
13 minus five. That's a pretty important thing to keep  
14 in mind.

15 We've got uncertainty on these core  
16 damage frequency estimates that might be a factor of  
17 three to 10 on the first significant figure. We're  
18 going now into the second and maybe third  
19 significant figure. That's a pretty significant  
20 calculational activity.

21 Here are the set of key technical issues  
22 that I was mentioning and Don's going to go over  
23 them. I think I'll just leave this with you and  
24 turn it over at this point to Don unless there are  
25 other questions, or would someone like to talk about

1 implementation before we move into the issues?

2 Other implementation factors.

3 MR. SATORIUS: Mark Satorius from the  
4 Inspection Program Branch, NRR. Now or maybe after  
5 you touch on the key technical issues. One thing I  
6 just wanted to say is we have a process that we go  
7 through when we pilot these new performance  
8 indicators or any part of the ROP.

9 We went through that same process, you  
10 may recall, when we looked at SCRAMS. We would  
11 count manual SCRAMS or not count manual SCRAMS back  
12 in the beginning of the ROP. That process is in  
13 inspection manual chapter 608.

14 Notwithstanding the technical issues  
15 which Don is going to go over right now, there are  
16 what I call nontechnical or program type issues or  
17 success criteria. These are the things like having  
18 the ability to have license report to requested data  
19 without problems, whether the new PI will continue  
20 to maintain safety and meet some of the other  
21 criteria that the ROP has in front of us.

22 We are still analyzing those  
23 nontechnical aspects of the success criteria and  
24 notwithstanding all the good work that research has  
25 been doing on the technical issues we are still

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

(202) 234-4433

[www.nealrgross.com](http://www.nealrgross.com)

1 looking at those nontechnical issues.

2 MR. ROSEN: Before you get to the next  
3 slide, the last bullet on your prior slide on the  
4 status of the pilot programs implies that having  
5 made a major effort to reconcile differences with  
6 the pilots, that you will have a similar major  
7 effort with all the other plants left. Is that not  
8 true?

9 MR. BARANOWSKY: We don't necessarily  
10 plan on having every single model capable to this  
11 degree unless there is some issue that causes us to  
12 believe we have to. We are looking at a scheme in  
13 which we use the SPAR models as a audit tool.

14 Based on our understanding of the normal  
15 SPAR model, QA process, and differences that are  
16 identified during that versus this much more  
17 enhanced activity, we can determine where we think  
18 we would like to spend the effort to bring SPAR  
19 models up to this level and then do an audit of  
20 licensee calculations.

21 Ultimately we might get there for all  
22 the plants, and actually I believe we have that  
23 budgeted but it doesn't necessarily need to be done  
24 immediately.

25 MR. DUBE: This is a different level

1 than in the i, 3.0(i)?

2 MR. BARANOWSKY: Yeah.

3 MR. DUBE: This is a notch up from that?

4 MR. BARANOWSKY: Yeah.

5 MR. ROSEN: Definitely.

6 MR. BARANOWSKY: It's enhanced models.

7 It includes additional detail on support systems,  
8 recovery actions, and other things that were found  
9 to be important.

10 MR. ROSEN: But all plants will use the  
11 new indicator if we go to a new indicator. All  
12 plants will be using their PRAs to give you the data  
13 to be manipulated to find the importance measures.

14 You'll be taking -- if you don't do this  
15 level of effort on all the other plants, those that  
16 were not in the pilot, then to a degree you will be  
17 relying on those licensee models more than you did  
18 rely entirely on the pilot plant's models. Right?

19 MR. BARANOWSKY: That's true but, at the  
20 same time, we are identifying insights that we have  
21 obtained from both the normal SPAR QA work and this  
22 enhanced activity which we will take a look at and  
23 determine if that needs to be fed into this process  
24 such that the models have some level of consistency  
25 in that regard.

1 A couple of issues that Don is going to  
2 cover like support system initiators and things like  
3 that. Those came out of our reviews and we have  
4 different ways of dealing with that if they are not,  
5 for instance, included in the PRA that a licensee  
6 has.

7 MR. SHACK: Can you identify in the  
8 licensee PRA elements that must be of a certain NEI  
9 quality standard that you would feel comfortable  
10 with, the results from them?

11 MR. BARANOWSKY: I think we've got sort  
12 of a list of things, a tentative list that we put  
13 together already. We need to look at it and we need  
14 to ask ourselves what do we gain by spending effort  
15 making anybody do these things? Is it the third  
16 significant figure? Does that change what the  
17 outcome would be in using this PI because there are  
18 several aspects about the way we have looked at the  
19 so-called invalid and -- oh, what was the other  
20 indicator?

21 MR. DUBE: Insensitive.

22 MR. BARANOWSKY: Insensitive indicators  
23 which make some of this a little bit moot, actually,  
24 which is good. It doesn't have to be so twitchy, so  
25 to speak.

1 MR. SIEBER: This is also in terms of  
2 delta CDF so you could have some fundamental error  
3 and still have the delta come out of it.

4 MR. BARANOWSKY: Well, I'm not sure  
5 about that. I'll be honest with you, I think we  
6 learned that when you're working with delta CDFs of  
7 10 to the -6 or smaller, it doesn't take much to get  
8 factors of two differences. If you've got eight  
9 times 10 to the minus seven here and 1.6 times 10 to  
10 the -6 there, there is not a lot of difference that  
11 gets you that.

12 That's a small delta CDF. Yet, that's  
13 the level at which 174 is being applied. It's a  
14 level above where risk informed tech specs are being  
15 applied. They are even going down into the 10 to  
16 the minus seven range. So whatever we've learned  
17 here certainly has some implications for other  
18 applications.

19 Nonetheless, I think we can identify how  
20 we can address concerns about how accurate one needs  
21 to be rather than calling it quality. Quality  
22 sometimes means documentation and does it look right  
23 and everything. For our purposes we just want to  
24 calculate things consistently, sort of robustly if  
25 you will.

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 MR. LEITCH: When the twenty plants in  
2 the pilot were selected, was the intention to cover  
3 the gamut of designs from very robust to --

4 MR. BARANOWSKY: That wasn't the  
5 intention. I don't know that we exactly did.

6 MR. LEITCH: Volunteers.

7 MR. BARANOWSKY: Will volunteers that  
8 cover the gamut step forward. They did all right.

9 MR. DUBE: And we have a mixture of  
10 Westinghouse low combustion engineering and  
11 preboiling water reactors. No BMWs but it's a  
12 reasonably representative of old and new plants.

13 MR. LEITCH: I was not thinking so much  
14 about the reactor manufacturers as diesel  
15 configurations.

16 MR. DUBE: Oh, we have from two diesels  
17 to four diesels, for example. From two aux feed  
18 pumps to four aux feed pumps.

19 MR. LEITCH: I guess another questions  
20 that comes into my mind is that it's plant specific  
21 indicator but is the green and white thresholds  
22 plant specific or is that one number?

23 MR. BARANOWSKY: That's actually a  
24 program threshold. How you calculate your plant's  
25 performance is plant specific. Everybody has to do

1 55 miles an hour or less but how you accelerate and  
2 break and whatever to do that, that's going to be a  
3 little different.

4 MR. LEITCH: So a plant with, let's say,  
5 more robust safety systems could be less  
6 conservative in the way he manages those safety  
7 systems and cannot cross the threshold.

8 MR. DUBE: It could tolerate more  
9 failures and more unavailability all other things  
10 being equal.

11 MR. BARANOWSKY: But we moved away from  
12 using a purely risk benchmark to a performance  
13 benchmark which doesn't allow such a wide spread.  
14 It allows some spread. It gives some credit. I  
15 think from what I'm hearing feedback wise it's about  
16 the right amount. That's a judgment call.

17 MR. LEITCH: One thing I was curious  
18 about and I kind of got lost a little bit in the  
19 White Paper was the merger of unavailability and  
20 unreliability because they say things are very much  
21 inter-related.

22 In other words, if one tries to drive  
23 the unavailability to zero, you could, and likely  
24 would, raise the unreliability. If you don't take  
25 the outages to do your preventive maintenance, your

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 unreliabilities kind of go up.

2           There's an inter-relationship between  
3 these two numbers. I'm just wondering how this  
4 indicator deals with that. I tried to figure my way  
5 through the math so I understand the inter-  
6 relationship but I couldn't quite see how that  
7 factored in here.

8           MR. DUBE: I can handle that. I think  
9 one of the reasons why this is an improvement is  
10 because the current indicator deals only with  
11 unavailability. You can find situations and  
12 industry representatives who will admit that they  
13 will manage to the indicator.

14           If there is a threshold here and their  
15 unavailability is going up, they will manage the  
16 indicator and perhaps in the long run to the  
17 detriment of reliability. Why I think this is an  
18 improvement it properly balances unavailability and  
19 unreliability so that in theory once you find that  
20 optimum, hopefully it's a broad optimum where the  
21 right preventive maintenance will give you an  
22 optimum.

23           I won't say zero but optimum  
24 unreliability and that's what the theory always  
25 tells you. And it weights unavailability and

1 unreliability by the importance measures. Vessel  
2 over UR which is kind of like a risk achievement  
3 minus one but it's an importance measure. It  
4 appropriately weights unavailability and  
5 unreliability in the appropriate amount and that's  
6 why I don't believe it is an improvement in that  
7 sense.

8           You are exactly right. In theory, if  
9 you're doing the right maintenance the sum of  
10 unavailability contribution to CDF and unreliability  
11 contribution to CDF should be a minimum if you're  
12 doing it just right.

13           MR. BARANOWSKY: I think the maintenance  
14 rule also pushes one in the direction of balancing  
15 unavailability and unreliability so that was another  
16 area where we were trying to be consistent. We  
17 could have taken these separately which is, by the  
18 way, what we did with the risk based performance  
19 indicators when we had a lot more indicators.

20           That becomes problematic with lots of  
21 indicators and not doing this tradeoff in one  
22 program in NRC whereas another one allows the  
23 tradeoff and you get inconsistencies and all of a  
24 sudden you've got two different requirements and  
25 it's not working.

1 MR. APOSTALAKIS: Is unavailability  
2 still defined in terms of maintenance?  
3 Unavailability is the ratio or what?

4 MR. DUBE: Yes. Planned maintenance and  
5 unplanned maintenance. There should also be some  
6 contribution picked up. If there is a failure and  
7 is corrected that should find its way in, too.

8 MR. APOSTALAKIS: But isn't that failure  
9 part of the evaluation? That's how you find it?

10 MR. BARANOWSKY: No. That failure goes  
11 into the unreliability, but what he means is if you  
12 take a component down to perform corrective  
13 maintenance, then that goes into unavailability.  
14 The so-called fault exposure time is captured by the  
15 unreliability term. There's no fault exposure time.

16 MR. APOSTALAKIS: There is a fault.  
17 They say you have to start. That goes to the  
18 unreliability. So what is it that goes to the  
19 unreliability?

20 MR. DUBE: If it was down three days for  
21 repair so that's an unplanned maintenance, that  
22 would find its way in the unavailability.

23 MR. APOSTALAKIS: Oh, okay. I see now.  
24 So the unreliability contribution then is just  
25 modified and there's no time.

1 MR. BARANOWSKY: Right. Failures per  
2 demand.

3 MR. ROSEN: And there's no assumption  
4 about how long it was unreliable prior to being  
5 discovered.

6 MR. BARANOWSKY: No, but it has to be  
7 failure that is detectable by the routine testing.  
8 You can't have something that was so unique that  
9 they went and did special test time and we've seen  
10 this. That's like an accident sequence. That gets  
11 special treatment.

12 MR. ROSEN: And that's what Graham  
13 referred to earlier was the point situation. That  
14 would be handled by the SDP, right?

15 MR. BARANOWSKY: Exactly.

16 MR. DUBE: The design deficiency of that  
17 nature.

18 MR. APOSTALAKIS: So if you find a phase  
19 to start on the 1st of February, you're not going to  
20 speculate how long it will be?

21 MR. DUBE: Exactly. That's correct.

22 MR. BARANOWSKY: We're just going to  
23 count up the number of demands over the period which  
24 we are measuring and the number of failures and we  
25 are going to do a calculation. Just the usual type

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 of PRA type calculation.

2 MR. SIEBER: That's unreliable.

3 MR. BARANOWSKY: It's demand  
4 reliability.

5 MR. SIEBER: Yes, it's demand.

6 MR. APOSTALAKIS: And then, of course,  
7 you have a separate reservation and you start to  
8 phrase for 45 minutes.

9 MR. BARANOWSKY: That's the usual run  
10 for reliability.

11 MR. APOSTALAKIS: So why did you decide  
12 not to speculate on how long it had been down?  
13 Isn't the average time usually one half?

14 MR. BARANOWSKY: That works if you have  
15 a long period for which you are going to collect  
16 data for that so-called speculative unavailability.  
17 For very short periods of time it gives you spikes  
18 and nothing. Spikes and nothing. What we are  
19 trying to do is over a period of three years taking  
20 demands and failures.

21 You also can't update that one, or at  
22 least we don't know how very well, using Bayesian  
23 statistics. It's consistent with the way we do  
24 PRAs. It's consistent with the way people do  
25 maintenance rule. That's the reason it shows it.

1 MR. APOSTALAKIS: In a PRA if you have  
2 the other test, you are averaging over time.

3 MR. DUBE: Right.

4 MR. APOSTALAKIS: For a single component  
5 if there is a failure it's not very large which is  
6 usually the amount. The average unavailability over  
7 that period is one half. That means this is the  
8 average probability. The average fraction of time  
9 or the interval is down.

10 MR. BARANOWSKY: Yeah.

11 MR. APOSTALAKIS: Now you're finding  
12 your failure on the test and you decide not to go  
13 that way but you're saying this is not a demand  
14 unavailability or failure.

15 MR. BARANOWSKY: I think maybe I can  
16 explain it. That's the constant failure rate  
17 assumption. As you ingrate over time T goes to  
18 infinity the probability of failure on demand equals  
19 exactly one half lambda for the constant failure  
20 assumption. So they are the same exact values.  
21 When you get into trouble is when you do it over  
22 short periods of time. Then your statistics get out  
23 of whack.

24 MR. DUBE: That's why we use a free year  
25 interval, too, to average things out.

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 MR. APOSTALAKIS: That's another thing.  
2 Why do you use the years? Can you use the years?  
3 Is this going to be used by the ROP?

4 MR. BARANOWSKY: Yes.

5 MR. APOSTALAKIS: And the ROP doesn't go  
6 by date.

7 MR. BARANOWSKY: It's a rolling three-  
8 year indicator. Rolling three years.

9 MR. APOSTALAKIS: I thought it was  
10 three-quarters.

11 MR. BARANOWSKY: No. That would be --  
12 the statistics would be so poor for three-quarters  
13 you couldn't really use these kinds of performance  
14 indicators. It's not clear that you would be  
15 chasing noise or real performance changes if you  
16 look at things over quarters.

17 MR. DUBE: There was a study of the risk  
18 based, NUREG 17 I believe it is, where we looked at  
19 varying intervals. That's a whole separate report  
20 but it was found that three years was about as  
21 optimum as what it could get. Too little and it's  
22 too sensitive. Any more and you're not really  
23 seeing the trend. Three years seemed all right.

24 MR. BARANOWSKY: That just happens to be  
25 the interval that is currently used with the

1 performance indicators.

2 MR. DUBE: Well, on to the key technical  
3 issues. I' Donald Dube. I came to the Commission  
4 in October and pretty much took over for Hussain  
5 Hamzehee so you've got a new face here.

6 When I took it over I thought this is  
7 going to be pretty easy, but it didn't take too  
8 long, two months into the project, to realize there  
9 were a number of key technical issues.

10 Certainly during the pilot program or  
11 workshop in January a large number of technical  
12 issues, as well as some implementation issues, came  
13 to the surface. I'm going to touch upon a lot of  
14 the major issues that came about over the next few  
15 hours or so.

16 I do want to say that there is no way I  
17 could have come on board in such a short time and  
18 tackled these issues without the assistance of the  
19 primary contractors, ISL and Idaho, and also Corey  
20 Atwood. I want to give them acknowledgement.

21 MR. APOSTALAKIS: You just left me out.

22 MR. BARANOWSKY: So is that an  
23 endorsement?

24 MR. APOSTALAKIS: Maybe in the future  
25 when you send those reports you can identify those

1 because I had no idea.

2 MS. WESTON: Right.

3 MR. DUBE: I've listed them here on the  
4 overview. Independent verification. One of the  
5 first things we found were the significant  
6 differences between the SPAR model and the plant  
7 PRA. Pat Baranowsky mentioned this earlier.

8 We thought when we were going into this  
9 that the importance measures, let's say for a  
10 particular component, might vary from the SPAR model  
11 to the plant PRA, let's say, for a diesel generator  
12 by maybe tens of percent or 50 percent or maybe a  
13 factor of two kinds of numbers.

14 Lo and behold we found significant  
15 differences. In many cases one order of magnitude  
16 difference and in other cases two orders of  
17 magnitude difference. It really begged a lot of  
18 questions.

19 As we were doing this and they started  
20 rolling in we asked ourselves what is going on here  
21 and what are the differences. We undertook a major  
22 effort to reconcile the differences and I'll be  
23 talking about that. A lot of it had to do with the  
24 fact that the SPAR's original intent, the S stands  
25 for standardized. One started by having more or

1 less a template for different series or classes of  
2 plants.

3 As years have gone by they have become  
4 somewhat more customized. But there were still  
5 significant differences specifically in many of the  
6 balance of plant systems and the cooling water  
7 support systems such as service water and cooling  
8 water we later found out.

9 So in parallel I will be addressing a  
10 lot of these other technical issues. A major effort  
11 was undertaken at Idaho to understand these  
12 differences and explain them. I'll show some  
13 examples.

14 We also early on had come to an issue  
15 that we called an invalid indicator. What that  
16 basically means is that if one component failure  
17 resulted in the system indication turning to white,  
18 one failure does not make a trend.

19 While one failure may result in  
20 exceeding delta CDF of 10 to the -6 on paper, does  
21 that necessarily mean that performance is degraded  
22 to the point that an indication should be actually  
23 white? It has come to be called invalid indicator.  
24 It has certain connotations so it's really a bad  
25 name for it by definition but it's come to be kind

1 of associated with that.

2 MR. APOSTALAKIS: So the first would be  
3 green, white, and green is still CDF based?

4 MR. BARANOWSKY: It's changing to  
5 performance based.

6 MR. APOSTALAKIS: It was always  
7 performance based.

8 MR. BARANOWSKY: We were delta CDF based  
9 the last time we talked. Now we are changing back  
10 to performance based.

11 MR. APOSTALAKIS: Just green?

12 MR. DUBE: It's a mixture.

13 MR. BARANOWSKY: Green and white.

14 MR. DUBE: No, it's for other, too.

15 MR. BARANOWSKY: It's for cases where we  
16 have to deal with these invalid and then insensitive  
17 indicators. I would just like to add one more thing  
18 about the invalid indicator.

19 The reason why we called it invalid, I  
20 think, was because we are collecting data over such  
21 a short period of time that the number of demands  
22 that one can get are too small to get a good  
23 statistical indication of what the demand failure  
24 rate is. One could get false/positive indications  
25 very easily and you need more information if you are

1 dealing with that period of time.

2 MR. DUBE: So what we're saying then is  
3 the process is implemented then and runs along for  
4 years those invalid indicators would be washed out.  
5 They would not --

6 MR. BARANOWSKY: We have a different way  
7 of treating them.

8 MR. LEITCH: If you're looking at three-  
9 month quarterly interval when you do a test once and  
10 it fails, is that an example of the kind of thing  
11 that would be an invalid indicator?

12 MR. DUBE: No. An invalid indicator  
13 would be an example where if there were no failures  
14 and the indicator was less than 10 to the -6 or  
15 green, one should not have a situation where just  
16 one failure of a particular component would turn it  
17 white above 10 to the -6. In that circumstance we  
18 are going to have an alternate formulation that will  
19 not call that white.

20 MR. APOSTALAKIS: I don't know about  
21 that. If it's 10 to the -6 and you've got one  
22 component, that is pretty significant. If you  
23 expect it is 10 to the -6 and you get one, yeah, you  
24 should worry.

25 MR. BARANOWSKY: Suppose you do this?

1 You look at data over a 10-year period of time and  
2 you have one failure. Take a look at five. You  
3 still have one failure. Then you look at three,  
4 then you look at two, then you look at one. Well, I  
5 take that same exact data and when I look at 10  
6 years it's not risk significant. When I decided to  
7 make the one-year look, it was down in risk  
8 contributor. What does that mean?

9 MR. APOSTALAKIS: But you have already  
10 decided to go back to years. What was the  
11 rationale?

12 MR. BARANOWSKY: Going to three years  
13 was we got enough data so we didn't have that kind  
14 of situation occurring. In the meantime between  
15 failures was such that we could collect several.

16 MR. APOSTALAKIS: I'm curious. You're  
17 still keeping the white, yellow, yellow, red based  
18 on delta CDF?

19 MR. DUBE: Right. Ten to the -6, 10 to  
20 -5, and 10 to -4.

21 MR. APOSTALAKIS: You know this  
22 Committee has criticized that.

23 MR. DUBE: Doesn't like it.

24 MR. BARANOWSKY: We're also looking at -  
25 -

1 MR. APOSTALAKIS: Performance guys, why  
2 didn't you ask the experts in the field to tell you  
3 what the yellow should be? There are so many people  
4 who have long experience. Two of them are here.  
5 When would you worry?

6 MR. BARANOWSKY: The fact of the matter  
7 is once you get into the white zone you address the  
8 issue.

9 MR. APOSTALAKIS: Exactly. That's  
10 actually true.

11 MR. DUBE: Well, that's a good point  
12 but, in essence --

13 MR. APOSTALAKIS: There are four, not  
14 two.

15 MR. DUBE: The best way to address the  
16 plant specific variations is why using some constant  
17 measure like a 10 to the -6 threshold and let the  
18 plant PRA manifest itself through the importance  
19 measures and the performance data into how many  
20 failures does that equate to to turn white or yellow  
21 or red as opposed to just picking some numbers out  
22 of the air that may be a one size fits all. Well,  
23 we can talk about it.

24 The third issue is the large number of  
25 failures to turn the system to white which is called

1 an insensitive indicator. In the sense that if  
2 something has a relatively high risk achievement or  
3 importance measure, it may take one failure to  
4 exceed the delta CDF of 10 to the -6.

5 At the other end there may be certain  
6 components that have such low contribution to CDF,  
7 have low importance measures that it may take  
8 theoretically a large number of failures before it  
9 turns to white. When I say large, I'm talking many,  
10 many dozens, for example. That's not indicative of  
11 a good measure.

12 MR. APOSTALAKIS: But you said white is  
13 performance based so it shouldn't take that many.  
14 Only when you have delta CDF phase thresholds you  
15 get that problem. Because if the expert tells you  
16 yeah, it's not very significant but if it should go  
17 about two failures over a certain period of time, I  
18 would worry.

19 If it should go from white to yellow,  
20 then your argument is valid because now it's rigid  
21 calculation. That's the advantage of using expert  
22 opinion. Anyway, isn't this the issue, though?  
23 Both of these colors are statistically minded.

24 If it has its own process and I want to  
25 establish a quality control program, isn't it the

1 issue of what is the number of failures that I  
2 should worry about and if I see more, I have a  
3 problem? That's really the issue we're facing here.  
4 The peculiarities of the rate is so low.

5 Corey, you want to say something?

6 MR. ATWOOD: Corey Atwood, Scott Wood  
7 Consulting. White was based on delta CDF.

8 MR. APOSTALAKIS: I understand that.

9 MR. ATWOOD: But if you're concerned in  
10 performance, then you would say how many do we  
11 expect, how many do we really not expect.

12 MR. APOSTALAKIS: Forget about the  
13 practice of the NRC. You want to establish a  
14 quality control program for its own process. I  
15 mean, the first quantity you're looking at is  
16 lambda, the average number you expect to see over a  
17 period of observation. What makes this complicated  
18 is that lambda is very low so you are trying to make  
19 it reasonable by going to three years.

20 In other cases it's going to be  
21 unreasonable. So I think fundamentally that's what  
22 we're facing. It was a side remarks. There was no  
23 question. There was no praise either. There should  
24 be, though.

25 MR. DUBE: Okay. Well, I appreciate

1 that. I stepped into the program here and we were  
2 developing a risk-based performance indicator and  
3 that's basically what it is. There are -- we have  
4 as a result of bullets No. 2 and 3 realized that  
5 relying on a strict algorithm that estimates the  
6 delta CDF and translates into number of failures.

7 Ruling on that can result in kind of  
8 ridiculously low numbers. On the one hand we call  
9 that invalid and ridiculously high. On the other  
10 end we call that insensitive. We will be proposing  
11 -- are proposing limits on both ends to avoid that  
12 situation. It will be fundamentally risk-based but  
13 with performance based limits at the upper end and  
14 the lower end to an event.

15 MR. APOSTALAKIS: Ultimately all of the  
16 thresholds will be performance based, right? It's  
17 about four or five years.

18 MR. DUBE: Yeah, four or five years.

19 MR. LEITCH: Do both of these programs  
20 greatly impact at the present? In other words, once  
21 the program runs for the full three years, will be  
22 issues disappear?

23 MR. DUBE: No. I mean we will resolve  
24 these issues but the fundamental reason of why one  
25 failure might result in delta CDF more than 10 to

1 the -6 is because it's a finite time frame of three  
2 years.

3 Certain components like a steam driven  
4 or steam pump have such a high importance measure,  
5 risk achievement where all it takes is one failure  
6 to give you a delta CDF in that three-year time  
7 frame or the 10 to the -6. Averaged over many years  
8 it's probably a wash because it's a fundamental  
9 issue that 10 to the -6 is kind of a low threshold.  
10 It's a very sensitive threshold.

11 MR. BONACA: You said you will propose  
12 leads so you have to have some criteria on what is  
13 reasonable.

14 MR. DUBE: And I'll talk a little bit  
15 about that. The fourth one is identification of  
16 system boundaries. This is more of a mechanistic  
17 thing having to do with bookkeeping and realizing,  
18 for example, that if there's a service water system  
19 providing cooling for a diesel generator and there's  
20 a valve and that valve's function is only to isolate  
21 or open flow to the diesel generator, then the way  
22 we are considering it is that valve is part of the  
23 diesel generator boundary as we define it because it  
24 only serves the function to that diesel generator  
25 and not as part of the service water.

[www.nealrgross.com](http://www.nealrgross.com)

1 I bring that up because there were a  
2 number of issues along these lines as the pilot  
3 program and a lot more issues than we thought. I'll  
4 show you how we addressed those.

5 Data collection burden. Many licensees  
6 did say that at the time it has been a burden to  
7 collect this data. Certainly the first time and  
8 there is a lot of data collection that has to be  
9 done up front because we are going back three years  
10 of historical performance data, demands and failures  
11 so there is quite a bit of effort there.

12 Then to some extent maintaining it but I  
13 will address how we are planning to integrate this  
14 with INPO, WANO, consolidated data entry system so  
15 that it would minimize that burden we think.

16 MR. APOSTALAKIS: There will be  
17 additional burden in the issue of SPAR versus plant  
18 specific model, right? Even though the plant works  
19 with you and makes sure that these discrepancies are  
20 resolved. At some point an indicator like this will  
21 require every licensee.

22 MR. DUBE: That's a good point. We have  
23 said going into the program for the purpose of this  
24 pilot that we don't expect any of the pilot plans to  
25 make any changes to their PRA. It's a voluntary

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

(202) 234-4433

[www.nealrgross.com](http://www.nealrgross.com)

1 process. We just want to exercise the method,  
2 collect the data, and see how it turns out.

3 But as part of the SPAR enhancement  
4 process and reconciliation, if there are significant  
5 differences between the plant PRA and the SPAR  
6 model, and we truly believe that the SPAR model is  
7 correct and the plant PRA model has an absolute  
8 error, it is expected that error has to be corrected  
9 or certainly addressed in one way, shape, or form or  
10 another.

11 MR. BONACA: But you found many  
12 instances where, in fact, the plant specific model  
13 had an error?

14 MR. DUBE: A number. Not a lot. I  
15 would say not a lot. A few, and these were the  
16 region inspectors that found these in the process.

17 MR. BONACA: I'm surprised. That's an  
18 interesting thing because the assumption is always  
19 the problem is going to be with SPAR and you're  
20 telling me that instead you found PRAs out there  
21 with the errors.

22 MR. DUBE: In some cases there were  
23 omissions. A particular valve that is needed for  
24 recirculation flow of a pump was not modeled.  
25 Things along those lines.

1 MR. BARANOWSKY: How about that Point  
2 Beach PRA? That didn't have anything about the  
3 requirement of instrument error to make the  
4 auxiliary feed water pumps work. That's the kind of  
5 thing we're talking about.

6 MR. DUBE: I think when I get to the  
7 next couple slides you'll have some eye openers.

8 MR. APOSTALAKIS: Judging from the  
9 examples that Don and Pat gave us, that was the  
10 motivation for asking in the last letter that people  
11 look at the operating experience much more carefully  
12 because I'm not sure that the word error would apply  
13 if somebody didn't analyze a particular failure  
14 mode. Unless everybody else in the world is doing  
15 it and it's a well-known fact, why would you call  
16 that an error? The way you learn is by looking at  
17 operating experience. I mean, I would, and that was  
18 the motivation.

19 MR. BARANOWSKY: Well, the second way,  
20 and maybe Tom can comment on this, was I think we  
21 all learned a lot when we tried to compare the two  
22 PRAs, the SPAR model versus the licensee's model.  
23 The bulk of the times we had to change the SPAR  
24 models. We have to fair about the situation.

25 MR. ROSEN: Well, that's what I would

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 expect. You would expect to have to change the SPAR  
2 model because of the PRA. Site specific PRA is more  
3 detailed and, in fact, says that SPAR model gives  
4 you an answer that is not conservative. The case  
5 that Mario raises is the one that is more  
6 troublesome and more surprising.

7 MR. DUBE: I can count on one hand those  
8 number of examples, but there were a number. As I  
9 said, it went both ways. If SPAR was out of sync  
10 with the plant PRA, they most likely would have been  
11 issued of not modeling cross connections between  
12 unit one and unit two or from train one to train two  
13 or some kind of things like that. It's pretty much  
14 not part of the standard.

15 MR. ROSEN: But they, in fact, affect a  
16 plant specific PRA in a very substantive way.

17 MR. DUBE: Oh, yes. Definitely.

18 MR. BARANOWSKY: Usually though only a  
19 factor of two or three on the total core damage  
20 frequency.

21 MR. ROSEN: Only.

22 MR. BARANOWSKY: Well, I say only  
23 because let's be honest about what the uncertainty  
24 is in these calculations.

25 MR. ROSEN: Ah, yes. When you reflect

1 it against uncertainty, I agree.

2 MR. BARANOWSKY: That's the big, big  
3 errors. Most of the changes we saw weren't even  
4 touching the first significant figure but they do  
5 impact the Fussell-Vesely importance measures. If  
6 you want to get the pecking order right, let's say  
7 right is the correct term. What is the most  
8 important thing and work your way down. Then you  
9 have to go beyond the first significant figure.

10 MR. DUBE: Okay. The next two issues  
11 I'll get into more detail but it basically relates  
12 to how does one treat the common cause failure  
13 contribution to Fussell-Vesely. That has to do with  
14 the fact that many models, plant PRAs, take into  
15 account the fact that if the independent failure  
16 rate or single failure rate changes, then there is  
17 some connection and some coupling to the common  
18 cause failure rate. We need to address that and I  
19 will talk a little bit about that.

20 Another item is support system  
21 contribution to Fussell-Vesely in that we are  
22 dealing with mitigating systems such as service  
23 water and component cooling water which are often  
24 sometimes called support systems. But those support  
25 systems can also be initiated as loss of service

1 water, loss of component cooling water.

2 A particular component that is an  
3 initiator will have a Fussell-Vesely associated with  
4 that initiator. Many PRAs use a single point, a  
5 point estimate for the initiating event frequency so  
6 it will get properly captured for a particular  
7 support system. We propose a --

8 MR. APOSTALAKIS: It's described in  
9 terms of frequency, right? It's a support system,  
10 it's unavailability and unreliability.

11 MR. DUBE: Yeah, but it would have also  
12 Fussell-Vesely associated with it, particularly like  
13 a service water pump is part of the loss of service  
14 water initiator there would be a contribution on the  
15 pump to the loss of service water frequency.

16 MR. APOSTALAKIS: A different quantity.

17 MR. DUBE: Correct.

18 MR. APOSTALAKIS: Are you going to come  
19 to that?

20 MR. DUBE: Yes.

21 MR. APOSTALAKIS: I noticed you are  
22 avoiding RAW. Will you explain to the subcommittee  
23 why? I couldn't find it anywhere.

24 MR. DUBE: Well, because the formulation  
25 is delta CDF as opposed to RAW is given a base what

**NEAL R. GROSS**

(202) 234-4433

[www.nealrgross.com](http://www.nealrgross.com)

1 is the factor by which a CDF increases so we use  
2 Fussell-Vesely over UR and that's approximately the  
3 risk achievement -1.

4 MR. APOSTALAKIS: Why do you bring into  
5 this the burn bomb? Are you going to talk about  
6 these things? The burn bomb measure is described  
7 but why I couldn't figure out.

8 MR. DUBE: Sometimes it's more  
9 convenient to use burn bomb.

10 MR. APOSTALAKIS: But what are these  
11 times? Are you ever using it? More convenient on  
12 Fussell-Vesely?

13 MR. BARANOWSKY: I think it's the way  
14 that things were originally thought out was in terms  
15 of burn bomb importance measure being the  
16 proportionality constant, if you will.

17 MR. APOSTALAKIS: Yeah, but it wasn't  
18 clear why it was discussed in the report.

19 MR. BARANOWSKY: The reason we went to  
20 Fussell-Vesely, this happened before Don was on  
21 board, was because everyone calculates Fussell-  
22 Vesely importance measures and not everyone  
23 calculates burn bomb importance measures. We just  
24 said, well, let's take this burn bomb and burn it  
25 into a Fussell-Vesely divided by a parameter. It's

**NEAL R. GROSS**

(202) 234-4433

[www.nealrgross.com](http://www.nealrgross.com)

1 the same thing. It's all proportionality.

2 MR. APOSTALAKIS: I think the fact that  
3 everybody calculate Fussell-Vesely and RAW becomes  
4 the driving force behind the analysis and I don't  
5 like that. The convenience of getting these things  
6 is making us do mental acrobatics to justify what we  
7 get and treat everything to Fussell-Vesely and RAW.

8 MR. DUBE: Yeah. One could very well  
9 use burn bomb and maybe we should have started with  
10 burn bomb.

11 MR. APOSTALAKIS: Yeah, but I mean more  
12 for analytical convenience but, for heavens sake, it  
13 shouldn't really drive what you do.

14 MR. BARANOWSKY: It really isn't driving  
15 anything. I mean --

16 MR. APOSTALAKIS: You dare tell the  
17 world that you don't like Fussell-Vesely, you see,  
18 because everybody gets it from the quotes.

19 MR. BARANOWSKY: We chose it because  
20 it's not going to make any difference whether we use  
21 burn bomb or Fussell-Vesely divided by  
22 unreliability. We're going to get the same exact  
23 values. Since everybody has it, it's a burden  
24 issue. If it was going to affect the way we did the  
25 calculation, then we would have said something about

1 it but it's really not going to change the  
2 calculation and the burden.

3 MR. DUBE: Okay. I mentioned support  
4 system contribution and then touched upon a  
5 relationship of SDP and PI and we'll talk about that  
6 again a little bit later.

7 MR. ROSEN: Are you going to go through  
8 each one of those things? Why don't we just  
9 summarize it. We ought to speed it up is what I'm  
10 trying to say.

11 MR. BONACA: I think we're getting some  
12 good results.

13 MR. DUBE: Okay. Let me talk about the  
14 independent verification. The original intent was  
15 to replicate the MSPI submittals from the licensee  
16 using the SPAR model. I mentioned before we  
17 expected them to be in pretty good agreement but in  
18 many cases we found significant differences in the  
19 importance measures, Fussell-Vesely over UR.

20 Just because there is high-level  
21 agreement doesn't mean that 10 to the -6 and lower  
22 level there is agreement. In many cases the  
23 importance measures weren't just off by factors of  
24 two and three but by one to two orders of magnitude,  
25 especially cooling water support systems.

1                   We had to reconcile the differences at  
2                   the lower level. We had to go one level deeper in  
3                   this SPAR model, we're calling it the SPAR  
4                   enhancement, and either change the SPAR or recommend  
5                   to the plant the PRA change was justified or both in  
6                   some instances. We undertook this effort to do it  
7                   for 11 distinct SPAR models for 20 nuclear units.

8                   Let me give you an example for  
9                   Bravewood. The PRA internal events CDF is 3 E to -5  
10                  per year. The SPAR before looking at it was 7 5 E  
11                  to -5 per year. I'll skip the third yellow bullet  
12                  for now. On average the Fussell-Vesely over UR was  
13                  too low in the old SPAR model by about a factor of  
14                  10.

15                 I mean, there was some factors of 30,  
16                 40, some factors of 2. Sometimes it would be close.  
17                 Far to great of a difference for this particular  
18                 application. I show you in this bottom table some  
19                 typical components, RHR pump, aux feed pump, diesel  
20                 generator, service water pump, volume control  
21                 isolation valve.

22                 What this is is the Fussell-Vesely over  
23                 UR ratio. That is the fundamental importance  
24                 measure in the MSPI. It's the Fussell-Vesely  
25                 divided by the unreliability. The middle column is

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

(202) 234-4433

[www.nealrgross.com](http://www.nealrgross.com)

1 the ratio of the ratio. It's the old SPAR model  
2 Fussell-Vesely over UR ratio to the plant PRA ratio.

3  
4 If the plant PRA and the old SPAR model  
5 were in perfect agreement, these factors would all  
6 be one, would be normalized to one. You can see  
7 that they are pretty much all over the universe.

8 On average, geometric average if you  
9 will, the old SPAR model was too low for a factor of  
10 10 so if the purpose of trying to replicate the MSPI  
11 results were to use the SPAR model and importance  
12 measures, we are already far off to begin with so we  
13 have to understand the differences.

14 At least understand the differences,  
15 reconcile the differences, and then back off. An  
16 effort was made to enhance -- I use the word  
17 enhance. It modified the SPAR models for Bravewood  
18 as well as all the other pilot plans to understand  
19 the differences and change the model.

20 With the enhancements to the SPAR model  
21 on average the agreement is within a factor of 2  
22 high or low. That's the last column so the new SPAR  
23 models for the plant PRA model. There's numbers  
24 high and there's numbers lower than 1 but take a  
25 geometric average it's within a factor of 2.

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

(202) 234-4433

[www.nealrgross.com](http://www.nealrgross.com)

1 MR. APOSTALAKIS: I'm confused. The  
2 White Paper says on page 4 the MSPI is formulated as  
3 the sum of changes related to unavailability and  
4 unreliability so it's the sum of the change.

5 MR. DUBE: Right.

6 MR. APOSTALAKIS: Why are you focusing  
7 on Fussell-Vesely divided by unreliability?

8 MR. DUBE: Because in the formulation  
9 the change in CDF is a factor of FV/UR. If that  
10 factor doesn't agree between the plant PRA and SPAR  
11 model, then everything else thereafter might as well  
12 not even continue.

13 We're saying that importance measures,  
14 which is a reflection of how much does this  
15 particular component contribute to the overall core  
16 damage frequency differed by factors of 10 and we're  
17 biased low in the SPAR and that says how can we even  
18 continue with the independent verification if we  
19 can't even understand where those differences are.

20 MR. APOSTALAKIS: So what were you  
21 verifying?

22 MR. BARANOWSKY: Verifying that we can  
23 calculate basically the same MSPI value by paying a  
24 little bit of attention to enhancing details of the  
25 SPAR models so that we understand the accuracy of

1 can't even understand where those differences are.

2 MEMBER APOSTOLAKIS: So what were you  
3 verifying?

4 MR. BARANOWSKY: Verifying that we can  
5 calculate basically the same MSPI value by paying a  
6 little bit of attention to enhancing details of the  
7 SPAR models so that we understand the accuracy of  
8 the licensee's calculation.

9 MEMBER APOSTOLAKIS: So you are working  
10 with the infrastructure.

11 MR. BARANOWSKY: Yes. Otherwise people  
12 just calculate things.

13 MEMBER ROSEN: And they have to buy it.

14 MR. BARANOWSKY: That's it.

15 MEMBER ROSEN: This way the SPAR model  
16 is tuned up, you could say, and you could go in and  
17 independently judge what you get.

18 MR. DUBE: That's exactly right.

19 MR. BARANOWSKY: If you want a risk-  
20 weight thing, you've got to be able to do this.

21 MEMBER ROSEN: You don't have to do this  
22 every time and you wouldn't.

23 MR. DUBE: I mean, to me this is the  
24 ultimate, quote, quality check, in that you are  
25 taking one PRA with all its models and assumptions,

1 and success criteria, and data, and bringing it to a  
2 whole different PRA developed for a separate purpose  
3 and separate applications, and trying to understand  
4 the differences.

5 And changing the one, or in some cases,  
6 the both, to get at least reasonable agreement  
7 typically within a factor of two on importance  
8 measures.

9 I don't think that we could ever do  
10 better than a factor of two. In some cases we do  
11 much better than a factor of two, and in some of the  
12 other plants, we just can't come to two.

13 MEMBER ROSEN: Well, what do we get?  
14 It's four. This is not about the search for  
15 ultimate --

16 MR. DUBE: No.

17 MEMBER ROSEN: This is about trying to  
18 decide what to do in the action matrix based upon  
19 inspection result in PRAs. So it has a very  
20 pragmatic reason. So if it didn't have that  
21 pragmatic reason, you might want to keep on working  
22 it until you get near perfect agreement.

23 But that is not the objective and we are  
24 only using a pragmatic reason to get into the action  
25 matrix and get it right.

1 MEMBER APOSTOLAKIS: And the action  
2 matrix already has intervals, and so the same  
3 accuracy is not really --

4 MR. DUBE: That's correct.

5 MEMBER LEITCH: I would like to think  
6 there is a backfit issue here, and suppose you run  
7 into a licensee who says that is my PRA and I am  
8 sticking to it.

9 MR. DUBE: Well, for the purposes of the  
10 pilot, I said that we were not going to make it, but  
11 in my opinion if there is -- an outright error has  
12 to be corrected, and if there is a difference of  
13 opinion, then there needs to be some reconciliation.

14 For example, and I will bring this up.  
15 I have a parentheses here, assume same success  
16 criteria for PORV. This is important, and given  
17 this assumption, that last column is what -- you  
18 know, the comparison, and then the third yellow  
19 bullet, used by Model 31E to the minus 5, is almost  
20 in perfect agreement with the plant PRA.

21 But that is an important assumption, and  
22 having supervised on one of my previous jobs about a  
23 dozen feed and bleed calculations on a plant  
24 specific basis, and realizing how sensitive the  
25 results are in terms of timing of operator action,

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 and the number of pressurizer pores, and the high  
2 pressure injection pumps and so forth, the success  
3 criteria is so sensitive to a number of assumptions  
4 that it is important that we have those analyses  
5 done with a high degree of accuracy.

6 The spy model right now has a success  
7 criteria of 2 out of 2 porches. The Braywood plant  
8 PRA is 1 out of 2 porches. Now, I am not saying  
9 that it is not impossible to have (inaudible) one  
10 out of two porch, but my own experience has been  
11 that Westinghouse plants of this vintage and the  
12 amounts that I am familiar with indicates that it  
13 may be closer to two porch than one porch.

14 But to show you how sensitive these core  
15 damage frequency results are to this one success  
16 criteria, because it is a two ox feed water plant,  
17 and a motor driven pump and a diesel driven pump, if  
18 the success criteria was changed from 1 out of 2 to  
19 2 out of 2, the core damage frequency goes up by a  
20 factor of three.

21 And it is a most sensitive -- I won't  
22 use the word assumption -- success criteria that I  
23 have probably ever seen in my career. So it is  
24 important to understand where these differences are  
25 and reconcile them before moving on.

1 And that is why there were examples not  
2 as dramatic as this, but there have been a number of  
3 them

4 MEMBER APOSTOLAKIS: Are you familiar  
5 with any PRA or aware of any PRAs where this  
6 uncertainty was explicitly stated?

7 MR. DUBE: Not in uncertainties.

8 MEMBER APOSTOLAKIS: Well, you are not  
9 sure it is 2 out of 2 either.

10 MR. DUBE: Right.

11 MEMBER APOSTOLAKIS: Are you aware of  
12 any PRAs that acknowledge this explicitly and do  
13 something about it?

14 MR. DUBE: No.

15 MEMBER APOSTOLAKIS: It is a factor of  
16 three, right?

17 MR. DUBE: Yes.

18 MEMBER APOSTOLAKIS: Okay. But you know  
19 about PRAs, right?

20 MR. DUBE: My point is that it is an  
21 open -- you know --

22 MEMBER APOSTOLAKIS: I am just trying to  
23 make a point.

24 MR. BARANOWSKY: I think the other thing  
25 is that there were some issues raised, well, what if

1 these plants meet the ASME standard for quality or  
2 whatever.

3 I don't know whether they meet it or  
4 not, but we can come up with a list of things that  
5 if you want to talk about payoff in terms of  
6 implications on the quantitative results, and the  
7 pecking order of what is important, we pretty much  
8 know what they are.

9 You can go and talk about whether their  
10 documentation is good, and if they have got all this  
11 other stuff. If you want to get the so-called right  
12 answer, these are the things that you are going to  
13 have to look at.

14 I think this is the heart if you will,  
15 the kernel of PRA quality issues, and you pass down  
16 the quantification values, and the pecking order of  
17 what is important.

18 MEMBER APOSTOLAKIS: When you say this,  
19 what are you referring to?

20 MR. BARANOWSKY: The items that we are  
21 able to find by doing this work.

22 MEMBER APOSTOLAKIS: Do you have a list  
23 of those?

24 MR. BARANOWSKY: We have a tentative  
25 list of those insights that we have gained by not

1       only looking at these 20 plants, but by doing a  
2       little more simplified look at the other eight.

3               MEMBER APOSTOLAKIS: And you can give  
4       that to the committee?

5               MR. BARANOWSKY: We are going to make  
6       that available.

7               MEMBER APOSTOLAKIS: We appreciate it.

8               ACTING CHAIRMAN BONACA: For this kind  
9       of work it is a fundamental level of the cooling,  
10      and in almost every scenario and therefore you have  
11      a measure mode of cooling with this kind of  
12      sensitivity, and it is not recognized as a  
13      sensitivity position, but yet in these other items,  
14      it is not stated or documented.

15              But yet it is not surprising that you  
16      would have a sensitivity to it, and whether or not  
17      you need 1 or 2, you know, it is a key element.

18              MR. BARANOWSKY: And we don't propose  
19      that this vehicle is the vehicle for going out and  
20      ensuring some, quote, level of quality with licensee  
21      PRAs. We are saying that we can provide insights.

22              Right now you are using PRAs to do all  
23      kinds of other things. This is a voluntary program,  
24      and we are just saying that these are the areas that  
25      we have learned can have significant quantitative

1 differences.

2 ACTING CHAIRMAN BONACA: You see, it  
3 opens up all kinds of questions and so let me ask it  
4 this way. For example, are these (inaudible), and I  
5 would say probably not.

6 So you have to assume that now how do  
7 you decide that if you need 2 out of 2 that you  
8 would be able to open both? How do you decide that  
9 you will have all this success with 1 out of 2; and  
10 you attempt to open both and you only open one?

11 I mean, you have so many issues that  
12 drive the issue of sensitivity. And again I don't  
13 want to raise too many questions on the source of  
14 the PRA.

15 MR. DUBE: Well, my whole point of  
16 bringing this was that there was a lot of lessons  
17 learned, and a lot of information that has gone  
18 actually both ways, in terms of making enhancements  
19 to this part, but identifying where SPAR models in  
20 the plant PRA had significant differences that still  
21 need to be reconciled.

22 The next example is Palo Verde, which is  
23 where I believe is the best example where the  
24 enhancements made to the plant PRA were extremely  
25 good, and we didn't find those kinds of gotchas if

1 you will in the particular PRA model.

2 You can see that there is a bunch of  
3 columns here, and I am showing them a little bit  
4 differently. I say at the top of the page that the  
5 Fussell-Vesely over the UR, and that is the  
6 importance measure, and on average within plus or  
7 minus 25 percent.

8 I mean, for the major components to be  
9 concerned in the MSVR. Previously I said that we  
10 can get it within a factor of two, and this is  
11 within 25 percent, which is even a closer agreement.

12 There is three columns; the plant PRA,  
13 and the SPAR enhanced, which is what we have done  
14 after we have made these efforts to reconcile the  
15 differences in the SPAR 3-i, which was before if you  
16 will. So that kind of flip-flopped there.

17 But it is important not only to get the  
18 overall core damage frequency, but to have agreement  
19 in terms of the contributors to the core damage  
20 frequency.

21 And while the first column, plant PRA in  
22 the SPAR 3-i, the core damage frequencies were like  
23 within 25 to 30 percent. The constituents that made  
24 it up in terms of contributions of transients and  
25 tube ruptures, and LOCAs, were not so close.

1 But as a result of the enhancement  
2 effort, not only did the overall core damage  
3 frequency come up reasonably close, but the  
4 contributions of the next level, which is  
5 contribution by percent to each particular  
6 initiator, has pretty darn good agreement.

7 And then even at the third level, which  
8 is the Fussell-Vesely over URs, we were able to get  
9 it to pretty good agreement. And in this particular  
10 example, we made a lot more changes in the proposal  
11 to the SPAR, and I believe there may have been a  
12 handful of recommendations that the plant PRA would  
13 take.

14 But again one of the important lessons  
15 learned if you will, and benefits of the overall  
16 record. Any questions on this?

17 (No response.)

18 MR. DUBE: Okay. I am going to talk  
19 about invalid indicators, and it has to do with the  
20 fact that components with high points measure one  
21 component failure and can result in a delta CDF of  
22 10 to the minus 6.

23 I won't go through the math, but if  
24 there is a high Fussell-Vesely UR, which is like a  
25 high risk achievement work, if the change in

1 reliability or unreliability times a high number,  
2 can exceed 10 to the minus 6 for this one particular  
3 failure, in this program we have been calling it an  
4 invalid indicator.

5 MEMBER APOSTOLAKIS: Again, this is a  
6 non-issue, because you are not going without a  
7 threshold. You are not establishing a threshold  
8 between why it is based on the CDM.

9 MR. DUBE: We are using 10 to the minus  
10 6 CDF as the primary means --

11 MEMBER APOSTOLAKIS: I thought you were  
12 switching to performance.

13 MR. DUBE: Well, we were using  
14 performance based at the lower end and the upper  
15 end. In this particular case, we would use a front  
16 stop here, which says that we are not going to allow  
17 one failure to become --

18 MR. BARANOWSKY: It is the false-  
19 positive fix. It is the fix for false-positive

20 MEMBER APOSTOLAKIS: And based on  
21 performance do you find that you can tolerate one  
22 phase, where does this come into play?

23 MR. BARANOWSKY: This is not based on  
24 performance.

25 MEMBER APOSTOLAKIS: Yes, but I thought

1 you said earlier that you are not using this  
2 anymore, and that you are switching back to  
3 performance. I understand what this is based on,  
4 but I am just questioning whether it is relevant  
5 anymore.

6 MR. BARANOWSKY: It is relevant for  
7 those indicators where if a single failure pushes  
8 you over the green-white interface from normal  
9 baseline to the one failure, and it takes you over  
10 the green-white interface, that is where this comes  
11 into play. And only for those cases.

12 MEMBER APOSTOLAKIS: Well, if you have a  
13 delta CDF criteria threshold.

14 MR. BARANOWSKY: Right. And if it turns  
15 out that one failure does take you over the delta  
16 CDF, then you go to this so-called frontstop  
17 approach, which allows more than one failure based  
18 on our analysis of concerns concerning false-  
19 positive indications.

20 MR. DUBE: And the frontstop would be  
21 the minimum number of failures within a system  
22 before the performance indicator turns white.

23 MEMBER APOSTOLAKIS: I still don't  
24 understand it.

25 MEMBER SIEBER: You may have missed one

1 of the flip-flops.

2 MR. THOMPSON: Let me see if I can  
3 clarify this. This is John Thompson from the  
4 Inspection Program Branch. We are implementing  
5 generic risk informed thresholds for every plant.  
6 If that plant determines that they have either the  
7 invalid or the insensitive issue, they will use the  
8 alternate means of determining what is the  
9 threshold.

10 But for purposes of the public, and they  
11 go on the webpage, they will see that 10 to the  
12 minus 6, and minus 5, and minus 4, and we have yet  
13 to work out the details.

14 But for those plants that have a system  
15 that might meet one of these two alternate  
16 approaches, there will be an asterisk, and then you  
17 will see what the new threshold is.

18 So thresholds are risk-informed, but it  
19 is just that for some systems at some plants the  
20 research is proposing to use the alternate. It is  
21 adding a degree of complexity that we in the program  
22 office have to deal with, and we are working with  
23 that.

24 MEMBER APOSTOLAKIS: Green to white was  
25 never risk based. Green to white was always

1 performance.

2 MR. BARANOWSKY: For the current  
3 performance indicators.

4 MEMBER APOSTOLAKIS: yes.

5 MR. BARANOWSKY: But the concept right  
6 from the beginning was risk-based, or risk-informed.

7 MEMBER APOSTOLAKIS: Okay. Now we are  
8 on record as opposing risk-based thresholds for all  
9 the (inaudible), and so in that sense what you are  
10 saying is interesting from the mathematical point of  
11 view.

12 But the committee does not accept your  
13 premise. Is that clear enough to everyone, or what  
14 is it that you are not understanding?

15 MR. BARANOWSKY: Well, let me also --

16 MEMBER SHACK: It's clear.

17 MR. BARANOWSKY: Let me also point out  
18 that presumably --

19 MEMBER APOSTOLAKIS: That does not mean  
20 what you are doing is wrong.

21 MR. BARANOWSKY: -- you may change your  
22 mind some day. What we are trying to say here is  
23 that you have some concerns about using risk  
24 thresholds because they give some results that just  
25 look ridiculous.

1           What we did is we said, well, why don't  
2 we try to get the best of both worlds. We will try  
3 to use risk as much as we can, because that is what  
4 the Commission told us to do.

5           But when it starts to look ridiculous,  
6 either on a false positive indication or false  
7 negative, we won't let things get way out of hand.  
8 We don't want it to be twitchy, and we don't want it  
9 to be so forgiving that it looks like anything goes.

10          So there is a vast number of systems and  
11 cases where we can use this thinking and get what  
12 looks like pretty reasonable results, and there are  
13 some that don't, and we take care of them with this.

14          MEMBER APOSTOLAKIS: On the other hand,  
15 you can say that this is a self-created problem? if  
16 it is one of 10 to the minus 6 for CDF, then that  
17 creates a problem.

18          MR. BARANOWSKY: But one would have to  
19 change the premise of the reactor oversight  
20 program's threshold evaluations from what was put in  
21 99-007 to something else.

22          MEMBER APOSTOLAKIS: Well, 99-007 did it  
23 right for green and white.

24          MR. BARANOWSKY: Well, that was an  
25 expedient thing, and they said it was.

1 MEMBER APOSTOLAKIS: Which turned out to  
2 be right.

3 MR. BARANOWSKY: Since I wrote that  
4 section of 99-007, I will accept that compliment.

5 MEMBER ROSEN: It's better to be lucky  
6 than smart.

7 MEMBER APOSTOLAKIS: You see, that is my  
8 point though. It was mentioned earlier that the  
9 committed doesn't like. It's not what the committee  
10 doesn't like. The committee wrote an argument in  
11 the report on why one should not do that. So it is  
12 not a matter of liking.

13 Now all the problems that you are having  
14 here could go or would go away if you went  
15 performance based, because the experts then would  
16 have told you, look, this is unacceptable. If I see  
17 one failure, you know.

18 So most people tolerate two failures.  
19 So the whole thing goes away.

20 MEMBER SHACK: From a pragmatic point of  
21 view, you have solved the problem, George.

22 MR. BARANOWSKY: George, I think you  
23 have a logical inconsistency if you will excuse me.  
24 If you want this thing to be risk informed --

25 MR. DUBE: And plant specific.

1 MR. BARANOWSKY: -- and plant specific -

2 -

3 MR. DUBE: There is no other way.

4 MR. BARANOWSKY: -- it can't be purely  
5 performance based. You have got to bring risk into  
6 the picture somehow, and I don't see how you do it  
7 by just saying everybody can take two failures on  
8 this end, or six failures on that end.

9 ACTING CHAIRMAN BONACA: But we want to  
10 certify that --

11 MEMBER APOSTOLAKIS: But it is risk  
12 informed.

13 MR. BARANOWSKY: But it is not plant  
14 specific. This is an ACRS comment. You are going  
15 to have to go back and change that one, too. You  
16 set it to reflect configuration of plant specific  
17 data, and now you are telling me not really. So  
18 just change everything.

19 MEMBER APOSTOLAKIS: Listen, listen, the  
20 way --

21 MEMBER ROSEN: One member in ACRS  
22 doesn't make. You can have George's opinion on  
23 that, and maybe the whole committee would --

24 MEMBER APOSTOLAKIS: I have not  
25 expressed an opinion that is inconsistent with the

1 letter so far.

2 MEMBER SIEBER: So far.

3 MEMBER APOSTOLAKIS: Now, the risk-  
4 informed, I think what this is going ultimately is  
5 that what would really matter would be the results  
6 of the SDP, and not the performance indicators.  
7 Performance indicators are just an indication of how  
8 you are rating with respect to your colleagues, the  
9 peers.

10 What really matters is what you find in  
11 the inspection and the risk (inaudible), which I  
12 think should be calculated, because how many PRAs  
13 have you seen where you go to core melt because one  
14 thing is of high frequency? No. It is a  
15 combination of events. And usual combinations are  
16 there.

17 It is not that something happened too  
18 many times, but it is interesting to know whether it  
19 happened too many times. If it happens 10 times to  
20 my plant, and everybody else is below three, well,  
21 then we have to know about it and do something about  
22 it. and this went below the level.

23 ACTING CHAIRMAN BONACA: Yes, but this  
24 committee took exception on that because certain  
25 issues were where it didn't make sense, okay? So to

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

(202) 234-4433

[www.nealrgross.com](http://www.nealrgross.com)

1 some degree, I think we are converging.

2 MR. BARANOWSKY: I think we tried to  
3 look at your whole argument and see what it was  
4 about, rather than just the one sentence, and we  
5 tried to address the whole argument.

6 MR. DUBE: For example, the second  
7 bullet on the resolution, the concept of front stop,  
8 and later we will talk about back stop, we adapted  
9 from the ERISA front tech spec initiative. There  
10 the effort is to identify and allow outage time that  
11 may result in a delta CDF of 5 to the minus 7.

12 Of an algorithm and calculation results  
13 in a number less than the existing tech spec, and  
14 let's say 72 hours, the front stop is that you use  
15 72 hours.

16 If the algorithm comes out with an allowed outage  
17 time or completion time of more than 30 days, and  
18 let's say 80 days, the back stop is 30 days.

19 So the limit, the lower limit if you  
20 will, which is the existing allowed outage time, and  
21 upper limit, which is 30 days, and the plant  
22 specific variation, and the Fussell-Vesely's, and  
23 the importance measures, and the plant performance,  
24 allows some variation in between.

25 And in many ways this is how this

1 project when I took it on had no front stop and no  
2 back stop. It was whatever the computer or spread  
3 sheet spit out is how many failures one would allow.

4 What we have done over the last few  
5 months is propose an adaption, which says that we  
6 are going to have a front stop with a lower limit,  
7 and a back stop, which is an upper limit number of  
8 failures, and the plant specific variation, the  
9 four-diesel configuration versus two diesel-  
10 configuration, will allow some variation in between.

11 MEMBER ROSEN: So you don't penalize  
12 people who have better, more robust, designs, by  
13 giving them the same text specs, or the same  
14 indicators that you give class or less robust  
15 designs.

16 MR. DUBE: Exactly.

17 MEMBER ROSEN: You get some credit for  
18 doing better.

19 MR. DUBE: Exactly, that is the  
20 fundamental purpose that we are proposing.

21 MR. BARANOWSKY: And we think that is a  
22 point that the ACRS made a few years ago, and we  
23 followed that --

24 MEMBER ROSEN: Over and over.

25 MR. BARANOWSKY: And so help me out.

1 That's why I say logically inconsistent. That's why  
2 we went back to the words and discussion on this  
3 issue, and not just the one sentence that said don't  
4 use risk.

5 MEMBER APOSTOLAKIS: You are right, Pat.  
6 The ACRS 3 or 4 years ago was not of the opinion  
7 that the performance indicators should be strictly  
8 performance based. You are absolutely right. We  
9 changed our mind on the way. Actually, we  
10 formulated an opinion on the way. So your confusion  
11 is justified.

12 MR. BARANOWSKY: We appreciate that.

13 MEMBER APOSTOLAKIS: And I just say that  
14 I, for example, at least am very pleased that you  
15 are actually paying attention to what we like.

16 MR. BARANOWSKY: Very astute.

17 MR. DUBE: So on that note --

18 MEMBER APOSTOLAKIS: We have to move on.  
19 I am the chairman, and --

20 MR. DUBE: The next slide shows you --  
21 and I will go over quickly the preliminary results.  
22 This is without any changes to the methodology.  
23 These were the first results.

24 Where were the invalid indicators coming  
25 and is there a pattern, and lo and behold, one did

1 find HRS, which is heat removal system, which  
2 includes ox feed water for pressurized water  
3 reactors or RCIC, or steam driven HPCI.

4 For boiling water reactors, we found a  
5 pattern where one of a kind steam driven ox feed  
6 pumps, for example, tended to have or to be more,  
7 quote, invalid, than other particular systems,  
8 because they had high importance measures.

9 If there was a failure, you couldn't  
10 spread that failure over many like components for  
11 the failure rate, because failures are over the  
12 number of demands. If you have got two pumps or  
13 four diesels, a given failure or one failure over a  
14 number of demands, you could spread it out and the  
15 failure probability that resulted would be low.

16 But when there is one of a kind that has  
17 high importance measures, they tend to show itself  
18 out as an invalid indicator. So this is what we had  
19 coming in pretty much in January, and this was the  
20 challenge before us.

21 The insensitive indicator is the  
22 opposite. If something has a low importance  
23 measure, it is going to take a lot of failures  
24 calculationaly to exceed 10 to the minus 6.

25 And it can be 10, and it can be 20, it

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1       could be 80, it could be hundreds even. And it is a  
2       result of the fact that we originally came into the  
3       MSPI using a deterministic criteria. We wanted to  
4       have enough components within a particular system.

5               We did not want to exclude stuff,  
6       because in some cases if you exclude everything with  
7       a low importance measure, there would be nothing  
8       left in the system.

9               MEMBER ROSEN: Now you are getting the  
10       idea.

11              MR. DUBE: And it is a result of the  
12       fact that we have some low important systems in  
13       here, but that was --

14              MEMBER ROSEN: Well, one design  
15       philosophy might be that to build a plant that is so  
16       robust that no one component matters much, and tell  
17       me what is exactly wrong with that?

18              MR. DUBE: There is nothing wrong with  
19       that. That is a good idea. But going into the  
20       program, the program is that you will include  
21       emergency A/C power, ox feed, RHR, service water  
22       component cooling water.

23              But some particular plants have such  
24       robust cooling water systems, and service water  
25       systems, and so plants have like four pumps in unit

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

(202) 234-4433

[www.nealrgross.com](http://www.nealrgross.com)

1 one, and four pumps on unit two, and you can cross-  
2 tie on train A an train B.

3 And you can cross-tie across units, and  
4 so the particular components aren't going to have  
5 low importance measures.

6 MEMBER ROSEN: Now, this is a good  
7 thing, except for the argument that therefore you  
8 can take all kinds of failures and the plant can  
9 summarily with a completely degraded maintenance  
10 program, because it is designed so robust, and that  
11 is the back stop.

12 MR. DUBE: That is exactly right,  
13 because otherwise we would have 80 or a hundred -- I  
14 mean, there was one calculation, and it was in many  
15 significant digits, number of failures to cross, and  
16 obviously that is not reasonable. So that's why the  
17 back stop comes in.

18 MEMBER LEITCH: Trying another input  
19 into that process is taking a corrective action  
20 program, and if you are having that many repetitive  
21 failures.

22 ACTING CHAIRMAN BONACA: But still I  
23 think the backstop puts some sense into the -0-

24 MR. DUBE: Exactly. So I mentioned the  
25 30 days, which is the time of the back stop, and it

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 is called completion time in the proposed risk-  
2 informed tech specs.

3 The next slide shows you on a first cut,  
4 and this is plant specific for San Onofre what  
5 exactly I mean. And here is the system on the left,  
6 the particular component, the failure modes, the  
7 number of failures to reach white, and in the  
8 Fussell-Vesely there will be UR, which again is  
9 roughly risk achievement worth minus one.

10 It shows an inverse relationship. The  
11 lower Fussell-Vesely over the UR, the more failures  
12 to get white. I mean, it is just basic algebra,  
13 basic math. The higher Fussell-Vesely over the UR,  
14 the lower number of failures.

15 MEMBER APOSTOLAKIS: Are you saying that  
16 Fussell-Vesely and risk are deterministically  
17 related? You keep saying that FV over U minus one  
18 is wrong.

19 MR. DUBE: Fussell-Vesely over UR for a  
20 low UR is approximately risk achievement minus one  
21 algebraically.

22 MEMBER APOSTOLAKIS: So why aren't we  
23 looking at both Fussell-Vesely and UR?

24 MR. BARANOWSKY: We're not.

25 MEMBER APOSTOLAKIS: Not here, but the

1 special treatment requirements staff does, and the  
2 argument is that they are independent. I mean, the  
3 risk reduction work is related to Fussell-Vesely,  
4 but that is a separate thing and now you are saying  
5 no.

6 MR. DUBE: Algebraically you can  
7 approximate Fussell-Vesely over UR, is approximately  
8 risk achievement worth minus one or a low UR.

9 MR. YOUNBLOOD: This is Bob Youngblood.  
10 Dividing by UR is the critical element.

11 MEMBER APOSTOLAKIS: I agree.

12 MEMBER SHACK: For a passive component  
13 where the unreliability is zip, the numbers sort of  
14 become meaningless.

15 MEMBER ROSEN: And the risk achievement  
16 for those very high reliability components gets to  
17 be enormous.

18 MR. DUBE: So there is an inverse  
19 relationship here, and lo and behold, the next  
20 transparency, which on your sheets are black and  
21 white, and my is colored, and the overhead  
22 transparency is colored, shows you the red, which  
23 are those which -- well, this is a phenomena that we  
24 didn't know how to deal with when it first came out.  
25 I will be honest, okay?

1                   We artificially said greater than 20  
2 failures is insensitive. Well, one can even argue  
3 something lower, but we have to pick some number,  
4 because when we were trying to adjust this model to  
5 address invalid indicators and insensitive  
6 indicators, and do sensitivity studies, we had to  
7 start with something to fine tune it, and so that's  
8 what we called it.

9                   But our backstop would not be minus 20,  
10 but this gives you an idea of where we were, and it  
11 was something like 11 percent of the systems are  
12 insensitive.

13                   So we have a number of the systems that  
14 are invalid, and a number of systems that are  
15 insensitive.

16                   ACTING CHAIRMAN BONACA: It is three  
17 o'clock, and why don't we take a break.

18                   (Whereupon, at 3:00 p.m., the meeting  
19 was recessed and resumed at 3:21 p.m.)

20                   ACTING CHAIRMAN BONACA: Let's get back  
21 to the meeting, and you were I believe at the  
22 identification system, page 18.

23                   MEMBER SIEBER: Page 18.

24                   MR. DUBE: Page 18. The next several  
25 issues are not maybe as profound as the issue in

1 value indicators and sensitive indicators, but they  
2 were major issues that came out of the workshop.

3 Something is -- you know, such as  
4 identifying the system boundaries, there is a  
5 definition in the guidance, but you find what is a  
6 train, and it is based on parallel heat exchanges,  
7 pumps, and flow path. But there is some different  
8 configurations out there that may not fit neatly  
9 into those definitions.

10 So the way that we are resolving this is  
11 that we have got a website where we pose and  
12 frequently ask questions, and we discuss them in the  
13 public meeting. We will revise -- or NEI will  
14 revise 99-02 with improved guidance.

15 And then before final implementation,  
16 assuming that this goes forward, there will be at  
17 least one, and probably several, lessons learned  
18 workshops where these experiences are shared and  
19 hopefully in an effort so that the plant  
20 implementing this won't have the same issues.

21 Data collection. For a number of  
22 plants, I have had an issue where they had a large  
23 number of components that needed to be monitored.  
24 On average, the number of components we found is  
25 about 50 per plant, which is not an unreasonable

1 number.

2 I mean, when you really think of it, the  
3 internal events, core damage frequency at the plant,  
4 at least for these six systems, can be represented  
5 by in large part by 50 components, which tells you  
6 something right there.

7 That much of the risk from active  
8 components falls on a small population relatively  
9 speaking. But because we had deterministic criteria  
10 way back when in the program for identifying whether  
11 a component needs to be in scope or not if you will,  
12 or monitored, there were some plants that had a  
13 large number of valves to monitor, like 35 or 40, or  
14 45, and so there were some concerns with that.

15 It had been a burden, but the resolution  
16 as we are coordinating this with INPO consolidated  
17 data entry program, so that licensees will be able  
18 to report the data through this mechanism and not  
19 have to make a separate report for the MSPI. It  
20 will be uploaded and downloaded relatively easily.

21 MEMBER SIEBER: That is the EPIX.

22 MR. DUBE: Correct.

23 MR. BARANOWSKY: The EPIX is a  
24 subelement of that whole thing.

25 MEMBER SIEBER: Right.

1 MR. BARANOWSKY: It used to be MPRDS,  
2 but with this consolidated data entry is going to  
3 include several things, like the old monthly  
4 operating reports. It will include the actual PI  
5 values that are not -- are they coming through NEI?  
6 How does that work now? They come through NEI?

7 MR. SATORIUS: Yes, the come through  
8 NEI.

9 MR. BARANOWSKY: So this CDE would be  
10 the place that they would stream into.

11 MR. SATORIUS: Yes.

12 MR. DUBE: A second way to handle the  
13 number of values and to reduce the number that need  
14 to be monitored is kind of a risk-based approach,  
15 which I am proposing to use 10 to the minus 6 per  
16 year.

17 And I know that George is going to say,  
18 well, you are mixing up the Fussell-Vesely and  
19 Bromberg all over again, but it turns out that we  
20 looked at Fussell-Vesely over UR as a cut-off means,  
21 as well as Bernbaum, and I think Bernbaum is the  
22 best, because it has the core damage frequency  
23 already impacted into it, and I will show you some  
24 slides in a second.

25 And the third item that I think we need

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 before we move forward, and this is my  
2 recommendation to the industry, I will proffer some  
3 software and some interface for data entry, because  
4 we did find a number of data entry problems, or I  
5 should say the inspectors when they did the  
6 inspection found this.

7 This is a number of valves that need to  
8 be monitored, and on the X-axis is the Bernbaum  
9 cutoff. In other words, if we set anything with an  
10 importance measure below this or not, we are going  
11 to exclude, and so the number of valves per plant on  
12 the Y-axis, and I have showed you for the 20 pilot  
13 plants, red is the plant with the highest number of  
14 valves to be monitored.

15 Blue is average, and I guess black is  
16 lowest, and it gives you an idea of how many valves  
17 have to be -- and you can see that there is a quick  
18 drop for very low Bernbaum, and then it kind of  
19 levels off. So this is the benefit if you will of  
20 having a cutoff value on Bernbaum for the number of  
21 valves to be monitored.

22 And keep that in the back of your mind,  
23 and then look at the next graph, which is what I  
24 call the unaccounted for URI, the unaccounted for  
25 delta CDF due to unreliability if we were to exclude

1 particular valves as the Bernbaum goes up.

2 And you can see that this is kind of the  
3 cost if you will, and it starts to take off around  
4 10 to the minus 6. So one could use a 10 to the  
5 minus 6 cutoff on Bernbaum, and reduce the number of  
6 valves that have to be monitored, particularly for  
7 the plants with the most number of valves.

8 And yet not lose the contribution to the  
9 index if you will to any great extent. One could  
10 have done this from the start if you will, and  
11 perhaps used an importance measure to begin with,  
12 but if you carry it to an extreme, you might have  
13 some systems with no components in it if you will.

14 So I think that this is a happy medium  
15 that for those few plants that had lots of valves to  
16 monitor, you will be able to reduce the number of  
17 valves to be monitored by a measurable amount, and  
18 not miss important contribution to delta core damage  
19 frequency or the index if you will.

20 MEMBER ROSEN: Do you mean monitor for  
21 the purposes of the index program?

22 MR. DUBE: Exactly.

23 MEMBER ROSEN: And that these plants  
24 will continue to maintain those valves?

25 MR. DUBE: Right.

1 MEMBER ROSEN: And to continue to  
2 monitor them for maintenance rules and --

3 MR. DUBE: But valves are particularly  
4 difficult to monitor, because you know that when a  
5 valve fails, you know it fails. There will be a  
6 condition report of some sort.

7 And pumps, you know, there are graphs,  
8 and even computer generated counts on pump starts,  
9 and run hours. But valves, most plants don't have  
10 little counters that count valve strokes.

11 And as part of this effort, you need to  
12 count demands, as well as failures. So having a lot  
13 of valves is kind of a data collection, but this is  
14 a reasonable approach that I believe is appropriate.

15 MEMBER ROSEN: Are you saying that  
16 plants are going to install hardware on their  
17 valves?

18 MR. DUBE: No, but they have to estimate  
19 the count, and they estimate the count based on how  
20 often do they do this surveillance, and how many  
21 times on average would they stroke this valve based  
22 on normal operations. So a number of these are  
23 based on estimates, less the demands.

24 MEMBER ROSEN: So not hardware?

25 MR. DUBE: Right. So I think that the

1 issue of data collection burden in my mind is  
2 resolvable relatively easily. The next couple of  
3 issues are tough ones, at least maybe conceptual,  
4 but let me start with a quote from NUREG CR-6819 and  
5 I am sure that there will be lots of opinions  
6 because there are some people around this table who  
7 have done a lot in common cause.

8 But in this report, it says approximate  
9 causes of CCF events are no different from the  
10 approximate causes of single components failures.  
11 It is reasonable to postulate that if fewer  
12 component failures occur that fewer CCF events would  
13 occur.

14 My opinion of that from my experiences  
15 is that the kinds of behavior, either maintenance,  
16 procedural, human error, what have you, that may  
17 change the independent failure rate and would also  
18 lend itself to perhaps change the common cause  
19 failure rate.

20 Now, there is a coupling, and that if  
21 there is a change in the independent failure rate,  
22 there is in all likelihood a change in the common  
23 cause failure.

24 MEMBER APOSTOLAKIS: Are you saying that  
25 your standard model for multiple Greek letter or

1 whatever, the common cause failure contribution is  
2 the independent failure rate times, say, data for  
3 two components. Are you saying that a common cause  
4 failure term would be affected because of LAN that  
5 has been reduced or it will affect data as well?

6 MR. DUBE: Data may be changing, but it  
7 certainly will change the LAN.

8 MEMBER APOSTOLAKIS: So in which case  
9 the term would be reduced.

10 MR. DUBE: Right.

11 MEMBER APOSTOLAKIS: So it is through  
12 that that there would be a primary reduction?

13 MR. DUBE: Right.

14 MEMBER APOSTOLAKIS: But data might  
15 considerably change.

16 MR. DUBE: It does change.

17 MR. BARANOWSKY: We had data to show  
18 that it does change.

19 MR. DUBE: Exactly, and backing this up  
20 with data, we actually looked at a number of  
21 components, and the common cause error rate has  
22 decreased tremendously over the last decade or 15  
23 years, and the single failure rate has gone down.

24 And in fact almost parallel, which kind  
25 of indicates as you said the coupling factor, which

1 is the data or -- over time may be changing, but it  
2 has been changing less.

3 MEMBER APOSTOLAKIS: It is not being  
4 inconsistent with the prevailing view that because  
5 of this major effort that was sponsored by the NRC  
6 and EPRI, or the NRC anyway, that people became more  
7 aware of the issue of common cause failures, and so  
8 they have paid more attention to the coupling  
9 factor, and they have reduced it. The coupling  
10 really itself has been reduced.

11 MR. DUBE: The coupling has gone down,  
12 but not as much as the overall failure rate.

13 MEMBER ROSEN: What's driving the fact  
14 is that these two things go together and what is  
15 driving that is improved management, safety culture  
16 if you will.

17 MEMBER APOSTOLAKIS: Yes.

18 MEMBER ROSEN: And they go together.

19 MR. DUBE: Right.

20 MEMBER APOSTOLAKIS: Yes, but the point  
21 is that Don is making is that the primary driver is  
22 the independent --

23 MR. DUBE: Well, they go together.

24 MEMBER ROSEN: NO, George that is the  
25 mathematical model. The primary driver is the guys

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 who work to keep it from going down. Better  
2 training, better procedures, better --

3 MEMBER APOSTOLAKIS: But I would agree  
4 that it is really the better training and better  
5 procedures that influences the coupling. The  
6 coupling itself.

7 MEMBER ROSEN: I don't think anybody  
8 knows that the coupling is there. I mean, the  
9 valves don't know the coupling is there, and whether  
10 somebody comes out and maintains it.

11 MR. DUBE: The coupling is something  
12 that I sometimes say to myself that statisticians  
13 calculate from the data, because there seems to be a  
14 correlation, but I am not sure people in the field  
15 are thinking, oh, .3 factor or so, and I would not  
16 get a independent failure because I might increase  
17 the common cause.

18 But I think that the change for the same  
19 reasons, the same improvements in maintenance  
20 practices, and procedures, and so forth. I only  
21 bring this up, because it is an important issue.

22 It is an issue of controversy and an  
23 issue of differences of opinion, and my second  
24 bullet says should not changes in CDF relating to  
25 changes in plant specific unreliability from single

1 component failures also include the effect from  
2 changes in the common cause factor rate given this  
3 coupling factor.

4 And if the answer to that is yes, it is  
5 a loaded question, then we need to add in the  
6 Fussell-Vesely importance from common cause for a  
7 particular common component type into the overall  
8 expression.

9 MEMBER APOSTOLAKIS: I have to problems.  
10 If I didn't do what you are suggesting, what would I  
11 do? Would I consider only the independent failure,  
12 the product of the failures?

13 MR. DUBE: The importance measure that  
14 is used in the algorithm as it is currently  
15 formulated would be just the Fussell-Vesely from  
16 independent failure of that pump.

17 Whereas, included in the common cause  
18 contribution would say if you change the independent  
19 failure rate and the common cause failure rate  
20 changes, and I need to capture that contribution in  
21 the Fussell-Vesely that I use in the algorithm, and  
22 the best way to show it may be to jump ahead, and  
23 clearly it has an impact on the algorithm and the  
24 index.

25 The screen shows this better since it is

1 in color, but this is the failure rate on the X-  
2 axis, failure to start. These are kind of high  
3 numbers, but just look at the concept here.

4 The bottom is if I just varied the  
5 independent failure rate, and how does the delta CDF  
6 calculated by the algorithm change? That is the  
7 thing that is either blue or green, or the black  
8 line on the bottom.

9 If I include the contribution of common  
10 cause to the Fussell-Vesely, and that as the single  
11 failure rate changes through a coupling, the common  
12 cause failure rate changes. The red shows how that  
13 affects the overall quantification.

14 What it means is that in practice it  
15 means that it takes somewhat fewer failures to cross  
16 the yellow white threshold in this particular case.

17 MEMBER APOSTOLAKIS: So right now the  
18 computer programs don't do this?

19 MR. DUBE: The current MSPI method is  
20 silent, is mute, on how to treat common cause, the  
21 contribution of common cause.

22 MEMBER APOSTOLAKIS: And what is the  
23 Fussell-Vesely importance of a component? In the  
24 calculations, it will not include the common cause  
25 failure term?

1 MR. DUBE: The common cause will have  
2 its own Fussell-Vesely.

3 MEMBER APOSTOLAKIS: As a separate --

4 MR. DUBE: Separately.

5 MR. BARANOWSKY: It may. Some will do  
6 it the other way.

7 MR. EIDE: Steve Eide, INEEL. The SPAR  
8 model, if you get a Fussell-Vesely for the  
9 independent failure, and you get a common cause  
10 event, that would be another Fussell-Vesely and they  
11 are not tied together in the Fussell-Vesely  
12 calculation.

13 MR. DUBE: Right, but you can get a  
14 group Fussell-Vesely in that, right?

15 MR. EIDE: Yes, you can get around that  
16 by selecting both (inaudible) common cause event,  
17 and doing a group Fussell-Vesely for that, and  
18 getting a single or combined Fussell-Vesely for that  
19 component group.

20 MEMBER SHACK: Well, as a performance  
21 measure, you could probably do without it based on  
22 your arguments, and if you insist on applying it to  
23 risk, you need to include it, right?

24 MR. BARANOWSKY: And this will reflect  
25 like if you have four pumps, three pumps, two pumps,

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 this will be significant.

2 MR. DUBE: Yes, it is an adjustment on  
3 how we or what we use for the Fussell-Vesely.  
4 Absolutely.

5 MEMBER APOSTOLAKIS: But this is  
6 important also for other interaction, special trip.

7 MEMBER SHACK: Well, yes, that has been  
8 discussed.

9 MR. DUBE: We derived the same issue  
10 separately.

11 MEMBER ROSEN: The Fussell-Vesely  
12 treatment as I recall was handled by sensitivity  
13 analyses, and it was shown that the impact of common  
14 cause was looked at through a set of sensitivity  
15 analyses.

16 MR. DUBE: Yes. This is one sensitivity  
17 here. We have just in the last days literally  
18 looked at some of our pilot plants the impact, and  
19 in some cases it may be a few percent, and in other  
20 cases it may be tens of percent or even more,  
21 depending on the configuration.

22 A 2 out of 2 situation, or in other  
23 words, two diesel generator plants, and adding in  
24 this Fussell-Vesely from common cause may not be a  
25 big adjustment. But a highly redundant plant, where

1 the Fussell-Vesely is very low because of the  
2 multiple density, adding in the common cause may  
3 increase that by factors of 2, 4, 5, even 10.

4 The thing is that 10 times is a small  
5 number, and still is not an unreasonable number.  
6 But unless --

7 MEMBER ROSEN: But it s a real  
8 reflection of the consideration, and if you have  
9 two, that's good, and if you have four is better,  
10 then why not 10? Well, obviously that is crossed in  
11 complexity, and you don't get the benefit is the  
12 common cause. It cuts it off.

13 So this has the effect of reflecting  
14 that in the analysis and in the indicator.

15 MR. DUBE: That is my opinion, and I  
16 think the opinion of the technical team on this.

17 MEMBER APOSTOLAKIS: But it would be a  
18 simple matter to find the importance for components  
19 if you have an expression from the common cause  
20 failure term that --

21 MR. DUBE: Yes, in practice.

22 MR. BARANOWSKY: Not everybody has it  
23 like that.

24 MR. DUBE: But in practice we think  
25 there is a way of doing it, and for the licensees to

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 do it is a simple mathematical approach. That is  
2 not the issue. The issue is the principal of  
3 whether we should include it or not. That is where  
4 there is no agreement.

5 MEMBER APOSTOLAKIS: That is why I made  
6 the comment earlier that sometimes what the code  
7 does is a boundary condition. This is the way that  
8 it should be done.

9 MR. BARANOWSKY: Well, this is the  
10 position that we are proposing, and we are telling  
11 you why.

12 MR. DUBE: And probably by the next --

13 MEMBER APOSTOLAKIS: Excuse me, but I am  
14 just curious, but if you have two redundant valves,  
15 and each one has a failure probability of  $Q$ , the  
16 independent failure term would be  $Q$  squared would it  
17 not?

18 MR. DUBE: Unavailability?

19 MEMBER APOSTOLAKIS: Yes.

20 MR. BARANOWSKY: Unreliability.

21 MEMBER ROSEN: You are talking about  
22 independent failure probability.

23 MR. DUBE: Unavailability or  
24 unreliability?

25 MEMBER APOSTOLAKIS: Unavailability.

1 MR. DUBE: Unavailability, you would  
2 probably --

3 MEMBER APOSTOLAKIS: Unreliability, 2  
4 squared.

5 MR. DUBE: Yes.

6 MEMBER APOSTOLAKIS: So what is the  
7 Fussell-Vesely event? What is the Fussell-Vesely of  
8 the component since you have a square term?

9 MR. DUBE: There is no easy way. When  
10 something is ended, there is no easy way to  
11 calculate Fussell-Vesely right off the top of your  
12 head. If they were orange you could. The computer  
13 would tell you what it is.

14 MEMBER APOSTOLAKIS: Yes, it would tell  
15 you what the importance of Q squared is, but when it  
16 calculates the importance of the component, a single  
17 component, how would you do that?

18 MR. DUBE: A single component?

19 MEMBER APOSTOLAKIS: Yes, from a single  
20 valve.

21 MR. DUBE: It adds up all the sequence,  
22 and all the cut sets with that component, and shows  
23 the ID that you use for it, the basic event name.  
24 It divides that by core damage frequency.

25 MEMBER APOSTOLAKIS: Even though some

1 terms are squares and some are --

2 MR. BARANOWSKY: But they don't show up  
3 --

4 MR. DUBE: They don't show up squared  
5 though. X-1 times X-2. It won't show up as X-1  
6 squared, right. It will show up as X-1 times X-2,  
7 even though X-1 and X-2 may be the same number.

8 Anyway, I think this is resolvable, and  
9 I think it is important, but it has been a difficult  
10 issue. The next one has to do with the support  
11 system initiated to Fussell-Vesely.

12 Again, 80 percent of this discussion  
13 hinges on this Fussell-Vesely and I am sure that  
14 Bill Vesely, when this term was named after him,  
15 didn't realize that it would be used in so many  
16 different ways.

17 But the algorithm depends on this  
18 particular measure, and that's why I put so much  
19 emphasis throughout this project that we have got to  
20 calculate this number pretty accurately because the  
21 approach depends on it, at least to a first order.

22 So the issue here is that the failures  
23 of components leading to support system initiator --  
24 and, for example, loss of service water --  
25 contribute to core damage frequency.

1                   And when we looked at the pilot plants,  
2                   about two-thirds of those 20 plants used fault trees  
3                   to quantify the initiating event frequency. So if  
4                   you had a loss of service water at the top of the  
5                   default tree, it would have, you know, if Pump A  
6                   fails, and Pump B fails, and Pump C fails, and so on  
7                   and so forth.

8                   And to the extent that they had a fault  
9                   tree when the computer calculated Fussell-Vesely, it  
10                  captured that contribution to the initiator, as well  
11                  as a support system. But one-third, the remainder  
12                  of the plants, used a point estimate.

13                  Instead of using a fault tree, they just  
14                  used a number of 10 to the minus 3 per year  
15                  initiating event frequency. So that 10 to the minus  
16                  3 did not have the constituents that made it up,  
17                  such as this pump failing and this pump failing.

18                  So in the pilot program, it identified  
19                  an inconsistent approach and it hinted that there  
20                  might be some contribution to Fussell-Vesely left  
21                  out. And so we have come up with a logical approach  
22                  to address it.

23                  For those models using point estimates,  
24                  that the contribution of the initiator to core  
25                  damage frequency is significant, either A, add the

**NEAL R. GROSS**

[www.nealrgross.com](http://www.nealrgross.com)

1 support system initiator fault tree.

2 So we are going to have to take this  
3 point estimate and create a little fault tree, or we  
4 have come up with an adjustment factor and it is a  
5 little bit beyond -- you know, we could spend an  
6 hour on it, but an adjustment factor that will be a  
7 little bit conservative, but both myself and  
8 representatives from industry agree that it is a  
9 reasonable approach to make sure that the support  
10 system captures all of the Fussell-Vesely, and that  
11 is a long story being short on that.

12 The final issue, SDP and MSPI, and we  
13 kind of talked about it at the beginning and I am  
14 going to hand the baton over to Pat, because he has  
15 been following a lot of these issues.

16 And this is one of the final technical  
17 issues, which has to do with have we thought about  
18 this MSPI versus SDP, and when is one going to be  
19 used instead of the other. You know, what were  
20 their original purposes for, and what are the  
21 aspects of implementing it.

22 MR. BARANOWSKY: Actually, I will just  
23 finish off the rest of the discussion. Let's go  
24 back a little bit in history so I can tell you a few  
25 things. When SECY 99-007 was put out, it had in

1 there the concept that performance indicators would  
2 be used as the principal measure of performance when  
3 they were available, and when they were not  
4 available, a risk informed inspection program and  
5 significance of inspection findings would be used.

6 Somewhere along the way both got  
7 implemented on the same things, and it was if I  
8 don't get you here, I have got you there kind of  
9 system, which is currently in practice.

10 And that has been going on now for  
11 several years. That is whatever is in the SECY is  
12 not the way the program is being implemented for  
13 whatever reasons. Well, because of these concerns  
14 that we have about some of the false positives in  
15 particular, wherein one failure of the diesel  
16 generator, when you look at a short time frame, like  
17 one year, one year you might have 12 tests.

18 And due to the unavailability associated  
19 with that in a one year time frame, it is pretty  
20 high and you could end up with a short term risk  
21 that is on the order of 10 to the minus 6.

22 But if the diesel generator was  
23 surveilled for 3, 4, or 5 years, you have a track  
24 record that when failure has a different  
25 implication. So for cases where the MSPI and the

1 SDP differ, what we are trying to do -- and we are  
2 not done with this, but we have done some looking at  
3 this, is to see if they differ because of that kind  
4 of a premise, or some other reason.

5 And if they differ, it doesn't make any  
6 sense. Now, as it turns out there is actually only  
7 a few cases in the historical record where the  
8 original formulation that didn't have all of these  
9 issues addressed that Don talked about today with  
10 the original formulation, showed that a different  
11 outcome of SDP versus MSPI.

12 The second thing that we want to look at  
13 also is whether or not the SDP and the ASP analyses  
14 were giving similar results, because in many cases  
15 the SDP is done with the simplest technique  
16 possible, and when there is a performance issue, and  
17 folks agree that there is a performance issue, and  
18 want to move on and fix it, and not worry too much  
19 about spending a lot of time doing risk  
20 calculations.

21 On the other hand, we know that the MSPI  
22 and the ASP analyses are trying to spend more time  
23 on the details of the risk analysis, as opposed to a  
24 fairly short handbook kind of thing.

25 So what we are proposing is that we go

1 back and look at these things, and make sure that  
2 the validity and the appropriateness of using the  
3 MSPI in those two cases, whether our differences are  
4 such.

5 Our best cut right now is that they are  
6 a small, small percentage of any of the -- what I  
7 call non-green findings, whether they be by PIs or  
8 by inspection activities.

9 So there is just a small interface where  
10 you might get a slightly different result. Now a  
11 concern also would be that, well, gee, what does  
12 that mean. Well, that means that you think about  
13 things a little differently, just like when we  
14 didn't have the reactor oversight process, and we  
15 had SALP.

16 We made some findings which if you went  
17 back and overlayed the reactor oversight process  
18 approach on it, you wouldn't necessarily come up  
19 with the same findings.

20 Sometimes we error on this side or that  
21 side, and it is not a very super precise thing, but  
22 we think we get the really significantly poor  
23 performers in each case.

24 And so that is our plan, is to basically  
25 document that and present the arguments as to why at

1 least on the face of the outcomes that it makes  
2 sense to use a performance indicator of this type,  
3 versus the significance determination process.

4 There was an ACRS letter written not too  
5 long ago that basically said the significance  
6 determination process was not a good way to measure  
7 performance, but it was a good way to assess the  
8 risk significance of performance findings.

9 And by the way, I completely agree with  
10 that. I think it is also the only thing that we  
11 have for rare events where you can't get a string of  
12 things that you can put into a performance measure  
13 that accumulates a performance if you will to look  
14 at trends.

15 In that case, when there are rare events  
16 that are outside what would be expected, and you  
17 would not call them false positives -- and an  
18 example would be that you have had a LOCA.

19 You don't expect a LOCA in a frequency  
20 in the plant, and so that when that occurs, it is  
21 kind of outside the norms. And I think it is fair  
22 to use risk at that point, or some common cause  
23 failures which occur very rarely by the way.

24 You know, there are not very many common  
25 cause failures where multiple components actually

1 fail at plants. So you can't really trend within a  
2 plant common cause failures very well.

3 You can look at the whole industry over  
4 a picture period of 20 years, which we have done,  
5 but that is with a hundred plants going all the  
6 time. There is no other country that can do that  
7 besides the U.S. They just don't have the data.

8 So it is for those cases where we think  
9 the SDP is a good measure of some sort that it  
10 should be used, and that is for inspection findings,  
11 these long duration outages that are not captured by  
12 routine tests and so forth.

13 And that the PIs, where there is an  
14 accumulation of performance information, such that  
15 one would compute reliability and unavailability  
16 accumulated over time to look at trends, that is a  
17 place where the MSPI is best used.

18 So this is sort of a philosophy that we  
19 are overlaying on top of a practical look at what  
20 the outcomes are, and there is a little bit of  
21 heartburn to be honest with you with some of the  
22 region folks who want to use an SDP evaluation,  
23 period, for everything, and we just need to work  
24 through this issue.

25 And we will present the results of our

1 detailed look at the individual instances when we do  
2 our final report.

3 MEMBER APOSTOLAKIS: What do you mean by  
4 --

5 MR. BARANOWSKY: By what?

6 MEMBER APOSTOLAKIS: You said they want  
7 to use an SDP evaluation for everything. What  
8 exactly does that mean?

9 MR. BARANOWSKY: For every item that  
10 could go into a performance indicator where a  
11 performance issue was identified. So if a valve  
12 failed and there was a performance issue identified  
13 with the failure of the valve, then there are some  
14 people who want to run an SDP on that every time,  
15 even if we are tracking valve performance using  
16 reliability and availability indicators.

17 MEMBER SIEBER: On the other hand that  
18 is mostly instigated by licensees, who say I am  
19 agreeing to a white threshold, but my calculation  
20 shows that it is not risk significant. So they ask  
21 for the SDP.

22 MR. BARANOWSKY: I think it goes both  
23 ways, but in most instances it is not valves as much  
24 as it is maybe a diesel generator, because the SDP  
25 looks at a one year period of time remember, and the

1 performance indicators cover a 3 year period of  
2 time.

3 Now, maybe that is an issue that ought  
4 to be looked at to see if they should have the same  
5 period of time.

6 In that case, you would be surprised at  
7 how much closer they could eventually come to the  
8 same outcomes.

9 MEMBER SIEBER: Actually, the SDP looks  
10 at the event, and then says if you come up with a  
11 failure it is probably unavailable half of the time  
12 since the last test. So it is less than a year and  
13 it sort of elevates the importance of that single  
14 event, compared to what it would have been averaged  
15 in over 3 years worth of data. That's what I think.

16 MR. BARANOWSKY: I think it gives a risk  
17 significance and importance of that finding or that  
18 incident. I mean, I wouldn't say negative things  
19 about the process because it is modeled after the  
20 accident sequence precursor program, which does the  
21 same thing.

22 But what we don't do with the accident  
23 sequence precursor program is take a single accident  
24 sequence precursor and go, oops, we had a major  
25 failure in poor regulation last year because we had

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 a precursor.

2 And then when we don't have one the next  
3 year, we go but we did very good the following hear.  
4 No, we have to take a string of these things,  
5 because we know that looking at one of them can't  
6 give you a performance trend.

7 And it is the same problem that goes  
8 with trying to use the significance determination  
9 process for things where you can have a string of  
10 issues, and look at them because the interval is  
11 such that you could have more than one hit if you  
12 will in that time frame.

13 MEMBER SIEBER: Let's say you were -- it  
14 seems to me that if you end up with an inspection  
15 finding that you should go to the SDP, as opposed  
16 to, say, that this modifies the performance index or  
17 this component.

18 On the other hand, if it is revealed  
19 through the performance index, you ought to use the  
20 thresholds that are appropriate to the performance  
21 index.

22 MR. BARANOWSKY: I think we are saying  
23 that.

24 MEMBER SIEBER: Well, it is not clear,  
25 because I think that you could run them one way or

1 another, depending on -- you know, if you are  
2 writing them, and you say this is the way it is  
3 going to be, then it will be that way.

4 On the other hand, if you have a choice,  
5 people will make the choice that causes the least  
6 amount of grief.

7 MR. DUBE: We agreed ahead of time on  
8 this.

9 MR. BARANOWSKY: And we do agree on this  
10 issue, and so what I am doing is giving you our  
11 tentative conclusion just based on some logical  
12 thinking and looking at the differences in these  
13 things. Now also to help me talk about this is Mark  
14 Satorius.

15 MR. SATORIUS: I am Mark Satorius with  
16 the staff. I was just going to point out that most  
17 of the examples that Pat is talking about are event  
18 driven, where we have an event response, and we do  
19 an inspection, and the result of that is that you  
20 can't know what you know.

21 So you identify certain performance  
22 issues during these event responses inspection, and  
23 those are relatively limited. But those are the  
24 ones I think that -- and wouldn't you agree, Pat,  
25 that is where you are going to get this overlap more

1 than anything else?

2 MR. BARANOWSKY: Yes. But there has  
3 been some concern because if you talk about a diesel  
4 generator failure and you look at the unavailability  
5 of that failure over a one year period of time, that  
6 is going to give you a different perspective than if  
7 you look at it over 3 years.

8 And what we were talking about earlier  
9 were this one-half lambda tau term in terms of  
10 unreliability is not going to be equal to the  
11 probability of a failure on demand. You have to  
12 have a time period sufficiently wrong and T has to  
13 go to infinity for observations in order for those  
14 two to be equal.

15 I guess anyone who has done any  
16 reliability 101 or whatever has derived that  
17 equation.

18 MEMBER APOSTOLAKIS: But I like your  
19 third bullet, which says PIs measures changes in  
20 performance. Now, what you mean from what you said  
21 is that the performance of this valve. You are not  
22 comparing with peers, right?

23 MR. BARANOWSKY: You are comparing with  
24 what?

25 MEMBER APOSTOLAKIS: With PI

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 performance. I mean, the same valve somewhere else?

2 MR. BARANOWSKY: No.

3 MEMBER APOSTOLAKIS: But still though if  
4 the PIs measure changes in performance, then it  
5 seems to me naturally that the thresholds should be  
6 performance based and not risk.

7 The risk calculations that you are doing  
8 can be a valuable input to the process of developing  
9 the performance based thresholds, but I agree with  
10 you that PIs measure changes in performance.

11 So the PIs and the SDPs are doing two  
12 different things.

13 MR. BARANOWSKY: Well, I would ask that  
14 you have an open mind in that we think that we have  
15 come up with a blend on here, and just take a step  
16 back.

17 MEMBER APOSTOLAKIS: They both  
18 contribute to the decision, that's true.

19 MR. BARANOWSKY: And I think that you  
20 will see that it is one way as Don said, you have  
21 got these front and back stops, and you have to  
22 figure out where you put these things. And you  
23 adjust them or some things based on how risk comes  
24 into the picture.

25 MEMBER APOSTOLAKIS: Yes.

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 MR. BARANOWSKY: But we just don't go  
2 with risk which allows a way, way wider span, okay?

3 MEMBER SIEBER: Well, you have the front  
4 stop and you have the back stop, and the adjustment  
5 factor in the middle.

6 MR. DUBE: Exactly.

7 MEMBER SIEBER: I think you scratch your  
8 head and is this really real, you know.

9 MR. BARANOWSKY: One of the things that  
10 I didn't mention at the beginning of the talk was  
11 that the white paper by the way, and which I did say  
12 was sort of a kick-off concept, we are going to  
13 document every one of these things in a written  
14 report.

15 And that will be coming in the fall  
16 before we ask to have the next meeting. So you will  
17 have a fair amount of time to see this stuff laid  
18 out a little bit more than just a few viewgraphs.

19 MR. DUBE: In following up on what  
20 George said on the issue, the alternative to having  
21 an algorithm if you will, and which basically  
22 calculates the number of failures and the  
23 unavailability to the threshold would be a multi-  
24 dimensional, big super matrix that says BWR-2 plant,  
25 and BWR-3 plant, combustion engineering plant with

1 pores, and combustion engineering plant with no  
2 pores. How many failures and it takes into account  
3 all the differences in design, and the differences  
4 in performance.

5 I mean, if one were to address plant  
6 specific aspects to the threshold, and even then I  
7 am not sure that expert judgment would come up with  
8 the right answer, because you have to take into  
9 account the variability of the design, the vintage  
10 of the plant, and so forth.

11 What this does is reduce this multi-  
12 dimensional matrix of thresholds to an algorithm  
13 that in essence calculates what that threshold is,  
14 but within certain limits. I mean, that is the way  
15 that I kind of view it, and that's it.

16 MEMBER SIEBER: Well, the first hurdle  
17 is to understand what it is that yo have done, and  
18 the second hurdle is to decide whether it meets the  
19 need or not.

20 MR. BARANOWSKY: The whole activity that  
21 we have gone through is fairly complex, and I am not  
22 saying that it isn't, because we have invested  
23 things that people had not thought of 2 years ago  
24 when we thought we knew quite a bit about risk-based  
25 performance indicators.

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

(202) 234-4433

[www.nealrgross.com](http://www.nealrgross.com)

1 But what we have come up with is a  
2 number of simplifying approaches to address all the  
3 complexities which are not as simple as adding one  
4 and one, but they are not as complex as doing an  
5 ECCS calculation either.

6 So you don't have to redo your PRA, and  
7 you don't have to redo your HRA, and you don't have  
8 to do any of that stuff, as long as the concepts --  
9 front stops and back stops -- using the importance  
10 measures in a simple equation, those things are all  
11 brought into it, and it is a pretty straightforward  
12 and grind it out.

13 So let me just summarize here, because  
14 then I want to just about some future activities.  
15 So the MSPI, as you have seen, it is highly risk  
16 informed, and it has plant specific design and plant  
17 specific data. We think that these maximum-minimum  
18 limits are a pretty big deal on making it kind of  
19 rational.

20 MEMBER APOSTOLAKIS: But are they any  
21 different from the performance based thresholds that  
22 we have requested? They are the same thing aren't  
23 they?

24 MR. BARANOWSKY: I am saying that I  
25 think that this is consistent with the detailed

1 discussions that I read that are behind the specific  
2 -- like one sentence position that you took to be  
3 honest with you.

4 MEMBER APOSTOLAKIS: Yes, and so that is  
5 what I am saying. That we are consistent.

6 MR. BARANOWSKY: I think so.

7 MEMBER ROSEN: For example, when we had  
8 a hard time with 23 SCRAMS, this deals with that.

9 MR. BARANOWSKY: This deals with it.

10 MEMBER APOSTOLAKIS: And then you would  
11 say there is a maximum.

12 MR. BARANOWSKY: Not for 23 SCRAMS it  
13 doesn't deal with it, but it could deal with it.  
14 And we have lots of technical --

15 MEMBER ROSEN: Well, if we ever went to  
16 this, that action matrix thing would not show this,  
17 right, with 23 SCRAMS?

18 MEMBER APOSTOLAKIS: It would not show  
19 the 23, no, because those guys would intervene and  
20 put a back stop.

21 MEMBER SIEBER: That would be a back  
22 stop.

23 MEMBER ROSEN: Back stop, okay.

24 MEMBER SIEBER: And then you would put  
25 in adjustment factors.

1 MEMBER APOSTOLAKIS: Are you suggesting,  
2 Mr. Sieber that we should do everything on a risk  
3 basis?

4 MEMBER SIEBER: No, I'm not.

5 MEMBER APOSTOLAKIS: Better me than you.

6 MR. BARANOWSKY: We expect to complete  
7 our analysis and then simulation analyses, and  
8 complete our analysis of these issues, and then do  
9 some simulations by the end of the summer to look at  
10 how all of these things fit together, because we  
11 have not really looked at them all together. So we  
12 need to do that.

13 And then if some new issues arise, we  
14 will address them, but we are fairly confident on a  
15 technical basis that if you will accept some of the  
16 philosophical thinking that went in here, we can  
17 probably address any residual things that might pop  
18 up in that regard.

19 So that is sort of the technical bottom  
20 line here. Now, that does not address all things  
21 regarding implementation, although this says  
22 tentative implementation schedule, let's look at a  
23 few things that are not really covered here that are  
24 also implementation related.

25 First of all, we are going to do the

1 technical work as a I stated, and at the end of  
2 August we will have the technical issues done, and  
3 we have done all the SPAR enhancements for the 20  
4 plants that are in the pilot program, and it will  
5 run all the things.

6 The pilot actually ends in September.  
7 It gives us a certain amount of time afterward the  
8 data collection to complete analysis and evaluation  
9 of the data. Then comes the big effort to see,  
10 well, what does this all mean in terms of the  
11 success criteria which Mark Satorius mentioned in a  
12 few items earlier?

13 Will it complete our table top analysis  
14 of the MSPI and the SDP issues and other  
15 implementation issues such as we will ask ourselves  
16 are we able to change the guidance for boundaries  
17 and data collection to eliminate some of the  
18 inefficiencies that occurred during the pilot.

19 Are we able to change the inspection  
20 guidance to eliminate some of the inefficiencies  
21 that occurred during the pilot. And I don't know if  
22 there are other issues, but we are going to have to  
23 work on guidance and what the costs in terms of  
24 burden of this thing is.

25 And I am sure that technically that this

1 is far superior to the current PI, but one has to  
2 make a decision as to whether or not implementation  
3 wise we are ready for it. We have issues regarding  
4 the PRAs and so forth, which we are not going to use  
5 this program as a wedge to go in and make the ASME  
6 standard work.

7 MEMBER SIEBER: Why not?

8 MR. BARANOWSKY: Because we have already  
9 got a cadre of people doing that, and I don't want  
10 to get them unemployed. But there are some insights  
11 that we have here that I think affect the bottom  
12 line of PRA and the qualitative outcomes of PRA that  
13 might help focus some of these things.

14 MEMBER SIEBER: I think that you are  
15 addressing things in your comparisons that the  
16 standard doesn't really deal with.

17 MR. BARANOWSKY: Well, they are in there  
18 inherently, but they should be explicitly in my  
19 opinion.

20 MEMBER SIEBER: I think if you follow  
21 the standards that you may end up with a high  
22 quality PRA, and then whatever discrepancies would  
23 in fact be (inaudible), but that is not consistently  
24 the case.

25 I could imagine now that you could go

1 through these standards, the PRA reviews, or peer  
2 reviews, and come out maybe okay, and still have  
3 some strictly inherent problems in your PRA. So  
4 this is just another way to look at that and I think  
5 it is good information.

6 MR. BARANOWSKY: Well, we are counting  
7 on the industry and the NRC working to implement the  
8 standard. That is an assumption that we have. It  
9 doesn't necessarily have to be all perfectly done in  
10 the beginning, because we have ways of identifying  
11 which plants we have the biggest questions about as  
12 I told you earlier.

13 MEMBER SIEBER: Well, you are going to  
14 reconcile the SPARs models to the plant PRAs anyway.

15 MR. BARANOWSKY: Yes.

16 MEMBER SIEBER: And that appears in a  
17 number of programs that once you do that, and you  
18 can rely on yours, or you can rely on theirs,  
19 provided that you know what the limitations are for  
20 each calculation model for the intended purpose.

21 MR. BARANOWSKY: I think ours are good  
22 for doing audit checks and for doing simulations to  
23 look at issues. They are really excellent for that.

24 MEMBER SIEBER: Let me ask a question.  
25 You have a schedule of things that you are going to

1 do, and so one of the things that the white paper  
2 talks about is a revision to NEI 99-02, which  
3 probably isn't out yet, but needs to come out in  
4 order for this to be a complete packet, and when  
5 will that happen? Maybe Tom, if he is still here,  
6 could tell us.

7 MR. BARANOWSKY: And Tom, when you get  
8 up to talk about that, as long as you are getting  
9 up, I had expressed an earlier interest in the  
10 industry's reaction to this. And maybe you could  
11 cover that as well.

12 MR. HOUGHTON: Sure. I am Tom Houghton  
13 from NEI. The NEI guidance document will be out in  
14 a draft a couple of weeks after we have decided  
15 these issues. According to that schedule that  
16 earlier fall effort before the go-no go is going to  
17 include industry also going through and putting all  
18 of these changes into the models and see what the  
19 results are that come out.

20 Because as Pat said, we don't know what  
21 the cumulative effect of all of these different  
22 activities that we are doing will have. But we  
23 think that in a couple of weeks after that these  
24 things will be wrapped up.

25 MEMBER SIEBER: You mean that fast?

1 Well, that's good.

2 MR. HOUGHTON: And then need to be out  
3 so that people can really focus on --

4 MR. SATORIUS: But the draft is already  
5 out because we used it to run the pilot. So I was  
6 not sure if that was clear.

7 MEMBER SIEBER: That's right. That is  
8 REV-2 isn't it?

9 MR. SATORIUS: Well, no, this was --  
10 what we did was that we pulled the format directly  
11 from REV-2 and then modeled it specifically for the  
12 pilot. So we already have a document that we are  
13 working on.

14 MR. HOUGHTON: That's right. The  
15 section of 99-2 REV-2, which relates to mitigation  
16 systems, is what is going to be replaced with this  
17 MSPI, and that that draft that Mark was talking  
18 about is that placement.

19 We didn't change it during the pilot  
20 because we didn't want to confuse everybody who was  
21 trying to report data for the 6 months of the pilot.  
22 So it stayed fix until we make these decisions, and  
23 then we will implement them into the document.

24 As far as the program is concerned,  
25 industry supports this program. We think it has the

1 advantages of resolving some of the complexity  
2 between maintenance rule definitions and WANO  
3 definitions.

4 We think that it is going to resolve  
5 some of the complications for system managers in  
6 trying to determine cascading, which we won't be  
7 doing anymore. That will make it more consistent  
8 with the way that people do maintenance rules.

9 We won't have this question of fault  
10 exposure and you get into lots of theoretically  
11 fault exposure, which is not an issue, but when you  
12 get into questions of would that failure mechanism  
13 reveal itself in a monthly test or an annual test,  
14 it gets quite confusing sometimes.

15 And that makes it very difficult. It is  
16 not the theory that is the problem. It is the issue  
17 of would this failure mechanism be exhibited in a  
18 test that is only an hour long, versus a full 24  
19 hour run. Things like that.

20 MEMBER APOSTOLAKIS: In this business of  
21 one-half lambda tau, I thought that was used as a  
22 means also of seeing what the impact on the  
23 unreliability would be if I changed the inspection  
24 interval.

25 MR. BARANOWSKY: That's with the

1 assumption that you have a long time period to make  
2 the calculation of lambda. If you calculate lambda  
3 every year using one year's worth of data, one year  
4 you get a low lambda, because you had no failures.

5 The next year you get a huge lambda  
6 because you had a failure. Then the next year you  
7 had no failures and you get a low lambda.

8 MEMBER APOSTOLAKIS: Well, 3 years, and  
9 I use 4 years, 5 years. I have a lot.

10 MR. BARANOWSKY: Then it becomes  
11 equivalent to basically the probability of failure  
12 on demand. They start to equate to each other.

13 MEMBER SIEBER: The longer --

14 MR. DUBE: That's right.

15 MR. BARANOWSKY: Well, one-half lambda  
16 tau becomes equal to the probability of failure on  
17 demand.

18 MEMBER SIEBER: The longer the period,  
19 the less significant is a single failure.

20 MR. DUBE: That's right.

21 MEMBER SIEBER: So there has to be a  
22 limit.

23 MR. BARANOWSKY: That's an approximation  
24 for small lambda, constant lambda, integrated, zero  
25 to infinity.

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 MEMBER APOSTOLAKIS: Let's say I am  
2 doing this on a monthly interval, and then someone  
3 who wants to successfully argue or wants to argue  
4 successfully that they can go to two months, are you  
5 saying then that your data then are invalid?

6 MR. BARANOWSKY: No.

7 MEMBER APOSTOLAKIS: Because they were  
8 connected under conditions of only one month?

9 MR. BARANOWSKY: No, what we do is just  
10 keep counting the demands.

11 MEMBER APOSTOLAKIS: But your basic  
12 calculation now is that you have an entirely new  
13 situation. I mean, you collect the data and you  
14 formulated a distribution that was based on the  
15 fundamental assumption of monthly tests, and I am  
16 telling you that I am going to do them every  
17 quarter. Can you really use that distribution again  
18 and start updating it with the new data?

19 MR. BARANOWSKY: I don't think that the  
20 days distribution are that sensitive. Remember, the  
21 ones that we are using are based on industry  
22 information and updated with plant specific. So  
23 what that means is that we have got weekly, monthly,  
24 quarterly stuff all mixed in there.

25 MEMBER APOSTOLAKIS: I am not saying

1 that what you are doing is wrong. I am just trying  
2 to figure out all the implications with the one-half  
3 lambda tau.

4 MR. HOUGHTON: Well, we would have a  
5 mixture until such time that the sliding 3 year  
6 average moves over and it would be a little  
7 inconsistent.

8 MEMBER APOSTOLAKIS: Well, you are  
9 producing a probability of failure per demand, and  
10 that is independent of time, correct?

11 MR. HOUGHTON: Yes.

12 MEMBER APOSTOLAKIS: It was developed  
13 under the assumption -- well, not assumption. It  
14 was reality that the tests are monthly. And if I  
15 change the interval and make it quarterly, do I  
16 start from scratch, or do I start from somewhere  
17 else?

18 At least with the one-half lambda tau, I  
19 had a way of going out and changing them to 3  
20 months, and coming back and saying, yes -- and which  
21 is also stupid to say that their unavailability is  
22 multiplied by three.

23 MR. BARANOWSKY: No, but you are making  
24 the assumption that --

25 MEMBER APOSTOLAKIS: That it is

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 different, which it may not be.

2 MR. BARANOWSKY: The assumption there is  
3 that there is not a demand dependent element to the  
4 failure rate.

5 MR. DUBE: And it is really that it has  
6 both, has both components in reality.

7 MR. BARANOWSKY: In reality, we know  
8 from actually taking data in several studies that  
9 have shown there are both elements that are in  
10 there.

11 MEMBER APOSTOLAKIS: But you have not  
12 taken data because it probably does not exist, but  
13 from one licensee who does it every three months,  
14 and another one who does it every month, and compare  
15 them and say there is no difference, because  
16 everybody does it monthly.

17 MR. BARANOWSKY: But what we had to do  
18 was take a licensee who does a monthly test, and  
19 another one who does it quarterly, and another one  
20 who does it weekly, --

21 MEMBER APOSTOLAKIS: The same test?

22 MR. BARANOWSKY: For the same equipment.

23 MEMBER APOSTOLAKIS: But the same test.

24 MEMBER APOSTOLAKIS: The same test.

25 MR. BARANOWSKY: But as close as we can

1 come up with, and looked at that.

2 MEMBER APOSTOLAKIS: But then if you see  
3 no difference, then I agree.

4 MR. BARANOWSKY: I am not saying that  
5 there has been no difference. What we are saying is  
6 that the true novel is one that has got a demand  
7 dependent element to it, as well as a time dependent  
8 element to it.

9 And when you plot a curve, you get a  
10 linear curve on these things usually, and you can  
11 come up with a proportionality factor that relates  
12 demands versus the run, versus the time dependent  
13 failure mechanisms. It is pretty complicated.

14 By the way, it is the second order  
15 effect in risk for most of these intervals that we  
16 are talking about, which I am not worried about in  
17 light of other inaccuracies. And we are talking a  
18 second or third decimal place of the risk equation.

19 MR. HOUGHTON: In terms of complexity,  
20 we think that we are making sausage right now in  
21 trying to develop this indicator. And there is  
22 complexity in it, but we think that it is going to  
23 be simpler when the program is in place and will be  
24 simpler for the utilities, because they are going to  
25 be just reporting demands, failures, and hours at

1 power when that equipment is unavailable.

2 And so once the computer algorithm is  
3 set up, that data can flow in without a lot of  
4 complication and a lot less what if's by the system  
5 engineer.

6 MEMBER SIEBER: And they don't even have  
7 to understand it.

8 MR. HOUGHTON: Another part of the  
9 complexity has been as Don and Pat have said, is  
10 what are the system boundaries and what are the  
11 components that are active and so on and so forth.

12 And we see that being able to be  
13 resolved through the other 80 units in a good change  
14 management plan, where there are a series of  
15 workshops, and where people can get together with  
16 what we learned from the process and develop those  
17 such that when the whistle blows to start the  
18 program that we don't have a lot of discussions  
19 about why is this valve in and why is that valve not  
20 in, and why didn't you model this, and why this or  
21 that.

22 That can be fixed so that this turning  
23 in complexity doesn't have to happen when it is  
24 implemented. So those are reasons why we think this  
25 is a better way to go and I think the only real

1 disadvantage from our point of view is the initial  
2 gathering of data.

3 Other than that, we think it is a better  
4 indicator, and it has less opportunities for arguing  
5 about when did it really fail, and what was going  
6 on. So we are in favor of it and in favor of the  
7 approaches that Don and Pat are talking about, about  
8 a front stop and a back stop, which will solve those  
9 problems.

10 And we were able to agree on what a  
11 reasonable number of SCRAMs was in the first one.

12 MEMBER SIEBER: 27.

13 MR. HOUGHTON: Three.

14 MEMBER APOSTOLAKIS: The green and  
15 white.

16 MR. HOUGHTON: The green and white.

17 MEMBER APOSTOLAKIS: I still think that  
18 expert judgment should play a role there and we have  
19 pioneered all these methods and don't just  
20 negotiate.

21 MEMBER ROSEN: That's what it was,  
22 expert judgment.

23 MEMBER SIEBER: It should be between  
24 smart people.

25 MEMBER ROSEN: Informed people.

1 MR. HOUGHTON: And we did have a rule  
2 where we tried to use the 95th percentile of  
3 performance.

4 MR. BARANOWSKY: Good. Thank you.

5 MEMBER SIEBER: Thank you.

6 MEMBER APOSTOLAKIS: So when is the  
7 letter going to be?

8 MR. BARANOWSKY: We are going to get  
9 that and get revised NEI guidance, and a report on  
10 all of this technical work, and the assessment of  
11 the success criteria. That will all be done in the  
12 fall. I think that is the package that comes here.

13 And then after that we have an ACRS  
14 meeting to go over and explain what we decided to do  
15 and see if you endorse that. Then we want a letter.

16 MEMBER APOSTOLAKIS: Is there going to  
17 be another subcommittee meeting or just straight to  
18 the full committee?

19 MR. BARANOWSKY: What do you think?

20 MEMBER SIEBER: If the documents are  
21 clear enough, I don't think we would need to have  
22 another subcommittee meeting unless you have changed  
23 the principles that you are going to use.

24 MR. DUBE: I don't think the principles  
25 have changed. Some of the details will.

1                   ACTING CHAIRMAN BONACA: Yes, that's  
2 right. One of the committees, the fact is one of  
3 the discrepancies is being resolved on this  
4 particular performance --

5                   MEMBER SIEBER: Well, I am sure that you  
6 are going to make a presentation to the full  
7 committee of an hour or two.

8                   MR. BARANOWSKY: Yes, but it won't be  
9 going into detail like we did here.

10                  MEMBER SIEBER: Right.

11                  MR. BARANOWSKY: I mean, you will have  
12 to accept the report as giving you that information.

13                  MEMBER ROSEN: But our own staff can do  
14 it once they get the package, and they can look at  
15 that and see what was said in prior letters, and  
16 help us understand whether this has been responsive  
17 to our points of view.

18                  MR. BARANOWSKY: And if someone will  
19 feed back to us issues that you would like for us to  
20 cover as a result of that, we can make sure that  
21 those are in our presentation.

22                  MEMBER APOSTOLAKIS: So how long will we  
23 have the package before the full committee?

24                  MR. BARANOWSKY: Oh, quite a while.

25                  MEMBER APOSTOLAKIS: Okay. Good.

1 That's good.

2 MS. WESTON: It has to be at least 30  
3 days.

4 MR. BARANOWSKY: It will be more than  
5 30, I'm sure.

6 MEMBER APOSTOLAKIS: Well, we don't meet  
7 in January anyway.

8 MR. BARANOWSKY: I think we were really  
9 thinking in February.

10 ACTING CHAIRMAN BONACA: That's it?

11 MR. BARANOWSKY: That's it.

12 ACTING CHAIRMAN BONACA: Any other  
13 comments or questions? One question I had was  
14 regarding this firewall. You did by the (inaudible)  
15 and you did get a lot of lessons learned, and many  
16 of them I am sure are just the plant specific, and  
17 adjustments that you had to make and too much plant  
18 specific PRAs, or vice versa in some cases.

19 In some cases, you must have learned  
20 some lessons that can be reflected on the other SPAR  
21 models. Are you going to have a lessons learned  
22 about it?

23 MR. BARANOWSKY: We have lessons  
24 learned, and maybe Pat O'Reilly, who actually runs  
25 the SPAR model development program can tell us how

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

(202) 234-4433

[www.nealgross.com](http://www.nealgross.com)

1 he would use this information to go through the rest  
2 of the SPAR models.

3 MR. O'REILLY: I am Pat O'Reilly from  
4 the Office of Research. As Pat pointed out we are  
5 doing the 11 plants, the 20 units that are in the  
6 pilot program, and based on that and what we have  
7 already learned from our on-site QA reviews at every  
8 plant site, we have a number of issues which we know  
9 apply across the board as SPARs that are  
10 standardized, and that this the important thing.

11 And so we know from this pilot program  
12 that Harrison exercised that there are a number of  
13 issues that will be implemented across all the PWR  
14 models, for instance, and BWR models, and in some  
15 cases across all 72 models. So we have learned  
16 enough from that so that we don't have to go through  
17 and do a detailed comparison exercise for the other  
18 61 models that aren't included here.

19 MEMBER SIEBER: Does every plant have a  
20 PRA that is suitable for this comparison?

21 MR. O'REILLY: You find a wide spectrum  
22 of PRAs out there, some which are very well done,  
23 very robust, very complete, and others which are  
24 about mediocre. They have some information, and  
25 there are some that just had the minimum that were

1 Generic Letter 88-20. They stuck to the letter of  
2 the law there.

3 MEMBER SIEBER: And in which percentage  
4 would that minimum set be?

5 MR. O'REILLY: That is a tough question,  
6 because some of our visits are complicated. The PRA  
7 is not necessarily of poor quality, but the staff  
8 that is there now is not the staff that worked on  
9 the development of the PRA, and there has been no  
10 technology transfers between the people that did the  
11 PRA and those that are there now. So that is an  
12 additional handicap.

13 MEMBER SIEBER: So they are basically  
14 clueless.

15 MR. O'REILLY: In some cases that is not  
16 a bad description.

17 MEMBER SIEBER: Okay.

18 MR. BARANOWSKY: We are going to be  
19 putting that together as something for us to use and  
20 possibly pass on to the quality activities.

21 MEMBER APOSTOLAKIS: And you said you  
22 would give us this other document, which was the key  
23 -- you said you were fully aware of where the  
24 sensitive parts of the PRAs were, model  
25 uncertainties.

1 MR. BARANOWSKY: We will probably have  
2 in our final report some listing of these things,  
3 because that is an issue of what does this all mean  
4 in terms of this program. So we need to cover that.

5 MS. WESTON: We are not going to get it  
6 before then?

7 MR. BARANOWSKY: I don't have a specific  
8 program activity to produce a report on this before  
9 this report, and whether it can or can't be done, I  
10 just can't say in this meeting. We are resource  
11 limited.

12 MEMBER SIEBER: That's a nice way to put  
13 it.

14 MR. BARANOWSKY: That's a fact. I  
15 request budget and I am told what I can get and we  
16 are working at 116 percent.

17 ACTING CHAIRMAN BONACA: With that, I  
18 adjourn this meeting.

19 (Whereupon, at 4:28 p.m., the meeting  
20 was concluded.)

# MITIGATING SYSTEMS PERFORMANCE INDEX

PRESENTATION TO ACRS SUBCOMMITTEES ON RELIABILITY AND PRA, AND  
PLANT OPERATIONS

PATRICK W. BARANOWSKY (301-415-7493) (pwb@nrc.gov)  
DONALD A. DUBE (301-415-5472) (dad3@nrc.gov)  
OPERATING EXPERIENCE RISK ANALYSIS BRANCH  
OFFICE OF NUCLEAR REGULATORY RESEARCH  
U.S. NUCLEAR REGULATORY COMMISSION

JULY 8, 2003

## PURPOSE AND OBJECTIVE OF MEETING

- Update progress on Mitigating Systems Performance Index (MSPI) development
- Address ACRS comments
- ACRS letter in 2004

## Table of Contents

- MSPI Overview
- ACRS comments from May 2002 briefing
- White Paper on Methodology
- Status of Pilot
- Key Technical Issues and Approach to Resolution
  - Independent verification and PRA Quality
  - "Invalid Indicator" (one failure to WHITE)
  - "Insensitive Indicator" (many failures to WHITE)
  - System boundary issues
  - Data collection
  - Common Cause Failure
  - Support system initiators
  - Relationship of SDP and PIs
- Summary
- Implementation Timeline

## MITIGATING SYSTEMS PERFORMANCE INDEX (MSPI)

- MSPI evolved from a feasibility study of Risk-Based Performance Indicators (RBPI)
- A highly risk-informed simplification to RBPIs that addresses recognized PI issues:
  - treatment of demand failures and fault exposure time
  - definition of unavailability and maintenance rule consistency issues
  - plant specific risk-informed performance thresholds
  - cascade failure treatment of cooling water support systems
- MSPI monitors risk impact of changes in performance of selected mitigating systems
  - accounts for plant specific design and data
  - scope consistent with current PIs: level-1, at power risk
  - covers unavailability and unreliability consistent with PRA modeling
  - uses detailed scope and calculation specifications to achieve consistency
  - performance thresholds consistent with basis for current PIs

## ACRS SUBCOMMITTEE BRIEFING OF MAY 2002: MAJOR COMMENTS AND QUESTIONS

- MSPI approach is "in the right direction and solves many of the problems ... in the current mitigating system"
- What has been learned from the Pilot?
- Should the PI deal with risk? Concern with the example of large number of SCRAMS to RED in the current ROP.
- Should the setting of the baseline be based on a plant's own historical performance, or measured against the industry performance?
- Are there sufficient data in EPIX?

## MSPI WHITE PAPER

- Presents Fundamental Concepts and Related Issues
- Mathematical Formulation
  - . Importance measure relationships
  - . Treatment of unreliability and unavailability
  - . Relatively simple calculation
- Benefits
  - . Proper accounting of demand unreliability
  - . Plant specific design and data
- Limitations
  - . Significance of multiple concurrent failures
  - . Conditions not capable of being discovered during normal surveillance tests
- Key Issues
  - . Differences between MSPI and SDP
  - . False negative/false positive indications
  - . Validation

## MSPI PILOT OBJECTIVES

- Exercise MSPI Guidance:
  - System boundary and component identification
  - Data collection
  - MSPI computation
- Validation and Verification:
  - Issue identification & special studies (Table Top)
  - SPAR comparisons
  - Relevance of SDP
- Perform Temporary Inspections

## Status of Pilot Program

- Held July 2002 Workshop prior to Pilot implementation.
- Issued Program Guidelines in NEI 99-02 Revision and Regulatory Issue Summary in September 2002.
- Licensees collected performance data Sept 2002 through Feb 2003 and submitted to NRC on monthly basis.
- NRC Issued Temporary Instruction and performed inspections of Pilot Plant implementation.
- Held January 2003 Workshop for mid-course assessment.
- Identified technical issues and have re-directed research efforts to resolve all key issues.
- Initiated a major effort to reconcile differences in SPAR and Plant PRAs for 11 distinct models (all 20 units in Pilot).

## Key Technical Issues

- Independent verification – significant differences between SPAR model and Plant PRA.
- One component failure resulting in system indication turning to WHITE (“Invalid Indicator”).
- Large number of failures to turn system to WHITE (“Insensitive Indicator”).
- Identification of system boundaries.
- Data collection burden.
- Treatment of Common Cause Failure contribution to Fussell-Vesely.
- Support system contribution to Fussell-Vesely.
- Relationship of SDP and PIs.

## Independent Verification

### Issues

- Replicate MSPI submittals using SPAR models.
- Expectation going into Pilot that SPAR models in good agreement with Plant PRAs.
- "High level" agreement not necessarily indicative of agreement for cut-sets at  $1\text{E-}6/\text{yr}$  and lower.
- Importance measures of components monitored in MSPI often differed by one to two orders of magnitude, especially cooling water support systems.

### Resolution

- Quality Improvement: Reconcile differences at lower cut-sets levels, and change SPAR and/or Plant PRA *where justified*.
- Major effort to enhance all 11 distinct SPAR models (20 nuclear units).

## Summary of Results for Braidwood

- Internal events CDF
  - Plant PRA =  $3.0\text{E-}5$  /yr
  - "Old" SPAR Model =  $7.5\text{E-}5$  /yr
  - "New" SPAR Model =  $3.1\text{E-}5$  /yr
- On average, FV/UR was too low in the old SPAR Model by about a factor of 10.
- With enhancements to SPAR Model, on average agreement within factor of about 2 (high or low).

(assumes same success criterion for feed & bleed)

Braidwood	FV/UR ratio	
Component	old SPAR/Plant PRA	new SPAR/Plant PRA
RHR Pump 1B	0.08	1.38
AFW Pump 1B	4.72	1.30
EDG 1A (T&M)	0.20	0.75
SW Pump 1B	0.05	1.57
VCT Outlet Isol valve	0.11	0.99

## Final Results for Palo Verde

- FV/UR's on average within plus/minus 25%

Parameter	Plant PRA	SPAR Enhanced	SPAR 3i
CDF	1.4E-05	1.2E-05	1.79E-05
Truncation	2E-11	1E-11	1E-15
<b>Contributors</b>			
Transients	35%	39%	26%
Loss of 4KV	29%	24%	0
SGTR	12%	6%	30%
Loss of MFW/COND	7%	9%	0
LOOP	7%	11%	34%
LOCA	4%	3%	7%
Loss of DC	2%	4%	1%
Other	3%	4%	1%
ISLOCA	<1%	<1%	<1%

## Invalid Indicators

### Issues

- For some components with high importance measure, one component failure can result in  $\sim 1\text{E-}6/\text{yr}$  delta CDF (i.e. WHITE).
- Can not determine an adverse performance trend from one failure (a form of "false positive").

### Resolution

- Use performance-based "Frontstop": Minimum number of failures within a system before performance indicator turns WHITE.
- Adapted from Risk-Informed Tech Spec initiative.
- Will resolve Invalid Indicator issue and substantially reduce *false positives*.

## Invalid Indicators - Preliminary Results

Licensees' Plant PRA Model	Number of Component Types with Invalid Indicators				
	EAC	HPI	HRS	RHR	SWS / CCW
Braidwood 1					
Braidwood 2					
Hope Creek					
Limerick 1					
Limerick 2					
Millstone 2

San Onofre 3					
South Texas 1					
South Texas 2					
Surry 1					
Surry 2					

Valid (all components within system are valid)  
 Invalid (one or more components are invalid)

## Insensitive Indicators

### Issues

- For some components with low importance measures, may require many failures to exceed delta CDF of  $1\text{E-}6/\text{yr}$ .
- Deterministic criteria to include sufficient number of components within system even if low importance.
- Approximately 11% of systems have at least one insensitive component.

### Resolution

- Use performance and statistically-based "backstop": Maximum number of allowed failures before performance is considered "degraded" and indication is WHITE.
- Adapted from Risk-Informed Tech Specs where maximum allowed outage time ("completion time") is 30 days regardless of analysis allowing delta CDF of  $5\text{E-}7/\text{yr}$ .

# Insensitive Indicator Study: Failures to Reach G-W Threshold (San Onofre)

South Texas 1					
South Texas 2					
Surry 1					
Surry 2					

Valid (all components within system are valid)

Insensitive (one or more components are insensitive)

## Identification of System Boundaries

### Issues

- Numerous questions as to which MSPI system to assign particular components and sub-systems for monitoring.
- Definition of "trains" is based on number of parallel heat exchangers, pumps, or flow paths, whichever is fewer.
- Numerous design configurations which do not fit neatly into definition, especially parallel/series branch lines.

### Resolution

- Submit questions for clarification to "Frequently Asked Questions" forum on the NRC web-site.
- Revise NEI 99-02 to include improved guidance.
- Conduct training and lessons-learned workshops prior to full implementation.

## Data Collection Burden

### Issues

- Average number of components to be monitored is about 50 per plant.
- Because of deterministic criteria for inclusion, some plants have large number of valves to monitor.
- Pilot Program identified some issues with estimation of demands, tabulation of data, and data entry.

### Resolution

- Consolidated Data Entry program through INPO will consolidate and ease reporting.
- Use cutoff of  $1\text{E-}6/\text{yr}$  on Birnbaum for valves to reduce number to be monitored.
- Recommend improved software interface for data entry for full implementation.

# Number of Valves Monitored

## Unaccounted for URI for Valves

## Contribution of Common-Cause to Fussell-Vesely Importance Measure

### Issues

- As noted in NUREG/CR-6819 CCF Event Insights:  
*"Proximate causes of CCF events are no different from the proximate causes of single component failures...it is reasonable to postulate that if fewer component failures occur, fewer CCF events would occur."*
- Thus, in the MSPI formulation: Should not changes in the CDF owing to changes in plant-specific unreliability from single component failures also include the effect from changes in CCF rate, given the coupling factor?

### Resolution

- Add-in the Fussell-Vesely importance from the common cause failure for a component type in the FV/UR value for a component.

## Common Cause Sensitivity (Hope Creek SACS)

## Contribution of Support System Initiators to Fussell-Vesely Importance

### Issue

- Failures of components leading to a support system initiator (e.g. loss of service water) contribute to CDF.
- About two-thirds of plant PRAs use fault trees to quantify initiating event frequency; the remainder use a point-estimate frequency, based on plant and/or industry experience.
- For a basic event, use of fault trees give higher FV than when a point-estimate frequency is simply provided.

### Resolution

- For those models using point-estimates, if the contribution of the initiator to CDF is significant, either: (a) add support system initiator fault tree(s), or (b) use an adjustment factor to FV.

## SDP AND MSPI COMPARISONS

### Issue

- . Comparison of original MSPI formulation with SDP historical results for in-scope inspection findings (i.e. normal surveillance demand failures) had differences in several instances.

### Resolution

- . Reassess MSPI analysis of historical data with "final" technical positions implemented.
- . Determine validity and appropriateness of any residual MSPI and SDP differences.
- . Document validity basis of "final" formulation and use in ROP assessments for in-scope application.

## RELATIONSHIP OF SDP AND PIs

- SDP measures risk significance of events or conditions that exist individually or concurrently and that can be due to performance related deficiencies; it is an episodic risk significance measure.
- SDP is a good measure to use when setting priorities for timeliness of corrective actions, need for effective root cause determination, and identification of events with risk significant value for inspection follow-up to verify corrective action adequacy and broader plant-specific or generic implications.
- PIs measure changes in performance; PIs can accommodate performance based and risk informed thresholds; it is a cumulative performance measure.
- MSPI measures change in risk associated with change in mitigating systems performance (within scope limitations).
- Tentative Conclusion: Use MSPI to measure performance within scope limitations.

## SUMMARY

- MSPI is a risk-informed performance indicator using plant-specific design configuration and equipment performance data.
- Minimum and maximum limits to the number of component failures before the component is deemed degraded (non-GREEN) will be effected (frontstop and backstop concepts).
- Numerous technical issues have arisen during the Pilot. Proposed solutions for the key issues expected to be fully developed by end of summer.
- Additional implementation issues will be addressed as the need arises.

## **Tentative Implementation Schedule**

<b>August '03</b>	<b>Resolution of all major technical issues; Completion of SPAR model enhancements.</b>
<b>September '03</b>	<b>End of Pilot Program.</b>
