SUBJECT: Yucca Mountain Project Branch - U.S. Geological Survey (YMPB-USGS)  
Progress Report, October, 2003

Attached is the USGS progress report in the required format for the month of October, 2003.

If you have any questions or need further information, please call Raye Ritchey Arnold at (303)236-5050, ext 296.

Sincerely,

Robert W. Craig  
Technical Project Officer  
Yucca Mountain Project Branch  
U.S. Geological Survey

**U.S. GEOLOGICAL SURVEY**  
Executive Summary  
**YUCCA MOUNTAIN PROJECT BRANCH**

October 2003

**GEOLOGIC STUDIES**

Geologic work by USGS staff in support of the Nye County early-warning drilling program (EWDP) continued. The data package entitled "Interpretation of the Lithostratigraphy in Deep Boreholes NC-EWDP-16P, NC-EWDP-27P, and NC-EWDP-28P, Nye County Early Warning Drilling Program, Phase IV A" continued in technical review. Those data represent the Yucca Mountain Project's initial examination and interpretation of subsurface lithostratigraphy near the southern part of Yucca Mountain. The data are intended for incorporation into cross sections and subsequent integration into hydrogeologic framework models. In further work with the Nye County boreholes, selected bit-cutting samples from boreholes NC-EWDP-24P and NC-EWDP-29P were examined.

Geologic mapping continued in support of determination of fracture and lithophysal characteristics of the repository host horizon (RHH). Lithophysal-panel mapping concluded in October, along with completion of the large-cavity lithophysal survey. The ECRB bulkhead at Station 17+60 was closed at the end of the month. The field portion of technical review of work conducted behind the bulkhead was completed this month to facilitate milestone completion.

Field mapping for review of the fault-related fracture array also was completed this month. All mapped faults exposed in the ECRB Cross Drift from the Solitario Canyon Fault to the intersection with the North Ramp were re-examined and evaluated to improve understanding of fracturing as it relates to faulting in the repository host horizon. Similar evaluation was completed for the South Ramp, Main Drift, and North Ramp of the ESF. The preliminary result of that exercise noted that fracturing appears asymmetrical in and around faults and fault zones. At the conclusion of field work, compilation of related data packages began.

Borehole fracture and lithophysal analysis continued as on-going investigations during the month, making use of video tape to improve definition of fracture and lithophysal distributions in the RHH. Creation and analysis of discrete [virtual] fracture networks through the use of length, spacing, and orientation data from detailed-line-survey (DLS) and full-periphery geologic mapping also continued. Such data were incorporated in the

writing and assembling of the SAR (Scientific Analysis Report) as they became available.

Preliminary evaluation of the borehole video for ThermK-015 (Thermal-K Test 4) was conducted to determine feature-specific locations of dm-sized (that is, 10-cm) lithophysae, clusters of cm-sized lithophysae and spots, and fractures. In that work supporting in situ testing to quantify lithophysal porosity, the resulting locations demonstrated good correlation when compared to preliminary neutron-log data. That information and correlation contributed to on-going development of specific procedures for thermal-test borehole logging.

## SATURATED-ZONE STUDIES

Reported work on modeling of the Death Valley regional flow system (DVRFS) focused on development of a base strategy for releasing (as a GIS coverage) the water-level data used in the transient model report. Staff also evaluated comments returned from a Chapter D, Transient Model, technical reviewer. Responses also were assembled to reviewer comments on Chapter F of that transient model report.

## UNSATURATED-ZONE STUDIES

The infiltration experiment in Alcove #8/Niche #3 continued, in on-going moisture monitoring. At weekly intervals, accumulated data were retrieved from the TCO, including weight data (reflecting amount of water applied to the large plot) from all 12 permeameters in Alcove #8. Barometric-pressure, temperature, and relative-humidity data were collected behind the bulkhead. Another station collected data from heat-dissipation probes (HDPs) surrounding the large plot. Additional data included measurement of background evaporation and signals from HDPs in the trench. Summarizing recent activity in the large-plot experiment, on August 28 water application was initiated (and continued, at this writing) in all twelve plots. Frequent equipment malfunctions typically have been caught early, but one malfunction resulted in a spill of some 2275 liters (600 gallons) of water—essentially an unplanned slug added to the left margin of the large plot over a two-day interval. The incident indicated that fractures and matrix around the large plot have the capacity to absorb a large amount of water quickly, and Niche #3 was wetter after the event. Observed behavior may represent fracture communication just below the surface of Alcove #8. Application rates remained at 60 to 70 liters per day, with application patterns in individual plots similar in many respects to previous experimental behavior.

Moisture monitoring in Alcove #7 also continued. Preliminary data for October were processed into spreadsheets; relative humidity remained near 100%. Monitoring equipment in Alcove #7 underwent various maintenance operations, plans were assembled for installation of an isolating transformer on the thermocouple data-logger battery chargers, and staff provided input to the UZ monitoring teleconference. Some

older probes are giving erroneous readings, probably due to condensation on the measurement grids. The newer-style probe, designed for condensing environments, continued to operate satisfactorily. In other moisture-monitoring work, plans were begun for extraction of monitoring equipment from the ESF.

Isotopic analysis by USGS labs continued in support of YMP investigations. Work to determine chemical and isotopic composition of pore water continued. The data package resulting from isotopic and chemical pore-water investigations reached final stages of preparation for submittal. In other work, additional samples from borehole ESF-HD-CHEMSAMP3 were requested from the SMF, in on-going isotopic support for thermal testing. In unscheduled work, USGS staff reviewed a revised Sandia National Laboratory procedure for "Borehole Water Sampling in the ESF." At the encouragement (and direction) of DOE, several staff members, including J. Stuckless, B. Marshall, K. Scofield, and K. Futa, and others, prepared separate presentations for the special session on the unsaturated zone held at the Geological Society of America annual meetings.

Laboratories of the USGS also provided isotopic and hydrochemical support to the Nye County early-warning drilling program (EWDP). Activity to collect water samples from Nye County and Inyo County (California) continued, and samples were collected from 25 different zones in Nye County EWDP wells during October. Major-ion and trace-metal analyses were completed on samples from six Nye County EWDP wells sampled during October.

In preparation for isotopic analysis in support of U-series delineation of UZ flow zones, samples collected in September from the transect across the Solitario Canyon Fault exposed in the ECRB Cross Drift were examined in the laboratory for signs of water/rock interaction. Samples within and adjacent to the fault show evidence of significant mineralogical alteration. The timing and degree of water/rock interaction responsible for those modifications will be addressed using  $^{234}\text{U}/^{238}\text{U}$  and  $^{230}\text{Th}/^{238}\text{U}$  isotope analyses in investigations over the next several months. In related developments, a necessary electrical transformer was ordered and will be installed in advance of the installation of the new Triton mass spectrometer itself (anticipated for November). Please note that the use of firm, trade, or brand names in this report is for identification purposes only and does not constitute endorsement by the U.S. Geological Survey, the Department of Energy, or other element of the U.S. Government.

Analysis of microclimate records in fracture minerals also continued. Samples were examined for use as candidates for additional analyses by ion microprobe, micro-digestion, and XRF microanalysis. A technical procedure for use of the Kevex Omicron XRF microanalyzer was initiated. The instrument will be used to map the abundance and spatial distribution of secondary minerals within coatings from UZ fracture and lithophysal cavities.

Twinned calcite in breccias in some faults at Yucca Mountain has been attributed to elevated temperature and rapid deposition/crystallization, conclusions sharply at odds with existing data and published studies (by the USGS and elsewhere in peer-reviewed

journals) of secondary calcite in the UZ and simulations of the thermal history of the Yucca Mountain unsaturated zone. Additional detailed geochemical analyses (and supporting analyses) will be performed for comparison to fracture-hosted calcite and to refine existing models of thermal history. The analytical team awaited a list of potential sampling localities, slated to arrive from the Southwest Research Institute and Bucknell College.

## WATER-RESOURCES MONITORING

Preparation of a quarterly report included review of data on ground-water levels and discharges collected and compiled for monitoring sites during July through September 2003. Staff prepared and delivered a letter report to the TPO and DOE on October 31, 2003, in completion of milestone **PAGSW266M4 [Prepare Monitoring Report 4th Qtr FY03]**, describing those monitoring observations. In related on-going work, ground-water levels were measured at 34 sites in routine monitoring, and ground-water discharge was measured at five springs and at one flowing well. Ground-water and spring-discharge monitoring data collected during October were checked and filed.
