114	TDM IX	7/10/1981	45.57	5235.09	5189.52	How does the measuring point elevation change over time? Need to correlate it to site operation	Response (1): The data were confirmed with the original field sheets if available, which had DTW entry and/or water level data. If the measuring pt. elevations were incorrect the correct elevation was entered and the water level elevations recalculated. If measuring pt. elevation data were not available and no notes about any changes, the previous original measuring point elevation was used and the water level elevations were recalculated.	75.2	5235.09	5159.89

Dear Bruce,

Here is a basic summary of the wells in question at the ExxonMobil Highland Site.

After finding the saturated borehole volume and calculating the three well volumes amount, you determine how long the well will take to pump by dividing the total gallons required to pump by the rate at which the well will produce water. Then after the required volume has been pumped, if the pH, conductivity and temperature levels are stable to satisfactory (within .1 on the pH and conductivity) the samples are ready to be taken.

Well BBL-2 – The total depth is 37.3'. The static water level (somewhere around 28.7', which varies from quarter to quarter) is subtracted from the TD which gives you the "feet of water" calculation required to find your saturated borehole volume. In this instance, 8.6' is the measurement of water in the casing. The "feet of water" measurement is then multiplied by the constant gallons per foot number provided by Joe Reed of MFG to reach your SBHV. In this case, 1.51 gallons per foot in a 4" casing is used. So then you use the formula $37.3 \text{ (TD)} - 28.7 \text{ (SWL)} + 8.6 \text{ (Feet water)} \times 1.51 \text{ (GPF)} = 12.986 \text{ (13) gallons per volume}$. Because three volumes are required before a well can be sampled, you simply multiply the SBHV by three, in this case giving us about 39 gallons in total to be pumped before the well can be sampled. This well only produced 1-gpm, so in order to collect the sample it must be pumped for 39 minutes. During the pumping process, a parameter of pH, conductivity and temperature are taken at .5 volumes, 1 volumes, 1.5 volumes, 2 volumes, 2.5 volumes and 3 volumes. If the pH and conductivity are within .1 of each other over the course of the full volume, the well can be sampled.

Well BBL-3 – This well is treated the same way as BBL-2, only with a TD of 41.35, a SWL of around 24.27 with a 4" casing. Therefore after working the formula you have a SBHV of 25.8, 3 volumes of 77.4 and a well capable of pumping 2-gpm requiring 39 minutes to pump the minimum 3 volumes.

Well 176 – This well is also treated the same with a TD of 161, SWL around 143.14 and 6" casing. The formula remains the same until you multiply by the gallons per foot constant which is 2.62 for 6". So you have $161 - 143.14 = 17.86 \times 2.62 = 46.8 \times 3 = 140.4 \text{ gallons} \div 4\text{-gpm} = 37 \text{ minutes}$.

Well 179 – This well is also 6" so the formula is the same as Well 176. This well produces 5-gpm giving you a total run time of 50 minutes. Occasionally this well and some others require extra run time to create stability among the pH and conductivity. When this happens it may be necessary to pump an extra .5 or 1 volume. Even more if that's what it takes to stabilize. A sample can't be collected until 3 volumes have been pumped and the parameters are within .1 across the duration of a full volume.

In the cases of Wells 120, 128 and 129, these wells only produce a certain amount of water per quarter total. These amounts are all the wells will produce over the course of one quarter. Even if a well was returned to at any time during the same quarter and pumped, it would not produce enough water to reach the surface. Even if the sampler was to attempt to pump the wells on two separate days during the same quarter, the wells will not produce any more water on the second day. These wells require three months of recovery to produce the miniscule amount. Because of this, in order to provide samples for analysis, the water samples must be collected upon the first instance of pumping and preserved and sent to Lancaster Labs or they will not meet the seven day hold time. In most instances, there is only enough volume for Lancaster Labs and not enough for Energy Lab to analyze. Well 120 makes 1 gallon, Well 128 makes 2 gallons, Well 129 makes 1.25 gallons.

Please let me know if you have any further questions.

Sincerely,

Shari Blakeley
Office Manager
