<b>PROJECT NO:</b> 10955	<b>CLIENT:</b> CENG - Calvert Cliff Nuclear Power Plant (CCNPP)		
<b>CALCULATION TITLE:</b> Criticality Evaluation for NUHOMS 32PHB System			
<b>SUMMARY DESCRIPTION:</b> <b>1) Calculation Summary</b> The purpose of this calculation package is to determine a worst-case bounding $k_{EFFECTIVE}$ for the NUHOMS®-32PHB Transportable Storage Canister for normal and accident conditions of storage (10CFR72) for several PWR fuel assembly types and configurations containing intact fuel assemblies. A maximum of 32 intact fuel assemblies can be stored in a single DSC. The criticality analysis calculations are carried out to determine the maximum enrichment of the intact fuel assemblies as a function of fixed poison loading to store PWR fuel assemblies. <b>2) Storage Media Description</b> Secure network server initially, then redundant tape backup containing the KENO V.a input and output files, the spreadsheets used in the calculation, and the Word file with the text of the calculation

## 1.0 PURPOSE

This calculation documents a series of criticality calculations performed for the NUHOMS®-32PHB Transportable Dry Storage Canister (referred to as DSC hereafter). The calculation results demonstrate the compliance with the criticality-related portions of 10CFR72 for storage of the DSC.

The DSC is transferred in the CCNPP-FC Transfer Cask and then stored in a NUHOMS® Horizontal Storage Module. The DSC is designed to store 32 PWR intact fuel assemblies with initial U-235 enrichment of 2.0 - 5.0 wt%.

## 1.1 Hardware Analyzed

The NUHOMS®-32PHB hardware design requirements are specified in the 32PHB Design Criteria Document [1]. The design parameters that are relevant to the criticality calculation are discussed in the following subsections.

### 1.1.1 NUHOMS® - 32PHB DSC

The DSC dimensions and their references are listed in Table 1.1-1. The DSC exhibits two patterns. One is the 2-dimensional horizontal layout of the 32 guide sleeves as shown in Figure 1.1 [4]. Another pattern is 3-dimensional and involves insert plates and poison plates, as shown in Figure 1.2 [4]. The orientation of the vertical pattern renders two views. One view shows a set of insert plates running along the east-west direction with a vertical spacing of 8.28". Poison plates are between insert plates. Another vertical view shows a set of insert plates running along the north-south direction with a vertical spacing of 8.28". Again, poison plates are between insert plates. There is a vertical gap between the insert plate and its adjacent poison plate.

Those two vertical views intersect at the junction of four guide sleeves. The north-south poison plates and the east-west poison plates intersect each other through the poison plate slots. There are vertical gaps that form inside the slot. The north-south insert plates sit on top of the east-west insert plates. They do not intersect each other. Instead, the north-south insert plates run through the east-west poison plates and the east-west insert plates run through the north-south poison plates. Again, there are vertical gaps that form inside the slot.

## Calculation

Calculation No.:	NUH32PHB-0600
Revision No.:	0
Page:	9 of 35

The nominal vertical gap between insert plate and poison plate and the nominal length of the poison plate slots are also given in Table 1.1-1. The nominal vertical gap between an insert plate and its adjacent poison plate shall be consistent with the nominal vertical distance between two insert plates and the nominal poison plate height.

The nominal vertical gaps inside the poison plate slots shall be consistent with the nominal length of the poison plate slot for the poison plate, the nominal length of the poison plate slot for the insert plate, the height of the insert plate and the part of the poison plate that goes through the slots.

**Table 1.1-1 DSC Dimensions**

DSC Dimension	Nominal	Tolerance	reference
External Diameter	67.25"	0.05"	2
Shell Thickness	0.63"	0.06"	3
Insert Plate Height	2.00"	N/A	4
Insert Plate Thickness	0.250"	0.030"	5
Vertical Distance Between Insert Plates	8.280"	N/A	4
Axial Length to be Modeled	10.28"	0.12"	4

## 1.2 Regulatory Requirements

### 1.2.1 Storage - 10CFR72

*"§ 72.124 Criteria for nuclear criticality safety*

*(a) Design for criticality safety.*

*... before a nuclear criticality accident is possible, at least two unlikely, independent, and concurrent or sequential changes have occurred ... The design ... must include margins of safety ..."*

The criticality analysis demonstrates that the DSC basket configuration is subcritical for all normal and off-normal operating conditions, with consideration for fabrication tolerances. The customary design margin of safety is 0.05, i.e.  $k_{\text{EFFECTIVE}} \leq \text{USL}$  (the USL is always below 0.95) including all applicable biases and uncertainties.

*"(b) Methods of criticality control.*

*When practicable, the design of an ISFSI ... must be based on favorable geometry, permanently fixed neutron absorbing materials (poisons), or both. Where solid neutron absorbing materials are used, the design shall provide for positive means to verify their continued efficacy."*

The NUHOMS® -32PHB DSC system's criticality safety is ensured by both fixed neutron absorbers and favorable geometry. The neutron absorber is present in the form of borated metallic plates. The absorbers' presence can be verified visually at the time of DSC fabrication or any time before DSC closure.

*"(c) Criticality Monitoring ..."*

Criticality monitoring is not required for NUHOMS® operations. All fuel handling is performed in either the fuel pool (beneath water shielding) or when the fuel is in dry and sealed canisters.

The analyses presented herein focus on transportation conditions and bound all storage conditions.

## 6.0 CRITICALITY EVALUATION

### 6.1 Discussion and Results

This criticality analysis shows that the NUHOMS®-32PHB system is capable of loading thirty-two (32) intact CE 14x14, VAP or Areva fuel lattices of maximum U-235 enrichment with 5.00 wt%, boron content in the borated water at 2450 PPM and B<sub>10</sub> areal density of 24.3 mg/cm<sup>2</sup>. The USL is determined to be 0.9410 and the worst case k<sub>EFFECTIVE</sub> for loading VAP fuel lattices is 0.9358.

### 6.2 Package Fuel Loading

The DSC payload is specified in the 32PHB Design Criteria Document [1]. It includes three fuel assembly types; Standard CE 14x14, VAP and AREVA. The fuel parameters that are relevant to the criticality calculation are listed in Table 6.2-1.

**Table 6.2-1 Fuel Assembly Types in 32PHB Payload**

Fuel Parameter	CE 14x14	VAP	AREVA
Clad Material	Zircaloy-4	Zircaloy-4	Zircaloy-4 <sup>(1)</sup>
Pellet stack UO <sub>2</sub> density (%TD)	93.5 - 96%	96%	96%
Number of Rods	176	176	176
Number of Water Holes	5	5	5
Fuel rod pitch	0.580"	0.580"	0.580"
Pellet OD	0.3765"	0.381"	0.3805"
Clad ID	0.384"	0.388"	0.387"
Clad OD	0.440"	0.440"	0.440"
Guide tube ID	1.035"	1.035"	1.035"
Guide tube OD	1.115"	1.115"	1.115"
Maximum Enrichment (wt% U-235)	4.50%	5.00%	5.00%

(1) The clad material of the Areva Fuel is M5 but is modeled as Zircloy-4. The reactivity effect is negligible.

### 6.3 Model Specification

#### 6.3.1 Calculation Model

The geometric configuration of the calculation model is enclosed in a rectangular cuboid (or cuboid in SCALE terminology). Its height is set to the length that accommodates one east-west insert plate at the bottom and one north-south insert plate at the top. Its base is a square that is tangent to the outmost wall of the transfer cask. The pair of parallel base faces in the vertical direction (z) has a periodic boundary condition and the other two pairs of parallel faces (in the x and y directions) have reflective boundary condition. Therefore, the model simulates infinite many units of the 32PHB Transfer Cask and DSC with infinite repetitions of the vertical pattern.

In the KENO V.a geometric configuration, the DSC guide sleeves, insert plates and poison plates are modeled with SCALE holes [10]. Fuel assemblies are modeled as a square lattice and placed into DSC guide sleeves with SCALE holes. The fuel lattice is positioned in the center of the guide sleeve. The baseline model is specified in Table 6.3-1.

**Table 6.3-1 32PHB Baseline Model**

Baseline Model	Geometry	Material
Transfer Cask Exterior	Cuboid	Water (VF=1)
Transfer Cask	Nominal dimensions	neutron shield is replaced with H <sub>2</sub> O (VF=1)
Gap between TC and DSC	0.375"	Filled with H <sub>2</sub> O (VF=1)
DSC	Nominal dimensions	N/A
Fuel Assembly Parameters	Nominal dimensions	CE 14x14 Pellet TD is set at 96%
Gap between Pellet and Clad	Nominal dimension	Filled with H <sub>2</sub> O (VF=1)
Poison Plate	poison plate thickness is 0.125"	B <sub>4</sub> C MMC
Fuel Assembly Placement Inside Guide Sleeve	Center	N/A

#### PROPRIETARY NOTICE

	<b>Calculation</b>	Calculation No.:	NUH32PHB-0600
		Revision No.:	0
		Page:	14 of 35

The neutron poisons that are used with the baseline model are specified Table 6.3-2. However, the VF value is to be adjusted during the analysis.

**Table 6.3-2 Neutron Poison in 32PHB Baseline Model**

Borated Water	Borated H <sub>2</sub> O with natural Boron at 2450 PPM (VF=0.7)
B <sub>10</sub> in Poison Plate (B <sub>4</sub> C MMC)	areal density is 23.4 mg/cm <sup>2</sup>

### 6.3.2 Package Regional Densities

The Oak Ridge National Laboratory (ORNL) SCALE code package [10] contains a standard material data library for common elements, compounds, and mixtures. All the materials used for the cask and canister analysis are available in this data library. The neutron shield material in the cask is modeled as water. The material data for the fuel assemblies were obtained from reference [1].

The cask neutron shield material is conservatively modeled as water. The hydrogen atom density of the solid neutron shield (for the transportation cask) is lower than that of water; therefore, replacing the neutron shield with water is slightly conservative.

## 6.4 Criticality Calculations

The criticality calculation is performed first by determining the most reactive fuel lattice. The most reactive intact fuel configuration is determined next. The final criticality analysis is to determine the maximum allowable U-235 enrichments for various poison loadings.

### 6.4.1 Calculation Method

The CSAS5 control module of the SCALE 6 Program [10] is used to calculate the effective multiplication factor ( $k_{\text{EFFECTIVE}}$ ) of the fuel in the cask. The maximum  $k_{\text{EFFECTIVE}}$  for the calculation was determined with the following formula:

$$k_{\text{EFFECTIVE}} = k_{\text{KENO}} + 2\sigma_{\text{KENO}}$$

The CSAS5 control module allows simplified data input to the functional modules BONAMI, NITAWL, and KENO V.a. These modules process the required cross

#### PROPRIETARY NOTICE

	<h1>Calculation</h1>	<b>Calculation No.:</b>	NUH32PHB-0600
		<b>Revision No.:</b>	0
		<b>Page:</b>	15 of 35

sections and calculate the  $k_{EFFECTIVE}$  of the system. BONAMI performs resonance self-shielding calculations for nuclides that have Bondarenko data associated with their cross sections. NITAWLII applies a Nordheim resonance self-shielding correction to nuclides having resonance parameters. Finally, KENO V.a calculates the  $k_{EFFECTIVE}$  of a three-dimensional system. A sufficiently large number of neutron histories are run so that the standard deviation is below 0.0010 for all calculations. The criticality analysis used the 44-group cross-section library built into the SCALE 6 Program. ORNL uses ENDF/B-V data to develop this broad-group library specifically for criticality analysis of a wide variety of thermal systems. The SCALE 6 computer code system was run with the Windows-XP operating system.

This calculation models the intact geometry of the fuel lattice, Transfer Cask, and DSC. However, the neutron shield is conservatively modeled as water. Other conservative assumptions are given as below.

- Temperatures of all materials are set at 293K. For the KENO calculation, it is conservative due to the negative temperature reactivity effect.
- Fuel rods are filled with 100% pure water in the fuel/cladding gap that increases the neutron moderation. For the KENO calculation, the reactivity effect is conservative.
- No credit is taken for burnable absorbers.
- No credit taken for fissile depletion or fission product poisoning.
- In the KENO model, the material inside the DSC is first filled with aluminum and then replaced with fuel and borated water. As a consequence, a small volume of borated water is replaced with aluminum. The reactivity effect is negligible but conservative.

## 6.4.2 Fuel Loading Optimization

### A. Determination of Most Reactive Fuel Lattice

The baseline model is used to determine the most reactive fuel lattice. The results are shown in Table 6.4-1. The  $k_{KENO}$  and  $\sigma$  produced by the SCALE 6 runs are given in Table 6.4-1. The  $k_{EFFECTIVE}$  is calculated in accordance with the formula given in Section 6.4.1, which is used to determine the most reactive fuel lattice.

Since the CE 14x14 Standard fuel lattice gives a significant lower  $k_{EFFECTIVE}$ , it is not used for the remaining criticality analysis. Further analysis is needed in order to determine the most reactive fuel lattice.

**Table 6.4-1 Most Reactive Fuel Lattice**

Fuel Type	$k_{KENO}$	$\sigma$	$k_{EFFECTIVE}$
CE 14x14 Standard	0.89691	0.00067	0.8983
VAP	0.92994	0.00069	0.9313
Areva	0.93054	0.00068	0.9319

### B. Determination of Most Reactive Intact Fuel Configuration

This section is to determine the design basis model that is defined as the most reactive intact fuel configuration. The design basis model is used to demonstrate compliance with the criticality-related portions of 10CFR72 for storage of the DSC.

The position of the fuel lattice in the guide sleeve is analyzed first. The baseline model is modified to have the most reactive fuel lattice positioned inwards (toward the DSC center). The  $k_{EFFECTIVE}$  values of the two placements for both the VAP and Areva fuel lattice are given in Table 6.4-2. The  $k_{KENO}$  and  $\sigma$  produced by the SCALE 6 run are also given. The  $k_{EFFECTIVE}$  is calculated in accordance with the formula given in Section 6.4.1, which is used to determine the most reactive intact fuel configuration.

Since the fuel lattice at the inward configuration for both VAP and Areva produces a higher  $k_{EFFECTIVE}$ , the inward configuration is used in the subsequent criticality calculations for determining the most reactive configuration.

#### PROPRIETARY NOTICE

This document, including the information contained herein and all associated attachments and enclosures, is the property of Transnuclear, Inc.. It contains proprietary information and may not be furnished to others without the express written permission of Transnuclear, Inc. This document and any drawings and any copies that may have been made must be returned to Transnuclear, Inc. upon request.

	<b>Calculation</b>	Calculation No.:	NUH32PHB-0600
		Revision No.:	0
		Page:	17 of 35

**Table 6.4-2 Fuel Lattice Placement**

Fuel Type	Fuel Lattice Placement	$k_{KENO}$	$\sigma$	$k_{EFFECTIVE}$
VAP	Centered	0.92994	0.00069	0.9313
	Inward	0.93240	0.00069	0.9338
Areva	Centered	0.93054	0.00068	0.9319
	Inward	0.93139	0.00073	0.9329

In the following analysis, the DSC geometrical dimension and material composition are varied in order to determine the design basis model. The changes in the baseline model are made to one parameter at a time unless there is a constraint among multiple dimensions.

The variation in geometry is mainly to account for hardware tolerance. The variation may go beyond the tolerance in order to accommodate more fabrication discrepancy. The parameter to be varied first is the inner width of the guide sleeve. The nominal value is 8.5". It is reduced to 8.47" in accordance with the tolerance given in Table 1.1-1. The results are shown in Table 6.4-3.

Since the VAP fuel lattice with the 8.47" guide sleeve inner width gives the highest  $k_{EFFECTIVE}$  value, it is used for the subsequent calculations.

**Table 6.4-3 Variation in Guide Sleeve Inner Width**

Fuel Type	Guide Sleeve Inner Width	$k_{KENO}$	$\sigma$	$k_{EFFECTIVE}$
VAP	8.50"	0.93240	0.00069	0.9338
	8.47"	0.93473	0.00076	0.9363
Areva	8.50"	0.93139	0.00073	0.9329
	8.47"	0.93316	0.00070	0.9346

## Calculation

Up to this point, the borated water density is analyzed with  $VF=0.7$  as given in Table 6.3-2. The water density used in the SCALE 6 Program [10] is  $0.9982 \text{ gm/cm}^3$ . The borated water density is to be varied in order to simulate fuel loading and transfer operations [1]. It is varied indirectly by changing the density multiplier ( $VF$ ). The results are shown in Table 6.4-4. The borated water density at  $VF=0.75$  produces the highest  $k_{\text{EFFECTIVE}}$ . Thus, it is used in the subsequent calculations.

**Table 6.4-4 Variation in Borated Water Density**

Borated Water Density ( $VF$ )	$k_{\text{KENO}}$	$\sigma$	$k_{\text{EFFECTIVE}}$
1.0	0.92564	0.00064	0.9269
0.9	0.93114	0.00071	0.9326
0.8	0.93452	0.00068	0.9359
0.75	0.93497	0.00079	0.9366

	<b>Calculation</b>	Calculation No.:	NUH32PHB-0600
		Revision No.:	0
		Page:	19 of 35

Next, the insert plate height is reduced from 2.00" to 1.88" and 1.76". The results are shown in Table 6.4-5. Since the change in  $k_{EFFECTIVE}$  is less than one standard deviation, the nominal value is used in the design basis model.

**Table 6.4-5 Insert Plate Height**

Fuel Type	Borated Water Density (VF)	Insert Plate Length	$k_{KENO}$	$\sigma$	$k_{EFFECTIVE}$
VAP	0.75	2.00" <sup>(1)</sup>	0.93497	0.00079	0.9366
		1.88"	0.93568	0.00068	0.9370
		1.76"	0.93488	0.00066	0.9362

Note: (1) from Table 6.4-4.

Next, the lengths of the two poison plate slots are increased by 0.12". They are also reduced by an amount that will accommodate other dimensions such as the insert plate. The results are shown in Table 6.4-6. The nominal values 3.18" and 2.06" will be used for the subsequent analysis.

**Table 6.4-6 Poison Plate Slot Length**

	Borated Water Density	Poison Plate Long Slot Length	Poison Plate Short Slot Length	$k_{KENO}$	$\sigma$	$k_{EFFECTIVE}$
VAP	0.75	3.18" <sup>(1)</sup>	2.06"	0.93497	0.00079	0.9366
		3.30"	2.06"	0.93488	0.00070	0.9363
		3.12"		0.93444	0.00072	0.9359
		3.18"	2.18"	0.93543	0.00066	0.9368
			2.04"	0.93530	0.00069	0.9367

Note: (1) from Table 6.4-4.

**PROPRIETARY NOTICE**

	<h1>Calculation</h1>	Calculation No.:	NUH32PHB-0600
		Revision No.:	0
		Page:	20 of 35

Next, the poison plate slot width is varied. The nominal value is 0.75". Since this dimension affects the amount of poison material more than the slot length, a detailed analysis is performed here.

The results are shown in Table 6.4-7. However, the  $k_{EFFECTIVE}$  values differ within one standard deviation. Thus, no conclusion can be drawn regarding the limiting poison plate slot width. Further analysis is necessary for determining the limiting poison plate slot width.

**Table 6.4-7 Poison Plate Slot Width**

Fuel Type	Borated Water Density	Poison Plate Slot Width	$k_{KENO}$	$\sigma$	$k_{EFFECTIVE}$
VAP	0.75	1.00"	0.93592	0.00067	0.9373
		0.84"	0.93565	0.00076	0.9372
		0.81"	0.93658	0.00066	0.9379
		0.78"	0.93545	0.00086	0.9372
		0.75" <sup>(1)</sup>	0.93497	0.00079	0.9366
		0.72"	0.93624	0.00070	0.9376
		0.69"	0.93657	0.00071	0.9380
		0.66"	0.93594	0.00070	0.9373
		0.50"	0.93592	0.00067	0.9373

Note: (1) from Table 6.4-4.

Compared to other dimensions, the changes to the poison plate height and the poison plate slot width have a greater effect on the amount of the poison material present in the DSC. Since the limiting poison plate thickness is not determined yet, the poison plate height and slot width are varied simultaneously. The poison plate height is varied with an increment of 0.12". Furthermore, the poison plate height is reduced to 8.01" in order to accommodate more tolerance as a result of the DSC fabrication.

	<b>Calculation</b>	Calculation No.:	NUH32PHB-0600
		Revision No.:	0
		Page:	22 of 35

The nominal thickness of the poison plate is 0.125", which results in a B<sub>4</sub>C weight fraction of 19%. The poison plate thickness is varied in such a manner that the B<sub>4</sub>C weight fraction would be 23% and 30%. These two weight fractions are the potential upper limits imposed by the DSC fabrication. The resulting poison plate thicknesses are 0.1032" and 0.0791". The nominal poison plate height (8.25") is used in the calculation. The  $k_{EFFECTIVE}$  is given in Table 6.4-9. It shows that the difference in  $k_{EFFECTIVE}$  is within one standard deviation. Since the 0.0791" thickness corresponds to the maximum B<sub>4</sub>C weight fraction, it is adopted in the design basis model.

**Table 6.4-9 Poison Plate Thickness**

Fuel Type	Borated Water Density	Poison Plate		$k_{KENO}$	$\sigma$	$k_{EFFECTIVE}$
		B <sub>4</sub> C Weight Fraction in %	Thickness			
VAP	0.75	19 <sup>(1)</sup>	0.125"	0.93497	0.00079	0.9366
		23	0.1032"	0.93567	0.00085	0.9374
		30	0.0791"	0.93583	0.00067	0.9372

Note: (1) from Table 6.4-4.

Based on the analysis so far, the geometrical differences between the design basis model and the baseline model are shown in Table 6.4-10.

**Table 6.4-10 32PHB Design Basis Model**

		Page:	23 of 35

The design basis model is used for verifying that the VAP fuel lattice is more reactive than the Areva Fuel lattice. It is also used to verify that the most reactive water density is at VF=0.75.

The results are shown in Table 6.4-11. In conclusion, the design basis model as shown in Table 6.4-10 combined with the borated water density of 0.75 and the VAP fuel lattice is the most reactive intact fuel configuration. It will be used in the criticality analysis.

**Table 6.4-11 Verification of Fuel Type and Water Density**

Fuel Type	Borated Water Density	Poison Plate Height	Poison Plate Slot Width	k <sub>KENO</sub>	$\sigma$	k <sub>EFFECTIVE</sub>
VAP	0.80	8.01"	0.75"	0.93668	0.00072	0.9381
	0.75			0.93653	0.00086	0.9383
	0.70			0.93572	0.00067	0.9371

	0.75			0.93507	0.00069	0.9365
	0.70			0.93494	0.00069	0.9363

### 6.4.3 Criticality Results

The minimum B<sub>10</sub> areal density of the poison plate is determined as a function of the maximum U-235 enrichment and the minimum boron content in borated water. Since the VAP fuel lattice is determined to be the most reactive fuel lattice, its maximum enrichment of 5.00 wt% is used in the criticality analysis. The minimum boron content in the borated water is 2450 PPM.

In the previous calculations, the B<sub>10</sub> areal density of the poison plate is 23.4 mg/cm<sup>2</sup>. For the criticality analysis, it is increased to 24.3 mg/cm<sup>2</sup> in order to achieve sufficient margin. As shown in Table 6.4-12, the k<sub>EFFECTIVE</sub> is 0.9358, which is less than the USL of 0.9410, as determined in Section 6.5.2.

#### PROPRIETARY NOTICE

	<b>Calculation</b>	Calculation No.:	NUH32PHB-0600
		Revision No.:	0
		Page:	24 of 35

**Table 6.4-12 Minimum B<sub>10</sub> areal density**

Fuel Lattice	U-235 Enrichment in wt%	Boron Content in Borated Water in PPM	k <sub>KENO</sub>	σ	k <sub>EFFECTIVE</sub>	Minimum B <sub>10</sub> Areal Density of Poison Plate in mg/cm <sup>2</sup>
VAP	5.00	2450	0.93439	0.0007	0.9358	24.3

Next, the maximum allowable U-235 enrichment is determined as a function of B<sub>10</sub> areal density of the poison plate and the boron content in borated water. The B<sub>10</sub> areal density is set to 17.1 mg/cm<sup>2</sup>. For boron content of 2450 PPM, the maximum allowable U-235 enrichment is determined to be 4.75 wt%.

If the boron content is increased to 2550 PPM, the maximum allowable U-235 enrichment is determined to be 4.85 wt%. As shown in Table 6.4-13, both values of k<sub>EFFECTIVE</sub> are below the USL of 0.9410.

**Table 6.4-13 Maximum Allowable U-235 Enrichment**

Fuel Lattice	B <sub>10</sub> Areal Density of Poison Plate in mg/cm <sup>2</sup>	Boron Content in Borated Water in PPM	k <sub>KENO</sub>	σ	k <sub>EFFECTIVE</sub>	U-235 Enrichment in wt%
VAP	17.1	2450	0.93493	0.00069	0.9363	4.75
		2550	0.93332	0.00072	0.9348	4.85

The B<sub>10</sub> areal densities in Table 6.4-12 and Table 6.4-13 are 24.3 and 17.1 mg/cm<sup>2</sup>. These are the actual values used in the criticality analysis. Adjustment is to be made in the next section for taking 90% credit for the B10 poison content.

		Page:	25 of 35

#### 6.4.4 Conclusions

The 32PHB basket containing poison plates with minimum B<sub>10</sub> areal density of 17.1 mg/cm<sup>2</sup> is assigned as "Basket A" and the 32PHB basket containing poison plates with minimum B<sub>10</sub> areal density of 24.3 mg/cm<sup>2</sup> is assigned as "Basket B".

Only 90% of the physically available B<sub>10</sub> in the poison plate can be taken credit for in the criticality analysis [1]. Therefore, the minimum physically available B<sub>10</sub> in the poison plates for Basket A and B shall be 19.0 mg/cm<sup>2</sup> and 27.0 mg/cm<sup>2</sup>, respectively.

The results of the criticality analysis for the NUHOMS<sup>®</sup>-32PHB system are summarized in Table 6.4-14.

**Table 6.4-14 NUHOMS<sup>®</sup>-32PHB Criticality Analysis**

Maximum Allowable U-235 Enrichment		Minimum Physically Available B <sub>10</sub> Areal Density of Poison Plate <sup>(1)</sup>	
		Basket A	Basket B
		19.0 mg/cm <sup>2</sup>	27.0 mg/cm <sup>2</sup>
Boron Content in Borated Water	2450 PPM	4.75 wt%	5.00 wt%
	2550 PPM	4.85 wt%	NA

<sup>(1)</sup> The criticality analysis takes credit for only 90% of the minimum physically available B<sub>10</sub> areal density in the poison plates.

End Drop Accident

The fuel end drop analysis [11] shows that there is no plastic deformation after the end drop accident. Thus, there is no need to analyze the fuel pin deformation geometry caused by the end drop event.

Side Drop Accident

The fuel side drop analysis [12] concludes that the fuel rods are compressed instead of expanded and they are also constrained by the outer boundaries of the spacer grids.

The rod pitch of some fuel rods may be reduced to the clad outside diameter (0.440", see Table 6.2-1). The USL as a function of the rod pitch decreases from 0.9424 to 0.9422 (see Table 6.5-1 and Table 6.5-2) under these conditions. Thus, the final USL is not affected. Reduced rod pitch also leads to less neutron moderation and, subsequently, k-effective decreases. Thus, the criticality results are not adversely affected.

The separation distance of fuel assemblies may increase. The USL as the function of separation distance increases with more fuel separation (see Table 6.5-1). Thus the final USL is not affected.

Since both the USL and reactivity are not negatively affected by the side drop event, there is no need to analyze the fuel pin deformation caused by the side drop event.

Reconstituted Fuel

The reactivity of a DSC loaded with less than 32 CE 14x14 Standard fuel assemblies is lower than that calculated here since the more absorbing borated water replaces the fuel in the empty locations. Reconstituted fuel assemblies, where the fuel pins are replaced by lower enriched fuel pins or non-fuel pins that displace the same amount of borated water, are considered intact fuel assemblies. The reactivity of the fuel assemblies with reconstituted pins will be bounded by those without reconstituted pins because the regular pins are modeled with the highest allowable enrichment while those with the reconstituted pins will contain lower enriched UO<sub>2</sub> or other non-fuel material.

## 6.5 Critical Benchmark Experiments

### 6.5.1 Benchmark Experiments and Applicability

One-hundred and two (102) critical experiments are available for the USL evaluation [9]. The selection of specific critical experiments for a USL parameter is determined based on the similarity of the geometrical, material composition and neutronic characteristics between the critical experiments and the NUHOMS®-32PHB system.

### 6.5.2 Results of Benchmark Calculations

The USL functions are given in Table 6.5-1. The parameters of USL functions are U-235 enrichment, energy of average lethargy of fission (EALF), H<sub>2</sub>O-to-UO<sub>2</sub> volume ratio, the fuel rod pitch, the separation distance between fuel lattice and the soluble boron loading.

**Table 6.5-1 32PHB USL Functions**

Parameter	Applicable Range	USL Function	
EALF in eV	[ 0.0826, 1.4006 ]	$0.9429 - 2.4237E-04 * X$	$X > 0.093812$
		0.9428	$X \leq 0.093812$
Boron Loading in PPM	[ 15, 3389 ]	$0.9429 + 3.8975E-07 * X$	
Separation Distance in cm	[ 0.18973, 20.78 ]	$0.9398 + 5.9633E-04 * X$	$X < 7.9338$
		0.9445	$X \geq 7.9338$
U-235 Enrichment in wt%	[ 2.35, 5.74 ]	$0.9382 + 1.6994E-03 * X$	$X < 3.4333$
		0.9440	$X \geq 3.4333$
H <sub>2</sub> O/UO <sub>2</sub> Volume Ratio	[ 1.376, 1.933 ]	$0.9560 - 7.3789E-03 * X$	$X > 1.6517$
		0.9438	$X \leq 1.6517$
Pitch in cm	[ 1.209, 1.715 ]	$0.9418 + 4.0604E-04 * X$

	<b>Calculation</b>	Calculation No.:	NUH32PHB-0600
		Revision No.:	0
		Page:	28 of 35

The USL evaluation is shown in Table 6.5-2. The limiting values of the USL parameters are calculated for the NUHOMS<sup>®</sup>-32PHB system with the exception that the EALF is obtained from the SCALE 6 output. The limiting separation distance is determined using the inward fuel lattice position as a conservative approach. The H<sub>2</sub>O/UO<sub>2</sub> volume ratio is determined by the formula given as below,

$$(\text{Pin Cell Area} - \text{Fuel Pin Area}) / (\text{Pellet Area})$$

The USL for the NUHOMS<sup>®</sup>-32PHB system is 0.9410, which is rendered by the USL parameter Separation Distance.

**Table 6.5-2 USL Evaluation**

Parameter	Limiting Value	USL
EALF in eV	0.9655	0.9427
Boron Loading in PPM	2450	0.9439
Separation Distance	2.03 <sup>(1)</sup>	0.9410
U-235 Enrichment	5.0	0.9440
H <sub>2</sub> O/UO <sub>2</sub> Volume Ratio	1.617	0.9441
Pitch in cm	1.4732	0.9424

- (1) The separation distance for the 4 fuel assemblies loaded in the center of the DSC is 1.59cm. The remaining 28 fuel assemblies have a separation distance of 2.03cm. If the 1.59cm is used for the USL evaluation, the limiting value is changed by 0.0003 (from 0.9410 to 0.9407). The difference is less than one-half of the standard deviation (1/2σ) in the KENO results.
