

**Comments on the Waste Confidence
Draft Generic Environmental Impact Statement
and Proposed Rule**

ML14154A175

Comments on the Waste Confidence Draft Generic Environmental Impact Statement and Proposed Rule

This document accompanies Appendix D of NUREG–2157, *Generic Environmental Impact Statement for Continued Storage of Spent Nuclear Fuel* (ADAMS Accession No. ML14198A440). Appendix D of the Generic Environmental Impact Statement (GEIS) includes summaries of comments received on the draft GEIS and proposed Rule, and responses to those comments. This document contains the text of the identified unique comments summarized in Appendix D of the GEIS.

Approximately 32,000 of the written submissions were form letters. The U.S. Nuclear Regulatory Commission (NRC) identified 12 form letter templates (see Table 1). The majority of the form letters were sponsored by the Sierra Club (ML13269A279) and Nuclear Information and Resource Service (ML13330A726). Identical comments contained in form letters were captured only once; however, any additional comments contained in form letters were treated as unique comments.

Table 1. Form Letter Identification Numbers

Correspondence Identifier	ADAMS Accession No.	Table of Author Names
WC-R-DR-00002	ML13269A282	Table 3
WC-R-DR-00003	ML13269A279	Table 4

Table 2, which follows the comments, provides a list of commenters who provided unique comment submissions (i.e., non-form letter submissions). The form letters are also included in Table 2, and the authors are noted as “Commenters, Multiple”. Authors and ADAMS accession numbers for form letter submissions are identified in Tables 3 through 14, one table per form letter, following the comments. The comments in Table 7 and Tables 9 through 14 were bundled and assigned a single ADAMS accession number for all authors.

Comment excerpts are listed below by category. Comments are identified by the comment identification number (correspondence number-comment number) and the name of the commenter at the end of each excerpt. The NRC categorized and consolidated comments according to subject area. The list of the 55 comment categories (i.e., subject areas) and the page where each category begins are provided below.

Comment Category	Page Number
1. Comments Concerning Rule Questions	4
2. Comments Concerning the Rulemaking Process.....	20
3. Comments Concerning the Rule Language	42
4. Comments Concerning Miscellaneous Issues.....	48
5. Comments Concerning the NEPA Process	60
6. Comments Concerning Public Participation	79
7. Comments Concerning the Scope of the GEIS	110
8. Comments Concerning Site-Specific Issues	120
9. Comments Concerning the Proposed Action & Purpose and Need.....	207
10. Comments Concerning Alternatives – General	243
11. Comments Concerning Alternatives – No Action/Site-Specific	254
12. Comments Concerning Alternatives – GEIS Only	322
13. Comments Concerning Alternatives – Policy Statement.....	323
14. Comments Concerning Alternatives – Considered but Eliminated	324
15. Comments Concerning Alternatives – Costs.....	349
16. Comments Concerning GEIS Assumptions and Analysis	353
17. Comments Concerning GEIS Assumptions – Dry Transfer System	401
18. Comments Concerning GEIS Assumptions – Timeframes	415
19. Comments Concerning GEIS Assumptions – Institutional Controls.....	435

13 Individuals Submitting the Form Postcard Sponsored by the Sierra Club with Correspondence ID 950 and ADAMS Accession No. ML14043A331	1702
14 Individuals Submitting the Form E-Mail with Correspondence ID 951 and ADAMS Accession No. ML14027A648	1706

1. Comments Concerning Rule Questions

Comment: Specific issues Commission seeks comments from public on: Issue 1. As outlined above, the statement in 51.23 regarding repository availability is not supported by App. B or the history of trying to site a repository in the U.S. (0027-2 [Vandenbosch, Robert])

Comment: Issue 2. To say in the rule 51.23(a)(2)(i) that the analysis in NUREG-2157 supports the determination that it is feasible to safely store" is a bit of a stretch in view of the statement in C3-b of the request for comments "Although the DGEIS does not primarily evaluate safety". (0027-3 [Vandenbosch, Robert])

Comment: Issue 3. You should not remove content as the public comments you are receiving are based on current text. (0027-4 [Vandenbosch, Robert])

Comment: I object to the way this Commission defines "waste confidence" in Discussion Section 3, Answer A2, in the September 13 waste confidence Federal Register Notice and on the waste confidence website that the Commission maintains today. The current Commission mischaracterizes waste confidence by defining it solely as a storage issue. From its inception, waste confidence has been, and continues to be, about confidence in the eventuality of deep geologic disposal. And, yes, it is also secondarily about the safety and availability of storage until offsite disposal or storage comes online. (0030-1-1 [Kotra, Janet])

Comment: For myself and for many members of the lay public, the waste confidence decision and rule touch on a most basic question. How can the Commission continue to allow a generation of spent nuclear fuel or permit operation of new generators unless it is confident that there will be permanent disposal of that waste? Contrary to how it is defined in the current regulatory notice, the original Federal Register Notice announcing the first waste confidence decision in 1984, the Commission stated and I quote, "The purpose of this proceeding is solely to assess the degree of assurance now available that radioactive waste can be safely disposed of." Unfortunately, today's rulemaking -- it went on to say other things, but it said up front that waste confidence was about the availability of disposal. Unfortunately, today's rulemaking in effect fails to answer this most important question by stating in effect, "We have confidence in disposal because we have confidence in the safety of long-term storage." I'm sorry. No matter how well technically justified that may be, this logic simply breaks down. NRC is dodging the question the public most cares about when it says disposal will become available when necessary. Deep geologic disposal is, and remains our nation's policy codified in U.S. law. The public deserves an answer to the question, is the Nuclear Regulatory Commission confident that the United States will implement a disposal solution for spent nuclear fuel in a reasonable and realistic timeframe? (0030-1-4 [Kotra, Janet])

Comment: It is important to recall, however, that the Commission also founded its confidence, both in 1984 and again in 1990, on confidence in the existence of a statutory framework enacted by a bipartisan Congress setting forth a process or a path forward for the development of repositories. At no time did the respective commissions involved contemplate that the process itself laid out in statute would become corrupted and unworkable. Nor did those commissions anticipate that subsequent commissioners would later be unable or unwilling to carry out their statutory obligations. Yet, as documented in the recent ruling of the second highest court in the land, this is precisely what has happened. The Commission must, therefore, as a result, declare that there no longer exists a basis for waste confidence. Such a bold declaration would not only be honest, it would address forthrightly the fundamental question undergirding the original purpose of the waste confidence policy. Recognizing the lack of waste

confidence would generate significant attention from both pro and anti-nuclear interests and provide NRC an opportunity to submit a substantive legislative proposal to the U.S. Congress to suggest amendments to existing legislation to amend or replace the Nuclear Waste Policy Act. (0030-1-7 [Kotra, Janet])

Comment: If we could get the definitions commonly found in the dictionary for "waste" and "confidence," I think we could get to the root of the matter here that we're dealing with, because there's a lot of words going around that a lot of meaning is getting lost. And the stories that we're going to script through this public comment time is very important. (0030-11-1 [Vandel, Niki])

Comment: I think the assumption is being made that if something can be found, that's it, we're done. I don't think so. I think that needs to be analyzed as well. Putting it down, you know, in various places for tens of thousands of years. All the places we've found so far have not passed muster. What is the muster? So I don't think this assumption that some day we might be able to find that is confidence-producing at all. It's like a pig in a poke. It's like jumping with no place to land. And another aspect is that there doesn't seem to be a way to currently isolate radioactive waste from effects on life, on the biosphere. So it's not confidence-producing to say they will find one. I think it's a false premise in the EIS to base the future on something we don't have yet. (0030-13-3 [Sondheim, Steven])

Comment: [W]e [Sierra Club] have no real confidence in waste confidence (0030-21-10 [Carberry, Mike])

Comment: [W]aste confidence did initially used to be about primarily geologic disposal. But over time our system has given us delays in geologic disposal, and now it has also become about storage, which is why in pools and in casks our ability to safely store it is indeed something that we can have confidence in. And we will continue to provide this confidence. (0030-6-4 [McCullum, Rod])

Comment: My first recommendation is to remove the misleading title of Waste Confidence. Waste Confidence simply does not exist in the public, nor the nuclear industry, and probably not even at NRC. (0045-6-3 [Andrews, Richard])

Comment: My first recommendation is to remove the misleading title of "Waste Confidence". Waste Confidence simply does not exist in the public, nor the nuclear industry, and probably not even at NRC. (0059-3 [Andrews, Richard])

Comment: It is telling that the NRC uses the term confidence when talking about safeguarding nuclear waste. That you dare use the word confidence when talking about safeguarding rad waste for hundreds of times longer than the entire Christian era is preposterous. (0112-11-2 [Agnew, David])

Comment: For a hazard that will last for thousands of years, Waste Confidence is an oxymoron. For a hazard that will last for hundreds of thousands of years, use of the word confidence is simply moronic. (0112-11-8 [Agnew, David])

Comment: I remember when the Waste Confidence rule came out in the 80s. And it's basically a way for the DOE and the industry to cover, to cover themselves for not coming up with a solution to the back end of the nuclear production cycle for commercial electric plants. (0112-15-1 [Williams, Chris])

Comment: We abhor the continued arrogance of the NRC to claim that they have confidence in dealing with this issue when they've clearly just been putting it off for future generations to deal with. (0112-5-7 [Bogen, Doug])

Comment: The problem I think the public has with this Waste Confidence rule is the word confidence. And I was talking to a fellow who worked for the NRC outside the room who was sort of nodding along with me and saying you should give that feedback. And I think the word confidence to the public really means it's somewhat of a cocky statement. In my mind it's like saying we have the utmost confidence that everything will be fine. Now, you know, the Japanese people were promised this as well in Fukushima and look what happened. So maybe a better use of the word -- a different word would be good in this position. So something like waste estimation rule, waste assumption rule. I think confidence is really going beyond what you can possibly, possibly believe in. So I think that that word is pitting the public against the NRC. And I think we need to work together here as NRC's supposed to represent the public and not the industry. (0112-9-3 [Baker, Anna])

Comment: Lastly, I wonder if there are NRC staffers who deduce that, given the problems at Fukushima and given all the problems with the waste that's building up at a lot of the sites, if the NRC staff deduces that there is no -- that they don't have confidence that the waste will be stored safely is there a way, an outlet for these people to give anonymous feedback? Maybe there is no such thing as confidence to some of the staffers that work at the NRC and maybe they're too afraid to speak up to their higher ups or to the government because they work for the NRC. Is there a way for people to give feedback to the NRC who work within the NRC that maybe there is no confidence that this waste plan is a good one? And I truly believe that a lot of people who work at the NRC are now starting to rethink whether or not confidence or this Waste Confidence rule is something that they should back. (0112-9-4 [Baker, Anna])

Comment: On behalf of UA Local 131 we agree with the removal of a timeline for the repository in the rule. Due to political and social constraints the proposed Yucca Mountain repository has withdrawn its application. Currently United States law supports the timely disposal of spent nuclear fuel in a geological repository. The inclusion of a timeline puts an undue burden on the commercial power producers while the Federal Government looks to site and build a repository. (0152-1 [Pelletier, David A.])

Comment: Because I am an English teacher, I can say with total certainty that the phrase "Nuclear Waste Confidence" is the biggest oxymoron ever uttered or appended in human history....And I can't believe that the NRC folks don't know that. And it was really smart word-smithing to come up with that one. You should pay those people a lot of money, whoever thought that up. (0163-14-1 [Schepart, Margot])

Comment: I didn't even get to the GEIS. I didn't get to anything. All I got to was "Waste Confidence." And that stopped me right there. I have to ask the NRC members who are here and the ones who are not here, whose confidence are we talking about? Are we talking about your confidence? Because you're not talking about our confidence. (0163-24-1 [Allen, Judy])

Comment: We in New Jersey join you in saying "No confidence." (0163-36-5 [Brown, Jeffrey])

Comment: I'm here to say "No confidence." (0163-49-1 [Evans, Laurie])

Comment: I have absolutely no confidence in the NRC. (0163-51-1 [DeCrescenzo, Jocelyn])

Comment: [T]he answer to the other one is "No."...Having a mined geological generic repository within 60 years following the license reactor is impossible....The only thing that's been allowed is a burial system, and there's been no investigation in reverse engineering. (0163-7-11 [Shapiro, Susan])

Comment: I just want to say that I vote No Confidence. (0163-9-4 [Gerard, Daniele])

Comment: For a hazard that will last for thousands of years, 'waste confidence' is an oxymoron. For a hazard that will last hundreds of thousands of years, use of the word 'confidence' is an unacceptable leap of faith. We are seven decades into 'too cheap to meter' and no one knows what to do with the industry's toxic waste. Whether the problem is NIMBY or scientific, the result is the same: no one has figured out what to do with the industry's toxic waste. (0230-2 [Garb, James])

Comment: Waste confidence, I have no waste confidence. (0245-35-3 [Seastrom, Tina])

Comment: Confidence, we all know, is in the eye of the beholder. So, sitting here tonight, people have different expectations of what confidence means. Certainly, when the NRC -- limited. We heard about maybe only two, the spent nuclear fuel and the generating site, but spent nuclear fuel goes well beyond that. And there's just a disparity of expectations because, as we know, until and unless the spent nuclear fuel becomes eligible to be put in the ground in a repository, I'm not too sure how much confidence the public is going to have. Certainly it is not within the scope of the GEIS but, however, they're interconnected. At some point, I think that in a large part either as a constraint or something, the EIS really has to mention automatically the interconnection with the repository which isn't available and we don't even see anything in sight. So, this is just an observation I have is that what kind of confidence do you have? And what expectations do you come to the public to say I have this confidence, what do you mean by that? (0245-5-1 [Chen, S.Y.])

Comment: I also personally think that the title of this, Waste Confidence, is very misleading. That's kind of an Orwellian title so that nobody really can understand what's happening right here. We're talking about nuclear waste dumping. If you're not putting that in the terms of this, no one is going to know what you're talking about and people aren't going to come out and express themselves. So, I think that just the title itself shows a certain lack of transparency that we need to look at. How can we have confidence in the system when they keep using words like Waste Confidence? We need to have a very descriptive title of what's going on so people can have a real understanding, and then we can have an honest debate. (0245-52-2 [Kalas, Mike])

Comment: I would first like to address the NRC's question in the Federal Register notice about whether the title of the Rule should be changed. NEI [Nuclear Energy Institute] strongly supports discontinuing using the term Waste Confidence. It is a historical artifact and it doesn't provide any useful description of the Agency's analysis and conclusions on repository availability and the continued safe and environmentally sound storage of used fuel. In fact, the term "Waste Confidence" simply derives from the Commission's statement dating from the late 1970s, that as a matter of policy, the NRC would not continue to license reactors if it did not have a reasonable confidence that waste can and will, in due course, be disposed of safely. Although the record amply supports a continued finding of reasonable confidence that safe disposal will become available, there is much confusion about that to which the term refers. To avoid the confusion and the mischaracterizations that the term "Waste Confidence" seems to engender, we strongly recommend that the Rule be retitled something along the lines "Storage of Spent Nuclear Fuel

for the Period After License Term of Reactor Operation." Simple, straightforward, and descriptive. The GEIS should be similarly renamed. (0246-14-1 [Ginsberg, Ellen])

Comment: I have no confidence in your Waste Confidence, (0250-11-3 [Kerr, Julius])

Comment: Some of the specifics that you wanted comments on, as far as time line for repository availability, I don't believe that there should be reference to a repository made in the Rule, because that will unintentionally tie us to that as part of the waste solution for perpetuity. There are other methods for taking care of nuclear waste other than spent fuel through reprocessing, through other utilizations and mentioning it in the Rule will only hamper those developments in the future. (0250-14-5 [Brookhart, Ryan])

Comment: Second, information from the Generic Environmental Impact Statement should be referenced but not repeated in the text of the Rule. Again, those crossing of references in federal regulations only makes it more complicated for people to understand what's really going on. (0250-14-6 [Brookhart, Ryan])

Comment: Third, streamlining of clarity is always an improvement to any regulation. So on the third question of whether you should streamline the text in the ruling, I certainly encourage you to do that. Again, for the reasons stated before, government regulations are complicated enough to understand. If you can do anything to streamline it, I would encourage it. (0250-14-7 [Brookhart, Ryan])

Comment: Regarding Issue 4 on the title of the rule - We provide no comment. (0262-10 [Patterson, Karen])

Comment: Regarding Issue 1 to remove the timeline for the availability of a disposal repository from the rule - We believe that the timeline for the availability of a repository should be removed from the rule. The draft GEIS analyzed several scenarios including never developing a repository, and concluded that the environmental impacts of spent fuel storage would be the same regardless of the length of storage. The obligation and responsibility to develop and implement a plan to site, construct, and operate a repository does not reside with the NRC. Indeed, the Department of Energy has the statutory obligation to develop a national spent nuclear fuel/high level waste disposal program. Although the likelihood of the federal government foregoing this obligation may be considered remote, an expansive NEPA analysis should consider (as this one does) the highly improbable scenario of no repository. Moreover, for NRC to include a time table for repository development could be imprecise or misleading to the public as the time tables in the Nuclear Waste Policy Act and others have demonstrated. (0262-3 [Patterson, Karen])

Comment: Regarding Issue 2 to include a statement in the rule related to the safety of continued spent fuel storage. We believe that such a validated statement related to the safety of continued spent fuel storage should be included. (0262-7 [Patterson, Karen])

Comment: In 2012, the U.S. District Court for the District of Columbia ruled that the waste confidence rulemaking is a major federal action requiring an EIS or an EA, and that the NEPA document should address specifically the impacts of potential fires and leaks in fuel pools. The NRC broadened its analyses to include additional considerations. The advantage of the larger scope in the EIS is that the expanded analyses validate the previous findings of the Commission regarding spent fuel storage and allow the Commission to conclude that used/spent fuel storage as practiced in this country is without significant adverse effects on the environment. We believe

that the record of previous spent fuel storage also leaves little room to argue that spent fuel storage is not safe. Because safety, more than environmental, considerations may drive spent fuel decisions, and are of the greatest concern to the public, we believe it is appropriate to summarize the NRC's views on the safety of interim and extended spent fuel storage. In other words, the GEIS is an environmental assessment under NEPA that examines the environmental impacts of continued spent fuel storage. While its primary purpose is NEPA-driven and therefore environmentally focused, the public should have the benefit of the NRC's determination that spent fuel may be stored for extended periods with reasonable assurance of safety. (0262-8 [Patterson, Karen])

Comment: Regarding Issue 3 to remove information that is redundant with information provided in the GEIS from the Discussion portion of the Statement of Consideration that will accompany the final rule's publication in the Federal Register. We believe the information should be published with the rule, thus ensuring that supporting information for the NRC's decision to amend the rule is maintained with the rule. Furthermore, the Discussion portion of the Statement of Considerations has "plain language" content that should increase public understanding of NRC's basis for its conclusions. (0262-9 [Patterson, Karen])

Comment: I do not share your Waste Confidence. (0277-8 [Pierman, Bette])

Comment: Confidence is generally described as a state of being. Certain either that a hypothesis or a prediction is correct, or that a chosen course of action is the best and most effective. Arrogance in this comparison is having unmerited confidence, believing something or someone is capable or correct when they are not. Time will determine whether the NRC's proposed waste plan is confident or arrogant. (0325-3-1 [Becker, Rochelle])

Comment: Number three, the Commission seeks public comment on whether the discussion portion, Section 3 of the Federal Register Notice of the Statement of Considerations, should be streamlined by removing content that is repeated from the DGEIS, in order to improve clarity of the discussion, now that the NRC has prepared an Environmental Impact Statement to support the Rule. I agree, because all of this should have been streamlined. I think we had about 17 people say the same thing. (0326-36-1 [Vandel, Nikohl])

Comment: Number four, the Commission seeks public comment on whether the title of the Rule should be changed in light of a GEIS being issued instead of a separate Waste Confidence decision. Absolutely. How the hell is the NRC going to make any kind of statement on Waste Confidence with Fukushima still uncontained[.] (0326-36-2 [Vandel, Nikohl])

Comment: And I believe that we're here to talk about this, which has nothing to do with Diablo Canyon. This is what the policy that is going to affect 103 communities that live with nuclear power. When I asked my friend, Liz Apfelberg, one of the founding members of Mothers for Peace, what Waste Confidence is she says well, they're confident that they're going to make waste, and they don't know what to do with it. (0326-56-1 [Homick, Nick])

Comment: In the morphic field of resonance, quantum physics, we all remain connected, and Michael, thank you for reminding us of that. And I think if the people from the NRC felt that connectedness, they wouldn't come here with the oxymoronic phrases like Waste Confidence. It's like having confidence in Bernie Madoff and the Ponzi scheme, or waste -- you know, using the term spent fuel, another oxymoron, and depleted uranium, another one. (0326-6-1 [Walking Turtle, Willow])

Comment: The State Building Trades supports the inclusion of a specific policy statement regarding the safety of the continued spent fuel storage of the Waste Confidence Rule. As previously detailed, these storage methods have been proven to be safe and, therefore, the Proposed Rule should reflect those findings. (0327-12-3 [Knisley, Mike])

Comment: First, regarding the additional issue number 4, I believe the term "Waste Confidence Rule" is a poor choice of words, and should be changed. It is an inelegant and anachronistic nomenclature from the 1980s based on predictions and assumptions which have proved to be erroneous and absurd. Thus, subjecting the Rule, the Proposed Rule to well-deserved mockery, derision, and ridicule. (0327-17-3 [Schonberger, David])

Comment: Secondly, regarding supplemental additional issue number 3, I believe that it is a good idea to streamline the Federal Register to remove redundancies and anachronisms. Conversely, I also believe that the NRC should increase and maximize redundancies in the "real world." In other words, generally speaking, the NRC should not be in the business of eliminating redundancies, redundancies should be augmented. (0327-18-2 [Schonberger, David])

Comment: First, with issue one, I think it's important to maintain discussion of timeline for a repository. I see that as a contract that we initiated with the nuclear industry, and it should be repeated throughout. (0327-28-2 [Greenwood, John])

Comment: Issue two, the safety of continued spent fuel storage to be made in the real text, I also support this. I believe it should be within the text, again, to, well, give people that are opposed to industry basis to make opposition. (0327-28-3 [Greenwood, John])

Comment: Issue three, streamline of the Federal Register. I am in high support of that because I search the Federal Register quite often, and when you dump extra explanation into it, it makes it a burden to search. (0327-28-4 [Greenwood, John])

Comment: The two types of storage facilities for spent nuclear fuel have been designed to withstand natural disasters and terrorist attacks. Both fuel pools and dry storage systems have never allowed the release of radioactive material. ACT Ohio [Affiliated Construction Trades Foundation of Ohio] also supports the inclusion of a specific policy statement regarding the safety of these storage methods. (0327-31-2 [Dorans, Rob])

Comment: Additionally, ACT Ohio [Affiliated Construction Trades Foundation of Ohio] supports streamlining the statement of considerations by removing the content repeated in the Generic Environmental Impact Statement, which will provide additional clarity to the nuclear industry and the public on the Proposed Rule. (0327-31-3 [Dorans, Rob])

Comment: I think the first thing to say to the NRC to this topic with the word confidence that you have used and I think maybe you were forced to use it by the courts. (0327-36-1 [Lamberger, Paul])

Comment: If there is one thing that we all know regardless of what side of the issue we're on, regardless of whether we think the issues are primarily technical or primarily political, we all know that we can't have any confidence in effective management of nuclear waste, particularly spent nuclear fuel rods. We all know that. (0328-11-3 [Muller, Alan])

Comment: On issue number three that we're working on in this particular focus, according to the documents anyway, related to the streamlining, I think footnotes with links so that both are connected in truth. (0329-6-3 [Vandel, Niki])

Comment: Yes, I do believe that we need to make this dialogue very understandable to a first grader because waste confidence, and this gets to issue four, should not be the title because, as we all know, all we have right now is shoulds, coulds. We don't have confidence. And if we go forward with this rule, with this illusion, lie, deviance from our reality, one, our NRC is going to look like a joke in the history book. And we don't need that. We don't want that. We want to be smart, and we want to look smart, so let's be smart. (0329-6-4 [Vandel, Niki])

Comment: For a hazard that will last for thousands of years, 'waste confidence' is an oxymoron. For a hazard that will last hundreds of thousands of years, use of the word 'confidence' is simply moronic. (0419-7 [Agnew, David])

Comment: My first recommendation is to remove the misleading title of "Waste Confidence". Waste Confidence simply does not exist in the public, nor the nuclear industry, and probably not even at NRC. This title is merely a buzz word phrase, deceptive at best, and clearly designed to mislead the public...and perhaps even to get NRC and nuclear industry personnel to believe their own propaganda of misinformation, to create a false sense of security and safety, and to duck responsibility for proper management and prompt disposal of these very dangerous man-made materials. (0447-1-3 [Andrews, Richard])

Comment: Are you serious? (0470-1 [Moran, Aliese])

Comment: Issue 1. Issue 1 contains a request for comment on whether the Commission should remove the timeline for repository availability from the rule. This question refers to the finding in the proposed 10 C.F.R. § 51.23(a)(2)(ii) that "it is feasible to have a mined geologic repository within 60 years following the licensed life for operation of a reactor." The sentence should be removed from the rule. The Commission is correct when, in the Federal Register notice accompanying the rule, it states that "there are national policy decisions, and societal and political factors that can significantly influence the actual timing of the availability of mined geologic repository, and these policy decisions are outside the Commission's control." As the D.C. Circuit has observed, the Commission has not been successful to date in estimating the timeframe by which a repository will be available. NRC asserts in the DGEIS that the "most likely, timeframe [for a permanent waste repository] is the short-term timeframe, which analyzes 60 years of continued storage after the end of a reactor's licensed life for operation." DGEIS at xxvii. This statement ignores the long history of NRC's failure to ever predict this date and the well-considered comments of Commissioner Svinicki (Notation Vote, September 2009 Response Sheets of Commissioner Svinicki at 2 (publicly released on September 25 and 28, 2009))("this is a particularly difficult time to be in the prediction business") that NRC is not able to make such predictions with any accuracy. Rather the Commission should remove from the DGEIS any prediction of the "likely" date when a permanent repository would be in existence, since it has no basis for that statement in the DGEIS, and should recognize in the final rule that while it is technologically feasible to have a mined geologic repository within 60 years following the licensed life for operation of a reactor, the Commission does not have a rational basis to predict when, if ever, the political and social factors the Commission has already acknowledged will be resolved such that a repository will actually exist. (0473-18-2 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Issue 2. Issue 2 contains a request for comment on whether the finding in the proposed 10 C.F.R. § 51.23(a)(2)(i) that "it is feasible to safely store spent nuclear fuel following the licensed life for operation of a reactor" should be included in the rule. The States, the Commonwealth, and the Tribe support removing this text from the rule. In the Federal Register notice accompanying the rule, the Commission states that "the policy statement on safety is not related to, or necessary for, the generic determination on environmental impacts of continued storage, nor does it provide the safety analysis for storage in a particular dry cask or storage at a particular site: A safety evaluation is still required to support a site-specific license for dry storage, or to store spent fuel in a spent fuel pool." Insofar as this statement is not necessary to the rule, the States, the Commonwealth, and the Tribe submits that it should be stricken. (0473-18-3 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Issue 3. Issue 3 contains a request for comment on whether the Discussion portion (Section III of this document) of the Statement of Considerations should be streamlined by removing content that is repeated from the DGEIS in order to improve clarity of the discussion. The States, the Commonwealth, and the Tribe take no position on Issue 3. (0473-18-4 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Issue 4. In Issue 4, the Commission is seeking specific comment on whether the title of the rule should be changed in light of a DGEIS being issued instead of a separate Waste Confidence Decision. The States, the Commonwealth, and the Tribe are in favor of removing any reference to "Waste Confidence" from the title of the rule, as the D.C. Circuit invalidated the premise of "confidence" as the basis for NRC decisionmaking. NRC should adopt a title that more accurately reflects the true federal action--i.e., licensing and relicensing of reactors and storage installations. (0473-18-5 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The Commission has incompletely, and as a result, incorrectly defined Waste Confidence in Discussion Section IV answer, A2 in the September 13, 2013 Federal Register Notice. This misrepresentation also appears on the Commission's website in response to the FAQ "What is Waste Confidence?" The Commission mischaracterizes Waste Confidence by representing it solely as a waste storage issue. From its inception, Waste Confidence has been and continues to be about confidence in the feasibility and availability of geologic disposal. It is also, secondarily, about the safety and availability of storage until offsite disposal or storage sited and designed specifically for the safety of that disposal or storage comes on line. (0532-1 [Kotra, Janet])

Comment: The Commission should acknowledge that there no longer exists a reliable basis for Waste Confidence. Such a bold declaration would not only be honest, it would also forthrightly address the fundamental question undergirding the original purpose of the Waste Confidence Policy. As I stated earlier, confidence in the technical feasibility of disposal has increased, but the governmental and societal structures upon which Americans (including Commissioners) must rely for implementing nuclear waste disposal policy under existing law are in turmoil. Failing to acknowledge that reality, while at the same time doing everything possible to assert a "false confidence" to justify the authorization of more and more waste generation, clearly harms NRC's reputation as an independent safety authority. Many may conclude that NRC cares more about the economic viability of its licensees than it does about protection of public health and safety or sound national energy and waste policy. Recognizing the all too obvious lack of Waste Confidence provides the Commission an opportunity to submit a legislative proposal to amend or replace the Nuclear Waste Policy Act. I respectfully and earnestly urge the Commission to reassert its role as a truly independent safety authority for the Nation and do just that. (0532-10 [Kotra, Janet])

Comment: Issue 1: I do not agree that NRC should remove discussion and time estimates for repository availability. (0532-11 [Kotra, Janet])

Comment: Issue 2: I do not agree that NRC should remove discussion of the safety of continued spent fuel storage from the rule. (0532-12 [Kotra, Janet])

Comment: Issue 3: I do not believe that the understanding of the public would be enhanced by the proposed "streamlining." Further, more plain language explanation may be warranted, but assuming that because "it's in the GEIS, it doesn't need to be in the SOC for the rule" is not appropriate. (0532-13 [Kotra, Janet])

Comment: Issue 4: For reasons discussed in my specific comments, I strenuously object to changing the title of the rule. (0532-14 [Kotra, Janet])

Comment: The Waste Confidence decision and rule came about to address a most fundamental question: "How can the Commission continue to allow the generation of spent nuclear fuel or (by implication) permit the operation of new generators of this material unless it has confidence that there is a solution to the permanent disposal of that waste?" Contrary to how it has been misapplied in the current Federal Register Notice, the original Federal Register Notice announcing the first Waste Confidence Decision, in 1984, the Commission stated, "The purpose of this proceeding is solely to assess the degree of assurance now available that radioactive waste can be safely disposed of, to determine when such disposal will be available and to determine whether radioactive waste can be safely stored past the expiration of existing...licenses until...disposal or storage...is available." Unfortunately, today's rulemaking in effect fails in its answer to this most important question by stating that "We have confidence in disposal because we have confidence in the safety of longterm storage," No matter how well technically justified such assertion may be, the logic simply does not follow. NRC is avoiding the question the public most cares about when it says, "Disposal will become available when necessary." This despite the fact that deep geologic disposal is and remains the Nation's policy codified in statute. The public deserves an answer to the question, "Is the Nuclear Regulatory Commission confident that the United States will implement a disposal solution for spent nuclear fuel in a realistic time frame?" (0532-2 [Kotra, Janet])

Comment: Just recently a representative of the nuclear industry asserted that the very term "Waste Confidence" is now nothing more than an historical artifact. This is an astonishingly short sighted and self-serving declaration. To jettison the need for establishing this basic confidence in waste disposal, as opposed to indefinite storage, disregards NRC's obligation to the longterm public health and safety and common defense and security and, ignores even the industry's long-term best interest. By the same token, certain irresponsible, self-described environmental advocates also seek to change the subject of Waste Confidence away from ultimate disposal. They would instead hawk indefinite so-called onsite "hardened storage," while at the same time sabotaging the NWPA and all serious attempts at locating and licensing a safe geologic repository. The motives of industry are fairly obvious-keep the kilowatts flowing and the ratepayers paying. Those of certain irresponsible, self-described environmentalists are only slightly less so (and by no means do all or even a majority of environmentalists fall in this category). Efforts of these select groups to downplay and discredit geologic disposal allow them to continue to argue that nuclear power should not be included as a carbon-free alternative in a rational long-term energy future for the U.S. because the "waste disposal problem can't be solved." (0532-3 [Kotra, Janet])

Comment: Rule Package, FR 56799, middle column, Issue 1. NWRPO believes the rule should not include a statement about the timeline for repository availability. As stated in the FR text. "Although conclusions about repository availability have been included in Waste Confidence proceedings since 1984, these statements are not necessary to the environmental review or for fulfilling the NRC's NEPA obligations." More importantly, because all phases of continued storage are shown to have small environmental impacts, no statement regarding repository availability within any particular timeline should be included. (0544-18 [Enriquez, Elizabeth])

Comment: Rule Package, FR 56799, last column, Issue 3. NWRPO believes the discussion section of the rule package should contain enough information that it can be used as a stand-alone document. The technical analysis from the GEIS should be included in the rule package to the extent necessary to provide a complete picture of waste confidence. (0544-19 [Enriquez, Elizabeth])

Comment: Issue #1: Recommended Action: Remove any and all specific Policy Statements regarding the timeline for mined geologic repository availability from the proposed revised text of the Waste Confidence Rule (10 CFR 51.23, Paragraph (a), Section (2)). Reasons: First, the NRC acknowledges that such statements (which have historically been "included" in "Waste Confidence proceedings since 1984") are "not necessary to the environmental review or for fulfilling the NRC's NEPA obligations," and the NRC has failed to make a compelling and convincing argument that the continuation of historical tradition is either justified on its own merits or appropriate in this case. Furthermore, I believe that it is more than a little duplicitous, deceptive and disingenuous -- possibly bordering on rogue -- for the NRC to brazenly include, inside an official CFR Rule, Policy Statements and language revisions which are beyond the scope and authority of the Agency to guarantee, implement, administer or enforce. I contend that such proposed language is an agency overreach and out-of-bounds of the force-of-law by definition, as the NRC itself admits that its own proclamations are independently and wholly unenforceable. The NRC concedes that "national policy decisions" as well as various "societal and political factors," all of which are "outside" the NRC's "control," "can significantly influence the actual timing of the availability of [a] mined geologic repository." (0603-15 [Schonberger, David])

Comment: Issue #2: Recommended Action: Remove any and all specific Policy Statements regarding the safety of spent nuclear fuel storage from the proposed revised text of the Waste Confidence Rule (10 CFR 51.23, Paragraph (a), Section (2)). Reasons: First, similarly as with Issue #1 above, the NRC acknowledges that such statements (which have historically been "included" in "Waste Confidence proceedings since 1984") are "not necessary to the environmental review or for fulfilling the NRC's NEPA obligations," and the NRC has failed to make a compelling and convincing argument that the continuation of historical tradition is either justified on its own merits or appropriate in this case. Furthermore, I believe that such proposed Policy Statements and language revisions represent the embodiment of hubris and bravado applied to a subject that calls for extreme caution and risk aversion, given the gravity of the potential consequences of both reasonably-foreseeable and unforeseeable occurrences. I believe that recent global events have demonstrated that it is not possible to effectively extrapolate safety calculations for the consideration of every possible circumstance or for an indefinite timeframe. Finally, I believe that the proposed Policy Statements regarding the safety of spent nuclear fuel storage are entirely unrelated and unnecessary to the intended purpose of the proposed Rule, that is, to improve the efficiency of the NRC's licensing process by serving and enabling the facilitation and expedition of major licensing decisions through the application of generic criteria. Ironically, the NRC appears to agree and fully concur with this assessment. Perhaps institutional complacency or inertia can explain the incongruity. (0603-16 [Schonberger, David])

Comment: Issue #3: I believe that it is a good idea to streamline the Federal Register to remove redundancies and anachronisms. Conversely, I also believe that the NRC should increase and maximize redundancies in the "real world." In other words, generally speaking, the NRC should NOT be in the business of eliminating redundancies. Redundancies should be augmented, and cost-benefit analyses should more effectively prioritize public interests over private profits. (0603-17 [Schonberger, David])

Comment: Issue #4: I believe the term "Waste Confidence Rule" is a poor choice of words and should be changed. It is an inelegant and anachronistic nomenclature from the 1980's based on predictions and assumptions which have proved to be erroneous and absurd, thus subjecting the proposed Rule to well-deserved mockery, derision and ridicule. Furthermore, the provenance of the proposed Rule is unusual in that it has emerged in response to and as a direct result of the unanimous decision of a Federal Court of Appeals, which vacated and remanded the previous incarnation of the so-called NRC Waste Confidence Rule. Another unusual aspect of the genesis of the current proposed Rule is described in the Federal Register (78 FR 56782, Section III, A12): "Preparation and reliance upon a GEIS is a fundamental departure from the approach used in past Waste Confidence proceedings. . . .Because a GEIS [Appendix B] is being issued, [the historical five "Findings"] are no longer necessary." Thus, as there is no separate Waste Confidence Decision document, I believe that the title (name) of the proposed Rule should be changed in order to reflect the evolving rulemaking process. In the Executive Summary of the DGEIS (p. xxiii), the NRC explains that the term "Waste Confidence applies to the storage of spent fuel after the end of the licensed life for operations of a nuclear reactor and before final disposal in a permanent repository. This timeframe is referred to as "continued storage" throughout this draft GEIS." I contend that there are two fundamental contradictions embedded in that language. First, there can be no genuine "confidence" until such time as "continued storage" has a defined and available endpoint with no ambiguity or open-endedness. Second, there can be no genuine "confidence" until such time as the NRC initiates regulatory action to require licensees to expedite the transfer of spent nuclear fuel from active wet storage (pools) to passively-safe dry storage systems with the ultimate goal of a complete phase-out of any nuclear reactor located in or near a seismically-active zone and any nuclear reactor of the U.S. GE Mark I and II BWR design, such as Fermi, Unit 2 in Southeast Michigan. Such regulatory actions would be very politically viable in the wake of the ongoing, horrific tragedy of Fukushima Dai-ichi and would demonstrate that a reexamination of bogus generic reactor and storage design criteria could realistically initiate at the NRC headquarters without the pretext of pressure, intervention or imposition from exogenous quarters. (0603-18 [Schonberger, David])

Comment: These shifting dates and timeframes have not inspired confidence that a national repository will become available, and have done much to frustrate host communities. While having a date included in 10 CFR 51.23 might be a reflection of current thinking of whether a repository might be available, it adds nothing. We do not believe that the final rule should include a timeframe by which a repository will become available. Instead we believe that the NRC should include a plan for updating the Waste Confidence GEIS that would be reflective of the current status of a repository. (0619-1-5 [Mahowald, Philip R.])

Comment: Issue 1 asks whether the specific policy statements regarding the timeline for repository availability should be removed from the rule text. The shifting dates and timeframes in previous update to the rule have not inspired confidence that a national repository will become available and in fact, have done much to frustrate host communities. While having a date included in 10 CFR 51.23 might be a reflection of current thinking of whether a repository might be available, it adds nothing. We do not believe that the final rule should include a timeframe by

which a repository will become available. Instead we believe that the NRC should include a plan for updating the GEIS that would be reflective of the current status of a repository. (0619-2-7 [Mahowald, Philip R.])

Comment: Issue 2 asks whether specific policy statements regarding the safety of continued spent fuel storage should be included in the rule, given the expansive and detailed information in the draft GEIS. In May 2012, the NRC issued the draft report "Identification and Prioritization of the Technical Information Needs Affecting Potential Regulation of Extended Storage and Transportation of Spent Nuclear Fuel." Our understanding was that this technical report was related to the NRC's Long-Term Waste Confidence Update, initiated in 2011. The "Extended Storage" technical report identified a number of technical issues related to long-term storage of spent nuclear fuel, such as the lack of monitoring or inspection capability for cladding, fuel cladding interactions, fuel assembly hardware and damaged fuel cans, fuel baskets, stainless steel canister, stainless steel canister, stainless steel canister and steel/cast iron and seals, polymer seals, neutron absorbers, and neutron shielding. These technical issues must be resolved. The Tribe recommends that the NRC finalize the "Extended Storage" technical report before issuing the final Waste Confidence GEIS. The information and conclusions in a final Extended Storage report would certainly help the public understand whether spent nuclear fuel for can be stored on-site for the long-term or indefinitely. Our comment letter to the NRC can be found in ADAMS (ML12191A218). (0619-2-8 [Mahowald, Philip R.])

Comment: I must say first of all that the term "confidence" when used to refer to nuclear waste is an oxymoron. To pretend that nuclear 'waste confidence' can be handled as a public relations/ terminology issue is to deny reality. (0640-1 [Geary, B.])

Comment: It is at least implicitly required because if there is no waste confidence, it is immoral to continue making nuclear waste, especially because much of that waste remains extremely dangerous for centuries and, in the cases of some radioisotopes, for millennia. (0679-2 [Sorgen, Phoebe])

Comment: The comedy of still including the 60 year mined geologic repository is lessened by the court's ruling on Yucca Mountain this past summer, but I do not think that the NRC does itself nor instills confidence by including this language and even idea when no determination to create such a site has been fully implemented. (0703-10 [Vandel, Nikohl] [Vandenberg Clermont, Elaine])

Comment: AREVA endorses revising the names of the proposed rule and draft GEIS and to discontinue the "Waste Confidence" and "Temporary storage of spent fuel after cessation of reactor operation-generic determination of no significant environmental impact" terms to a more effective title that defines the contents of the rule and GEIS in general words. Moreover, "Waste Confidence" is a historic artifact that does not stand alone without a technical explanation of how the title originated. The names fail to clearly convey the intent of the proposed rule, which details the safe storage of spent fuel after the end of a reactor's operating life. AREVA supports the following NEI suggestions of new titles for the proposed rule and draft GEIS: "Storage of Spent Nuclear Fuel after Licensed Term of Operation" and "Generic Environmental Impact Statement for the Storage of Spent Nuclear Fuel after Licensed Term of Operation." These suggested titles, or similar revisions, would better state the purpose of the rule and GEIS. (0745-4 [Kelley, Devin])

Comment: The term "Waste Confidence" is a historical artifact from the NRC's policy determination addressed in the NRDC petition for rulemaking and the subsequent court

decision. The term fails to transparently capture the purpose of the proposed rule, which relates primarily to the storage of spent fuel after the end of a reactor's operating life. For that reason, as will be discussed further below, NEI encourages the NRC to discontinue the use of "Waste Confidence" to describe the environmental impacts of interim storage. (0827-1-2 [Ginsberg, Ellen])

Comment: Similarly, NEI believes that the title of the current proposed rule, "Environmental Impacts of Storage of Spent Nuclear Fuel Beyond the Licensed Life for Operation of a Reactor," should be changed. As discussed further below, NEI supports a rule title such as the "Storage of Spent Nuclear Fuel After Licensed Term of Operation." Similarly, the GEIS could be named the "Generic Environmental Impact Statement for the Storage of Spent Nuclear Fuel After Licensed Term of Operation." These titles would more clearly articulate the purpose and substance of the rule and GEIS. (0827-1-3 [Ginsberg, Ellen])

Comment: NEI does not believe that streamlining of the statements of consideration and rule is necessary or advantageous. Summarizing the content in the SOC that is also contained in the GEIS will only enhance public understanding of the relationship between the GEIS and rulemaking package. The GEIS achieves a slightly different purpose than the prior WCD Findings. Therefore, it would be logical to address the traditional WCD Findings and the relevant information contained in the GEIS in either the rule or the SOC for the rule, rather than including that information only in the GEIS. The SOC should address the bases for the rule, including a discussion of the feasibility and reasonable assurance of safe spent fuel storage and repository availability. (0827-6-10 [Ginsberg, Ellen])

Comment: NEI supports changing the name of the rule and GEIS. We recommend the NRC to discontinue using "Waste Confidence" and "Temporary storage of spent fuel after cessation of reactor operation--generic determination of no significant environmental impact" and adopt a title that better describes the contents of the rule and GEIS. Moreover, by adopting a clearer title, the purpose and limited application of the rule will be more evident to members of the public who are not aware of the historical basis for the "Waste Confidence" term. NEI supports a rule title such as the "Storage of Spent Nuclear Fuel After Licensed Term of Operation." Similarly, the GEIS could be named the "Generic Environmental Impact Statement for the Storage of Spent Nuclear Fuel After Licensed Term of Operation." (0827-6-11 [Ginsberg, Ellen])

Comment: The SOC for the revised TSR should explain the basis for the rule, retaining much of the discussion in current Section C. It would make clear that the rule preserves and updates the previous WCD Findings - supplemented and supported by the GEIS. However, there would be no need to label them as specific "Findings" as done in the past. Additionally, the GEIS assesses the environmental impacts of interim spent fuel storage, including the issues remanded by the D.C. Circuit, and summarizes the record supporting the rule. Presenting all necessary elements in the rule would be the simplest and most straightforward approach. The SOC would explain the basis for the rule and include "Conclusions" (as it does now) that support the rule. (0827-6-3 [Ginsberg, Ellen])

Comment: The revised rule text need not articulate specific timelines for repository availability in order to capture the Commission's essential finding that a repository can be available when necessary. NEI believes that a more general, "when necessary" finding is appropriate in the rule text. The robust discussion of specific timeframes for repository availability contained in the SOC and GEIS - including the Commission's conclusion that it is feasible to have a mined geologic repository within 60 years of licensed life for operation of a reactor - would support such a finding. Thus, NEI's proposed rule language provided above would not include a specific timeline for, or prediction regarding, repository availability. There is no legal requirement that the

rule include such a timeline or prediction. Nonetheless, the Commission's more specific predictive findings regarding repository availability should be maintained - whether in the SOC, the GEIS, or both - because such findings are useful in framing the agency's assessment of the safety and environmental impacts of continued spent fuel storage. Although the GEIS examines very long time periods, the Commission's specific conclusion regarding repository availability is that "a reasonable timeframe for repository availability is within 60 years beyond the licensed life for operation of a reactor."¹¹⁷ [footnote 117 text: 78 Fed. Reg. 56794.] The Commission also finds that it is "technically feasible to safely and securely store spent fuel in either wet or dry storage for *at least* 60 years beyond a reactor's licensed life for operation with only routine maintenance" and "that spent nuclear fuel can be safely managed in spent fuel pools in the short-term timeframe and dry casks during the short-term, long-term, and indefinite timeframes evaluated in the DGEIS."¹¹⁸ [footnote 118 text: *Id.* at 56799 (emphasis added).] So, the Commission's more specific predictive conclusions regarding repository availability (and the supporting analysis) provide both a basis for more general "when necessary" rule language, and context for more general safety conclusions regarding continued storage. Thus, NEI's proposed rule language discussed above would continue to include "when necessary" as the timeframe for repository availability. (0827-6-8 [Ginsberg, Ellen])

Comment: Specific statements capturing the Commission's conclusions regarding the safety of spent fuel storage during the continued storage period should be included in the rule text. This approach is simple and transparent; appropriately addresses the issues raised in *Minnesota v. NRC*, as well as *New York v. NRC*; and is consistent with the agency's long-standing approach to addressing continued storage. Thus, NEI's proposed rule language would include a specific policy statement regarding the safety of continued storage. Although policy statements regarding the safety of continued spent fuel storage need not be included in the rule text *per se*, such statements (whether in a rule, a Finding, a Conclusion, or in a GEIS) are necessary to resolve issues raised in both *Minnesota v. NRC* and *New York v. NRC*. NEI believes that the rule should capture the essential finding, backed up by more specific Conclusions in the SOC, which are, in turn, consistent with the record summarized in the draft GEIS and prior WCD Findings. Although the GEIS includes comprehensive information regarding safe spent fuel storage, the GEIS itself is an environmental document assessing the environmental impacts of continued spent fuel storage. The GEIS supports conclusions regarding safe spent fuel storage, but its primary purpose is to satisfy the agency's environmental obligations under NEPA. To directly address the showing suggested in *Minnesota v. NRC*, NEI encourages the Commission to retain determinations regarding the safety of continued spent fuel storage in the rule, supported by similar "Conclusions" in the SOC. (0827-6-9 [Ginsberg, Ellen])

Comment: For Additional Issue 1, I do not support the inclusion of timelines on the availability of a future geologic repository in the final rule. The history of the development of a permanent repository, since the passing of the NWPA, is replete with missed timelines. No guarantee is available that future performance in developing, licensing, and constructing a repository will be any better. Therefore, to simplify the final rule, I would remove language dealing with repository timelines. However, I would retain any statements providing a duration on how long spent fuel can be safely stored, especially in dry storage systems (casks). (0841-3 [Corrino, G])

Comment: For Additional Issue 2, I support inclusion of policy statements within the rule text. Purpose, scope, and objective language is found in many other places in 10 CFR Chapter 1. Its inclusion here would be consistent with the Commission's openness and transparency goals. (0841-4 [Corrino, G])

Comment: For Additional Issue 3, I support inclusion of additional details within the final rule FRN's preamble. The FRN is more readily available and searchable to the public, than is an NRC NUREG GEIS. Therefore, it will be more helpful to future users to have this critical information in searchable location. (0841-5 [Corrino, G])

Comment: For Additional Issue 4, I support revising the title of the final rule. (0841-6 [Corrino, G])

Comment: Disavow "Waste Confidence" when it is impossible to guarantee the safe future of nuclear waste[.] (0890-6 [Arnason, Deb])

Comment: As a private citizen long concerned about nuclear power, particularly in Michigan but worldwide also, I have searched the "Waste Confidence Generic Environmental Impact Statement Draft Report for Comment" in vain for a simple, straight forward definition. Now I recall being at the NRC meeting long ago in Lansing, Michigan, where their discussion led to the decision to eliminate definitions as the most inexpensive and most effective [least responsible?] pathway to proceed in the development of nuclear power. Therefore, my major comments will be on a seeming obfuscation via use of terms in a specific NRC fashion, in employing language all too often twisted from its normal uses. (0910-1 [Carey, Corinne])

Comment: On page xxiii ESI is titled "What is Waste Confidence?" gives NO definition, only "determination" and other references to the misleading "confidence". Included is "before final disposal in a permanent repository", and "continued storage", a situation proving impossible in the history of nuclear power. (0910-5 [Carey, Corinne])

Comment: Issue 1. The Department believes the specific policy statements regarding the timeline for repository availability should remain in the rule because the availability of a repository is the most critical issue affecting long term dry cask storage at-reactor or away-from reactor. The inclusion of the statements in the rule indicates the importance the Commission places on this key assumption of the GEIS. As reflected in the above comments, the Department believes geologic repository disposal provides permanency, control, and overall radiation safety. (0913-12 [Bevill, Bernard])

Comment: Issue 2. The Department does not believe it is necessary to include specific policy statements in the rule addressing continued spent fuel storage, given the proposed wording of Paragraph 51.23(a)(2). sufficiently states the Commission's "policy" storage. It seems this wording on continued spent fuel[.] (0913-13 [Bevill, Bernard])

Comment: Issue 3. The Department agrees the Discussion portion of the Statement of Consideration should be "streamlined" to avoid unnecessary duplication. (0913-14 [Bevill, Bernard])

Comment: Issue 4. The Department believes the title of the rule should be changed to accurately reflect the purpose of the analysis, evaluation, and conclusions of the study of continued storage of spent nuclear fuel. It is no longer a Waste Confidence Decision. (0913-15 [Bevill, Bernard])

Comment: The very first time I ever heard the phrase "Nuclear Waste Confidence" was in March 2003 - right around the time the George W. Bush administration launched the invasion of Iraq --at an Early Site Permit public meeting held at the public library in Clinton, IL, having to do with a proposed new Exelon reactor targeted at that town (since cancelled, thankfully!). An elder

local farmer, sitting in the front row, raised his hand early on in the meeting. He asked how Exelon and NRC could even be considering building a new reactor in Clinton, IL, when the high-level radioactive waste from the first reactor already operating in Clinton had nowhere to go, and no solution in sight. One after another, several NRC staff persons attempted an answer, all to no avail. Each punted to his or her NRC co-worker around the room. After a number of such punts, the last NRC staff person was about to punt the question to Exelon officials, several of whom were also in attendance. At this point, the NRC facilitator - Chip Cameron, who has also facilitated numerous of the WC DGEIS public comment meetings of recent months - intervened. "What about the Nuclear Waste Confidence Rule," Chip Cameron - who has also long worked for NRC's Office of General Counsel, in addition to its Office of Public Affairs --prompted his colleagues, who then, having remembered their lines, cheerfully informed the concerned local resident that NRC has "Confidence" that a repository will be opened somewhere, somehow, someday, by someone, and in the meantime, the highly radioactive wastes are safe and sound right where they are in Clinton, IL. The farmer seemed a little less than convinced. I also did not share NRC's "confidence." It seemed very much a con game. (0919-1-5 [Kamps, Kevin])

Comment: To begin with, the use of the word confidence is to imbed the notion that there might be any *confidence* in the draft statement. There could be none because of the history of the NRC faulty assumptions and its actions. (0933-1 [Anonymous, Janet])

Comment: The term "Waste Confidence" is a meaningless term -- other than the clear fact that I have 100% confidence that radioactive waste from nuclear power facilities will exist somewhere for many millenia to come. It is appalling that the NRC has been playing this word game of charades with the public ever since 1983 with this term. They clearly want to help the industry so are "kicking the ball down the field" to hopefully (in the industry perspective) do many more favors for the nuclear industry before finally getting to seriously addressing threatening radioactive waste issues. (0937-15 [Campbell, Bruce])

Comment: Admission from both the nuclear industry and young nuclear engineers IS that the safe waste storage issue has not yet been solved. They promise to work on it with earnest. The public and the NRC can NOT go forward with CONFIDENCE. {deleted text: until s}Solutions MUST BE SOUGHT {deleted text: are found and verified} AND IMPLEMENTED FOR THE WASTE ALREADY PRODUCED. This is a reason for a generic finding of NO CONFIDENCE. (0938-13 [Sondheim, Steven])

Comment: Finally, Exelon is in favor of changing the name of this rulemaking from Waste Confidence to a more factual name such as "Storage of Spent Fuel after Licensed Term of Operation." The term "waste confidence" now fails to transparently capture the purpose of the proposed rule, which relates primarily to the storage of spent fuel after the end of a reactor's operating life. (0942-11 [Helker, David P.])

2. Comments Concerning the Rulemaking Process

Comment: The Commission has the legal authority to supervise the activities of the Regulatory Staff (Reorganization Plan No. 1 of 1980, 5 USC App. I, Section 1), including supervision over any rulemaking proceeding. *Private Fuel Storage L.L.C.* (Independent Spent Fuel Storage Installation), CLI-02-11, 55 N.R.C. 260 (2002) (Commission chose to "exercise ... [its] inherent supervisory authority over adjudications and rulemakings"). Thus, it has the legal authority to review and reverse decisions of the Regulatory Staff, particularly ones related to the ongoing - waste confidence and temporary storage rule proceedings and the accompanying GEIS, which

have been initiated as a direct result of the Commission's decisions in Staff Requirements - COMSECY-12-0016-Approach For Addressing Policy Issues Resulting from Court Decision to Vacate Waste Confidence Decision and Rule (Sept. 6, 2012), ML12250A132 ("Staff Requirements-COMSECY-12-0016"). (0001-5 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: In addition, the Commission has set forth standards for when it would consider reviewing an order issued by an Atomic Safety and Licensing Board. The Staff Scoping Decision, although not issued in a licensing proceeding within the meaning of 10 C.F.R. Part 2 and not subject to the rights and obligations of that Part 2, nonetheless meets the standards established for interlocutory review by the Commission under the provisions of 10 C.F.R. § 2.341(f)(2). (0001-6 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: In addition, the proceedings in which the Staff Scoping Decision was issued should be considered adjudications within the meaning of 5 U.S.C. § 551(7), given that the result of these proceedings will be an Order by the Commission that directly affects ongoing licensing proceedings and future licensing proceedings. See *Calvert Cliffs Nuclear Project, L.L.C.* (Calvert Cliffs Nuclear Power Plant, Unit 3), *et. al.*, CLI-12-16, _N.R.C._, slip op. at 4 (Aug. 7, 2012) ("Waste confidence undergirds certain agency licensing decisions, in particular new reactor licensing and reactor license renewal [I]n recognition of our duties under the law, we will not issue licenses dependent upon the Waste Confidence Decision or the Temporary Storage Rule until the court's remand is appropriately addressed.").¹ [Footnote 1 text: Although the scoping process is not where the ultimate application of the waste confidence GEIS conclusions and the rulemaking outcomes will be determined, Petitioners believe it is important that modifications to the Commission's prior conclusions regarding the environmental impacts of spent fuel storage following plant shutdown, particularly previously unexamined impacts associated with long-term storage of spent fuel at reactor sites, and alternatives that can mitigate those impacts, should be applied at least to those facilities that received operating licenses or license extensions on or after December 23, 2010, when the Commission formally abandoned the position that it could establish a date by which a permanent nuclear waste repository would be available. 75 Fed. Reg. 81032 (Consideration of Environmental Impacts of Temporary Storage of Spent Fuel After Cessation of Reactor Operation) (Dec. 23, 2010). While this right should exist regardless of whether such issues were sought to be raised at the time of the previous licensing action and should not be limited to contested licenses or previously admitted parties, it is notable that at least two of the Commenters in the waste confidence GEIS proceedings, the State of Vermont and the Commonwealth of Massachusetts, attempted to raise similar issues in license renewal proceedings for Vermont Yankee and Pilgrim, but were prevented from doing so by application of the limitations imposed by 10 C.F.R. §§ 51.23(b), 51.53(c)(2), and 51.95(c)(2). See *Entergy Nuclear Vt. Yankee, LLC* (Vermont Yankee Nuclear Power Station), LBP-06-20, 64 N.R.C. 131, 170 (Sept. 22, 2006); *Entergy Nuclear Generation Co.* (Pilgrim Nuclear Power Station), LBP06-23, 64 N.R.C. 257,280-81 (Oct. 16, 2006); *Commonwealth of Massachusetts v. NRC*, 522 F.3d 115, 124-26 (1st Cir. 2008) (Pilgrim and Vermont Yankee facilities).] (0001-7 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: "The Commission may, in its discretion, grant interlocutory review at the request of a party." *Entergy Nuclear Operations, Inc.* (Indian Point Nuclear Generating Units 2 and 3), CLI-09-06, 69 N.R.C. 128, 132-33 (Mar. 5, 2009). Such petitions are granted under 10 C.F.R. § 2.341(f)(2) when the party demonstrates that the issue: (i) Threatens the party adversely affected by it with immediate and serious irreparable impact which, as a practical matter, could not be alleviated through a petition for review of the presiding officer's final decision; or (ii) Affects the basic structure of the proceeding in a pervasive or unusual manner. *Id.* While the

Commission grants such petitions only in "extraordinary circumstances," *id.*, the situation presented here involves extraordinary circumstances that "[a]ffect[] the basic structure of the proceeding in a pervasive or unusual manner." *Id.* (0001-8 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: I'm very concerned about the entire process of this EIS. The NRC seems to be in a hurry to proceed to the end of the process without giving it careful review. (0030-12-1 [March, Leslie])

Comment: The timely resolution of this rulemaking is important for long-term power planning. This issue is directly affecting relicensing of nuclear plants and approval of pending construction applications for new reactors, which are vital if we are serious about our commitment to a reliable, safe, and secure source of electricity. (0030-20-4 [Lapiska, Evan])

Comment: I applaud the courts. I applaud them for making -- having the industry. And if you're truly a responsible industry and if the NRC is truly responsible to the American electorate that it serves, then it behooves you take this time, I've read the potential of seven years to study this. I don't care how long it takes. It could take 10 years. It can take 20. That's a drop in the bucket to the life of these radioisotopes. It deserves it. Do not rush this through. Do not do it generically. Consider places like Illinois where we are relying on you. And I thank you for your time. (0030-22-6 [Headington, Maureen])

Comment: With respect to waste confidence, the NRC encourages the Nuclear Regulatory Commission to complete the Waste Confidence EIS rulemaking in a timely manner. (0030-23-3 [Blee, David])

Comment: Completing this rulemaking will allow the NRC to resume issuing licenses and license renewals for nuclear power plants and independent spent fuel storage installations and effectively end the moratorium that is currently impacting those procedures. (0030-23-5 [Blee, David])

Comment: I'd like to highlight the importance of a timely resolution of these waste confidence issues. We strongly support maintaining this rulemaking as a priority. (0030-3-2 [Ginsberg, Ellen])

Comment: I think in terms of the Nuclear Regulatory Commission, the only reason we are having this exercise, and the public is having the opportunity to comment, is it took a Federal court ruling to vacate the Nuclear Regulatory Commission's Waste Confidence rule. It had been challenged internally by people concerned that it made no sense, that it was circular thinking with no base in reality, and it took a Federal court to require the reconsideration. (0030-5-3 [Safer, Don])

Comment: We commend the agency's efforts that have brought us this far, and encourage the continued engagement of the Commissioners, senior NRC management, and the technical staff to complete the rulemaking in a timely manner. Timely resolution is critically important. The Commission has suspended a number of licensing decisions pending resolution of this issue. Deferral of these decisions has impacts with the organizations affected. Licensing decisions are essential for the long-term power planning and other business decisions, such as schedules for capital improvements. This essential decision-making will remain disrupted and inefficient until licensing decisions resume. (0030-7-1 [Matthews, Tim])

Comment: Timely completion of the draft GEIS demonstrates what the NRC staff can accomplish when given clear Commission direction, management engagement, and adequate

resources. This rulemaking should serve as a benchmark for other significant NRC activities, such as licensing and design certification reviews, extended schedules for which seem to have become accepted in some corners as a new norm. The example demonstrates conclusively that the agency -- what the agency can do. (0030-7-2 [Matthews, Tim])

Comment: While many safety reviews of licensing actions have continued on schedule, in some cases the parallel environmental review schedules have slipped as resources have become diverted to support this GEIS effort. The staff should promptly return those -- to those environmental reviews and prioritize review resources so that further delay in adjudicatory proceedings or licensing issuances is avoided. (0030-7-3 [Matthews, Tim])

Comment: In the fall of 2012, the Commission ordered that consideration of waste confidence contentions in adjudicatory proceedings before the Atomic Safety and Licensing Board be held in abeyance while the agency determined how it would address the issues remanded by the D.C. Circuit. The agency has now established a clear path and is well along the way to generic resolution of the remanded issues. Accordingly, the staff should promptly recommend to the Commission options for resumption of adjudicatory reviews, and specifically, the exclusion of waste confidence-related issues from review in individual licensing proceedings, absent the grant of a case-specific waiver to challenge a matter that is the subject of an ongoing generic rulemaking. (0030-7-4 [Matthews, Tim])

Comment: Timely completion of the draft GEIS demonstrates what the NRC staff can accomplish when given clear Commission direction, management engagement, and adequate resources. This rulemaking should serve as a benchmark for other significant NRC activities, such as licensing and design certification reviews, extended schedules for which seem to have become accepted in some corners as a new norm. The example demonstrates conclusively that the agency -- what the agency can do. I would like to touch briefly on the impact of the waste confidence decision in individual licensing actions. While many safety reviews of licensing actions have continued on schedule, in some cases the parallel environmental review schedules have slipped as resources have become diverted to support this GEIS effort. The staff should promptly return those -- to those environmental reviews and prioritize review resources so that further delay in adjudicatory proceedings or licensing issuances is avoided. (0030-7-9 [Matthews, Tim])

Comment: I am very concerned about the entire process of this EIS. The NRC seemed to be in a hurry to proceed to the end of the process without giving any part of it careful review. (0045-11-1 [March, Leslie])

Comment: Our statement today focuses on encouraging the NRC to complete the Waste Confidence Environmental Impact Statement and Rulemaking in a timely fashion. Nuclear energy is an important part of America's energy security providing two-thirds of the Nation's emission-free electricity 24 hours a day. Given these stakes, prompt completion of the Rulemaking is critical to ending the current moratoria on a wide range of final nuclear energy licensing, including issuance of operating licenses for new plants, license renewals for operating nuclear plants, and extension of licenses for independent spent fuel storage facilities. (0045-14-1 [Frankland, Chris])

Comment: [ConverDyn] encourage[s] the NRC to proceed promptly with this Rulemaking. (0045-15-3 [Sandos, Theann])

Comment: CA [Consumer Energy Alliance] strongly supports the NRC's efforts to keep nuclear facilities safe and reliable. And as you continue in the waste confidence rulemaking, we urge you to proceed efficiently and quickly. A timely resolution on this matter is essential. And existing and future nuclear facilities need greater certainties about licensing time-lines and decisions, in order to maintain and expand this vital part of the U.S. energy portfolio. (0045-4-4 [Martini, Shawn])

Comment: The timely resolution of this rulemaking is important for long-term power planning. This issue is directly affecting relicensing of nuclear plants and approval of pending construction applications for new reactors -- which are vital if we are serious about our commitment to a reliable, safe and secure source of electricity. (0060-4 [Lapiska, Evan])

Comment: [T]imely resolution of this rulemaking is important for long-term power planning. This issue halts the building of new reactors and ultimately puts a delay on our energy efficiency. (0112-21-4 [Morris, Kelsi])

Comment: Second, NRC's rulemaking process is vague. And I say this because it's like very, you know, complex terminology that the average person can't understand. That experts and lawyers spend a very long time researching and pouring over. And it's contradictory. It's kind of obtuse. It's like almost like church or something. Not in a bad way. I don't intend to insult any church. But if you make comments or criticisms, technical arguments, you point out design flaws, you point out things like the underground pipes at Vermont Yankee that weren't disclosed, your comments disappear into the rulemaking process. And it could be years before NRC turns around with a real solution. Cite specific arguments and move to rulemaking and address basically after years of study. So nothing is done quickly. (0112-31-3 [Johanson, Birgit])

Comment: So on any given day in the normal day in the life of the NRC there's no transparency and no real opportunity for the public to have any meaningful input into how the reactors are run, how they operate, and certainly no real opportunity input into the best available methods for managing the spent fuel. And because of the sort of the nature of the dialogue itself the way the rulemaking is set up, you're only allowed to address certain specific issues. Anything that falls outside of the question being asked is not considered. So the nature of the dialogue itself limits inquiry and intelligent discussion. To close, rulemaking that's vague and has, I guess, many holes in it --It's more of an obstacle to real solution than a help. The guidelines are in principle founded upon assumptions formed in the 1950s and before in the war time era. To continue to build on such an outdated foundation is a hazard. To stay in rigid compliance with its own rules NRC has, in effect, bound its own hands and put the public at enormous risk. I support redesigning the entire legal basis for the NRC's regulatory enforcement. (0112-31-6 [Johanson, Birgit])

Comment: While it is the federal government's responsibility to remove used fuel from nuclear plants, the federal government has not moved a single used fuel assembly. As such, it is important for the NRC to continue transparent and efficient efforts to maintain its 24-month schedule for the current waste confidence proceedings so that progress on both plant licensing and used fuel management can continue. (0115-2 [Salley, Lawrence])

Comment: The US Nuclear Regulatory Commission has always applied due diligence and demonstrated its dedication to public safety. The rule-making process currently underway for used fuel management is another example of the NRC's commitment to safety and transparency. (0118-2 [Westchester, Business Council of])

Comment: [W]e urge you to stick with the 24-month review period to eliminate uncertainty in the decision making process. In this regard, the NRC is taking the appropriate steps toward avoiding costly, inefficient and unnecessary case-by-case reviews of the issue. (0118-5 [Westchester, Business Council of])

Comment: We have two choices. As a human race, AND as corporate utility decision makers. To become more conscious in our decisions. Or to become more Unconscious in our decisions. There is no longer an in-between place to dwell in. To date, the NRC decision makers have been hiding in the in-between places. Hiding inside the anonymity of the commission process. In this way each decision maker participates knowingly in the issuance of harm-making decisions, the same way the members of a firing squad each agree to pull the trigger, knowing they will never be held personally accountable. And they are paid too. It's quite the same. (0120-5 [Seeman, Laurie])

Comment: We [NAYGN] believe it is important for the NRC to continue its transparent and efficient efforts to maintain its 24-month schedule for the current Waste Confidence proceedings so that progress on both plant licensing and used fuel management can continue. (0163-17-3 [Schepperly, David])

Comment: The timely resolution of this rulemaking is important for long-term power planning. This issue is directly affecting re-licensing of nuclear plants and approval of pending instruction applications for new reactors which are vital if we are serious about our commitment to reliable, safe, and secure source of electricity that will help combat climate change. (0163-18-5 [Lapiska, Evan])

Comment: I would like to thank the NRC for having us and Attorney General Schneiderman for making this issue come to the courts. (0163-48-1 [Meyer, Bill])

Comment: I urge the NRC to approve the Waste Confidence Rule as soon as possible in its current proposed state (or similar), so that we, as a country, can resume licensing/relicensing clean, safe, carbon-free nuclear power plants such as we are accustomed to here in the Carolinas. (0179-1 [Graham, Susan])

Comment: Accordingly, timely resolution to the issue of waste confidence plays an important part of meeting this strategic need, and we join the rest of the industry in strongly supporting making this rulemaking a high priority. Not only is resumption of ongoing licensing activities essential for long-term power planning decisions, but it is also important to reestablish confidence in the nation's ability to conduct new licensing proceedings. (0182-3 [Vytlačil, Gordon])

Comment: I look forward to a timely resolution of this rulemaking so that the NRC can get back to some of the important tasks they handle each and every day that have been placed on hold while this plays out, including the relicensing of nuclear plants and approval of pending construction applications for new reactors. (0212-5 [Lapiska, Evan])

Comment: The timely resolution of this rulemaking is important for long-term power planning. This issue is directly affecting relicensing of nuclear plants and approval of pending construction applications for new reactors -which are vital if we are serious about our commitment to a reliable, safe and secure source of electricity. (0213-5 [Coalition, Clean and Safe Energy])

Comment: The proposed rule is essential to the NRC. The continued licensing of nuclear energy facilities cannot continue without the rule change. The absence of a rule change would be a serious burden on the nuclear energy industry and their production of 20% of the nation's electricity. (0219-3 [Olmstead, Stan])

Comment: In the proposed rule that accompanies the draft GEIS, the NRC also proposes to incorporate into every reactor license the Draft GEIS' conclusion that spent fuel can be safely stored above ground forever. Thus, the NRC would forbid any further public discussion, in individual reactor licensing actions, of the serious question of whether generation of additional spent fuel is justifiable in light of the absence of any means of safe disposal. (0221-2 [Ferguson, Tom])

Comment: In sum, we recommend that the Commission heed the advice of those who estimate that the waste confidence rule should take three to four times as long as what the Commission has ordained. (0222-10 [Zeller, Lou])

Comment: The NRC is rushing the process. NRC must resolve many technical issues including long-term waste integrity, vulnerability, deterioration and accidents. For example, the nuclear waste stored at Fukushima is still being evaluated. According to an NRC staff plan, a long-term waste confidence update was expected to take eight years⁸ [Footnote 8 text: "Waste Confidence Decision: Background," Christine Pineda, NRC Office of Nuclear Material Safety and Safeguards, October 4, 2011, <http://www.nrc.gov/waste/spent-fuel-storage/christine-pineda-10-04-2011.pdf>] Yet the NRC has set a deadline of September 2014 to finalize the new rule. The agency's two-year deadline is rushing the process and the public will suffer if the NRC persists in pleasing the industry at the expense of public safety. (0222-6 [Zeller, Lou])

Comment: This is the fourth one of these meetings that I've attended, and they continue to be, what I would consider, a shining example of the way our regulatory processes work. It is a very rigorous process, it is very open, it is very transparent. It is a very necessary process. The rulings of the Court do need to be responded to and this is an issue we should weigh very seriously. It also is being conducted on schedule, and this is very important that you continue to be conducted on schedule. (0244-11-1 [McCullum, Rod])

Comment: We believe that is important that the NRC continue its transparent and efficient efforts to maintain this 24-month schedule for the current Waste Confidence proceedings so that progress on both licensing and spent nuclear fuel disposal can continue. (0244-2-4 [Knowles, Berdell])

Comment: The NRC must now revise these -- review these transcripts and then complete the edits of the Environmental Impact Statement called for by the Court, and publish the EIS and the revised Rule, and it should not take a year to do it. (0244-4-5 [Rossin, A. David])

Comment: We believe that the NRC should move promptly to finalize the Waste Confidence Generic Environmental Impact Statement. A delay in this process is detrimental to the future of our state's long-term energy portfolio. (0244-7-4 [Kuntawala, Jitesh])

Comment: The Proposed Rule simply clarifies the issues and processes surrounding the safe and secure storage of spent nuclear fuel. It does not authorize individual licenses. It is only one step in the Commission's National Environmental Policy Act review. And hence, the clarity of this policy will lead to a more efficient licensing process which would benefit consumers throughout our region. In addition, the NRC rulemaking process is the kind of open and

transparent process that should take place in all aspects of government regulation, especially the widespread participation of all aspects of government, industry, and the public in order to ensure that all viewpoints are considered. A total of 12 public meetings will take place, and members of the public will have the opportunity to submit comments to the Commission through December 20th of 2013. Upon the completion of this process, it is my hope that NRC will complete this rulemaking in an expeditious manner. (0245-1-2 [Wilson, Reed])

Comment: The Federal courts have said NRC must have a valid and realistic assessment of the environmental impact of long-term storage of spent nuclear fuel. In response, the NRC plans to take only two years for the EIS, and more correctly, the environmental review. NRC's own staff says it will take seven years to do an EIS. The two-year time frame NRC is using has been only enough time to summarize the currently available information about the risks of long-term storage and the existing information is inadequate. One study that's looking at the long-term storage has been started but it will take until 2019 to finish. (0245-15-1 [McComb, Sandy])

Comment: I urge you to finalize the Waste Confidence Rule in a timely manner to help our company work to its best. (0245-18-4 [Stenson, Amanda])

Comment: We encourage you to carefully consider the economic impact of regulations governing the transportation and storage of spent nuclear fuel. (0245-9-2 [Peck, Jerry])

Comment: [W]e believe it is important for the NRC to continue its efforts and to maintain its current schedule for Waste Confidence proceedings, so that progress on both plant licensing and used fuel management can continue. Again, thank you to the NRC for hosting this public meeting and providing the opportunity for comments. (0246-1-4 [Husch, Ben])

Comment: We compliment the Directorate's outreach efforts, as well as their ability to adhere to the schedule laid out by the Commission. We underscore the importance of maintaining the schedule so the NRC licensing decisions will not be unduly delayed. (0246-12-2 [McMurrian, Katrina])

Comment: From the documents, the very thorough, extensive documents that NRC has provided for comment, all the way through these meetings, this has and continues to be a shining example of the rigor with which the regulatory processes that govern the nuclear industry work. (0246-19-1 [McCullum, Rod])

Comment: I look forward to a timely resolution of this rulemaking so that the NRC can get back to some of the important tasks they handle each and every day that have been placed on hold while this plays out, including the relicensing of nuclear plants and approval of pending construction applications for new reactors. (0246-20-5 [Lapiska, Evan])

Comment: I would like to take my three minutes to set a couple three things straight on the record about some misleading statements that NRC has made in this draft Generic Environmental Impact Statement and at the hearings that have taken place. So, I would like to go back to a New York Times article in February of 2010 about the lawsuit brought by several states and several environmental groups that led to the Court ruling in June of 2012, that ordered NRC to undertake this EIS proceeding. And in that article, a top spokesman for the Office of Public Affairs at NRC made the statement that the Nuclear Waste Confidence Rule has nothing to do with licensing at NRC. And this statement, this idea has been carried into this document itself at various places. I would like to read from Section 7.3 on page 78, just the first paragraph. And I quote: "In the proposed action, the NRC implements a regulatory approach

that includes an update to the Waste Confidence Rule, 10 CFR 51.23, that codifies the results of this draft GEIS. The update would clarify that. Because the impacts of continued storage have been generically assessed in the GEIs and codified in a Rule, the NEPA analyses for future reactor and spent fuel storage facility licensing actions would not need to independently consider the environmental impacts of continued storage. The Rule also serves to preclude any challenge to the NRC's assessment of the environmental impacts of continued storage in the site-specific licensing action. Unless a petitioner can show that sufficient 'special circumstances' exist to justify waiving 10 CFR 51.23 in a particular proceeding." And they cite 10 CFR 2.335. And I end quote. So, the statement that has been made is that this Nuclear Waste Confidence Rule has nothing to do with licensing new reactors or extending the licenses of old reactors. And this is very misleading. This is deceptive. In fact, the Nuclear Waste Confidence Rule lays the basis for that licensing. As I just quoted, it would bar public intervention in the future. It would lock the public out as much as we have been locked out for decades on raising the issue of high-level radioactive waste generation in licensing proceedings. And I can personally attest to that from the license extension proceeding at Palisades in Michigan where we raised this issue, as well as the new reactor licensing proceeding at Fermi 3. This absolutely has to do with licensing. It lays the groundwork. It greases the skids. So, NRC statements to the contrary in this document, at these public hearings, are quite misleading, actually. (0246-32-1 [Kamps, Kevin])

Comment: The timely resolution of this rulemaking is important for long-term power planning. This issue is directly affecting relicensing of nuclear plants and approval of pending construction applications for new reactors, which are vital if we are serious about our commitment to reliable, safe, and secure source of electricity. (0246-8-3 [Vince, Jenny])

Comment: So I encourage the NRC to complete the Waste Confidence EIS rulemaking. This is an important part of our future for nuclear power[.] (0250-14-2 [Brookhart, Ryan])

Comment: The NRC is reviewing this Waste Confidence Rule, and I again encourage them to complete the rulemaking, to allow them to resume issuing licenses and continuing to process installations. (0250-14-4 [Brookhart, Ryan])

Comment: I urge the NRC to continue on a priority basis with this rulemaking process. (0250-15-5 [Rodack, Tom])

Comment: We urge the Commission to complete the Waste Confidence rulemaking, and move forward with licensing of renewed, operating licensing for existing plants and new units to come. (0250-21-2 [Gunn, George])

Comment: Due to nuclear energy's crucial role in our nation's diversified portfolio, it is essential that the NRC complete the Waste Confidence rulemaking and resume issuing new operating licenses and license renewals for nuclear plants. (0250-24-3 [Rogers, Tim])

Comment: We believe it is important for the NRC to continue its transparent and efficient efforts and to maintain its 24-month schedule for the current Waste Confidence proceedings so that progress on both plant licensing and used fuel management can continue. (0250-32-4 [Wesley, Ashleigh])

Comment: Finally, I must emphasize how important it is the NRC completes this rulemaking in a timely manner. The Court remand of the Waste Confidence Rule led to a suspension of NRC licensing activities. (0250-6-6 [Nesbit, Steve])

Comment: Completing the Waste Confidence rulemaking will allow the NRC to fulfill its obligation to license and oversee nuclear facilities. (0250-6-8 [Nesbit, Steve])

Comment: And I think, lastly, the most important thing is meeting commitments. So I think we have got to resolve this issue in a timely basis to remove not only that uncertainty but provide some surety going forward in this process so we can address these issues in a safe, dependable, and economic fashion going forward. (0250-61-5 [Little, Jim])

Comment: I do request the NRC to bring this to closure and to continue these public meetings and get the comments and the dialogue going but close the issue and get it to the commissioners so we can make a decision and move on. It is really important. (0250-62-3 [Fregonese, Vic])

Comment: Accordingly, timely resolution to the issue of Waste Confidence plays an important part of meeting the strategic need. And we join the rest of the industry in strongly supporting making this rulemaking a high priority. Not only is resumption of ongoing licensing activities essential for long-term power-planning decisions, but it is also important to reestablish confidence in the nation's ability to conduct new licensing proceedings. (0250-65-3 [Vytlačil, Gordon])

Comment: I would just like to say that we don't think this is a streamlining process. We're afraid this is a steam-rolling process. (0250-7-6 [Corbett, Susan])

Comment: It is important for the NRC to continue its efforts and maintain its 24-month schedule for the current waste confidence proceedings - as this will help to ensure that the industry can continue to move forward with both plant licensing and used fuel management. I would like to thank the NRC for hosting this public meeting and providing an opportunity for comments. (0253-7 [Avilla, Karen])

Comment: Following the completion of this process, it is my hope that the NRC will complete this rulemaking in an expeditious manner. (0273-4 [Kinzinger, Adam])

Comment: We urge the Nuclear Regulatory Commission to complete the waste confidence rulemaking and move forward with issuing renewed operating licenses for existing nuclear plants and licenses to build and operate new plants. (0307-5 [Fuentes, Julio])

Comment: I strongly urge members of the Nuclear Regulatory Commission to complete the waste confidence rulemaking so that progress on both plant licensing and used-fuel management can continue. (0308-3 [Weinberg, Luz])

Comment: I believe it's important for the NRC to continue its practice of conducting regulatory, licensing, and oversight activities in an open and transparent manner. Equally important is the need for the NRC to maintain its 24-month schedule for the current Waste Confidence proceedings to properly inform the process leading to the development of a Final Generic Environmental Impact Statement and Proposed Rule so that the progress on both nuclear plant licensing and used fuel management can continue. (0325-13-7 [Wicks, Tonja])

Comment: The timely resolution of this rulemaking is important for the long-term planning of our nation's electricity infrastructure. This issue directly impacts the relicensing of nuclear plants and approval of pending construction applications for new reactors, both of which are vital if we

are serious about our commitment to fighting climate change and insuring a reliable, affordable source of electricity for all Americans. (0325-16-4 [Bailey, Savannah])

Comment: I urge the NRC to enhance its priority on the oversight role for the management, transportation, and disposal of used nuclear fuel. This work must be done in an expedited manner. It's critical the NRC press on with transparency, while staying true to the 24-month schedule for its current Waste Confidence proceedings. Staying on track and staying on schedule will help ensure that plant licensing and used fuel management efforts can continue while allowing people like those in this room to have their voices heard. The NRC mission is safety. We need to have safe, reliable nuclear energy to produce carbon-free energy. (0325-4-4 [Quinn, Ted])

Comment: The timely resolution of this rulemaking is important for the long-term planning of our nation's electricity infrastructure and meeting our country's ambitious goals for greenhouse gas reduction. This issue directly impacts the re-licensing of nuclear plants and approval of pending construction applications, both of which are vital if we are serious about our commitment to slowing climate change and ensuring a reliable, affordable source of electricity for all Americans. (0326-25-4 [Bailey, Savannah])

Comment: 10 CFR 51.23, it's a lot of gobbledygook, that refers to the proposed regulation that was mentioned at the outset. That regulation effectively accepts onsite storage forever if that becomes necessary. The NRC has very craftily used this court remand that was won by the hard fought environmental warriors that took them. The NRC is using the rulemaking as a means of cutting out the public. Generic Environmental Impact Statement means here in 2013-2014 they're making a decision and, essentially, forever. Let's say if forever only means a couple of hundred years, so long after we're dead, no one will be able to challenge the environmental effects as these casks deteriorate, have to be replaced, are bombed, are destroyed by elements, are flooded. No one will be able from the public to meaningfully question and legally attack the sufficiency of the storage scheme. (0327-13-3 [Lodge, Terry])

Comment: Furthermore, the provenance of the revised rule is unusual in that it has emerged in response to, and as a result of, the unanimous decision of a Federal Court of Appeals which vacated and remanded the previous 2010 version of the NRC Waste Confidence Rule. (0327-18-1 [Schonberger, David])

Comment: First backed by the courts to do an environmental impact statement process, which generally takes seven years, is now jammed into two years. We have a series of meetings across the country perfunctorily manufacturing consent that it's okay to go on generating more and more of this. This is a confidence scheme. This is a fraud perpetrated on the taxpayers and the rate payers; a scam. (0327-2-2 [Keegan, Michael])

Comment: I find this whole process to be extremely demoralizing and futile. I've been through it many times on the protesting side, or on the conciliatory just testifying without making a ruckus sort of thing. I think the whole -- this whole process is a sham and a fraud. (0327-6-1 [Leonardi, Michael])

Comment: So, you know, my recommendation to you would be that you extend the time line of this process, and that you go away and you involve an appropriate spectrum of stakeholders in developing a GEIS that has some meaning and some substance to it, and addresses the issue that preoccupy us in connection with the nuclear industry. (0328-11-4 [Muller, Alan])

Comment: I'm concerned about a number of things. We have this additional issues for public comment where there are four issues laid out, and this is, as others have said, this is very circular. And if you look at issue 1, and issue 2, or issue 3, the NRC has prepared an Environmental Impact Statement to support the Rule. Well, that's not, like, how you prepare an environmental impact statement. You don't prepare it to support the rule. No. You do the environmental impact statement, you know, and see what it says, see what issues are raised, not to support the rule. You're going about this backwards. It's not going to work, it's backwards engineered. (0328-14-1 [Overland, Carol])

Comment: I feel as if it's being rushed through, and storing waste which is going into infinity is not something you just do lightly[.] (0329-15-2 [Star, Priscilla])

Comment: [O]ne of the reasons I think this process is being rushed is because the Watts Bar 2 operating license for the new reactor may be the first one that is effective by any delay in having a waste confidence regulation, which would allow that license to be issued. If I were the NRC, I wouldn't worry about TVA and Watts Bar 2. TVA already finally admitted that it was going to take more than two more years and another billion dollars, more than a billion dollars, to build that. So, like every reactor ever built in the United States, it did not come in on time and on budget. And a delay to get the issue of licensing right is perfectly appropriate. (0329-25-4 [Paddock, Brian])

Comment: I also have serious doubts and concerns about the integrity and independence of the NRC's administrative rulemaking process. (0329-7-3 [Schonberger, David])

Comment: THE OUTCOME OF NRC'S COURT-ORDERED HIGH-LEVEL RADIOACTIVE WASTE STUDY MUST BE INCORPORATED INTO LIMERICK'S FINAL EIS, REGARDLESS OF THE LENGTH OF TIME REQUIRED (0377-5-10 [Cuthbert, Lewis])

Comment: 2 YEARS IS NOT ADEQUATE FOR A VALID RELIABLE RADIOACTIVE WASTE STUDY! NOTE: NRC'S own technical staff estimated it would take until 2019 for data collection and analysis of impacts of long-term storage of spent fuel. That is 6 years, not 2 years as currently planned in NRC's rushed study. NOTE: Dr. Makhijani, an independent expert, and others said: NRC will not be able to gather information within 2 years. THE BODY OF EVIDENCE ACE PROVIDED IN THESE COMMENTS REVEALS A LONG LIST OF UNANSWERED RADIOACTIVE WASTE QUESTIONS, ISSUES, AND CONCERNS. THE CONSEQUENCES OF NRC'S REGULATORY NEGLIGENCE CONCERNING HIGH-LEVEL RADIOACTIVE WASTES COULD HAVE DEVASTATING CONSEQUENCES TO OUR REGION, OUR NATION, AND THE WORLD. A 6-YEAR RADIOACTIVE WASTE STUDY SHOULD BE IMPERATIVE IF IMMEDIATE PRECAUTIONARY ACTIONS RECOMMENDED IN THIS REPORT ARE NOT TAKEN (0377-5-11 [Cuthbert, Lewis])

Comment: The rushed two-year timeframe for environmental review falls far short of the 2019 estimate of NRC's own technical staff for data collecting and analysis on the impacts of long-term storage of spent nuclear fuel; NRC currently lacks sufficient information to reach scientifically, well-founded conclusions about the impacts of such storage; NRC also lacks information regarding the impacts associated with the eventual disposal of spent nuclear fuel; According to Dr. Makhijani, the NRC will not be able to gather this information within its truncated, self-imposed two-year timeframe; The short timeframe provided for environmental review will also not permit post-Fukushima information about U.S. reactors to be fully collected and evaluated; Current federal law requires that the NRC conduct a comprehensive environmental impact statement (EIS) study before issuing a revised Waste Confidence

Decision; ACE concurs with the 24 groups that on January 3, 2013, requested a full review of the three issues outlined in June 2012 by the U.S. Court of Appeals for the D.C. Circuit that would take at least seven years. This was originally projected by the NRC staff, and likely considerably longer. 1. long-term storage risks for spent nuclear fuel; 2. spent fuel pool fire risks; 3. spent fuel pool leakage risks; ACE agrees that: 1. NRC is unnecessarily rushing the Nuclear "Waste Confidence" process and NOT satisfying court-ordered requirements; 2. NRC's incomplete process should trigger continued suspension of all reactor licensing and re-licensing (0377-5-13 [Cuthbert, Lewis])

Comment: Spent fuel storage should have brought about a two-year relicensing delay by NRC; Until the recent challenge in court, NRC took the negligent position that spent fuel was so safe, it was not to be considered in re-licensing, but a court decision overturned NRC's irrational conclusion[.] (0377-5-7 [Cuthbert, Lewis])

Comment: I believe it is important for the NRC to continue its transparent and efficient efforts to issue the current waste confidence proceedings so that progress on both plant licensing and used fuel management can continue. (0398-3 [Helsel, Adam])

Comment: I believe it is important for the NRC to continue its transparent and efficient efforts to issue the current waste confidence proceedings so that progress on both plant licensing and used fuel management can continue. (0399-3 [Sylvester, Richard])

Comment: I believe it is important for the NRC to continue its transparent and efficient efforts to issue the current waste confidence proceedings so that progress on both plant licensing and used fuel management can continue. (0400-3 [Blankenmyer, Eric])

Comment: It is obvious the NRC has hastily put together a document in the wake of last summer's federal court take-down of the "waste confidence" principle. It is also crystal clear that the NRC wants to overturn the agency's forced moratorium on reactor licensing and renewal procedures. (0443-4 [Sabo, Betty])

Comment: The proposed rule, relying on the findings in NUREG-2157, provides that "no discussion of environmental impacts of spent nuclear fuel storage in reactor facility storage pool or an independent spent fuel storage installations (ISFSI) for the period following the term of the reactor operating license or amendment, reactor combined license or amendment, or ISFSI license, renewal, or amendment for which application is made" is required. 75 Fed. Reg. at 56804. Thus, any possible environmental consequences or alternatives to mitigate those consequences, whether applicable to all plants - i.e., generic - or applicable only to a one or a few plants - i.e., site-specific - that is related to allowing the generation of additional spent fuel by any reactor, or related to the manner in which spent fuel is stored at a reactor site, or related to the duration of the time such storage is allowed at any reactor, may not be considered in deciding whether to allow such spent fuel generation or storage to occur. (0473-6-1 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: NAYGN commends the NRC for assigning a high priority to completing this rulemaking on a planned 24-month schedule, staffing the matter with knowledgeable and experienced personnel, and permitting broad public participation. (0535-2 [Damratoski, Katie] [Thornton, Adam])

Comment: NAYGN encourages the NRC to continue its excellent work and maintain the schedule for completing this rulemaking. The Commission has suspended licensing decisions

until it completes this rulemaking. Therefore, it remains critically important for the NRC to complete this rulemaking on a planned 24-month schedule. (0535-5 [Damratoski, Katie] [Thornton, Adam])

Comment: It is essential for the Nuclear Regulatory Commission to complete the waste confidence rulemaking and move forward with issuing renewed operating licenses for existing nuclear plants and with issuing licenses to build and operate new plants. The proposed rulemaking will enhance efficiency in individual licensing reviews by utilizing the Waste Confidence Generic Environmental Impact Statement to satisfy the requirements of the National Environmental Policy Act with regards to continued storage of spent nuclear fuel, which are the same or largely similar at each nuclear site. (0549-1 [Williams, Robert])

Comment: I believe it is important for the NRC to continue its transparent and efficient efforts to issue the current waste confidence proceedings so that progress on both plant licensing and used fuel management can continue. (0549-4 [Williams, Robert])

Comment: A timely resolution on this matter is essential. Existing and future nuclear facilities need greater certainty about licensing timelines and decisions in order to maintain and expand this vital part of the U.S. energy portfolio. (0555-2 [Contreras, Raquel])

Comment: Finally, the Proposed Rule and supporting documents are premature. The National Academies were asked by Congress to determine the adequacy of NRC's safety regulations in light of Fukushima, with specific emphasis on the advisability of spent fuel pool storage. PW believes NRC's fast moving train relative to continuing high density storage should be halted until NAS finishes its quality assurance review. (0556-1-7 [Lampert, Mary])

Comment: I believe it is important for the NRC to continue its practice of conducting regulatory, licensing and oversight activities in an open and transparent manner. Equally important is the need for the NRC to maintain its 24-month schedule for the current waste confidence proceedings to properly inform the process leading to the development of the Generic Environmental Impact Statement and Proposed Rule, so that progress on both nuclear plant licensing and used fuel management can continue. (0598-7 [Wicks, Tonja])

Comment: It is essential that the Nuclear Regulatory Commission complete the waste confidence rulemaking and move forward with issuing renewed operating licenses for existing nuclear plants...and licenses to build and operate new plants. The proposed rulemaking will enhance efficiency in individual licensing reviews by utilizing the Waste Confidence Generic Environmental Impact Statement to satisfy the requirements of the National Environmental Policy Act with regards to continued storage of spent nuclear fuel, which are the same or largely similar at each nuclear site. (0601-1 [Manfredi, Timonhy])

Comment: I believe it is important for the NRC to continue its transparent and efficient efforts to issue the current waste confidence proceedings so that progress on both plant licensing and used fuel management can continue. (0601-4 [Manfredi, Timonhy])

Comment: I also have serious doubts and concerns about the integrity and independence of the NRC's administrative rulemaking process as well as concerns about NRC compliance with the intention and spirit of relevant federal laws governing the processes of regulatory agencies, including the National Environmental Policy Act (NEPA) and the Administrative Procedures Act (5 U.S.C. Chapters 5 through 8), as I have personally witnessed the "revolving door" operating between the nuclear industry, the regulatory agency and the pro-nuclear academic departments

and institutions -- thus leading me to believe that the NRC is an "industry-captured," biased regulator with a reassuring front-end (website) and a structurally-compromised back-end. (0603-3 [Schonberger, David])

Comment: The two-year period for an environmental review is far short of the period of time needed to do a comprehensive review of the impacts of storing spent fuel from this nation's commercial nuclear reactors. (0610-1 [Brechin, Vernon])

Comment: The NRC comment reviewers should take into account the thousands of people who have commented opposing the two-year EIS preparation period. It may be easy to dismiss the input of many commenters due to their lack of technical qualifications but their voices still should count. (0610-12 [Brechin, Vernon])

Comment: The Draft GEIS fails to provide the necessary environmental analysis sufficient to justify eliminating consideration of spent fuel disposal impacts or storage impacts from every licensing proceeding, as proposed in 10 C.F.R § 51.23. (0611-15 [Shapiro, Susan])

Comment: The schedule set forth by the NRC to conduct and complete its EIS review is unrealistic, imprudent and arbitrary. The issues related to storing for thousand of tons of nuclear waste produced by the United States over the past 50 years is one of the most important long term environmental and fiscal decisions this nation must face now, and for the future. The NRC's plan to rush the EIS to be able to grant new licenses and license extensions fly in the face of the D.C. Court's decision that held the NRC's Waste Confidence rule was arbitrary and inadequate. In the case New York, et al v. NRC, the Court ordered NRC to conduct a "full analysis" of "the potential environmental effects" of storing spent fuel onsite at nuclear plants "on a permanent basis." 681 F.3d at 479. (0611-8 [Shapiro, Susan])

Comment: While we do recognize that the Waste Confidence Rule does not explicitly authorize individual licensing actions (i.e., reactor and ISFSI), it is important to note that the Waste Confidence Rule allows for indefinite on-site storage of spent nuclear fuel by stating that on-site storage is safe for 60 to 160 years, or even indefinitely. It is because of the Waste Confidence Rule that the Administration can state that we can do better than Yucca Mountain and Congress has lost any sense of urgency in solving the nation's nuclear waste issues. (0619-1-4 [Mahowald, Philip R.])

Comment: The Waste Confidence final GEIS, when adopted, will provide the regulatory basis for the proposed amendment to the 10 CFR 51.23 (the Waste Confidence Decision and Temporary Storage Rule). The effect of 10 CFR 51.23 is that the public is prevented from raising (or litigating) issues regarding the environmental impacts of continued storage of spent nuclear fuel during licensing actions (either reactor or spent fuel storage installations). (0619-1-9 [Mahowald, Philip R.])

Comment: We encourage the Commission and staff to complete the Waste Confidence review and rulemaking on the planned 24 month schedule. (0638-2 [Glass, Peter])

Comment: I strongly support the NRC's efforts to keep our nuclear facilities safe and reliable. As the NRC continues its Waste Confidence rule making, I urge the NRC to proceed efficiently. A timely resolution on this matter is essential. Existing and future nuclear facilities need greater certainty about licensing timelines and decisions in order to maintain and expand this vital part of the U.S. energy portfolio. (0642-1 [Picking, Brian])

Comment: The proposed Waste Confidence Rule would effectively exclude public comments on nuclear waste production as part of future reactor licensing procedures. Because the rule would incorporate the draft GEIS's assumption that nuclear waste can and will be safely stored indefinitely, discussion about waste storage would not be up for public discourse, a vital element of a publically accepted nuclear waste program. (0646-22 [Hanson, Courtney])

Comment: Duke Energy encourages the NRC to continue to adhere to its schedule to complete the rulemaking by August 2014. Given the substantial experience base associated with on-site used fuel storage and extensive environmental analyses performed by federal agencies in the past, the remaining time should be sufficient for completing the EIS and finalizing the Waste Confidence rule. (0672-4 [Jamil, Dhiaa])

Comment: I recognize that "efficiency" and "timeliness" are defined as priorities in the regulatory process; however, it is essential that these terms be understood appropriately. Efficiency needs to involve more than speed or cost-containment; it also requires that institutional goals are met adequately. In the case of the NRC, those goals are to protect people and the environment. Those goals may prove inconsistent with goals of promoting nuclear energy production or ensuring its profitability, but the latter are not part of the NRC mandate. Timeliness does not necessarily mean promptness; it means accomplishing the task in the time frame the task requires, as long as that might be. (0684-6 [Kinsella, William])

Comment: Given that the NRC has announced it does not plan to issue new licenses or renewals until the Court of Appeals' remand on the waste confidence proceeding has been addressed satisfactorily, the need for urgent action is clear. (0685-2 [Davis, Ed])

Comment: NIC strongly encourages the NRC to continue to adhere to its schedule to complete the rulemaking by no later than August 2014. Given the substantial experience base associated with on-site used fuel storage and extensive environmental analyses performed by federal agencies in the past, the remaining time should be sufficient for completing the EIS and finalizing the Waste Confidence rule. (0685-5 [Davis, Ed])

Comment: The Waste Confidence Decision and Rule have their genesis in a federal court decision in 1979, *Minnesota v. NRC*, 602 F.2d 412 (D.C. Cir. 1979). That case arose from requests by reactor licensees for license amendments to permit expansion of on-site spent fuel storage capacity. In evaluating these license amendment requests, the NRC failed to consider the implications arising from the possibility that a permanent repository for the radioactive waste might never be found and thus, the reactor sites would become permanent storage facilities. The court held, therefore, that the NRC must "consider the safety and environmental implications of indefinite storage on-site after decommissioning of the reactor." *Id.* at 415. In order to comply with the *Minnesota* case, the NRC promulgated its Waste Confidence Decision and Rule in 1984. The Waste Confidence Decision purported to be an environmental assessment with a finding of no significant impact. The subsequent history of the Waste Confidence Decision and Rule is recited in *New York v. NRC*, 681 F.3d 471 (D.C. Cir. 1012). The important point to be understood is that the Waste Confidence Decision and Rule are an integral part of the licensing process for nuclear reactors. (0688-3 [Taylor, Wallace])

Comment: In addition, the NWSC recognizes the Directorate's ability to adhere to the schedule laid out by the Commission. We underscore the importance of maintaining the schedule so that NRC licensing decisions will not be unduly delayed. (0689-2 [Boyd, David])

Comment: The current Waste Confidence Decision and rulemaking seek to obfuscate and circumvent the public's due process in addressing the adverse environmental impacts created and compounded by the expansion and extension of a larger radioactive waste burden without a scientifically proven and societal accepted radioactive waste management facility. The public reasonably recognizes that the newly licensed and relicensed nuclear facilities themselves then become the de facto permanent nuclear waste storage facilities and, as proposed, without the site-specific environmental impact statement review and public hearing rights required by National Environmental Policy Acts. (0691-5 [Gunter, Paul])

Comment: In summary, the NRC has conducted the waste confidence rulemaking in accordance with NEPA requirements in an open and transparent manner and with numerous opportunities for public involvement. (0694-1-13 [Shea, Joseph])

Comment: TVA notes that the NRC placed a high priority on the review and analysis of the rulemaking and that it was performed in an open and transparent manner appropriate for this issue. TVA urges the Commission to complete the rulemaking in a timely manner and on the original schedule. This action is vital to timely completion of ongoing licensing activities, including the pending operating license application for Watts Bar Unit 2. (0694-1-4 [Shea, Joseph])

Comment: TVA fully supports the comments of the Nuclear Energy Institute ("NEI") that were submitted on behalf of the U.S. nuclear power industry. In particular, TVA agrees that the NRC's use of a generic rulemaking is appropriate; the NRC's rulemaking process has fostered considerable transparency and public participation; the Proposed Rule and the DGEIS specifically address the issues identified by the D.C. Circuit as requiring further evaluation in an Environmental Impact Statement ("EIS"); and the Proposed Rule and DGEIS consider appropriate timeframes for continued SNF storage. NEI's comments demonstrate that the NRC should proceed with timely issuance of the Final Rule. (0694-1-8 [Shea, Joseph])

Comment: In summary, the NRC has conducted the waste confidence rulemaking fully in accordance with NEPA requirements in an open and transparent manner and with numerous opportunities for substantial public involvement. (0697-1-17 [Bessette, Paul] [Kuyler, Raphael])

Comment: Entergy notes that the NRC placed a high priority on the review and analysis of the rulemaking and that it is being performed in an open and transparent manner. Entergy urges the Commission to complete the rulemaking in a timely manner and on the original schedule. This action is vital to completion of ongoing licensing activities, including the renewal of the Indian Point operating licenses. (0697-1-5 [Bessette, Paul] [Kuyler, Raphael])

Comment: Entergy fully supports the comments of the Nuclear Energy Institute ("NEI") that were submitted on behalf of the U.S. nuclear power industry. In particular, Entergy agrees that the NRC's use of a generic rulemaking is appropriate; the NRC's rulemaking process has fostered considerable transparency and public participation; the Proposed Rule and the DGEIS specifically address the issues identified by the D.C. Circuit as requiring further evaluation in an Environmental Impact Statement ("EIS"); and the Proposed Rule and DGEIS consider appropriate timeframes for continued SNF storage. NEI's comments demonstrate that the NRC should proceed with timely issuance of the Final Rule. (0697-1-8 [Bessette, Paul] [Kuyler, Raphael])

Comment: The proposed Waste Confidence Rule would effectively exclude public comments on nuclear waste production as part of future reactor licensing procedures. Because the rule would incorporate the draft GEIS's assumption that nuclear waste can and will be safely stored

indefinitely, discussion about waste storage would not be up for public discourse. (0700-6 [Women's Action for New Direction, Georgia])

Comment: If the Commission desires to promote nuclear energy, the responsible approach would be to strengthen, not weaken, the requirements for the prompt and safe disposal of SNF. Instead of accommodating the detachment of SNF disposal responsibilities from nuclear energy generation and development, the Commission should instead maintain the integral connection between the generation of SNF and the ensuring proper and timely SNF disposal. Unfortunately, the Commission's DGEIS and proposed rule may serve to facilitate, accommodate, and encourage continued delays toward SNF disposal. (0704-10 [Callen, Ronald C.] [Keskey, Donald L.])

Comment: NRC's response signified notable problems for this EIS process at the outset, for the following reasons. First, the agency's grasp of its NEPA obligation conflicts with the holding of the D.C. Circuit that vacated the Waste Confidence Determination and remanded this matter to the agency. The Court squarely addressed this matter in its opinion and we, again, include the entirety of its discussion so there is no mistaking the Court's meaning: Under NEPA, each federal agency must prepare an Environmental Impact Statement ("EIS") before taking a "major Federal action significantly affecting the quality of the human environment." 42 U.S.C. § 4332(2)(C). ... *The issuance or reissuance of a reactor license is a major federal action affecting the quality of the human environment...**** The parties here dispute whether the Waste Confidence Determination ["WCD"] itself constitutes a major federal action. To petitioners, the WCD is a major federal action because it is a predicate to every decision to license or relicense a nuclear plant, and the findings made in the WCD are not challengeable at the time a plant seeks licensure. *The Commission contends that because the WCD does not authorize the licensing of any nuclear reactor or storage facility, and because a site-specific EIS will be conducted for each facility at the time it seeks licensure, the WCD is not a major federal action.* To the Commission, the WCD is simply an answer to this court's mandate in *Minnesota* to ensure that plants are only licensed while the NRC has reasonable assurance that permanent disposal of the resulting waste will be available. The Commission also contends that the WCD constitutes an EA supporting the revision of 10 C.F.R. § 51.23(a), and because the EA found no significant environmental impact, an EIS is not required. *** We agree with petitioners that the WCD rulemaking is a major federal action requiring either a FONSI or an EIS. *The Commission's contrary argument treating the WCD as separate from the individual licensing decisions it enables fails under controlling precedent.* *** It is not only reasonably foreseeable but eminently clear *that the WCD will be used to enable licensing decisions based on its findings.* The Commission and the intervenors contend that the site-specific factors that differ from plant to plant can be challenged at the time of a specific plant's licensing, *but the WCD nonetheless renders uncontestable general conclusions about the environmental effects of plant licensure that will apply in every licensing decision.* *New York et al.* at 476-477 (explanatory brackets inserted, emphasis added, citations omitted). The D.C. Circuit has heard the argument the Waste Confidence Determination is not a licensing action and rejected it. NRC's adherence to this position mere months after the decision demonstrates an inclination to flout NEPA and the Court's decision. (0706-1-5 [Fettus, Geoffrey])

Comment: There is no doubt that the environmental impacts of irradiated fuel storage must be addressed in all NRC reactor licensing decisions. The courts have held that the waste confidence decision ("WCD") is a "predicate" to every licensing decision.³ [footnote 3 text: *Id.* at 8] On June 8, 2012, the DC Circuit Court held that: The WCD makes generic findings that have a preclusive effect in all future licensing decisions—it is a pre-determined "stage" of each licensing decision.⁴ [footnote 4 text: *Id.* at 8] And further, It is not only reasonably foreseeable but

eminently clear that the WCD will be used to enable licensing decisions based on its findings. The Commission and the intervenors contend that the site-specific factors that differ from plant to plant can be challenged at the time of a specific plant's licensing, but the WCD nonetheless renders uncontested general conclusions about the environmental effects of plant licensure that will apply in every licensing decision. See 10 C.F.R. § 51.23(b).⁵ [footnote 5 text: *Id.* at 9] For over a decade, the Blue Ridge Environmental Defense League and its chapters have opposed nuclear reactors in part because there was no place for the high-level nuclear waste produced by them to go. That is the reason why on February 10, 2011 we joined with others to bring the original action against the waste confidence rule, 10 CFR § 51.23. The rule presumed that waste stored at the nation's nuclear power plants would go to a waste dump someday. Our lawsuit said that the end of DOE's pursuit of a dump in Nevada invalidated this presumption. The court agreed. (0720-1 [Zeller, Louis])

Comment: *It is certainly an extraordinary situation that the well-being of so many generations to come are to some significant degree held in the hands of a few individuals before whom they cannot appear to plead their case and yet on whom their lives may depend.* Indeed, even members of today's public, concerned about the implications for those not yet born, have long been barred from raising the issue of waste disposal in the licensing proceedings for nuclear power plants, one of the most important questions that should lie at the heart of decisions whether to grant licenses that would produce more waste for which there is no disposal solution. The U.S. Nuclear Regulatory Commission (NRC) has by rule—a kind of nuclear gag rule, some observers have called it—prohibited perhaps the most critical issue about whether the license should issue from being raised. NRC has done so by its "waste confidence rule," in which it expressed confidence that a solution will soon be found and therefore barred consideration of what would happen if their confidence were misplaced. (0738-4 [Hirsch, Daniel])

Comment: Please put public safety ahead of profit for the industry in considering this ruling. (0754-1 [Individual, Anonymous])

Comment: The draft regulations' attempt to bar public comments on waste disposal in license extension proceedings reinforces public suspicion that the NRC is untrustworthy in its alleged commitment to transparency and to public health and safety. (0821-5 [Paddock, Brian])

Comment: The NRC's response fully satisfies the Court's remand, as the agency has produced its most comprehensive analysis of the safety and environmental impacts of post-licensed-life used fuel storage to date. The agency has a long history of evaluating continued storage, and appropriately incorporated its previous work in addressing the Court's concerns. Further, the NRC staff has maintained the aggressive 24-month schedule set by the Commission, despite a government shutdown and while maintaining extremely high levels of transparency and public participation. NEI's enclosed comments support the NRC's work and suggest a number of changes that would more clearly articulate the agency's conclusions that used nuclear fuel can continue to be stored in a safe and environmentally sound manner. Notably, our comments recommend changes to the title of the rule and GEIS, as well as the proposed rule language, which we believe will more clearly and directly capture the nature of the NRC's work in this area and the conclusions reached by the agency. Finally, NEI commends the Commission for assigning a high priority to completing the draft GEIS and rulemaking, staffing the matter with knowledgeable and experienced personnel, and permitting broad public participation. The process has been a model of transparency in agency action. NEI encourages the Commission and NRC staff to continue the excellent work and to maintain the schedule to completion of the rulemaking. (0827-1-1 [Ginsberg, Ellen])

Comment: Adopting this GEIS at any existing NWO [nuclear waste operation] should require a LICENSE AMENDMENT process, because the original license did not include the notion that the NWO may exist on the site for an indefinite period. It seems this GEIS is a sneaky way to expand the license term to an indefinite period. This circumvents the oversight process that is necessary to ensure appropriate actions by the industry and regulatory agencies. (0836-13 [Davis, Anonymous])

Comment: You say on Page 1-5 that this only modifies 10 CFR 51.23, and "This draft GEIS does not authorize issuance of any NRC license." But it does expand SIGNIFICANTLY the licenses that were previously granted, and therefore is a sneaky and disgusting attempt to work around the normal license amendment procedures. THIS CHANGE DOES CHANGE THE LICENSES THAT DO EXIST AND THEREFORE EACH MUST BE SUBJECTED TO A LICENSE AMENDMENT PROCESS, which includes the opportunity to intervene and request a hearing by members of the public. (0836-24 [Davis, Anonymous])

Comment: We are extremely disappointed that the NRC is proposing to process these changes using a NRC policy statement. You say it is not a licensing action, yet when combined with the policy statement, as you propose, it has the effect of granting indefinite approval to store nuclear waste at every operating nuclear plant without any time limit, and without any further processing, hearings, intervention, or critical site-specific review. You therefore propose circumventing all opportunities for the public and others to intervene in this process and request a hearing, which would normally be the case if each license were processed individually. By handling it as one big policy statement and a "Generic" EIS, then you circumvent the oversight that would otherwise occur. (0836-9 [Davis, Anonymous])

Comment: We believe it is essential to proceed on schedule with development and implementation of the updated Waste Confidence Rule system, so that applications for licenses for new nuclear power plants may proceed. (0863-2 [Brinton, Samuel] [Curtis, Daniel])

Comment: The NRC should consider its own staff recommendations of a seven year process and take the time and exert the effort to analyze the issues in a more robust manner. (0867-3-34 [Griffin, William])

Comment: Actually, it is the Commissioners who must compile evidence and make decisions. Then tell the public what the decisions are and why they were made. It is much more important that we hear from you. (we pay you to do this, you do not pay us. (0889-4 [Rossin, A. David])

Comment: The DGEIS acknowledges that the proposed rule is a major federal action. *Id.* at 1-3. But NRC denies that by generically resolving environmental issues with respect to reactor licensing, the proposed rule constitutes a licensing action: (0897-2-1 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: THE PROPOSED RULE HAS SIGNIFICANT ENVIRONMENTAL IMPACTS THAT MUST BE PLUGGED INTO INDIVIDUAL REACTOR LICENSING DECISIONS[.] As the Supreme Court observed in *Baltimore Gas and Electric Co.*: Congress did not enact NEPA . . . so that an agency would contemplate the environmental impact of an action as an abstract exercise. Rather, Congress intended that the 'hard look' be incorporated as part of the agency's process of deciding whether to pursue a particular federal action. It was on this ground that the Court of Appeals faulted the Commission's action, for failing to allow the uncertainties potentially to 'tip the balance' in a particular licensing decision. As a general proposition, we can agree with

the Court of Appeals' determination that an agency must allow all significant environmental risks to be factored into the decision whether to undertake a proposed action. 462 U.S. at 101. Here, the environmental impacts of the spent fuel to be generated by new or re-licensed reactors, and the costs of avoiding or mitigating those impacts, are potentially enormous. Yet, in violation of NEPA, the DGEIS provides no mechanism for integrating those costs and impacts back into individual licensing decisions. (0897-7-1 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: In order to bring the NRC's disjointed regulatory program for safety and environmental analysis of spent fuel management and disposal risks into compliance with NEPA, the Organizations respectfully request the NRC to revise and integrate its disparate and inconsistent regulations regarding spent fuel storage and disposal in a cohesive and consistent whole. The NRC should prepare a programmatic EIS to ensure that the cumulative nature of the impacts covered by these balkanized regulations are considered. The regulations that must be revised and integrated are: Table S-3. As discussed above and in the Makhijani Declaration, the basis for Table S-3 has been repudiated. It is also inconsistent with Table B-1. Table B-1 is inconsistent with Table S-3. For one thing, Table B-1 does not include a finding as to whether the impacts of spent fuel disposal are significant or not. Instead, it states that the impacts are not large enough to change a license renewal decision. This suggests that the impacts *would* be large enough to change an initial licensing decision (which is covered by Table S-3). The inconsistencies and questions raised by comparing Table S-3 and Table B-1 are unacceptable under NEPA's standard for clarity and rigor of scientific analysis. 10 C.F.R. §§ 51.53(c) and 51.71(d). These regulations excuse license renewal applicants and the NRC from addressing spent fuel storage impacts in license renewal cases. They also excuse any discussion of need for power. As demonstrated above, it is essential to incorporate the economic costs of spent fuel storage and disposal in reactor cost-benefit analyses. In addition, as Dr. Thompson points out, by excluding need for power from consideration in re-licensing decisions, the DGEIS cripples its ability to assess the environmental impacts of storing spent fuel. Thompson Declaration, par. IX-2. This results in an "unbounded" analysis of radiological risk from spent fuel fires. Thompson Declaration, par. IX-3. (0897-7-20 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Thus, it is deceptive and misleading for NRC to claim that "The Waste Confidence rulemaking is not a licensing action." Not only was "Waste Confidence" invoked to silence the concerned local farmer's very legitimate, fundamental question at the Clinton, IL Early Site Permit public meeting in March 2003, it was also invoked by an NRC ASLB - backed by the NRC Commission itself - to reject irradiated nuclear fuel-related contentions in a legal proceeding regarding the 20-year license extension at Palisades atomic reactor. The "Waste Confidence Rule" was used to reject our official legal contentions, and instead rubberstamp a 20-year license extension at Palisades. (0919-1-18 [Kamps, Kevin])

Comment: For example, on Page xxvi in section ES.7 of the Executive Summary (lines 12-20, inset box), NRC states: "The Waste Confidence rulemaking is *not* a licensing action. It does not permit a nuclear power plant or any other facility to operate or store spent fuel. Every nuclear power plant or specifically licensed spent fuel storage facility must undergo an environmental review as part of its site-specific licensing process." (emphasis in original) This is very deceptive and misleading on NRC's part. Obviously, if this WC DGEIS is finalized into a WC FGEIS (Final Generic EIS), and a Record of Decision is issued, then that would serve as a pre-ordained license approval for all future licensing actions, at least insofar as the generation of irradiated nuclear fuel, its storage, and its ultimate disposition is concerned. (0919-1-2 [Kamps, Kevin])

Comment: NRC admits as much, in Section 1.5, "Purpose of and Need for the Proposed Action," on Page 1-6, lines 2 to 10. NRC states: "The purpose and need for the proposed action are threefold: (1) to improve the efficiency of the NRC's licensing process by generically addressing the environmental impacts of continued storage; (2) to prepare a single document that reflects the NRC's current understanding of these environmental impact statements; and (3) to respond to the issues identified in the remand by the Court in the New York v. NRC decision. The NRC intends to codify the results of its analyses in this draft GEIS at 10 CFR 51.23. NRC licensing proceedings for nuclear reactors and ISFSIs will continue to rely on the generic determination in 10 CFR 51.23 to satisfy obligations under NEPA with respect to the environmental impacts of continued storage." Thus, NRC would effectively block any future public or state government interventions, against old reactor license extensions, or new reactor combined license applications, raising challenges regarding the safety, security, cost, risk, etc. implications of the generation, storage or disposal of irradiated nuclear fuel. (0919-1-3 [Kamps, Kevin])

Comment: While typos and grammatical errors are very minor in significance, compared to the radiological risks to people and environment of irradiated nuclear fuel, which should be the focus of this DGEIS comment and discussion, such errors are an indication of the rush NRC has displayed in racing through this EIS proceeding. NRC staff had previously indicated it would take 7 years to carry out such an EIS. Instead, a mere two years has been allotted. (0919-4-14 [Kamps, Kevin])

Comment: You say on Page 1-5 that this only modifies 10 CFR 51.23, and "This draft GEIS does not authorize issuance of any NRC license." But it does expand SIGNIFICANTLY the licenses that were previously granted, and therefore is a sneaky and disgusting attempt to work around the normal license amendment procedures. THIS CHANGE DOES CHANGE THE LICENSES THAT DO E.I.S.T AND THEREFORE EACH MUST BE SUBJECTED TO A LICENSE AMENDMENT PROCESS, which includes the opportunity to intervene and request a hearing by members of the public. (0930-1-17 [Lutz, Ray])

Comment: We are extremely disappointed that the NRC is proposing to process these changes using a NRC policy statement. You say it is not a licensing action, yet when combined with the policy statement, as you propose, it has the effect of granting indefinite approval to store nuclear waste at every operating nuclear plant without any time limit, and without any further processing, hearings, intervention, or critical site-specific review. You therefore propose circumventing all opportunities for the public and others to intervene in this process and request a hearing, which would normally be the case if each license were processed individually. By handling it as one big policy statement and a "Generic" EIS, then you circumvent the oversight that would otherwise occur. (0930-1-2 [Lutz, Ray])

Comment: Adopting this GEIS at any existing NWO should require a LICENSE AMENDMENT process, because the original license did not include the notion that the NWO may exist on the site for an indefinite period. It seems this GEIS is a sneaky way to expand the license term to an indefinite period. This circumvents the oversight process that is necessary to ensure appropriate actions by the industry and regulatory agencies. (0930-1-6 [Lutz, Ray])

Comment: Although this rule, Docket ID NRC-2012-0246, applies to nuclear power spent fuel, it is of the same mindset which since the inception of the Manhattan Project has poisoned so many lives with the exposure and impending exposure of burgeoning radioactivity at fuel and waste sites. There is no conscionable choice when there is no actual scientific solution. I applaud the Federal judge who has questioned the NRC's legal maneuvering, and the intention

to force a solution by requiring one for spent fuel. Without nuclear waste and spent fuel storage options that are protective of, at least, human life and genetic diversity, there should never be a temporary arrangement for the nuclear industry watchdog, the NRC. (0935-2 [Uhlis, Agnes])

Comment: NAYGN commends the NRC for assigning a high priority to completing this rulemaking on a planned 24-month schedule, staffing the matter with knowledgeable and experienced personnel, and permitting broad public participation. (0948-2 [Commenters, Multiple])

Comment: NAYGN encourages the NRC to continue its excellent work and maintain the schedule for completing this rulemaking. The Commission has suspended licensing decisions until it completes this rulemaking. Therefore, it remains critically important for NRC to complete this rulemaking on a planned 24-month schedule. (0948-5 [Commenters, Multiple])

3. Comments Concerning the Rule Language

Comment: The Staff also failed to propose amendments to 10 C.F.R. §§ 51.23(b), 51.53(c)(2), and 51.95(c)(2) to clarify that certain spent fuel issues not addressed in the GEIS may be addressed in individual licensing decisions. This has placed the GEIS on a path which is substantially narrower than required by law. If these errors are not corrected now, they can only be corrected following completion of the GEIS process and will necessarily require the issuance of a supplemental draft GEIS. See 10 C.F.R. § 51.92(a)(2); *Marsh v. Or. Natural Res. Council*, 490 U.S. 360, 372 (1989) (agency shall supplement a final EIS if "[t]here are significant new circumstances or information relevant to environmental concerns and bearing on the proposed action or its impacts"). That will add significant time to the resolution of these proceedings. In *Hydro Resources, Inc.* (2929 Coors Road, Suite 101, Albuquerque, NM 87120), CLI-99-22, 50 N.R.C. 3 (1999), the Commission articulated its test for when a supplemental environmental impact statement is required: As a general matter, the agency must consider whether the new information is significant enough to require preparation of a supplement. The new information must present a seriously different picture of the environmental impact of the proposed project from what was previously envisioned. *Id.* at 14 (footnote and quotation omitted). (0001-10 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: The Staff Scoping Decision fails to include any consideration of any amendments to 10 C.F.R. §§ 51.23(b), 51.53(c)(2), or 51.95(c)(2). This is problematic because those provisions currently preclude parties from raising important site-specific issues in licensing proceedings: Accordingly, as provided in §§ 51.30(b), 51.53, 51.61, 51.80(b), 51.95, and 51.97(a), and within the scope of the generic determination in paragraph (a) of this section, no discussion of any environmental impact of spent fuel storage in reactor facility storage pools or independent spent fuel storage installations (ISFSI) for the period following the term of the reactor operating license or amendment, reactor combined license or amendment, or initial ISFSI license or amendment for which application is made, is required in any environmental report, environmental impact statement, environmental assessment, or other analysis prepared in connection with the issuance or amendment of an operating license for a nuclear power reactor under parts 50 and 54 of this chapter, or issuance or amendment of a combined license for a nuclear power reactor under parts 52 and 54 of this chapter, or the issuance of an initial license for storage of spent fuel at an ISFSI, or any amendment thereto. 10 C.F.R. § 51.23(b); see also *id.* § 51.53(c)(2) (license applicant's "environmental report need not discuss any aspect of the storage of spent fuel for the facility within the scope of the generic determination in § 51.23(a) and in accordance with § 51.23(b)"); *id.* § 51.95(c)(2) ("[T]he supplemental environmental impact statement prepared at the license renewal stage need not discuss ... any aspect of the storage of spent

fuel for the facility within the scope of the generic determination in § 51.23(a) and in accordance with § 51.23(b)."). (0001-26 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: [T]he Staff has consistently taken the position in the past that so long as § 51.23(b) exists, no effort to discuss any aspect of spent fuel storage after operations have ceased is permitted, regardless of whether the matter was specifically addressed in § 51.23(a). See, e.g., *Entergy Nuclear Operations, Inc.* (Indian Point Nuclear Generating Units 2 and 3), NRC Staff's Response to Intervenor (1) Joint Motion For Leave to File a New Contention Concerning the Onsite Storage of Nuclear Waste at Indian Point And (2) Joint Contention NYS-39/RK-EC9/CW-EC-10, at 8 (Aug. 2, 2012), ML12215A565. In light of the broad language of 10 C.F.R. §§ 51.23(b), 51.53(c)(2), and 51.95(c)(2), and in light of the Staff's past interpretation of these provisions, the Staff Scoping Decision errs by failing to identify the need to amend these provisions to ensure that matters that are clearly site-specific and not appropriate for generic treatment can be raised in individual licensing proceedings. (0001-27 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: Assuming that some impacts will be identified in the GEIS as appropriate for-review in site-specific proceedings, the Staff Scoping Decision must be altered to ensure that the scope of the GEIS will be expanded to consider amendments to 10 C.F.R. §§ 51.23(b), 51.53(c)(2), and 51.95(c)(2). (0001-29 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: Assuming that some impacts will be identified in the GEIS as appropriate for-review in site-specific proceedings, the Staff Scoping Decision must be altered to ensure that the scope of the current proceedings will be expanded to include guidance on which issues will be allowed to be considered on a site-specific basis following issuance of the GEIS, and to consider amendments to 10 C.F.R. §§ 51.23(b), 51.53(c)(2), and 51.95(c)(2). (0001-30 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: Petitioners [The State of Vermont with the Vermont Department of Public Service, the State of Connecticut, the State of New York, and the Commonwealth of Massachusetts] request that the Commission reverse the following errors that were made in the Staff Scoping Decision: Failing to provide any guidance on which issues will be allowed to be considered on a site-specific basis following issuance of the GEIS, including failure to consider amendments to 10 C.F.R. §§ 51.23(b), 51.53(c)(2), and 51.95(c)(2) to allow consideration of site-specific spent fuel related issues for the period after plant shutdown. (0001-4 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: My greatest concern with the draft Waste Confidence Generic Environmental Impact Statement (DGEIS) and proposed Rule is with the assertion on when a geological repository will be available. The proposed rule says at 51.23 (a)(1) feasible to... (ii) have a mined geologic repository within 60 years following the licensed operation of a reactor". Only App. B of the DGEIS addresses repository availability. On line 5 of p. B-6 it says "In recognition of the uncertainty in reaching a national consensus on repository selection, the third timeframe assumes that a repository never becomes available and the spent fuel needs to be stored indefinitely". The above statement in the proposed Rule is not consistent with or justified in App. B of the DGEIS. The draft environmental impact statement deals primarily with technical feasibility, not social or political feasibility. (0027-1 [Vandenbosch, Robert])

Comment: But one of the particulars is that in the assessment, the Proposed Rule would make amendments --.

The Proposed Rule would also clarify that the generic determination applies to the license renewal for independent spent fuel storage installation (0250-1-5 [Zeller, Lou])

Comment: And then, to the NRC, I would like to specifically recommend, and this has to do with the rulemaking, that in light of the fact that nuclear energy is the most dangerous substance known to man in the universe, that they should require that nuclear waste be handled and stored using these absolute safest methods available no matter what, not the method that their cost benefit/risk analysis shows to be the best, but the safest no matter what. That just makes the most sense to me. (0326-60-2 [Spooner, Rena])

Comment: I also, let's see, in reference to their Proposed Rule on this little paper here I, let's see, my other recommendation to the NRC is to require that all spent fuel rods be transferred to dry casks as soon as possible, way sooner than 60 years after the nuclear power plant is decommissioned. I also recommend that they discontinue the authorization of the use of pools out in the open for long-term storage or temporary storage as soon as possible. (0326-60-3 [Spooner, Rena])

Comment: Rather, I suggest that the Commission substitute for it's proposed rule the following language: The Commission will ensure that an environmental impact statement be developed analyzing the environmental impacts of storage of spent nuclear fuel beyond the licensed life for operation of a reactor jointly and cooperatively with those state, regional and municipal agencies situated in the area where the reactor is sited and which are charged with land use and environmental and socioeconomic concerns. (0354-2 [Oeser, Robert])

Comment: Recommend NRC add the below wording to the proposed rule: 1) Nuclear storage casks, nuclear storage/pools, and storage areas will be able to withstand 11.0 Earthquakes. 2: Nuclear storage casks, nuclear storage/pools and storage areas will be able to withstand a total lack of cooling capabilities /electricity for 60 years proposed for future containment in a mined geologic repository. 3) Currently property owners are not protected financially in case of a nuclear fuel storage accident. Private homeowners Insurances do not cover this type of event. The insurance coverage for a facility, 300 Million USD, can not cover damages at current cost structures. To protect US citizens from nuclear fuel storage damages, NRC must will develop a program for low rate, property insurance to cover private citizens from radiation and nuclear damages from NRC's storage of nuclear fuel. NRC funded Insurance subsidies for homeowners must/will be provided to cover the actual cost of this insurance plan. Insurance must be similar to current US flood insurance. 4) NRC must/will provide full health and medical care to all persons damaged by accidental release of radiation from spent fuel storage. This will include in home health care, daily transportation, all medical treatments and will cover all medical costs to include medical deductables and insurance costs. Most if not all insurance companies do not cover illnesses caused by nuclear damage. NRC must add the wording to Affordable Care Act for this coverage. 5) NRC must/will make "whole" all persons and properties damaged by nuclear spent fuel accidents. This is to include property buy out at full value, plus funding all relocation costs (both for personal property and business property). 6) NRC will keep manual and automatic radiation monitoring devices at all nuclear spent fuel storage locations on a minute by minute basis, provide full public release of the data from those devices on a accessible monitoring system via the internet, provide 24X7 human monitoring of each fuel storage location with hourly logging of events, and 24X7 video recording. Video will be available for viewing by the public via internet access. This will be provided for the 60 year storage plan for all spent fuel continued storage. 7) Relocation of all spent fuel will be done with full knowledge and agreement of all communities the spent fuel will transit through, PRIOR to said transit. (0517-3 [Anonymous, JEC])

Comment: Please rewrite the plan to say the following: (1) All waste currently in transportable casks should be moved to the designated temporary site within one year. (2) All waste which is safe to remove from pools should be done so immediately with a high-priority accelerated schedule. Once in casks, it should be moved quickly to the temporary storage area. (3) All remaining fuel in the pools should be removed and casked and sent to the site as soon as the fuel is cool enough to place in dry casks. (4) All fuel pools at closed plants should be emptied ASAP. (0618-9 [Johnson, Roger])

Comment: CCNR [Canadian Coalition for Nuclear Responsibility] recommends that NRC elaborate a set of rules and policies predicated on the possibility that no safe permanent solution to the problem of high-level nuclear waste will be demonstrated and/or available in the foreseeable future. In particular, CCNR urges the NRC to rule that high-level nuclear waste must not be subject to abandonment under any circumstances, but must be fully retrievable and subject to continual monitoring at all times, until such time as a scientifically verifiable safe permanent solution to the nuclear waste problem has been demonstrated beyond doubt. (0714-1-3 [Edwards, Gordon])

Comment: The Proposed Rule itself does not specifically mention ESP applications in any manner. Nonetheless, the language of the Proposed Rule and its Statement of Considerations (SOC) support the conclusion that the Proposed Rule, and waste confidence issues more generally, do not apply to ESP applications. These statements confirm that the waste confidence issues apply to applications for operating licenses, COLs, and ISFSIs. There is no mention of ESP applications. (0810-3 [Mallon, James])

Comment: Comment No. 1 - The rulemaking documents for the waste confidence rulemaking should include an affirmative statement that waste confidence issues do not apply to ESP applications. PSEG's position that the waste confidence issues do not apply to ESP applications is supported by a number of different justifications: • The Waste Confidence Decision and the Temporary Storage Rule at 10 CFR § 51.23 that are at issue in the D.C. Circuit decision do not mention ESP applications, but appropriately only refer to applications for operating licenses, COLs, and ISFSIs. As discussed above, the proposed 10 CFR § 51.23 and the SOC for the Proposed Rule also do not encompass ESP applications. • This is consistent with 10 CFR § 51.75, which specifically requires a Draft Environmental Impact Statement (EIS) for COL applications to address spent fuel storage and 10 CFR § 51.23, but does not include a similar requirement for a Draft EIS for ESP applications. (0810-6 [Mallon, James])

Comment: Because 10 CFR § 51.23 has never encompassed construction permits¹ [footnote 1 text: The original 10 CFR § 51.23(b) stated that no discussion of any environmental impact of spent fuel storage for the period following the term of the license "is required in any environmental report, environmental impact statement, environmental assessment or other analysis prepared in connection with the issuance or amendment of an operating license for a nuclear reactor or in connection with the issuance of an initial license for storage of spent fuel at an ISFSI, or any amendment thereto." Requirements for Licensee Actions Regarding the Disposition of Spent Fuel Upon Expiration of Reactor Operating Licenses, 49 Fed. Reg. 34,688, 34,694 (Aug. 31, 1984).], it also should not encompass ESPs, which are considered partial construction permits. See 10 CFR § 52.1 (definition of Early Site Permit). (0810-7 [Mallon, James])

Comment: For the above reasons, and the fact that an approved ESP does not allow the ESP holder to generate any spent nuclear fuel governed by the ESP, PSEG concludes that ESP applications are unaffected by the Commission's statement in CLI-12-16 that it "will not issue licenses dependent upon the Waste Confidence Decision or the Temporary Storage Rule until

the court's remand is appropriately addressed," because, as a legal matter, these waste confidence issues do not apply to ESP applications. The rulemaking documents for the waste confidence rulemaking should make this clear in order to prevent any unnecessary confusion or resource expenditures during ESP application reviews. (0810-8 [Mallon, James])

Comment: For these reasons, PSEG requests that the NRC Staff include an affirmative statement in the rulemaking documents for the waste confidence rulemaking that waste confidence issues do not apply to ESP applications. PSEG proposes the following statement, or its equivalent: "The issues encompassed by 10 CFR § 51.23 and NUREG-2157 do not apply to ESP applications. Because ESPs do not authorize their holders to generate or store spent nuclear fuel, the NEPA analysis for ESP applications does not need to consider the environmental impacts of continued storage of spent nuclear fuel beyond a reactor's licensed life for operation and prior to ultimate disposal." (0810-9 [Mallon, James])

Comment: NEI's modified language incorporates language from the 2010 TSR regarding the timeframe by which the Commission has reasonable assurance that a repository can be available. Although Waste Confidence case law does not require the Commission to put forth a timeframe for repository availability, the prior WCDs and TSRs have included a timeframe, which has guided the assessment of the safety and environmental impacts of continued spent fuel storage. NEI agrees with the Commission that it is reasonable to assume that a repository will be available within 60 years beyond a reactor's operating life. This assumption is well-supported in the record and should continue to be emphasized in the SOC and draft GEIS. However, given the societal and political uncertainties surrounding the establishment of a repository, NEI's suggested rule language expresses the Commission's reasonable assurance that a mined geologic repository can be available "when necessary." This approach would acknowledge the inherent nature of conclusions regarding repository availability: as the Court in *Minnesota v. NRC* stated, "...the ultimate determination can never rise above a prediction..."¹¹⁵ [footnote 115 text: 602 F.2d at 417.] It is also consistent with the description of the Commission's repository availability finding provided in *NRDC v. NRC* (see language quoted above). Furthermore, continuing to find reasonable assurance that a repository will be available "when necessary" would not run afoul of the 2012 remand. Although the D.C. Circuit invalidated elements of the 2010 rule and WCD that relied on the "when necessary" timeframe, it did so on the basis that for NEPA purposes the agency had failed to adequately assess the environmental impacts of a failure to establish a repository. The agency has now fully met its NEPA obligations by assessing those impacts the draft GEIS, and can continue to find (based on its expert evaluation) that a repository will be available when necessary. (0827-6-2 [Ginsberg, Ellen])

Comment: In the revision to Table B-1 (in Appendix B to Subpart A), middle paragraph, the NRC's proposed language specified "a dose limit of 15 millirem (0.15 mSv) per year for the first 10,000 years and 100 millirem (1.0 mSv) per year between 10,000 years and 1 million years". While I have no objection to these values, they are not presented in a manner consistent with the Commission's Policy statement on conversion to the metric system (see 61 FR 31169; 19 Jun 1996). In the third paragraph of this statement of metric policy, the Commission stated that "In dual unit documents, the first unit presented will be in the International System of Units with the English units shown [thereafter] in brackets." This standard was not met in the proposed rule text. Consequently, these dose limits should be changed to "0.15 mSv [15 millirem]" and "1.0 mSv [100 millirem]". (0841-2 [Corrino, G])

Comment: Third, the NRC again fails to consider the impacts of additional storage time, as required by the Court. See *id.* (The NRC "must actually concern itself with the extra years of storage."). This shortfall is even more concerning because the DGEIS contemplates indefinite

storage – and not merely storage for an additional 30 years. The proposed rule also lacks any time limit for environmental and safety findings regarding pool storage of spent fuel. (0897-4-22 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Therefore, NRC's own documents demonstrate that there is a reasonably foreseeable potential that spent fuel will be stored in reactor pools for more than 60 years. The DGEIS should account for this potentially extended time frame for pool storage. If it does not, the proposed rule should be changed to limit the prediction of environmental impacts to only 60 years. (0897-6-12 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: First, the language of the proposed rule itself is not limited to 60 years of storage in pools. The new proposed 10 C.F.R. § 51.23(a)(2) puts no time limit on the NRC's finding that it is feasible to safely store spent fuel. (*Compare* the proposed 10 C.F.R. § 51.23(a)(2) "it is feasible to safely store spent nuclear fuel following the licensed life for operation of a reactor" *with* the 2010 regulation, "spent fuel generated in any reactor can be stored safely and without significant environmental impacts for at least 60 years beyond the licensed life for operation."). The time period for storage contemplated by the proposed regulation is therefore indefinite. Given the indefinite time period of the safety finding in proposed 10 C.F.R. § 51.23(a)(2), the DGEIS wrongly assumes that spent fuel will be stored in pools for only 60 years. (0897-6-9 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Further, the NRC has no valid environmental analysis on which it can rely for an evaluation of spent fuel disposal impacts. Table B-1 depends on the EPA standard for Yucca Mountain.¹⁷ [footnote 17 text: The Yucca Mountain standard at 40 CFR 197] The proposed rule simply asserts that because the Yucca Mountain rule limits radiation doses in principle, "that the impacts would not be sufficiently large to require the NEPA conclusion, for any plant, that the option of extended operation under 10 CFR part 54 should be eliminated."¹⁸ [footnote 18 text: NRC 2013b] This is like saying that the existence of a law against drunken driving allows society to conclude that the impacts of drunken driving would in fact not be large enough to worry about. In addition, the licensing proceeding for Yucca Mountain is far from complete (if it is ever completed); so it is not clear that Yucca Mountain would meet the required performance specified in 40 CFR 197. (0898-1-8 [Curran, Diane] [Makhijani, Arjun])

Comment: The proposed changes to 10 CFR 51, Table B-1, make reference to the Yucca Mountain standards as follows: For the high-level waste and spent-fuel disposal component of the fuel cycle, the EPA established a dose limit of 15 millirem (0.15 mSv) per year for the first 10,000 years and 100 millirem (1.0 mSv) per year between 10,000 years and million years for offsite releases of radionuclides at the proposed repository at Yucca Mountain, Nevada. The Commission concludes that the impacts would not be sufficiently large to require the NEPA conclusion, for any plant, that the option of extended operation under 10 CFR part 54 should be eliminated. Accordingly, while the Commission has not assigned a single level of significance for the impacts of spent fuel and high level waste disposal, this issue is considered Category 1. 8.10. The second paragraph in the quote from Table B-1 above does not follow the first. The existence of a standard does not provide any assurance or even any indication of the actual performance of the site. Indeed, it is a *non sequitur*. (0898-4-18 [Curran, Diane] [Makhijani, Arjun])

Comment: The NRC has no valid environmental analysis on which it can rely for an evaluation of spent fuel disposal impacts. Table B-1 cites the EPA Yucca Mountain standard, which does not apply to any other repository. Moreover, since the licensing proceeding for Yucca Mountain is far from complete (if it is ever completed); so it is not clear that Yucca Mountain would meet the required performance specified in 40 CFR 197. The proposed rule simply refers to the rule

and asserts "that the impacts would not be sufficiently large to require the NEPA conclusion, for any plant, that the option of extended operation under 10 CFR part 54 should be eliminated."¹³⁹ [footnote 139 text: NRC 2013b, p. 56805] This is a non sequitur. It is much like saying that the existence of a law against drunken driving allows one to conclude that the impacts of drunken driving would in fact not be large enough to worry about. (0898-5-21 [Curran, Diane] [Makhijani, Arjun])

4. Comments Concerning Miscellaneous Issues

Comment: [T]he Staff Scoping Decision cannot be reconciled with the history and legal status of the waste confidence issue. This issue was first presented in *Minnesota v. NRC*, 602 F.2d 412 (D.C. Cir. 1979), where the Court described the central issue: "The crux of the case is current uncertainty about the prospects for developing and implementing safe methods for the ultimate disposal or even long-term storage of the highly toxic radioactive wastes created in the process of nuclear power generation." *Id.* at 413. The Court concluded that the case must be remanded to the NRC for a serious consideration of those issues, noting the following: *Cf. NRDC v. NRC*, 178 U.S.App.D.C. 336,361,547 F.2d 633,658 (1976) (Tamm, J., concurring in result) ("*NEPA requires the Commission fully to assure itself that safe and adequate storage methods are technologically and economically feasible. It forbids reckless decisions to mortgage the future for the present, glibly assuring critics that technological advancement can be counted upon to save us from the consequences of our decisions*"). As appears below, the Supreme Court, in *Vermont Yankee Nuclear Power Corp. v. NRDC*, 435 U.S. 519, (1978), reversed the ruling of the majority opinion requiring further procedures but remanded for the kind of inquiry called for in Judge Tamm's concurring opinion. *Id.* at 417 n.6 (emphasis added to identify the portion of Judge Tamm's concurrence in *NRDC v. NRC* cited with approval by Commissioner Svinicki at the time of her vote on the now-voided version of the waste confidence rule (Notation Vote, Response Sheet, Sept. 24, 2009 at 3)). In the *Minnesota* case, Judge Tamm also concurred, concluding that: if the Commission determines it is not reasonably probable that an offsite waste disposal solution will be available when the licenses of the plants in question expire, it then must determine whether it is reasonably probable that the spent fuel can be stored safely onsite for an indefinite period. Answers to these inquiries are essential for adequate consideration of the safety and environmental standards of the relevant statutes. It is undisputed that questions involving storage and disposal of nuclear waste pose serious concerns for health and the environment. See *Vermont Yankee Nuclear Power Corp. v. NRDC*, 435 U.S. 519, 538-39, 98 S. Ct. 1197, 1208-09, 55 L. Ed. 2d 460, 475-76 (1978); ***, Our opinion merely remands this case to the Commission for such proceedings as it deems appropriate to determine whether there is reasonable assurance that an offsite storage solution will be available when needed in this case, by the years 2007-2009. *Id.* 602 F.2d at 419-20 (Tamm, J., concurring) (footnotes omitted). In short, the Commission was given a clear mandate to use the NEPA process to evaluate the question of when and whether nuclear wastes would be permanently disposed, including looking into all of the environmental implications of those issues. *Id.* at 417 (majority opinion). (0001-14 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: The NRC came forward saying that they don't believe the Federal Courts have a right to rule on what the NRC decides. That was this year, 2013. I'd like someone to respond to that[.] (0112-1-5 [Sachs, Gary])

Comment: While the NRC mentions its role under the Atomic Energy Act to establish criteria for licensing power plants, it fails to acknowledge that it "would not continue to license reactors if

it did not have reasonable confidence that the wastes can and will in due course be disposed of safely." 78 Fed. Reg. 56776, 56778 (Sept. 13, 2013), quoting 42 Fed. Reg. 34391, 34391; July 5, 1977, pet for rev. dismissed sub nom., *NRDC v. NRC*, 582 F.2d 166 (2d Cir. 1978). Thus, the NRC appears to have abandoned this rational policy as it now states that "without Congressional direction to do so, the NRC may not deny a reactor license unless it determines that a license applicant has not met the NRC's regulatory standards for issuance of a license." DGEIS at 1-9. In other words, the Commission is now taking the irrational position here that it would continue to license nuclear power plants even if there is no place to safely store the waste and even if it concluded that continuing to license the plants to produce additional nuclear wastes would cause substantial adverse environmental consequences. See IE report, Ex. E. (0473-11-4 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: ²⁴ [footnote 24 text: NRC may believe that the provision of 10 C.F.R. § 2.335, allowing for waiver of regulations, could be used in such cases. However, the DGEIS description of purpose and need for the proposed 10 C.F.R. § 51.23 makes that impossible. Because the asserted purpose and need is to develop a generic analysis of impacts, no waiver can be obtained because no one will be able to show that the purpose and need of the rule will not be served unless a site-specific analysis is conducted. Exelon Generation Company, LLC (Limerick Generating Station, Units 1 and 2), CLI-13-07, 2013 NRC LEXIS 7 (Oct. 31, 2013).] (0473-13-11 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: As the Waste Confidence Decision Update was vacated wholesale as being arbitrary and capricious, reliance on statements therein is per se arbitrary. Statements supported by reference to the Waste Confidence Decision Update are therefore unsupported, and cannot form the basis for conclusions regarding the safe storage of nuclear waste or the basis for the promulgation of 10 C.F.R. § 51.23 (especially when the statements in the Waste Confidence Decision Update are themselves uncited and unsubstantiated, as discussed above). (0473-17-7 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The promulgation of the proposed 10 C.F.R. § 51.23 is not lawful based on the D.C. Circuit's ruling, which conditioned the NRC's generic analysis of the impacts of long-term nuclear waste storage on the "Commission's use of conservative bounding assumptions and the opportunity for concerned parties to raise site-specific differences at the time of a specific site's licensing." *New York v. NRC*, 681 F.3d 471, 480 (D.C. Cir. 2012). The regulation as proposed reads as follows: (b) As provided in §§ 51.30(b), 51.53, 51.61, 51.80(b), 51.95, and 51.97(a), and within the scope of the generic determinations in paragraph (a) of this section, no discussion of environmental impacts of spent nuclear fuel storage in reactor facility storage pool or an independent spent fuel storage installations (ISFSI) for the period following the term of the reactor operating license or amendment, reactor combined license or amendment, or ISFSI license, renewal, or amendment for which application is made, is required in any environmental report, environmental impact statement, environmental assessment, or other analysis prepared in connection with the issuance or amendment of an operating license for a nuclear power reactor under parts 50 and 54 of this chapter, or issuance or amendment of a combined license for a nuclear power reactor under parts 52 and 54 of this chapter, or the issuance of a license for storage of spent nuclear fuel at an ISFSI, or any amendment thereto. Proposed 10 C.F.R. § 51.23(b); 78 Fed. Reg. 56804 (Sept. 13, 2013). The NRC argued in *New York v. NRC* that the NRC's waiver provision provided for this site-specific review. Brief for Respondents at 40-41, *New York v. NRC*, 681 F.3d 471 (No.11-1045). But as the States argued to the D.C. Circuit, the NRC has never granted a waiver petition (Final Brief for States of New York, Vermont, Connecticut, and New Jersey, and the Prairie Island Community at 30-31, *New York v. NRC*, 681 F.3d 471 (No.11-1045)), and based on a recent NRC ruling, it appears NRC will never find

that the requirements for waiver will be met. Exelon Generation Company, LLC (Limerick Generating Station, Units 1 and 2), CLI-13-07, 2013 NRC LEXIS 7 (Oct. 31, 2013). The provision found at 10 C.F.R. § 2.335 does not afford a meaningful opportunity for site-specific analysis in licensing proceedings, where NRC routinely denies requests for waivers. NRC's burden-shifting proposal is necessarily ineffective for identifying all relevant environmental risks. Unlike NRC, the States and other affected parties do not have full access to nuclear reactor sites, nor do they have NRC's ability to request data from plant operators. As the primary federal regulator, NRC cannot shed its NEPA responsibilities by asking affected parties to compile site-specific data and independently evaluate environmental risks and impacts, obligations that NEPA imposes on NRC alone. (0473-18-1 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Through this DGEIS and rulemaking process, the NRC once again seeks to address the issues associated with the continued production of nuclear wastes when there is not a permanent, safe, and secure facility for the disposal of such wastes and when NRC has finally acknowledged that it does not have confidence that such a facility will be available by any specific date, if ever. (0473-5-1 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The NRC stated in 1977 that it "would not continue to license reactors if it did not have reasonable confidence that the wastes can and will in due course be disposed of safely." 42 Fed. Reg. 34391. The Waste Confidence process was the mechanism adopted by NRC to fulfill that obligation (see Final Waste Confidence Decision, Statement of Consideration (49 Fed. Reg. 34658 (Aug. 31, 1984)) and the DGEIS is the NEPA-mandated analysis that NRC must complete before it can make that determination. (0473-9-15 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The proposed rule finds that sufficient mined geologic repository capacity will be available "when necessary", and that "continued storage" can be safely provided (under NRC regulation) until permanent disposal is available, or even (in "indefinite storage") if it is not provided. This is the latest revision of a rule in which NRC has concluded that its regulation can assure safe storage (and safe subsequent transportation) in a repeatedly extended (and now indefinite) interim period. Such a conclusion requires increasingly heavy reliance on the capabilities of current technology and the persistence of current institutional controls. To the D.C. Circuit Court's challenge that the NRC must address whether SNF will be managed safely if a federal repository is not made available, the NRC might respond that its "hard look" does not provide assurance that SNF can be managed safely into the indefinite future, and that NRC cannot solve this problem for Congress and other federal agencies. (0505-9 [Williams, Jim])

Comment: The draft GEIS fails to address the full range of risks associated with spent fuel pools in terms of fires and leaks, and thus fails to provide adequate protection for public health and safety. Spent fuel pools in the US are currently packed beyond their originally engineered capacity, in some cases up to nine times beyond capacity.ⁱ [footnote i text: See Lochbaum, David, Director, Nuclear Safety Project, Union of Concerned Scientists, testimony before the Senate Committee on energy and Natural Resources, July 20, 2013. http://www.energy.senate.gov/public/index.cfm/files/serve?File_id=89dbc888-171c-4f77-8ecf-83a0055fcfb9] (0646-19 [Hanson, Courtney])

Comment: During the summer of 2013, the NRC held public meetings on the scope of the GEIS. At one of those meetings, the NRC refused to discuss their safety analysis, which supposedly fed into the regulatory analysis. We now understand why. NRC did NO safety analysis. (0693-1-7 [Warren, Barbara])

Comment: We present several concerns for the Commission's consideration. One concern is that the commission's DGEIS and proposed rule again signal a retreat by the Commission from its Waste Confidence Decisions issued decades ago. (0704-1 [Callen, Ronald C.] [Keskey, Donald L.])

Comment: Nor does NRC have a sufficient technical understanding of the risks of extended spent fuel storage to support a safety-related reasonable assurance finding. No existing environmental or other study has attempted to predict the environmental impacts of storing spent fuel on site for hundreds of years, or perhaps indefinitely (and the Draft GEIS certainly does not, as our comments detail). Indeed, all NRC's previous Waste Confidence iterations and associated studies were premised on the opposite conclusion -a repository will be available in the near future. NRC has commenced a study of the issue: the "Long-Term Waste Confidence Update Project," where NRC proposes to assess the environmental impacts of storing spent fuel for 200 years after cessation of licensing. See the WCD, 75 Fed. Reg. at 81,040.¹¹ [footnote 11 text: As the Court observed in *State of New York*, that rulemaking may address "some or all of the problems" that it remanded to the agency. 681 F.3d at 483.] But work on the Long-Term Waste Confidence Update Project had only just begun at the time of the D.C. Circuit's decision, and it is far from complete. NRC currently has no sound footing for its necessary safety findings under the AEA. (0706-1-10 [Fettus, Geoffrey])

Comment: Further, we request NRC withdraw the proposed rule until it has substantially improved evidentiary basis upon which to base a reasonable assurance finding about the safety of extended spent fuel storage[.] (0706-1-13 [Fettus, Geoffrey])

Comment: Page 1-5. "This draft GEIS assesses the environmental impacts of continued storage and, if adopted, would provide a regulatory basis for the NRC's proposed amendment to 10 CFR 51.23...This draft GEIS does not authorize issuance of any NRC license, but rather discloses the environmental impacts associated with the continued storage of spent fuel. In addition, this draft GEIS considers alternative approaches to assessing the environmental impacts of continued storage (see Section 1.6)." NRDC Comment[:] As NRDC details below, this Draft GEIS fails to assess key aspects of the environmental impacts of continued storage and would thus fail to provide a regulatory basis for an amended TSR or even new Waste Confidence Rule. Further, this description of purpose is a fundamental departure from the Waste Confidence Findings of the past and should be explained as such. Specifically, there will no longer be waste confidence findings. Rather, there will be a rule supported by a Generic EIS. In contrast to the previous findings, the proposed rule finds only that it is "feasible" to "safely store spent nuclear fuel following the licensed life for operation of a reactor" and that it is "feasible" to "have a mined geologic repository within 60 years following the licensed life for operation of a reactor." 78 Fed. Reg. at 56,804. (0706-1-16 [Fettus, Geoffrey])

Comment: In contrast to previous Waste Confidence Findings that ignored NEPA obligations, the agency has now ignored its AEA responsibilities by eliminating any "reasonable assurance" safety findings regarding the safety of spent fuel storage or the availability of spent fuel disposal capacity. The only safety finding in the proposed rule is a statement in the preamble that the NRC lacks confidence to make a reasonable assurance finding regarding the availability of a "disposal solution" at "the end of a reactor's licensed life for operation." 78 Fed. Reg. at 56,784.

Further, NRC acknowledges "reasonable assurance" findings regarding an "offsite storage solution" and interim storage are required by law (78 Fed. Reg. at 56,778 n. 1 (citing *Minnesota*, 602 F.2d at 418)), NRC asserts the proposed rule's purpose is to codify the results of a NEPA analysis. See 78 Fed Reg. 56,783-84. (0706-1-8 [Fettus, Geoffrey])

Comment: The proposed rule and the Draft GEIS do not address why NRC no longer makes a safety finding under the AEA and nor does it answer the question of whether the NRC has a reasonable basis for confidence in the availability of sufficient repository capacity when it is needed. The only place NRDC could identify where NRC approaches the issue is Appendix B, Technical Feasibility of Continued Storage and Repository Availability. Draft GEIS, Appendix B. But in *B.2 Repository Capacity will be Available to Dispose of Spent Fuel*, NRC makes no assertion it has a technical or evidentiary basis for a finding of reasonable assurance that sufficient repository capacity will be available when it is necessary (much less by any date certain). And as our comments will detail, nor does the Draft GEIS contain meaningful analysis of the safety or environmental risks should sufficient repository capacity not become available when it is needed. (0706-1-9 [Fettus, Geoffrey])

Comment: The Nuclear Waste Confidence Decision was first executed in response to state challenges to the Federal Government, to ensure that waste would not be left indefinitely on site. Minnesota is part of this history. Minnesota's state legislature, citizens, environmental organizations, state agencies, and host communities, including the Prairie Island Indian Community have participated in many proceedings at state and federal level. From all perspectives, Minnesota has produced thousands of pages of testimony, briefs, analysis and decision making documents. (0820-2 [Eide-Tollefson, Kristen])

Comment: The NRC's proposed rule language for 10 C.F.R. § 51.23(a) summarizes and streamlines the Conclusions into two statements: • The GEIS addresses the environmental impacts of storage of spent nuclear fuel beyond the licensed operating life of a reactor; and • It "is feasible" to safely store spent nuclear fuel following the license life for operations of a reactor and to have a mined geologic repository within 60 years following the licensed life for operation of a reactor. The NRC's proposal differs from the language in the 2010 TSR and WCD. The most notable difference is the Commission's conclusion that it is feasible to store spent fuel safely. Although the prior TSR also concluded that spent fuel can be stored safely, the prior WCD Finding stated that the Commission has reasonable assurance that spent fuel will be managed safely until sufficient geologic repository capacity is made available. Thus, the proposed rule and associated Conclusions do not express precisely the same determination regarding the safety of spent fuel storage as the prior rule and Findings. The prior rule and predictive Findings, based on "reasonable assurance," better reflect the showing suggested in *Minnesota v. NRC* and the discussion of the Commission's repository availability finding in *NRDC v. NRC*. These reasonable assurance findings are amply supported by the draft GEIS and SOC published with the proposed rule. (0827-5-10 [Ginsberg, Ellen])

Comment: Additionally, the SOC and draft GEIS explain that the agency has already established criteria through its existing regulatory framework that provide reasonable assurance of public health and safety of continued spent fuel storage. However, NEI believes that the statement "regulatory oversight has been shown to enhance safety designs and operations"¹¹ [footnote 111 text: *Id* at 56,788.] represents a significant understatement of the basis for continued safe spent fuel storage. Regulatory oversight assures compliance with NRC's regulations, but compliance is only the minimal standard of safety. Industry's commitment to safe operations goes far beyond this and industry has consistently demonstrated a level of performance that not only meets, but exceeds regulatory requirements by a wide margin.

Finally, in the area of dry storage it should be noted that, currently in the US, dry storage systems are manufactured by three highly competitive suppliers. This competition drives a continuous cycle of innovation which leads to technological advances that result in improved systems capable of providing ever increasing safety margins. We encourage the agency to further explain this Conclusion and reflect it in the SOC and rule, to ensure that the essential elements of the WCD Findings are adequately addressed. (0827-5-11 [Ginsberg, Ellen])

Comment: In the rulemaking amending the TSR, 10 C.F.R. § 51.23, the NRC proposes new rule language and a new approach to summarizing its conclusions with respect to continued storage. NEI believes the NRC should clarify its approach to ensure that the essential elements of the traditional WCD Findings are preserved, either in the TSR, the Statements of Consideration (SOC), or as conclusions in the GEIS. NEI does not advocate retaining a separate WCD document containing Findings. Instead, the rule, the SOC, and the GEIS should consistently include the requisite determinations. (0827-5-2 [Ginsberg, Ellen])

Comment: The draft GEIS and supporting record is entirely consistent with Findings 1, 3, and 5. The draft GEIS clearly revises and appropriately supplements prior Findings 2 and 4 by including, for NEPA purposes, the "no repository" scenario, the long-term storage scenario, and further analyses of the environmental impacts of potential spent fuel pool leaks and fires. Findings 2 and 4 as previously drafted in the 2010 WCD remain valid. Therefore, the enhanced record of this rulemaking proceeding would clearly support continuation of all five WCD Findings for both AEA and NEPA purposes. At bottom, however, the key elements of Waste Confidence as required by *Minnesota v. NRC* and *New York v. NRC* are: (1) reasonable assurance that spent fuel can be safely stored until a permanent repository is made available, and (2) an assessment of the environmental impacts of interim spent fuel storage until a permanent repository is made available. (0827-5-3 [Ginsberg, Ellen])

Comment: While the NRC's Conclusions are well-supported by the record and summarized in the draft GEIS, NEI believes that the essential aspects of the Conclusions and traditional WCD Findings could be reflected more fully in the rule itself to provide clarity to the public and to assure consistency with the past WCD Findings. Specifically, NEI recommends that the NRC adopt the rule language provided below because: (1) it more directly addresses the questions and issues identified in the foundational case law (i.e., *Minnesota v. NRC* and *NRDC v. NRC*), and (2) it is more consistent with the agency's traditional WCD findings. NEI also believes that the Conclusions can be drafted in the SOC to better reflect the record and to be more consistent with the traditional WCD Findings. (0827-5-9 [Ginsberg, Ellen])

Comment: NEI proposes that the rule be clarified to address the prior court decisions by including all necessary elements of the WCD Findings in the rule itself. This could be accomplished by making modest changes to the proposed rule language. Specifically, section 51.23(a) and (b) should be revised as follows¹¹² [footnote 112 text: The entirety of 10 C.F.R. § 51.23 as suggested by NEI under this approach is set forth in Appendix A.] (a) The Commission has developed a generic environmental impact statement (NUREG-2157) analyzing the environmental impacts of storage of spent nuclear fuel beyond the licensed life for operation of a reactor. (b) The Commission has reasonable assurance that: (i) sufficient mined geologic repository capacity to dispose of spent nuclear fuel generated in any reactor can be available when necessary, and (ii) spent nuclear fuel can be safely stored until that time. We recognize that this modified rule language would include non-environmental conclusions (regarding spent fuel storage and repository availability) in a Part 51 environmental regulation. However, this approach would more directly ensure that the agency satisfies the recent D.C. Circuit remand. First, the rule would acknowledge that the generic environmental impacts of continued spent

fuel storage have been assessed in the GEIS. Second, the rule would explicitly reconfirm the agency's reasonable assurance that spent fuel can be managed safely (previously captured in WCD Findings 3, 4, and 5) and that a repository can be available when necessary (previously captured in the TSR and Finding 2). Reasonable assurance conclusions in the rule, rather than those related to feasibility, would update and replace the current Findings adopted after *Minnesota v. NRC*. Again, the inquiry in *Minnesota* was "whether there is reasonable assurance that an off-site storage solution will be available by the years 2007-2009" and if not, whether there is reasonable assurance that the fuel can be stored safely at the sites beyond those dates."¹¹³ [footnote 113 text: *Minnesota v. NRC*, 602 F.2d at 418.] In addition, with respect to repository availability, the U.S. Court of Appeals for the Second Circuit described the NRC's finding as "an implied finding of reasonable assurance that safe permanent disposal of such wastes can be available when needed."¹¹⁴ [footnote 114 text: *NRDC v. NRC*, 582 F.2d at 170.] (0827-6-1 [Ginsberg, Ellen])

Comment: No specific conclusion in the SOC would be necessary for prior Finding 4 regarding the safety and environmental impacts of continued spent fuel storage, since those determinations would be captured in the rule itself. The rule language regarding continued safe storage of spent fuel would be supported by the other SOC conclusions, particularly the conclusion described immediately above (prior Finding 3). (0827-6-6 [Ginsberg, Ellen])

Comment: Finally, the SOC should explicitly express the NRC's conclusion that it is reasonable to assume that safe independent onsite or offsite spent fuel storage will be made available if such storage capacity is needed. This conclusion tracks to prior Finding 5 and is based on the rationale in prior WCDs, such as the obligations under the Nuclear Waste Policy Act, NRC regulatory requirements, and the industry's commitment to continued safe storage pending disposal. The SOC's discussion of safe storage should continue to include the Commission's conclusion that spent nuclear fuel can be safely managed in spent fuel pools in the short-term timeframe and dry casks during the short-term, long-term, and indefinite timeframes evaluated in the draft GEIS. This conclusion is based on technical studies, operating experience, regulatory oversight, and the draft GEIS. (0827-6-7 [Ginsberg, Ellen])

Comment: § 51.23 Storage of Spent Nuclear Fuel After Licensed Term of Operation. (a) The Commission has developed a generic environmental impact statement (NUREG-2157) analyzing the environmental impacts of storage of spent nuclear fuel beyond the licensed life for operation of a reactor. (b) The Commission has reasonable assurance that: (i) sufficient mined geologic repository capacity to dispose of spent nuclear fuel generated in any reactor can be available when necessary, and (ii) spent nuclear fuel can be safely stored until that time. (c) As provided in §§ 51.30(b), 51.53, 51.61, 51.80(b), 51.95, and 51.97(a), and within the scope of the generic determinations in paragraph (a) of this section, no discussion of environmental impacts of spent nuclear fuel storage in reactor facility storage pool or an independent spent fuel storage installations (ISFSI) for the period following the term of the reactor operating license or amendment, reactor combined license or amendment, or ISFSI license, renewal, or amendment for which application is made, is required in any environmental report, environmental impact statement, environmental assessment, or other analysis prepared in connection with the issuance or amendment of an operating license for a nuclear power reactor under parts 50 and 54 of this chapter, or issuance or amendment of a combined license for a nuclear power reactor under parts 52 and 54 of this chapter, or the issuance of a license for storage of spent nuclear fuel at an ISFSI, or any amendment thereto. The Statements of Consideration would set forth "Conclusions" similar to the traditional WCD Findings to explain the basis for the rule and to link the rule to the prior WCD Findings and the current GEIS. (0827-7-1 [Ginsberg, Ellen])

Comment: On Page 1-9, you say that "unless a threat to the public health and safety of the common defense and security exists, the NRC has no authority to deprive current licensees of their vested interest in licenses...." This means that we can never decide that we have made a very big mistake by ever getting these plants running from a safety standpoint. Once we decided to allow it, then we can never turn back? WRONG. (0836-70 [Davis, Anonymous])

Comment: Instead of supporting its reasonable assurance findings by conducting an appropriate environmental analysis of the probability of failing to site sufficient repository capacity and the consequences of such a failure, the NRC simply abandons those findings in the proposed rule. The words "reasonable assurance" — the key language of compliance with the Atomic Energy Act — do not appear in the proposed rule. Instead of predicting with "reasonable assurance" that spent fuel "will" be safely stored and disposed of, the NRC asserts — without any assurance — that it *can* be safely disposed of, *i.e.* that it is "feasible." These words confirm that, in the words of the Court of Appeals, "[t]he Commission apparently has no long-term plan other than hoping for a geologic repository." (0897-1-1 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: But mere hope cannot satisfy the Atomic Energy Act. Under the Act and over thirty years of NRC and judicial interpretations, the proposed rule's failure to make reasonable assurance findings regarding the availability of a disposal solution for spent fuel deprives the NRC of any authority to license or re-license reactors. (0897-1-2 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Moreover, even if the NRC were to attempt to make reasonable assurance findings, it lacks any technical basis for such findings. The DGEIS contains no analysis of the probability that sufficient repository capacity will be available or unavailable when needed. Such an analysis would require an evaluation of the likelihood that spent fuel repositories could be found that meet the U.S. Environmental Protection Agency's standards for a repository and the capacity of various geologic sites to accommodate the quantity of spent fuel to be generated. The last study the NRC did of that issue was in the mid-1970s, and it is severely outdated. (0897-1-3 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Similarly, in order to provide sufficient support for a reasonable assurance finding regarding the safety of storing spent fuel for many decades if a repository is delayed, the NRC would have to catch up on long- delayed research regarding the long-term behavior of spent fuel in dry storage conditions. But the NRC is years away from obtaining adequate research results to make informed judgments about the safety of storing spent fuel for lengthy periods. (0897-1-4 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Without "reasonable assurance" safety findings regarding the availability of sufficient repository capacity or means of safely storing spent fuel for lengthy time periods -- or a technical basis for such findings -- the NRC has no authority under the Atomic Energy Act to continue licensing reactors to generate spent fuel. This failure to satisfy the Atomic Energy Act cannot be cured by the DGEIS, because a NEPA analysis cannot substitute for the safety findings that are independently required by the Atomic Energy Act. (0897-1-5 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The proposed rule violates the Atomic Energy Act by completely eliminating any "reasonable assurance" safety findings regarding the safety of spent fuel storage or the availability of spent fuel disposal capacity. The only safety finding made in the proposed rule is a statement in the preamble that the NRC lacks confidence to make a reasonable assurance

finding regarding the availability of a "disposal solution" at "the end of a reactor's licensed life for operation." 78 Fed. Reg. at 56,784. (0897-2-10 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: While admitting in a footnote that "reasonable assurance" findings regarding an "offsite storage solution" and interim storage are required by law (78 Fed. Reg. at 56,778 n. 1 (citing *Minnesota*, 602 F.2d at 418)), the NRC asserts that the proposed rule's only purpose is to codify the results of a NEPA analysis: *B. Waste Confidence Rulemaking* B1. What is the purpose of this Waste Confidence rulemaking? The NRC's use of a rule to generically satisfy its NEPA obligations with respect to continued storage will enhance efficiency in individual licensing reviews by analyzing the environmental impacts of continued storage, which are the same or largely similar at each nuclear power reactor or storage site, and codifying the results of that analysis. Part of the environmental analysis for a nuclear power reactor or storage facility license includes a review of the impacts caused by the spent nuclear fuel generated in the reactor. That analysis must assess the impacts of the spent nuclear fuel from generation through disposal. If the Commission lacks reasonable assurance that a disposal solution will be available at the end of a reactor's licensed life for operation, NEPA requires that the Commission assess the impacts of continued storage of the spent nuclear fuel pending disposal at a repository. (0897-2-11 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: But the NRC's complete substitution of NEPA findings for safety findings is unlawful. The NRC must comply with *both* the Atomic Energy Act *and* NEPA. *Limerick Ecology Action v. NRC*, 869 F.2d 719, 729 (3d Cir. 1989). The two statutes are independent and distinct in their requirements. The Atomic Energy Act establishes a minimum level of protection of public health and safety against radiological hazards. NEPA, on the other hand, requires disclosure and weighing of risks posed by licensing actions that are authorized by the NRC under the Atomic Energy Act; but it does not establish minimum standards. The two statutes do overlap. For example, NEPA requires the NRC to consider the reasonably foreseeable risk that siting sufficient repository capacity will not be feasible, and what would be the impacts if it is not feasible. But compliance with one statute does not excuse compliance with the other. *Limerick Ecology Action*, 869 F.2d at 729-30 (noting that case law "do[es] not suggest that NEPA can never require consideration of additional alternatives simply because there is some overlap in the considerations required by both statutes"). Moreover, while the Court of Appeals in New York focused on the NRC's noncompliance with NEPA in promulgating the 2010 Waste Confidence Decision, nothing in the Court's opinion could be read to reverse *Natural Resources Defense Council* or *Minnesota*'s holdings that the NRC must make waste confidence safety findings that comply with the Atomic Energy Act. In the absence of such reasonable assurance findings, the NRC has no lawful basis for issuing or re-issuing reactor licenses. 42 Fed. Reg. at 34,393; *Natural Resources Defense Council*, 582 F.2d at 170; *Minnesota v. NRC*, 602 F.2d at 418. (0897-2-12 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: B. The Proposed Rule Violates the Atomic Energy Act by Removing the Previous Finding Regarding Sufficiency of Repository Capacity[.] As discussed above, until the instant proposed rule, all NRC "waste confidence" decisions have included "reasonable assurance" findings. In addition, until the proposed rule, all "waste confidence" decisions have specifically addressed the question of whether the NRC has reasonable assurance that sufficient repository capacity will be available to accommodate spent reactor fuel when it is needed. This change can be seen by comparing the proposed rule with all of the quotations from Findings 2 and 4 in Section A above. In contrast to these previous findings, the proposed rule finds only that it is "feasible" to "safely store spent nuclear fuel following the licensed life for operation of a reactor" and that it is "feasible" to "have a mined geologic repository within 60 years following the licensed life for operation of a reactor." 78 Fed. Reg. at 56,804.¹ [footnote 1 text: In previous

waste confidence decisions, the NRC used the term “feasible” in reasonable assurance findings regarding high-level waste disposal. See, e.g., Finding 1 of the 1990 waste confidence decision: “The Commission finds reasonable assurance that safe disposal of high-level radioactive waste and spent fuel in a mined geologic repository is technically feasible.” 55 Fed. Reg. at 38,475 (1990).] The NRC’s previous reasonable assurance finding regarding the availability of sufficient repository capacity for disposal of spent fuel *has completely disappeared from the NRC’s regulations*. Its disappearance is not explained. Neither the proposed rule nor the accompanying DGEIS gives any explanation as to why the proposed rule now fails to address the question of whether the NRC has a reasonable basis for confidence in the availability of sufficient repository capacity when it is needed. The closest the NRC comes to addressing the issue is by entitling a section in Appendix B “Repository Capacity will be Available to Dispose of Spent Fuel.” *Id.* at B-2. But the heading makes no reference to reasonable assurance or the sufficiency of capacity, and the text that accompanies that heading makes no assertion that the NRC has a technical basis for a finding of reasonable assurance that sufficient repository capacity will be available when it is necessary. Nor does the DGEIS contain any analysis of the risk that sufficient repository capacity will not become available when it is needed. (0897-2-13 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Nor does the NRC have a sufficient technical understanding of the risks of extended spent fuel storage to support a reasonable assurance finding. As discussed in the Organizations’ comments on the scope of the DGEIS, NRC’s own documents show that existing information is grossly inadequate to support any reasonable predictive findings about the safety of such long-term spent fuel storage.³ [footnote 3 text: The Organizations’ scoping comments and supporting declaration of Dr. Arjun Makhijani (“Makhijani Scoping Declaration”) are attached to these comments as Exhibits E and F, respectively.] There is no existing environmental or other study that has even attempted to predict the environmental impacts of storing spent fuel on site for hundreds of years, or perhaps indefinitely. Indeed, all other studies have been premised on the opposite conclusion – that a repository will be available in the relatively near future. NRC has commenced a study of the issue: the “Long-Term Waste Confidence Update Project,” in which the NRC proposes to assess the environmental impacts of storing spent fuel for 200 years after cessation of licensing. See 75 Fed. Reg. at 81,040.⁴ [footnote 4 text: As the Court observed in *State of New York*, that rulemaking may address “some or all of the problems: that it remanded the agency. 681 F3dat483.] But work on the Long-Term Waste Confidence Update Project had only just begun at the time of the D.C. Circuit’s decision, and it is far from complete. The NRC Staff has estimated that the Long-Term Waste Confidence Update Project EIS will take until 2019 to finish. COMSECY-12-0016, Memorandum from R.W. Borchardt to NRC Commissioners re: Approach for Addressing Policy Issues Resulting from Court Decision to Vacate Waste Confidence Decision and Rule at 3 (July 9, 2012) (“COMSECY-12-0016”). Two preliminary studies issued as part of the Project support the Staff’s seven-year time estimate by demonstrating (a) the complexity of the issues raised by long-term and indefinite spent fuel storage and (b) the Commission’s lack of knowledge on the subject. The first study, issued for comment in December 2011, sets forth a series of topics that must be addressed in the Long-Term Waste Confidence Update Project EIS, including the degree to which nuclear power will be used in the future, the nature of future dry cask storage and transportation technology, prospects for long-term maintenance of institutional and regulatory control, and accidents to be considered. Draft Report for Comment: Background and Preliminary Assumptions for an Environmental Impact Statement – Long-Term Waste Confidence Update (Dec. 2011) (the “Preliminary Assumptions Document”). While the NRC proposed, as a preliminary matter, to make assumptions about many of these topics, comments show that they may not be assumed and instead should be the subject of the EIS for the Long-Term Waste Confidence Update Project. See comments by Institute for Energy and

Environmental Research, Blue Ridge Environmental Defense League, Natural Resources Defense Council, Riverkeeper, and Southern Alliance for Clean Energy on NRC Report Updating Preliminary Assumptions for an EIS on Long-Term Spent Fuel Storage Impacts (Feb. 17, 2012) (copy attached as Exhibit G). The second study, issued for comment in May 2012, identifies an array of technical issues regarding dry storage and transportation impacts on which the NRC must collect additional data before it can evaluate dry cask long-term integrity and cask vulnerability to degradation and accidents. Draft Report for Comment: Identification and Prioritization of the Technical Information Needs Affecting Potential Regulation of Extended Storage and Transportation of Spent Nuclear Fuel (May 2012) ("Technical Needs Document"). (0897-2-18 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The NRC attempts to rationalize its lack of support for a reasonable assurance finding about the safety of interim spent fuel storage by characterizing the finding as a "policy statement." 78 Fed. Reg. at 56,799. The characterization is fallacious and evasive of the NRC's responsibilities under the Atomic Energy Act. The Atomic Energy Act requires that safety must be assured by factual predictions that are based on technical evidence, not by policy statements. *Limerick Ecology Act*, 869 F.2d at 734-35. Thus, the lack of reasonable assurance findings in the proposed rule renders them invalid as a matter of law for supporting the issuance of new reactor licenses or the re-issuance of existing licenses. The NRC cannot cure this fatal deficiency by inserting the "magic words" of "reasonable assurance." Instead, it must have a technical basis for such findings. As discussed above, it has no such basis. In light of the fatal deficiencies in the proposed rule, the NRC lacks lawful grounds for issuing or re-issuing any reactor licenses. *Calvert Cliffs Nuclear Project, L.L.C. and Unistar Nuclear Operating Services, L.L.C.* (Calvert Cliffs Nuclear Power Plant, Unit 3), CLI-12-16, 76 NRC 63, 66 ("Waste confidence undergirds certain agency licensing decisions, in particular new reactor licensing and license renewal.") (0897-2-21 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The Proposed Rule Violates the Atomic Energy Act by Eliminating Previous Safety Findings That Are Essential to Atomic Energy Act Compliance (0897-2-7 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: As the NRC conceded in its first waste confidence pronouncement (Denial of Petition for Rulemaking, 42 Fed. Reg. 34,391 (July 5, 1977)) and as affirmed by the U.S. Court of Appeals in *Natural Resources Defense Council v. NRC*, 582 F.2d 166 (2nd Cir. 1978), in order to satisfy the Atomic Energy Act, NRC reactor licensing decisions must include predictive reasonable assurance findings regarding (a) the availability of sufficient and safe spent fuel disposal capacity when it is necessary and (b) the safety of spent fuel storage in the meantime. See also *Minnesota v. NRC*, 602 F.2d 412 (D.C. Cir. 1979). As the NRC explained in 1977, in its first pronouncement on the issue: (0897-2-8 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: While these reasonable assurance findings do not need to be as rigorous as other safety findings because they predict events far in the future, they must demonstrate a technical basis for a reasonable level of "confidence" that reactor fuel will be isolated from humans and the environment as long as it remains radioactive. 44 Fed. Reg. at 34,393. (0897-2-9 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Thus, the DGEIS fails to provide an adequate technical basis for a reasonable assurance finding regarding the safety of long-term or indefinite spent fuel storage. Worse, the DGEIS ignores a wealth of studies concluding that much more study of spent fuel behavior is required before it is possible to reach informed conclusions about its behavior under extended storage conditions. Finally, the DGEIS ignores the safety and environmental risks posed by

variations in spent fuel about which it has little knowledge. Not only has the NRC failed to obtain the information it needs to make a safety finding, but it has not even analyzed the uncertainty created by the lack of information. (0897-4-18 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Makhijani Declaration, par. 4.16 (quoting Kadak 2012). Of equal concern as the serious data gaps identified by the National Academy of Engineering is the fact that as recently as 2012, neither the NRC nor the nuclear power industry had implemented the periodic examinations of spent fuel recommended by the NWTRB in 2010. *Id.* Without this basic information, the NRC has an inadequate foundation for any predictive safety finding regarding the behavior of spent fuel in long-term storage conditions. And any EIS that is prepared to discuss these matters should acknowledge and analyze the considerable uncertainty that exists. (0897-4-9 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Here, the disjointed nature of NRC's program for evaluation of environmental impacts related to spent fuel storage and disposal is not only piecemeal but internally inconsistent, full of gaps, and riddled with outdated information. As a result, the NRC utterly fails to support its safety findings with an adequate environmental analysis, thus violating both the Atomic Energy Act and NEPA. (0897-7-18 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: 10 C.F.R. §51.23 (the proposed rule). This proposed rule appears in Part 51 of NRC regulations, indicating that it is an environmental regulation. Yet, it has safety language. To make matters more confusing, the NRC has dropped the "reasonable assurance" findings formerly made in the waste confidence decision. The Atomic Energy Act and NEPA both require the NRC to make findings. Safety findings should be included in Parts 50 and 52 and environmental findings should be included in Part 51. The NRC should also explain that safety findings must be supported by an adequate NEPA analysis. After three decades of distorted and partial environmental analysis leading to uninformed licensing and re-licensing decisions, it is time now for the NRC to come into compliance with NEPA. The NRC must update its outdated and repudiated assumptions, conduct an environmental study that provides an integrated examination of all environmental impacts and costs related to spent fuel management, and promulgate a new set of regulations that provides for meaningful consideration of these impacts in individual licensing decisions. (0897-7-21 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: In the proposed waste confidence rule, the NRC makes a finding that spent fuel disposal is feasible, but it fails to make any reasonable assurance finding regarding the availability of sufficient repository capacity to accommodate the spent fuel that will be generated as a result of future NRC licensing decisions. While the Court directed the NRC to analyze the uncertainty associated with failure to site a repository, the NRC simply dropped the safety finding from its regulations. (0897-7-8 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: In the Draft GEIS, NRC seeks to support three findings that are presented in proposed 10 CFR 51.23(a)(2) and Table B-1: (a) that it is feasible to store spent fuel safely and without significant adverse environmental impacts for an indefinite period, (b) that it is feasible to have a mined geologic repository within 60 years following the life of a licensed reactor, and (c) that spent fuel disposal will not have impacts on the environment that are significant enough to foreclose extended operation for any nuclear power plant.¹⁰ [footnote 10 text: NRC 2013b, p. 56804-56805] In my professional opinion, the Draft GEIS is extremely inadequate to support these proposed findings. Significant evidence exists to show that the environmental impacts of long-term or indefinite storage of spent fuel will likely be significant and could cause significant risks to human health. In the case of indefinite storage, they are likely to be catastrophic; among other things it is likely that institutional control will be lost. (0898-1-1 [Curran, Diane] [Makhijani, Arjun])

Comment: 4.0 THE NRC'S PROPOSED FINDING THAT SPENT FUEL CAN BE STORED FOR A LONG-TERM OR INDEFINITE PERIOD SAFELY AND WITHOUT SIGNIFICANT ENVIRONMENTAL IMPACTS IS NOT SUPPORTED BY ADEQUATE DATA OR ANALYSIS.

4.1. The NRC's first proposed findings are that spent fuel can be safely stored for an indefinite time period (10 CFR 51.23(a)(2)(i)) without significant adverse environmental impacts (Table B-1). These findings are almost devoid of valid technical support so far as long-term and indefinite storage is concerned. (0898-1-12 [Curran, Diane] [Makhijani, Arjun])

Comment: In view of the above, it is my conclusion that the NRC lacks a factual and scientific basis for a finding of confidence that spent fuel can be safely stored for the long-term, much less indefinitely. (0898-1-9 [Curran, Diane] [Makhijani, Arjun])

Comment: The failure of the proposed rule to assure that sufficient repository capacity will be available is contrary to the prior waste confidence assertion in the 2008 version of 10 CFR 51.23, which stated: Further, the Commission believes there is *reasonable assurance* that *at least one* mined geologic repository will be available within the first quarter of the twenty-first century, and *sufficient repository capacity* will be available within 30 years beyond the licensed life for operation of any reactor to dispose of the commercial high level waste and spent fuel originating in such reactor and generated up to that time.¹¹⁴ [footnote 114 text: 10 CFR 51 2008, at 51.23(a); italics added] (0898-4-11 [Curran, Diane] [Makhijani, Arjun])

Comment: In view of the above, it is my conclusion that the NRC lacks a factual and scientific basis for a finding of confidence that spent fuel can be safely stored for the long-term, much less indefinitely. The NRC also lacks a factual and scientific basis for a finding of confidence that spent fuel can be disposed of safely within acceptable, legally binding health and safety standards. In fact, the available evidence suggests that both long-term storage and disposal of spent fuel could pose significant safety and environmental risks. The NRC should prepare a new Draft GEIS that meaningfully examines these risks. (0898-5-24 [Curran, Diane] [Makhijani, Arjun])

Comment: On Page 1-9, you say that "unless a threat to the public health and safety of the common defense and security exists, the NRC has no authority to deprive current licensees of their vested interest in licenses...." This means that we can never decide that we have made a very big mistake by ever getting these plants running from a safety standpoint. Once we decided to allow it, then we can never turn back? WRONG. The NRC does have the authority to pull licenses if they decide the plant is not safe, period. It does not matter if the licensee has some vested interest. (0930-2-23 [Lutz, Ray])

5. Comments Concerning the NEPA Process

Comment: Petitioners [The State of Vermont with the Vermont Department of Public Service, the State of Connecticut, the State of New York, and the Commonwealth of Massachusetts] request that the Commission review and reverse certain conclusions reached by the Regulatory Staff in the Waste Confidence Generic Environmental Impact Statement Scoping Process Summary Report (March 2013) ML13060A128 ("Staff Scoping Decision"). The Commission has inherent supervisory authority over the Staff and should act now in furtherance of the Commission's stated goal of resolving the pending proceedings expeditiously. (0001-1 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: The Staff Scoping Decision is inconsistent with Commission directives. In Staff Requirements COMSECY-12-0016, the Commission directed Staff to be guided by the "Council

on Environmental Quality's Guidance on Improving the Process for Preparing Efficient and Timely Reviews Under NEPA" ("CEQ Guidance"). Staff Requirements COMSECY-12-0016. In that Guidance, CEQ reminds federal agencies that "NEPA requires Federal agencies to consider the potential environmental consequences of their proposed action, and any reasonable alternatives, before deciding whether and in what form to take an action." CEQ Guidance, 77 Fed. Reg. 14473, 14475 (Mar. 12, 2012). While the Guidance encourages agencies to incorporate by reference completed analyses from other documents (see, e.g., 77 Fed. Reg. at 14475 ("NEPA reviews should coordinate and take appropriate advantage of existing documents and studies, including through adoption and incorporation by reference")), nowhere does it authorize Federal agencies to avoid consideration of impacts or alternatives and proceed to a final decision on a major federal action merely because another, yet to be completed, proceeding is evaluating some of those issues. To the contrary, the Guidance makes clear that the NEPA process must be fully completed *before* a decision is made on the major federal action: Agencies must integrate the NEPA process into their planning at the earliest possible time to ensure that planning and decisions reflect environmental values, avoid delays later in the process, and anticipate and attempt to resolve potential issues. NEPA should not become an after-the-fact process that justifies decisions that have already been made.;***;[A]n agency shall prepare an EIS so that it can inform the decisionmaking process in a timely manner "and will not be used to rationalize or justify decisions already made."; CEQ Guidance, 77 Fed. Reg. at 14476-77 (footnotes and citations omitted). Thus, if the Staff wishes to use any environmental analyses conducted in the "Rulemaking Revising Security Requirements for Facilities Storing SNF and HLW" as part of the GEIS process in these proceedings, it will have to wait for that rulemaking to complete its environmental impact statement analysis, a delay that will substantially interfere with the Commission's clear goal of completing the GEIS within 24 months of its initiation. (0001-19 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: [I]t appears from the Federal Register Notice for the Rulemaking Revising Security Requirements for Facilities Storing SNF and HLW (74 Fed. Reg. 66589 (Dec. 16, 2009)) that the scope of that analysis is far narrower than the scope of a proper consideration of dry cask storage as an alternative to the long-term or indefinite use of spent fuel pools. The rulemaking on security revisions is focused only on security issues at Independent Spent Fuel Storage Installations (ISFSI) and Monitored Retrievable Storage Installation (MRS): The Nuclear Regulatory Commission (Commission or NRC) is seeking input from the public, licensees, certificate holders, and other stakeholders on a draft technical basis for a proposed rulemaking that would revise the NRC's security requirements for the storage of spent nuclear fuel (SNF) at an Independent Spent Fuel Storage Installation (ISFSI) and the storage of SNF and/or high-level radioactive waste (HLW) at a Monitored Retrievable Storage Installation (MRS). 74 Fed. Reg. at 66589. The scope of that proceeding thus appears to ignore the many environmental impacts at over 100 reactor sites that may occur as a result of accidental releases from spent fuel pools, or fires at spent fuel pools, and it also appears to ignore the environmental and economic impacts of the continued use of a reactor site for waste storage for a long-term or indefinite period after the reactor has shutdown. Whether that rulemaking will even consider requiring dry cask storage at reactor sites remains unresolved. (0001-20 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: It is essential that these scoping issues be resolved as quickly as possible. The current GEIS process and rulemaking are part of a saga spanning 35 years. During that time, the Commission has struggled with whether it is environmentally prudent to allow nuclear wastes to be generated before there exists a facility of sufficient size to safely and permanently dispose of that waste. Because such a facility does not yet exist, the Commission has also

struggled with whether there is reasonable assurance that nuclear wastes can be safely stored at reactor sites with acceptable environmental risks that have been mitigated to the fullest extent possible forever. The Commission has already made several important first steps in its efforts to achieve the legally required analysis by: (1) choosing to conduct its review by using the full power of NEPA to develop a comprehensive GEIS; and (2) choosing to suspend the issuance of any new authority to generate nuclear wastes until this review process has been finally completed. But to resolve these matters fully, fairly, and efficiently by the end of 2014, the Commission must act now to review the Staff Scoping Decision before the problems that are inherent in that decision adversely affect the rest of the GEIS process. To that end, Petitioners respectfully request that the Commission establish the following schedule for immediate action on this Petition: 1. May 31, 2013-Any entity that participated in the scoping process can file a brief supporting or opposing the request for the Commission to hear the Petition on the merits; 2. June 7, 2013-Commission decides whether it will address the merits of the Petition; 3. June 14, 2013-Any entity that participated in the scoping process can file a brief on the merits of the Petition; 4. June 21, 2013-Any entity that filed a pleading on June 14 files any reply; 5. July 2013-Commission decides the merits of the Petition.; Time is of the essence, and the Commission should act quickly to ensure that the scope of the GEIS complies with NEPA and with the D.C. Circuit's decision in *New York v. NRC*. (0001-31 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: [T]he purpose of the Staff Scoping Decision was to define the parameters of the GEIS, essentially deciding for these proceedings what will be analyzed and what will not be analyzed. The Commission's regulations identify the determination of the scope of a proposed EIS as a central decision point in the EIS process which controls the future EIS analysis: (a) Scope. The draft environmental impact statement will be prepared in accordance with the scope decided upon in the scoping process required by §§ 51.26 and 51.29. As appropriate and *to the extent required by the scope*, the draft statement will address the topics in paragraphs (b), (c), (d) and (e) of this section and the matters specified in §§ 51.45, 51.50, 51.51, 51.52, 51.53, 51.54, 51.61 and 51.62. 10 C.F.R. § 51.71(a) (emphasis added). Thus, the Staff Scoping Decision is effectively the final word on that issue and will define the parameters of both the proceeding and draft and final GEIS. If the Staff has erred in determining the proper scope, as is clearly the case here, the error will infect the entire GEIS process and the two proceedings which will be relying on the GEIS. That error will ultimately result in either review and reversal by the Commission or more federal court review and more delay in the completion of this important process. See, e.g., Notation Vote, Chair Macfarlane (Aug. 10, 2012) (recognizing that serious errors in the initial NEPA process can cause substantial delays in the final resolution of the issues: "Experience has shown that on issues of particular controversy, an environmental assessment will not result in resource or time savings in the end, because of the likelihood of challenges to the finding of no significant impact."). The Staff's overly narrow and erroneous conclusions in the Scoping Decision will, if allowed to stand, "[a]ffect[] the basic structure of the proceeding in a pervasive or unusual manner." 10 C.F.R. § 2.341(f)(2). The Staff limited the scope of the evaluation of alternatives in the GEIS and failed to identify in the Staff Scoping Decision the criteria to be applied in deciding what issues will be subject to resolution on a site-specific basis. (0001-9 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: There is no such thing as "small" or "moderate" dangers. This being nuclear waste, it is ALL highly dangerous. I suggest the "small" and "moderate" terminology should be deleted. As you know, it is absurd. (0020-1 [Carter, Pat])

Comment: The NRC effectively assumes licensing, and then goes on from there to look at the impacts of irradiated nuclear fuel storage, although it does a very poor, woefully inadequate,

and, in my opinion, legally insufficient and violative job of doing that. The whole point of the environmental impact statement is to allow an informed decision regarding whether to license the reactor in the first place; that is, to allow the creation of irradiated nuclear fuel. NRC does not even attempt to answer that question in this environmental impact statement. (0030-2-2 [Kamps, Kevin])

Comment: I would also like to remind everyone that it is important to keep in mind the relevant NEPA principles -- National Environmental Policy Act principles -- as the NRC proceeds through this rulemaking. First and foremost, an EIS serves two purposes. It is intended to ensure that Federal agencies have available and consider detailed information on the environmental impacts of major federal actions. This is the so-called "hard look." Second, the EIS also is intended to ensure that information is made available to the public and other stakeholders who may also play a role in the decision-making process. (0030-3-5 [Ginsberg, Ellen])

Comment: NEPA itself does not mandate specific results or licensing decisions, but, rather, it prescribes a process designed to prevent uninformed agency action. Agencies may take action, even in situations where significant environmental impacts may result, because the agency has carefully balanced the various environmental and other impacts and is not to elevate such impacts over other considerations. Finally, NEPA does not require that an agency delay action until better or other information becomes available. CEQ regulations directly address the notion of incomplete or unavailable information and suggest that worst case assumptions simply are not required. (0030-3-6 [Ginsberg, Ellen])

Comment: I would like to close with two points. First, the agency has an established history of addressing this set of waste confidence issues generically. That approach was not the subject of criticism by the D.C. Circuit. In fact, the generic approach and reliance on the substantial body of existing work was anticipated by the Court. Second, NEPA does not require unanimity of public opinion or even consensus. It requires that the agency take a look at the available information and apply a rule of reason. NRC already has gone well beyond the requirements of NEPA to establish -- to evaluate the issues in this draft GEIS. It should now complete the process and timely issue the final GEIS and the final rule. (0030-7-8 [Matthews, Tim])

Comment: The National Environmental Policy Act (NEPA) requires consideration of all reasonably foreseeable environmental impacts of a proposed action ---- from cradle to grave. The question that must be answered in an atomic reactor licensing decision is: If you look all the way, to the end of the reactor's life, including decommissioning, spent nuclear fuel/irradiated nuclear fuel/high-level radioactive waste storage, and disposal, is having that source of electricity generation -- nuclear power -- worth all the environmental and economic costs, risks, and impacts that will then inevitably ensue? As soon as NRC licenses a reactor, the generation/creation of irradiated nuclear fuel and all its related costs, risks, and impacts will then follow. The NRC effectively assumes licensing, and goes on from there to look at the impacts of irradiated nuclear fuel storage, although it does a very poor, woefully inadequate job of that! But the whole point of the Environmental Impact Statement is to allow an informed decision regarding whether to license the reactor in the first place, that is, to allow the generation of irradiated nuclear fuel. NRC does not even attempt to answer that question. (0034-1 [Wagner, Jim and Virginia])

Comment: As a threshold matter, APS [Arizona Public Service Company] agrees with the Court versus NRC, that the National Environmental Policy Act is a procedural statute that is intended to ensure fully informed and well-considered decision making. (0045-2-3 [Green, Michael])

Comment: Although, it's too early to tell, we believe it's fair to say, that the NRC is likely going to receive many comments that challenge the staff's conclusions regarding environmental impacts of short-term, long-term, and indefinite storage, as well as postulated accidents and potential acts of sabotage or terrorism. As the staff reviews the comments made in this public comment period, we remind the staff to keep in mind the fundamental proposition that the National Environmental Policy Act is a process statute. (0045-2-6 [Green, Michael])

Comment: I am advocating for the U.S. Nuclear Regulatory Commission to update and revise its 2010 Waste Confidence Generic Environmental Impact Statement (GEIS). According to the U.S. Court of Appeals for the DC Circuit (2012), the NRC's 2010 Waste Confidence GEIS did not fulfill its responsibility to meet the required NEPA expectations regarding spent nuclear fuel storage. (0047-1 [Anonymous, Anonymous])

Comment: I believe that it should be mandatory for the NRC to continually research the potential human health and environmental impacts that could result from storing nuclear spent fuel even after their proposed regulatory document is considered to fulfill their NEPA obligations. By doing this, the NRC could potentially discover new findings and address them instantaneously rather than waiting for parties to discover flaws and challenge their projections in court. I think this process would be ideal because the NRC could inform the public of new pertinent information, which in turn would allow the public to be aware of these findings immediately and adapt accordingly. (0047-5 [Anonymous, Anonymous])

Comment: First, I would advise that we stop the train on this whole issue. The reason being first the national -- the Congress charged the National Academy of Sciences to determine the adequacy of NRC regulations. And it asked specifically an emphasis on waste storage. Until that document is completed, it is premature to carry on with this business you're doing. (0112-3-1 [Lampert, Mary])

Comment: I urge the Nuclear Regulatory Commission (NRC) to develop a valid, realistic assessment of the environmental impacts of radioactive waste. Radioactive waste is one of the most toxic and persistent threats to human health and it is paramount that we consider its storage with full research, overview and detailed long-range environmental impact studies. (0144-1 [O'Nan, Margaret S.])

Comment: EI's recommendations were ignored, including the request that evidence brought out through cross-examination at adjudicatory proceedings be included in the references in order for the NRC to use them in addressing the court's ruling. Numerous requests and recommendations from others were also ignored. (0174-7 [Thomas, Ellen] [Thomas, Ruth])

Comment: This updated EIS needs to be written in order to for us, as a human race, to morally deal with a possible problem that can put many lives at stake. I am not saying that if this updated EIS is not signed that we fail at being humane. It just feels wrong to have this major power in our hands and not give it our best in order to make it work at the best level it can possibly perform at. As well as being morale, it's also just relatively not a good idea from a health aspect to let such potentially dangerous power go unnoticed. (0192-11 [Einhorn, Jeremy])

Comment: It is time that the NRC creates an updated EIS so that everything is up to current standards. To have an out of date EIS is pretty dangerous actually, as it probably misses a lot of potential hazards that have occurred. (0192-13 [Einhorn, Jeremy])

Comment: The more updated and more accurate this EIS is, the better chance that the community is more prepared for any situation to arise. As well as being more prepared, the community also has the chance to further educate themselves on nuclear waste, and ways to protect themselves from it. This EIS really is not just for the NRC or any company; it can majorly impact our society we live in a great way. (0192-4 [Einhorn, Jeremy])

Comment: So, not only is it beneficial for U.S. citizens to have an updated EIS, but it has the potential to greatly benefit the NRC as problems such are far less likely to occur. (0192-7 [Einhorn, Jeremy])

Comment: NEPA, established in 1969, was solely created to protect the environment we live in. Through various policies, it makes sure that what we do as a society affects the environment as little as possible. In an article written in Science magazine, the authors say that, "It [NEPA] was meant to force agencies to 'insure the integrated use of the natural and social-sciences' in planning and decision-making" (Bronstein, Baer, Bryan, DiMento, Narayan, 2005). This clearly states that it is the agencies job, in this case the NRC, to have sound research when it comes to the creating of something or planning. When it comes to the update of the EIS in regards to nuclear waste, I think it's more than obvious that sound research is needed to make this EIS as effective as possible. Going off of that, the EIS needs to be as effective as possible in order to reduce any ill effects, which is the responsibility of the NRC. This is clearly is a matter that is of grave importance and needs to be handled with delicate procedures by the NRC. I've been talking a lot about benefits for both the agency and the community if the NRC was to update the EIS in regards to nuclear waste. (0192-8 [Einhorn, Jeremy])

Comment: The Court ruling to which the NRC is responding, with this Draft GEIS, requires the NRC to examine the risks of spent fuel storage and did not allow the NRC to merely assume that storage would be safe. Instead of examining what would happen if spent fuel remained unprotected at reactor sites indefinitely the NRC assumed the spent fuel can be safely managed in service storage for an indefinite period. To this end the NRC is essentially involved in the same fallacy that rendered the Waste Confidence rule insufficient. (0244-3-2 [Hancock, Mandy])

Comment: The guidance from the Environmental Protection Agency and the Council on Environmental Quality called for a section in the Environmental Impact Statements on the alternatives to the proposed project, and the NRC has done that with this revision for the Waste Confidence Rule. I wrote a memo to the agencies suggesting that the guidance add a section on the environmental and national impacts of not going ahead with the project. Not going ahead. The Council on Environmental Quality rejected the idea, but I think the NRC should provide a clear analysis of the potential environmental impacts and the national impacts if the Waste Confidence Rule continues to be derailed. (0244-4-2 [Rossin, A. David])

Comment: The Court ruled correctly that NRC did not justify its waste confidence, which is, in a sense, allowing more nuclear waste to be created. It withdrew that confidence. It said no more should be created, unless you can really guarantee that it can be taken care of, or at least have confidence that the environmental impacts will not be significant. (0246-2-3 [D'Arrigo, Diane])

Comment: Thank you for accepting this supplemental comment. I am sorry I did not have time to make this comment during my oral comments. I was disturbed because Paul (NRC staff) indicated that NRC is not required to prepare responses to comment to finalize the EIS. This seems contrary to NEPA, and I feel cheated. (0284-15 [Borchmann, Patricia])

Comment: The environmental impact statement the Nuclear Regulatory Commission prepared for its "Waste Confidence Rule" in response to New York v. NRC fails to take the required "hard look" at the future impacts of nuclear waste at U.S. nuclear reactors, including Indian Point, which is located just 35 miles from Midtown Manhattan in New York State. (0324-1 [O'Mahony, Emily])

Comment: So, that is my sort of -- my constructive request for how the GEIS might actually gain a sense of purpose, and a sense of direction, and a sense that the NRC is actually connecting this GEIS process to the mandates that it has to protect the public health and safety, and the environment. I would have a very specific recommendation that I've made a very long time ago, and have continued to make, and that is that in 2002 and 2004, the NEPA Task Force Council on Environmental Quality created a report about modernizing NEPA implementation. And one of the things that it highly recommended was to incorporate adaptive management and monitoring strategies into these kinds of challenges, long-term challenges that we face. In Canada, their council there is using adaptive management and monitoring for their permanent storage facility, and I think that at the very barest minimum the NEPA recommendations on adaptive management and monitoring should be seriously considered by the NRC in addressing -- in this GEIS in evaluating the GEIS, and that adaptive management and monitoring guidance should be applied to precisely the timeframes that the GEIS address, which is short, long-term, and indeterminate storage. (0328-12-7 [Eide-Tollefson, Kristen])

Comment: While the EIS framework has a long history in addressing environmental impacts, it may be inappropriate for risk assessment of spent nuclear fuel hazards over decades. Thus, even the most thorough EIS could be irrelevant to the critical issues at hand. (0431-1 [Pascall, Glenn] [Watland, George])

Comment: I am writing to you to urge you to support and encourage truthful information disclosure to the American public, as well as to all relevant persons and agencies, regarding the current condition of our nuclear waste sites. We can only make wise and safe choices about our nuclear waste when we see, speak, and share what the needs are. (0432-1 [Wopat, Jeen])

Comment: Furthermore, the entire concept of a generic EIS is challenged as incompatible with the intent of the National Environmental Policy Act (NEPA). (0447-2-8 [Andrews, Richard])

Comment: The GEIS framework may not be adequate or appropriate for nuclear risk assessment. (0464-1 [Nelson, Pam])

Comment: The environmental impact statement the Nuclear Regulatory Commission prepared for its "Waste Confidence Rule" in response to New York v. NRC fails to take the required "hard look" at the future impacts of nuclear waste at U.S. nuclear reactors, including Indian Point, which is located just 35 miles from Midtown Manhattan in New York State. (0465-1 [Commenters, Multiple])

Comment: At this time the Commission does not have any legally sufficient analysis, under NEPA, that addresses the issue of the environmental impacts of spent fuel storage beyond 30 years after plant shutdown or alternatives that could be used to mitigate those impacts. In fact, the Commission has only one document that purports to comprehensively address those issues under NEPA, NUREG-0575. However, as noted above, that document only looked at the issue of spent fuel storage at reactor sites for the period up to 2000, when it assumed a permanent waste repository would be available. Further, it is outdated for a number of reasons, including ignoring what is now known to be a credible threat of a terrorist attack.¹⁷ [footnote 17 text: In the

Generic Environmental Impact Statement for License Renewal of Nuclear Plants, NUREG-1437 (1996) ("NUREG-1437") and its update NUREG-1437 Rev. 1 (June 2013) ("NUREG-1437 Rev. 1") NRC purported to look at the environmental impacts of spent fuel storage at reactor sites during plant operations but did not separately look at the question of storage at reactor sites after plant shutdown. NUREG-1437; NUREG-1437 Rev. 1 at 4-175. In addition, neither of those updates addressed the issue of environmental impacts with consideration of the information NRC Staff assembled in its non-NEPA analysis included with COMSECY-13-0300 including its conclusions that under several scenarios, spent fuel storage in dry casks would reduce environmental consequences of spent fuel storage in pools at a cost that was less than the benefits to be gained by such dry cask storage. See COMSECY-13-0300.] (0473-10-3 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: NRC's Use of "Small," "Medium," and "Large" Does Not Comport With NEPA: NEPA provides for a detailed statement of "(i) the environmental impact of the proposed action, [and] (ii) any adverse environmental effects which cannot be avoided should the proposal be implemented." 42 U.S.C. § 4332(2)(C). The NRC frames its impacts by using the vague terms of "Small," "Medium," or "Large," although neither NEPA, CEQ regulations, nor NRC regulations reference, define, or sanction the use of such terms. NRC's basis for so doing appears to be that it has done so before. DGEIS at xx ("NRC used terms in other NEPA documents... for defining the standard of significance for assessing environmental issues" and does the same here). Yet this set of terms has no relevance under NEPA, CEQ, or NRC NEPA regulations, and does not comport with NEPA's "significant impacts vs. non-significant impacts" parlance. NEPA requires the NRC to include in every recommendation or report on proposals for ... Federal actions significantly affecting the quality of the human environment, a detailed statement by the responsible official on -- (i) the environmental impact of the proposed action, (ii) any adverse environmental effects which cannot be avoided should the proposal be implemented, (iii) alternatives to the proposed action, (iv) the relationship between local short-term uses of man's environment and the maintenance and enhancement of long-term productivity, and (v) any irreversible and irretrievable commitments of resources which would be involved in the proposed action should it be implemented. 42 U.S.C. § 4332(2)(c)(i)-(v). The DGEIS does not directly relate back to this statutory scheme. NRC's Small/Medium/Large characterization does not explain what adverse environmental effects cannot be avoided should the proposal be implemented, for example, or irreversible and irretrievable commitments of resources which would be involved in the proposed action should it be implemented, nor does it provide any specific values that can be included in the ultimate cost benefit analyses that will have to be conducted for each licensing action that will rely on the final generic impact statement. (0473-10-4 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Under NEPA, the discussion of adverse effects must not improperly minimize negative side effects. *Western Watersheds Project v. Kraayenbrink*, 632 F.3d 472, 491 (9th Cir. 2011) (quoting *Earth Island Inst. v. U.S. Forest Serv.*, 442 F.3d 1147, 1159 (9th Cir. 2006), abrogated on other grounds by *Winter v. Natural Res. Def. Council, Inc.*, 555 U.S. 7 (2008)). NRC's vague analysis of impacts is particularly troubling given the D.C. Circuit's direction to NRC in the context of waste confidence that "[o]nly if the harm in question is so 'remote and speculative' as to reduce the effective probability of its occurrence to zero may the agency dispense with the consequences portion of the [NEPA] analysis." *New York v. NRC*, 681 F.3d 471, 482 (D.C. Cir. 2012). Thus, NRC cannot avoid a discussion of even "small" impacts in the DGEIS. By using the term "small," "medium," and "large," NRC is cloaking impacts in vague terms that avoid disclosing what the actual impacts are. (0473-10-5 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Moreover, for some of these impacts, NRC has no basis for even making these findings. See DGEIS at 6-56 (acknowledging that "[a]ctivities that involve bare fuel handling in a postulated dry transfer facility at nearby facilities could involve additional accident risk" but postulating that those impacts would be "Small;" without any functioning DTS facility anywhere in this country, the NRC does not have a factual basis for making this finding.) (0473-10-6 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: This is unacceptable under NEPA, and the DGEIS should be revised to include a qualitative and quantitative assessment of each impact and its significance in plain language. At a minimum, NRC must clearly set out the legal authority that supports the use of these terms, and include an explanation of what the "small," "medium," and "large" label means for each individual impact. (0473-10-7 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: As the States raised in their scoping petition, the NRC cannot defer discussion of NEPA-required information because another, yet to be completed, non- NEPA proceeding is evaluating some of those issues in the context of an AEA rulemaking. To the contrary, the Guidance makes clear that the NEPA process must be fully completed before a decision is made on the major federal action: Agencies must integrate the NEPA process into their planning at the earliest possible time to ensure that planning and decisions reflect environmental values, avoid delays later in the process, and anticipate and attempt to resolve potential issues. NEPA should not become an after-the-fact process that justifies decisions that have already been made. *** [A]n agency shall prepare an EIS so that it can inform the decisionmaking process in a timely manner "and will not be used to rationalize or justify decisions already made." CEQ Guidance, 77 Fed. Reg. at 14476-77 (footnotes and citations omitted). The "Rulemaking Revising Security Requirements for Facilities Storing SNF and HLW" contains no analysis of the environmental impacts of spent fuel, and thus cannot serve as any deterrent to the full exploration of all of those impacts here. Moreover, if the NRC wanted to rely on that rulemaking as part of the DGEIS process in these proceedings, it would have to wait for that rulemaking to be finalized before completing its environmental impact statement analysis here. (0473-11-12 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: NRC has the full authority to order expedited fuel transfer under the AEA, but is also obligated to discuss environmental impacts of this option in the context of mitigation measures or alternatives under NEPA. The expedited fuel transfer should be examined as an alternative so it can be assessed for all plants, not in an ad hoc way under the backfit or other NRC procedure.¹⁹ [footnote 19 text: Former Commission Chairman Jaczko explained the problems and uncertainties inherent in the "so-called 'backfit' regulations that allow licensed reactors to avoid compliance with new safety enhancements based on considerations like implementation costs" and the "difficulty of requiring timely compliance with new safety requirements that are not tied down in the license." Southern Nuclear Operating Co. (Vogtle Electric Generating Plant, Units 3 and 4), Dkt. Nos. 52-025-COL & 52-026-COL, Memorandum and Order, CLI-12-02 (Feb. 9, 2012) (Jaczko, dissenting).] Additionally, to the extent the DGEIS is relying upon the Spent Fuel Pool Study, it should expressly explain any such reliance. (0473-11-15 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Finally, since the Spent Fuel Pool Study has only now been finalized, a supplemental DGEIS will be now required if the NRC seeks to incorporate its conclusions in this rulemaking. (0473-11-16 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The Draft GEIS fails to demonstrate that site-specific evaluations would not result in different findings than the GEIS with respect to environmental consequences. This demonstration is required to support the decision to follow a GEIS approach with no issues identified as requiring site-specific analysis. (0473-12-1 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Also, the NRC's reliance on the future DTS licensing idea has resulted in the NRC failing to do a number of other required analyses here. For example, there is no environmental justice analysis for long term-storage because the NRC asserts that will be done as part of the DTS licensing proceedings taking place at each facility. This segmented approach fails to provide the adequate information in this DGEIS for all impacts related to the storage of waste. (0473-12-19 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The Draft GEIS only considers environmental impacts of limited storage scenarios and does not specify whether, and in what context, additional scenarios may be considered at a given site or in general. In short, while the Draft GEIS appears to conclude that site specific factors can be considered at a later time, the overall conclusion is that no such site specific analyses would be required with respect to environmental impacts of continued storage. (0473-12-3 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The IE Report identifies how the DGEIS subverts the NEPA process by failing to justify the use of a generic approach to address problems that are widely considered to be site-specific. What the DGEIS would have needed to do, but has not done, is to demonstrate that the many differences between reactor sites that bear on the environmental consequences of spent fuel storage for indefinite periods at those sites are either captured in the environmental analysis or are not sufficiently different to warrant separate treatment. As the IE Report demonstrates, the DGEIS does neither but, instead, assumes away the differences. The use of assumptions instead of analysis is not an acceptable approach under NEPA. (0473-12-4 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: In any case, studies referenced in the vacated 2010 document are years out of date. See, e.g., 75 Fed. Reg. 81037, 81053 (citing a 2001 National Academy of Science report). (0473-17-8 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Moreover, the DGEIS fails to meet the requirements of NRC's own regulations requiring it to use plain language in EISs. By referring a concerned member of the public back to an invalid federal register notice, after which the public must then find the relevant page number of that notice and then find the citations cited therein, NRC Staff unduly burden reviewers of the EIS. The NRC Inspector General has recently faulted the NRC Staff for this practice. The DGEIS should cite clearly, with as much information as possible, the source of the assertions it makes concerning the safe storage of nuclear waste in American communities. (0473-17-9 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Rather, based on the findings and analysis of the DGEIS, NRC will merely note in any site-specific environmental impact statement regarding issuance of any license or amendment to a license, that the impacts of spent fuel storage at the plant are "small" and that there are no alternatives to how the applicant/licensee proposes to store the spent fuel at the reactor site that need to be considered and no alternatives to how long the applicant/licensee proposes to store the spent fuel at the reactor site. (0473-6-2 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: On March 4, 2013, the NRC released the Waste Confidence Generic Environmental Impact Statement Scoping Process Summary Report, ML13060A128. The NRC did not propose any changes to the proposed Waste Confidence DGEIS scope based on the State Scoping Comments, nor did it provide a substantive and thorough explanation of the basis for its rejection of these comments. (0473-7-1 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The Office of the Inspector General recently took NRC to task for its failure to meet its NEPA obligations in a way that is accessible to the public. Office of the Inspector General, Nuclear Regulatory Commission, Audit Report: Audit of NRC's Compliance with 10 CFR Part 51 Relative to Environmental Impact Statements (OIG-13-A-20) (ML13232A192) (Aug. 20, 2013) ("OIG Report"). The OIG report found that NRC's NEPA documentation "does not clearly present, in an accessible way, the proposed action, alternatives, and conclusions to stakeholders" and "undermines its extensive efforts to be clear, open, and transparent." OIG Report at 12. The OIG criticized NRC's EIS documents for being "lengthy and complex" and "overwhelming to the average person." OIG Report at 7, 10-11; see also id. at 15. The OIG Report cited suggestions from stakeholders that "NRC ought to break down the information "in a common sense approach so the average person can do a quick read and learn how they may be impacted by the action." Id. at 15. The NRC has again failed to produce an EIS here that is easily amenable to public review. (0473-9-10 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The DGEIS Should Have A Scope of Issues and Alternatives At Least As Broad as NRC's Previous Generic Analysis in NUREG-0575: For over 30 years, the NRC has been struggling with whether spent fuel will ever leave reactor sites and the environmental consequences of continued onsite storage. NRC's one generic impact statement addressing these issues (NUREG- 0575) is out of date and relies on assumptions that are no longer valid. Further, it fails to include new and significant information that demonstrates that its conclusions are ill-founded. That waste confidence decision and its predecessors relied on NUREG-0575 and its findings in reaching conclusions about whether spent fuel could be safely stored at reactor sites for 30 or even 60 years after plant shutdown. As already noted, the need for the generic analysis in NUREG-0575 was the dilemma caused by the absence of an anticipated place where spent fuel would be sent - in that case for reprocessing. The cause of the problem today is the absence of a permanent waste repository but the dilemma is the same. In both cases reactors were generating spent fuel while licensees expected it would be removed from the site in a finite period of time. Now it is clear that expectation will not be met. Thus, there remains the same need for the same type of generic analysis of the environmental consequences of long term and possibly permanent spent fuel storage at reactor sites, and reservation of appropriate issues for site-specific review. (0473-9-11 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Because the "waste confidence findings" were in place for so many years, no generic or site-specific EIS since 1984, which relied substantially on NUREG-0575, has included an analysis of the environmental impacts of nuclear waste generation or storage. (0473-9-2 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The scope of the WCGEIS involves consideration of options and alternatives for storage and disposition of the national inventory of spent-fuel from the nation's fleet of operating nuclear power reactor. This constitutes a "new national program." A programmatic EIS is required to be prepared for a new national program of this scope and complexity. The purpose of a programmatic EIS (PEIS) is to identify, evaluate, and determine a national course of action.

As its name implies, the WCGEIS is a generic EIS, designed to assess generic issues common to the storage and disposal of spent fuel. The WCGEIS is NOT a programmatic EIS. Thus, NRC needs to prepare a programmatic EIS to rigorously study alternatives and develop a national path forward, and then supplement it with the WCGEIS to determine generic issues for use in preparing later tiered LR EISs. (0496-13 [Batobato, Alicia])

Comment: By limiting its generic analysis to only 60 years, the NRC bases its analysis on nothing more than hope, and therefore failed to take the hard look required by NEPA. In order to satisfy its obligations under NEPA, the NRC must either convincingly explain why 60 years is a reasonable timeframe for analysis, or expand the timeframe for analysis to a period that reasonably reflects the availability of permanent waste storage. Brushing off the inquiry as speculative or unlikely is not sufficient. "[O]ne of the functions of a NEPA statement is to indicate the extent to which environmental effects are essentially unknown.... Reasonable forecasting and speculation is thus implicit in NEPA, and we must reject any attempt by agencies to shirk their responsibilities under NEPA by labeling any and all discussion of future environmental effects as 'crystal ball inquiry.'" *Scientists' Inst. for Pub. Info., Inc. v. Atomic Energy Comm'n*, 481 F.2d 1079, 1092 (D.C. Cir. 1973); see also *N. Plains Res. Council, Inc. v. Surface Transp. Bd.*, 668 F.3d 1067, 1079 (9th Cir. 2011) (same). (0558-2 [Strell, Ethan])

Comment: Staff acknowledges that NEPA requires NRC to "analyze the impacts of continued storage at the facility until ultimate disposal for the spent fuel is available."¹⁶ [footnote 16 text: Draft GEIS at 1-4.] Nevertheless, NRC prohibited the evaluation of the environmental and safety impacts of continued storage at the proposed PFS facility. For example, because of the Commission's pronouncement in its waste confidence decision that spent fuel can be safely stored without significant environmental impact for "at least" 100 years, the NRC, Atomic Safety and Licensing Board rejected a contention that the "repository's inability to absorb the PFS stored fuel until 'at least' the last quarter of the twenty-first century increases fuel removal and decommissioning costs, extends environmental impacts, and may cause funding shortfall-related safety problems."¹⁷ [footnote 17 text: In the Matter of Private Fuel Storage, LBP-98-07 at xiii.] Continued storage impacts were not considered in the PFS evaluation. Also, as the lead agency in the preparation of the final EIS for the PFS facility, NRC restricted other cooperating agencies, such as the U.S. Bureau of Indian Affairs ("BIA") from considering environmental impacts from the ultimate disposition of the spent fuel. The PFS FEIS states "BIA's NEPA review is limited to the scope of the proposed lease negotiated between the parties, not evaluation of actions outside the lease (e.g., ultimate disposition of the SNF [or spent nuclear fuel])."¹⁸ [footnote 18 text: PFS FEIS at 1-17.] Because of the inability to address impacts from continued storage, the BIA disapproved the PFS lease agreement, in part, as a result of their concern that "years-long delays in construction of a permanent SNF repository, reflected in the Waste Confidence Decisions of the NRC, provides no firm basis to determine when and under what circumstances SNF might be taken away from trust land if the proposed ISFSI is built."¹⁹ [footnote 19 text: U.S. Bureau of Indian Affairs, Record of Decision for the Construction and Operation of an Independent Spent Fuel Storage Installation (ISFSI) on the Reservation of the Skull Valley Band of Goshute Indians (Band) in Tooele County, Utah (BIA ROD), September 7, 2006, at 19.] BIA was further concerned that the PFS EIS "fails to adequately address the impacts of transportation of SNF away from the PFS facility."²⁰ [footnote 20 text: Id. at 21.] The BIA ROD disapproving the PFS lease agreement was vacated and remanded back to BIA.²¹ [footnote 21 text: *Skull Valley Band of Goshute Indians v. Davis*, 728 F. Supp. 2d 1287 (D. Utah 2010) (holding that the Records of Decision for the U.S. Bureau of Indian Affairs and the U.S. Bureau of Land Management be vacated and remanded back to the agencies, but the court stated that the agencies could deny the lease agreement and the right-of-way requests if performed in manner consistent with the decision).] Notwithstanding that the BIA decision was

overturned, impacts from continued spent fuel storage were not addressed for the PFS facility. (0579-12 [Smith, Amanda])

Comment: Utah agrees and appreciates that the Draft GEIS states NRC will prepare a site-specific environmental analysis prior to "any future NRC licensing action."¹² [footnote 12 text: Draft GEIS at 3-10.] (0579-7 [Smith, Amanda])

Comment: Although the Preparers do indeed cite many research studies and References to support their analysis and conclusions, an Environmental Impact Statement is mandated, at least in spirit (by NEPA), to be an original and independent, fresh assessment which necessarily requires a thorough and comprehensive scoping process and a gold-standard, rigorous investigation, NOT an anemic, "B-team," copy-and-paste approach. It is no wonder, then, that the NRC's Waste Confidence Rule has been unanimously rebuked by the U.S. Federal Court of Appeals of the DC Circuit (New York v. NRC, June 2012); and, going forward, the NRC should certainly expect further legal challenges stemming from multiple states acting through the Federal Court system. (0603-14 [Schonberger, David])

Comment: The NRC's decision to conduct a Generic EIS does not meet the NEPA requirements. A GEIS cannot and does not adequately address all the various site specific issues of long term on reactor site storage on sites with differing surrounding population densities, seismic, geological and structural issues. (0611-16 [Shapiro, Susan])

Comment: The GEIS fails to consider the worst case scenario at Indian Point and therefore cannot be relied upon as a comprehensive environmental impact statement. (0611-18 [Shapiro, Susan])

Comment: Since in the GEIS the NRC arbitrary without basis considers the vast majority of impacts of thousands of tons of nuclear waste to be SMALL, this is a red flag that the NRC is not capable to taking the required hard look necessary to comply with NEPA. (0611-50 [Shapiro, Susan])

Comment: For these reasons it is equally inappropriate for the NRC staff to repeatedly describe nuclear waste management as "a small piece of the puzzle" as they have been doing. Waste Confidence is a lynch-pin, an Achilles' Heel, a show-stopper. Over time it will undoubtedly become the most expensive piece of the puzzle, by far -- not small at all. (0616-5 [Hoffman, Ace])

Comment: With respect to drafting a document that reflects the NRC's current understanding of the environmental impacts of continued storage, we see no discussion regarding the NRC's plan to update the GEIS in the future. The final GEIS published in 2014 should not be the final word on environmental impacts in the year 2174 or beyond. The final GEIS should include some discussion regarding the NRC's plan or ideas about how or whether the final GEIS would be revised or updated. It should not be left to the public to litigate an update to this important document. (0619-1-8 [Mahowald, Philip R.])

Comment: In 2013, we are no closer to having a mined geological repository for this waste than we were when the Commission denied a petition for rule making in 1977, stating that, as a matter of policy, it "... would not continue to license reactors if it did not have reasonable confidence that the wastes can and will in due course be disposed of safely" (42 FR 34391, 34393; July 5, 1977, pet. for rev. dismissed sub nom., NRDC v. NRC, 582 F.2d 166 (2d Cir. 1978)). What "due course" has since emboldened the Commission to continue permitting and expanding the capacity of pools to store high-level irradiated fuel, enabling 70,000 metric tons of

commercial high-level radioactive waste to accumulate across this country in such configurations with little, if any, attention paid to its ultimate status? The D. C. Court's 2012 finding that these pools and the temporary storage casks currently in use do pose undue risk to public health and safety does more than imply that the Commission, in effect, has not complied with the nation's own nuclear waste laws. (0620-6 [Rivera, Evelyn])

Comment: It is unclear how the updated waste confidence rule affects plants that have recently been relicensed - for example, Pilgrim was relicensed in 2012, only two weeks before the D.C. Circuit Court of Appeals ruled that the Waste Confidence Rule was unsatisfactory. Pilgrim's pool currently holds nearly four times the number of fuel assemblies than it was originally licensed for, and its ISFSI is being built - with little oversight, no apparent assessment of its vulnerability to sea level rise and other climate change effects, and before the NRC finishes addressing environmental impacts of continued spent fuel. (0622-1-2 [Vale, Karen])

Comment: The NRC does not explain how the updated waste confidence rule would affect plants that have recently been relicensed -for example, Pilgrim was relicensed in 2012, only two weeks before the D.C. Circuit Court of Appeals ruled that the Waste Confidence Rule was unsatisfactory. (0622-1-7 [Vale, Karen])

Comment: Furthermore, the NRC needs to clarify how the updated waste confidence rule would affect plants recently relicensed, such as Pilgrim. (0622-4-15 [Vale, Karen])

Comment: With respect to the effect of the Waste Confidence Decision on revoking renewed licenses, there are two classes of reactor relicensing decisions: those that were issued before the December 23, 2010 Waste Confidence Decision and those issued after that decision. The former, first issued in 2000, were issued when the 1990 Waste Confidence Decision was in effect. The latter were issued when the 2010 Waste Confidence Decision was in effect. Any reactor licensed after 2010 should be subject to the findings of the Court of Appeals that the Waste Confidence Decision is invalid and cannot form the basis for relicensing. If pending licensing and relicensing proceedings cannot result in licenses being issued, the renewed licenses after 2010 should not have been issued because those relicensings are based on a "condition[] . . . which would warrant the Commission to refuse to grant a license on an original application." The licenses renewed before December 23, 2010 are invalid because the 1990 Waste Confidence Decision suffered from the same infirmity that invalidated the 2010 decision. In fact, the 1990 Waste Confidence Decision predicted a permanent repository by 2025, a date that no one now believes is even remotely realistic. This is clearly shown by the NRC's now aborted attempt to justify on-site storage for 200 plus years. Thus, the relicensing decisions prior to the issuance of the 2010 Waste Confidence Decision were based on a false premise and those renewed licenses would be issued in violation of 42 U.S.C. § 2133(d) and 10 C.F.R. § 50.57(a)(3). (0688-14 [Taylor, Wallace])

Comment: The National Environmental Policy Act (NEPA) is the basis for the DGEIS in this case. NEPA "declares a broad national commitment to protecting and promoting environmental quality." *Robertson v. Methow Valley Citizens Council*, 490 U.S. 332, 348, 109 S.Ct. 1835 (1989). NEPA has in fact become the "basic national charter for protection of the environment." 40 C.F.R. § 1500.1. Compliance with NEPA ensures that federal agencies will consider significant environmental impacts of federal action, make available the relevant information, and open to public scrutiny their decision making process. *Churchill County v. Norton*, 276 F.3d 1060, 1072 (9th Cir. 2001). In order to comply with NEPA an agency must take a "hard look" at the environmental impacts of a project before acting. *Sierra Club v. Kimbell*, 623 F.3d 549 (8th Cir. 2010). An agency takes a hard look when it "obtains opinions from experts outside the

agency, gives careful scientific scrutiny, and responds to all legitimate concerns that are raised." *Marsh v. Oregon Natural Resources Council*, 490 U.S. 360, 377, 109 S.Ct. 1851 (1989). But the agency cannot take a hard look and then "ignore what it saw." *Audubon Soc. of Cent. Arkansas v. Dailey*, 977 F.2d 428, 436 (8th Cir. 1992). (0688-4 [Taylor, Wallace])

Comment: The draft GEIS claims that NRC did not identify any cooperating agencies and did not receive any formal requests. Yet NRC knows that DOE is charged with developing a repository and with management of hundreds of nuclear waste facilities and sites. There can be no excuse for the lack of involvement by DOE in the Waste Confidence GEIS, especially given the fact that DOE has identified close to 100 technical or data gaps associated with nuclear fuel storage and transportation. (DOE Review of Used Nuclear Fuel Storage and Transportation Technical Gap Analyses, 7/31/2012. <http://1.usa.gov/1bQr5xO>)[.] Not involving DOE is very convenient, when discussing these knowledge gaps might pose difficulties for an EIS. (0693-2-2 [Warren, Barbara])

Comment: The majority of the references in the GEIS are to NRC evaluations and assessments, in contrast to technical studies. We provided an important reference in our scoping comments that was not used for the GEIS. Of particular significance, the article was written by a team of authors, including Allison Macfarlane, the current NRC Chairperson. The entire article as well as other studies of spent fuel pools, such as the National Academy of Sciences study should have been used for the EIS analysis. (0693-2-3 [Warren, Barbara])

Comment: Page 1-23. "1.8.5 Significance of Environmental Impacts." NRDC Comment[:] As noted above, the Draft GEIS is a deficient presentation that fails a federal agency's basic duties to both define the scope of a major federal action and take a "hard look" at the significant environmental impacts associated with that action.⁴¹ [footnote 41 text: NEPA directs NRC take a "hard look" at the environmental impacts of its proposed program and compare them to alternative means of fulfilling the same purpose and need for agency action that may avoid or mitigate environmental harms or risks posed by the proposed action. "What constitutes a 'hard look' cannot be outlined with rule-like precision, but it at least encompasses a thorough investigation into the environmental impacts of an agency's action and a candid acknowledgement of the risks that those impacts entail." *Nat'l Audubon Soc. V. Dept of the Navy*, 422 F.3d 174, 185 (4th Cir. 2005).] Indeed, NEPA is clear in its well-established mandates. NEPA characterizes environmental impacts broadly to include not only ecological effects, such as physical, chemical, radiological and biological effects, but also aesthetic, historic, cultural, economic, and social effects. 40 CFR § 1508.8. NEPA requires an agency to consider both the direct effects caused by an action and any indirect effects which are reasonably foreseeable. Effects include direct effects caused by the action and occurring at the same time and place and indirect effects caused by the action, but later in time or farther removed in distance, but still reasonably foreseeable. 40 CFR § 1508.8. Rather than comply with these well-established NEPA requirements, the Draft GEIS submits a set of quantitatively baseless set of environmental conclusions (that impacts will be SMALL) about an arbitrarily and generically presented set of broad assumptions, without any integration of meaningful site specific data. While the NRC's taxonomy (small, moderate, or large impacts) for classifying and characterizing environment impacts has been established for some time, the way it has evolved in its use is inadequate and the Draft GEIS illustrates these problems. This Draft GEIS is clearly not in conformity with the agency's own NEPA regulation requiring that "the analysis for all draft environmental impact statements will, *to the fullest extent practicable, quantify* the various factors considered." Slapping vague qualitative labels on impacts is only permitted "to the extent that there are important qualitative considerations or *factors that cannot be quantified...*" 10 CFR 51.71 (d). Indeed, this Draft GEIS simply abandons any effort to quantify "the environmental

effects of the proposed action; the environmental impacts of alternatives to the proposed action; and alternatives available for reducing or avoiding adverse environmental effects," [*Id.*] because its analysis of reasonable alternatives *is entirely divorced from its consideration of* environmental consequences, which are themselves quantified in vague terms that do not conform to any reasonable interpretation of the phrase "to the fullest extent practicable." Specifically, such terms are no longer tied to any consistent set of quantitative or otherwise objectively ascertainable metrics for assessing and comparing the impacts of indefinite storage of SNF activities on groundwater or any other environmental resource, or on human health. (0706-3-17 [Fettus, Geoffrey])

Comment: In 1984 the Nuclear Regulatory Commission (NRC) issued its first 'waste confidence' decision, which claimed that permanent nuclear waste storage was technically feasible. This enabled the NRC to license and renew aging nuclear reactors without considering public concerns about the effects of extended waste storage for each individual site, given their "confidence" that a permanent repository would be found. In Wisconsin, the NRC renewed the operating license for the Kewaunee Power Station 2011, which would have extended the station's operation an additional 20 years until 2033, had it not ceased operations earlier in 2013 due to economic issues. The NRC renewed the operating license for our remaining nuclear reactors, Point Beach Unit 1, with a capacity of 512 MW, operating since 1970, until 2030; and Point Beach Unit 2, with a capacity of 514 MW, operating since 1973, until 2033. (0707-1 [Werner, Shahla M.]

Comment: There is no way to "clean up" and dispose of radioactive waste, except in a temporary manner, by keeping it densely packed in irradiated fuel pools. Dry casks are predicted to last 30-70 years, and that is as far as the nuclear industry has made plans. Why am I mentioning that at this point? Because we can't take a snapshot of one moment in time, such as is suggested with the GEIS, without ignoring that radioactive elements and isotopes will continue to decay and emit significant amounts of radiation for the half lives of the various elements which extend to thousands of years. These chain reactions go on at the subatomic level and they are ever changing. One GEIS at one point in time cannot capture the reality of how atomic and subatomic particles behave. (0708-6 [Lewison, Linda])

Comment: For these reasons it is equally inappropriate for the NRC staff to repeatedly describe nuclear waste management as "a small piece of the puzzle" as they have been doing. Waste Confidence is a lynch-pin, an Achilles' Heel, a show-stopper. Over time it will undoubtedly become the most expensive piece of the puzzle, by far -- not small at all. (0709-5 [Wythe Elnagar, Romi])

Comment: The GEIS is premature. There are many fundamental questions that have never been adequately addressed in radioactive waste management, storage and eventual isolation. NRC should use this opportunity to put resources (and time) into answering those questions rather than ignoring, dismissing, or using incomplete, out-dated, partial and in some cases inappropriate and unreliable information. It is particularly egregious that NRC has recently started studies on high burnup waste that are not complete, but it is proceeding with this EIS. See the "Questions" attachment to these comments for a partial list of questions that should be answered (and published as a resource for all) before any kind of EIS is issued. (0711-3 [Olson, Mary])

Comment: What is the significance of the levels of impact in the DGEIS (SMALL, MODERATE, LARGE)? The NRC describes the affected environment in terms of resource areas: Land use, socioeconomics, environmental justice, air quality, climate change, geology and soils, surface

water, groundwater, terrestrial resources, aquatic ecology, ecology, special status species and habitats, historic and cultural resources, noise, aesthetics, waste management, transportation and public and occupational health. Table 1 indicates the environmental impact - small, moderate or large - of these specified areas: Short-term storage, Long-term storage and Indefinite storage. "Small" is the predominant description of the environmental impact given in this table. Yet, facts have been presented regarding Indian Point that indicate "large" environmental impact" in these areas. (0762-2 [Skopic, Catherine])

Comment: While the City [Red Wing, MN] understands that the scoping decision for the Draft GEIS has been completed, there was never an opportunity to respond after the scoping decision for the Draft GEIS was finalized. In other words, while parties had an opportunity to weigh in, as the City did in its January 2, 2013, Comment Letter (which is identified as Document No: 291), there was no period or timeframe for comments after the parties comments were considered and required. While the City focuses its comments below on the scoping decision, these comments also apply to the Draft GEIS and should be considered equally with the same. (0783-1-4 [Harlan, Thomas])

Comment: The same basic position of non-compliance which started with the AEC has continued with the NRC. The approach of the Commission has become more flawed over the years. Rule-making procedures have been and go on being used to place concerns beyond NEPA reviews, such as the buildup of radioactive waste, the transport of radioactive materials, even liquids. Generic is now applied to more facilities and projects, such as the relicensing of old reactors. These are tactics to block public participation and it is going on with the issue of there not being a repository for radioactive waste by-products of the nuclear industry. (0813-1 [Thomas, Ruth])

Comment: NEPA requires that agencies take a "hard look" at the environmental consequences of major federal actions.¹⁹ [footnote 19 text: *Kleppe v. Sierra Club*, 427 U.S. 390, 410 n.21 (1985) (citation omitted).] The hard look mandated by NEPA is subject to a "rule of reason."²⁰ [footnote 20 text: *See Davis v. Latschar*, 202 F.3d 359, 368 (D.C. Cir. 2000); *San Luis Obispo Mothers for Peace v. NRC*, 751 F.2d 1287, 1300-01 (D.C. Cir. 1984), *vacated on other grounds*, 760 F.2d 1320 (D.C. Cir. 1985).] As a result, an agency's environmental review need not include all theoretically possible environmental impacts arising out of an action, but only those impacts that are shown to have some likelihood of occurring.²¹ [footnote 21 text: *See Northern States Power Co. (Prairie Island Nuclear Generating Plant, Units 1 & 2)*, ALAB-455, 7 NRC 41, 48, 49 (1978).] Thus, NEPA only requires a discussion of "reasonably foreseeable" impacts.²² [footnote 22 text: *See, e.g., Wyoming Outdoor Council, Inc. v. U.S. Forest Serv.*, 165 F.3d 43, 49 (D.C. Cir. 1999); *Sierra Club v. Marsh*, 976 F.2d 763, 767 (1st Cir. 1992).] Similarly, it is well-settled that environmental reviews need not consider "remote and speculative"²³ [footnote 23 text: *See Limerick Ecology Action v. NRC*, 869 F.2d 719, 739 (3d Cir. 1989); *Trout Unlimited v. Morton*, 509 F.2d 1276, 1283 (9th Cir. 1974).] impacts or "worst case" scenarios.²⁴ [footnote 24 text: *See Robertson v. Methow Valley Citizens Council*, 490 U.S. 332, 354 (1989); *Edwardson v. U.S. Dept. of the Interior*, 268 F.3d 781, 785 (9th Cir. 2001).] (0827-1-4 [Ginsberg, Ellen])

Comment: For these reasons it is equally inappropriate for the NRC staff to repeatedly describe nuclear waste management as "a small piece of the puzzle" as they have been doing. Waste Confidence is a lynch-pin, an Achilles' Heel, a show-stopper. Over time it will undoubtedly become the most expensive piece of the puzzle, by far --not small at all. (0856-5 [Fritz, John])

Comment: In order to comply with NEPA, the NRC must show that it has made a thorough assessment of the environmental risks of siting a repository and storing spent fuel for lengthy and perhaps indefinite periods. As discussed in the attached declarations by Dr. Arjun Makhijani, Dr. Gordon Thompson, and David Lochbaum, these impacts are significant. (0897-1-14 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Nor does the DGEIS satisfy NEPA. Even if the NRC could have made the reasonable assurance findings required by the Atomic Energy Act, the DGEIS is completely inadequate to support the licensing or re-licensing of reactors to generate spent fuel. (0897-1-6 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Therefore, the NRC has years of research to do in order to gather sufficient data regarding spent fuel degradation and transportation and handling risks. (0897-2-19 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: In Violation of NEPA and *New York v. NRC*, the DGEIS Assumes that NRC Will Continue to License Reactors to Generate Spent Fuel, and that the Proposed Rule is Unrelated to Those Decisions[.] The DGEIS also indicates that the NRC has made a pre-conceived determination that reactors *will* be licensed and re-licensed, and that the DGEIS is a mere formality. In Section 7, the NRC claims to have considered whether to include one set of physical impacts in its cost-benefit analysis, *i.e.*, the costs and benefits related to “the environmental impacts of continued storage.” DGEIS at 7-2. But the NRC explains that the DGEIS omits such an analysis because “continued storage [is] an activity that will occur regardless of the alternative that the NRC selects to consider its impacts.” DGEIS at 7-1. This assertion can only be true if the decision to allow the future generation of spent fuel is “foreordained.” *Citizens Against Burlington*, 938 F.2d at 195. Thus, the DGEIS effectively confirms that consideration of the environmental impacts of spent fuel generation will not affect reactor licensing or re-licensing decisions in any way. This is a blatant violation of NEPA and the Court’s decision in *New York v. NRC* that the NRC’s evaluation of the environmental impacts of spent fuel generation is “not separate” from licensing decisions for nuclear reactors. 681 F.3d at 476. (0897-3-12 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: THE DGEIS VIOLATES NEPA BECAUSE IT DOES NOT FULLY CONSIDER THE REASONABLY FORESEEABLE IMPACTS OF THE PROPOSED RULE (0897-3-17 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The NRC’s piecemeal and disjointed approach to the consideration of spent fuel storage and disposal impacts violates the NEPA principle that an agency may not segment its analysis in a manner that conceals the environmental significance of its action. *Taxpayers Watchdog, Inc. v. Stanley*, 819 F.2d 294, 298 (D.C. Cir. 1987) (“‘Piecemealing’ or ‘Segmentation’ allows an agency to avoid the NEPA requirement that an EIS be prepared for all major federal actions with significant impacts by dividing an overall plan into component parts, each involving action with less significant environmental effects.”). See also *Coalition on Sensible Transportation v. Dole*, 826 F.2d 60, 68 (D.C. Cir. 1987). See also *National Wildlife Federation v. Appalachian Regional Commission*, 677 F.2d 883, 890 (D.C. Cir. 1981) (“The existence of a comprehensive program with cumulative environmental effects cannot be escaped by disingenuously describing it as only an amalgamation of unrelated smaller projects.”); *Natural Resources Defense Council v. Hodel*, 865 F.2d 288, 297-98 (1988). In order to provide a true picture of the environmental impacts of pool storage of spent fuel, for example, the NRC may not divide it into smaller segments based on arbitrary time periods. And it is “simply illogical” to view the admittedly interrelated waste confidence proposed rule and DGEIS

separately from NRC's environmental impact analyses for spent fuel disposal. See *One Thousand Friends of Iowa v. Mineta*, 364 F.3d 890, 894 (8th Cir. 2004) ("A segmentation is improper when the segmented project . . . is simply illogical when viewed in isolation."). (0897-7-16 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The NRC claims that its piecemeal approach constitutes permissible "tiering." DGEIS at 1-17– 1-22.³² [footnote 32 text: 32 The CEQ regulations explain tiering as follows: A. Tiering refers to the coverage of general matters in broader environmental impact statements . . . with subsequent narrower statements or environmental analyses . . . incorporating by reference the general discussions and concentrating solely on the issues specific to the statement subsequently prepared. Tiering is appropriate when the sequence of statements or analyses is: (a) From a program, plan, or policy environmental impact statement to a program, plan, or policy statement or analysis of lesser scope or to a site specific statement or analysis. (b) From an environmental impact statement on a specific action at an early stage (such as need and site selection) to a supplement (which is preferred) or a subsequent statement or analysis at a later stage (such as environmental mitigation). Tiering in such cases is appropriate when it helps the lead agency to focus on the issues which are ripe for decision and exclude from consideration issues already decided or not yet ripe. 10 C.F.R. § 1508.28; see also 10 C.F.R. Part 51, App'x A(1)(b).] But tiering is only permissible when the cross-referenced environmental analyses are valid. Here, the NRC relies to a significant extent on Table S-3, whose basis the NRC itself has repudiated. An agency "errs when it relies on old data without showing that the data remains accurate." *Western Watersheds Project v. Abbey*, 719 F.3d 1035, 1052 (9th Cir. 2013) (citing *N. Plains Res. Council, Inc. v. Surface Transp. Bd.*, 668 F.3d 1067, 1086–87 (9th Cir.2011) (concluding that the Surface Transportation Board did not take a "hard look" at environmental impacts when it relied on ten-year-old aerial surveys)). See also 10 C.F.R. § 51.92 (requiring NRC to prepare supplemental EISs if, "[t]here are significant new circumstances or information relevant to environmental concerns and bearing on the proposed action or its impacts"); *City of Olmsted Falls, OH v. FAA*, 292 F.3d 261 (D.C. Cir 2002) (quoting *Wisconsin v. Weinberger*, 745 F.2d 412 (7th Cir. 1984)) (agency must consider new information that "provides a seriously different picture of the environmental landscape.") (0897-7-17 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: THE PROPOSED RULE AND DRAFT WASTE CONFIDENCE EIS VIOLATE NEPA BECAUSE THEY SEGMENT THE ANALYSIS OF ENVIRONMENTAL IMPACTS OF SPENT FUEL STORAGE AND DISPOSAL[.] The NRC has splintered the analysis of safety and environmental issues associated with management of spent fuel into myriad of separate subparts. This hodgepodge of regulatory provisions and environmental findings is characterized by inconsistencies, internal deficiencies, and huge analytical gaps. Although all of them are related, the NRC refuses to consider their relationship or to reform any of them. The result is that any decisions NRC makes about licensing of reactors are utterly uninformed about the environmental impacts of spent fuel storage or disposal. (0897-7-7 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: It is unacceptable for NRC to foreclose all such future challenges under NEPA, regarding the generation, storage, or disposal of irradiated nuclear fuel - one of the most hazardous materials humans have ever generated - based on such a shallow to non-existent NEPA analysis as is currently included in the WC DGEIS. NRC has abused its "Waste Confidence" Decision, Rule, and Policy in just such a way for a long time. (0919-1-4 [Kamps, Kevin])

6. Comments Concerning Public Participation

Comment: I'm calling from the state which has the most nuclear reactors and the most stored nuclear waste from those reactors of any state in the country. I just want to say I have a comment on maximizing the opportunity for public comment. With a total of three hours allowed at each of these 12 hearings for public comment, these meetings, minus the time for introductions, protocols, NRC presentations and a break, which took today over 30 minutes, the whole country has less than 30 hours total of publicly facilitated commentary time spread across the entire nation. Two of the twelve meetings, the first and the last, will have teleconference Web casting available to the public to listen and make commentary. This is not maximizing the opportunity for public comment. This is not a thorough or comprehensive process as the nuclear industry's spokesperson stated earlier, and certainly if any meetings are canceled due to the Government shutdown and not rescheduled, that would make it even worse. (0030-10-1 [Snyder, Gail])

Comment: It's my contention that the comments made at a public hearing process of any governmental hearing is an important component in community involvement and transparency that has a different but equally important role from the submission of written comments. Publicly made statements allow for the discourse on the topic to be shared in real time that facilitates immediate feedback and stimulates conversation and thought among the participants of the community. If this process were not important, all comments would be submitted in written form. So I would just like to submit to you that many people would like the opportunity to participate in all 12 of the public hearings, or public hearings that don't currently have the Web casting teleconference option available. I would like to request that the NRC facilitate all 12 meetings or as many as possible with the teleconferencing Web casting, and I don't think that a task is an unreasonable request to ask of NRC. You're already familiar with this process. I know it's not perfect, but I know you're familiar with it and I don't think it's unreasonable to request. (0030-10-2 [Snyder, Gail])

Comment: The public meetings are not being held near reactor communities with the exception of the California meetings. The public was not given enough notice for the first meetings. Those of you who have seen the GEIS, you know, we could use it for a doorstop, and it's been less than 30 days since it was submitted to the public for us to read. So I want to reproach the NRC for trying to rush this process. (0030-12-2 [March, Leslie])

Comment: I wanted to mention on the phone the other day with Waste Confidence talking about these meetings we were told that only the first and the last meeting were going to be Web cast and teleconferenced, and I think that's not democratic and it's not fair for the rest of the people in the country to hear what's going on in their communities. I also don't like the idea that after the 12 meetings are done, from what I understand, this Waste Confidence Generic Environmental Impact Statement will be finalized. And so the public won't have another chance at all to comment on any revisions or anything that's done, and I think that's really, really wrong. So really transparency isn't the real good rule here that we're going by. (0030-15-3 [Gray, Erica])

Comment: [W]e (Nuclear Energy Institute) commend the NRC for its efforts to explain the context of the current waste confidence proceeding and we encourage the Agency to continue to keep that context in mind as the process continues and we look forward to you continuing to participate in these public meetings (0030-16-7 [Bonanno, Jerry])

Comment: I'd like to start by thanking the NRC for holding this public hearing today, and particularly the hard work that the staff has done and is doing. It's been a long afternoon and I appreciate the opportunity to speak. (0030-18-1 [Curtin, Kenneth])

Comment: I'd like to first thank the NRC for this opportunity, as well as my fellow participants. It's an important discussion and one that we need to be having. (0030-20-1 [Lapiska, Evan])

Comment: I do want to say that in terms of transparency I want to thank you for the appearance of transparency, but I think it can go far, far further. I think every meeting, every hearing needs to be as today's was where the public has the ability to weigh in, even if it's just on their lunch hour. (0030-22-1 [Headington, Maureen])

Comment: I appreciate you having a light hand on the trigger here. It's actually great to hear the lively dialogue here and I think to really let the public have a chance. I think, you know, notwithstanding the complications of the sequester, I'm not surprised to see the Waste Confidence Team here. I think they've had a very thorough, professional, open, and transparent approach all the way through. (0030-23-1 [Blee, David])

Comment: We commend the agency for encouraging and embracing wide public participation through multiple avenues, allowing the agency to consider stakeholder comments from all and various viewpoints. This approach will ensure that the Waste Confidence rule and GEIS are grounded in a thorough and comprehensive record. (0030-3-1 [Ginsberg, Ellen])

Comment: The waste confidence decision has always been, and continues to be, somewhat of a confusing item. We support the NRC's efforts, therefore, to clarify the related issues. As Andy stated, from a substantive viewpoint, it is important to understand that the waste confidence issues continue -- does not constitute a licensing decision. The rule does not authorize licenses and, instead, it compromises just one element of the agency's NEPA analysis as licenses and renewed licenses are considered. Individual plants must still separately obtain a license and be reviewed for the necessary safety and environmental issues. The industry commends the staff's effort to communicate how the waste confidence fits into the broader regulatory context, and we urge you to continue doing this as you proceed through these meetings. (0030-3-4 [Ginsberg, Ellen])

Comment: I want to echo what Ellen Ginsberg said and thank the NRC for its openness in providing this opportunity. At a time where we may be questioning our faith in our government during the shutdown, this is certainly an example of how our democratic processes do work, that we do have independent agencies that do reasoned considerations of important issues such as this. (0030-6-1 [McCullum, Rod])

Comment: So, basically we will ask that the comment period be extended, since it is apparently likely -- I missed the beginning here on whether the rest of the hearings are going to take place or what the plan is for those. But we would like to have the comment period extended, since the government has shut down. (0030-8-1 [D'Arrigo, Diane])

Comment: The public meetings are not being held near reactor communities with the exception of the California meetings. The public was not given enough notice for the meetings. It has been less than 30 days since the draft EIS was submitted on September 13 by the NRC. I want to reproach the NRC for trying to rush this whole process. (0045-11-2 [March, Leslie])

Comment: I would like to thank the members of the Commission and its staff who are here today and for holding this public hearing. (0061-1 [Kirton, Kenneth])

Comment: I want to thank the Commission and its staff again for the opportunity to speak and their commitment to an open and transparent process. (0061-6 [Kirton, Kenneth])

Comment: I'm grateful that the public comment period was extended for nearly a year; however, the fact that such a brief comment period was initially proposed indicates the NRC's disregard for public involvement. (0112-11-1 [Agnew, David])

Comment: I'd like to commend the NRC on having these meetings and giving the public an opportunity, including myself, to attend and to speak on these issues and to voice our thoughts, and each of our thoughts on these issues. And I would like to also say that Chelmsford obviously is a good location for the Northeast and I think the turn out reflects that. (0112-17-1 [Stamm, Steve])

Comment: This seems -- feels like an exercise of futility because our words are really meaningless to the NRC. But I guess it's a good way to communicate with each other and vent about our frustrations. (0112-22-1 [Nestel, Hattie])

Comment: This is supposed to be a democracy in which the common citizen has a voice, but you are not listening. We need your help and not what Sally [Shaw] called your faith-based science. (0112-24-5 [Darling, Ann])

Comment: I'm also heartened to see that we have not only robust engineering, but we have robust public process. We've had a lot of energetic discussion here. A lot of strong views on both sides. That's what makes America a great country. This is part of our process. And I thank NRC for providing that. It reminds me of my favorite Winston Churchill quote. Winston Churchill once said, "Democracy is the worst system of government ever known to man except for all the others." And American democracy I think is particularly good at being at least not as bad as all the others. (0112-25-3 [McCullum, Rod])

Comment: Again, I want to thank the Commission and its staff for committing to this process and allowing an open and honest conversation about this important issue. (0122-3 [Bailey, Savannah])

Comment: It's important to have you in our community hearing from the people directly, having our comments be officially on the record. (0163-15-1 [Garner-Ritter, Maureen])

Comment: I want to thank the NRC for holding this public meeting and providing an opportunity for comments. (0163-17-4 [Schepperly, David])

Comment: This is an important discussion to be having and I applaud the NRC for taking the time to hold these public meetings and for rescheduling those affected by the shutdown. (0163-18-2 [Lapiska, Evan])

Comment: I would like to thank the members of the Commission and its staff for holding this public hearing and giving us the opportunity to share our perspective. (0163-29-2 [Bailey, Savannah])

Comment: One is that it is so rare that the public gets to voice our feelings. We're so helpless at the mercy of the government's corporate masters. Let me assure you that when the

government policy is set to benefit corporate interests, we the public lose every single time. (0163-9-1 [Gerard, Daniele])

Comment: Throughout the scoping process and the meetings and teleconferences which followed, we observed that the inputs from the public interest viewpoint rarely were acknowledged as being useful or of value to those working on developing a nuclear waste plan, even recommendations and evidence offered by knowledgeable scientists. For example, Arjun Makhijani warned against the use of Department of Energy (DOE) reports as references because DOE's work was not verified by the NRC. On the other hand, Nuclear Energy Institute (NEI) and other nuclear industry representatives received favorable acceptance (0174-6 [Thomas, Ellen] [Thomas, Ruth])

Comment: On behalf of GmP, I want to express our thanks for the opportunity to provide comments on the proposed Waste Confidence rule. GmP considers it one of the hallmarks of the US regulatory process that the NRC embraces the concept of stakeholder input, and the Waste Confidence rulemaking has been no exception. (0182-1 [Vytlačil, Gordon])

Comment: I would like to thank the NRC for engaging in public outreach, and for the opportunity to provide comments on the Waste Confidence Rule. (0201-1 [Fregonese, Vic])

Comment: Nothing I say will change this document, which might be slightly nihilistic of me but not without its truths, so do whatever you can to make that dollar stretch. Money means more than people, doesn't it? (0203-2 [Louise, Tiffany])

Comment: I was disappointed that the commissioners were not available in person to comment at the public hearing. Since their 'confidence' has been sufficient for the past 30+ years concerning nuclear safety, it would have been insightful to have asked, if they had considered their actions in those 30+ years as sufficient and prudent in the safety and welfare of the people of the United States. (0204-1 [Stein, Tami])

Comment: I would like to thank the NRC for this opportunity, and having attended a few of these meetings throughout the hearing period I applaud their efforts to allow all sides to be heard. (0212-2 [Lapiska, Evan])

Comment: One consequence of the foreshortened schedule is that it has eliminated any opportunity to participate by members of the public who live far from NRC Headquarters or have not the capability to access Internet webinars. This practice creates an artificial divide, favoring those in locations with high-speed Internet and the latest hardware and software. This is patently discriminatory and manifestly unfair. Within the context of the extant EIS process, the Commission should stop and reassess this procedure. (0222-7 [Zeller, Lou])

Comment: Public meetings for the EIS should be in every reactor community (0230-8 [Garb, James])

Comment: I commend the NRC for having these meetings to provide an opportunity for interested parties to provide comments on the Waste Confidence Draft Generic Environmental Impact Statements and the Proposed Rule. (0244-1-5 [Tulenko, James])

Comment: It is an impressive document, we urge the NRC to continue to collect comments, to respond to them. Again, I look forward to that Comment Response Document. I look forward to the rest of this process. (0244-11-14 [McCullum, Rod])

Comment: I, of course, come to these meetings to state the industry's -- one thing I must digress on. Another good aspect of this process will be that all that is said tonight and all that's been said in the previous meetings, and all that will be written and sent into NRC -- and this is why it's going to take you almost a year to complete this process after you've closed the last hearing -- will be put into something called a Comment Summary Document. I know I went through a similar process with Yucca Mountain, where they produced -- they had an Environmental Impact Statement of similar scope and produced a Comment Summary Document. I found that to be one of the most useful documents ever produced there, and I'm sure that what you guys produce will be the same. Because all of the questions that are being asked on both sides in these meetings will continue to be asked over time as we continue to safely store used nuclear fuel. And that will truly be one of the best references we can look back for the answer, so I really look forward to that. (0244-11-3 [McCullum, Rod])

Comment: Thank you for making this evening possible and allowing people from diverse backgrounds to participate in the planning process regarding nuclear waste confidence. Waste confidence revision warrants careful examination because it serves as a foundation to several key safety and environmental findings regarding the operation of nuclear power plants and the disposal of waste that they generate. (0244-14-1 [Prescott, Lisa Marie])

Comment: I would like to thank the NRC for hosting this public meeting and providing an opportunity for AABE to comment. (0244-2-5 [Knowles, Berdell])

Comment: Before I comment on the Draft Generic Environmental Impact Statement or DGEIS, I'd like to address the accessibility of this meeting location. As the gentleman mentioned in the beginning, there is not a very big turnout here. And a meeting in Atlanta, Georgia was requested by U.S. Representative Hank Johnson, which was echoed by several organizations including SACE. Despite Atlanta having 11 nuclear reactors within 170 miles compared to the 5 reactors within 250 miles of Orlando, the NRC denied the request, citing, in part, a lack of resources. This is surprising rationale considering the location of NRC's Region 2 headquarters in the city. Atlanta is also a major metro area and serves as a hub for airline and bus transportation for multiple surrounding states, which would have made it much more accessible and affordable than Orlando to organizations and residents from many reactor communities. I personally know of several people in Atlanta that were forced to travel nearly six hours to attend the Charlotte hearing on Monday. We still request an additional meeting be held in Atlanta. (0244-3-1 [Hancock, Mandy])

Comment: The NRC can't even handle a speaking list with integrity. How sad. (0244-5-1 [Klutho, Mark])

Comment: We'd first like to thank the NRC for holding this hearing and allowing us -- allowing public comment during this process. (0244-7-1 [Kuntawala, Jitesh])

Comment: We again would like to commend the U.S. Nuclear Regulatory Commission for holding this hearing and allowing us the opportunity to express our comments and concerns on Waste Confidence. (0244-7-6 [Kuntawala, Jitesh])

Comment: I wanted to first thank you, Mr. Director, and NRC staff, for taking the time, not just to hold these proceedings, but to do it all across the country and to come to a place like Florida. And hopefully today is an opportunity for you to hear a few Florida-specific pieces of input. (0244-9-1 [Paul, Jerry])

Comment: I think you heard a little bit of that from Professor James Tulenko, who talked about the work that's being done here at the University of Florida, many years of research, high-level technical analysis by technical experts like Mr. -- Professor Tulenko, people like Mr. Rossin who has a PhD in Nuclear Science with many years in the nuclear industry. And it was nice to hear from a group of undergraduate and graduate level nuclear engineering students right here from the University of Florida here in this state. I would like to point out, respectfully, that the credible, factually correct, technically correct testimony that you've heard today has largely been from those who have indeed studied these issues, have spent time at these plants, and have, quite frankly, been the ones who have spoken most directly to the issue that is on the table today. (0244-9-2 [Paul, Jerry])

Comment: People quote movies, but this one I'd like to quote, "What we have here is a failure to communicate." This NRC meeting, I can't thank you for, it's a farce. It was not publicized. I was told that they had paid to publicize this. There's many newspapers and organizations that would put it out there. (0245-17-2 [Thompson, Tammy])

Comment: I appreciate the chance to speak to the NRC's, or in the NRC's confidence game. (0245-25-1 [Lehman, Dale])

Comment: We represent nearly 900 supporters in Illinois, 34 states, and 4 countries. And we thank the Commission for allowing us three minutes of meaningful comment on a problem destined to haunt humankind for tens of thousands of years. We hope we've demonstrated that people in Illinois, while not having the original NRC list of sites for the GEIS public meeting, are indeed interested in radioactive waste issues after all. And we hope you enjoy Orlando, one of the NRC's originally proposed sites despite the turn out in what was Disney World central. (0245-3-1 [Kraft, David])

Comment: Our government works and I really am gratified not by just hearing my friends and supporters out here, but all the commentary, all the discussion. This is our process at work. This is us asking questions. I'm confident NRC will come up with the answers. I look forward and I support this process. (0245-34-6 [McCullum, Rod])

Comment: And thank you for this opportunity to speak, yet for the record I want to mention that the only way I found about this meeting was just I have friends who are in environmental organizations. So, I don't believe that this was widely announced. And the fact that there is no mainstream media here is evidence of that. (0245-43-1 [Michaud, Debra])

Comment: I want to express my gratitude that you all stuck through this this long, to have this kind of conversation to kind of explore where we're at and where we're going. I appreciate the NRC offering and inviting us to discuss. (0245-44-1 [Gallagher, Dr. Terry])

Comment: I want to thank for your comments. I hope they are heard, not just pushed aside. I don't want this to be a show. And all of you lovely people who work for the industry, I did appreciate that you would support the industry. But I think it is a statement of where we are at that almost everyone except me, one person, who has testified on behalf of this and on behalf of the NRC are with the industry. Now, that should tell us something. That should tell us that they are not speaking for the public, and that those people who are here who have spoken before me who are incredibly knowledgeable are the ones that are speaking in facts, not claims but facts. And I think that's what we should listen to. (0245-48-1 [Walter, Beverly])

Comment: I just want to address the fact that there is no mainstream media reporters here covering the story. You would think that this would be on the front page of every newspaper. We're talking about an issue that's going to affect people for perhaps hundreds of thousands of years, things that are happening right now with this conference, and yet almost nobody has known about it. And, on top of that, even though no one is getting the word out, I think it's worth noting that there is an overwhelming majority of support here from people who are against nuclear waste, concerning this nuclear issue. The only people that have really shown up here are representing the industry that they're in favor. They all have a bias because they're getting paid. There's a profit motive there. Pretty much unanimously, all the people who are not getting any money are against this proposition, I think that should be stated for the record. (0245-52-1 [Kalas, Mike])

Comment: [W]e are grateful for this and other numerous opportunities provided by the NRC for stakeholder input before making a final decision. (0246-12-1 [McMurrian, Katrina])

Comment: I appreciate that there are hearings, but there really are places that wanted hearings that didn't get them. I'm sure you have heard this before, but you did say that you thought you had accommodated and a lot of people feel like they haven't been. (0246-2-1 [D'Arrigo, Diane])

Comment: I would first like to thank the NRC for this opportunity. And having attended a few of these meetings throughout the hearing period, I applaud their effort to allow all sides to be heard. (0246-20-2 [Lapiska, Evan])

Comment: I am here today because my home state [Virginia] has been left out of conversation. It has not been in the news, it has not been in the newspapers, yet our state capital is in 50-miles radius of two aging nuclear power stations, North Anna and Surry. (0246-3-1 [Gray, Erica])

Comment: So again, I thank the NRC for running such an open forum, where we can have the free exchange of ideas, and I would encourage everyone, I think has been mentioned a couple of times here, to research all of the facts that you hear tonight, both in support of the ruling and against the ruling. (0250-14-1 [Brookhart, Ryan])

Comment: I want to thank the NRC for the opportunity tonight to provide these comments. I commend the NRC on the transparency of this rulemaking process, and I applaud your scheduling of these meetings around the country to get stakeholder feedback. (0250-15-2 [Rodack, Tom])

Comment: I'm personally disappointed that not one out of the five Commissioners could be here to see the faces of some humanity here to get a feeling of what's going on emotionally with people. I would suggest that that happen at the future activities. (0250-22-1 [Hands, Tara])

Comment: I appreciate the opportunity to provide comments this evening on the draft Waste Confidence and GEIS. I also want to commend the NRC's efforts to encourage and engage the public through a number of public meetings and other venues. Over my 30 plus years in the nuclear industry, I've witnessed the NRC's efforts to ensure public engagement and transparency, and this meeting is yet another example of that commitment. (0250-3-1 [Archie, Jeff])

Comment: I would like to thank the NRC for hosting this public meeting and providing opportunity for comments. (0250-32-5 [Wesley, Ashleigh])

Comment: This public meeting is supposed to be an important part of the Democratic system where the many voices can be heard, and much more importantly, be respected. (0250-34-3 [Sorenson, Ole])

Comment: I hope you'll hear everyone who speaks tonight with an open mind, and especially those who are coming from their own home states where nuclear waste is emitted, or is created and has been leaking into the environment. The future of our precious planet depends on what you decide to do. (0250-39-2 [Richards, Kitty Katherine])

Comment: Throughout the scoping process for the EIS and the meetings and teleconferences which followed, we observed that the inputs from the public interest viewpoint rarely were acknowledged as being useful or of value to those working on developing a nuclear waste plan, even recommendations and evidence offered by knowledgably scientists. On the other hand, Nuclear Energy Institute and other nuclear industry representatives received favorable acceptance. (0250-51-5 [Thomas, Ellen])

Comment: And please pay close attention to what everybody has to say and not just the people in the industry. (0250-51-9 [Thomas, Ellen])

Comment: I would like to thank you, the Nuclear Regulatory Commission, for undertaking this task and allowing for public comment on this issue. (0250-57-5 [Jones, Lauren])

Comment: First off, I would like to thank you all for allowing me to speak and thank you to the NRC for continuing their culture of public involvement and transparency with respect to nuclear issues. It really is a great thing for all of us to be here to talk and to listen today. (0250-58-1 [Cagnetta, Matt])

Comment: First, let me thank you for the opportunity to provide comments on the draft Waste Confidence EIS and Proposed Rule. It's a very important rulemaking on the part of the NRC. I appreciate the extent to which the NRC has gone to gather public input on it. Thank you for holding one of your public meetings in Charlotte, which is the center of a large and growing hub of energy-related industry and education here in the southeast. Nuclear power is an essential part of the energy mix in this region. (0250-6-1 [Nesbit, Steve])

Comment: I appreciate the NRC's process to allow comment on the Generic EIS and the proposed rulemaking. It is probably one of the best-run processes I know in the federal government. (0250-61-2 [Little, Jim])

Comment: The second thing is providing transparency. I think this rulemaking process does allow for that. It is very unique. It's a well-administered process by the NRC. And I think it allows all of the public, even the members of the opposition, the opportunity to provide their input and comment. (0250-61-4 [Little, Jim])

Comment: But I think first and foremost is that I think the industry is one where transparency and even listening to members of the opposition allows us I think that integrity to be able to address comments from wherever in addressing those things. So I think the ability to get that transparency and that dialogue is important. So I welcome the opportunity to provide these comments as I also welcome the opportunity to listen to the various views tonight. (0250-61-8 [Little, Jim])

Comment: And I thank the NRC for the opportunity to comment tonight on the proposed EIS, especially here in Charlotte, North Carolina. We have had a great turnout. (0250-62-1 [Fregonese, Vic])

Comment: On behalf of GmP, I wanted to express our thanks for the opportunity to provide comments on the proposed Waste Confidence Rule. GmP considers it one of the hallmarks of the U.S. regulatory process that the NRC embraces the concept of stakeholder input. And the Waste Confidence rulemaking has been no exception. (0250-65-1 [Vytlačil, Gordon])

Comment: I would like to start by highlighting that I am actually not very surprised that you have only seen people from companies in the nuclear industry speaking in favor of it tonight. This is a sophisticated technology. It is very typical for someone to have years of college education, even more years of experience to fully understand it, let alone to speak to it confidently. And it is simply something that many laymen probably wouldn't be able to do. (0250-67-1 [DeVoe, Joe])

Comment: You cannot cut the public out of these future discussions. That would be a wrong thing to do. We need to be involved in this every step of the way. (0250-7-7 [Corbett, Susan])

Comment: Thank you for coming to San Luis Obispo and soliciting comments from citizens near the Diablo Canyon Nuclear Power Plant (DCNPP.) It is important that the Nuclear Regulatory Commission hear from the people most at risk in the case of a radiation release from the plant. (0255-1 [Frank, Fred])

Comment: [T]he NRC's rulemaking process is the kind of open and transparent process that should take place in all aspects of government regulation. There has been widespread participation from all aspects of government, industry, and the public in order to ensure that all viewpoints are considered. A total of twelve public meetings will take place, and members of the public will have the opportunity to submit comments to the commission through December 20, 2013. (0273-3 [Kinzinger, Adam])

Comment: We thanks the Commission for allowing us three minutes of meaningful comment on a problem destined to haunt humankind for tens of thousands of years. We hope we have demonstrated that people in Illinois, while not on the original NRC list of sites for a DGEIS public meeting, are indeed interested in radioactive waste issues after all. (0274-1 [Kraft, David])

Comment: I thank the Commission for allowing me three minutes to speak. (0276-1 [Kurz, Carol])

Comment: Unable to stay long enough to speak, I would like to share my story with you. You are the agency that can change the world by your action—for positive or disaster. I appeal to your humanity to hear my story. (0292-1 [Comer, Gail])

Comment: I commend the Commission for holding public hearing. As a citizen with many concerns about nuclear issues, I traveled a long way, to Charlotte, NC, to express some of these to you, in relation to spent fuel waster and your assessment and plans for it. Since being unable to testify at the Charlotte hearing, I am submitting the comments, below, for the record, on these matters. (0303-1 [Lamberts, Frances])

Comment: The NRC must stop listening to and giving in to the small group of vocal Anti-Nuclear activists that keep pushing the NRC around. The NRC must take the political heat that

these people create knowing that they are indeed a small vocal minority. They will go away if they are ignored. Hear them once, answer them and then ignore them. (0312-1 [Meyer, Charles])

Comment: This public meeting is supposed to be an important part of the democratic system, where the many voices are to be heard AND more importantly respected. (0314-3 [Sorensen, Ole])

Comment: The San Clemente City Council respectfully requests your consideration of extending the public comment period for the Waste Confidence Draft Generic Environmental Impact Statement to February 28, 2014 to allow Council sufficient time to review the document. (0315-2 [Brown, Tim])

Comment: And I'm glad we're having this meeting tonight, but we wouldn't have had it if it wasn't ordered by the Court. And I think it's really important that we do this more often and with real expertise, and with a determination to solve this problem. Somewhere between unsafe storage and unsafe transportation, we're going to have to do something, and it's got to be the best answer we can come up with. (0325-1-3 [Headrick, Gary])

Comment: I appreciate the opportunity to provide oral comment here tonight on the important topic of Waste Confidence and its relationship to the continued nuclear plant licensing and operations (0325-13-1 [Wicks, Tonja])

Comment: I would like to thank the NRC for hosting this public meeting and providing the opportunity for public comments (0325-13-8 [Wicks, Tonja])

Comment: In closing, I would like to thank the Commission for holding these public hearings to discuss such an important issue (0325-16-5 [Bailey, Savannah])

Comment: [T]onight, in my opinion, is a dog and pony dance because it has nothing to do with establishing any confidence. (0325-21-3 [Iwane, Cathy])

Comment: One of the things that I hope to happen this evening is that the folks that have come here from Washington have learned what our concerns are. The reason I say that is we're here to help with rulemaking and adjudication. Is that what this is about? (0325-24-1 [Kernahan, Gary])

Comment: We're interested that whatever that [our concerns] means, it conveys for us the significance of facing clearly from our point of view they can see it, how the people in the communities around here are jeopardized, how we are concerned, and it isn't about changing rulemaking or helping giving better clues about adjudication. (0325-24-2 [Kernahan, Gary])

Comment: I appreciate the opportunity to participate in this public meeting and share my thoughts with some of those who are responsible for regulating the nuclear safety here in the United States. (0325-26-1 [Hannaman, Bill])

Comment: There's two words tonight that stand out. The first one is confidence, and there's one thing about this meeting which gives me confidence, and that's the fact that someone from Senator Feinstein's office is here tonight. Thank you for that. And I would like to know is there a representative -- from Congressman Issa's office here tonight? Please raise your hand. Is the NRC in touch with Congressman Issa? It's under his jurisdiction, this area. To my knowledge, he has not had any impact at all on this whole process. Have you people been meeting with him? Why not? What is his position? Why hasn't he said anything? (0325-31-1 [Johnson, Roger])

Comment: So, thank you for listening. I appreciate it. It's nice to listen to everybody else[.] (0325-32-5 [Lord, Stephen])

Comment: I want to start by thanking everybody here tonight, including the NRC, for both coming out to this meeting and hosting this meeting. (0325-5-1 [Kirton, Stratton])

Comment: We will be following up, I know, with the NRC Commission itself. They have been very responsive in the past to our concerns, including Chairperson McFarland, so we hope to be able to bring this back up to your Board of Supervisors in the coming months as well. So my letter is in, the Board's letter is forthcoming, and again, I appreciate everybody being here tonight. (0326-1-3 [Hill, Adam])

Comment: I appreciate the NRC holding this meeting and allowing a very vigorous discussion on this issue. (0326-18-2 [Schrader, Ken])

Comment: Thank you, all, for taking your time this evening to join us in the opportunity to speak out about something that is really not very sensible. (0326-22-1 [Davies, Phyllis])

Comment: Thank you, NRC. Thank you very much for having us here. I respect everybody's opinion. I don't think there's anybody here who has ulterior motives. Everybody's sincere, whether they're pro or con, so, you know, our media kind of teaches us nowadays to distrust the next person; the next race; the next gender. You know, I trust everybody. I think everybody is very sincere. (0326-24-1 [Gloege, William])

Comment: In closing, I would like to thank the Commission for holding these public hearings to discuss such an important issue. (0326-25-5 [Bailey, Savannah])

Comment: Thank you, NRC, for coming this evening and spending some time here with us that live with this nuclear plant. (0326-35-1 [Owen, Linde])

Comment: I first wanted to thank the NRC staff. I know the rulemaking process is a lot like sausage making, and, you know, really respect you coming out and hearing everybody's point of view tonight. (0326-37-1 [Rethmeier, Blain])

Comment: I very much appreciated hearing everyone's thinking. This is one of the most exciting things about living in our country, that we still can voice our strong thinking and our passionate thinking about any side of an argument. I'm speaking tonight as a concerned citizen, a parent, a grandparent, a retired educator, and a taxpayer. (0326-39-1 [Weissglass, Theresa])

Comment: There's a lot of suits here taking our testimony because they have to. They're very well paid by us. The fleet of PG&E lawyers that come to every NRSE meeting are ultimately paid for by us against our couple of attorneys. And I just mainly want to say tonight that I am in full support of our legal interveners, the Mothers for Peace, who have for over 40 years, represented us in trying to protect our best interests, the people of this state, and not private commercial interests. (0326-50-2 [Evans, Pete])

Comment: And I hope that you folks that are here to listen to us will put that foremost in your mind and heed the words of the two Americans who spoke tonight and many of the immigrants who spoke, raising the alarm of the legitimacy, validity and safety of this plant and especially our atrocious treatment of the waste storage problem. (0326-50-3 [Evans, Pete])

Comment: I wanted to start by thanking the NRC and PG&E for holding this meeting. And I know it's not easy to have a bunch of hecklers but we're all passionate here for a reason. So I would also encourage environmentalists to be as polite as they can when engaging people they feel are their enemies. I worked for an environmental non-profit and I found that we were the most successful when we all came to the table and focused on our goals. And that's when we were able to be successful and actually achieve those goals. So I would also invite-- like to invite people who do not like having Diablo nuclear power plant in their backyards to, on a regular basis, visualize it being decommissioned. Think about the positive. What do you want to happen, not what do you hope never happens. (0326-60-1 [Spooner, Rena])

Comment: Oh, this is really important. Because an accident could affect the entire Pacific Rim I recommend that the NRC invite the entire Pacific Rim, and I'm dead serious. I know it sounds silly, but to engage in this dialogue as well whenever you have this type of review because it really does affect them. What happened in Japan is going to affect us. And so they never asked us if we wanted, you know, that thing over there. (0326-60-6 [Spooner, Rena])

Comment: Just to kind of wind this up, I wish I had more time. One thing I might suggest, if this happens in the future, I think at each location that's chosen for public comment there should be two days of public comment, just a suggestion. (0327-11-7 [Kline, Connie])

Comment: I have several things to say. One of them is, this is an absurd site to have a public hearing. It's nearly half a mile from the nearest right-of-way. There were 30 people or so who attempted to express themselves with their feet, with their presence, but they couldn't make a very effective message because it's a half mile away. It's sort of like having NRC hearings at Camp Perry, which is also very quite commonplace. (0327-13-1 [Lodge, Terry])

Comment: Many of us feel these hearings are a waste of our time. We do not have confidence that the NRC is listening. (0327-3-1 [Todd, Doug])

Comment: Well, in any case, what can we do? We can talk here. We can write to our congresspeople, who seem to be the ones that are supposed to make the laws by which the agencies are invented, and we can write them over, and over, and over, and over again and demand answers, real answers. (0327-33-3 [Carey, Corinne])

Comment: In conclusion, we need to always be concerned about the stakeholders. Stakeholders, not only those that are active that's showing up to these meetings or those that get paid to be here. Many of us were not. We have to be understanding that stakeholders are those that will be with us now and those in the major future. So any policy, we must always be thinking about the short, the long, and then, I'm sorry to say, the indefinite because we do not have the technological whereabouts to look beyond two years when we can't even get a healthcare.gov working, okay? (0327-38-3 [Stansberry, Mark])

Comment: According to the NRC, Davis-Besse has been the source of two of the top five most dangerous nuclear incidents in the United States since 1979. When I read in the Toledo Blade that the NRC is asking the public what to do about spent nuclear waste, I laughed out loud. Perhaps we should be flattered we're being asked what our opinion is. We're not flattered, we're angry. Is this akin to NASA asking the public the best way to get astronauts back safely from a space mission? Should this problem have been figured out before the first plant was ever built? (0327-42-1 [Faris, Kelly])

Comment: I guess the first thing I got to talk about is a long time ago when I was, like, 18 or so, my grandfather told me, he said, you know, if you ever stand up before a commission, stand up before a city council, some type of hearing or something, or even for a judge, he says the decision is already probably made. And, you know, I tried to prove him a liar for many, many years. It's been a long time, and what I found is that he was right. So right now, as far as the agency here, I'm asking you to prove him a liar. (0327-44-1 [Chavez, Tim])

Comment: But this hearing here tonight is about sorting out the laws and/or making new laws. I hope it's also about protecting the future, making good on the NRC logo that states they are promoting, protecting the people and the environment. I have lived through the Fermi 1 meltdown, Three Mile Island, Chernobyl, and now Fukushima which is not over yet, so I try to educate myself on the dangers of living near a possible Fukushima-type accident. I say try because most of the information I review is labeled proprietary and not available for me to review. (0327-5-2 [Collins, Jessie Pauline])

Comment: We want to take this opportunity to thank the NRC for scheduling this meeting in Minnesota to take comments for the Waste Confidence Draft Generic Environmental Impact Statement. (0328-1-1 [Johnson, Ron])

Comment: The Prairie Island Indian Community appreciates the opportunity to be here tonight. We do have some additional comments to make, and will submit additional written comments during the comment period. (0328-1-11 [Johnson, Ron])

Comment: There are probably others waiting to talk, but I do have a procedural question. You've identified December 20th as the end of the public comment period. Could we have some assurance the transcript of this meeting will be available, say a week before that deadline, so that use could be made of it in preparing supplemental comments? (0328-11-7 [Muller, Alan])

Comment: This is an unfair, unconstitutional, outrageous hearing, but I do appreciate the chance to be here and give my testimony. (0328-15-6 [Davis, Leslie])

Comment: Everybody that's not here, and all of Minneapolis, and all of Minnesota, and all of the United States, and all around the world, everybody that is not here has a right to be represented. (0328-16-4 [Bonniwell, Colleen])

Comment: I have a question, actually, for many of the people here in this group, here in this room. How many of us here have any faith at all in this process, that process being where we come here, come to a little public forum and we pretend that you hear us, governmental officials, and you get to pretend that you're listening to us. This is much like, for example, the Public Utility Commission's hearings going on in St. Paul on the Enbridge XL Tar Sands Pipeline, Clipper number 67 going through Norton, Minnesota, or in Dade, Governor Dayton's little environmental roundtable discussions, which was going on about six, seven months ago. All of this, all of this is a sham. It is a complete sham. We know you don't give a shit what we say. We know that you don't care what our views are. (0328-17-4 [Cavlan, Michael])

Comment: I would like to thank you, the representatives of the NRC, for being here tonight and affording the city and other interested parties the opportunity to publically state certain comments and concerns that we have with respect to the Generic Environmental Impact Statement. (0328-2-1 [Rauterkus, Ralph])

Comment: I'd like to thank the NRC for providing the opportunity for the public to comment during this process. (0328-8-1 [Cummings, Kristopher])

Comment: I want to thank the NRC for having provided these forums, the 13 public meetings and this call. (0329-10-1 [McCullum, Rod])

Comment: There have been a number of parties that have asked for an extension for the comments deadline and, to my knowledge, nobody has received an answer to that. There was a statement made that there would be comments allowed 30 days after the last meeting, at the very least. Well, the last meeting was December 4th, and then there's this meeting. So I ask that there be a decision and that we be informed about that. (0329-14-2 [Sondheim, Steven])

Comment: The first one is an agreement with Steven Sondheim to extend the public commentary period for these hearings, that the GEIS is highly flawed and I believe that we should be having these public commentary, this public commentary period until the NRC has satisfied all that the public needs to have confidence in the NRC, which we clearly do not have, to proceed with what to do with storing high-level or low-level radioactive waste. (0329-15-1 [Star, Priscilla])

Comment: I've been listening lately, up in Canada they're having hearings on a waste dump that's going to be maybe created just off of the Great Lakes, and these have been going on for, literally, months and they go on, you know, I don't attend them every day. They're on the internet. They go on for hours and hours, and the people that want to talk, like here we've been given the opportunity to talk for more than three minutes. I probably won't do that, but they're allowed to talk for as much as 30 minutes. And then after that there's rebuttal, and then there's rebuttal to answer the rebuttal. It can go on quite a bit. And then the commissioners ask questions, and everybody talks with everybody. It's pretty different from what we're doing here, which is a couple of hours a week for a couple of months, and then it's over. After today, it's over. So I'd like to see more interaction between them and we. I think that would be a good thing. And what's really funny, I guess, is that they're discussing a low-level waste dump, which means we're discussing something that's perhaps a million times more important than what they're discussing and, yet, they're putting more time into it than we are. And I think that's a shame. (0329-16-1 [Hoffman, Ace])

Comment: And the first thing I would like to talk about is those meetings themselves. I think that the NRC did a disservice to the public by holding those meetings in very inaccessible locations. They were mostly in suburbs or away from public transportation. A lot of the people I know that wanted to comment or wanted to show up in person had to try to arrange carpools. A lot of the people do not have cars or just were very inaccessible. They were at very expensive hotels, people that were coming from out of town. They were very inconvenient places to have them. (0329-18-1 [Carberry, Mike])

Comment: Also, I don't believe all of the locations selected were opportune places. I think they should have had some meetings in Georgia or a meeting in Georgia, also in the TVA area. (0329-18-2 [Carberry, Mike])

Comment: [T]here is a general sense of noblesse oblige by the Nuclear Regulatory Commission to listen and basically just pass on the comments without doing much more than that. I'm concerned that the times that you have had these meetings, listening and acting wholly transparent in some way that you believe that you are, is the opposite and a very opaque method being used to move on and do what you want to do without really fully canvassing the

public as to what the public would like to see you do. And it's the process that seems to stink like the hole in the head process, like we're kind of absorbing all that you're doing in rapid speed, but we don't accept it. If you had town hall meetings, which I'm sure would be highly improbable, I think everybody in the country would be understanding these issues better. Most of the people don't have the time to pay attention to them, just get their paychecks. (0329-21-1 [Star, Priscilla])

Comment: I just want to say before I start that I agree with Priscilla [Star] and with Mike Carberry that this process, although you may mean well, is essentially demeaning to the public. Giving us three-minute limits for such remarks is in itself demeaning. And all of the other points that Mike and Priscilla made about the process I would certainly concur with. (0329-23-1 [Lewison, Linda])

Comment: And so another definition of confidence is actually when it's talking about a scam. And that is "or relating or involving a swindle or a fraud, a confidence scheme, a confidence trickster." I believe this whole waste confidence issue in these hearings has been kind of a waste confidence con and a swindle. And the people are really tired of it. And I really think that things need to change. I think the Congress needs to step up. The people need to step up. We are trying to speak up. I don't think we've had a very good opportunity. I mean, I get three more minutes, but, you know, we should have been allowed a lot more time. The time of the written should be extended. We had a month of government shutdown. We had just a lot of, you know, bait and switch, shell game-type tactics that have made this whole process just very unpalatable. So, again, I thank you for my additional three minutes, but it's really not enough. (0329-31-4 [Carberry, Mike])

Comment: I would like to first comment that I have been trying to get on the line for about 25 minutes. And I pressed *1 probably a dozen times. And I hung up and called back. So your system is not perfect is what I am saying. And there may be other people who have experienced the same problem because it's not going through for some reason. So that is my first comment. (0329-32-1 [Seeley, Linda])

Comment: I know I sound snarky, but I don't mean to be snarky. I mean to be outraged, concerned, feeling helpless against an institution that is deaf to the logical and sensible and practical and hard-fought lessons that we have been trying to tell you all over this country in your 12 public meetings. As I said before, I am hopeless that it will do any good. But there is nothing else that we can do as citizens. And so that is why we're doing this because this is our venue. And if I could fall on the ground in front of you and beg you and think that that would make a difference, I would do that. I would do whatever I could do and will do whatever I can do in my life as long as I live to try to help you understand what you are doing to this Earth that we are all inhabiting together. And you are the only ones who have the power to do anything about it. And so that is why. That is why we spend our nights and our days not getting paid, not getting rewarded, but for the sake of our world is why we're doing this. And so, you know, I wish I had a magic word that would go into your brain that would go ping and you would suddenly wake up and look at it through our eyes. I know that won't happen, but I want you to hear the words. (0329-32-8 [Seeley, Linda])

Comment: I would like to reiterate our disappointment that a public meeting was not held in Atlanta, Georgia. A meeting in Atlanta was requested by U.S. Representative Hank Johnson and was supported by several organizations, including SACE. Despite Atlanta having 11 nuclear reactors within 170 miles, compared to the five reactors within 250 miles of Orlando, the NRC denied the request, citing, in part, a lack of resources. Yet, Atlanta is NRC's Region II

Headquarters. Atlanta is also a major metro area and serves as a hub for airline and bus transportation for multiple surrounding states, which would have made it far more accessible and affordable than Orlando to organizations and residents from many reactor communities. People in Atlanta were forced to travel nearly 6 hours to attend the Charlotte, North Carolina hearing. And for NRC staff that attending the Orlando meeting, you are well aware that the participation was very low in Orlando in comparison to the other public meeting locations. Just a couple dozen of people attended. Members of the public living in the TVA region, among other utility service territories, were offered, essentially, no reasonable opportunity to attend an in-person meeting. The NRC should have held more meetings in more locations across the country. (0329-5-1 [Barczak, Sara])

Comment: Thank you for this opportunity to comment and thank you for running a very professional meeting on December 2nd, 2013 in Perrysburg, Ohio. I attended the December 2nd, 2013 Perrysburg, OH public comment period on NRC Nuclear waste confidence and was taken aback by the passion in the room, not on the issue of nuclear waste, but upon the issue of nuclear energy generation. I assumed I was there to comment upon nuclear waste and not to argue the merits of nuclear energy production. (0347-1 [Morrow, Jon Paul])

Comment: Nuclear waste, is deadly, and is toxic, and should be handled and stored with the greatest of respect. With that being said, the public has a lot of passion about the issue of nuclear waste and of nuclear energy, and this passion is built upon personal perception. No thought out solutions to our energy problems were submitted and no respect was given to the problems America would face without nuclear energy. One side dominated the discussion and that was the flavor of capitalism and personal profit motive were destroying the American dream. (0347-2 [Morrow, Jon Paul])

Comment: But, the hearing here tonight is about sorting out the laws and/or making new laws. I hope it is also about protecting the future, making good on the NRC logo stating they are protecting the people and the environment. I have lived through the Fermi 1 meltdown; the Three Mile Island, Chernobyl, and now Fukushima which is not over yet. And so I try to educate myself about the dangers of living near a possible Fukushima type accident. I say try because much of the information I review is labeled proprietary and not available for me to review. I certainly hope the officials here have full review of documents, proprietary or not. (0349-2 [Collins, Jessie Pauline])

Comment: Will the Commission provide an adequate comment period after the issuance of relevant reports referred to in the above email concerning the actions before the Advisory Committee on Reactor Safeguards? (0376-4 [Lewis, Marvin])

Comment: Instead of wanting to protect our air, water, earth, all living things from the obvious dangers of the nuclear industry, I felt the NRC was protecting the nuclear industry from the citizens most vulnerable to the problems it poses. I found a group of very intelligent, conscious, knowledgeable, and rightfully concerned, fearful and angry citizens "talking to the wall". There was no evidence whatsoever to me that those representing the NRC listened or heard or cared to hear what these people had to say. (0381-3 [Fasten, Susan])

Comment: Thank you for giving me the opportunity to comment on this proposed regulatory action. I hope you will read these comments carefully, objectively and with the constructive spirit in which they are meant and then address these concerns and issues in your final report. (0410-33 [Nelson, Dennis])

Comment: After studying the issue, I believe that the proposed rule for handling/unhandling nuclear waste is invalid. It is vague, and it leaves the public out of the process. The NRC should continue to have public meetings where the public can address concerns. (0416-1 [Barnes, Kathryn])

Comment: The nuclear industry and the regulatory agency, the NRC, must act responsibly and not write themselves out of the issue, nor should they end public involvement in solutions. (0416-3 [Barnes, Kathryn])

Comment: I am grateful that the public comment period was extended for nearly a year. However the fact that such a brief comment period was initially proposed indicates the NRC's disregard for public involvement. (0419-1 [Agnew, David])

Comment: I completely agree with Ace Hoffman's email [requesting that NRC make all Waste Confidence public meetings available by audio and/or video]. (0420-1 [Rudolph, Shannon])

Comment: Thank you for the opportunity to speak at the Perrysburg, Ohio meeting on 12/2/2013. Because of the three-minute time constraint I appreciate your considering the more detailed explanation of my concerns in written form. (0421-1 [Clemons, Victoria])

Comment: SUGGESTIONS ON WAYS THE NRC CAN IMPROVE ITS PUBLIC MEETINGS [:] Acknowledge that we are all in this together. (0445-1 [Fasten, Susan])

Comment: Respect what attendees have to say and include their requests, fears, and concerns in your "regulating". These people live in close proximity to nuclear facilities. Their lives, families, homes, and communities are in constant jeopardy. They are your best and most invested source for the corrections, precautions, and actions needed. Treating the critics of the present nuclear situation with arrogance, dismissiveness, and a smug air of superiority is not constructive or smart. Nor is paying more attention to the length of their comments than to the content. These caring, dedicated, knowledgeable people have nothing to gain politically or financially, no job to protect, no superiors to impress or answer to, and no ego to feed. They spend their own time and money preparing for and travelling to these meetings and speaking up because they understand that their lives and all of our lives as well as the lives of generations to come are on the line. Why do the NRC representatives and the drafters of the GEIS not seem to get it? (0445-4 [Fasten, Susan])

Comment: Earn the "confidence" label. Invite, incorporate, and embrace these very knowledgeable, dedicated, and concerned citizens in your decisions and actions. Remember that we are all in this together. (0445-6 [Fasten, Susan])

Comment: I have long advocated for NRC to embrace the use of plain language in its regulatory products. I worked very hard to that end while employed at the NRC. This proposal is a credible effort in that direction. I strongly support any and all efforts on the part of NRC to communicate with the public, the regulated community and the U.S. Congress in plain language. (0532-15 [Kotra, Janet])

Comment: NRC's commitment to providing extensive opportunities for public participation in its decision-making process has been a model of openness and transparency. (0535-3 [Damratoski, Katie] [Thornton, Adam])

Comment: Thank you for giving me, as a citizen of the United States of America, the opportunity to comment on this important issue. I would have gone to the meeting in Minnesota

to make my comments in person, but the road conditions that evening were bad. (0543-1 [Senkiw, Sheryl])

Comment: During the protocol portion of the Waste (No-)Confidence proceedings, which are scheduled to start October 1st, I (and others) repeat asked for the ability to view, and participate in all the hearings which are to be held nationally. Webcast, phone-in, webinar -- all have been denied. So at the last Waste (No-)Confidence protocol phone-in earlier this week, instead of asking yet again for one of these things, I commented instead on the SCOPE of the Waste (No-)Confidence decisions being considered. That comment was also denied but in a different way: I was told it would be a good comment to submit during the Waste (No-)Confidence comment period, which began the next day. I therefore am submitting those comments, as suggested. As it turns out, I had thought to record the comment with my smartphone at the last moment, so I can submit it not only word-for-word, but inflection-for-inflection by submitting it as an audio recording. But inflection also only carries part of the meaning. There's still nothing to see. That is why NRC is required to meet in the same room with the ratepayers, advocates, concerned citizens, and other interested parties and stakeholders in their decisions. That is why the NRC is required to come out to the local communities. (0561-1 [Hoffman, Ace])

Comment: Visual accompaniment -- either of the speaker or of the speaker's presentations (slides, videos, etc.) -is another important part of communication. Therefore I took the recording of the comments I made at the Waste (No-)Confidence protocol phone-in, which I was told should be submitted during the comment period, and added visual aids to further explain what I'm talking about. That video has been uploaded to You-Tube and is available here: <http://youtu.be/P6zqHtGZ-N4>. The audio is uncut and unedited, and runs under two minutes. I would like this video to be played at the opening hearing to be held October 1st, 2013 at the central NRC headquarters in Maryland. Additionally, if possible, it would be very convenient if my time to speak is scheduled fairly accurately for that hearing, because the California Public Utilities Commission is holding a hearing locally (in San Diego, 30 miles from my home) the same day, about decommissioning San Onofre. I would like to speak at both hearings if I can arrange it, since the topics are tightly intertwined. I will probably end up listening to and watching the Waste (No-)Confidence proceedings with earbuds on my smartphone while physically at the other hearing, paying as close attention to it as possible with my other ear. If my 4G connection fails so I am unable to speak, at least the video could be played. If I have a live connection, as I expect to have, then I hope I could also add a minute or two of additional commentary such as responding to the NRC staffer's additional comment that I should take a look at page 4 -79 of the recently-published Waste Confidence document, which I have since done, and which was not enlightening in any way. (0561-2 [Hoffman, Ace])

Comment: Why can't the Nuclear Regulatory Commission set up some form of Internet bi-directional connection for EACH of the dozen Waste (No-)Confidence meetings around the nation? Of course you don't want to be loaded up with the same people "preaching to the choir" over and over again -- but there are ways to avoid that. So why not transmit the audio and video and have a live audio/video chat line or at least a typed questions column? It's something that literally tens of thousands of other organizations (and you too, probably) do every day. So why not for these vitally-important, judicially-mandated proceedings? After all, this is 2013. NRC needs to get real about the technological challenges it faces regarding nuclear waste. NRC should also get real about the technological marvels that are available in the real world to help them follow their mandates: To protect the world from radioactive accidents (best done by switching to solar power), to properly inform the public of their regulatory decisions, and to allow the public to take part in formulating our national nuclear policies. Those policies have been irrational for too long. Not allowing ALL of the public to witness and be a part of ALL of these

historic "65-years-of-failure" Waste (No-) Confidence proceedings is a criminal act of denial -of- service. Even to drive 50 miles round trip these days can be a significant expense for a struggling household. A nuclear accident can easily affect 100s of miles around. Roughly 80% of the population of the United States lives that close to a nuclear power plant, nuclear infrastructure (such as a fuel fabrication facility) or transportation route for nuclear waste. NRC's "Waste (No-)Confidence" decisions affect everybody. Everybody should have a right and an opportunity to participate. In fact, the hearings -- sorry, meetings -- should allow people to speak for far more than the usual three minutes if they need too. I would like to also submit the following video, called "THE PHYSICS OF SPENT NUCLEAR FUEL" which we made from a live Internet chat I did a couple of months ago: <http://youtu.be/xfVx-UysJol>. It's a 31 1/2 minute video, but if there's a more appropriate kickoff to explain to interested parties what the issues are regarding "Waste (No-)Confidence" I haven't seen it, which is why we made it. The team that created these videos (myself and my buddies) would be happy to go to EACH of the NRC's "Waste (No-)Confidence" meetings and ensure that some form of live transmission occurs. We would also record the meetings in HD. We could live-broadcast all the proceedings for the NRC -unforeseeable technological hurdles notwithstanding (unlike nuclear power operators, we are realists). For financial reasons of course, it would be impractical for us to do so without compensation for travel, time and expenses, but the public would undoubtedly appreciate the money being spent so they could see and even participate in the proceedings live as they occur. NRC should already know the public wants this, based on the many comments requesting Internet access that were made during the protocol phone-ins. I'm sure, however, if NRC was willing to pay for it, they could ensure that each hearing is broadcast on their own, without our help. Most universities these days can do it from any classroom, for instance. I'm sure NRC could do it too, if they tried. (0561-3 [Hoffman, Ace])

Comment: Hearings on the Nuclear Regulatory Commission's proposed Generic Environment Impact Statement (GEIS) for nuclear waste were held nationally over the past few months and attended by more than 1400 people. The comment period (for written comments) for "NRC NUREG-2157" ends December 20th. In California, about 150 people attended a hearing in Carlsbad, and over 200 attended the San Luis Obispo meeting. Tonight in San Clemente, citizens will ask their city council to request an extension of the comment period. (0562-1 [Hoffman, Ace])

Comment: Let me first begin by saying I attended the Waste Confidence meeting the NRC held on December 2, 2013 in Perrysburg, Ohio and I was quite disappointed. The moderator said oral comments would be taken based upon the initial sign-up of the speaker. I signed up months ago to speak at the initial hearing (In October, prior to postponement due to the government shutdown), yet I wasn't called on until after individuals who signed up at the hearing. Unfortunately, due to the latest of the hour (after 10:00 PM) and the fact I had a three hour drive, I left before being called on to give my below listed presentation. (0578-1 [Blackburn, Lee])

Comment: I appreciate the opportunity to provide oral comment on the important topic of waste confidence and its relationship to continued nuclear plant licensing and operations. (0598-1 [Wicks, Tonja])

Comment: I would like to thank the NRC for hosting this public meeting and providing an opportunity for comments. (0598-8 [Wicks, Tonja])

Comment: Re: Scoping Process and DGEIS review; To the best of my knowledge, the vast majority of participants who attended or spoke at the NRC's public comment meetings,

sessions, forums and national teleconference agreed that the NRC has "stacked the deck" to prevent an honest, holistic and comprehensive debate and discussion of the DGEIS. Note the brilliantly devious and clever evasion on page xxvi, lines 12 - 25 of the DGEIS Executive Summary. Throughout the process, the NRC has narrowed the scope and parameters of discussion to such a degree that any reasonable and serious alternative to the NRC's proposal is automatically and summarily dismissed, rejected and disallowed for further consideration, thus cutting off debate and effectively giving the NRC's proposal a "rubber stamp" of approval. Nevertheless, the overwhelming reaction of the public proves that Abe Lincoln was entirely correct when he famously stated: ". . . you cannot fool all of the people all of the time." (0603-21 [Schonberger, David])

Comment: Just because a human being is in science, it does not prevent hubris. And that is what I saw in the young Exelon engineers at the hearing. Faith in science can be erroneous. I was frightened to see how sure the young engineers of Exelon seemed to truly believe that they knew everything that they needed to know about nuclear safety. At the end of the meeting in Oak Brook, a woman testified as to her fear and despair at trying to find out more information when the millions of gallons of radioactive water was released into the Kankakee River. As she spoke, the young engineers of Exelon--what did they do? They laughed at her and mocked her. Truly, that was a shocking moment to me. These young engineers, who are so sure of themselves, I question their character and their judgment. Can such people who jeer at a woman seeking information regarding a terrible nuclear event--are they truly concerned about all the far-reaching consequences of our nuclear energy plan? Can they really care about safety if they are so callous? Even if these young engineers of Exelon may not all be hubristic, did any of them challenge their peers to truly address the process issue of what happened at Braidwood? Was there any discipline applied, any sanctions internally to the appalling behavior of the young engineers? (0612-5 [Takarabe, Tamae])

Comment: I point out that I cannot present Chairman MacFarlane's exact words as the transcript of that meeting is not available yet. This is a further reason to extend the comment period past today. (0615-2 [Lewis, Marvin])

Comment: I've shared several thoughts, mostly questions, because the truth is, as I am sure you are well aware of, my voice means very little in the construct of a rule on nuclear waste management. I'm just an average Stakeholder. As mom, private citizen, an enthusiast in all things nuclear and its connection to our exploration in space, I merely have an interest in healthy life on earth to make all the but I really do not know anything that you do not already know and I am sure you have your own well-informed perception on the issue of nuclear waste management and, as is the subject of this dialogue, confidence in the ability to manage the growth, expansion and reclamation of nuclear products. (0639-1 [Vandel, Nikohl])

Comment: ANA appreciates the Nuclear Regulatory Commission's efforts to collect public input on the draft Generic Waste Confidence Environmental Impact Statement through written comments as well as public meetings, which ANA groups attended in their regions. (0646-1 [Hanson, Courtney])

Comment: ANA supports an early and substantive role for tribes, states, and the public in decision making. ANA's experience with DOE sites demonstrates that the effects of nuclear activities extend far beyond the immediate area. In fact, the "affected public" is not just people in the "host" community, but includes people near other nuclear facilities and even other states. (0646-11 [Hanson, Courtney])

Comment: Duke Energy commends the Nuclear Regulatory Commission (NRC) for its inclusive approach to obtaining public input throughout the development of the draft Environmental Impact Statement (EIS) and proposed rule. (0672-2 [Jamil, Dhiaa])

Comment: In terms of risk communication, it is a democratic imperative that parties affected by regulatory policies and practices be adequately informed, involved substantively in decision making, and influential (rather than simply included) in the decision process. I believe that the NRC has good intentions in this regard, and having served with a U.S. Department of Energy site-specific advisory board (Hanford site) I recognize the many difficulties that challenge efforts at robust public engagement. Nevertheless, the very legitimacy of the NRC is at stake, as is the legitimacy of the nuclear industry. The conversation I have observed in connection with the Waste Confidence public involvement process has been restricted to the "usual suspects": the NRC, the nuclear industry, and a limited number of public interest groups that have technical resources and are able to make the necessary commitments of time and effort. The latter are grossly underrepresented in the conversation, and the result is a conversation that does not adequately represent the full range of public interests. (0684-4 [Kinsella, William])

Comment: Public interest groups and individual citizens have presented substantial evidence to the contrary at the recent Waste Confidence public meetings, but those concerns have not been incorporated into the draft GEIS. Numerous questions regarding seismology, fire safety, reactor safety, security against hostile parties, radiological hazard models, fuel storage configurations, storage of high-burn-up fuels, and other issues, all impinging on spent fuel storage and all requiring site-specific analysis, have been raised frequently and credibly but are dismissed in the draft GEIS. (0684-9 [Kinsella, William])

Comment: NIC commends the Nuclear Regulatory Commission (NRC) for its broad, comprehensive, and inclusive approach to obtaining public input throughout the development of the draft Environmental Impact Statement (EIS) and proposed rule. (0685-3 [Davis, Ed])

Comment: All of the people who spoke in support of DCNPP at this meeting were either employees of PG&E, most of them working at the plant, or from other groups funded by the profits of the nuclear power industry. It is clear that they were all protecting their jobs, for which they are highly paid, or their hopes of getting a job in the future for which they will be highly paid. (0686-18 [Malboeuf, Simone])

Comment: [O]ur members follow the issue of waste confidence closely, and we are grateful for this and numerous other opportunities provided by the Nuclear Regulatory Commission (NRC) for stakeholder input before making a final decision. Specifically, we compliment the NRC Waste Confidence Directorate's outreach efforts. Not only have they planned and successfully conducted 13 public meetings across the country, they have presented information on numerous status calls and at various stakeholder events to provide significant opportunities for all those interested to stay fully apprised of relevant waste confidence activities. (0689-1 [Boyd, David])

Comment: VI. The President's Blue Ribbon Commission (BRC) strongly recommended a process of involving the public and gaining their consent for the siting of nuclear waste facilities. Despite making reference to the BRC in the GEIS, the NRC's proposed action actually involves long term and even indefinite waste storage, while the public is excluded from any future involvement in these major decisions. (0693-3-3 [Warren, Barbara])

Comment: This means that the proposed NRC process is not consent-based as the BRC envisioned. The public, local government agencies, elected officials and emergency responders deserve the opportunity to present any relevant information pertaining to the storage of large quantities of highly radioactive spent fuel on-site at reactors, its management and the safety issues of concern. The NRC proposed action is the opposite of consent-based. With the proposed waste confidence rule, NRC is acting to prevent the public from having any role in matters that require transparency and public scrutiny in order to protect public safety. (0693-3-9 [Warren, Barbara])

Comment: TVA also agrees that the NRC's waste confidence rulemaking process fully satisfies NEPA in that it has included considerable transparency and public participation. As NEI notes, the process has been a model of transparency in agency action.²³ [footnote 23 text: NEI comments.] The NRC has afforded all stakeholders numerous and timely opportunities to participate directly in the rulemaking process. For example, the NRC has held numerous meetings, conferences, and workshops to inform the public about the rulemaking and to solicit input, including comments on the Proposed Rule. (0694-1-12 [Shea, Joseph])

Comment: Entergy also agrees that the NRC's waste confidence rulemaking process fully satisfies NEPA in that it has included transparency and public participation. As NEI notes, the process has been "a model of transparency in agency action."²⁰ [footnote 20 text: NEI comments (Cover Letter).] The NRC has afforded all stakeholders numerous and timely opportunities to participate directly in the rulemaking process. For example, the NRC has held numerous meetings, conferences, and workshops to inform the public about the rulemaking and to solicit input, including comments on the Proposed Rule. (0697-1-16 [Bessette, Paul] [Kuyler, Raphael])

Comment: Thank you for your considered effort to bring the issue of Nuclear Waste Confidence to the forefront of the common citizen in our nation. I believe the NRC could have utilized its connections with National Public Television and the news networks to bring even more attention of this issue to the every-day citizen not aware of nuclear power and weapons and the great risk of nuclear waste in our local communities. (0703-1 [Vandel, Nikohl] [Vandenberg Clermont, Elaine])

Comment: It was my intention to read carefully the U.S. Nuclear Regulatory Commission's entire *Waste Confidence Generic EIS* (Draft Report for Comment) before submitting comments by today's December 20 deadline. I am disappointed I have not had sufficient time to complete my study of this document. (0715-1 [Drey, Kay])

Comment: I also agree with Priscilla Starr and with Mike Carberry that this public process, although you may mean well, is essentially demeaning to the public. Giving us three-minute limits for commenting on such a grave threat to all living things is in itself demeaning. All of the other points that Mike and Priscilla made about the process I would concur with also. (0717-3 [Lewison, Linda])

Comment: First I would like to thank you all for considering my comments here and all the testimony submitted by concerned people who have approached you with a concern for the children, the people and All Life of Today and Tomorrow. Never forget the by, for and of the people, and the prior, free, informed consent governance that so many have sacrificed to defend, without it, you will get no confidence in the NRC's con-fidence! (0744-1 [Bonniwell, Colleen])

Comment: Do not ! like Japan - restrict Freedom of Speech! Allow those (us) Life Protectors to Stand Strong - United and have our voices heard. (0744-10 [Bonniwell, Colleen])

Comment: Had THE PEOPLES' right to vote on a law that effected them (us) from the beginning (1920's-TESLA) it would not have brought us here where we are today at this late hour. Have confidence in the people. This issue will take the patience of all to get right - when ever we can. The process must remain open! Give consideration to the Peoples ideas. (0744-3 [Bonniwell, Colleen])

Comment: Vista 360 thanks the U.S. Nuclear Regulatory Commission for it efforts in addressing the Waste Confidence issue and carrying out the long standing practice of conducting your regulatory, licensing and oversight activities in an open manner. Informing the public and taking its unvarnished perspective into account should be an institutional imperative of the highest order and providing opportunities for participation in a defined process and your decision making process is a laudable goal and objective. (0809-1 [Rielly, Thomas P.])

Comment: After deliberations are concluded, we challenge the U.S. Nuclear Regulatory Commission and the DGEIS professional staff to outline to the public (by methodology) the means by which solicited comments were organized for consideration and review, then how the solicited public comments were correlated by applicability and then incorporated by reference into the final work product of the Waste Confidence Environmental Impact Statement. Respectively, this disclosure effort should be conducted and carried out by the dictates of the Government Performance Results Act of 1993 and in the spirit of openness as purported by the U.S. Nuclear Regulatory Commission in its stated policies. (0809-2 [Rielly, Thomas P.])

Comment: I point out that I cannot present Chairman MacFarlane's exact words as the transcript of that meeting is not available yet. This is a further reason to extend the comment period past today. (0818-3 [Lewis, Marvin])

Comment: Your public engagement plan, including public meetings across the country, accessible website links to documents and clear directions about comment opportunities and deadlines, was well executed. Facilitation of the public meeting in Minnesota was excellent. I particularly appreciated the teams' openness to discussion after the meeting. This is a critical document, which will be pivotal in the mission of the NRC to "ensure the safe use of radioactive materials for beneficial civilian purposes while protecting people and the environment". (0820-1 [Eide-Tollefson, Kristen])

Comment: Scientific overview through assessment and analysis of safety priority requires development of methods of accepting official public testimony at any time that does not limit submission of official comments to limited scheduled timeframes. Such submissions require some way to appropriately prioritize by the timeliness of any safety issues, particularly to strictly contain any and all ionizing isotopes from leakage source through the entire timeframe of their cumulative ionizing impacts in consideration of the duration of time required for all the sets of half-lives to display until totally expired. From sufficient overview, a method should be required to promote identifying and addressing safety more certainly within an open timeframe permitting submission of new information, new concerns, new approaches, and insights into safety issues as well as the discovery of past fatal flaws, incomplete or inaccurate information and/or conclusions, unsafe practices, or any concerns about failures of sufficient oversight. (0823-18 [Michetti, Susan])

Comment: For example, the International Joint Commission of Great Lakes Water Quality was formed around scientific principles for scientific academics and professionals and developed a policy to accept official comments continually in order to be alerted to a need to focus on emerging issues of concern in a timely way. To the extent that the NRC employs a process that does not permit a continual influx of official comments of concern with a sufficient method to ensure that each is prioritized to be addressed in the timely way required by any safety concerns, that is the extent to which the NRC is blocking the ability to apply the brightest and best application of scientific thinking, methods, and principles in the most timely way, which, in turn, is required to protect the environment and the public as safely as possible in the most timely way. (0823-19 [Michetti, Susan])

Comment: This is a terrible time to ask for comments when you know family and friends are celebrating Christmas. (0824-1 [Ingram, Gwen])

Comment: The Nuclear Regulatory Commission has been transparent throughout its processes and reiterated on many occasions the safety and security of used nuclear fuel management in post-Fukushima. (0825-4 [Palomarez, Javier])

Comment: Please extend the comment period for the "Waste Confidence Draft Generic Environmental Impact Statement (GEIS)", Docket ID No. NRC- 14 2012-0246." This is a very serious issue and will need more time for the public to understand the impacts of any decisions. (0836-1 [Davis, Anonymous])

Comment: The document says "Any interested party may submit comments on this report for consideration by the NRC." We take this to mean that "anyone" may submit comments, and we reject the notion that you have to have a specific "interest" by residing within 50 miles of a nuclear plant, or the notion that you have to suffer actual harm, and the notion that you have to be an official "party" to the proceeding. The NRC Staff and Nuclear Industry attorneys have carried their arguments to an extreme on this point. We would prefer that you discard this troublesome language, and simply say "anyone," and leave out the "interested" qualifier, as well as the notion of "party," which has legal connotations. Of course, if someone takes the time to comment, they must be interested. Using "interested" opens the door for the industry to argue that the comments are coming from a party that is "not interested enough" because they do not have a financial interest that goes beyond being a ratepayer, or because they have not suffered actual -- not hypothetical -- harm and injury. We know this because these arguments were used by NRC Staff and industry attorneys who have a singleminded agenda to block any input from the public. (0836-11 [Davis, Anonymous])

Comment: Please, if you really want participation, change "interested party" in your statement regarding standing to "anyone." (0836-12 [Davis, Anonymous])

Comment: I've shared several thoughts, mostly questions, because the truth is, as I am sure you are well aware of, my voice means very little in the construct of a rule on nuclear waste management. I know so little in comparison to those who work on these matters every day. I'm just an average Stakeholder. As mom, private citizen, an enthusiast in all things nuclear and its connection to our exploration in space, I merely have an interest in healthy life on earth to make all the but I really do not know anything that you do not already know and I am sure you have your own well-informed perception on the issue of nuclear waste management and, as is the subject of this dialogue, confidence in the ability to manage the growth, expansion and reclamation of nuclear products. (0838-1 [Clermont, Elaine])

Comment: Thank you for your considered effort to bring the issue of Nuclear Waste Confidence to the forefront of the common citizen in our nation. I believe the NRC could have utilized its connections with National Public Television and the news networks to bring even more attention of this issue to the every-day citizen not aware of nuclear power and weapons and the great risk of nuclear waste in our local communities. Yet, I do feel at some point, we do what we can do with where we are as a nation, exactly where we are, here we are. (0838-2 [Clermont, Elaine])

Comment: I was particularly interested in the NRC's methodology used to engage the public with the development of the report. Unfortunately, it appears that the public was not directly involved in creation of the report, but was merely presented previously created information and asked to provide an assessment. For example, the report states that, "The NRC announced that it was planning to develop an EIS and requested comments..." (xxvi) which does not indicate the direct engagement of the public with the development of the EIS. Furthermore, while the statement that, "...technical knowledge and experience alone are not sufficient to bring about the broad social and political acceptance needed to construct a repository" (B-5) shows some recognition of the need to directly involve the public, it seems to imply that the effort to convince the public is simply an obstacle to overcome so the right solution can be implemented. While I appreciate the NRC's efforts to involve the public I argue that the public must be an active participant in the process of NRC rulemaking. These observations lead me to ask, "Did the NRC engage social-scientists as participants in their assessment?" A total focus upon the technical artifacts of an issue is a flawed approach. The NRC must fully address the nuclear waste problem with the full range of expert knowledge AND the public. (0847-1 [Miller, Daniel])

Comment: Also it would help if you weren't discussing having drinks together with industry reps after the hearing in front of everyone there; or sit with industry folks & stop staging the events with the public vs. paid industry personnel. SERIOUSLY?!!! You used the same person at the last hearing to follow my comments & you made it impossible for people who were signed up to speak at all on purpose. How do I know, I know when they signed up & you refused to let them speak by making them wait all night until they were forced to leave due to the long drive home & jobs they have in the morning. (0862-10 [Thompson, Tammy])

Comment: You are liars who say its public comments & nothing about this fiasco & or NRC "ideas" to date have been made public. (0862-5 [Thompson, Tammy])

Comment: Next time you host a meeting try to make sure your microphones work; you blame the hotel but you are the ones ultimately responsible & responsibility is not something you are found to be credible or able to do. (0862-7 [Thompson, Tammy])

Comment: Thank you for opportunity to submit public comment - However due to the extreme importance of this proposal upon impacted communities, and the limited extent so far of OBJECTIVE media coverage of this proposal for long term storage of spent nuclear fuel, (especially on extremely large population centers within 50 miles of San Onofre = over 8.4 million people, on the unprecedented economic risks, and realistic risks (not a remote risk) of catastrophic damage to local, regional, statewide infrastructure, food and water supply, and the real limit(s) for victims for physical, social, economic recovery from catastrophic losses), it is imperative that NRC should EXTEND THE COMMENT PERIOD for a reasonable time -- until February 28, 2014. (0866-1 [Borchmann, Patricia])

Comment: In letter from San Clemente Mayor Tim Brown (dated December 18, 2013) to Annette Vietti-Cook (Secretary of NRC), Mayor Brown indicated "...The City Council takes its

responsibility to represent and protect our citizens with utmost seriousness. San Clement City Council respectfully requests your consideration of extending public comment period for the Waste Confidence Draft Generic Environmental Impact Statement to February 28, 2014 to allow Council sufficient time to review the document". There are several other cities (San Juan Capistrano, Dana Point, Oceanside) within 20 miles of SONGS, who have also been asked to support the same action taken by San Clemente. Beyond the 20 miles, many other local cities and agencies within 50 miles should also be extended the same courtesy. (I'm asking City of Escondido, where I live). (0866-3 [Borchmann, Patricia])

Comment: Basically, the meeting was to show what the NRC has in mind regarding storage of nuclear energy waste on site. A "draft" booklet (GEIS) was handed out for the purpose of gaining public opinion before the NRC establishes a "rule" or "rules" about it. Generally, they want to know if the public would feel "confident" (safe) continuing to store nuclear lethal waste (spent rods) in either water pools, or in the recently created dry casks for periods of: 1) "Short" term-approx. 60 years, or 2) "long" term-about 120 years--until an envisioned US repository is made available, or, 3) indefinitely because no repository is or will be made available. All three "options" boil down to storage in on-site in un-time-tested dry casks. (0868-1 [Tilbury, Don])

Comment: I believe the NRC knows beforehand that their meetings will be attended mostly by persons or groups that oppose nuclear power. (0868-3 [Tilbury, Don])

Comment: The meetings should be held on the weekends to increase attendance. The facility should be large enough to accommodate all participants and their parking needs. (0869-1 [Homick, Nick])

Comment: This GEIS meeting should be held in every single community that has a nuclear reactor - not just a select few. (0869-2 [Homick, Nick])

Comment: The anti-nuclear comments were enlightening and intelligent. I learned nothing from the NRC. (0872-2 [Wilvert, Calvin])

Comment: There was a terrible echo from the microphone. (0872-3 [Wilvert, Calvin])

Comment: A STUPID statement! *[Attendees were listened to and understood by NRC Staff]* The NRC staff sat there, but they gave no evidence that they understood the concerns of most of the speakers. (0872-4 [Wilvert, Calvin])

Comment: The NRC statements were not "balanced." (0872-5 [Wilvert, Calvin])

Comment: The NRC staff simply repeated the "company line." Obviously, they would be fired if they didn't do this. (0872-6 [Wilvert, Calvin])

Comment: A major point: The pro-nuclear speakers appeared to be employees of PG and E or from other pro-nuclear groups. Their statements appeared scripted, as if they had all been written by the same person in the P.R. office of PG and E. (0872-7 [Wilvert, Calvin])

Comment: My understanding was that the meeting was to provide public input as to what could be done with nuclear waste. There didn't seem to be any discussion of that in the first 1-1/2 hours so three of us retired engineers left and didn't hear all the talks. (0873-1 [Thome, William L.])

Comment: Most of the public comments were by anti-nuclear people. To them nuclear energy causes many problems with potentially huge future problems. I believe one of the speakers even mentioned Emerald Ash Borer being caused by nuclear waste. We have heard all their arguments before and there didn't seem to be anything new. Two speakers spoke for nuclear power. First was a Ottawa County Commissioner. He was looking at the tax base and jobs provided by the Davis Besse plant. A second was a union leader from Columbus who liked the jobs provided in building nuclear plants. (0873-2 [Thome, William L.])

Comment: None of the speakers addressed the stated purpose of the meeting of input on what to do with the nuclear waste. I believe the NRC should provide about ten minutes for the anti-nuclear group to present their case. After that any speaker who deviated from the intended purpose would have the microphone shut off and they would be asked to leave the podium. (Possibly police assistance would be required.) Then the NRC should present a technical presentation on what options have been considered with the pluses and minuses of each option. Then let the public comment on the options or other methods of handling the waste. (0873-3 [Thome, William L.])

Comment: The NRC staff did a great job at this hearing! I was very impressed in how they stayed so calm and polite despite the VERY angry and disrespectful Anti Nuke people! (0875-1 [Szabo, Lou])

Comment: Hands down. NRC staff are very patient and professional in their demeanor at these meetings. (0876-1 [Anonymous, Anonymous])

Comment: Perhaps future meetings would either require speakers to elect 1 speaker representing any group including concerned citizen and then continue to allow unlimited written comments. Many concerned citizens only wanted a soapbox to complain not to comment on document. (0876-2 [Anonymous, Anonymous])

Comment: I don't think the NRC really listens to people who are concerned about the extreme dangers of nuclear issues, including nuclear waste. If they ever listened they wouldn't propose rules to disenfranchise the public of their rights to protect the environment and therefore strip us of rights to equality, happiness, etc. (0877-1 [Anonymous, Anonymous])

Comment: The NRC should keep to the start time published. (0878-1 [Ellison, David])

Comment: The NRC should ask questions of the public and actually listen to their answers- The pre-meeting time was helpful and good-but if the meeting is scheduled at dinner-time, there should be some sort of crackers or food, in addition to water and caffeinated drinks. There should be more informal interaction with staff. (0878-2 [Ellison, David])

Comment: THIS WAS MY FIRST VISIT TO AN NRC PUBLIC MEETING. SO, I HAVE NO REAL FEEL FOR AN IMPROVEMENT IN THE NRC'S PUBLIC MEETING PROCESS(ES). POSSIBLY, A MOVEMENT WITHIN NRC MORE ALIGNED DIRECTLY INFLUENCING HIGHER LEVEL MANAGEMENT IS IN ORDER TO SERVE PUBLIC INTEREST(S)[.] (0879-1 [McCraney, Richard])

Comment: These should have been 2 day meetings. (0880-1 [Anonymous, Anonymous])

Comment: If, as rumored, public comments will not be permitted after the NRC decision is made, I would consider that a denial of my First Amendment rights. (0882-4 [Wright, Margaret Z.])

Comment: There was an annoying delay in the speaker system, and not enough seats. (0888-2 [Wilvert, Rosemary])

Comment: No questions were permitted. (0888-3 [Wilvert, Rosemary])

Comment: It's hard to feel "listened to" when we're hearing the same as 35 years ago[.] (0888-4 [Wilvert, Rosemary])

Comment: The pro-nuclear speakers seemed scripted and were often employees of PG and E. (0888-5 [Wilvert, Rosemary])

Comment: The NRC staff keeps telling us the same things, and expects confidence. (0888-6 [Wilvert, Rosemary])

Comment: Introduction to comment period was repetitive and a total time-waster. Each NRC speaker said the same thing the previous speaker had said. We all know that this show is only a show. NRC has all the info it needs. The Chair believes in the show biz of public comment. If anything new actually came out of this meeting or any other, it would be a huge surprise! We were told how our comments would be important. But our time is apparently not. (0889-1 [Rossin, A. David])

Comment: We all understand that the "public meeting" can be felt to be necessary when active critics can challenge NRC actions. But when funds are tight, they should have low priority. (0889-2 [Rossin, A. David])

Comment: I wanted to ask if any of the costs of this set of public meetings were covered by any \$ in the Waste Fund. You can reply by email. (0889-3 [Rossin, A. David])

Comment: However, from past experience and the FACT that the only participants who were FOR the GEIS and more nuclear licensing were folks whose JOBS depended on "liking nuclear" and vouching for its safety! (0890-10 [Arnason, Deb])

Comment: I think the NRC did a good, non-combative job of conducting the hearing. (But do they listen really?) (0890-2 [Arnason, Deb])

Comment: It was hard to know if we were "listened to and understood" by the staff. (0891-1 [Clark, Brita Larsen])

Comment: I was concerned that the NRC speakers, and others supporting the GEIS did not acknowledge that the problem of long-term high level waste disposal is very complex, with no clear, "good," solution. They seemed to dismiss many of the concerns expressed by the public speakers. If the staff had forthrightly addressed the fact that there are many difficulties ahead, (instead of blithely dismissing them), it would be harder for concerned citizens to assume that they (the staff) are biased rather than neutral guardians of the public safety. (0891-2 [Clark, Brita Larsen])

Comment: Since the audience and people wishing to testify were so large, time for individual testimony could have been shortened to allow everyone to speak. I, having pre-registered (via the website) to do so was unable to. (0892-1 [Lamberts, Frances])

Comment: The Hearing officer, most courteous, should however have requested (and seen to it) that audience applause be held (= not allowed) since-- predictably following each speaker, it

both wasted precious time and delayed or made inaudible the announcements of speaker sequences to follow. (0892-2 [Lamberts, Frances])

Comment: I believe the process could have been made considerably calmer and more efficient, so that all could have been heard. (0892-3 [Lamberts, Frances])

Comment: I think the NRC runs a public meeting very well. (0893-1 [Wylie, Robert])

Comment: It seemed as if little recognition was given to the 40 people who came + or minus 100 miles from Asheville and that preference seemed to favor those who worked for the industry. (0894-1 [Patrie, Lewis])

Comment: SOME ATTENDEES WHO IDENTIFIED THEMSELVES AS LEADERS OR EXECUTIVES OF ENTITIES IN FAVOR OF THE WCDGEIS AND P RULE, BRAZENLY EXCEEDED THEIR COMMENT TIME AND IT WAS TOLERATED, THEN APPLAUDED. (0895-1 [Stein, Ed])

Comment: I WAS DISAPPOINTED AT THE GUFFAWS, SNICKERS, AND COMMENTS PASSED AROUND WHEN NON-TECHNICAL HEART FELT COMMENTS WERE MADE BY CITIZEN SPEAKERS. THOSE OPPOSING THE RULE MANAGED TO KEEP IT TO SIMPLY GASPING AT THE HUBRIS OF MANY OF THE PRO-RULE SPEAKERS. (0895-3 [Stein, Ed])

Comment: THE CONDECISION AND HUBRIS DISPLAYED BY MANY OF THE NUCLEAR INDUSTRY EMPLOYEES IN THE ROOM WAS DISTURBING. LIKE A SUB-CULTURE OF SUPERIOR BEINGS. (0895-4 [Stein, Ed])

Comment: IT WAS WORTH ATTENDING, BUT DISTURBING. I APPRECIATE THE OPPORTUNITY TO COMMENT...BUT FEEL IT'S A CHARADE. (0895-5 [Stein, Ed])

Comment: This meeting was a sham. It was held so the NRC can say it listen's to the public's concerns. (0902-1 [Fasten, Susan])

Comment: Embrace and incorporate these very knowledgeable, concerned, invested citizens in your decisions and actions. Remember that we are all in this together. (0902-11 [Fasten, Susan])

Comment: More attention was paid to not letting them [attendees] talk too long than to the content of their valid concerns. (0902-3 [Fasten, Susan])

Comment: Attendees concerns and facts were basically dismissed and ignored by NRC staff. (0902-4 [Fasten, Susan])

Comment: Suggestions on ways the NRC can improve their public meetings: --Acknowledge that we are all in this together. (0902-5 [Fasten, Susan])

Comment: Respect what attendees have to say and include their requests, fears and concerns in your "regulating." Their lives, families, homes, and communities are on the line. They know what the problems and risks are and are your best source for the corrections needed. (0902-8 [Fasten, Susan])

Comment: Treating the critics of the present nuclear situation with arrogance, dismissiveness, and a smug air of superiority is not constructive or smart, nor is cutting their comments short.

These caring, dedicated people have nothing to gain politically or financially, have no job to protect, have no superiors to answer to. They spend their own time and money travelling to and preparing for these meetings and speaking up because they understand that their lives and all of our lives are on the line. Why do you not get it that your lives and families and communities are on the line as well? (0902-9 [Fasten, Susan])

Comment: This meeting was a sham. IT was held so the NRC can say it listens to the public's concerns. Comments were cut short. Not heard or understood. (0903-1 [Fasten, Susan])

Comment: Please provide any suggestions you have on ways the NRC could improve their public meetings: -Acknowledge that we are all in this together. (0903-2 [Fasten, Susan])

Comment: Respect what critics have to say. Include their requests, fears, and concerns in your "regulating." Their lives, families, homes, and communities are at risk. They know what the problems and risks are and are your best and most invested source for the corrections and precautions needed. (0903-5 [Fasten, Susan])

Comment: Treating the critics of the present nuclear situation with arrogance, dismissiveness, and a smug air of superiority is not constructive or smart. These caring, dedicated, knowledgeable people have nothing to gain politically or financially, no job to protect, no superiors to answer to. They spend their own time and money travelling to and preparing for these meetings and speaking up because they understand that their lives and all of our lives are on the line. (0903-6 [Fasten, Susan])

Comment: Invite, incorporate, and embrace these very concerned, knowledgeable, invested citizens in your decisions and actions. -Remember that we are all in this together. (0903-8 [Fasten, Susan])

Comment: I also request that the Comment Period for the Waste Confidence GEIS ,Nureg 2157, be extended to include the time needed to reanalyze Table S-3 in light of the above deficiencies. (0906-2 [Lewis, Marvin])

Comment: Thank you for the opportunity to comment. (0913-16 [Bevill, Bernard])

Comment: But one unpleasant aspect of NRC's rush job has been its enforcement of mere three minute public comment opportunities at meetings across the country. It is certainly difficult to say much in three minutes about a topic as societally significant, not just for current, but for all future generations, as irradiated nuclear fuel generation, storage, and disposition. (0919-4-22 [Kamps, Kevin])

Comment: Re: Page 3-37, Section 3.15 Transportation, where NRC admits: "For transportation of radioactive material from a nuclear power plant site, the affected environment includes all rural, suburban, and urban populations living along the transportation routes within range of exposure to radiation emitted from the packaged material during normal transportation activities or that could be exposed in the unlikely event of a severe accident involving release of radioactive material. The affected environment also includes those members of the public that could be exposed to radiation emitted from the packaged material during normal transportation activities including people in vehicles on the same transportation route, people living along transportation routes, and people at truck stops and workers that are involved with the transportation activities"...Given this admission, NRC should have expanded its public comment opportunities, given this important issue of transportation risks more focus and attention, and

held public comment meetings along likely transport corridor locations on the roads, rails, and waterways to centralized interim storage, away-from-reactor, parking lot dumpsites. No such focus, attention, or meetings took place in this entire public comment proceeding. (0919-6-4 [Kamps, Kevin])

Comment: After the Nov. 12, 2013 Nuke Waste Con public comment meeting in Oak Brook, IL, Nuclear Energy Info. Service of Chicago put out a one-sider entitled "IT ALL BOILS DOWN TO-DO WE TRUST THE NRC?" I so endorse what it says that I made copies of it available on the Beyond Nuclear information table at the Perrysburg, OH Nuke Waste Con public comment meeting in on Dec. 2, 2013. I staffed the info. table as much as I could that evening, although I did have to go into the big room to make my 3 minute public comment orally, had to do media interviews, etc. But the entire time I staffed the table, not a single one of the large number of NRC staff who were in attendance even so much as stopped by to glance at our table. So I assume that no NRC staff took a copy of this. And even if they did, I am fairly certain it would not find its way into the official record as public comment in this proceeding. (0921-1 [Kamps, Kevin])

Comment: The document says "Any interested party may submit comments on this report for consideration by the NRC." We take this to mean that "anyone" may submit comments, and we reject the notion that you have to have a specific "interest" by residing within 50 miles of a nuclear plant, or the notion that you have to suffer actual harm, and the notion that you have to be an official "party" to the proceeding. The NRC Staff and Nuclear Industry attorneys have carried their arguments to an extreme on this point. We would prefer that you discard this troublesome language, and simply say "anyone," and leave out the "interested" qualifier, as well as the notion of "party," which has legal connotations. Of course, if someone takes the time to comment, they must be interested. Using "interested" opens the door for the industry to argue that the comments are coming from a party that is "not interested enough" because they do not have a financial interest that goes beyond being a ratepayer, or because they have not suffered actual -- not hypothetical -- harm and injury. We know this because these arguments were used by NRC Staff and industry attorneys who have a singleminded agenda to block any input from the public. (0930-1-4 [Lutz, Ray])

Comment: Please, if you really want participation, change "interested party" in your statement regarding standing to "anyone." (0930-1-5 [Lutz, Ray])

Comment: I don't expect my words to be considered in any decision. No one of us, of the 99% is ever listened to. I feel we are talking to deaf ears. The only voices that are heard are of the 1% and lapdog agencies such as the NRC. But I am totally without hope. Democracy is what the people want, maybe someday it will happen. (0933-10 [Anonymous, Janet])

Comment: NRC's commitment to providing extensive opportunities for public participation in its decision-making process has been a model of openness and transparency. (0948-3 [Commenters, Multiple])

Comment: Since the current comment period ends November 27, 2013, since public hearings are currently scheduled for as late as November 20, and since several public hearings have not yet been set, the Commission should extend the deadline for written comments on the waste confidence rule. The deadline for written comments should be at least thirty days after the final public hearing. Also, to facilitate written comments, the Commission should make transcripts or recordings of each of the public hearings available to those wishing to refer to oral comments in

their written comments--an ample time before the conclusion of the written comment period. (0955-1 [Haggerty, Bernard])

Comment: Since the onset of the initial scoping period, Vista 360 has been involved as a participant of record in the U.S. Nuclear Regulatory Commission's ongoing Waste Confidence Generic Environmental Impact Study and Rule making efforts and process. Pursuant to today's GEIS Status Update Conference Call (Wednesday, October 30, 2013) and questions and remarks related to the present closing date for the Public Comment Period as formally determined by the NRC's previous reference as being Friday, December 20th, 2013, we formally request by this communication that the Public Comment Period be extended to a closing date of Friday, January 31, 2014. As stated briefly today, Vista 360 has unilaterally determined that the GEIS subject matter depth, volume, scope and complexity calls for an extended Public Comment Period as a process imperative. (0956-1 [Rielly, Thomas P.])

Comment: I am writing to you in the hopes that this important request does not get lost in the myriad of emails Chair Macfarlane receives every day. On Tuesday, 12/17 the San Clemente City Council will be voting on a resolution which expresses deep concerns about nuclear waste in our surrounding communities. Seeing how they voted unanimously to initiate this resolution, I am certain this will be an important message for the NRC to consider. Fortunately, we were able to convey some recently understood facts about high burnup fuel in time to make the latest deadline. Unfortunately, there is not enough time to reach out to the other cities, groups and individuals who will likely follow San Clemente's lead. Judging from the NRC's wording below, there seems to be an opportunity to consider comments that come in after the deadline. We will proceed with that assumption in mind, but it would be very helpful to have this confirmed by the NRC. We are also seeking the help of Senator Boxer's office in this matter. We understand it may be difficult to arrange yet another extension following the government shutdown, however we also feel that this is justified by the discovery that high burnup fuel, and it's excessive thermal and radioactive heat accelerating the degradation of dry cask storage containers, has not been adequately addressed in the GEIS. With the holidays and vacations and changing of mayors and other elected officials, we respectfully request the deadline for comments be extended at least until the end of January. The 5000 + members of San Clemente Green would greatly appreciate you forwarding this message on our behalf. (0957-1 [Headrick, Gary])

Comment: I respectfully submit a request for an extension of the comment period on NUREG 2157 and associated rulemaking actions. I recently found a notice that states the Commission will meet on January 6, 2014, to discuss and be briefed on Spent Fuel Pool Safety and Expedited Transfer. Closing the comment period before the Commission is presented the staff's finding and conclusions is a very limited approach. The Commission may offer a solution that makes the Nureg mute or provides findings that have little to do with the NUREG. At a minimum, the comment period needs to be extended past the January 6 Commissioners' Meeting. (0958-1 [Lewis, Marvin])

7. Comments Concerning the Scope of the GEIS

Comment: That said, I would like the scope of waste handling to include the complete safety of land, water, air and all of the living and interdependent organism in those elements to be protected until the waste is no longer harmful. The scoping should include the economic impact to tax payers based on prior mishandling, accidents of man and nature regarding nuclear waste storage. The scoping should include a study on the industry which produces the waste and

their liability for the complete handling of the waste now and of unforeseen consequences which may be statistically calculated on past miscalculations by this industry. (0011-2 [Follett, Carol])

Comment: Small Module Reactor (SMR) technology also is not fully developed or licensed and should not be included in the Environmental Impact Statement. (0023-3 [Bridges, Martha])

Comment: The EIS needs to consider the entire fuel cycle in its scope, including the effects of mining, milling, processing, transport, reactor operation, decommissioning and final storage. (0030-21-11 [Carberry, Mike])

Comment: Prevention and precaution. The EIS must consider and analyze the variety of potential methods for storing the more than 80,000 tons of highly-radioactive irradiated spent fuel that is currently housed at our reactors. The risk of a pool storage and cask storage needs to be carefully considered. Overcrowded and irradiated and spent fuel pools is an unacceptable risk to the public. The NRC should take immediate action to reduce the number of fuel assemblies in the water-filled pools, as well as analyzing the deficiencies of the current dry cask storage. New potentially less dangerous methods such as hardened on-site storage, also known as HOSS, should be fully evaluated in the EIS. The storage and transport of high-burnup fuel must be fully evaluated also in the EIS. (0030-21-3 [Carberry, Mike])

Comment: NRC case law holding in part that NEPA did not require the NRC to withhold the granting of a renewed license simply because there may be some future available -- future information that is not currently available. So, in conclusion, while the NRC has chosen to broadly address the environmental impacts of waste storage in the draft GEIS, it is important to recognize and not to exaggerate what the Court of Appeals directed the agency to address; that is, spent fuel pool fires, leaks, and the no repository scenario. And in addressing the agency, the Court asked the agency to provide a basis for its conclusions. The Court of Appeals did not reject the NRC's longstanding findings on the feasibility of a geologic repository or the safety of spent fuel pool storage -- spent fuel storage pending disposal. The prior findings and record continue to support the current rulemaking and GEIS. (0030-3-7 [Ginsberg, Ellen])

Comment: The GEIS includes detailed sections and appendices that thoroughly address the three issues identified by the D.C. Circuit in New York v. NRC. Specifically, the no repository scenario, spent fuel leaks, and spent fuel pool fires. Notably, the no repository scenario is fully evaluated throughout the GEIS as the in-depth storage scenario. And, furthermore, the GEIS includes a detailed technical evaluation of the environmental risks of spent fuel pool leaks and fires, and in particular the supporting appendices in the GEIS fully demonstrate that the risk-based impacts of spent fuel pool leaks and fires both are small. (0030-7-7 [Matthews, Tim])

Comment: I am proposing that the EIS meet its and EPA requirements by offering alternatives, considering each reactor site separately, and to evaluate all costs involved, not just how much it will cost to do an EIS. (0045-11-11 [March, Leslie])

Comment: New rules, yes! An EIS clearly compares the environmental footprint of nuclear power from the mine to the construction and operation of the reactor to the disposal of the waste and decommissioning of the reactor with the footprint of renewables and energy efficiency. (0075-2 [Hill, Barbara])

Comment: However, I have a very first and specific concern that I would like to consider -- that I would like the NRC to consider. Specifically it is on the public confidence about reclamation of orphan sites. Measures must be taken to seek the input from the local residents around an

extended storage site on the fairness of continued storage at that site after the decommissioning of the reactor. As the NRC knows, there are multiple sites across the country at which a reactor has been decommissioned already and the dry cask storage remains as the only remnant of this important energy production. (0112-28-3 [Diaconeasa, Mihai])

Comment: [A]nalysis must include: sabotage and terrorist acts; current and future leaks from SFPs. (0230-10 [Garb, James])

Comment: And I wanted to correct something from two nights ago in Chicago. A question was asked before the public comment period began and Keith McConnell answered it but incompletely. Significantly incompletely, when you said that this document and this proceeding has to do with at-reactor storage, or perhaps you used the term onsite storage. Yes, that is true there is an entire chapter about at-reactor onsite storage in this document. There is another complete separate chapter about away-from-reactor storage. And of course when you have away-from-reactor storage, that brings up the issue of transportation, which is also covered inadequately, very shallowly in this document. And of course, the Court ruled and ordered the NRC to deal with the repository issue, the lack of a repository or the presence of a repository. And so, this document has to do with all of those things, not just onsite storage. (0246-32-2 [Kamps, Kevin])

Comment: Every day of my life, high-level radioactive waste has been generated, and every ten years of my life there has been a major reactor accident which took that which was fuel and rendered it to that which must be called waste, and quite frankly, we have to add to this Generic Environmental Impact Statement the consideration of all phases of this material, not only those that are assemblies in pools or in casks. (0250-2-1 [Olson, Mary])

Comment: So, I think that there are some really critical functions that this GEIS needs to -- can address if it were not assuming that all of the things that are necessary for responsible nuclear waste management are already taken care of, because they're not. They're not taken care of, and we don't have those frameworks, and we don't have those pieces in place that we very much need. (0328-12-6 [Eide-Tollefson, Kristen])

Comment: The GEIS supports three storage timeframes that include both implementation of a repository and failure to secure a repository. The GEIS does not cover reprocessing and therefore is appropriately silent on the potential for spent fuel to be used for reprocessing. (0534-4 [Vetter, Richard])

Comment: The HPS notes that the NRC has restarted a review of the Department of Energy license application for the Yucca Mountain repository. That decision is also appropriately outside the scope of the GEIS. (0534-6 [Vetter, Richard])

Comment: *An accounting of the public cost of reactors from uranium mining through shielding and monitoring of nuclear waste forever has not been done and must be included in the GEIS. That will demonstrate the better alternative: energy efficiency, conservation, wind, solar, hydro.* (0552-1-17 [Macks, Vic])

Comment: The analysis needed to answer these questions would require a detailed assessment of the role nuclear power can reasonably be expected to play in the commercial energy sector into the distant future. There is no such assessment in this Draft GEIS. (0608-7 [Crocker, George])

Comment: Since NRC failed to include in the scope of this GEIS site specific issues, the GEIS fails to comply with the requirements of NEPA. (0611-19 [Shapiro, Susan])

Comment: I would like to respond to the Nuclear Energy Institute's (NEI's) self-serving claim that the Nuclear Regulatory Commission (NRC) "need not assess the environmental impacts of nuclear plant operation more generally" in order to fulfill the requirements of the Waste Confidence Decision (WCD). Perhaps this is true -- they "need not" as in, it is not explicitly stated that they do so by the judgement. But assessing environmental impacts of nuclear plant operation more generally is implicitly required because if there is no waste confidence, it is immoral to continue making nuclear waste. (0616-1 [Hoffman, Ace])

Comment: The plan should include Class C or greater waste (rather than exclude it as the current GEIS plan does). (0618-11 [Johnson, Roger])

Comment: Please make site specific recommendations for removing nuclear waster from closed nuclear reactors. (0624-1 [Large, Gerry])

Comment: We also believe that the analyzed scenarios for the intermediate term storage must be emphasized, clarified, and defined as addressing at reactor ISFSIs and away from reactor ISFSIs. The staff chose not to include Consolidated Interim Storage as an analyzed scenario in its work. In doing so, it would leave the Commission with less to defend its tenet that it does not intend to endorse indefinite storage. While Chapter 5 of the draft GEIS reasonably addresses the impacts of away-from reactor storage, the Commission should work to ensure that the GEIS addresses a Consolidated Interim Storage site or sites as well as at reactor ISFSIs. This might best be done by additional emphasis early in its executive summary and consistently throughout the text. (0637-10 [Norton, Wayne])

Comment: The NRC also decided that the "density and concentration of spent fuel is outside the scope of the proposed action." p. 1-9. This issue is at the heart of the problem of producing more nuclear waste than the government or industry can handle. It is also at the heart of the potentially catastrophic impacts of dangerous storage in overcrowded spent fuel pools. Of course, NRC was the agency that determined the scope of the proposed action, and this circular reasoning explains nothing, while evading what was essential to evaluate if public safety were a priority. (0693-1-11 [Warren, Barbara])

Comment: •Reprocessing logically should have been evaluated in this GEIS since the NRC has already engaged in meetings in which it is considering approving reprocessing activities. The past record of reprocessing and the reasons for the past moratorium could have been thoroughly reviewed in the GEIS. (0693-4-8 [Warren, Barbara])

Comment: TVA believes that the DGEIS already encompasses nuclear plants used for tritium production. For example, the DGEIS states that it encompasses "fuel types that have been used in the past and continue to be stored under an NRC license" and "fuel types that are presently used."⁷¹ [footnote 71 text: DGEIS at 2-5. Additionally, the DGEIS specifically mentions WBN-1. See, e.g., DGEIS at 7-5.] Nonetheless, for clarity, TVA requests that the NRC address the issue of tritium production in the Final GEIS by confirming it is bounded and reference the substantial body of additional environmental analyses supporting this conclusion. (0694-2-20 [Shea, Joseph])

Comment: Entergy first notes that the scope of the Proposed Rule and the DGEIS is appropriate. The scope includes the environmental impacts of continued storage of SNF from the end of a reactor's licensed life for operation until disposal of the SNF.⁵³ [footnote 53 text:

DGEIS at 1-4 to 1-5.] This scope encompasses spent fuel storage issues applicable to Entergy's nuclear plants. (0697-2-2 [Bessette, Paul] [Kuyler, Raphael])

Comment: The DGEIS explains that certain issues are eliminated from review in the GEIS, including foreign spent fuel, need for nuclear power, and reprocessing of commercial spent fuel.⁵⁴ [footnote 54 text: *Id.* at 1-23 to 1-24.] The DGEIS also explains that the waste confidence rulemaking does not include whether NRC licensing activities and operation of commercial reactors should continue and does not include whether the NRC should impose additional requirements on spent fuel storage.⁵⁵ [footnote 55 text: *Id.* at xxvi, 1-9 to 1-10.] Specifically, the DGEIS states: Imposing new regulatory requirements, such as requiring licensees to implement hardened at-reactor storage systems, reduce the density of spent fuel in pools, or expedite transfer of spent fuel from pools to ISFSIs, is outside the scope of this proposed action, which includes alternatives that improve the efficiency of the NRC's licensing process by generically addressing the environmental impacts of continued storage. Adoption of a revised 10 CFR 51.23, supported by this draft GEIS, is not a licensing action, and does not impose new requirements on licensees or applicants. Therefore, the NRC cannot impose new requirements or regulations on the duration of spent fuel storage in pools through this proposed action.⁵⁶ [footnote 56 text: *Id.* at 1-9.] Entergy agrees that these issues are outside the scope of the waste confidence rulemaking. Additionally, the exclusion of any of these topics does not impact the applicability of the Proposed Rule and DGEIS to Entergy's plants. (0697-2-22 [Bessette, Paul] [Kuyler, Raphael])

Comment: Federal Register Vol. 78, p. 56780, In response to "A6" and "A7." Mostly, it seemed that these answers were for the "nuNukes" -- the newer nuclear technology, rather than the established power plants in operation. The statement that made me cringe, was, "Small modular will use fuel very similar in form and materials to the existing operating reactors and will not, therefore introduce new technical challenges to the disposal of spent nuclear fuel." Ok. But, since we have EXISTING technical challenges (never mind any NEW ones) in the maintenance of spent nuclear waste, and we all know this is reality, what does this really mean? Is the NRC is going to use the old standards for the new plants and that's acceptable? (0703-11 [Vandel, Nikohl] [Vandenberg Clermont, Elaine])

Comment: Page 1-4. "For both power reactor and storage facilities, NEPA requires that the NRC address direct, indirect, and cumulative impacts of its licensing actions. Thus, in issuing a power reactor license, the NRC must analyze the environmental impacts resulting from the generation of spent fuel by the reactor and its continued storage pending ultimate disposal. Likewise, for an ISFSI [Independent Spent Fuel Storage Installation], the NRC must analyze the impacts of continued storage at the facility until ultimate disposal for the spent fuel is available. The environmental impacts addressed in this draft GEIS are limited to the environmental impacts of continued storage." NRDC Comment[:] NRDC concurs with the NRC that it must address the direct, indirect, and cumulative impacts of its licensing actions. But NRC's presentation of the proper scope is inadequate and the agency must evaluate the environmental effects of all reasonable alternatives for on-site and off-site storage of waste during and after the period of extended operation; offsite land, water, and air use impacts of continued operations and the storage of additional spent fuel on the surrounding areas; whether the current GEIS adequately evaluates the long term impacts and safety of the generation and long-term storage of radioactive waste; the comparative impacts of SNF storage in pools versus in dry casks; the implications of on-site storage of waste for decommissioning; the effects of spent fuel disposal and the effects of SNF storage and disposal in the event of extended delay or if no final disposal option or repository is ever identified , with extended loss of institutional control over the SNF and the storage facility; and alternatives to mitigate these impacts, among other issues. Many of

these issues have a site specific component and cannot be dealt with entirely within the confines of a generic analysis. Rather than seeking to use this DGEIS as blanket to suffocate all future consideration of continued SNF storage issues in future licensing decisions, the NRC should regard this DGEIS as one in which broad programmatic issues and impacts are addressed, thus enabling the "tiering" of subsequent site-specific EIS documents from this overall analysis. (0706-1-15 [Fettus, Geoffrey])

Comment: Page 1-22. "The environmental impacts of portions of the uranium fuel cycle that occur before new fuel is delivered to the plant and after spent fuel is sent to a disposal site have been evaluated and are codified in regulation (10 CFR 51.51, Table S-3)." (See also, Figure 1-2 at 1-18). NRDC Comment. As noted in our February 2009 comments on NRC's last iteration of the Waste Confidence Determination, NRC has no basis for continued reliance on Table S-3, the outdated uranium fuel cycle rule—which itself was contingent upon the now vacated Waste Confidence Rule—that depends on assumptions long since proven wrong or, simply, no longer applicable by virtue of current law. We detail the reasons for Table S-3's inadequacy in Appendix B to these comments. And we remind the agency to the DC Circuit's direction regarding the relationship between Table S-3 and its new iteration of the TSR and its Waste Confidence obligations: The Commission argues that its "Table S-3" already accounts for the environmental effects of the nuclear fuel cycle and finds no significant impact. Not so. Table S-3, like the Commission itself, presumes the existence of a geologic repository. Therefore, it cannot explain the environmental effects of a failure to secure a permanent facility. The Commission also complains that conducting a full analysis regarding permanent storage would be an "abstract exercise." Perhaps the Commission thinks so because it perceives the required analysis to be of the effects of the permanent repository itself. *But we are focused on the effects of a failure to secure permanent storage.* The Commission apparently has no long-term plan other than hoping for a geologic repository. If the government continues to fail in its quest to establish one, then SNF will seemingly be stored on site at nuclear plants on a permanent basis. The Commission can and must assess the potential environmental effects of such a failure. *New York et al.*, at 479. NRDC agrees Table S-3 attempts to evaluate the environmental impacts after spent fuel is sent to a disposal site—not the environmental effects of a failure to secure permanent storage that must be analyzed here (and later incorporated into the fuel cycle rule). But it is a rule that depends on assumptions long since proven wrong are no longer applicable simply by virtue of current law. (0706-3-15 [Fettus, Geoffrey])

Comment: 3. There is no basis for continued reliance on an outdated uranium fuel cycle rule -- which itself is contingent upon the Waste Confidence Rule -- that depends on assumptions long since proven wrong or, simply, no longer applicable by virtue of current law[.] Finally, the NRC's lack of a basis for any determination that there is "confidence" in a final disposal option for some or all of the nation's spent fuel fatally undermines Table S-3 of the NRC's Uranium Fuel Cycle Rule, which depends on the assumption that radioactive releases from a repository will be zero. Final Rule, Licensing and Regulatory Policy and Procedures for Environmental Protection; Uranium Fuel Cycle Impacts From Spent Fuel Reprocessing and Radioactive Waste Management, 44 Fed. Reg. 45,362 (August 12, 1979). (0706-5-3 [Fettus, Geoffrey])

Comment: The life cycle costs of nuclear power should be assessed in detail in the EIS, including the substantial front end subsidies, uranium mining and enrichment impacts, and the long term, substantial costs of safely, properly decommissioning and managing nuclear waste. (0707-8 [Werner, Shahla M.]

Comment: I would like to respond to the Nuclear Energy Institute's (NEI's) self-serving claim that the Nuclear Regulatory Commission (NRC) "need not assess the environmental impacts of

nuclear plant operation more generally" in order to fulfill the requirements of the Waste Confidence Decision (WCD). Perhaps this is true -- they "need not" as in, it is not explicitly stated that they do so by the judgement. But assessing environmental impacts of nuclear plant operation more generally is implicitly required because if there is no waste confidence, it is immoral to continue making nuclear waste. (0709-1 [Wythe Elnagar, Romi])

Comment: The U.S. Nuclear Regulatory Commission (NRC) has failed to address adequately the scope of the ultimate environmental, political and economic challenges associated with the continued production and accumulation of longlived radiotoxic waste materials, absent a well-planned and scientifically based strategy for the long-term management of these wastes over a period of time that dwarfs the span of human history. (0714-1-23 [Edwards, Gordon])

Comment: Under section ES.12, page xxxi-xxxii, under table ES-1, there is no articulable public safety component and how it would play into various affected areas identified in the Draft GEIS. In addition, consistent with the general objections, the narrowness of the affected area, as defined in the Draft GEIS, is too narrow to effectively analyze the impact of continued storage on both the human and natural environments. Public safety has to be included in the analysis and the analysis itself must be expanded to include indirect impacts of continued storage. (0783-1-15 [Harlan, Thomas])

Comment: In summary, the rulemaking documents for the waste confidence rulemaking should include an affirmative statement that waste confidence issues do not apply to Early Site Permit (ESP) applications , and the DGEIS should be revised accordingly. (0810-1 [Mallon, James])

Comment: Comment No. 2 - The DGEIS should be revised to remove any implications that waste confidence issues apply to ESP applications and also should include an affirmative statement that waste confidence issues do not apply to ESP applications. As discussed above, the DGEIS includes a few statements that could be interpreted to incorrectly imply that waste confidence issues apply to ESP applications. The DGEIS should be revised to prevent any unnecessary confusion or resource expenditures due to the confusion during ESP application reviews. To accomplish this, PSEG requests that the NRC revise the DGEIS as follows:

- Remove any discussion of ESPs or ESP applications from Section 7.1 of the DGEIS, and instead discuss new reactor applications affected by waste confidence issues, including COL or operating license applications. ° On page 7-3, lines 8-9 , delete "and one early site permit (ESP) application." ° On page.7-3, line 10, delete "and ESP." ° On page 7-3, line 16, delete "and ESP." ° On page 7-3, line 18, delete "and ESP." ° On page 7-5, line 8, delete "or ESP." (0810-10 [Mallon, James])

Comment: Add a statement in Section 7.1 to clarify that the waste confidence issues do not apply to ESP applications. PSEG proposes the following statement, or its equivalent: • "The issues encompassed by 10 CFR § 51.23 and NUREG-2157 do not apply to ESP applications. Because ESPs do not authorize their holders to generate or store spent nuclear fuel, the NEPA analysis for ESP applications does not need to consider the environmental impacts of continued storage of spent nuclear fuel beyond a reactor's licensed life for operation and prior to ultimate disposal." (0810-11 [Mallon, James])

Comment: Remove any discussion of ESPs or ESP applications from Table H-1 of the DGEIS, and instead discuss only new reactor applications affected by waste confidence issues, including COL or operating license applications. • Revise any discussion of "new reactors" or similar phrases to clarify that they only apply to new reactors affected by waste confidence issues. • Remove any discussion of the PSEG ESP from the last sentence of Footnote (d).

PSEG proposes the following revised sentence, or its equivalent: "Bell Bend is treated as a new review because the NRC is not likely to issue a draft EIS by the end of fiscal year 2014; the NRC assumes that the environmental impacts of continued storage will be addressed within a normal review schedule for that project." • Revise Table H-1 to the extent that it assumes a site-specific review of waste confidence issues for the PSEG ESP application. If the NRC intended Table H-1 to be based on a future potential site-specific review of a COL application that references a future PSEG ESP , then that should be clarified. (0810-12 [Mallon, James])

Comment: Revise the discussion of the cost-benefit analysis in Chapter 7 or elsewhere in the DGEIS to the extent it is otherwise affected by the above changes. (0810-13 [Mallon, James])

Comment: Because ESPs do not authorize their holders to generate or store spent nuclear fuel, the National Environmental Policy Act (NEPA) analysis for ESP applications does not need to consider the environmental impacts of continued storage of spent nuclear fuel beyond a reactor's licensed life for operation and prior to ultimate disposal. (0810-2 [Mallon, James])

Comment: Notwithstanding the above statements that support a conclusion that the waste confidence issues do not apply to ESP applications, the DGEIS raises some confusion. For example, Section 7.1 of the DGEIS addresses assumptions for the cost-benefit analysis for the proposed action. Section 7.1.1 addresses new reactor applications, including the PSEG ESP application, because it is the only pending ESP application. That section states: "In general, COL and ESP application reviews take longer and require more staff effort to complete than other NRC reviews that rely on the Waste Confidence rule." This statement could be interpreted to mean that the NRC believes that the Proposed Rule applies to ESP applications. (0810-4 [Mallon, James])

Comment: Furthermore, Appendix H of the DGEIS provides the estimated costs of alternatives used in the cost portion of the costs and benefits analysis in Chapter 7 of the DGEIS. Table H-1 provides estimated site-specific costs for new reactor reviews. Footnote (d) to this table bins the Bell Bend project with the PSEG ESP and states that they are "treated as new reviews because the NRC is not likely to issue a draft EIS by the end of fiscal year 2014; the NRC assumes that the environmental impacts of continued storage will be addressed within a normal review schedule for those projects." This statement also could be interpreted to mean that the NRC concludes that the waste confidence issues apply to the PSEG ESP application. (0810-5 [Mallon, James])

Comment: In the District of Columbia Circuit Court of Appeals decision June 8, 2012, the Court vacates the NRC's Waste Confidence Decision update, remanding it for further proceedings. The judges objected to the NRC's depending on its "Table S-3" which finds that there would be "no significant impact" from the environmental effects of the nuclear fuel cycle." (0813-3 [Thomas, Ruth])

Comment: The GEIS adopted by the Commission must include a planning component to direct utilities and responsible federal stakeholders to engage in strategic planning, funding, and execution of technical and environmental protection requirements to ensure responsible - safe - long term storage. NRC's charge to protect the public health and safety requires *direct action*, *not evasion*, of the potential impacts of long term and indefinite at reactor site storage. This should include at least the following: 1. Execute: A. Full phased Environmental Site Evaluation for existing shut down sites, and extended long term (beyond 60 years) storage at any plant site. This should be done before permit decision or license extension for plants or ISFSIs are granted. a) Engage all relevant federal agency expertise including EPA, Geological Survey and

Corps; b) Provide for local, state and tribal stakeholder education and involvement. c) Provide funding for a full Health Assessment for long term storage host communities B. An Adaptive Phased Management Plan for long term/indefinite storage at reactor sites. See attached documentation and recommendations from Federal Council on Environmental Quality - CEQ. 2. Analyze and apply a) The three engineering studies for the No-Action alternative to the federal EIS for Yucca Mountain - analyzing deterioration effects on casks of precipitation and temperature variations in different zones. b) Effects of uprated burn up fuels on both initial pool and cask storage for each of the periods. c) Detailed deterioration factors - and impacts of radiological releases under several scenarios, including the 350 year peak release. d) A demographic and environmental analysis of long term exposures -different for each plant and including the multiplier of skyshine effects of dry cask storage for each period. 3. Initiate: a) Guidance documents for institutional controls for indefinite at reactor site storage b) Health assessments for host communities facing indefinite at reactor site storage 4. Adopt: a) Minimum standards and criteria for long range at reactor/ISFSI site storage b) Optimum standards and criteria for long range at reactor/ISFSI site storage c) Incentives and mechanisms, including funding, to close the gap. 5. Direct: a. Utilities to do long range planning specifying what technology, funding, cask and facility design options will be needed to ensure complete replacement every 100 years. b. Utilities to establish escrow accounts for Long Term Storage Funding Assurance, in addition to and separate from their decommissioning funds. c. Establishment of federal funding for utilities to partner with host communities and states on long term institutional controls, including monitoring, education, emergency planning for indefinite storage. 5. Establish: a) Estimated costs for the above; b) Mechanisms to ensure funding for long term/indefinite storage. There is no responsible or safe nuclear waste storage - without adequate planning, funding, and institutional controls. (Reference: PINGP- EIS, MN PUC docket 08-690) (0820-15 [Eide-Tollefson, Kristen])

Comment: While these facts show just why nuclear energy is a vital part of our electricity portfolio and economy, we also understand that there is a need to address the transportation, storage and disposal of used nuclear fuel. (0825-3 [Palomarez, Javier])

Comment: GEIS section 1.8.6: NRC has eliminated greater-than-class-C LLW (GTCC) from consideration. Industry has considerable experience with the storage of GTCC after the operating life of a reactor. GTCC is currently stored in dry casks at ISFSIs on six shutdown reactor sites. Because of the possibility that GTCC may share a common disposal path with spent fuel, it would be useful if NRC, based on existing knowledge of the nature of GTCC, could conclude that the analysis and safety conclusions in this GEIS would apply equally to GTCC. (0827-7-3 [Ginsberg, Ellen])

Comment: I would like to respond to the Nuclear Energy Institute's (NEI's) self-serving claim that the Nuclear Regulatory Commission (NRC) "need not assess the environmental impacts of nuclear plant operation more generally" in order to fulfill the requirements of the Waste Confidence Decision (WCD). This is for Docket I.D. No. NRC-2012-0246. Perhaps this is true -- they "need not" as in, it is not explicitly stated that they do so by the judgement. But assessing environmental impacts of nuclear plant operation more generally is implicitly required because if there is no waste confidence, it is immoral to continue making nuclear waste. (0856-1 [Fritz, John])

Comment: There are tons of DoD waste in addition to civilian spent fuel. What is the GEIS/Proposed Ruling doing to address that issue? (0896-1 [Anonymous, Anonymous])

Comment: • The Draft GEIS claims that environmental impacts of spent fuel disposal are irrelevant to the DGEIS. But when the NRC promulgated its final license renewal rule in 2013, it did not include any conclusions regarding the environmental impacts of spent fuel disposal, stating that “[t]he generic conclusion on offsite radiological impacts of spent nuclear fuel and high-level waste is not being finalized pending the completion of a generic environmental impact statement on waste confidence.” 78 Fed. Reg. 37,282 37,322 (June 20, 2013). In a footnote, the NRC further explained: As a result of the decision of United States Court of Appeals in *New York v. NRC*, 681 F.3d 471 (DC Cir. 2012), the NRC cannot rely upon its Waste Confidence Decision and Rule until it has taken those actions that will address the deficiencies identified by the D.C. Circuit. Although the Waste Confidence Decision and Rule did not assess the impacts associated with disposal of spent nuclear fuel and high-level waste in a repository, it did reflect the Commission’s confidence, at the time, in the technical feasibility of a repository and when that repository could have been expected to become available. Without the analysis in the Waste Confidence Decision and Rule regarding the technical feasibility and availability of a repository, the NRC cannot assess how long the spent fuel will need to be stored onsite. 78 Fed. Reg. at 37,323. Clearly, despite denying the existence of a relationship between waste confidence findings and spent fuel disposal impacts in the DGEIS, the NRC considered the relationship significant enough to hold off finalizing environmental findings regarding spent fuel disposal impacts in the license renewal rule. (0897-7-12 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: As the Commission acknowledges, the question of feasibility of spent fuel disposal is integrally related with the question of what are the environmental impacts of spent fuel storage for an indeterminate period of time. By evaluating only spent fuel storage impacts, the NRC excludes a major part of the picture regarding the environmental impacts of the back end of the nuclear fuel cycle. Specifically, if a repository becomes available, some spent fuel storage impacts will be avoided, and there will be some repository impacts. Similarly, if there is no repository, the spent fuel storage impacts will increase considerably, for a variety of reasons, including the potential loss of institutional control. (0898-4-24 [Curran, Diane] [Makhijani, Arjun])

Comment: The NEI scoping comments made a point to emphasize that there is no basis from which one could re-examine the 5 earlier Waste Confidence findings. Please publish these 5 findings, and discuss the implications of them in the final document. Are these 5 findings any more relevant to a real examination of comparative safety of various modes of radioactive waste storage. I note on page 2 of the NEI's scoping comments where they pointed out that it was a comparatively skimpy environmental assessment. An EA is not very thorough, and given that we are contending with extremely hazardous and long-lived wastes, the whole document deserves to have a thorough EIS completed with a reasonable range of alternatives and while thoroughly examining the mystery of those 5 earlier Waste Confidence findings. (0937-24 [Campbell, Bruce])

Comment: As part of the NEI's scoping comments on the Waste Confidence Generic EIS (under "Reasonably Forseeable Spent Fuel Storage Alternatives"), they try to (and succeeded in) convincing the NRC not to analyze an alternative featuring centralized interim storage of radwaste, and they are hoping that a skimpy Environmental Assessment may suffice for this analysis rather than the usually more thorough Environmental Impact Statement. I will quote two NEI sentences from their scoping comments on page 6, "However, such a facility is speculative at this point. And a full discussion of the environmental impacts of a centralized interim storage facility would be set forth in an environmental assessment or EIS supporting issuance of a license for such a facility." If a centralized "interim" storage may only call for an EA, then they likely figure that since nuclear power facilities have less radwaste at their individual sites than a

centralized interim storage facility, that they may be able to get away with a mere EA in analyzing those situations. (0937-8 [Campbell, Bruce])

8. Comments Concerning Site-Specific Issues

Comment: We are writing today to urge you to put a stop to creating more nuclear waste ASAP. It's the only way to safely deal with nuclear waste. We must move to wind & solar & away from nuclear. We live near Diablo Canyon Power Plant. The idea that a nuclear plant was ever situated on/near 13 earthquake faults & a tsunami zone is ludicrous and a horrific danger. Diablo continues to create waste everyday, with nowhere to put it. When does this madness stop? Let's do it now! (0022-1 [Smith, Diane])

Comment: Less than half an hour ago, on September 23, 2013, news was posted online that more cracks have been found in the Davis-Besse nuclear reactor in the Toledo, Ohio, area. The report also said that cracks which were previously found have widened. If something bad happens at that plant, it will happen to me and my husband and our precious children and grandchildren. And to hundreds of thousands of other people who are just as important to their loved ones. Please be diligent and honest, and keep us safe. (0025-1 [Schmitz, Diane])

Comment: It's very discouraging that while we're talking about this important document in 12 meetings that we hold across the country that Dominion is full steam ahead looking at putting the third reactor at North Anna, even prior to any of this being done. Supposedly that's legal. (0030-15-2 [Gray, Erica])

Comment: I live in the most nuclear state in the nation, Illinois. And I can tell you that most people aren't aware of it. They have become more recently. Actually, because Braidwood, the 10 years of dumping radioactive wastewater laced with tritium on that community took the front page of Chicago Tribune and people started waking up. Or more recently what's going in Byron. Every time something's on the news to allay fear, it's not injurious, it's not harmful. But I can tell you that I personally know of the families of multiple cancers in the Braidwood area. So I think that their stories need to be told. (0030-22-3 [Headington, Maureen])

Comment: I have personal experience with -- the high flux beam reactor in Long Island. I was in the Department of Energy. I worked on that. I worked with the people who went out into the communities and took the steps we needed to assure people that their drinking water would be safe. No regulatory limits were ever exceeded or approached. We don't just meet regulations; we exceed regulations. (0030-6-8 [McCullum, Rod])

Comment: Leslie March and her mother in 1955-- I first learned about "atomic waste" in my high chair; I grew up in the fifties in Washington State and my grandfather frequently had business at the Hanford Reservation (now the most contaminated nuclear waste site in North America). I remember my mother arguing with him about the dangers of nuclear waste: she was concerned about the health of the Columbia River; he trusted that the plant would be safe. But my mother was right: the tanks containing highly radioactive waste are leaking, and the Columbia River is at risk. We now have the opportunity to protect communities across the nation from radioactive waste. Please take action today! The reactors at Hanford are now closed. But when I discovered that another nuclear reactor (the same kind used at Fukushima) now operates within miles of the Columbia River, I was motivated to take action to protect the river, and began organizing in my community. I was dismayed when the Nuclear Regulatory Commission (NRC) recently relicensed the Columbia Generating Station for another 20 years -- even though they don't have a solid plan for storing the waste safely. (0039-2 [Littlejohn, Nick])

Comment: I've been aware of the nuclear waste problem for 50 years or more here in St. Louis. The Mallinckrodt Chemical Company was a subcontractor on the Manhattan Project since 1942, and was located in Downtown St. Louis, Missouri. They contracted with a company to remove the waste from that project, and from there the saga begins...A Brief History of Waste Management at West Lake and Nuclear Waste in St. Louis; 1939 - West Lake Landfill, owned by Rock Road Industries, opens as a limestone quarry and crushing operation; 1942 - Mallinckrodt Chemical Works agrees to enrich uranium for the first atomic bomb under the Manhattan Project (between July and December they produce a ton of pure uranium oxide per day); 1947 - The Manhattan Project condemns 21.7 acres north of Lambert Field Airport to serve as a disposal site for waste from Mallinckrodt and other facilities; 1950 - Portions of the quarried areas in West Lake begin to be used as a landfill; 1957 - Mallinckrodt signs a contract with the Atomic Energy Commission; move uranium processing facilities from downtown to St. Louis to Weldon Springs; Early 1960s - Mallinckrodt hauls some 5,000 truckloads of waste from downtown to abandoned limestone quarry near their new plant; 1966 - Mallinckrodt closes down their uranium enrichment plants and hires Cotter to discard of the waste; 1973 - Cotter illegally dumps radiologically-contaminated soil at West Lake Landfill; 1976 - The Missouri Department of Natural Resources (MDNR) closes West Lake Landfill; 1982 - Radiation Management Corporation conducts a radiological survey of West Lake that indicates elevated levels of uranium and thorium; 1988 - U.S. Nuclear Regulatory Commission releases report of West Lake, determining that the site has two contaminated areas with about 150,000 tons of contaminated nuclear waste; 1990 - West Lake Landfill added to EPA's national Superfund Site Priorities List (a list of sites around the US requiring long-term clean-up efforts); 1993 - Army Corps of Engineers conducts several risk assessment studies and determines that if nothing is done to cleanup various nuclear waste dumpsites, the public will be exposed to unacceptable levels of radiation; 2006 - EPA's Remedial Investigation and Feasibility Study work completed; 2008 - EPA's Record of Decision completed and released; states that waste is best left at the site and that they will continue to closely monitor the area in case of groundwater contamination; 2010 - Opposition to EPA decision leads to commissioning of Supplemental Feasibility Study (which lays out two additional options for remediation at West Lake); 2011- 1,400 page Supplemental Feasibility Study for West Lake is finalized and made public; January 2012 - EPA's National Remedy and Review Board has been reviewing the SFS report; April 2012 - 16 people file class action suit against Mallinckrodt, Inc and other companies involved in production and disposal of nuclear waste, alleging that the mishandling of nuclear waste caused untimely illnesses; Summer 2012 - EPA returns to West Lake site to conduct groundwater testing and take gamma scan measurements; October 2012 - Two more people file suit against Mallinckrodt, et al; one is a father whose 23-year old daughter died in 2009 after being diagnosed with malignant pleural effusion and acute respiratory failure; November 13, 2012 - Missouri Coalition for the Environment holds public meeting and calls on citizens to write EPA, government officials and demand that West Lake be transferred to Army Corps of Engineers; January 2013 - EPA says they will host a public meeting to discuss findings. But it never seems to end, or even be still long enough to forget about it. Its a matter of coming up with two parameters. One, to find a way to safely store the material until the danger subsides. AND.. Two, to stop producing the stuff until the PERMANENT repository is found. (0043-1 [Lewis, Dave])

Comment: In my case, the Columbia Generating Station is in the agricultural center of Washington State. An accident there threatens \$9.5 billion worth of products in Washington and another \$6 billion in Oregon. This is besides having Seattle, Spokane, and Portland affected based on what direction the wind blows. We also have the risk of contaminating the Columbia River and the double jeopardy of having the Hanford reservation next door. (0045-11-7 [March, Leslie])

Comment: Right now the waste tanks for nuclear at the Savannah River site are raging into the Savannah River. Oh, right, I forgot to mention that as a member of the Colorado Coalition for Prevention of a Nuclear War, I work with the Alliance for Nuclear Accountability and we know and we documented that leak. (0045-12-5 [Kinsey, Bob])

Comment: The tanks in Hanford are leaking into the Columbia Reach and are impacting the roe of the salmon that is spawn there. And nuclear plutonium has been found in the salmon off the Coast of the Columbia River in the Pacific Ocean. (0045-12-6 [Kinsey, Bob])

Comment: Palo Verde, for an example, is a major employer in Arizona and it also makes a substantial amount of local purchases from suppliers, supporting the region's economy. The plant directly employs 2,800 employees and contractors with the combined annual payroll of \$255 million. It also indirectly supports an additional 5,800 jobs and \$253.7 million in payroll annually in other businesses throughout the state. (0045-9-5 [Baker, Tammera])

Comment: Again using Palo Verde as my point of reference, the plant creates an economic impact of \$1.8 billion in the Arizona economy, and it's the largest single commercial taxpayer in Arizona, paying approximately \$50 million in property taxes alone. These tax dollars benefit our schools, our roads, and other state and local infrastructure, not to mention the generosity of the Palo Verde employees who donate over a million dollars every year to local charities. (0045-9-7 [Baker, Tammera])

Comment: When and where is the spent fuel at Millstone and Conn Yankee going to be put under ground? (0050-5 [Waterman, Charles])

Comment: I live in Florida and we have several nuclear reactors in this state, located at Crystal River and at Turkey Point in St.Lucie. We have fortunately been able to cancel Offshore Power Systems at the Port of Jacksonville and the Levy County nuclear power plant. However, Florida was the site of the Tooth Fairy Project showing that children living near nuclear powerplants have a radioactive body burden that increases their rate of cancer, and Florida has suffered negligence in management of radioactive waste. The nuclear reactors in Florida are located at the coastline and subject to a high potential for flooding from hurricanes as well as sea level rise, and tidal waves. Even earthquakes will become increasingly likely as a result of extensive and careless offshore drilling in the Gulf, and fracking being permitted in Florida. I do not want my beautiful state, which remains a good place to live in spite of the efforts of industries to destroy its natural beauty and small farms, to be destroyed by irresponsible negligence with high level nuclear waste on the part of the NRC now or in the future. This plan is irresponsible and absurd, and must be improved. (0053-1 [Minno, Maria])

Comment: It is ridiculous that states do not have power to decommission specific nuclear power plants when safety violations and health hazards have been proven. The good state of Vermont acted to protect its citizens from Vermont Yankee Nuclear Power's history of abuses by voting to not renew its license. The NRC should have backed up the local state government when the federal Judge declared that it was the NRC only that had the power to shut down a power plant, not the state. While the judge over ruled the state's attempt to protect its citizens, the NRC should have jumped in and shut down the power plant on its own. The state of Vermont would still be tied up in the fight if the aging nuclear power plant itself hadn't finally decided to close down due to its own financial concerns. . Please take your job with the seriousness that is necessary and shut down all nuclear power plants in the nation and be a responsible watchdog to make sure the shutdowns are done as safely as possible for the dozens of miles surrounding communities that house them. (0054-3 [Kurland, Miriam])

Comment: I too grew up in Washington State. It was known in the 1950s that the entire "tri-cities" Hanford area was contaminated and cancer rates there were huge. Discolored lakes and rivers in that region produced deformed fish. Most people refused to even drive past the towns in the area. Half a century later it is apparently the same. The NRC should at long last take action to reduce the number of fuel assemblies in the Hanford reactor's water-filled disposal pools. (0057-2 [Lamont, Dana])

Comment: Since 1998, the taxpayer has been paying billions of dollars to the Nuclear Energy companies like SCE to store nuclear waste on site until a place can be found to dispose of it. This fine goes on as long as the spent fuel is stored on site. How much money has SCE been paid by the Federal government since 1998 for the spent fuel it has stored at SONGS? How was that money used? How much money will SCE get each year even with the plant shut down for leaving the spent fuel at SONGS? Is there any law forcing SCE to spend the money from this fine for moving the spent fuel into transportable casks? Must the money be used for something related to storage of spent nuclear fuel or does it just go into the SCE or for that matter the International Edison general fund? (0063-11 [Magda, Marni])

Comment: SONGS must have attention paid immediately to its vulnerable spent fuel. The two years to create a PSDAR is too long to get in motion the kind of actions that are necessary to save Southern California from calamity and must begin today, not in two years. Southern California Edison has lied to the public about safety problems at SONGS of which the company was well aware. They knew the steam generators were a faulty design before they were installed. They have in a constant record that is public information now of failures to adhere to safety regulations. The company puts profit before safety. With this terrible record, they must not be given oversight of the Decommissioning of SONGS. There is a history that would show the \$4 billion dollars set aside to decommission SONGS would not be used for immediate, final solutions. There is profit for Edison in keeping the spent fuel on site. Since a US Military Base is in jeopardy if anything goes wrong with the spent fuel sitting at SONGS, and it is on military land, can the execution of the removal of the spent fuel be placed in the capable hands of someone from the military, protecting the future of Camp Pendleton Marine Base? When for two years Elmo Collins, who was then the administrative director of NRC Region IV, met with the public at NRC hearings and told us that SONGS was safe, he listed each of the possible disasters and said behind it, "adequate protection." He was referring to the nuclear fuel within the reactor domes. With the shutdown of SONGS, the public has learned that the 1631 tons of spent fuel on site is not held to that standard of safety. The spent fuel cooling pools are outside the reactor domes. They were not created for long term storage and are not required to have "defense-in-depth" nuclear safety features. SCE has the worst safety record of all nuclear energy companies in the United States. They are going to continue to falsely tell the public that safety is their first concern. We are playing with our future every day the spent fuel sits at SONGS. (0063-2 [Magda, Marni])

Comment: There is a vast difference in the type of the dry storage casks being used around the country for storing nuclear spent fuel. According to the Blue Ribbon Committee's report to the President in January of 2012, the US Navy has 50 final geologic disposal, transportable casks for its movement of nuclear waste out of Idaho by 2035. It will have 350 more before that date. How long does it take to make these casks? What do they cost? Is there any reason we can't use them at SONGS? Final disposal and transportable - that must be our goal. SCE profit in storing nuclear spent fuel on site at SONGS cannot be allowed to make us pretend that spent fuel should stay at SONGS for years. It shouldn't be there for even days. The Friends of the Earth report by Alvarez said the casks SCE is considering will be a million dollars each. Who determines the certification of the number of years a cask is safe? Many in the country currently

are said to be certified at 30 to 40 years. What makes a ten year difference? What do we do after the thirty or 40 years are up? Who sets the value of a cask, another corporation like SCE who values profit over public safety? (0063-6 [Magda, Marni])

Comment: When the four billion dollars projected to be spent decommissioning SONGS is spent, does that include final disposal of all spent fuel created at SONGS, even that which lasts 24,000 years? What dates did the current 42 casks for dry storage get fuel placed in them? These casks were constructed somewhere near SONGS. What is their certification for length of safe storage? Are these dry storage casks considered transportable? In Sept 2014, SCE wants to lower safety standards by using the NUHOMS 32PTH2 dry cask system. This requires crowding 32 fuel assemblies into the same size cask that currently holds 24. Who makes the approval of such a change? Edison always chooses profit over safety. Who will decide? What safety consideration would allow that change? (0063-8 [Magda, Marni])

Comment: [A]t the Seabrook nuclear power plant, which stores most of its spent fuel in wet storage, a 4.0-level earthquake hit recently only 20 miles from the plant. The Seabrook plant has been identified as one of the most vulnerable nuclear power plants in the nation to flooding and storm surges (Stanford University researcher, 2012). Yet, the public has not been informed if the plant has taken steps to protect against interruption of electrical generation for wet storage as a result of flooding or earthquake. (0064-10 [Skud, Bruce])

Comment: I am writing with great concern over the construction of the W.S. Lee nuclear plant in Gaffney, SC just 60 miles from Asheville, NC where I live. There is simply no safe way to store spent fuel over the long term. Radioactive nuclear wastes present a huge threat when they are transported, as well; they are dangerous for many thousands of years, and there is no such thing as a safe dose. This is all just "business as usual." The threat of an accident magnifies the risks many times over. Have we learned nothing from the Chernobyl and Fukushima tragedies? And if the safety and health hazards were not enough, take a look at the economics of nuclear power. It is FAR less expensive to use energy saving technology, wind power, and now even solar photovoltaic electricity is less expensive than nuclear generated electricity, especially if the cost of decommissioning and long term storage of radioactive waste are taken into consideration. There is just no excuse for building a nuclear power plant. Please take action to stop WS Lee before it's too late. (0066-1 [Holt, Cathy])

Comment: Just a note: I worked at the West Valley, NY waste site I lasted 2 weeks and was very frightened by what I experienced there. I was in the pool area (they store the radioactive cylinders under water) when we came out after reading the meter we had to scan ourselves with a Geiger counter in a small out building. When I scanned my left foot the counter went crazy! I freaked out, the coworker with me started laughing and said it was the breeze blowing over the waste tank farm carrying radiation. When I was hired I was told that only about .03rems escaped per year, is this really enough to set off the Geiger counter? Who knows, anyway, I quit rather than take the chance of more exposure. The gauge I wore was almost full everyday! Very disconcerting to say the least. (0076-1 [Jensen, Phyllis])

Comment: As a resident of New Hampshire living on the power grid that is directly supplied by nuclear energy, I am writing in support of any and all efforts to maintain and continue the operations of Seabrook Station. Nuclear energy plays a vital role in meeting our nation's electricity needs and diversity. Seabrook Station has, for decades, produced energy efficiently and cleanly. It is vital to our economic security that its operations continue. (0087-1 [Hinch, Richard])

Comment: I don't agree with the NRC's stance that the problem of nuclear waste will be solved in the future and therefore recommends relicensing of the power plant [Diablo Canyon]. In fact, the NRC is exposing the county and the people of the state to the real probability of a horrendous nuclear accident. There is no scientifically proven solution for safely disposing of nuclear waste. The plant was not built to store waste and the waste is stored in vulnerable pools. The only solution is to shut down the plant and move the spent waste into dry casks as soon as possible. Lastly, the plant sits on or near several active earthquake faults which represent a seismic hazard beyond which the plant was built to withstand according to the United States Geological Survey, namely Dr Jean Hardebeck, who discovered the Shoreline fault. Thus the possibility of a major earthquake at the site is very possible. I ask what would happen to the highly radioactive nuclear waste then? Another Fukushima. (0095-1 [Caulfield, Lee])

Comment: Please continue to maintain the DC Court of Appeals Waste Confidence Ruling making it illegal for Duke Energy to obtain a license for a new nuclear power plant in Gaffney, SC. This will help prevent the additional production of nuclear waste material for which we currently have no means of safely disposing. (0098-1 [Pluta, Tim])

Comment: It is incomprehensible to me that with all the information that's out there on the amount of spent fuel being stored at Indian Point and the questionable way in which Entergy is storing it, that with all the experience we've had with terrorism and catastrophic accidents here and abroad (911, Fukushima), not to mention the president's campaigning against the Yucca Mountain site starting in 2008 and finally scuttling it in 2011, that most of our New York electeds cannot find a way to come out against storing such seriously hazardous waste in this part of their state. (0102-5 [Woodward, Julie])

Comment: NOR SHOULD WE ALLOW PLANTS TO SEND THEIR WASTE TO OTHER PLANTS LIKE that at the Shearon Harris nuclear plant here in North Carolina: http://www.organicconsumers.org/articles/article_19936.cfm. There have already been frightening irregularities in plant operations that could prove fatal if SUCH storage capacities are operated. (0106-1 [Pipes, Betty])

Comment: And at Seabrook there was a 4.0 level earthquake only 20 miles from the plant just a few -- just a year ago. And as Doug Bogen mentioned, it's destined to be coated with -- covered with water some day. (0112-10-7 [Skud, Bruce])

Comment: Entergy began construction on the ISFSI at Pilgrim a year ago and has sited the facility 106-feet from the ocean at an elevation of 24-feet above sea level. Entergy failed to obtain any local zoning or construction permits for this facility until citizens notified the town that construction was underway. Entergy then applied for and received local zoning permits; however, relying heavily on the idea that the NRC provides oversight and regulation of dry cask storage facilities and nuclear waste generally, the town rubber stamped Entergy's construction and did not require public hearings or environmental review regarding this multi-million dollar project. Plymouth citizens have appealed the town's decision to Massachusetts land court. Judge Foster is hearing the appeal and recently ordered Entergy to notify him directly 90 days prior to storing any nuclear waste. He has taken citizen concerns seriously and warned Entergy that they are continuing construction at this site at their own risk. Entergy has stated that the ISFSI site will be safe over the long run in terms of flooding, sea-level rise, and coastal erosion because the site falls within the design conditions of the plant, itself -- conditions established when the plant was built 40 years ago and based on storm surge data from the 1600s through the 1960s. No Entergy or NRC representative has been able to identify any updates to this data. As of today there has been no site-specific environmental review of Pilgrim's ISFSI either at the

Federal or the local level. I hope you can understand why citizens can see this as a cause for alarm. (0112-13-2 [Byrne, Genevieve])

Comment: The only thing I want to say is that when Seabrook was built it was designed with a place to put these spent rods into a pool. Shortly thereafter it wasn't big enough so they got the idea that they could double up in the pool, and that was risky. And now they want to put them into casks and that's a hopeful afterthought, that's my only opinion, it's an afterthought. Forget the engineering, they don't know what to do with it, it's just an afterthought. (0112-14-1 [Tilbury, Don])

Comment: But, you know, I want to take just a couple minutes, because that's all I've got, to talk about the reality of something now that we're having to face in Vermont now that Entergy has announced that they've lost enough money and they've given up. I want to remind everybody that Entergy was amongst a group of large utilities who back in the 90s made the case that they wanted free markets and open markets for energy and we need, you know, vigorous, you know, market competition. Part of their announcement in closing Vermont Yankee was these markets are flawed and messed up and they just don't work. And I just wanted to make that note. (0112-15-2 [Williams, Chris])

Comment: So in Vermont we're going to close Vermont Yankee down in one year. And when it closes we're then going to have to deal with decommissioning and the spent fuel. There's about 800-tons sitting in the pool at Vermont Yankee about 120 miles from here. It's going to cost, according to Entergy, a little over a billion dollars to decommission the plant. A billion dollars. Because, as part of their sales agreement in 2002, Entergy, insisted -- and the State of Vermont foolishly agreed -- that they wouldn't make anymore contributions to the decommissioning fund. We, in Vermont, have \$580 million. Entergy has the option to go into safe store and they also have the option in safe store to not move anymore of that fuel out of that pool for up to 60 years. NRC, this is real. This isn't, you know, generic, this isn't theoretical. We need your help. We need your understanding. We need action. We have \$580 million. That \$580 million will only grow if the market's gone. It actually lost money in 2008 when the markets went down. And like everybody's IRA, it came back a little. (0112-15-3 [Williams, Chris])

Comment: Because, frankly, if you stand back and look at it, what conclusion can you draw? That they [Pilgrim Nuclear Generating Station] don't have enough money to do the preventative maintenance that needs to be done to continue to operate in a way that any rational person would consider safe. At a conference at the Mass State House a couple of weeks ago -- Arnie Gundersen -- when you hear a plant is safe what should you assume? "You should assume," -- and this is quoting Arnie -- "it is meeting the minimal requirements of a compliant agency." (0112-2-2 [Lampert, Jim])

Comment: The other point I really want to bring up is the lies that have come down from Entergy and been completely ignored by the NRC. At Vermont Yankee 11 people, top people in the Entergy corporation, swore under oath at the Department of Public Service that there were no underground pipes that could possibly exist or leak. They were caught in their lies. (0112-22-4 [Nestel, Hattie])

Comment: I just wanted to tell you a little bit about our experience with Pilgrim and their building of a dry cask storage area. And I think it speaks to the Entergy culture similarly to the way Hattie [Nestel]-- Hattie's experience was up at Vermont Yankee. You know, we're watching Pilgrim morph into a -- from an energy-producing plant to a dry cask -- to a nuclear waste storage dump. And they started this, as Genevieve [Byrne] said, without any permitting at all.

And it was only noticed by citizens from an aerial photograph that saw some scarring on the ground that looked like construction activity. And so we called up the nuclear -- we, like, we e-mailed the Nuclear Regulatory Agency, a Mr. Dean I think is who I exchanged e-mails with. And he reported that Entergy was just doing preliminary work. You know, grading, cutting trees, moving material around. We went down to the building department and found out, well, they didn't have any permits for any of this yet and that they were actually pouring concrete for the approached slabs, the heavy-haul path, and the turning slabs. And they were getting ready to build the retaining wall. So what they did was they applied for a fractional permit. They didn't apply for a permit to build a nuclear waste dump site. They applied for a permit to build a retaining wall so that they could build the slab where the pads go. By doing that, they avoided a comprehensive review of the project. This was done by design. They started the construction before having permits. This is a company that's got permits for administration buildings, sheds for equipment, meteorological towers, parking lot changes, tents to have -- they get permits for tents to have functions outside that they can't do inside. And so now they're building a nuclear waste dump site without any permitting at all. You know, this is not a casual mistake. So that's the culture of Entergy. And it just boggles my mind that in the town of Plymouth it is harder to get a permit to put a deck on your house than it is to get a permit to build a nuclear waste dump site. (0112-23-1 [Maurer, Bill])

Comment: So I first came to Vermont in 1972, the same year that Vermont Yankee was built. And at the time I took a tour of this sparkling new facility and I was in awe. I was like the bridge the bridge of the Starship Enterprise, I mean, it was just amazing. And I just, you know, 40 years later I'm in a very different place. I've moved from awe to deep, deep fear. (0112-24-2 [Darling, Ann])

Comment: In going to some of these meetings I'm always looking at people with a lot of confidence in looking at the science behind what they're doing. And about in 1999 I went to Washington at a WAN conference with Helen Caldicott. And at the conference we were trying to make people aware about the possibility of what might happen to the grid during the change over to 2000, the Y2K issue. And we addressed several issues. And one of them was Helen, you know, asked us to go back to our nuclear power plants, which in my case was Plymouth, and find out what they would do if there was a loss of electricity and how we were prepared to have generators backup. The other thing that she asked me to ask the nuclear power plant was what would we do if we had a terrorist attack. And she gave us two options to ask the nuclear power plant. What would you do if you had, you know, a terrorist attack that attacked you by plane filled with fuel? So this is 1999. So I talked to nuclear power plant at Plymouth and I said, I asked them what they were going to do as a backup and they did have a backup plan. But they didn't have another backup one in case that one didn't work. (0112-29-1 [Roman, Margo])

Comment: We heard from the spokesman from the Seabrook plant back in 2006 that, quote, "Environmentalists can submit as many plans as they want. The decision on dry cask storage has already been approved." And that was from Alan Griffith, the spokesman for Seabrook in 2006, seven years ago. There's never been a public hearing on that site, on the process. And to this day we haven't really heard the details. (0112-5-8 [Bogen, Doug])

Comment: A year from now Vermont Yankee will be closed and that means it will no longer be producing nuclear waste. But we're not celebrating. We're not celebrating for the reason that we're all in this room. We don't know what to do with that waste. We don't know what to do with 40-plus years of this stuff. And like Doug [Bogen] said, we've been working on it for 40-plus years. Vermont Yankee has 2,627 fuel assemblies in its spent fuel pool, seven stories above the

Connecticut River. That's four times as many as it was designed to hold. That's many more times than the fuel in Fukushima. (0112-7-1 [Sachs, Leslie Sullivan])

Comment: [A] lot of us are not necessarily anti-nuclear. You don't have to be anti-nuclear to believe that there are many problems at the current plants we have running. Call yourself whatever you want, it doesn't mean that Pilgrim, for example, doesn't have a mass of problems that could eliminate our whole geographic area and sacrifice our lives and livelihoods. (0112-9-2 [Baker, Anna])

Comment: We [The African American Men of Westchester] strongly believe that Indian Point's continued operation is imperative to reducing reliance on fossil fuel generators, which are unequally located in minority and low income communities. If Indian Point shuts down, there will be significant pressure to replace this carbon-free facility with power from fossil fuel plants, the majority of which are located in African American and other minority communities in the New York metropolitan area. In fact, a 2011 study commissioned by the New York City Department of Environmental Protection found that Indian Point's closure would cause carbon emissions to increase by up to 15 percent and nitrous oxide emissions to increase by 7-8 percent in both the City and State. This will only exacerbate the disproportionate incidence of childhood asthma, and other health related problems in these communities caused by air pollution. (0115-1 [Salley, Lawrence])

Comment: I am sure that most of those in charge of renewing the license for Indian Point as well as finding a safe way to store the waste, also have find the time to raise our voices to stop the path we are on. We are rightfully concerned, as compassionate people in our great country, about the use of chemical weapons as a crime against humanity, when other countries poison and kill innocent civilians and people in their own community. Now we are on a path in New York State to use chemical warfare against ourselves by ignoring the hazards of nuclear waste. Until we receive evidence of a substantial number of requests to the NRC to allow everyone within 70 miles of the plant to risk death or relocation, we respectfully request that the Commission do what is best for everyone. We must not allow ourselves to commit suicide by ignoring what is obvious. Dr Kevorkian was requested by people who wished to terminate their lives. I have seen no documentation that this something anyone in the Greater New York Area wishes to see happen to them or their families. There is no documentation of any citizens in the Greater New York Area requesting that we become a new JonesTown. Intelligent action to save a tragedy from occurring at Indian Point can set an example to the whole country that our government is still devoted to serving the needs of the people it represents. I respectfully request, on behalf of all my neighbors, my friends and family, and with equal respect to all of you [at NRC] and your friends and families, to choose a solution to assure our survival. Your decision at NRC will determine our shared destinies. (0117-4 [Amram, David])

Comment: The Business Council of Westchester and our more than 1,000 members recognize the substantial contribution to our region by the Indian Point Energy Center, and we support its continued operation. (0118-1 [Westchester, Business Council of])

Comment: The Business Council of Westchester supports Indian Point because it is an important asset to the reliability and affordability of electricity in the State of New York. Additionally, Indian Point is a major contributor to the local economy of Westchester County. According to a study that our organization commissioned in September of last year, Indian Point's closure would result in the elimination of 3,300 local jobs, \$75 million in revenue funding for local services, and millions more in economic development resources. These staggering losses would have a dramatic negative impact on the region. (0118-3 [Westchester, Business Council of])

Comment: Entergy has spent more than \$1 billion upgrading and enhancing the facility and preparing the plant for safe operation during the 20-year period under a renewed operating license. For nine years in a row, Indian Point has received the NRC's highest annual safety evaluation. These are the findings of trained experts who spend tens of thousands of hours evaluating the Indian Point's operations and they agree the plant is unequivocally safe. (0119-2 [Mooney, William])

Comment: Recently, I received a geiger counter to take part in the project monitoring radiation from levels in our atmosphere caused by Indian Point for citizens who live within the 10-mile dead zone, the "impossible" to evacuate zone, and I work with children. The experience of using the geiger counter makes the reality of Fukushima so profoundly real. I have seen a documentary with the citizens of Fukushima with Geiger counters. It is haunting to walk about with a geiger counter, thinking of what it means that we need a detection program. We can only hope that this detection program is only going to be something that will wisely inform the shutdown of Indian Point, and never to become a program that tells us which of our beds and pillows are too contaminated to lay down on at night. (0120-2 [Seeman, Laurie])

Comment: People need to realize the vulnerability we live with every day with Indian Point is tick-tocking towards the eventuality of causing increased sickness. The women of Fukushima came here to tell the people of the Hudson Valley and the NRC, - Learn from Fukushima! Do not let this happen to you!! So while we can only hope that Indian Point will never wreak devastation, the NRC can more than hope. The NRC can assure that this devastation will never occur. Has anyone in the NRC heard and understood the truth of the messages from Fukushima? Have the citizens of the Hudson Valley heard this message? What is next? (0120-4 [Seeman, Laurie])

Comment: I am waiting for the Indian Point decision makers to get scared. To see what has happened in Fukushima that is poisoning not only the coastal waters of Japan, but now the whole planet. I am waiting for the Indian Point decision makers to say, enough. We need to wind this down. The stakes are way too high at Indian Point. This is a risk we cannot afford to take. This is the time to proceed with closing Indian Point. It is notably slated for retirement. Failure to listen to this precaution would be much the same as TEPCO in Fukushima failing to heed the pre-caution to build a higher sea wall. They did not do that. Now what is the cost? To TEPCO? To the world? There are a many tons of radioactive material impounded at Indian Point. The agreement to relicense Indian Point is a sentence to add 50% more tons of poorly contained lethal matter to our environment. We are already suffering. And in Rockland County the people are wildly opposing the drinking water that would be withdrawn from just 3.5 miles downstream of the plant. This must all stop! With the Geiger counter unit that I now have, I will be alerting the authorities and the medical science people when things are not right, when radiation is rising. (0120-6 [Seeman, Laurie])

Comment: This is the beginning of how Indian Point is going to be monitored into closing down. To the NRC, I say, start planning the decommissioning now. Ensure that the funds are in order. Shut this plant down properly, with every respectful precaution for safety. I have been to Three Mile Island Pennsylvania three years after the 1979 Un-reported accident, which is called by the people there the "Accident without end", and again in 2009 for the events of the 30-year commemoration. The people of Three Mile Island would give every penny they ever earned to go back to the day before March 28th, 1979. They will tell you there is no cost saving on energy that is worth the perpetual worry about sickness that they live with now ever since. One mom told me she looked at her daughter every year at her birthday party and wondered if this was the year she would become sick. They worry too for the genetic flaws in their future generations too.

Please close Indian Point nuclear power plant. It is the right and conscionable time to retire it. It has come to the end of it life span. (0120-8 [Seeman, Laurie])

Comment: In baseball, one has three strikes and you're out. In the nuclear industry, we've had three strikes: Three-Mile Island, Chemobyl and Fukushima. You're out! It's time to close Indian Point! This deadly nuclear plant threatens the lives of over 21 million people in the most densely populated Metropolitan area, poisons the Hudson River and ground water. Indian Point is situated on two fault lines. Scientists of Columbia University reported that a 7.0 magnitude earthquake is possible at Indian Point; and this aging structure was built to withstand a 6.1 earthquake only. (0121-1 [Skopic, Catherine])

Comment: Indian Point uses 2.5 billion gallons of water daily, circulates it through the system and dumps it back into the river, hotter, untreated and now containing strontium-90. The Westchester Journal News reported in 2007 that 4 out of 12 fish sampled showed detectible levels of strontium-90 in their flesh. Cancer rates are 66% above the US average in communities surrounding Indian Point, according to the U.S. Centers for Disease Control and Prevention. There is NO EVACUATION PLAN! (0121-3 [Skopic, Catherine])

Comment: We don't even need the electricity produced here - reported to be sometimes as low as 4%. We have a surplus of electricity. New transmission lines have been approved that will save consumers money and preserve the environment. I encourage Entergy to go green, along with the rest of the world's movement in this direction. (0121-4 [Skopic, Catherine])

Comment: This summer, I paddled down the Hudson River with about two hundred native and non-native people for the 400th anniversary of the Two Row Wampum - the 1st covenant between Native Peoples and Europeans that agrees to respect each other, work together and protect Mother Earth. No matter what side of this issue we are on, we are called to honor this covenant today. The time of environmental destruction is over - it is now a time of healing for each other, for the earth, for all creation. Going back even further than 400 years, and I quote, "The earth lies polluted under its covenant." Isaiah 24: 5 It's time to close Indian Point! (0121-5 [Skopic, Catherine])

Comment: As someone who resides and works within 50 miles of Indian Point, I would like to express my informed opinion that Indian Point should be permanently closed (0125-1 [Kidney, Barbara A.])

Comment: As a long term resident of Charlotte and the Carolinas, my concern is the number of nuclear sites in this region and the ongoing storage of radioactive waste at these sites. Charlotte is a burgeoning population center, as are the I-85 and I-40 corridors. Millions of us are at risk, and consequences can be catastrophic. (0131-1 [Felder, H.M.])

Comment: I live 5.5 miles from the Indian Point Nuclear plant and I have been trying to close the plant since Indian Point2 had a steam pipe rupture in February 2000 and became the first nuclear plant in this country to earn a red rating from the NRC. Indian Point 2 stayed offline for almost a year after the steam pipe rupture. That rupture spread radioactive steam into the air near my house and irradiated water through the Buchanan sewer system into the Hudson, a US Heritage waterway that belongs to all the American people. (0136-1 [Shaw, Gary])

Comment: That is the same type of oversight we have seen from this agency that did not ensure that the IP2 [Indian Point 2] transformer would not explode three years after the same transformer at IP3 [Indian Point 3] exploded, that has not prevented ruptures and leaks from

underground piping and that did not know that there was spent fuel pool leakage, probably for years, until the operator started excavating to prepare to move high level radioactive waste into dry cask storage and. That leakage included Strontium 90. Again, Indian Point became the first nuclear plant in our country to set a bad standard. And the GAO has identified Indian Point as the nuclear plant with the highest number of safety violations in the past year. And this agency has granted numerous exemptions from regulatory standards including the waiver of the requirement that Hemyc fire wrap protect critical safety cables in the automatic shutdown system from fire for an hour. The same person who let the Davis-Besse plant in Ohio get within a quarter of an inch from breach of containment then oversaw the reduction of the Hemyc 60-minute requirement to 24-minutes. In a public meeting, when NRC was asked how many exemptions have been granted at Indian Point, not one member of the NRC panel knew the number. Now you are telling us that you have a workable plan to secure and keep the public safe from the thousands of tons of high level wastes that are currently sitting in the plant and the additional tonnage that will accumulate if the plant gets a new twenty year operating license. If that wasn't so scary it would be funny. (0136-3 [Shaw, Gary])

Comment: It is my understanding that only about 15% of the spent fuel assemblies that have been accumulating at Indian Point for these last 40+ years have been moved to on-site dry cask storage although far more, perhaps 75% - 80% is cool enough to be moved, and you seem in no hurry to reduce the dense packing that has resulted in many times more fuel assemblies than design basis specified. (0136-4 [Shaw, Gary])

Comment: But we [Indian Point Energy Center] have had 10 more years of wet storage since that report was issued with very little waste moved. Why? Because it costs the operator money. (0136-6 [Shaw, Gary])

Comment: Suggestion: Solar energy jobs could be made available within a fifty mile radius of Indian Point. These jobs would be to transform Indian Point from using nuclear energy to using solar energy. Could there also be a job program to install solar panels on qualifying homes? Could there be a manufacturing plant established for solar devices in some less prosperous town in the 50 mile radius, such as Beacon or Newburgh? Money for such job projects could be transferred from the amount scheduled for new nuclear plants or for repair of present plants. (0137-1 [Cypser, Betty])

Comment: Quote from Entergy (Indian Point Energy Center) "Indian Point safely and reliably provides about 25 percent of New York City and Westchester's power, with virtually no greenhouse gas emissions, at far lower costs than other power plants. Its continued operation is a vital component of the region's economic and environmental future."

<http://www.safesecurevital.com/rightfornewyork/?gclid=CJXp75GW6KoCFaoSNAoduTU6dQ>. Is it true that the coal necessary to make uranium usable, is costly, dirty, and has greenhouse gas emissions? If so, is the above quote unreliable? Is it true that Indian Point and its waste products are "safe and reliable" for the people of the 50 mile radius, or for the people all over the world who have been subjected to weaponry of depleted uranium? Another quote: "Exelon Corp. said that four of its nuclear power plants declared "unusual events" following the earthquake. Exelon's Limerick plant near Philadelphia; Oyster Creek plant near Toms River, NJ; Peach Bottom plant near Lancaster, Pa.; and Three Mile Island Unit 1 near Harrisburg, Pa., all declared "unusual events," the lowest of four emergency classifications used by the NRC. Plant operators are inspecting facilities and equipment to check for any damage or impacts, an Exelon spokesperson said." (Dow Jones, Aug. 23, 2011)

<http://www.ww4report.com/node/10250>. Do you know if Indian Point had any "unusual events" to report on August 23rd, 2011? Another quote: "A nuclear power plant that was shut down after

an earthquake struck central Virginia Aug. 23, 2011 had seismographs removed in the 1990s to save money. Officials said that the North Anna Power Station, which has two reactors, lost offsite power and switched to diesel generators to maintain cooling operations after the 5.9 quake. The North Anna plant, which was near the epicenter of the quake, is reportedly located on a fault line. The US Nuclear Regulatory Commission (NRC) rates the plant as the seventh most likely to receive core damage from a quake, although it says the odds are very low. According to the Virginia Department of Mines, Minerals and Energy (DMME), the Virginia Tech Seismological Observatory (VTSO) removed all seismographs from around the plant in the 1990s due to budget cuts. In February, Dominion Virginia Power announced plans to add a third reactor at the plant." (Raw Story, Aug. 23) <http://www.ww4report.com/node/10250>. Do you know if Indian Point is first in line as the most likely to receive core damage from a quake? (0137-3 [Cypser, Betty])

Comment: Already we have Energy Solutions Corp. storing waste which was never sanctioned and stored illegally without the State's permission. Now we have hotter waste than was allowed, yet the citizens have no recourse for its removal. (0158-4 [Payne, Joanne])

Comment: So I have a bill. It's A-10-38 and Entergy has lobbied heavily against this bill. If we're going to play the science card, let's look at this bill. This bill will study under the Energy, it will amend the Energy law to study alternative sources of energy to Indian Point. It does not say close Indian Point. It says study. And to the gentlemen who represent the 400 people who work at the site, this law, if it became a law, this bill will in fact protect your jobs and look at new ways to relocate because we respect the work that you do in the Valley. And I call upon the NRC to support me in this effort and to please communicate to Entergy that we should work on, in the name of science and truth, getting this bill passed so that we can really look at the impact of this bill and we can look at -- we can stop the production of long-term waste. (0163-13-2 [Jaffee, Ellen])

Comment: You've heard many people tonight who are forced to live with the continued threat of Indian Point every day and the waste that it produces. And, you know, what's in a name? So I don't think EIS -- I don't think there should be the "G" before it. It's a generic. Indian Point is anything but generic. It is a specific power plant in the most crowded region of the United States with 20 million people living in a 50 mile radius, so I think to apply a generic EIS is ludicrous. (0163-15-2 [Garner-Ritter, Maureen])

Comment: I just have four questions that I do want to answer to the -- ask the NRC, is how does the fact that if IP is making waste now and it is now considered actually a storage facility instead of a generation -- place of generation? That's one question I have. (0163-15-7 [Garner-Ritter, Maureen])

Comment: My deep concern about Indian Point started some years ago when Entergy couldn't get the sirens to work properly, and I wondered if they can't get something that simple outside the plant to work, what's going on inside the plant. (0163-16-1 [Wolf, Peter])

Comment: We're here tonight to discuss nuclear waste, and it's probably a much more serious topic than even our discussion about the ongoing licensing at Indian Point because this will go on for decades, and we do not know how the protection will go, who will pay for it, and who will monitor it. It's difficult to predict what will happen in the future. Yesterday was the first anniversary of Sandy's visit. Many didn't foresee the type or extent of that type of damage. When we look back at just the last dozen years, we did not envision 9/11. We did not envision

Katrina. We did not envision the Deep Water Horizon, and we did not envision Fukushima. And as we know, Fukushima is still leaking today. (0163-16-6 [Wolf, Peter])

Comment: Indian Point is considered by some to be the least safe site of any reactor in the country. We live with possible disasters, remote yet frightening possibility. In addition, of course, Indian Point leaks invisible radiation constantly as well as heating river water that it draws in vast quantity every day to operate the reactor and cool the ever increasing number of irradiated fuel rods. (0163-20-3 [Gellert, Sally Jane])

Comment: As we know, the NRC does not want to discuss the percentage of high burn-up fuel at Indian Point. It was suggested that that is a matter of national security. However, local security must also be considered. Without enough of an idea of how much irradiated fuel rods are stored safely, Woodcliff Lake and the area surrounding are less secure than they might be. I therefore request this information be made public. (0163-20-6 [Gellert, Sally Jane])

Comment: I live six miles from Indian Point. This hotel is less than 20 miles from the nuclear power plant. Do you remember when Fukushima began to melt down and the NRC told all the Americans in Japan that it was dangerous to be within 50 miles of the reactors in spent fuel pools. If we heard sirens right now, we have to get in our cars and drive 30 miles. Unfortunately, the sirens can't be heard this far from Indian Point. That's one of the many reasons that Raging Grannies demand that Indian Point be shut down immediately. Here you are within the 50-mile range, okay. (0163-25-1 [Armer, Sunny])

Comment: Indian Point's a nuclear power plant near here. Nineteen Miles. That makes 50 tons of spent fuel every year. That waste is stored in pools and because we are not fools, we know we have good reasons to be scared. Sing along. If Entergy keeps spinning what it's spun, and their fight for re-licensing is won, 15 million on the roads will flee their doomed abodes. A 50-mile race they'll have to run. A terrorist could hit it with a bomb. The earthquake in Japan gave us some qualms. Where will we find the answer to protecting folks from cancer, who haven't yet been blown to kingdom come? Bring us solar, bring us hydro, bring us wind. Bring us energy from sources that won't end. Before we could trust uranium, we'd need holes in our cranium. We haven't yet gone that far 'round the bend. (0163-25-2 [Armer, Sunny])

Comment: Oh, we are a gaggle of grannies urging you off of your fannies. Indian Point is a dangerous joint. Shut it down. With all that Entergy's spending to keep their license from ending, you'd think go broke with mirrors and smoke. Shut it down. The NRC approves of waste storage by Entergy. The NRC is a lapdog to the nuclear industry. So, we may be a gaggle of grannies, but we've gotten off of our fannies. Stop Entergy's spin. If they lose, we win. Shut it down. We really mean it. Shut it down. And we mean business. Shut it down. Shut it down. (0163-25-3 [Armer, Sunny])

Comment: The National Regulatory Commission has the chance today to avoid another one at our backyard. I'm sure that most of those in charge of renewing the license for Indian Point, as well as planning a safe way to store the waste, also have families and have worked hard their whole lives to give their kids a better life than they had. That's the great tradition of our country. (0163-26-3 [Amram, David])

Comment: And unless we receive a substantial number of requests of the NRC to allow everyone within 70 miles of the plant to request the Commission what's best for everyone, we cannot allow ourselves to commit suicide by ignoring what's obvious. Dr. Kevorkian was requested by people who wished to terminate their lives and there's no documentation of

anyone in the greater New York area who has requested another Jamestown.....So I request on behalf of my neighbors, my friends, and my family with equal respect to all of you and your friends at the Nuclear Regulatory Commission and your families, a solution to ensure our survival. Your decision at the National Regulatory Commission will determine our shared destiny. (0163-26-5 [Amram, David])

Comment: In baseball one has three strikes and you're out. In the nuclear industry we've had three strikes. Three Mile Island, Chernobyl, and Fukushima. You're out. It's time to close Indian Point. This deadly nuclear plant threatens the lives of over 21 million people in the most densely populated metropolitan area, poisons the Hudson River and groundwater. Indian Point is situated on two fault lines. Scientists of Columbia University reported that a 7.0 magnitude earthquake is possible at Indian Point, and this aging structure was built to withstand a 6.1 earthquake only. In 2005 NRC and Entergy reported that radioactive water was leaking from IP2 spent fuel pool. 2007 -- a tritium leak was found, leaks into the ground water and Hudson River. (0163-32-1 [Skopic, Catherine])

Comment: Indian Point uses 2.5 billion gallons of water and the fish have been found with strontium-90 in their flesh. Cancer rates are 66 percent above the average in communities surrounding Indian Point according to U.S. Centers for Disease Control and Prevention. There is no evacuation plan and we don't need it. We have viable renewable energy. This summer I paddled on the Hudson River with about 200 native and non-native people. (0163-32-4 [Skopic, Catherine])

Comment: For the 400th anniversary of the Two-Row Wampum in the first covenant between native peoples and Europeans. They agreed to respect each other, work together, and protect Mother Earth. No matter what side of this issue one is on, we are called to honor this covenant today. The time of environmental destruction is over. It is now a time of healing for each other, for the earth, for all creation. And lastly, going back even further than 400 years and I quote, "The earth lies polluted under its inhabitants for they have transgressed laws, violated the statutes, broken the everlasting covenant." Isaiah 24:5. It's time to close Indian Point. (0163-32-5 [Skopic, Catherine])

Comment: So I would like to contextualize what I'm saying in that context as well as the fact that as Cathy pointed out, Indian Point is located on these faults and that the possibility of a 7-point earthquake is probable. When is up for grabs. Well, we don't have to worry about earthquakes because severe hurricanes are expected sooner than later, and I remember during Hurricane Sandy I was up all night listening to reports about anticipating the surge, the storm surge, and it came within inches of the fuel ponds here at Indian Point. (0163-33-3 [Geist, Sheila])

Comment: Now, New York City does not need the energy from Indian Point, and they -- it's clear from just a few days ago, the Public Service Commission approved a series of three projects that would enable the upstate energy to get downstate through changes in the transfer policies and in changing the grid. So it's not for any kind of necessity that we need Indian Point and we must move -- not only shut it down, not produce any more waste and put this waste that we have into dry cask storage. And I would wish that somebody knew about that. (0163-33-4 [Geist, Sheila])

Comment: Where is the money for decommissioning Indian Point? Does this fund include plans for converting to hard cask storage? What happens if Entergy walks away and goes out of business? If the operating permits are not renewed now, when does the de-commissioning start? Under whose management? The guy outside told me that Entergy wouldn't have to do

anything for 60 years if it stopped, you know, operating the plant. The last question is what money and plans are in place to oversee this transformation? (0163-33-5 [Geist, Sheila])

Comment: [W]e're [Alliance for a Green Economy] concerned about the waste building up at Indian Point, as well as New York's four other nuclear reactors, which are all on the shore of Lake Ontario, Fitzpatrick, Ginna, Nine Mile Point 1, and Nine Mile Point 2. (0163-34-1 [Azulay, Jessica])

Comment: Not only that, the seismic reality at Indian Point is ridiculous and that's not something that any gridlock in Washington can affect either. (0163-35-3 [Shaw, Jeanne])

Comment: Senator Gillibrand seemed even less concerned. Lohud reported almost two years ago that she actually supported building new reactors in communities that want them. Her quote "There's lots of places in the state that would certainly welcome a nuclear facility." One minute. Really? I guess so. So the point that I'm trying to make is that it is incomprehensible to me that with all the information that's out there on the amount of spent fuel being stored at Indian Point and the questionable way in which Entergy is storing it, that with all the experience we've had with terrorism and catastrophic accidents here and abroad, not to mention the President's campaigning against the Yucca Mountain site starting in 2008, scudding it in 2011, that most of New York electeds cannot find a way to come out against storing such seriously hazardous waste in this part of their state. (0163-37-2 [Woodward, Julie])

Comment: "For the record, Entergy has spent more than one billion dollars upgrading and enhancing the facility and preparing the plant for the safe operation during a 20-year period under a renewed operating license. For nine years in a row Indian Point has received the NRC's highest safest rate in its annual safety evaluation. These are the findings of trained experts who spend tens of thousands of hours evaluating the Indian Point's operations and they agree that the plant is unequivocally safe." (0163-4-2 [Thomas, Richard])

Comment: We've gone through a lot of technologies. The coal that we were mining, we thought was harmless and we found that tens of thousands of people died of black lung disease. The manufactured gas that was manufactured here in Tarrytown, \$14,000,000 to clean up the coal tar...all of the new technologies we've gone through whether it was leaking gas, gas tanks that have taken out aquifers in Armonk, New York, where I lived, permanently destroyed the aquifer in Wilton. All of these technologies were unproven and brought with them all kinds of risk that were unmeasurable at the time. We thought it was all safe. We think this is safe. In my view it is not safe technology. We didn't expect the pools to leak. They're leaking into the Hudson River I love right now this minute as we are speaking. These are unacceptable risks. (0163-42-2 [Fry, Mark])

Comment: "I have no confidence that under any rules that waste stored at Indian Point will be handled appropriately." This is Laurie speaking. "Recently I received a Geiger counter to take part in the project for monitoring radiation from levels in our atmosphere caused by Indian Point for citizens to live within the ten-mile dead zone. The impossible-to-evacuate zone, and I work with children. The experience of using the Geiger counter makes the reality of Fukushima so profoundly real. I've seen a documentary with the citizens of Fukushima with Geiger counters. It is haunting to walk about with a Geiger counter thinking of what it means that we need a detection program. We can only hope that this detection program is only going to be something that will wisely inform the shutdown of Indian Point and never to become a program that tells us which of our beds and pillows are too contaminated to lay down on at night. When the women farmers from Fukushima came here a year ago, as they did, that is one thing that they said that

stuck with me hard. That in Fukushima they had no place to rest safely at the end of each exhausting day. This is traumatic. Imagine you go to lie down and you know your pillow was contaminated with radiation. Then also imagine that your family is divided maybe forever. The elders did not want to leave their homes. Men stayed behind to work while women left with children. Imagine. Imagine. But don't just imagine. People need to realize the vulnerability we live with every day with Indian Point is tick-tocking toward the eventuality of causing increased sickness. The women of Fukushima came here to tell the people of the Hudson Valley and the NRC 'learn from Fukushima. Do not let this happen to you.'" (0163-45-1 [Seeman, Laurie])

Comment: [L]et's close Indian Point and the many tons of radioactive material that are impounded at Indian Point. If we relicense Indian Point we're going to add at least 50 percent more. This is -- this is lunacy. (0163-45-2 [Klein, George])

Comment: I'm listening to all of this and I'm thinking we're dealing with Entergy. It's a specific corporation. It does specific things. Its stockholders decided not to change the spent fuel rods that were ready to go into dry cask. Only 15 percent of them in dry cask. 85 percent is left and they don't do anything. They don't care about it. Who is going to pay for it when they depart from the scene? Entergy ran Indian Point during Sandy. The buses had been canceled the day before. The trains had been canceled the day before. There were logs all over the roadways. They had no evacuation. Not even a pretend evacuation. And still they decided to keep running it. We're leaving the responsibility for something as dangerous as this to a corporation that doesn't act as if it cares. It doesn't believe that its responsibility is to take some of the profit and put the spent fuel rods that are aged enough out of the pools which are too crowded and put them in dry cask. I don't believe the Nuclear Regulatory Commission can actually twist it enough to follow -- get them to follow anything that's real and I'm not assured that their staff, their engineers, and anything have a bigger picture in mind. And so, I would say let's close Indian Point. (0163-46-1 [Leiter, Susan])

Comment: It's time now to shut down Indian Point and put the fuel that is already there into dry cask storage. (0163-49-3 [Evans, Laurie])

Comment: I know I should say thank you for being here, but I don't thank you. You had two years to work on similar problem with Indian Point and nothing is done. It's just another rubber stamp. I think your arrogance is shameful and I don't know how any one of you can look at me full in the face and tell me that I am safe. I'd like to hear one of you say that to me. I don't believe that. And I'm -- I'm very upset. I think quite honestly that you've all insulted the intelligence of many people here tonight, and I am really shocked and dismayed by this, so that's all I have to say. I want Indian Point shut down immediately if not sooner, and I agree with my sister's statement that you can -- well, she said it very well. I don't need to repeat that. So do your jobs and protect the public. I am the public. You are the public too. Protect me. That's your job so do it. (0163-51-3 [DeCrescenzo, Jocelyn])

Comment: The NRC conducts detailed rigorous annual safety inspections at each of the country's 100 nuclear power plants. Due to political pressure, Indian Point is the most scrutinized and it has -- and it continues to receive the NRC's highest safest rating year after year. These inspections include comprehensive review and oversight of the process for using used fuel onsite at Indian Point in both cooling pools and dry cask storage, the state-of-the-art solution. The Hudson Valley Gateway Chamber of Commerce supports the continued operation of Indian Point because we understand its importance for the region's energy supply, electrical grid reliability, and the economy. New York does not have the generation or transmission infrastructure to replace the 2,000 megawatts of power that Indian Point supplies each day. Let

alone a proposed replacement source that could provide comparable economic benefits and not result in higher electricity rates. (0163-8-2 [Milone, Deb])

Comment: At the November 14, 2012 NRC hearing/teleconference, Ruth Thomas of EI called attention to Duke Power Company's Oconee Nuclear Station. Its three reactors are located approximately halfway between a series of lakes. Here are some facts about Oconee: 1. The Oconee reactors were built in the 1970's. Oconee was the second plant to be relicensed, until 2033-34. 2. Duke Energy has noted that a failure of the Jocassee dam could flood the plant and cause the loss of power and safety equipment, potentially damaging its three reactor cores within 8 to 9 hours. It could further lead to reactor containment failure within 59 to 68 hours, triggering a significant release of radioactivity into the environment. Duke informed the NRC about this flooding hazard as early as January 1996. (Wikipedia) 3. The owner/operator Duke Energy Carolinas has been served with a Notice of Violation, Severity Level III, July 1, 2013. This violation involved Duke's failure to complete three changes in the requirements for the Fire Protection Program License of Units 1, 2 and 3. 4. The NRC's own engineers were concerned that the agency was not doing enough to address the risks associated with Jocassee dam failure. Public Employees for Environmental Responsibility (PEER) filed a lawsuit against the NRC in the federal court in Washington for not providing answers to their Freedom of Information Act requests (Spartanburg Herald Journal, September 1, 2013) 5. Disaster plans were not kept in a critical area and other copies were outdated. (Greenville News, July 15, 2011) 6. The NRC has failed and continues to fail to recognize the long-term damaging effects of radiation from numerous sources. (0174-10 [Thomas, Ellen] [Thomas, Ruth])

Comment: For example, the people of Vernon, Vermont are extremely worried now about the economic impact, loss of jobs, and loss of tax revenue that will be realized next year when Vermont Yankee closes. (0181-5 [Waters, Christine])

Comment: For example, the people of Vernon, Vermont are extremely worried now about the economic impact, loss of jobs, and loss of tax revenue that will be realized next year when Vermont Yankee closes. (0183-5 [Green, Carlyn])

Comment: This is true for all nuclear reactor sites, over a hundred in the United States. Many of those are clustered near coastal waters and centers of population, like all five of Florida's nuclear plants, and hence vulnerable to colossal storm surges. (0190-4 [Phelan, Steven] [Phelan, Walter])

Comment: More importantly, I want Diablo Canyon closed so no more nuclear waste is being created in my backyard. I have no confidence whatsoever that nuclear waste is being safely stored here in SLO [San Luis Obispo] county. (0207-2 [Denton, Jill])

Comment: I would like assurance that the pool storage for spent fuel from San Onofre, especially the high burn-up fuel, is safe under credible tsunami conditions. If a tsunami were to damage the pool storage in a way that would cause loss of pool water while shoving the waste containers into a corner of the pool (causing unsafe geometry for cooling) the results could be catastrophic, even if the emergency generators can perform their function of providing emergency cooling. Typically, nuclear systems that could have a catastrophic failure are designed to withstand natural phenomena that could occur with an expected frequency of 1/1000 per year. In the case of tornadoes, because of the uncertainty in historical data, the design is 1/10,000. Because of poor documentation of past tsunamis, and the demonstrated inability of the scientific community to predict tsunami magnitudes (e.g., Fukushima), I think the

pool cooling at San Onofre should be designed for the worst tsunami expected in 10,000 years. I do not see where this has been accomplished. (0214-1 [Deshotels, Bob])

Comment: Another credible new unanalyzed threat should receive scrutiny in an updated, more rigorous scientific analysis, which consists of the possible designation for San Diego as a new 'drone testing' facility. While 'drone analysts' might believe that designating San Diego as a new drone testing facility poses minimal, or no risk(s), I am unconvinced, and I have requested County of San Diego Board of Supervisors to reevaluate that recent action. (0218-4 [Borchmann, Patricia])

Comment: California's nuclear waste is sited on an eroding coastline, in tsunami zones, and is exposed to a highly humid and corrosive coastal environment. NRC's NUREG/CR-7030 states "atmospheric corrosion of sea salt can lead to stress corrosion cracking within 32 and 128 weeks in austenitic (corrosion resistant) steel canisters" It would be impossible to evacuate the millions of people living near California's Waste. Of the 34 million people in California, over 8.5 million reside within 50 miles of San Onofre !! A radiological disaster impacts the nations, and world's security, economy, and food supply. California is the eighth (8th) ranking economy in the world, virtually tied with Italy and Russian Federation, larger than Canada, Australia, and Spain. More than 40 percent of containerized imports enter the country through California ports. A radiological release from San Onofre would destroy public infrastructure, and disable Ports of Long Beach, Los Angeles, and possibly San Diego, causing irreversible economic damage at a local, regional, statewide, national, global scale. California produces nearly 1/2 of US grown fruits, nuts, vegetables. Californias remained the number one state in case farm receipts in 2011, with \$43.5 billion in revenue representing 11.6 percent of US total. US customers regularly purchase several crops produced solely in California. San Onofre is located adjacent to the primary vehicle transportation artery between Los Angeles and San Diego (I-5), and one of the largest military installations (and targets) on West Coast (Camp Pendleton). (0218-6 [Borchmann, Patricia])

Comment: The projected Scope of Decommissioning Project, and Decommissioning Costs are currently still preliminary, only in early stages being prepared by SCE, or considered by CPUC, CEC, and NRC, and are still largely UNCERTAIN. It is important that NRC will require Licensee to fully perform Decommissioning at SONGS in safest, most reliable method, the most "in Public Interest" method possible, and not necessarily the least expensive for Licensee (SCE), contractors, or subcontractors. Timing of NRC actions should be more carefully coordinated with action(s) also pending with CPUC, CEC, California Coastal Commission. (0218-9 [Borchmann, Patricia])

Comment: When I heard that the NRC intends to leave the nuclear waste on site at San Onofre for, potentially, three hundred years, I was nothing short of appalled. The idea that we must leave such dangerous materials in an earthquake zone surrounded by some 10 million people is an abomination. Is it really possible that the kind of scientific minds who created the plant in the first place are capable of painting us into such a corner? If so, it will surely go down as one of the greatest and most horrifying screw-ups in the history of mankind. (0220-1 [Degher, Darius])

Comment: And no, leaving the nuclear waste in crowded Southern California is NOT just as good as leaving it somewhere else, such as a desert in Nevada. An accident involving leaking nuclear waste in the desert, far from population centers, would be very unfortunate, but it would be surmountable. On the other hand, a Fukushima type of accident here could cost millions of lives, the destruction of food sources, the destruction of cultural and economic sources the likes

of which the world has never seen. An accident at that particular location, near both San Diego and Los Angeles, would have economic impacts that would last generations. Such economic impacts would dwarf those of the Great Recession, as real estate values in Southern California would tumble permanently. A major accident at San Onofre would end California as we know it. We cannot take such chances. No, I refuse to accept Mr. Dricks' evaluation of the situation, that the nuclear waste must remain on site. And I hope other Californians will do the same thing. Let's pay whatever it takes and get those materials away from our population centers. If we don't, our children and grandchildren will never have security. (0220-3 [Degher, Darius])

Comment: Finally, I am living in St. Louis, MO, a city that has been contaminated by nuclear waste for seven decades. The Mallinckroft corporation took part in the Manhattan Project, and purified the uranium that was eventually used in the creation of Big Boy and Little Boy, the nuclear bombs dropped on Hiroshima and Nagasaki. The nuclear waste left over from this purification process was stored in metal drums that rusted under the sun and weather in a parking lot north of Lambert Field airport for two decades before being buried in landfills across the city, like West Lake Landfill. These landfills were not set up to retain nuclear waste; there are no concrete and lead bunkers for the material...just clay. These drums have been leaking for decades into the environment and a local stream, Cold Water Creek, that then empties into the Missouri River, eight miles upstream from the spot where St. Louis draws its drinking water supply. As a result, St. Louis has THE largest cancer cluster in the nation. Although the residents here in the city have tried to work with the EPA and with Republic Services, the owner-operator of the landfill, the nuclear waste remains in place with an underground landfill fire racing towards it. Within one year, we may have a dirty bomb situation in St. Louis. I am appalled at the conditions here, and across the country. If we cannot use nuclear power in a safe manner, then we should not use it at all. (0223-1 [Doctor, Appalled])

Comment: [I]t is my opinion that the use of nuclear energy for electric power, with the attendant problems of nuclear waste generation and storage, represents the single greatest threat to public health that we face in this country. For a few of the 100 nuclear reactors located around the US, including the Pilgrim Nuclear Power Station in Plymouth Massachusetts, the danger is magnified because, in the event of a nuclear accident, a significant population (240,000 on Cape Cod in the off-season) would have to drive toward the disaster in order to escape from it due to limited egress routes. (0230-1 [Garb, James])

Comment: Finally the Pilgrim Nuclear Power Station is an old facility with the same flawed reactor design as at Fukushima, poorly sited, and plagued by mechanical difficulties. It should be shut down immediately before the unthinkable happens. (0230-14 [Garb, James])

Comment: Because of the complex geometry of the San Onofre site, and possibly other pool storage sites, a simple static analysis is not sufficient. Because the San Onofre pools are located between the reactor containment structures on the ocean side, and a steep cliff on the land side, the high-speed linear motion of a tsunami would be converted into a lower-speed very turbulent flow pattern. It is conceivable that this resulting turbulence and possible reflection of the water flow could result in damage to the fuel support structure, displacement of fuel containers, filling the pool with mud or sand, or damage that could reduce the level of water in the pool. The effect could possibly be loss of critically-safe geometry, and/or unsafe reduction in cooling. (0231-2 [Deshotels, Bob])

Comment: It is vital that a new in-depth analysis of the situation be undertaken, especially with regards to spent fuel. There is no long-term solution - there is no safe storage place, there is no

safe transportation. It is almost certain that this spent fuel will be in San Luis Obispo county for thousands of years posing a potential hazard. (0232-2 [Hall, Caroline])

Comment: Just as it is around the country, the spent fuel pools in our region, Calvert Cliffs and Peachbottom have several times as much radioactivity as Daichi #4.(1) Peachbottom shares the Mark 1 design like the Fukushima reactors with the precarious elevated spent fuel pool. (0233-1 [Dubois, Gwen L])

Comment: I live 10 miles downwind from Diablo Canyon NPP, on the central coast of California, a place that is very seismicly active. It is an area of steep hills and ridges, most of which are much steeper than the angle of repose. It is obvious that these hills have been pushed up recently and dramatically and that it is a dynamic landscape. Despite the assurance from PG&E that "it can't happen here" (it referring to the Fukushima disaster) I believe that it could happen here -- Mother Earth is unpredictable. And Diablo Canyon is a disaster waiting to happen. DCNPP is vulnerable not only to earthquakes, but also to extreme storms, tsunamis and terrorist attacks. If --or when -- an emission accident occurs at DCNPP, I will be forced to leave my home, perhaps forever. I would lose my possessions, my life saving (tied up in my home), my garden where I grow most of my food and my community. There would be no recourse for me or for any of my neighbors, since this would be an uninsured disaster. Tens of thousands of people would be affected, along with our prime farmland, scenic coastline and wide ocean. This is a beautiful part of the world but it could be lost to humankind forever. (0236-1 [Reinheimer, Alice])

Comment: Second, do not re-license DCNPP, in fact, revoke it's current operating license. There is no viable plan for removal of radioactive waste from the site. Yet, it cannot be stored safely and indefinitely because of the instability of the ground it sits on. It is folly and arrogance to continue to build up waste when it cannot be safely stored and it cannot be safely removed. This makes no sense and should be stopped as quickly as possible. New solar farms in San Luis Obispo county are currently providing power equivalent to 1/4 of DCNPP's peak output. DCNPP can be replaced with safer alternatives. (0236-3 [Reinheimer, Alice])

Comment: I am writing you because I am concerned that the Columbia Generating Station (CGS) nuclear reactor has been relicensed and approved to generate more waste until 2043. In the last thirty years it has generated 200 million Curies of high level radioactive waste. At this rate, by the end of another thirty years, CGS will have generated 400 million Curies of radioactive waste. This will be more high level radioactive waste than exists on the Hanford Reservation - the most contaminated site in the United States. The DOE has not been able to clean up Hanford. There is nowhere for this waste to go. (0243-1 [Hoch, Susan])

Comment: Communities in the Southeast bear a heavy load of burden when it comes to highly radioactive spent nuclear fuel. There are only five states with over 3,000 metric tons of spent fuel and two of those are in the Southeast in North and South Carolina. Of the 104 licensed reactors in the country, 33 of them are in our region, and all 5 of the reactors currently under construction are here. (0244-3-6 [Hancock, Mandy])

Comment: And I brought with me an article -- I have copies of this for anyone who's interested, and I also have a Rolling Stone article that talks specifically about Miami and Turkey Point. And we think it's pretty interesting that the Rolling Stone is supporting the consensus among scientists, yet it doesn't seem that the NRC is heavily weighing those factors. (0244-3-8 [Hancock, Mandy])

Comment: I want to address my remarks especially to speak about Zion. 40 miles up the road at the Zion Nuclear Power Generation Plant in December, over a thousand tons of high-level radioactive waste is going to be transferred into dry casks, as reported by Pat Daley of Zion Solutions in August 2013. In the near future, in Fukushima, over 400 tons of high-level radioactive waste were transferred out and into dry casks. Zion was operating from '76 to '78. Fukushima was operating from '78 to 2011. What we have here is a situation where we in the Chicago-Milwaukee Metropolitan Area, over six million people, are going to be exposed to comparative or greater risk - from a larger and dirtier radioactive waste fuel transfer, which is projected to take about a year to complete in both places - than what's going to happen soon at Fukushima. Although everyone is doing their best at Zion Solutions, a shell company authorized through Exelon, the scale of decommissioning fuel transfers has never, this scale of decommissioning has never been attempted before. We the people who live within a 50-mile radius of Zion remain deeply concerned because the public oversight and transparency is far from adequate to the enormity and riskiness of the task. Irradiated fuel transfers have never been attempted before on this scale. (0245-10-1 [Lewison, Linda])

Comment: There's the largest General Electric Mark I boiling water reactor in the world at Fermi Unit 2 in Monroe, Michigan, and ironically enough it shares a lot in common with Fukushima Daiichi Unit Number 4. Some 40 years ago, the structural wells were not put in place that can support the crane and the hundred-ton waste transfer casks that would be used to remove the fuel. So, despite having a permit for dry cask storage for several years now, Fermi Unit 2 still has all the waste it's ever generated in its high-level radioactive waste storage pool. (0245-13-3 [Kamps, Kevin])

Comment: I want to just shift with my remaining time to dry cask storage risks in this part of the country. The way I got involved in these issues 20 years ago was at Palisades near Kalamazoo on the Lake Michigan shoreline. A lot of people, including the Attorney General of Michigan, fought the loading of those dry casks, and for a very good reason. They're a hundred yards from the water of Lake Michigan. In fact, they're in violation of NRC earthquake safety regulations. This was brought to light in February of 1994 by the NRC Region III Dry Cask Storage Inspector Dr. Ross Landsman who is now retired. He warned that an earthquake could open up the sand that those casks rest on and they could find themselves on the bottom of Lake Michigan. And in fact, there's enough fissile material still in the waste that, in the presence of water, you could have a chain reaction in the waste. So, that's a risk going on on the Lake Michigan shoreline right now. (0245-13-5 [Kamps, Kevin])

Comment: Another thing about safety is that Braidwood has created a VPP star safety site. And that's not something that corporate pays for, that's something that comes from the people that work there. A lot of people have jobs in other manufacturing industries, you may have to wear a hard hat, you may have to wear safety glasses, you may have to wear steel-toed shoes. Those are just requirements to work in our plants. And it goes beyond just those things, too. It goes to the level of checking components to a degree that you never would have thought that we actually do. So, that's another reason why I have confidence in our station's safety. The first week that I started at Braidwood, I started in radiation protection as I mentioned before, the first for me was on dry cask storage. And it wasn't because I was on a team, it was because I work for a power plant and they wanted me to understand what they were going to be doing outside. And that's the kind of level of effort that our company puts on its employees. They want us to understand what's going on and how to explain to other people, I give a lot of tours and, you know, watch citizens come in and talk to them about the safety of the plant and just really answering any question that they have. I've also talked to college students as well about this as well. And that's why I'm confident. (0245-18-3 [Stenson, Amanda])

Comment: St. Louis purified the first uranium self-sustaining nuclear chain reaction. We have some of the oldest radioactive waste on the planet and it doesn't take a nuclear accident to have to worry about cleaning it up. We're still dealing with it. So, regardless of a hypothetical accident, release of radioactivity into the environment is a significant challenge that takes decades to address. (0245-19-1 [Smith, Ed])

Comment: One problem we have, just so everybody knows, is some of this radioactive material, a significant amount of thorium-230, made it into a landfill in the Missouri River, unlined, which is currently experiencing a surface landfill fire a thousand feet away from the radioactive wastes. And we're bickering with the EPA and other government agencies on exactly how to disposition these radioactive wastes. There's actually people who want to leave it there. (0245-19-2 [Smith, Ed])

Comment: But when we went to go challenge the [Callaway] license extension, we faced challenges including challenges with respect to nuclear fuel pool. We'd have to prove that there were site-specific degradation to the fuel pool is my understanding. I'm not a lawyer but we couldn't comment or challenge the future integrity of that unless we had experienced issues. (0245-19-4 [Smith, Ed])

Comment: Here in Illinois, I don't know how many people from the NRC come from this state, but we have more reactors than any other state, four are the same make and model as the ones that blew in Fukushima. Again, we have the safety violations which are treated so routinely, they're seldom reported in the news except the headlines at Braidwood. So, I would take exception with how fine Braidwood's track record has been, especially dumping polluted, irradiated water on the community unbeknownst to them for ten years. In addition to leaks, we also have, in recent days, the felonies created by folks over at Dresden. So, if our futures are in the hands of an entity and we hear that the people that they're hiring are of this caliber, I do not have confidence. I don't have confidence in an industry that relies on our tax dollars to subsidize its own interests, long guarantees to build new reactors, expecting main street to invest in what Wall Street will not. Wall Street refuses to take on the risk and why should we? For that, I have no confidence. (0245-6-3 [Headington, Maureen])

Comment: Gulf State [River Bend Station] is a nuclear waste site dump, or should be one. (0246-16-5 [Michetti, Susan])

Comment: Three of the worst risks at Limerick are, first, Limerick's use of high burn nuclear fuel; second, its overcrowded, corroding, and thinning fuel pools; and third, its above ground concrete cask storage system is not designed to last the length of time that the waste could be stored in them. First, regarding Limerick's use of high burn nuclear fuel, evidence suggests its use is far more dangerous than fuel previously used at Limerick. Higher radioactive gas releases, increased corrosion, thinning and brittleness of fuel cap cladding, increased radioactivity and decay heat from spent fuels, and increased damage to the fuel rods in the reactors*all these can results ** leading to radiation leaks in the spent fuel pools and casks. My first question is this. Is Exelon using high burn nuclear fuel without regulatory oversight? Second, regarding Limerick's overcrowded fuel pools. These packed, vulnerable, thinning, and corroding pools post catastrophic risks to our heavily populated region. Yet, the NRC is failing to adequate action for precaution. Why does the NRC fail to require Exelon to adequately guard against air strikes or missiles? Why do Limerick's two pools have more spent fuel than even older nuclear plants and twice as much as Fukushima's four pools? Why has the NRC allowed Exelon to put off even studying the risks related to earthquakes when the plant sits on an earthquake fault, is located within 17 miles of four other earthquake faults, and is number three

on the nation's earthquake risk list? Why does the NRC not require immediate recoding of Limerick's fuel pool liners when an NRC safety evaluation found them corroding and thinning up to ten times faster than estimated? Third, regarding Limerick's aboveground concrete cask storage, this is a short-term solution to a long-term problem. (0246-17-3 [Dugdale, Jane])

Comment: Why did the NRC deny the corrosion risks found by a recent NRC safety evaluation and stop its own 2005 study when corrosion concerns were identified? Why were the concerns that ACE expressed to the NRC ignored regarding the design flaws of Limerick's concrete casks? (0246-17-5 [Dugdale, Jane])

Comment: In these tough economic times, this plant [Calvert Cliffs Nuclear Power Station] has provided my community with a stable tax base and jobs. (0246-18-2 [Karbowsky, Brad])

Comment: Now, to get back to Limerick, the Limerick Nuke Plant has an earthquake fault line directly under it, which is called the Sanatoga fault line and there are four others within 17 miles. I, well, started researching these to see if there were any earthquake fault lines and I received a map but I didn't receive the Sanatoga fault line that was directly under it. That was missing from the map I was given by the NRC. Hmm, so I don't know what that was all about. But anyway, Limerick has miles of underground pipes and that really worries my family and friends. They have taken so much water from the Schuylkill River, which is our bathing water and we drink it. Now, it is contaminated with mine water from Wadesville Mine. They are pumping in massive amounts of it. They use millions of gallons a day, more than three times a day just to make that power plant work. Pretty soon, there is not going to be any water left. (0246-23-4 [Ruppe, Lorraine])

Comment: I would just like to provide one example regarding issues of spent fuel storage. And this is an example of current unsafe conditions in Indian Point Unit 2's spent fuel pool. So, just some background. In an NRC meeting in September 2013 regarding Japan Lessons Learned Project, Rod McCullum of the Nuclear Energy Institute stated, "We understand in the industry we can no longer rely on boroflex." Boroflex is a neutron absorber which is intended to help prevent criticality accidents and it is located in spent fuel racks. Boroflex has a documented history of degrading. Nonetheless, it is still used in a number of spent fuel pools, including Indian Point Unit 2's spent fuel pool. And there is a document from 2002 that says that the high-density storage racks in Region 1-2 of the Indian Point Unit 2 spent fuel pool were "assumed to have sustained a 50 percent loss of boroflex." That is due to degradation. That can be found in your ADAMS database at ML021230367. So, that is back in 2002. However, that is actually based on a criticality analysis that was done in September 20, 2001 because there is an NRC letter regarding Indian Point Unit 2 that is from that September 24, 2013. And that letter says that the current criticality analysis of record, which takes credit for boroflex insert as neutron absorbers was submitted back in 2001. And then it also notes that subsequent operating experience has demonstrated the non-uniform physical degradation of boroflex inserts. Now, that is in ADAMS database at ML13256A086. So, basically back in 2001 your current analysis of record for criticality concerns, that assumed a sustained loss of 50 percent of boroflex that was in the Region 1-2 part of the spent fuel pool. So, how much boroflex is left now, 12 years later? Apparently, there was a criticality analysis that was supposed to come out in November of this year. I'm not sure if that has been released yet. But basically, there was assumed that there was a loss at that time, 12 years ago. And even Entergy, the licensee of Indian Point, even they have acknowledged that the current, at least the one from 2001 was non-conservative. So, I mean this is just one little example of a myriad of other problems that are going on with spent fuel pools and I just wanted to cite it just to give some concrete evidence. This is Indian Point. (0246-28-1 [Leyse, Mark])

Comment: But Illinois has even more in common with Fukushima than just four Fukushima twin reactors that need to be shut down for safety inspections. Just as Fukushima is about to start the high-risk, high-level radioactive waste fuel transfers out of Unit 4, 40 miles north of Chicago, the Zion Nuclear Generation Plant is about to start its own fuel transfer operation in December of irradiated fuel of over 1,000 tons of high-level radioactive waste, almost three times the amount that, as Erica described -- this very high-risk operation is going to happen in Japan. This is the largest scale decommissioning in history. (0246-9-3 [Lewison, Linda])

Comment: In conclusion, there can be NO CONFIDENCE that Limerick's nuclear wastes do not jeopardize our future. (0249-13 [Dugdale, Jane])

Comment: o The steel rails holding the steel containers inside the casks are highly vulnerable to corrosion, likely rendering the containers they support virtually impossible to extract. Highly corrosive air from Limerick's massive cooling tower plume enters the vents of the cask system, according to its design. This plume is so corrosive it can crack steel within a year, according to an NRC recent safety evaluation. Why did the NRC deny this corrosion risk and stop its own 2005 study when corrosion concerns were identified? o Because Limerick's concrete casks have serious design flaws, including faulty concrete and undetectable corrosion. ACE expressed concerns to NRC and elected officials. Why were our concerns ignored? (0249-16 [Dugdale, Jane])

Comment: Three of the worst risks at Limerick are, first, Limerick's use of "high-burn" nuclear fuel; second, its overcrowded, corroding and thinning fuel pools; and third, its above ground concrete cask storage system, not designed to last the length of time the wastes could be stored in them. (0249-4 [Dugdale, Jane])

Comment: Second, regarding Limerick's overcrowded fuel pools, these packed, vulnerable, thinning and corroding pools pose catastrophic risks to our heavily populated region, yet the NRC is failing to take adequate action for precaution. These pools, similar to the roof-top pools at Fukushima now threatening the world, are highly vulnerable to loss of water, meltdown, and fire. o Loss of water can be caused by earthquakes, terrorist planes, or missiles. As the world now knows, with loss of water, roof-top spent fuel rods will heat up, self-ignite, and burn in an unstoppable fire, causing tens of thousands of deaths up to 500 miles away. Why does the NRC fail to require Exelon to adequately guard against air strikes or missiles? o Limerick's two fuel pools, packed far beyond design basis, contain twice as much radioactive waste as the four Fukushima fuel pools, and far more than many other, older US nuclear plants. Why does Limerick have so much so-called "spent" fuel in its roof-top pools? Why does Limerick have more spent fuel than even older nuclear plants? o Limerick's fuel pools were constructed with substandard cement, according to a Limerick construction site engineer, and the plant sits on an earthquake fault. In addition, it is located within 17 miles of four other earthquake faults, but the NRC has allowed Exelon until 2017 to complete even an earthquake study. Why? Why has the NRC allowed Exelon to put off even studying the risks related to earthquakes, when the plant is #3 on the nation's earthquake risk list? o Limerick's fuel pool liners are corroding and thinning up to 10 times faster than estimated, according to an NRC Safety Evaluation. NRC staff told Exelon to immediately recoat the liners, but then the NRC caved in to Exelon's request to put off the recoating for a decade. Why? Why did the NRC not require immediate recoating? o Why is the NRC allowing Limerick to transfer fuel rods from the fuel pools to dry storage casks after just 1-3 years, when the NRC literature states it is unsafe to remove them from the fuel pools for cask storage before five years? (0249-6 [Dugdale, Jane])

Comment: Third, regarding Limerick's above ground concrete cask storage system, this is a short term solution to a long term problem. (0249-7 [Dugdale, Jane])

Comment: Recently, I was over doing my civic duty, voting absentee since I am working the polls tomorrow, and lo and behold on the television news on the TV overhead in the room over at the Election Commission meeting, the TV reporter reported tritium leaks over at the nearby Catawba Plant, not far from Charlotte, fact, not emotion. For the first time, I heard several voters, black, white, all walks of life, expressing their unanimous concern over tritium leaking from the Catawba Plant. (0250-20-1 [Cooper, Elaine])

Comment: Closer to home, V.C. Summer has waste that is an overcrowded -- it's spent fuel pools. Residents who live around V.C. Summer express their extreme concern over the risk to the public from these overcrowded spent fuel pools to me, saying that as I man the booth over at the State Fair. And I think many of the residents heard this over a period of two weeks over and over, that residents were concerned about spent fuel being piled up in overcrowded spent fuel pools. (0250-20-4 [Cooper, Elaine])

Comment: I'm wondering if some of you have heard that Plant Vogtle, as mentioned on the radio last week, had 75 violations. (0250-22-2 [Hands, Tara])

Comment: And I looked up the Catawba accident leak and, of course, the response is that there's no problem, everything is safe. They've got it under control, but the very last sentence of this article from WBTV says, "The U.S. Environmental Protection Agency says drinking water that contains tritium can increase the risk of developing cancer." (0250-29-9 [Rivard, Betsey])

Comment: The Unit 3 concrete pour was a continuous pour lasting approximately 43 hours, with the placement of approximately 7,000 cubic yards of concrete. Safe, reliable electric generation is a high priority for our customers in South Carolina. (0250-3-3 [Archie, Jeff])

Comment: I have been studying the nuclear waste situation for the past 20 years, having lived in the shadow of nuclear energy plants both here in North Carolina and previously in Florida, and also being made to pay for them advance, even if they don't come on line. Now, that's my own added. I have attended conferences to deal with this issue and have heard former government employees say that this area of the Southern U.S., at least a five-state radius, has been referred to as a nuclear sacrifice zone. I wonder if you ever heard that. I've heard it several times. (0250-42-3 [Arnason, Deb])

Comment: Now I live on the Cumberland Plateau in Tennessee, not too far from the Watts Bar Nuclear Reactor, the last reactor completed in this country. They were going to build two there, but they abandoned one because they went so far over budget, which is pretty common with this industry. And currently at that reactor, they are making tritium and using it to maintain the stockpile of U.S. nuclear weapons, which is really shameful when they should be destroying those. And the tritium is getting into the water of the Tennessee River and affecting that ecosystem as well. And they're currently trying to finish that reactor that they abandoned so many years ago. The Tennessee Valley Authority is. It's one of the sites where they are constructing a new reactor. (0250-50-1 [Blevins, Eric])

Comment: And a really important part of this work is working with communities that live near Plant Vogtle, which, as you know, is the construction site for the first two new nuclear reactors in the U.S. in about three decades; and also the Savannah River site, which is a Superfund toxic nuclear waste facility that is -- well, waste and weapons facility that is struggling to clean up its

tanks and is also slated to start producing mixed oxide plutonium fuel for nuclear power reactors. These communities are dealing with a long legacy of nuclear waste, of contamination, of environmental racism, and economic depression. So in Georgia, we really have a lot at stake when it comes to this Waste Confidence Rule and also the draft Environmental Impact Statement, which I can assure you we have read in full. And this is why we [Georgia WAND] have stood up together to oppose expansion at Vogtle and also to oppose consolidated interim storage at Savannah River site. (0250-66-1 [Hanson, Courtney])

Comment: In South Carolina, like I said, we're very concerned about nuclear waste. We have seven operating reactors. I don't think any of the fuel at V.C. Summer has left the pool. I don't think there's any dry casks, so that pool has got to be pretty full. We have a low-level site, Barnwell. It's been leaking for decades. It's been migrating underground, contaminating nearby groundwater and streams. And of course we have the Savannah River site, which is an ongoing problem. (0250-7-2 [Corbett, Susan])

Comment: We just had a situation down at the Savannah River site because there was a proposal brought to the Citizens Advisory Board, asking them to sign off on Savannah River site being used as interim storage. After many months of discussions, the Citizens Advisory Board voted 17 to 6, opposing any spent fuel storage in Savannah River site. (0250-7-5 [Corbett, Susan])

Comment: Presently, highly radioactive used spent fuel cells are stored on site. At Diablo Canyon nuclear plant, most are in pools. These pools are overcrowded and becoming more so as spent fuel cells are regularly replaced. These overcrowded pools of spent fuel cells are a threat to the health and safety of the community. Diablo Canyon nuclear plant is constructed on and surrounded by earthquake faults. The potential for unexpected damage to the plant as a result of earthquakes is always present. In addition to the possibility of a greater than anticipated natural disaster, the plant is also vulnerable to human error accidents and damage intentionally created. (0252-2 [Golden, Leon] [Goldin, Martha])

Comment: The closing of the San Onofre nuclear power plant means that 1,100 workers will lose their jobs. As an elected official that visited this plant, along with other members of Hispanic Elected Local Officials (HELO), I saw first-hand the number of jobs this plant was providing to CA residents. The decision to close this plant will have economic repercussions. (0253-2 [Avilla, Karen])

Comment: I suggest this material be stored in the backyards of the NRC which permitted this plant to even operate. It should NOT stored at Diablo (which is on top of earthquake faults like Japan) which is upwind to Nipomo. (0254-3 [Denneen, Bill])

Comment: Another potential "hot spot" for my part of the country is the former Trojan Nuclear Plant, also situated on the Columbia River. There is still nuclear waste being stored on that site, with no place for it to be taken for more permanent and safer storage. (0269-2 [Gale, Maradel])

Comment: Finally, please do not allow Illinois to become a nuclear waste dump. No dangerous high-level radioactive wastes should be coming to or being transported through Illinois. (0272-4 [Leighton, Taigen])

Comment: Of all the reasons people give us for wanting to move away from Illinois, I can say that no one has ever mentioned the stored nuclear waste as a reason. The tax structure, the pension problem, the high workers camp rates, the destructive attitudes in Springfield to the

business community -- THOSE are radioactive issues that keep business from coming to or growing in our state. (0275-4 [Wolf, Tom])

Comment: Since 1998, the taxpayer has been paying billions of dollars to the Nuclear Energy companies like SCE to store nuclear waste on site until a place can be found to dispose of it. This fine goes on as long as the spent fuel is stored on site. How much money has SCE been paid by the Federal government since 1998 for the spent fuel it has stored at SONGS? How was that money used? How much money will SCE get each year even with the plant shut down for leaving the spent fuel at SONGS? Is there any law forcing SCE to spend the money from this fine for moving the spent fuel into transportable casks? Must the money be used for something related to storage of spent nuclear fuel or does it just go into the SCE or for that matter the International Edison general fund? (0280-11 [Magda, Marni])

Comment: SONGS must have attention paid immediately to its vulnerable spent fuel. The two years to create a PSDAR is too long to get in motion the kind of actions that are necessary to save Southern California from calamity and must begin today, not in two years. Southern California Edison has lied to the public about safety problems at SONGS of which the company was well aware. They knew the steam generators were a faulty design before they were installed. They have a constant record that is public information now of failures to adhere to safety regulations. The company puts profit before safety. With this terrible record, they must not be given oversight of the Decommissioning of SONGS. There is a history that would show the \$4 billion dollars set aside to decommission SONGS would not be used for immediate, final solutions. There is profit for Edison in keeping the spent fuel on site. Since a US Military Base is in jeopardy if anything goes wrong with the spent fuel sitting at SONGS, and it is on military land, can the execution of the removal of the spent fuel be placed in the capable hands of someone from the military, protecting the future of Camp Pendleton Marine Base? When for two years Elmo Collins, who was then the administrative director of NRC Region IV, met with the public at NRC hearings and told us that SONGS was safe, he listed each of the possible disasters and said behind it, "adequate protection." He was referring to the nuclear fuel within the reactor domes. With the shutdown of SONGS, the public has learned that the 1631 tons of spent fuel on site is not held to that standard of safety. The spent fuel cooling pools are outside the reactor domes. They were not created for long term storage and are not required to have "defense-in-depth" nuclear safety features. SCE has the worst safety record of all nuclear energy companies in the United States. They are going to continue to falsely tell the public that safety is their first concern. We are playing with our future every day the spent fuel sits at SONGS. (0280-2 [Magda, Marni])

Comment: There is a vast difference in the type of the dry storage casks being used around the country for storing nuclear spent fuel. According to the Blue Ribbon Committee's report to the President in January of 2012, the US Navy has 50 final geologic disposal, transportable casks for its movement of nuclear waste out of Idaho by 2035. It will have 350 more before that date. How long does it take to make these casks? What do they cost? Is there any reason we can't use them at SONGS? Final disposal and transportable -that must be our goal. SCE profit in storing nuclear spent fuel on site at SONGS cannot be allowed to make us pretend that spent fuel should stay at SONGS for years. It shouldn't be there for even days. The Friends of the Earth report by Alvarez said the casks SCE is considering will be a million dollars each. Who determines the certification of the number of years a cask is safe? Many in the country currently are said to be certified at 30 to 40 years. What makes a ten year difference? What do we do after the thirty or 40 years are up? Who sets the value of a cask, another corporation like SCE who values profit over public safety? (0280-6 [Magda, Marni])

Comment: When the four billion dollars projected to be spent decommissioning SONGS is spent, does that include final disposal of all spent fuel created at SONGS, even that which lasts 24,000 years? What dates did the current 42 casks for dry storage get fuel placed in them? These casks were constructed somewhere near SONGS. What is their certification for length of safe storage? Are these dry storage casks considered transportable? In Sept 2014, SCE wants to lower safety standards by using the NUHOMS 32PTH2 dry cask system. This requires crowding 32 fuel assemblies into the same size cask that currently holds 24. Who makes the approval of such a change? Edison always chooses profit over safety. Who will decide? What safety consideration would allow that change? (0280-8 [Magda, Marni])

Comment: Dr. Arjun Makhijani, President of the Institute for Energy and Environmental Research, noted ironically that "the domes are the most visible part of a nuclear plant. They exist to protect against meltdown of the reactor core. Once the reactor is shut, the domes are just decoration." Makhijani said San Onofre has 3200 -3400 spent fuel assemblies containing 120 million curies of radioactive waste. "A curie is a lot of radioactivity. Each curie represents 37 billion radioactive disintegrations per second." Makhijani warned, "After a nuclear plant ceases operation a large part of the risk remains, especially the spent fuel pools. A fuel pool fire would create almost 100 times as much radiation as a dry cask fire." Like Resnikoff, Makhijani addressed the high burn fuel issue. "San Onofre has been authorized to use fuel rods that run hotter and contain more radiation but they seem to have exceeded to NRC high burn limit of 62.5 gigawatts. What we know about spent fuel in dry storage is based entirely on experience with low-burn fuel. Why high-burn was authorized at San Onofre without knowing how it might affect storage is a huge concern." The greatest risk during decommissioning, Makhijani said, is in maintaining pool storage and in dealing with dry casks that are certified only for 20 years. "We don't want to be transferring spent fuel from one cask to another if an assembly has been damaged. And in actual experience, there has never been a transfer from one dry cask to another under any circumstance." The endgame in Makhijani's view: "We need to work on a repository. All other solutions are much less adequate. A worst-case event on the surface, especially in a sensitive area like San Onofre, is an order of magnitude more severe than worst-case in deep geologic storage. Our goal should be to store waste in a way where the worst-case is not catastrophic." Makhijani asked why the U.S. government and international agencies aren't thinking more about precluding unacceptable consequences. One reason he cited is a kind of "risk analysis" that cancels out the seriousness of outcomes by rating the worst cases as extremely improbable. "Yet at Chernobyl and Fukushima they have happened," he concluded. (0283-2 [Pascall, Glenn] [Watland, George])

Comment: Bottom line for the Sierra Club: In the shutdown phase, the minimal response -fast track restart -was not adequate and did not prevail. In the decommissioning phase, the minimal response -San Onofre as a long-term mausoleum for "high burn" and other nuclear fuel waste - is not adequate and should not prevail. Our goal is a "better outcome" that creates a new national standard. (0283-3 [Pascall, Glenn] [Watland, George])

Comment: The projected Scope of Decommissioning Project, and Decommissioning Costs are currently still preliminary, only in early stages being prepared by SCE, or considered by CPUC, CEC, and NRC, and are still largely UNCERTAIN. It is important that NRC will require Licensee to fully perform Decommissioning at SONGS in safest, most reliable method, the most "in Public Interest" method possible, and not necessarily the least expensive for Licensee (SCE), contractors, or subcontractors. Timing of NRC actions should be more carefully coordinated with action(s) also pending with CPUC, CEC, California Coastal Commission. (0284-11 [Borchmann, Patricia])

Comment: Another credible new unanalyzed threat should receive scrutiny in an updated, more rigorous scientific analysis, which consists of the possible designation for San Diego as a new 'drone testing' facility. While 'drone analysts' might believe that designating San Diego as a new drone testing facility poses minimal, or no risk(s), I am unconvinced, and I have requested County of San Diego Board of Supervisors to reevaluate that recent action. (0284-4 [Borchmann, Patricia])

Comment: Our beach communities near SanO are more vulnerable than ever to radioactive disasters, thanks to planned major construction on the I-5 in 2014 through 2017. This planned widening will start from the San Juan Creek Rd. and finish just south of Avenida Pico. The I-5 is our lifeline to evacuation. Should, God forbid, any natural or terrorist disaster occur to disrupt the tons of thermonuclear waste stored at SanO, We are trapped. We are dead for sure. San Onofre's waste must be moved inland away from population concentrations as a national number one priority. In the meantime, we must stop this freeway widening, bridge demolition I-5 project before it starts. That freeway is the only possible way of escape from disasters to our stored nuclear waste --if any is possible, for people living in and visiting our beach communities. (0285-1 [Kernahan, Mel])

Comment: I am in favor of the safe restart of San Onofre, because it had significant economic value, it was a stabilizing power source for Southern California, and operated safely with a zero carbon footprint. But the decision was made to shut down both units. Thus, provision for safe storage of the spent fuel rods must be made before site clean up plans can be finalized. This is a national issue for plants across the nation, not San Onofre alone. (0286-1 [Hannaman, Bill])

Comment: In the case of Diablo, the stakes are way too high to allow these false assumptions. 1. Diablo's two reactors are surrounded by 13 earthquake faults, one of which is only one kilometer from Unit 1 -the Shoreline. And the Diablo Cove fault cuts into the bedrock of that reactor and appears to intersect with the Shoreline fault. (0287-4 [Swanson, Jane])

Comment: My recommendation is that Diablo Canyon Nuclear Power Plant be shut down now and the spent fuel removed. (0289-1 [Curren, Elizabeth])

Comment: I am very concerned, even more so after listening to this meeting. PG&G need to be brought into safety compliance. Earthquake faults (13??) No final repository plan[.] (0291-1 [Mauter, Nancy])

Comment: I pray for you to close the plant and begin the long road to cleaning up the mess we have created for future generations. Be the one remembered for being the catalyst that made a difference. Rather than carrying the Karma from all of us who have been affected by your decisions. Be the change—close Diablo today! (0292-4 [Comer, Gail])

Comment: DCPD [Diablo Canyon Power Plant] is located on one a piece of coastline that has very high potential for serious seismic activity. I have fished the coast commercially, near-shore, for 17 years from Point Purisima To Point Año Nuevo. It is obvious from a simple view from the water, that DCPD is located in a place where violent seismic activity has occurred in the past. The only other places on the entire stretch of coast I have described that have anything even close to the type of violent seismically formed rock structures as that surrounding DCPD, are that of Point Lobos Reserve area, and some of the coastline along Big Sur. DCPD is a nightmare waiting to happen. (0298-1 [Terra, Ben])

Comment: Please do the job that you are paid to do, and see to it that DCPD [Diablo Canyon Power Plant] is shut down. (0298-3 [Terra, Ben])

Comment: It is also time for Diablo Canyon to shut down. Old plant. Sits on earthquake faults. Once-through-cooling system doing detrimental damage. Over-filled waste storage. (0299-2 [Smith, Diane])

Comment: Close Diablo Canyon Plant. There can be no confidence in nuclear waste disposal. There is no viable alternative to closing the plant. There are large concerns that cannot be mitigated. (0301-1 [Hayati, Sally])

Comment: As a resident of San Luis Obispo I am very concerned about the storage of spent nuclear waste at Diablo Nuclear Plant. I understand it stays radioactive for a very long time. After the Fukushima disaster I hope the NRC will seriously consider closing Diablo and making sure the storage of the waste already there is as safe as humanly possible. (0311-1 [Johnson, Madeleine])

Comment: San Onofre needs to be rebuilt with new technology reactors that use the spent fuel from the old reactors. After all the electric generators and infrastructure are all there. (0312-3 [Meyer, Charles])

Comment: I live in the 10 mile zone of Indian Point Nuclear Facility. The spent fuel pools are old, leaking and require many backup systems. (0318-1 [Saltzman, Dale])

Comment: And back on the whole seismic topic, we only have to go back to 1930 here in California where off the coast of Redondo Beach was a rock slide triggered by a fairly small on land earthquake, that triggered a 9-foot tsunami, that went right ashore within about two minutes of the onshore 3.0 earthquake. This huge tsunami just sprang up, swept inward to places which are now LAX and downtown LA, Orange County were all inundated, so we really have no advance warning. We never know when that wave will come. So with that, I yield back my time. (0325-10-2 [Chambers, Fred])

Comment: What frightens me is the hours and hours of human beings putting this together when what we need is solid answers for San Onofre right now, not two years from now, not Southern California Edison making the decisions, but please, Diane Feinstein, Senator Feinstein, Congresswoman Loretta Sanchez, Congressman Dana Rohrabacher, Senator Barbara Boxer, we must have you with Jerry Brown, Governor Jerry Brown. We must have a political solution beginning immediately that takes this responsibility away from a company that has two years where they get our taxpayer's money, taxpayer's money to keep the fuel for 60 years where it is. We keep paying the fine. (0325-12-2 [Magda, Marni])

Comment: We need to have thermal nuclear base in California, away from the 8.4 million people, where we are away from the ocean, the rising tides. We don't have 60 years to leave this here. We know that, it's like we're sitting here like foolish children. We know we must move it. We've got to put all of our best minds together and put the money -- if it costs \$10 million per cask, we've got to find it and do it now. (0325-12-6 [Magda, Marni])

Comment: In 1993, we did cross-ties to make it even more efficient than it is today, so that if something goes over here, it can go over there. What just happened over there recently had nothing to do with who built the plant, how we built the plant, or nothing. Okay? That was something they had somewhere else and they brought it here. They tried to do something, but it worked for 27 years and was not a problem. And we didn't have any of these meetings at all, did

we? We didn't have all this stuff going on. Does the NRC need to do things? Of course they do. Do they try to do it? All the time they try to do it; every day they try to move forward and make things better. Don't think they're not. These people down here don't want to die. Think about that. They're not just blowing this stuff up to play games. Okay? They're here to make it happen, and to make it work. (0325-14-2 [Sallis, Gary])

Comment: Our student group applauds the NRC's handling of San Onofre, both locally and through in-person discussions, which I've had with Chairman McFarland during the student delegation (0325-17-3 [Pearson, Jeremy])

Comment: I think, and this is personal feeling, I think the NRC has done a wonderful job protecting workers at the San Onofre plant, the workers that I represent, 35,000 strong who have lost their jobs due to the shutdown of the nuclear plant. (0325-18-3 [Lemmon, Tom])

Comment: When we talk about nuclear waste, obviously we have Hanford Reservation leaking into the Columbia River. We've had several issues with Indian Point leaking into -- tritium into the Hudson River. We've got all sorts of issues, aboveground nuclear testing that went on all over this country in several sites until 1963. We have a history of accidents reported, unreported, and we always have our regulatory agencies coming in and saying there is no immediate problem. The public is not at risk. There is no problem with public health. (0325-21-1 [Iwane, Cathy])

Comment: Believe me, if you've been to San Onofre, if you walked the beach there, you know how close to the ocean it is. If you've lived in San Clemente, you know it's been a concern just down the road. We're almost next door. We have this concern for people. Now, if we're here to help rewrite some rules or help with adjudication, I'm sorry, I'm not qualified for that. But I am qualified, I think, as a person who's lived here a long time to care about my family, my neighbors, what happens on the freeway, the fact that the toll roads are considering building an extension that would end at the trestles. It was in the paper the other day. I mean, that's our neighbor down there, and it's a very sick neighbor. And to think that there's anything that can be done other than moving it, at least the dangerous stuff, inland where it is not within the reach of the sea, then I'm afraid that I have to differ with them. And it's a personal thing. It isn't theoretical, it isn't about what an agency should do, it's about how we're going to live here. (0325-24-4 [Kernahan, Gary])

Comment: [I]t's heartbreaking what the nuclear industry has done to our state, not only from this side of the Pacific, but the General Electric plant that is seeping and flowing to our shores from Fukushima. (0325-28-1 [Branigan, Mary Beth])

Comment: I believe that as long as San Onofre's high-level nuclear waste remains onsite it should be stored as safely as possible until it be safely moved, if ever. (0325-29-1 [Feathers, Jösan])

Comment: At SONGS, the NRC assured the state that they followed their 50.59 process to the letter, and yet steam generators were dysfunctional and will be subject to years of litigation and unanticipated rate payer and utility costs. At Diablo Canyon, the NRC is assuring the State that although Diablo Canyon does not meet its safe shutdown earthquake requirements, we should trust the NRC's Probabilistic Risk Assessment process that they will eventually determine that we need not be concerned. I'd like to mention that the evaluation released today uses the word "seismic" more than 100 times. California can have no confidence that waste can safely remain on our vulnerable coast. The NRC itself has been able to find a solution, yet the NRC's

decisions will eventually be paid for generations that will never receive a kilowatt of benefit from SCE's [Southern California Edison's] or PG&E's aging reactors. (0325-3-4 [Becker, Rochelle])

Comment: The tsunamis we talked about. We didn't even talk about what happens if there's an offshore landslide like what happened in 2004 in Banda Aceh, causing a tsunami that is way, way bigger than any of these estimates that they have for a long far-away tsunami wave finally getting to us. We can have a thousand-foot wave right here. (0325-7-5 [Hoffman, Ace])

Comment: [T]he first thing we have to do is shut down Diablo Canyon. (0325-7-8 [Hoffman, Ace])

Comment: Through the years, all of our concerns and our research about the defective and the now closed San Onofre plant continuously spotlights new revelations that actually continually bring us less confidence. (0325-8-1 [Von Thillo, Grace])

Comment: The proposal to store this waste indefinitely on our seismically active coastline dismisses the value of the health and prosperity of all of us living in this community. (0326-10-2 [ZamEk, Jill])

Comment: "I am here this evening to support the reasoning of many in this county who have a great concern over the huge and growing amount of nuclear waste accumulating at Diablo Canyon Plant. The high-level waste of the cooling pools is of critical importance." (0326-14-1 [Brown, Marti])

Comment: The only solution is to stop making the waste by shutting down Diablo and moving the waste to dry casks as soon as possible. The NRC is mandated by the Atomic Energy Act to put the health and safety of people above the economic interests of the nuclear power industry. A major earthquake greater than Diablo was built to withstand is possible according to the U.S. Geological Survey. What will happen then? Another Fukushima? (0326-20-3 [Caulfield, Lee])

Comment: I lived in Santa Barbara, actually, in Isla Vista, under the shadow of Diablo, and it's been over me since 1980, which is long enough. In 1981 and '82, I studied all aspects of the nuclear industry, the economics, the waste, the history, the mining, the accidents; I studied all the aspects, and Diablo specifically, and I was there when they put the reactor in backwards, and said, oh, it's just a minor mistake. It's all right. And from '81 to '82, I continued to study the nuclear industry and Diablo, to defend the arrest of 500 people who protested the licensing of Diablo, and it's still here today. (0326-21-1 [Conn, Diane])

Comment: The U.S. is still working on the plan for long-term storage of nuclear power plant waste. Please raise your hand now if you have confidence in the NRC's radioactive waste storage and environmental impact plan. The first and only storage repository in the world is under construction in Finland. Onkalo should be completed around 2020. The estimated price tag? About 818 million Euros, to be paid for by the power consuming customers. Just how stable is the world's political situation, and for how long? Diablo Canyon sits near 13 fault lines on an unprotected coast. It's fuel rods are in overcrowded water pools. A temporary holding place, we are told. They need, now, to be stored as safely as possible in dry casks and moved to a permanent storage facility as soon as that is available by the Federal government, away from San Luis Obispo County. (0326-23-3 [Malboeuf, Simone])

Comment: I was born and raised in the City of San Luis Obispo and chose to return to the City of San Luis Obispo and raise my children here. I have toured the plant and I believe in the work that PG&E is doing there, and I support the work that PG&E is doing there. (0326-27-1 [Devitt, Andrea])

Comment: First, I would like to acknowledge my respect, trust, and confidence in PG&E and its employees. For several decades now, PG&E and its employees have been our caring and involved community partner. Over the years, they have supported our mission by generously sharing their resources through volunteer time and donations. They continue to sit on our Board and are the parents of some of our youth board members. Additionally, I have always been pleased with the way they operate the Diablo Power Plant from the several opportunities I have had to visit and tour the plant. (0326-33-1 [London, Rick])

Comment: Where my concern lies, which is relevant to this evening's public meeting on Waste Confidence, comes from my 14 years living on Long Island, New York. My concern comes from the fact that during the 11 years it took to build the Shoreham Nuclear Power Plant, Suffolk County residents were promised an evacuation plan that ended up not being possible. The plant was never approved for operation and most of the \$6 billion cost was passed on to the Long Island residents. To this day, I wonder why the Long Island Lighting Company was ever allowed to break ground. Of course, it was because we were promised the certainty of a safe and sound evacuation plan. (0326-33-3 [London, Rick])

Comment: We talk about -- somebody mentioned that, Carrie Safford, I believe, said that rulemaking is one of the most important things we do at the NRC, that's what we're talking about, this Rule on waste; well, that's all good and well, but if you don't obey your rules, if you don't follow them, then it doesn't mean anything, and we're currently not following them regarding the license at Diablo Canyon. They are exceeding -- well, we don't know the seismic risk of the Hosgri and Shoreline faults; it may very well exceed the design basis of the plant. We don't know because the calculations haven't been properly done. If the rules were being followed, Diablo would be shut down right now, and they're not doing it. So in some sense, this meeting is kind of a farce because, if you don't follow the rules, what's the point of talking a whole lot about what they're going to be? (0326-34-3 [Phillips, Mark])

Comment: And then, I want to also say that I took the tour at Diablo earlier this year, and I asked how many solar panels they had installed. Well, they have about 15 of them on some light poles. They have no solar production. It's embarrassing. So I challenge them to continue shutting this plant down. It is too old to be safe. (0326-35-3 [Owen, Linde])

Comment: And I would ask that you begin tomorrow designing wind, safe solar that does not kill birds, wave generation, and then get us on to a good rooftop program, and give us a chance to shut that thing down [Diablo Canyon Nuclear Power Plant] and have enough energy. (0326-35-4 [Owen, Linde])

Comment: The second is that, as a resident living not far from the plant, I certainly have the confidence in PG&E and their ability to continue to store the spent fuel and operate the plant in a safe and secure manner. (0326-37-3 [Rethmeier, Blain])

Comment: First, if the Nuclear Regulatory Commission is seriously concerned about the health and safety of the citizens living on the Central Coast of California, it should, one, immediately suspend the operating licenses of the Diablo Canyon Plant until that nuclear plant is brought into compliance with existing NRC safety regulations regarding earthquake threats. And two, immediately move all of the fuel stored in spent fuel pools to an offsite location not vulnerable to earthquake risks and subsequently transfer them to dry cask storage. (0326-4-2 [Brown, Jerry])

Comment: A recent report by the Union of Concerned Scientists says that, in the case of Diablo Canyon, the NRC is ignoring its regulations, unfairly exposing millions of Americans to undue risk. There is a one in six risk of an accident, an earthquake, a serious earthquake at Diablo Canyon every year that this plant operates. One in six. (0326-4-5 [Brown, Jerry])

Comment: So I'd like to have a much shorter range solution to Diablo Canyon, and that would be to have it be converted to solar, wind production, wave production, and for decommission. (0326-43-2 [Rippner, Sharon])

Comment: What makes the situation at Fukushima right now, with the dangerous transitions from their open pools to their dry casks is that, this all was very unnecessary. All of Fukushima's dry casks containing spent fuel assemblies that were stored prior to the earthquake tsunami have survived without damage or release into the environment. The similarities between Fukushima and Diablo Canyon are chilling in the type of plant, the manner of storage, the proximity to earthquake faults, and the lack of government insistence that storage regulations be followed.. (0326-43-5 [Rippner, Sharon])

Comment: Since time immemorial, there are stories that have been handed down from generation to generation of dangers of Diablo Canyon. There is also documentation in the mission records, even more in recent history, as well as current studies, which is enough proof that Diablo Canyon Nuclear Power Plant is in a catastrophic location without projecting potential dangers of climate change. As stated before, Diablo Cove faults run directly under Unit 1 Reactor. Seismologist Jim Brune proved the faults around Diablo Canyon Nuclear Power Plant would give vertical acceleration. (0326-45-2 [Baker, Crystal])

Comment: My children, I have a little picture of them here, right there, and one thing that haunts me is the question; when you knew Diablo was not safe, what did you do? I hope we can, one day, say that we shut it down. You can't see it very well, but this is a map of Fukushima, the 12-mile radius is there; this is pretty much us, which is about 8-1/2 miles. I'm not just speaking as a parent and as a, you know, crazy liberal, if you will. I am a mechanical engineer, a software engineer; I have never had a design fail where I thought it would fail. I appreciate all of the Diablo engineers talking about how safe they think it is. I actually worked at PG&E at one point, and I understand how things fail, and it's not how you expect it. (0326-47-2 [Monge, Roberto])

Comment: One last thing, we have an ordinance here in San Luis Obispo. It's called the Neighborhood Preservation Ordinance. You have to bring in your garbage cans within 12 hours of putting it out. So I would like Diablo to take in their garbage. (0326-47-4 [Monge, Roberto])

Comment: I guess I want to speak of the underwater landslides that exist off of the coast of Isla Vista in Santa Barbara. It would take 12 minutes for a tsunami, rumor has it, to go from that location to San Pedro. How long and what would be the size of that tsunami from that location? You look on the map, you will go under the sea. There are three landslides there. (0326-52-4 [Fosmo, Vaughn])

Comment: I have a rhetorical question to ask, and please just humor me, but how many people have heard of Fukushima Daiichi? Would you please raise your hand? Okay, for those that haven't raised your hands, I'm just kind of wondering where your head had been in the last couple of years. But, so now could you raise your hand if you've heard of Fukushima Daiichi three years ago? Okay, not too many people. And why would that be? It would be because Fukushima Daiichi had a very safe record at that time, just like Diablo does. Diablo will be safe

until something happens. And it will happen. The USGS says that we are over 50 years due for a major earthquake. And we have 14 earthquake faults just sitting off of Diablo. (0326-53-1 [McGibney, Patrick])

Comment: One thing I want to point out, I've noticed that throughout the evening that most of the people supporting Diablo tend to work there. And I think it's just human nature to support whatever's putting money in your pocket. I think it's kind of what everybody does. But I'll try to make this short and to the point. This is for the record. I just want to say that I'm opposed to storing any spent fuel at all at Diablo. (0326-54-1 [Crimmel, Steve])

Comment: We, the citizens, must be an active part of this enterprise, reasonable negotiators for a fair and balanced management contract, something new and responsibly purposeful. We're all in this quandary together. And you don't want to kill a state, the bread basket of the country, while Fukushima Daiichi has already begun to sicken us and destroy the Pacific Ocean. The onus of responsibility, personal responsibility, falls on each of you, on your shoulders, to engage and include the citizenry in the plan to make Diablo Canyon safe, really safe, for the present and for the next 250, 000 years or more. (0326-58-2 [Davis, Adrienne])

Comment: I also urge the NRC to not renew the license for Diablo Canyon power plant when such license renewal is submitted. (0326-59-3 [Cordes, Reo])

Comment: The Diablo Canyon nuclear power plant was built before the truth was known about the many earthquake faults that are beneath and near the plant. With the truth known, that plant would never have been built then, and it would not be allowed to be built today. Given the known facts, to even consider extending Diablo's operating license defies all common sense. It will be a complete disregard of public safety if the NRC allows the continued production and onsite storage of highly radioactive nuclear waste in a seismically active location which jeopardizes the life, the health, and the property of every one of us who lives here. I hope that we can have confidence the NRC will do the right thing, halt the production of deadly radioactive waste which will be a danger to each and every person who lives here and for generations to come. Diablo Canyon nuclear power plant is in an unsafe location. Shut it down before it's too late. (0326-62-1 [Mellow, Marion])

Comment: I thought it was disingenuous that Daryl at PG&E Diablo was talking about construction to be able to store 138 casks rather than 38, but he didn't even go into the difference between the more traditional spent fuel and the spent fuel from high burnup fuel. (0326-63-5 [Campbell, Bruce])

Comment: In the case of Diablo Canyon, the stakes are far too high to allow these false assumptions. Number one, Diablo's two reactors are surrounded by 13 earthquake faults. One of them is only 1 kilometer away, the Shoreline Fault. It comes that close. And there's the Diablo Cove Fault, a little sub-fault that goes directly under Unit 1 Reactor and connects with the Shoreline Fault. The stakes are really high. (0326-8-4 [Swanson, Jane])

Comment: If the NRC were actually looking out for the welfare of the people and the environment, the Commissioners would order the immediate shutdown of Diablo Canyon. It's seismically unsafe and it's America's potential Fukushima, but your mandate is to protect the public while facilitating the use of nuclear power. Those two directives are inherently incompatible. I want you to know that we will fight every step of the way and we will use all of our resources to protect the future generations from this intolerable legacy we are leaving for them. It's a real David and Goliath battle, but we will never give up. (0326-9-7 [Seeley, Linda])

Comment: And regarding West Michigan, I wanted to mention since this is kind of the midwest, one of the two midwest public comment meetings on Nuclear Waste Confidence, that in October of 2005, the Palisades atomic reactor had a cask dangle accident where the 107 ton waste transfer cask was suspended over the fuel pool for a couple of days. The workers, inexperienced as most of the experienced workers had been dismissed by the company to save money, tried to override the emergency brake on the crane which could have sent the 107 ton weight plummeting through the floor of the pool, which could have drained the water away. And the worst case scenario is a partial drain down where there's water in the bottom of the pool, it blocks airflow, and the radioactive waste in the pool could catch fire. If that were to happen at Fukushima Daiichi Unit 4, for example, it would dwarf the radioactive releases that have occurred thus far in that global catastrophe. (0327-10-1 [Kamps, Kevin])

Comment: I just wanted to echo what Keith Gunter mentioned earlier, that this is the 71st anniversary of Enrico Fermi with his prototype reactor splitting the atom, a chain reaction, the first high-level radioactive waste in human history, and we don't know what to do with the first cupful of radioactive waste that Fermi generated. It's still, in a sense, in interim storage. So, of course, just up the road from here we have the Fermi 2 atomic reactor, and Ed McArdle just mentioned that Fermi 2 has way too much in common with Fukushima Daiichi Unit 4. (0327-10-2 [Kamps, Kevin])

Comment: Another site-specific issue at Davis-Besse is a pool leak which is listed in one of the tables in this draft GEIS in Appendix E, radioactive water leaking out of the pool, borated water which is corrosive. Davis-Besse seems to have a problem with leakage of borated water, so what you've got is a reactor pressure vessel that has continual lid corrosion and near breaches, the worst accident since the Three Mile Island meltdown happened at Davis-Besse with the hole in the head fiasco. You've got corrosion of the inner steel containment vessel, and you've got significant severe worsening cracking of the shield building. So, it's a recipe for disaster at Davis-Besse. (0327-10-4 [Kamps, Kevin])

Comment: There should be no license extension at Davis-Besse. The reactor should be closed today. Certainly, it has to be closed by Earth Day of 2017, when the 40-year license expires. I just wanted to give the figures for how much waste there is. By spring of 2010 there were 505 metric tons of high-level radioactive waste at Davis-Besse, so by spring of 2014 that'll be 585 metric tons. By 50 years of operations, 825 metric tons; 60 years of operations over 1,000 metric tons. (0327-10-5 [Kamps, Kevin])

Comment: And natural disasters, you know, often you hear tsunamis can't happen on the Great Lakes. Well, speaking of Tecumseh, War of 1812, some of the worst earthquakes in North American history, 1811, '12, '13, 8.0 magnitudes --Giant waves. Giant waves on the Great Lakes. (0327-10-7 [Kamps, Kevin])

Comment: I cut my teeth on Davis-Besse in 1972, so I've been doing this for a very long time. And as much as things change, nothing really changes. Mike Keegan mentioned the storm that occurred on Lake Erie in October of 1972 when 300 feet of dikes collapsed. They were washed away by the storm, flooding the Davis-Besse site which, fortunately, was not operational at the time. These are aerial photographs that were taken three days after the site was flooded. People had to be air lifted out from the site, cars were not salvageable. You cannot keep these. I will probably be submitting these with my -- Okay. I just presented aerial photographs of the Davis-Besse site three days after this storm. It's pretty unbelievable. All you can see are the tops of the trees. (0327-11-2 [Kline, Connie])

Comment: Specific to this region, and I'm going to talk about Lake Erie, is flooding potential. There is what is known as a seiche where you have straight line winds which blow the water out to Buffalo, and the water sloshes back. In 1972, the Davis-Besse site was flooded for over a month. If the plant had been operating at that time, it would have been a disaster. (0327-2-5 [Keegan, Michael])

Comment: In the UK, as well as in Canada the nuclear waste leadership role has been removed from the scientists and being handed to prominent citizens, and using philosophical and social science knowledge to gain their approvals. Upon a formal adoption of any new policies, then implementation is done by another authority. The U.S. Nuclear Regulatory Commission, the regulators, the stakeholders all seem to be waiting on the sidelines, as Canada is inching closer to a deep geological repository in the next few months. The entrance that repository is less than one-half mile from Lake Huron, and the possibility of radioactive contamination of Lake Huron and other waters downstream, including Lake Erie, Lake Ontario, and the St. Lawrence River are frightening. In Kincardine, Ontario, approximately 8,000 voters approved to host such a facility, and you call it volunteeristic siting, but the definition of a community for this planned burial requires the engagement and acceptance of 40 million other people that live on the Great Lakes, that live, work, eat, and drink from the Great Lakes. Consent-based management in this instance is a failure, and it's sitting on an international body of fresh water, the largest in the world. (0327-20-2 [Clemons, Victoria])

Comment: I have been working with my county commissioners. I am thankful that they are here, and keeping themselves informed, Mr. Sass, Mr. Arndt, and Ms. Regal. I hope that my hometown of Port Clinton, Ohio will be the third Ohio city to pass a resolution opposing the Canadian dump, and any dump on the Great Lakes watershed. (0327-20-3 [Clemons, Victoria])

Comment: I live in Cleveland. I worked on the Davis-Besse campaign with Ohio Citizen Action from the beginning to the end of that campaign. I also know about FirstEnergy, I call them worst energy's safety problems and their culture of safety. Culture of safety. That's special. And I also know very well about the goings-on inside the plant. I'm not going to repeat all this stuff because you guys are on it, and I love you all for coming out. (0327-22-2 [Muser, Mary Jo])

Comment: Fermi 2 has an overcrowded fuel pool. It is at risk for weather-related events, loss of coolant, or terrorist attack. (0327-27-6 [Macks, Vic])

Comment: The official story is wrong very often, time and time again. For example, here at Davis-Besse we have cracks in our containment dome. The official story is those were caused by the blizzard of '77 and that they've fixed them now and they haven't gotten any bigger. Yet, the last time they looked the cracks grew. This means that the cause was not the blizzard of '77 and that their solution is inadequate and wrong. So the official story was wrong. (0327-29-2 [DeMare, Joseph])

Comment: I certainly hope all you officials have full review of documents, proprietary or not. For example, let me refer to the Fermi 2 NRC Integrated Inspection Report dated October 22nd, 2013. It states, "selected CARDS were reviewed." At first I thought how appropriate since they're gambling with our lives, but then I found out CARDS stood for Condition Assessment Resolution Document. One CARD Fermi received was for foundation damage below several radial beams. The report goes on to say, "proprietary information was examined during this inspection, but is not discussed in this report." Endangerment to the bio region is proprietary? Shouldn't foundation damage below several radial beams be made public knowledge? Damage to Fermi 2's foundation is a danger to our lives. The same inspection report vaguely discussed and

approved problems associated with the radioactive waste, but they were properly addressed for resolution in the corrective actions. What problems associated with the waste? More proprietary dangers? And isn't NRC's oversight of these facilities a bit too lenient? For example, in March 2012, NRC issued an order to require Edison to have a reliable indication of the water level in the spent fuel pool. A year later, Detroit Edison responded saying that they would do that by the fall of 2012. (0327-5-3 [Collins, Jessie Pauline])

Comment: I've lived in Michigan most of my life, and I can remember times when I was a child I'd go swimming in Lake Michigan. I could drink the water. It didn't taste like chemicals, it tasted like tap water. It was pure. And there weren't very many people living on the lake at the time, and there were no nuclear reactors. And we were never afraid of the water, but now I don't like to swim in Lake Michigan. It doesn't taste the same, get rashes. And you think about well, they just had a spill, 91 gallons of radioactive waste went into the lake from Palisades, you know. And there's leaking tritium, and we have tremendous problems right now with nuclear waste. (0327-8-1 [Barnes, Kathryn])

Comment: Of course, some sites are not appropriate for cask storage, such as a previous speaker pointed out, Palisades Nuclear Station where they were placed in unstable sand dunes. And it should be realized there is a special problem with Fermi 2. They are unable to transfer irradiated waste from fuel pools to casks because of defects in original construction. Meanwhile, the NRC continues to allow waste to be stored in the fuel pools at Fermi 2 way beyond the design capacity. There is now over 620 tons of the most dangerous substances on earth stored in the pool five stories above the reactor. This is more irradiated fuel than all the Fukushimas put together. (0327-9-4 [McArdle, Ed])

Comment: And let's all remember, folks, that the Monticello Nuclear Power Plant is the exact same model, the exact same type as the Fukushima plant. (0328-17-3 [Cavlan, Michael])

Comment: Right now, Sequoyah is targeted by TVA for putting some irradiated fuel into dry cask storage, and they have appropriated somewhere under \$500 million for this activity to go to the lowest bidder, a bidder for these cask construction that actually, until a few months before the award of the TVA contract, had been debarred from Federal contracting for prior fraudulent activities. (0329-12-1 [Paddock, Brian])

Comment: We [BEST/MATRR] recently published a study called "Radioactive Emissions and Health Hazards Surrounding Browns Ferry Nuclear Power Plant," which shared our own radiation monitoring results at 50 sites we established around Browns Ferry. And it showed basically background radiation upwind but readings up to 40 times background downwind. The epidemiological data in that study found alarming rises in mortality rates downwind of Browns Ferry to over 20 percent above the average U.S. community. Over 300 million curies of radiation is stored at Browns Ferry, and, at last reporting, over 85 percent of that is stored in raised fuel pooling pools of the same design as Fukushima. BFN, Browns Ferry, is infamous for multiple fire events, a major vulnerability for any plant. But Browns Ferry still has not fulfilled the fire requirements its 1975 fire initiated. We are also now recognizing the extreme tornado dangers to these vulnerable raised cooling pools that are covered overhead only by metal roofing, such as we saw blown off in the Fukushima explosion. (0329-13-1 [Johnston, Gretel])

Comment: [W]e request that further studies be done at Browns Ferry on the radiation emissions which appear to be illustrating a bathtub effect as Browns Ferry approaches 40 years of age. (0329-13-3 [Johnston, Gretel])

Comment: I wanted to talk about Dr. Ross Landsman, an NRC whistleblower from Region III, dry cask storage inspector, who in February of 1994 identified the fact that the dry cask storage at Palisades Nuclear Power Plant in Southwest Michigan on the Lake Michigan shoreline is in violation of NRC earthquake safety regulations. That's just 150 yards from the water of the drinking water supply for tens of millions of people downstream. And since that time, Palisades has put in another dry cask storage pad, which, again, Dr. Landsman in full disclosure -- he served as our [Beyond Nuclear] expert witness when we took this issue back to the NRC in an emergency enforcement petition, when we took it to the Federal courts. And he warns that the newer of the dry cask storage pads, in addition to the older one, is also in violation of NRC earthquake safety regulations. (0329-20-4 [Kamps, Kevin])

Comment: However, as we are seeing with the decommissioning or dismantling of the nuclear reactor at Zion -- and we have been following it very closely -- our problems are just beginning. Zion, site of the largest dismantling of a reactor in history with almost a billion-dollar budget, is scheduled to start the irradiated waste fuel transfer in the next few months. One thousand metric tons of irradiated fuel will be transferred into dry casks over the course of the next 12 months. HOSS hasn't even been on the table, hardened onsite storage. This is over twice the 400 metric tons being transferred at unit 3 at Fukushima currently. Since the Zion decommissioning began, there have been two license transfers through the NRC. Now Zion Solutions, LLC, a privately held company, has been granted authority by the NRC to manage the decommissioning. As a privately held company, they are legally entitled to take a profit. When I, along with others as Con Ed ratepayers, contributed to the public funding of this project with a charge on our monthly electric bills, we expected that if there were any funds left over, they would be rebated back to the public. There are precedents for this in the last 20 years in the millions in Illinois with Con Ed. According to the NRC, their only responsibility; that is, Zion Solutions', Energy Solutions', only responsibility -- excuse me. According to the NRC, the NRC's only responsibility is to see that there is enough money to cover the cost of the project. At this point, those costs include a profit margin. Even if it turns out there is no profit to be made from the Zion decommissioning, the precedent is set for a privately held company to manage public funds and build in a profit into the budget. As a Con Ed ratepayer, I did not agree to this "public-private ownership" model. As a Con Ed ratepayer, I did not agree that the public could legally be prohibited from access to the records of a privately held entity. There is already one lawsuit in the courts challenging the Zion project. There may be more in the future. At the last sham of a public meeting of the Zion Community Action Panel, which is a group of local people appointed by Zion Solutions who were not elected in a public process and whose backgrounds do not encompass the oversight of a billion-dollar decommissioning project, Pat Daly, who has been managing this decommissioning up until now from Zion Solutions, announced that he was leaving the post and going back to Tennessee. And he introduced the new executive, who will be starting now. He is leaving us at the most vulnerable time, when the fuel transfers are due to start and when we, the public, will be at the most risk. How can we possibly have confidence in the NRC that is allowing this to happen? Whatever the next executive's fine credentials may be, this is not the way for this to unfold and to put the public at this risk. We do not oppose the fuel transfers. We oppose the process that is going on at Zion. And we are very concerned about the role or the lack of role of the NRC, where we feel we are all in clear and present danger. (0329-23-3 [Lewison, Linda])

Comment: I served on TVA's stakeholder group for its first integrated resource plan. And what I saw there as TVA as part of the nuclear industry and highly invested, even at that point, was that nuclear power and the departments in TVA that benefitted from that activity had control of the policy. And, for example, the first IRP that TVA did, which it is now in the process of starting over again because the facts on the ground have changed so much, but the nuclear people

said, "Oh, you've got to put in starting and finishing Bellefonte in your integrated resource plan because if we don't start by a certain time, we can't finish the reactors within the license period for construction." Of course, since then, TVA has essentially walked away and said, "We have no need for the power. And we are not going to build Bellefonte," although they haven't turned back in the licenses. (0329-25-1 [Paddock, Brian])

Comment: What I did want to make the point of in the limited time is that this is not a border issue. To say that we are dealing with this for the United States is very wrong. This spills over borders. We have got blatant examples: the hearings that were held in Great Lakes for the Great Lakes repository and the risk to Lake Huron. (0329-29-3 [Messer, Diane])

Comment: I am here in Maine. And just over the border into New Brunswick is the Point Lepreau Plant, which is, oh, less than 50 miles away from populated area, native population that has been very concerned. And we have reservation land there, Satiq, along the border between Maine and New Brunswick. And people have spoken to me that live there that are very concerned about the impacts of that Point Lepreau, which has had severe safety issues and been shut down for long periods of time. And they're pushing them to get back up, even though the problems, the faults have not been corrected, because it's costing them money to keep it idle. (0329-29-4 [Messer, Diane])

Comment: For more than a decade now, the Alliance for a Clean Environment has been researching and investigating Limerick Nuclear Plant's high-level radioactive waste fuel pools, storage casks, and risks associated with transportation of high-level radioactive waste. A body of compelling evidence is now posted on the ACE website, which is at www.acereport.org. And section number nine specifically addresses high-level radioactive waste is a ticking time bomb. For purposes of this study, ACE is going to be submitting a 25-page summary that combines previous and current findings (0329-3-1 [Cuthbert, Lewis])

Comment: I had an opportunity to work for the BLM in Roswell, New Mexico, just north of the WIPP pilot project, which is now actually running. I had a chance to review a lot of that documentation as a geology intern and found it very interesting that the parameters for how close the closest well would change every time they found a well closer than they wanted, big concerns with that, still have those big concerns, not to mention the area has a lot of issues with hydrogeology and salt zones, et cetera. (0329-34-1 [Myers, Susan])

Comment: We have been very fortunate in Maine to have shut down Maine Yankee. Back in 2005, the government committed to an agreement to remove the nuclear waste. None of it has been removed, no attempt has been made, no efforts. (0329-4-1 [Messer, Diane])

Comment: And, therefore, the spent fuel at Turkey Point and at St. Lucie needs to be moved to high grounds either in Florida or somewhere in southern Georgia, some place that's above and out of the reach of this tsunami. It would probably be around Wildwood to Ocala or Gainesville area, which is at the top of the Florida Turnpike, which is a fairly safe road. It should be shipped on the toll road because if you ship it on I-95 there's a chance, greater chances of accidents or wrecks or whatever. I used to drive semis, and the last company I worked for, they said to take all toll roads as often as possible because they do have fewer wrecks on them. (0329-8-2 [Wilson, Greg])

Comment: As far as Crystal River goes, that's on the Gulf side and who knows what's going to go on out there, especially with every drilling company in the world wanting to drill in the Gulf of Mexico. (0329-8-4 [Wilson, Greg])

Comment: As a resident of Washington State, I am affected both by the constant question of how to further clean up Hanford and the question of how Japan's recent reactor problems will impact the Pacific fisheries. (0334-1 [Nuccio, Theresa])

Comment: It is unacceptable to NOT develop a definitive plan to properly and fully decommission the San Onofre power plant by storing and moving the radioactive waste from the highly populated South Orange and North San Diego County areas that surround the plant. Please develop a timely and COMPLETE decommission process for San Onofre. (0337-1 [Johnson, Reed])

Comment: Regarding the decommissioning of the San Onofre Nuclear Power Plant. It is unacceptable to not develop a definitive plan to properly and fully decommission the San Onofre power plant. Storing and not moving the highly dangerous radioactive waste from the highly populated South Orange and North San Diego County areas that surround the plant is irresponsible. I ask that you please develop a timely, thorough and complete decommission process for San Onofre, and share that plan with the public and in particular, the residences of South Orange and North San Diego County for our input into the process. Our property and more importantly, our health are at stake if the radioactive waste leaks into the environment that is our home. (0338-1 [Johnson, Arlene])

Comment: We, here in San Luis Obispo County, have anxiety about the amount of waste that is mounting at Diablo - with several earthquake faults in close proximity to the plant. PLEASE QUIT MAKING MORE WASTE TO BE STORED IN A SEISMICALLY ACTIVE AREA. (0344-2 [Heald, Deborah])

Comment: Please do not allow any further delays in removing radioactive waste from Diablo Nuclear Power Plant. Do not allow for license renewal until a safe, permanent off-site location is built. (0345-1 [Rochte, Tim])

Comment: In the case of Entergy's Pilgrim Nuclear Power Station (PNPS) in Plymouth, which is of special concern to we the undersigned, shutdowns and malfunctions have been so numerous that the NRC itself has flagged the plant for intensive oversight. Presently on-site storage in dry casks is the only solution, but it is only a relatively short-term fix for a problem requiring containment for hundreds of thousands of years. So far the design for the Interim Spent Fuel Storage Installation (ISFSI) is underfunded, and its location is vulnerable to sea level rise, flooding and terrorism. The casks would not be separated by protective berms although that would obviously lessen the impact of an aircraft attack. (0348-4 [Agnew, David] [Roscoe, Lee])

Comment: For example, let me refer to the Fermi 2 NRC Integrated Inspection Report 05000341/2013004, dated Oct. 22, 2013. It states, "Selected CARDS were reviewed.." At first I thought how appropriate since they are gambling with our lives, but then I found out that CARDS stood for Condition Assessment Resolution Document. One CARD Fermi received, 13-26522 was for Foundation Damage Below Several Radial Beams. The report goes on to say, "Proprietary information was examined during this inspection, but is not specifically discussed in this report." Endangerment to the bio-region is proprietary? Shouldn't foundation damage below several radial beams be made public knowledge? Damage in Fermi 2's foundation is a danger to our lives. The same inspection report vaguely discussed and approved "...problems associated with radioactive waste...were properly addressed for resolution in the licensee's corrective actions..." What problems associate with the waste? More proprietary dangers? And isn't NRC's oversight of these facilities is a bit too lenient. For example, on Mar. 12, 2012, the NRC issued an order to require Edison to have a reliable indication of the water level in spent

fuel pools. DTE responded a year later, 28 Feb. 2013, describing how they would do that by the fall of 2015. NRC staff evaluation, dated 25 Nov. 2013, notes, "further information regarding the potential dose rate impact of other materials stored in the Spent Fuel Pool is not currently available for review." What kind of materials is stored in the SPF that would make this more proprietary information? (0349-3 [Collins, Jessie Pauline])

Comment: In the case of Entergy's Pilgrim Nuclear Power Station (PNPS) in Plymouth, which is of special concern to we the undersigned, shutdowns and malfunctions have been so numerous that the NRC itself has flagged the plant for intensive oversight. Presently on-site storage in dry casks is the only solution, but it is only a relatively short-term fix for a problem requiring containment for hundreds of thousands of years. So far the design for the Interim Spent Fuel Storage Installation (ISFSI) is underfunded, and its location is vulnerable to sea level rise, flooding and terrorism. The casks would not be separated by protective berms although that would obviously lessen the impact of an aircraft attack. (0352-4 [Roscoe, Lee])

Comment: I crossed a blue line and was arrested in front of the entrance to Diablo in 1978 because as a responsible Biologist I felt nuclear waste should NOT be produced until proper safe storage is provided. Radiation modifies DNA!!!! I paid a fine and went to jail. At the time PG&E claimed it would have proper storage when needed---I guess Yucca Mt. Why does the NRC permit Diablo to operate?? Diablo has earthquake faults like the Japanese Disaster. The NRC should demand that PG&E STOP producing this terrible nuclear waste or pay a fine & go to jail as I did. Tomorrow, Dec. 7th, I will be demonstrating in front of main gate of Diablo at 10am (but not crossing the blue line)----all legal. Our signs: NO DIABLO (0365-1 [Denneen, Bill])

Comment: Any of the following is reason enough to close Diablo Canyon Nuclear Powerplant/Waste dump: - The ratepayers deserve to have more inexpensive ways to generate power. - Nuclear is inefficient both in short term and long term. - It is immoral to inflict deadly waste on the humans and environment for the next 240,000 years. - Siting a nuclear powerplant/waste dump on multiple earthquake faults is insanity. - Fukushima (0369-1 [Georgi, David])

Comment: In the case of Entergy's Pilgrim Nuclear Power Station (PNPS) in Plymouth, which is of special concern to we the undersigned, shutdowns and malfunctions have been so numerous that the NRC itself has flagged the plant for intensive oversight. Presently on-site storage in dry casks is the only solution, but it is only a relatively short-term fix for a problem requiring containment for hundreds of thousands of years. So far the design for the Interim Spent Fuel Storage Installation (ISFSI) is underfunded, and its location is vulnerable to sea level rise, flooding and terrorism. The casks would not be separated by protective berms although that would obviously lessen the impact of an aircraft attack. (0373-4 [O'Malley, Brian])

Comment: Residents in our region have already been forced to live with the unacceptable risks of a defacto high-level radioactive waste dump, with wastes stored in fuel pools made of substandard cement and liners that are corroding and thinning at rates up to 10 times higher than expected, and steel in casks that can corrode in as little as 4 to 52 weeks based on corrosives in the air from Limerick's cooling towers. (0377-1-2 [Cuthbert, Lewis])

Comment: Loss of cooling water or power for Limerick's fuel pools, or a terrorist attack could have long-term devastating impacts on the future environment and public health in the entire Greater Philadelphia Region. An accident or terrorist attack on massive amounts of the most deadly materials on earth stored in fuel pools at Limerick Nuclear Plant could render the entire Philadelphia Region uninhabitable for centuries, if not forever. (0377-3-10 [Cuthbert, Lewis])

Comment: THE LIMERICK EXAMPLE PROVIDES EVIDENCE TO SUPPORT THE NEED FOR IMMEDIATE REMOVAL OF WASTE IN FUEL POOLS: Limerick's Fuel Pools are OVERLOADED, far beyond the original design basis since at least 2006. Over an estimated 1,000 metric tons of these lethal wastes are vulnerable to fire from meltdowns or terrorist attack, potentially creating a disaster 100 times worse than Hiroshima (0377-3-11 [Cuthbert, Lewis])

Comment: Pools are filled with radioactive fluids that can boil away due to an accident, natural disaster, or terrorist attack, introducing large volumes of radiation into the air. Pools are vulnerable to a 9/11 type terrorist attack with a plane or missile. An attack on Limerick's fuel pools could result in an unstoppable radioactive fire, with potentially worse consequences than Chernobyl. That kind of attack could lead to an unstoppable radioactive fire which could impact people hundreds of miles away, according to an NRC study (2000). Pools are outside the reinforced containment structures for the reactors. (0377-3-12 [Cuthbert, Lewis])

Comment: Cement used to construct Limerick's fuel pools is documented to be substandard. NRC'S FAILURE TO REQUIRE EXELON TO IMMEDIATELY REMOVE ALL 5-YEAR OR OLDER WASTES FROM LIMERICK'S FUEL POOLS FASTER SHOULD BE CONSIDERED REGULATORY MALPRACTICE, ESPECIALLY AFTER WATCHING THE FUEL POOL DISASTER UNFOLDING AT FUKUSHIMA. NRC'S INACTION RELATED TO LIMERICK'S FUEL POOLS CONSTITUTES GROSS NEGLIGENCE. NRC IS AWARE OF LIMERICK'S FUEL POOL DESIGN FLAWS AND RISKS FOR CATASTROPHE. NRC knows Limerick's fuel pools are corroding and thinning at rates 2 to 10 times faster than originally estimated, yet NRC has allowed Exelon to wait for over a decade to even recoat the pools. NRC was informed by Limerick's safety inspector, that Limerick's fuel pools were poured with substandard cement, and why that should concern NRC related to earthquake risk at Limerick. NRC should also see why this increases the risk from a terrorist missile or plane strike. NRC knows Limerick is among the nation's nuclear plants most at risk from earthquakes with a fault right under the site and four others within 17 miles, and that alarms went off in the control room at Limerick from the 9-23-11 Virginia earthquake, and yet NRC is allowing Exelon to wait 3 years (until 2017) to even complete an earthquake risk study. NRC knows there is not enough water available to adequately deal with extended loss of water and potential meltdowns in Limerick's fuel pools. NRC knows there is not enough back-up power available on site, to simultaneously prevent meltdowns in Limerick's 2 reactors and 2 fuel pools. Knowing about unfixable design flaws at Limerick and watching the fuel pool disaster in Fukushima's similar fuel pool design. NRC is failing to require Exelon to build on-site casks faster at Limerick for removal from pools. NRC is planning to relicense Limerick, knowing each year Limerick operates tons more of this deadly waste will be produced and there is no safe way to deal with this lethal waste (0377-3-13 [Cuthbert, Lewis])

Comment: NRC Is Jeopardizing Our Future When Failing To Address Major Issues and Concerns Related to Limerick's Fuel Pools: 1. Corrosion and Thinning Documented in Limerick's Fuel Pool Liners at Rates up to 10 times Faster than Anticipated; 2. High-Level Radioactive Wastes Stored in Limerick's Fuel Pools Beyond Design Capacity; 3. Limerick Previous Accepting Waste From Other Nuclear Plants Permit Changed in 2012 Without A Hearing; 4. Structural Deficiencies in the Concrete of Limerick's Fuel Pools; 5. Limerick's Fuel Pools Are Similar to Those That Exploded at Fukushima High Above Reactors With NO Containment; 6. Inadequate Alternative Back-Up Power; 7. Fuel Pool Instrumentation; 8. Spent Fuel Pools Are At High Risk For Meltdowns From Loss of Cooling Water Due To: Earthquakes, Cracking, Aging, Brittle, Deteriorating, Substandard Cement, Leakage and Evaporation, Explosion Inside or Outside Pool Building, Terrorist Acts With Planes Or Missiles Fuel Pools Are Not Protected Against Air Strikes or Missiles, Aircraft or Missile Impact, Siphoning,

Pumping. 12 Accidental or Deliberate Drop of Fuel In Transfer See: Spent Fuel Pools Pose A Danger - Associated Press - March 17, 2011 (0377-3-15 [Cuthbert, Lewis])

Comment: The Following Detailed Summaries Reveal NRC's Gross Negligence, And The Need For NRC To Take Immediate Action To Reduce Risks. CORROSION and LOSS of THICKNESS in LIMERICK'S SPENT FUEL POOLS: NRC caved in to Exelon, ignoring NRC's own objections to Exelon's request to delay coating of Limerick's fuel pools. NRC plans to ignore documented cracking, corrosion, pitting, and cavitations in Limerick's fuel pools holding the most deadly materials on earth, related to relicensing approval. Limerick could be relicensed with no guarantee Exelon ever can or will coat or provide other protective measures on Limerick's fuel pools. NRC told Exelon that to delay coating the degraded fuel pool areas is unacceptable. NRC outlined "Substantial Corrosion" and loss of thickness issues in Limerick's fuel pool liners. (Documented in 7-20-12 NRC letter to Exelon). The documented corrosion rate is far higher than original corrosion rate calculations for fuel pools. Pitting corrosion rates are unpredictable (usually 2 to 10 times more than the general corrosion rates). In spite of cracking, corrosion, pitting, and cavitations in Limerick's fuel pools, documented by NRC: 1. Exelon requested deferring protective measures like coating until Limerick's current licenses expires (a delay of 12 to 17 years) 2. Exelon proposes inspection only every 10 years. GROSS NEGLIGENCE: NRC CAVED IN TO EXELON. NRC officials made the inexplicable decision to allow delayed coating of Limerick's fuel pools, despite NRC staff's conclusion that to delay coating fuel pools was unacceptable. Despite proven adverse impacts on the safety and integrity of Limerick's fuel pools and associated unprecedented threats to public health and safety, NRC revised regulations to accommodate Exelon's requests to delay coating Limerick's fuel pools. We believe it is negligent for NRC to assume Limerick's fuel pools will remain safe until Exelon agrees to re-coat them. Corrosion has already been documented at rates far faster than originally calculated. ACE asked NRC to provide the names and contact information for NRC officials who made this dangerous decision. To date: NO NRC RESPONSE (0377-3-16 [Cuthbert, Lewis])

Comment: ACE Asked NRC To Explain Why NRC Assumes Limerick's Fuel Pools Can Be Re-Coated. Explain the exact process in detail that Exelon would use to coat liners, now or in the future. Answer critical questions below: a. Won't all radioactive water and radioactive wastes need to be removed from fuel pools for repair and coating? -As long as Limerick continues to operate, 2 more tons each year of this deadly radioactive waste will need to be cooled in Limerick's fuel pools for at least 5 years -Limerick's fuel pools are already overloaded, far beyond design basis, with this waste that requires cooling for a minimum of five years, to avoid combustion resulting in a devastating radioactive fire; b. Where would the radioactive wastes currently stored in the pools go until pools are coated? That waste will still need to be cooled.; c. Where will the massive amount of radioactive water go when drained for recoating? To date: NO NRC RESPONSE to any questions above (0377-3-17 [Cuthbert, Lewis])

Comment: Additional ACE Questions - NO NRC RESPONSE: 1. Did anyone except Exelon ever inspect fuel pool liners for cracking, corrosion, pitting, and cavitations? 2. Were fuel pool liners ever inspected by NRC? 3. How does NRC justify inspection only every 10 years, when pitting corrosion rates have proven to be much greater than original rate calculations? (0377-3-18 [Cuthbert, Lewis])

Comment: With loss of cooling water, Limerick's fuel rods can heat up, self-ignite, and burn in an unstoppable fire, causing tens of thousands of deaths up to 500 miles away, according to a 2000 NRC study. Health and Financial Costs Would Be Astronomical: Limerick Nuclear Plant's Fuel Pools Are A Major Threat To Public Health, Safety, And The Economy In The Greater Philadelphia Region, The 2nd Most Populated Region Around A Nuclear Plant. (0377-3-7 [Cuthbert, Lewis])

Comment: Limerick's Fuel Rods Are At Risk For Loss Of Water And Fire: NRC failed to require Limerick to follow the safest fire safety regulations. NRC allowed Limerick to use a second set of less stringent standards, determined to be "safe enough". That constitutes regulatory negligence, given the potential consequences. Limerick's fuel pools are outside the containment and vulnerable to a 9/11 type terrorist attack and fire from jet fuel. Yet, NRC failed to require Exelon to guard against this type attack. There is not an ample water supply to avoid meltdowns in the fuel pools. The closest body of water available to try to deal with leaking fuel pools is dangerously depleted due to Limerick's cooling tower use over decades. (0377-3-8 [Cuthbert, Lewis])

Comment: The Fukushima catastrophe shows why fuel must be removed from pools as soon as possible, regardless of costs to the nuclear industry, especially in reactor designs like Limerick's, similar to Fukushima's. (0377-3-9 [Cuthbert, Lewis])

Comment: LIMERICK'S FUEL POOLS ARE PACKED, FAR BEYOND DESIGN BASIS, CONTAINING FAR MORE THAN FUKUSHIMA'S AND OLDER US NUKES: Limerick's Fuel Pools Contain Far More Assemblies Than Other U.S. Nuclear Plants, Including Exelon's Three Mile Island and Oyster Creek. Compared to Fukushima: More Than Twice As Much In 2 Limerick Fuel Pools Than 4 At Fukushima. 6,203 Assemblies -2 LIMERICK FUEL POOLS (Estimated Spent Fuel At Limerick 1,143 Tons) 2,400 Assemblies -4 FUKUSHIMA FUEL POOLS. Information Above From The Institute for Policy Studies by Bob Alvarez, "Spent Nuclear Fuel Pools in the U.S.: Reducing the Deadly Effects of Storage" Appendix A: Site Specific Estimates of Radioactivity in U.S. Spent Fuel Page 26 Source: DOE/EIS-0250, Appendix A, Tables A-7, A-8, A-9, & A-1 (0377-4-1 [Cuthbert, Lewis])

Comment: UNDENIABLE EVIDENCE ABOVE CONFIRMS WHY EXELON SHOULD BE REQUIRED TO IMMEDIATELY START TO BUILD ENOUGH CASKS, IN THE SAFEST WAY POSSIBLE, TO DRY-STORE ALL THE WASTES THAT CAN SAFELY BE REMOVED FROM LIMERICK'S FUEL POOLS UNTIL LIMERICK'S FUEL POOLS CAN BE EMPTIED, EXELON SHOULD BE REQUIRED TO GUARD AGAINST AIR AND MISSILE STRIKES. A TERRORIST ATTACK COULD TRIGGER MELTDOWNS IN LIMERICK'S FUEL POOLS, YET VULNERABLE LIMERICK FUEL POOLS ARE NOT PROTECTED FROM TERRORISTS' MISSILES OR AIR STRIKES. NRC REFUSED TO PROVIDE A RISK ASSESSMENT FOR TERRORISTS. ACE REPEATEDLY URGED NRC TO PROVIDE A RISK ASSESSMENT FOR TERRORIST ATTACKS ON CASKS. Limerick has the 2nd most densely populated region in the U.S. NRC was negligent in failing to provide a risk assessment for terrorist attacks related to above ground storage of high-level radioactive wastes at Limerick Nuclear Plant A Federal Court Ordered NRC To Assess Terrorist Threats In California. A 2006 U.S. Court of Appeals 9th Circuit decision forced NRC to assess the threat of a terrorist attack on above ground storage at the Diablo Canyon Nuclear Plant in California. Similar threats exist at Limerick Nuclear Plant. ACE Asked NRC To Consider The Same Threats As Were Required At Diablo Canyon: 1) The threat posed by a land-based vehicle bomb; 2) A ground assault with the use of an insider; 3) A water-borne assault; 4) A large aircraft impact similar in magnitude to the attacks of September 11, 2001. NRC inexplicably claimed an assessment was not necessary at Limerick, dismissing harmful health impacts from radiation exposure and irrationally claiming a significant release of radiation affecting the public is not reasonably expected to occur. Army testing suggests otherwise. NRC also ignored potential for rods overheating and combusting. Specific Issues Not Included For A Risk Assessment For Limerick's Updated EIS: 1) Limerick is not guarded against airplane or missile attacks; 2) Nuke waste housing can be penetrated by missiles (proven by army testing); 3) THREE AIRPORTS are too close to Limerick Nuclear Plant. Army testing proves missiles can penetrate casks. Pilots take lessons at Limerick Airport, only 1 mile away;

Helicopters fly into the Limerick Airport from which missiles could be launched; 4) An industrial railroad runs through the nuclear plant site. Industrial rail tracks run directly through the nuclear plant property, providing a way for terrorists to enter the site undetected; 5) A large portion of the site is bordered by the Schuylkill River, Limerick Nuclear Plant property is bordered by the Schuylkill River (over a long distance), presenting a difficult, if not impossible challenge, for too few guards.; 6) Too few guards have to cover Limerick's 600 acres; 7) Heavily populated region surrounds Limerick Nuclear Plant - Almost 8 Million people within 50 miles (**0377-4-11** [Cuthbert, Lewis])

Comment: How much of this deadly high-level radioactive waste will be stored in how many of these casks on the Limerick site by 2029? 2049? Limerick is using new high-burn fuel which impacts the outer covering of the fuel (**0377-4-13** [Cuthbert, Lewis])

Comment: TO AVOID RADIOACTIVE WASTE INTERNAL COMBUSTION AND FIRES INSIDE CASKS, NRC SHOULD STOP ALLOWING LIMERICK NUCLEAR PLANT TO REMOVE WASTES PRIOR TO THE FIVE YEARS IN POOLS CALLED FOR BY THE TECHNICAL SPECIFICATIONS OF THE CASK SYSTEM. •NRC is allowing risky removal of fuel rods to accommodate Exelon's profits. This is yet another example of NRC lowering safety protections at Limerick Nuclear Plant to accommodate Exelon's profits. Clearly Exelon wants to load casks more quickly to free space and make room for more. •Early removal is far too risky. The less cool down time in fuel pools, the thermally hotter and more radioactive the waste - the more risk of internal combustion and an unstoppable radioactive fire. •Even if older rods are wrapped around newer rods that have been cooling in pools less than five years (as we have been told is being done at Limerick), there is no proof that this deviation from the 5-year technical specification requirement will not lead to combustion and fire over time. Removing Limerick's Radioactive Rods Sooner Than The 5-Year Technical Specification Requirement Jeopardizes Workers' Health and Safety. •Since 2006, when Exelon first tried to convince the public that cask storage was safe, NRC and Exelon repeatedly stated 5 years was required to safely remove fuel rods from Limerick's fuel pools. •However, that 's not what is happening at Limerick since 2010. May 6, 2010 -Exelon Employee At A Limerick Open House Said: Older and newer "spent fuel rods" are removed from Limerick's fuel pools at the same time. Older rods are stored outside newer rods in assemblies (sometimes 1-year old). •This could have been going on since 2008. Limerick's Independent Fuel Storage Installation was placed in service starting July 21, 2008. NRC Deception Speaks Volumes: •Dry cask technical specifications state: Radiation shielding and thermal heat removal require around 5 YEARS, minimum, cool down time in the pool before transfer to dry casks. 1. Yet, June 16, 2006, NRC in a letter to ACE claimed 1 year storage in the fuel pool at Limerick was sufficient before removal for above ground storage. 2. July 13, 2006 at a meeting in Limerick NRC again clearly stated cool down time before removal from fuel pools was at least 5 years. 3. July 25, 2006 ACE received an e-mail from NRC: NRC inexplicably said cooling time in the pool is: 1 year or 3 years or 5 years. From: James Trapp - NRC Date: 07/25/06 07:04:34 NRC's Pamphlet Proves How Dangerous Nuclear Power Plant High-Level Radioactive Waste Is. 10 years after removal of spent fuel from a reactor: Radiation dose 1 meter away from a spent fuel assembly exceeds 20,000 Rems Per Hour; 5,000 Rems would be expected to cause immediate incapacitation and death within 1 week. Information From: NRC's own pamphlet NUREG/BR-0216, Rev.2 May 2002: Removing spent fuel rods from pools to load dry casks far sooner than the 5-year requirement is an extremely dangerous experiment that needs to be stopped at Limerick. While it frees space in pools for new wastes to make more money for Exelon, it presents unacceptable risks to workers and the public. Consider The Following: 211 Radioactive Poisons found in every 10-yr. old irradiated fuel bundle (Canadian Study); Polonium 210 Just 1 of 211 the type that poisoned Alexander Litvinenko in 2006 is an alpha emitter with the ability to become airborne. 1 Gram

could poison 100 million people - Extremely dangerous in milligrams or micrograms. Biological life in humans is 30 to 50 days; Targets organs - liver and spleen. Short-term exposure carries long-term risk of death from cancer. (0377-4-14 [Cuthbert, Lewis])

Comment: NRC PROVES CORROSION FROM LIMERICK'S COOLING TOWERS CORRODES STEEL AND CAUSES CRACKING IN 4 TO 52 WEEKS: June 12, 2012 RAI B.2.1.25-1.1 Stress Corrosion Cracking for stainless steel surfaces in an outdoor air environment in auxiliary and steam and power conversion systems. -LIMERICK'S NPDES PERMIT SAYS:16,000 TO 58,000 lbs per day of CHLORINE (sodium hypochlorite) are used at Limerick Nuclear plant. - Exelon told NRC even though CHLORINE is ADDED to COOLING TOWERS AS SODIUM HYPOCHLORITE, there is no concern (for stress corrosion cracking of stainless steel surfaces) because COOLING TOWER PLUME IS DIRECTED AWAY FROM THE PLANT. NRC Responses to Exelon: Studies and industry operating experience in chloride-containing environments have shown that stainless steel exposed to an outdoor air environment can crack at temperatures as low as 104 to 120 degrees F, depending on humidity, component surface temperature, and contaminant concentration and composition. Cracking can occur in 4 to 52 weeks. NRC cannot conclude recent inspections are sufficient to demonstrate an aging effect will not occur during the period of extended operation. A prevailing wind does not result in the absence of contaminant deposition by the cooling tower plume. Information has not been provided on the potential for chloride contamination from the onsite soil or nearby agriculture and industrial sources NRC lacks sufficient information to conclude that stress corrosion cracking cannot occur in stainless steel components located in an outdoor air environment. Corrosion can make it difficult, if not impossible, to move Limerick's extremely heavy casks. To date, there is no proof Limerick's radioactive fuel rods can be moved safely after years of exposure to corrosive air. (0377-4-17 [Cuthbert, Lewis])

Comment: NRC'S DENIAL AND NEGLIGENCE COULD EVENTUALLY LEAD TO DISASTER RELATED TO LIMERICK'S CASKS: NRC admits there were fabrication deficiencies in materials used for Limerick's canisters and concrete, but refuses to call them flaws, and claims they were corrected, even though that may not be entirely accurate. While the company was fined a nominal amount, in years to come, we could find cask design flaws could lead to a radioactive disaster. July, 2006 Areva, the company making Limerick casks, received a Notice of Violation, documenting specific problems with casks already in place, yet NRC allowed casks for Limerick to continue to be built by this company. November, 2006 in a whistle blower letter it was revealed that there were specific concerns about casks planned to be used at Limerick. In an 11/06 letter to ACE, both NRC and Transnuclear (Areva) admitted there would be corrosion and settling of ground beneath 40 ton casks, yet NRC failed to require air testing in the vicinity of casks for corrosives against metals being used for casks (0377-4-18 [Cuthbert, Lewis])

Comment: REGULATORY NEGLIGENCE: NRC'S 2005 STUDY FOUND PROBLEMS WITH CORROSION RATES OF METALS USED TO STORE NUCLEAR WASTE, YET NRC STOPPED THE RESEARCH INSTEAD OF ADDRESSING THE CORROSIVE STEEL. 2006 Testimony to Congress by Public Citizen - Provided evidence of scientific misconduct by NRC and DOE related to corrosion rates of metals used to store nuclear wastes -In 2005 NRC found problems with the corrosion rates of metals used to store nuclear waste, yet failed to address the corrosion problems -Research identifying corrosion problems was stopped, not the use of steel that would corrode. 2006 NRC dismissed important evidence identified by ACE related to corrosion of steel planned to hold Limerick's high level radioactive wastes in above ground casks -Every day Limerick adds massive amounts of toxic chemicals to cooling tower waters - MSDS sheets identify 10 of them to be corrosive, some highly corrosive and some specifically corrosive to steel -There is NO FILTRATION to prevent corrosive chemicals from entering the

air from cooling tower steam -Synergistic combinations of the corrosive additives can result in a serious corrosive threat to people and everything exposed to the drift from the cooling towers (44 million gallons every day), including steel holding deadly radioactive wastes stored inside casks that require cooling with outdoor air -Corrosive air enters casks holding high-level radioactive waste rods stored in steel -NRC admits corrosion will happen, yet dismissed ACE concerns without site-specific testing of cooling tower emissions for specific and conversion corrosives -NRC's dismissive, misleading, and irresponsible conclusions defy logic. They can lead to irreparable disaster in our region (0377-4-19 [Cuthbert, Lewis])

Comment: TO DATE: NRC FAILED TO ANSWER THE FOLLOWING QUESTIONS. WHY DO LIMERICK'S FUEL POOLS CONTAIN SO MANY MORE FUEL ASSEMBLIES THAN OTHER NUCLEAR PLANTS OPERATING LONGER? Did Limerick ever take spent fuel from other nuclear plants? Did Limerick ever take spent fuel from Three Mile Island after the partial meltdown? NRC's 5-18-12 written response to ACE about quantity of fuel used at Limerick was puzzling. "Exact amounts of 'special nuclear material' in a licensee's possession is considered to be security sensitive information and not permitted to be released to the public." 1. We believe the public has a right to know how much waste is at Limerick and where it came from. 2. Approximately 2 tons produced each year for the 28 years Limerick operated should be 56 tons, NOT 1,143 tons. Explain in detail. Why is there so much more from two Limerick reactors than 4 Fukushima reactors? 3. Even if it is 2 tons per reactor per year, the amount stored in Limerick's pools should only be 106 Tons, NOT 1,143 Tons. This discrepancy needs to be fully understood by the public. If the amount of waste used per reactor each year can be estimated, there is NO LOGICAL REASON NRC should refuse to provide the public with approximate totals. Anyone should be able to do the math, including terrorists and NRC. NRC's response made us wonder what is really going on. Did Limerick's Operating License Amended 12-19-11 Allow Limerick To Receive and Possess Spent Fuel Rods From Other Nuclear Plants? YES OR NO. Limerick's Operating License Permit Was Amended (12-19-11). Language Included To Allow Limerick to Receive and Possess Fuel Assemblies and Fuel Channels From Other Nuclear Plants, Such As That Already Received From Shoreham Decades Earlier. Exact language (Below) Is From Limerick's Amended Operating Permit 12-19-11: UNITED STATES NUCLEAR REGULATORY COMMISSION WASHINGTON, D.C. 20555-00; EXELON GENERATION COMPANY, LLC DOCKET NO. 50-353 LIMERICK GENERATING STATION, UNIT 2 AMENDMENT TO FACILITY OPERATING LICENSE Amendment No. 167 License No. NPF-85 Page 3; (4) Pursuant to the Act and 10 CFR Parts 30, 40, 70, to receive, possess, and use in amounts as required any byproduct, source or special nuclear material without restriction to chemical or physical form, for sample analysis or instrument calibration or associated with radioactive apparatus or components; and (5) Pursuant to the Act and 10 CFR Parts 30, 40 and 70, to possess, but not separate, such byproduct and special nuclear materials as may be produced by the operation of the facility, and to receive and possess, but not separate, such source, byproduct, and special nuclear materials as contained in the fuel assemblies and fuel channels from the Shoreham Nuclear Power Station. (0377-4-2 [Cuthbert, Lewis])

Comment: DID NRC ALLOW LIMERICK TO ACCEPT HIGH-LEVEL RADIOACTIVE WASTES FROM OTHER NUCLEAR PLANTS DECADES AGO, BUT JUST CHANGE LIMERICK'S OPERATING PERMIT TO ALLOW THAT 12-19-11? 14. ACE Requested Detailed Explanations From NRC, But Didn't Even Receive A Response To The Following Questions: 1. Why Would Limerick Have Its Operating License Amended In 2011 To Receive and Possess Radioactive Waste From Other Nuclear Plants, When Limerick Already Received These Wastes From Shoreham and Possibly TMI? 2. Did receipt and possession of Shoreham's waste violate Limerick's original operating permit? 3. When Limerick received waste from Shoreham decades ago, wasn't that in violation of Limerick's operating permit? 4. This Is A Major Permit Change,

Which Adds Dramatically to The Risk In Our Entire Region and the Transportation Route. Why Wasn't The Public Widely Informed With An Opportunity To Comment and Have A Public Hearing? (0377-4-3 [Cuthbert, Lewis])

Comment: How long will it take Exelon to remove most of Limerick's deadly wastes from dangerous fuel pools and store it in above ground casks? STRUCTURALLY SUBSTANDARD CEMENT IN LIMERICK'S FUEL POOLS. Defective concrete in Limerick's fuel pools could have serious adverse effects on the structural adequacy to prevent leaks and meltdowns triggered by an earthquake or a terrorist attack with a plane or missile. NRC's 5-12 response to ACE acknowledges the structural defect from the concrete pour of Limerick's fuel pools, but refers to a decades old unsubstantiated NRC "assumption" that it would have no adverse effect on the structural adequacy. NRC'S "ASSUMPTION" IS FAULTY AND UNSUBSTANTIATED. NRC's "assumption" was indefensible from the beginning, but it's worse now, with increasing threats from earthquakes and terrorist attacks with planes or missiles on the stories high fuel pools. We remind NRC that if Limerick's fuel pools suffer cracks and cooling water starts to leak, it can be the beginning of a catastrophic disaster. (0377-4-4 [Cuthbert, Lewis])

Comment: INADEQUATE FUEL POOL INSTRUMENTATION TO DETECT LOSS OF WATER TO PREVENT MELTDOWNS. March, 2012, Older reactors with General Electric Co (GE) design containment structures like Limerick's (similar to those that failed at Fukushima) were ordered by NRC to have sturdier venting systems to prevent damage to reactor cores. NRC rules required Exelon to install new, more reliable instrumentation at Limerick, to measure Limerick's spent fuel cooling pools - no later than within 2 refueling cycles. Exelon was given 60 days to respond. Limerick's spent fuel instrumentation may only be capable of monitoring under normal conditions. -Spent fuel pools rely on maintenance of an adequate inventory of water under accident conditions to provide containment to prevent meltdowns, as well as for cooling and shielding -Emergency responders need reliable information on water in spent fuel pools to prioritize emergency actions -At Fukushima responders were without reliable instrumentation to determine water level in the spent fuel pool -This caused concerns that the pool may have boiled dry, resulting in fuel damage. Fukushima demonstrated confusion and misapplication of resources that can result from inadequate instrumentation. Exelon's response was due by May 12, 2012. Orders were issued by NRC August 30, 2012. ACE ASKED IF HAS EXELON REPLACED LIMERICK'S FUEL POOL LEVEL INSTRUMENTATION. IF SO, WHEN? IF NOT, WHY NOT? (To Date: NO NRC RESPONSE) (0377-4-5 [Cuthbert, Lewis])

Comment: There is an earthquake fault under the Limerick site, with four others within 17 miles of the site. Still, NRC gave Exelon until 2017 to deal with earthquake risks at Limerick To date: NO Responses from NRC to ACE concerns below. What exactly will Exelon do to reduce threats of cracking of brittle cement in Limerick's fuel pools? Given the consequences, whatever can be done should be required immediately. Why would NRC allow Exelon to wait until 2017 to complete a study, when the 8-23-11 Virginia earthquake felt in Limerick's control room shows it is far too risky to wait? (0377-4-7 [Cuthbert, Lewis])

Comment: Summary: Large volumes of Limerick's high-level radioactive wastes produced since 1985, are among the most deadly materials on earth and are being stored in fuel pools and casks on the Limerick site. Limerick has become a defacto radioactive waste dump that will remain dangerous virtually forever. (EPA gave storage for high-level radioactive waste a million-year health standard). As long as Limerick operates, tons more of this deadly waste will be produced each year. Limerick's Spent Fuel Pools Are Packed Beyond Design Basis, And Vulnerable. Limerick's Spent Fuel Pools Are At High Risk From Loss of Cooling Water Through Leaks Due To The Many Valid Threats Identified. Release of Radiation From Limerick's Fuel

Pools Could Render The Entire Greater Philadelphia Region Uninhabitable For Generations
(0377-4-8 [Cuthbert, Lewis])

Comment: How much of this deadly waste will be sitting in our back yard by 2029 when Limerick's current license expires? Or 2049 if Limerick's license is extended? (0377-5-3 [Cuthbert, Lewis])

Comment: NRC MUST PROVIDE IMPROVED REGULATIONS AND OVERSIGHT FOR DRY STORAGE. Limerick's dangerous and deadly radioactive wastes will likely remain in our backyard forever, posing serious threats to us and future generations. Containers holding these deadly wastes are estimated to safely contain the waste for only 50 years, when the wastes remain deadly for hundreds of thousands of years. (0377-5-4 [Cuthbert, Lewis])

Comment: EACH YEAR LIMERICK OPERATES MANY TONS MORE OF LIMERICK'S DEADLY HIGH-LEVEL RADIOACTIVE WASTES WILL BE PRODUCED. VOLUMES MORE WILL INCREASE RISK IF LIMERICK IS RELICENSED (0377-5-9 [Cuthbert, Lewis])

Comment: I am a close neighbor to the Diablo Nuclear Power Plant located near Avila Beach California. I am very pleased with the work that has been done at the site. It is an operation that makes perfect sense, producing much needed power for the PG&E grid. (0382-1 [Tognazzini, Randall])

Comment: I am writing today to urge the New York State Department of State to object to Entergy's unfounded certification that a proposed 20 year license extension for its Indian Point nuclear power plant is consistent with NYS's Coastal Management Program and enforceable NYS coastal zone policies. Indian Point is an outdated, unsafe, and environmentally destructive nuclear plant, which inflicts severe and unnecessary impacts to the ecologically significant coastal resources of NYS. If Indian Point operates for an additional 20 years, it will continue to devastate, as well as pose an incredible risk to, NYS coastal areas. I encourage you to carefully consider the numerous ways in which the continued operation of Indian Point would be inconsistent with various of NYS's coastal policies, including, but not limited to, the following: -- Policy 7: The protection, preservation, and restoration of significant coastal fish and wildlife habitats: Indian Point's antiquated cooling water intake structure, located in the vicinity of the designated significant fish and wildlife habitat of Haverstraw Bay, slaughters millions of aquatic organisms in Hudson River every year. Decades of such devastation has contributed to the decline of 10 out of 13 key species in the river. If Entergy were to continue running the plant the way they want to, it would result in ongoing impacts, and clearly not in the protection, preservation, and restoration of significant coastal fish and wildlife habitats. -- Policy 8: The protection of fish and wildlife resources from hazardous wastes and pollution: 1,500+ tons of "spent" nuclear waste from Indian Point currently sit on the banks of the Hudson River. Should Indian Point continue to operate, the plant will generate approximately 1,000 additional tons of waste to also be stored at the site. This waste, which is largely in tightly packed, degraded, leaking, and highly radioactive waste storage pools, poses an exceptional risk of accident and attendant large scale release of radiation to the surrounding coastal area, and demonstrably not in the protection of NYS coastal resources from hazardous pollutants. -- Policies 9 & 19: Protection and expansion of recreational uses of and access to coastal resources: Historic and rampant radiological leaks from spent fuel pools, buried pipes, and other structures at Indian Point since the 1990s have resulted in extensive plumes of contamination underlying the site. These plumes include highly toxic radionuclides that are known to bioaccumulate in aquatic organisms and interfere with human health. Entergy's solution? Let the plumes leach into the Hudson River. This has been happening for years and will continue for decades, especially as

the plant continues aging, breaking down, and leaking additional radioactivity to the environment. Entergy's complacency completely fails to assure the protection of NYS coastal resources for recreational activities, such as fishing and swimming. The proposed continued operation of Indian Point violates letter and intent of these, as well as other, NYS coastal policies. I, thus, urge you to ensure that Indian Point is disallowed to continue operating at the expense of NYS coastal resources by strongly objecting to Entergy's entirely unjustified coastal consistency certification. (0395-1 [DeCrescenzo, Jocelyn])

Comment: I am writing today to urge the New York State Department of State to object to Entergy's unfounded certification that a proposed 20 year license extension for its Indian Point nuclear power plant is consistent with NYS's Coastal Management Program and enforceable NYS coastal zone policies. I, thus, urge you to ensure that Indian Point is disallowed to continue operating at the expense of NYS coastal resources by strongly objecting to Entergy's entirely unjustified coastal consistency certification. (0397-1 [Stadnik, George])

Comment: We in Illinois don't want high-level radioactive waste being stored in Illinois or being transported through our state. The idea of creating storage in Illinois for 9000 tones of spent fuel from the nation's closed reactors makes no sense given the proximity of the City of Chicago and Lake Michigan, America's major source of drinking water. In fact, nuclear reactors need additional large amount of water to cool the reactors when they are running. This is a huge waste of our drinking water that is already threatened by droughts and chemical/radioactive contamination from fracturing operations throughout America. Close them down now. (0406-5 [Gerleman, Douglas])

Comment: Regarding the New York versus NRC case, please rule to shut down Indian Point so that no more highly radioactive waste continues to be produced in the tri-state area (just 35 miles from Midtown Manhattan in New York State and less than 15 miles from parts of New York City's drinking water supply) where approximately 6% of the population of the United States lives and works. (0407-1 [Kerr, Mary Ellen])

Comment: The security and health issues of storing highly radioactive spent nuclear fuel stored in an unprotected and unhardened industrial building is too high risk to 20 million people living and working in the New York, New Jersey and Connecticut areas. Note that current and former security guards of Indian Point indicated disturbing details about security at the plants which is potentially deadly. If there is an accident or terrorist attack involving this enormously

dangerous toxic waste dump, there no possible way to evacuate people within a 50 mile radius of the waste dump (note that 50 mile radius evacuation is what the NRC recommended in the case of the Fukushima disaster). Beyond the terrible health and property damage to the people living and working in the tri-state area, it would also cause terrible impacts to the world economy since it is the financial capital of the world. A 2004 study by the Union of Concerned Scientists, indicated that a "hypothetical terrorist attack" at Indian Point could kill 44,000 people in the short term and another 500,000 over the long term. The cost of such a disaster would be about \$2 trillion. In today's dollars, I expect that cost to be higher. Currently, the Indian Point waste dump leaks toxic radioactivity such as tritium and strontium-90 into the Hudson River and into the ground water around the aging Indian Point nuclear power plants which has been an on-going problem since at least the 1990s and it has not been fixed. (0407-2 [Kerr, Mary Ellen])

Comment: PG&E has proven that they are very good at public relations. However, accidents like San Bruno leave me to wonder how careful they are. No matter, PG&E believes that the ratepayers should pay for their mistakes rather than their CEOs or shareholders. It is pretty hard to trust them, and we are within a few miles of a radiation producing plant that could have problems at any moment. (0413-2 [Palaia, Joyce])

Comment: U.S. nuclear waste regulators and stakeholders currently are waiting on the sidelines as Canada inches closer to approval of their Deep Geological Repository in the next few months. The entrance to this radioactive repository would be less than one-half mile from Lake Huron and the possibility of radioactive contamination of Lake Huron and other waters downstream including Lake Erie, Lake Ontario and the St. Lawrence River are frightening. In Kincardine, Ontario approximately 8000 voters approved to host such a facility, you call it "voluntaristic siting"... but...the definition of "community" for this planned burial requires the engagement and acceptance of 40 million other people who live, work, play, eat and drink from the Great Lakes. Consent-Based-Siting in this instance is...a failure...SITTING on an international body of FRESH water, the LARGEST in the world. My hometown of Port Clinton, Ohio is the third Ohio city to pass a resolution opposing radioactive waste burial in the Great Lakes watershed. The Lake Erie Caucus of the House of Ohio State Representatives will also be writing a resolution, joining Michigan in opposing the Canadian Nuclear Waste Repository. (0421-4 [Clemons, Victoria])

Comment: As you explore options for the plant in Avila, on the Pacific Ocean, near a large population, in an earthquake zone, with a storehouse of waste, I ask you to protect us and our beautiful environment. Don't allow this dangerous game to continue. (0434-1 [Malone, Patricia])

Comment: Arizona already has a problem with radiation contamination. One only needs to walk through parts of the Navajo Nation where uranium and yellow dust are out in the open, on the ground where people and animals are easily in contact. Winds also spread the contamination. (0435-1 [Coor, Kristen])

Comment: TODAY, ONE OF THE TOXIC WASTE POOLS LOST A LEVY ON ONE SIDE AND EMPTIES MANY MILLIONS OF GALLONS OF HIGHLY TOXIC WASTE INTO THE ATHEABASKA RIVER IN ALBERTA. THIS WAS FROM A COAL MINE. IMAGINE IF IT HAD BEEN THE TYPE OF TOXINS THAT ARE USED IN BREAKING DOWN THE TAR SANDS AND/OR FRACKING. ALREADY THE LARGE RIVERS IN ALBERTA ARE AT A SERIOUS POINT AND CANNOT BE USED TO DRINK OR WATER CATTLE. THE FISH ARE DYING AND THE RIVERS ARE BECOMING 'DEAD ZONES'. AND THE PEOPLE IN THE REGION AND ESPECIALLY THOSE WHO LIVE ALONG THE VERY LONG RIVERS WHERE THE KEYSTONE/KEARL PROJECTS ARE SPILLING THEIR TOXIC WASTES, ARE HAVING

WHOLE FAMILIES SICK AND DYING FROM LIVER CANCERS, THROAT CANCERS, NOT TO MENTION THE INFANTS AND CHILDREN WHO ARE USED TO SWIMMING IN THESE ONCE PRISTINE WATERS BUT MUST NOT DO SO AGAIN. (0442-1 [Butler, Dee])

Comment: A factor to consider is that the damaged spent fuel pool inventories at Fukushima were far less than exist at almost all of the USA nuclear power reactor spent fuel pools. As an example, the Vermont Yankee BWR reactor spent fuel pool holds about 100 million Curies, three times the amount of spent fuel that was in the damaged pool of Fukushima Dai-Ichi Unit 4. And the Millstone units 1, 2 and 3 have more than 400 million Curies of spent fuel in storage. Clearly this disaster should be a wake up call to NRC of the potential disasters in waiting in the USA. (0447-1-18 [Andrews, Richard])

Comment: PGE's record of untruths and profit over safety mandates distrust. (0450-6 [Bast, Nancy])

Comment: CLOSE DIABLO CANYON NUCLEAR POWER PLANT. You are playing Russian Roulette with our lives and other living beings. It must be a terrifying responsibility. (0450-8 [Bast, Nancy])

Comment: I don't want the nuclear waste from San Onofre to be stored near me. I live in Santa Monica. Please close this down. (0469-1 [Joslyn, Celia])

Comment: Indian Point is environmentally destructive and runs afoul of various coastal policies, Entergy should not get a coastal consistency certification because of: a) The rampant and ongoing radioactive leaks from Indian Point that indisputably release to the Hudson River and will continue to do so for decades; (0476-1 [Amram, David] [Geist, Sheila])

Comment: Indian Point is environmentally destructive and runs afoul of various coastal policies, Entergy should not get a coastal consistency certification because of: b) The safety risks of storing thousands of tons of highly radioactive nuclear waste for decades, if not centuries, overly crowded leaking spent fuel pools and temporary dry cask storage structures; (0476-2 [Amram, David] [Geist, Sheila])

Comment: Indian Point is environmentally destructive and runs afoul of various coastal policies, Entergy should not get a coastal consistency certification because of: c) The 1.2 billion fish and other aquatic organisms killed annually by Indian Point's one-through-cooling water intake system, and the devastating impacts on the aquatic biota of nearby State and Federally designated Significant Coastal Fish and Wildlife Habitat in Haverstraw Bay. (0476-3 [Amram, David] [Geist, Sheila])

Comment: How is it possible that San Onofre power station will be used for a nuclear waste dump when we don't even know how much radiation was being released when it was fully operational? (0478-2 [Higgins, Kevin])

Comment: Spent fuel at San Onofre must be removed to MRS immediately. A waste policy for all nuclear plants must include looking at each individually. Nuclear waste is not like other dangers. A probability curve is crazy. Japan knew they should be safe until the not probable happened. San Onofre is in danger everyday due to firestorm from regular seasonal high winds, due to earthquake, tsunami, rising ocean levels, and terrorist attack. We are not a remote nuclear location. 8.4 million people will have to be relocated. (0481-1 [Magda, Marni])

Comment: Please do not continue to store nuclear waste at San Onofre. Please find an alternative. (0482-1 [Butler, Ruth])

Comment: SHOULD NUCLEAR WASTE BE STORED AT AT SAN ONOFRE FOREVER? I say no. (0487-1 [Giese, Mark M.])

Comment: First, if the US NRC is seriously concerned about the health and safety of the citizens living on the Central Coast of California, the NRC should (1) immediately suspend the operating license of the Diablo Canyon nuclear plant until it is brought into compliance with NRC safety regulations regarding earthquake threats; and (2) immediately move all of the nuclear fuel stored in spent fuel pools to an off-site location, not vulnerable to earthquake and tsunami risks, and subsequently transfer them to dry cask storage as soon as possible. (0501-1 [Brown, Jerry])

Comment: A recent report by the prestigious Union of Concerned Scientists, titled "Seismic Shift: Diablo Canyon Literally and Figuratively on Shaky Ground," found that "in the case of Diablo Canyon, the NRC is ignoring its regulations, unfairly exposing millions of Americans to undue risk." This is because Diablo Canyon, even after significant seismic upgrades in the 1980s, is not designed to meet current NRC safety regulations, given the unique, level of multiple, known earthquake threats surrounding the plant, including the Hosgri and Shoreline faults -- and given that, over the 40 year life of the plant, the chance that a large earthquake will occur at Diablo Canyon in any one year is about 1 in 6. One in six! This means that the NRC is playing radioactive roulette with the lives and livelihood of the people and businesses on the Central Coast of California. (0501-4 [Brown, Jerry])

Comment: That plant [Oyster Creek] never should have been built where it was and because it is the oldest in the nation, it was and is maintained at the lowest of all safety standards. To that, this area was hit by Storm Sandy last year and that plant wasn't even built to withstand a hurricane. The entire place needs to be leveled and cleaned up permanently. Manhattan would be the ultimate receiver of a disaster here because for most of the year the wind blows from the south and south west. (0510-2 [Holmes, Helen])

Comment: 6. Do not allow the storage of nuclear waste in Texas, which could impact the Oglalla Aquifer. (0515-11 [Stennes, Nancy])

Comment: We are, of course, particularly interested in issues regarding spent nuclear fuel now stored in our county at the Diablo Canyon Power Plant (DCPP) (0548-1 [Gibson, Bruce])

Comment: Our comments are informed by the location of the Diablo Canyon Power Plant in our county. This facility is sited in a tectonically-active region of the Pacific Coast and thus potentially subject to significant ground shaking from large-magnitude earthquakes. (0548-11 [Gibson, Bruce])

Comment: In the aftermath of the Fukushima disaster, our Board has considered a number of issues regarding DCPP, a facility that has long had major impacts on San Luis Obispo County. DCPP is a major component of our local economy and generates considerable tax revenue supporting both our schools and local government. At the same time, this nuclear power plant is sited in a tectonically active area and subject to considerable risk from earthquake ground motion. As you know, the earthquake risk to the plant in general is under active study through a process convened by the California Public Utilities Commission. (0548-5 [Gibson, Bruce])

Comment: The storage of spent fuel at DCPD is an ongoing concern for us. In particular, spent fuel pools are potentially vulnerable to natural disasters, human-caused accidents, and sabotage. The spent fuel pools at DCPD have also been reconfigured, and now contain more than twice the number of fuel assemblies that they were originally designed to hold. While we are assured by PG&E that risks of this configuration are completely mitigated, but we believe this issue is worthy of extensive review. (0548-6 [Gibson, Bruce])

Comment: Fermi 2 has an over crowded fuel pool with 600 tons of spent fuel. It is the largest GE Mark 1 reactor. It is at risk for weather events, loss of coolant, or terrorist attack. Like Dai-ichi reactors and all 23 GE Mark 1 reactors in the U.S., it's cooling pool does not have back up cooling. It has no diesel generators for cooling pool water circulation to rely on in loss of electrical grid emergency. There are 1,331 highly radioactive irradiated spent nuclear fuel assemblies in Fukushima Daiichi Unit 4's storage pool. Fermi 2's high-level radioactive waste storage pool contained 2,898 irradiated nuclear fuel assemblies by spring 2010, according to U.S. Department of Energy projections documented in the Yucca Mountain Final Environmental Impact Statement (Feb. 2002, Table A-7, Proposed Action spent nuclear fuel inventory). Fermi 2 could generate another 443 irradiated nuclear fuel assemblies between spring 2010 and spring 2014, meaning by next spring, a total of $2,898 + 443 = 3,341$ irradiated nuclear fuel assemblies. So, by next spring, Fermi 2's storage pool could hold 2.5 times as much high-level radioactive withdrawn fuel rods than Fukushima Daiichi Unit 4's pool! (0552-2-13 [Macks, Vic])

Comment: Building the proposed Fermi 3, and its high-level radioactive waste storage pool, right next to Fermi 2, and its high-level radioactive waste storage pool, is akin to the multi-unit Fukushima Daiichi site, where the meltdown and hydrogen gas generation at Unit 3 contributed directly to the explosion at Unit 4 which now imperils the Unit 4 high-level radioactive waste storage pool. Thus, Fermi 3's combined Construction and Operations License Application (COLA) should be rejected by NRC. So should Fermi 2's bid for a 20-year license extension, which Detroit Edison is poised to apply for next year. (NRC has rubberstamped 73 of 73 reactor 20-year license extensions applied for across the U.S. thus far!) The risks, and inevitable environmental impacts over time, of the high-level radioactive wastes that would be generated at Fermi 3, and at Fermi 2 during a 20-year license extension, are just too great, and therefore should be deemed unacceptable under the National Environmental Policy Act. (0552-2-14 [Macks, Vic])

Comment: NUCLEAR NEAR-MISSES IN 2012 THAT PUT AT RISK THE REACTORS AS WELL AS ONSITE STORED HIGHLY RADIOACTIVE SPENT FUEL: Reactor & Location; Owner; Highlights: SIT=10x increase in risk of reactor core damage, AIT=100x increase in risk of reactor core damage. Brunswick Steam Electric Plant, Unit 2, Southport, NC, Progress Energy: SIT: Excessive leakage of cooling water from the reactor vessel, determined to have been caused by the improper installation of the reactor vessel's head, led to an emergency being declared and the reactor being shut down. Byron Station, Unit 2, Byron, IL, Exelon Generation Co., LLC: SIT: Equipment failure in the switchyard triggered an automatic shut-down of the reactor. A design deficiency caused emergency equipment to be de-energized until workers took steps to isolate the problem and restore power from the emergency diesel generators. Catawba Nuclear Station, Unit 1, York, SC, Duke Energy Corp.: SIT: After an age-related problem caused one of four reactor coolant pumps to fail, the Unit 1 reactor and turbine automatically shut down as designed. Due to a design error in a recent modification, the decreasing voltage output by the main generator caused electrical breakers to open that disconnected Units 1 and 2 from the offsite power grid. One of the emergency diesel generators started but failed to supply electricity to safety equipment due to another design error when it was installed in 1984. Farley Nuclear Plant, Units 1 and 2, Dothan, AL, Southern Nuclear

Operating Company, Inc.: SIT: Security problems prompted the NRC to conduct a special inspection. Details of the problems, their causes, and their fixes are not publicly available. Fort Calhoun Station, Omaha, NE, Omaha Public Power District: SIT: The NRC investigated a fire that disabled half of the 4160 volt and two-thirds of the 480 volt power supplies for emergency equipment at the plant and triggered the declaration of an Alert-the third most serious of the NRC's four emergency classifications. Fort Calhoun Station, Omaha, NE, Omaha Public Power District: SIT: Security problems prompted the NRC to conduct a special inspection. Details of the problems, their causes, and their fixes are not publicly available. (0552-3-1 [Macks, Vic])

Comment: NUCLEAR NEAR-MISSES IN 2012 THAT PUT AT RISK THE REACTORS AS WELL AS ONSITE STORED HIGHLY RADIOACTIVE SPENT FUEL: Reactor & Location; Owner; Highlights: SIT=10x increase in risk of reactor core damage, AIT=100x increase in risk of reactor core damage. Harris Nuclear Power Plant, Raleigh, NC, Progress Energy: SIT: As the reactor was being shut down for a scheduled refueling outage, workers tested the closing time of the three main steam isolation valves. These valves are designed to close within five seconds during an accident to limit the amount of radioactivity released to the atmosphere. The NRC dispatched an SIT after it took one valve 37 minutes to close and another 4 hours and 7 minutes. Palisades Nuclear Plant, South Haven, MI, Entergy Nuclear Operations, Inc.: SIT: Workers shut down the reactor about a month after they detected a small cooling water leak. The NRC sent an SIT to the site after the source of the leak was determined to be a location where any leakage required the plant to be shut down within six hours. Palo Verde Nuclear Generating Station, Units 1, 2, and 3, Wintersburg, AZ, Arizona Public Service Company: SIT: Security problems prompted the NRC to conduct a special inspection. Details of the problems, their causes, and their fixes are not publicly available. Perry Nuclear Power Plant, Perry, OH, FirstEnergy Nuclear Operating Company: SIT: Security problems involving failures to prevent unauthorized individuals from entering secure areas of the plant prompted the NRC to conduct a special inspection. River Bend Station, St. Francisville, LA, Entergy Operations, Inc.: AIT: The operators manually shut down the reactor on May 24 after an electrical fault on the motor of a feedwater pump caused it to stop running. A failed relay prevented the electrical breaker for the motor from opening to isolate the electrical fault. The fault propagated through the electrical distribution system, causing the breaker supplying power to the 13,800 volt electrical bus to open. Due to another electrical cable problem on May 21, all of the plant's circulating water pumps and non-emergency cooling water pumps were being powered from this single electrical bus. Its loss caused the plant's normal heat sink to be lost and stopped the supply of cooling water to equipment in the turbine building and to some emergency equipment. San Onofre Nuclear Generating Station, Units 2 and 3, San Clemente, CA, Southern California Edison Company: AIT: Operators shut down the Unit 3 reactor following a leak inside a steam generator replaced less than a year earlier. The NRC dispatched an AIT after eight steam generators tubes failed pressure testing and inspections identified extensive and unusual degradation in the steam generators of both units. Wolf Creek Generating Station, Burlington, KS, Wolf Creek Nuclear Operating Corporation: SIT: Erratic performance of an emergency diesel generator during a routine test prompted the NRC's special inspection. The SIT determined that an improper fix to another problem four months earlier impaired the emergency diesel generator's control system. Wolf Creek Generating Station, Burlington, KS, Wolf Creek Nuclear Operating Corporation: AIT: After one electrical fault in the switchyard caused the main generator to shut down automatically, a second electrical fault disconnected the plant from its offsite electrical grid. (0552-3-2 [Macks, Vic])

Comment: I would like to submit a public comment pertaining to the thousands of fuel assemblies now in wet storage at the Pilgrim Nuclear Power Plant in Plymouth, MA, facility. Please note I am the author of *Fukushima Daiichi:Nuclear Information Handbook* (380 pages),

which contains a lot of information about the similarity of the design of the spent fuel pools at Fukushima and at Plymouth. This text is available for purchase on amazon.com. I would like to make the following comments: Reactor operations at Plymouth should be stopped as soon as possible due to the extreme hazard the plant, and especially its spent fuel pool, poses to public safety. The Plymouth plant shares the same "subprime real estate" design as the Fukushima plant. My first choice for storage of Plymouth-derived spent fuel wastes would be at the Yucca Mountain facility in Nevada. Since that will not be built in the foreseeable future, the next safest alternative would be onsite dry cask storage similar to that now used at Wiscasset, Maine for the fuel assemblies of the decommissioned Maine Yankee Atomic Power Plant facility. I would also like to note that opposition to any dry cask storage facility by well-meaning environmentalists often results in what I have called in my publications, the "least safe storage" of fuel assemblies, i.e. as now typified by the storage of the fuel assemblies at the Plymouth plant. As of 2002, there were 2274 assemblies at Plymouth (see pg. 111 of Fukushima Daiichi: Nuclear Information Handbook). Currently the number now exceeds 3,000. Comments on safe alternatives to dry cask storage would be welcomed. (0554-1 [Brack, H.G.]

Comment: Diablo Canyon, 250 miles to the north of SanO, is even more dangerous than SanO: Its freshest spent fuel is dozens of times more radioactive than anything at San Onofre -- now that SanO has been shut for nearly 2 years. And the fuel that's still inside DC's reactors is thousands of times more radioactive than that! (0562-11 [Hoffman, Ace])

Comment: The spent fuel at San Onofre, that is NOT being removed, can certainly do that. Each time Edison does a transfer to dry casks, that operation is about a million times more dangerous than this RPHV transfer, but there are no announcements warning about those operations. It just goes on daily, about one new cask per month, until the job is done and Edison can walk away, leaving southern Californians with a pile of waste which can destroy our paradise at any moment, for who-knows-how-many-generations. Edison has NO plans for removing the nuclear waste, and neither does the NRC. Outrageous! (0562-3 [Hoffman, Ace])

Comment: SanO is one of them. I say "randomly" because the sites were never picked because they would be waste dumps at all, let alone appropriate ones: When the reactors were built, the public was told the waste would be removed within a few MONTHS after it is discharged from the reactor! Instead, virtually all of SanO's used reactor cores remain on site. (0562-7 [Hoffman, Ace])

Comment: Is San Onofre a good location for a nuclear waste dump, permanent or not? Hardly! Earthquakes, tsunamis, sabotage, large surrounding population, poor egress, no radiation emergency supplies to speak of anywhere in the nearby counties to handle a spent fuel fire resulting from an airplane impact... and it's upwind from the entire United States, so everyone in the country will be contaminated if there is an accident at SanO. (0562-9 [Hoffman, Ace])

Comment: Do not allow the storage of nuclear waste in Texas, which could impact the Oglalla Aquifer. (0566-11 [Tocornal, John])

Comment: We in South Carolina are sitting on overcrowded commercial spent fuel storage sites that could explode if not tended continuously with water. We are behind the projected cleanup of the Cold War legacy waste at the SRS and in fact are dealing with leaks from that tank farm. (The tanks are almost 60 years old and we were told they would last 50 years). We are having budgetary constraints that are impacting the cleanup and frankly CSRA citizens through Don't Waste Aiken and the SC citizens through Conservation Voters are waking up to the fact that the NRC has no policy in place for this waste since Yucca Mountain was removed. (0571-2 [Young, Jane])

Comment: We want the spent nuclear fuel to be taken away from San Onofre as soon as possible. If San Onofre has to keep spent nuclear fuel on site, then some kind of process to make the nuclear fuel 'dry' is absolutely needed. My family and I are San Clemente residents. Thank you for your consideration. (0584-1 [Babski, Mark])

Comment: Having lived within a 30 mile radius of San Onofre Nuclear radiation repository (and directly downwind, as the residents of Belarus would testify) these past ten years, I feel no more safe than I felt when the plant was in full operation. Please empathize with someone who cannot afford to sell their home and relocate permanently far away from such an impending invisible toxic calamity. Remember the fact that the plant was build long before the much recent discovery of the local off shore earthquake fault. (0589-1 [Broska, Robert])

Comment: The unique combination of these precipitous factors conjure SONGS into an unprecedented cauldron of genetic devastation for the 8.5 million residents and their progeny who plan on living within the 50 mile radius. How can we foresee even a temporary evacuation plan? Let us activate a plan of waste removal to model for the rest of the 100 reactors in our country by being the first penguin to leap into the waters of peace and safety. Please give SONGS the exceptional priority of waste relocation that it uniquely deserves. Let us finally rest when this unnecessary threat is removed. (0589-3 [Broska, Robert])

Comment: As residents of San Clemente, CA, my wife and I are disappointed that the NRC chooses to neglect our city's dangerous nuclear waste problem and prefers instead to handle the San Onofre closedown in typical bureaucratic fashion. From the information that has been provided, there appears to be real danger here; and NRC does not seem to be acting accordingly. (0591-1 [Lange, Howard])

Comment: I did not speak up that evening as I thought the main points spoken about in opposition to plans for Fermi-3 were covered and I endorse all of them. I emphasis my support for what Vic Macks wrote in the "Fall 2013" issue of Peace Action of Michigan's newsletter, FLASH on page 8. Of special note is: "Monroe County, MI: During the period 1979 to 1988, Monroe had 21.2% fewer cancer deaths than the U.S. as a whole. During the period 1989 to 2005, correlating with Fermi 2 being online, Monroe had 45.5% higher cancer deaths than the U.S, as a whole. This is reported in a study by The Radiation and Public Health Project which utilized Center for Disease Control statistics." Do NOT build Fermi-3 as it would be too dangerous for human health, our environment (especially Lake Erie) plants and animals. (0597-2 [Bergier, Kim])

Comment: I agree with all the points brought up in this fact sheet and will be sharing this with activists as we are determined to not let your lies and obfuscation choose money over people. <http://www.athf3.org/wp-content/uploads/2013/03/ATHF3-Fact-Sheet.pdf> (0597-4 [Bergier, Kim])

Comment: I did not speak up as I thought the main points spoken about in opposition to plans for Fermi-3 were covered and I endorse all of them. I emphasis my support for what Vic Macks wrote in the Fall issue of Peace Action of Michigan's newsletter, FLASH on page 8: "Monroe County, MI: During the period 1979 to 1988, Monroe had 21.2% fewer cancer deaths than the U.S. as a whole. This is reported in a study by The Radiation and Public Health Project which utilized Center for Disease Control statistics." Do NOT build Fermi-3 as it would be too dangerous for human health, our environment (especially Lake Erie) and animals. (0599-2 [Bergier, Kim])

Comment: For Indian Point, these include: --More than 20 million people live within a 50 mile radius of Indian Point, which is the evacuation area the United States recommended during the Fukushima disaster. --Indian Point is near New York State designated significant fish and coastal wildlife habitats. --Radioactive nuclides such as tritium and strontium 90 have been leaking from two spent fuel pools since the 1990s into the groundwater and Hudson River. Tritium and strontium 90 have been found in water drawn from the Hudson by United Water New York's pilot desalination plant located 3.5 miles downstream from Indian Point. --The water supply for Rockland County is proposed to be drawn from the Hudson River by United Water New York downstream from Indian Point, while parts of New York City's water supply are less than 15 miles away from Indian Point. --Indian Point sits at the intersection of two active earthquake faults; these faults could produce upwards of a 7.0 magnitude earthquake, which Indian Point was not initially built to withstand. --The Spectra Energy Corporation's Algonquin expanded 42" natural gas pipeline is proposed to go under the Hudson River, enter Westchester and intersect with proposed mega-voltage electric lines near Indian Point's 40 years of spent nuclear fuel rods, all in close proximity to the Ramapo faultline. --Indian Point's spent fuel pools, which were never designed to hold the nearly 2,000 tons of toxic waste now stored at the plant, are highly vulnerable to terrorism and accidents. The planes which slammed into the World Trade Center on September 11, 2001, flew along the Hudson and passed directly over Indian Point. It does not seem possible to guard against this kind of terrorist activity. (0604-4 [Pisha, Gayla])

Comment: WHEREAS, San Clemente is home to 65,000 residents and is located entirely within the 10-mile Emergency Planning Zone for the San Onofre Nuclear Generating Station; and WHEREAS, in June 2013, following more than a year of investigation and analysis by both Southern California Edison (SCE) and the Nuclear Regulatory Commission (NRC), SCE determined that San Onofre should be permanently decommissioned; and WHEREAS, in response to Southern California Edison's decision to decommission SONGS, the City of San Clemente urges SCE and the NRC to ensure that public safety remains paramount during the decommissioning process and beyond; and WHEREAS, Congress assigned to the Energy Department the task of creating an underground repository for nuclear waste as a result of the Nuclear Waste Policy Act of 1982, however, that task has yet to be completed; and WHEREAS, the storage of spent fuel rods onsite at SONGS continues to be a concern to the residents of San Clemente; and WHEREAS, the Nuclear Regulatory Commission (NRC) controls the decommissioning of nuclear facilities to ensure that safety requirements are being met, and WHEREAS, the City Council of the City of San Clemente takes its responsibility to represent its citizens with utmost seriousness and, as such, desires to be included in the decommissioning process for SONGS. (0605-1 [Baade, Joanne])

Comment: The plant's [Pilgrim] age is also cause for concern, as former Nuclear Regulatory Commission member Peter Bradford explained at a recent panel on nuclear issues at the Massachusetts State House. (0607-4 [Messinger, Michael])

Comment: Thus I consider myself an ardent advocate and defender of the county and its riches as well as a reasonably well-informed citizen about the dangers it faces. The primary one being, the risks we run by living in proximity to the Diablo plant and the spiderweb of earthquake faults that surround it on land and underwater. No one can know when the next "big one" will hit. However, anyone can see that we also face a heinous short-term risk, a foolishly high one, posed by the growing pileup of spent fuel rods in the pools at Diablo. (0609-1 [Leon, Vicki])

Comment: We, the residents of SLO county, along with the Diablo plant, sit alongside a sea just as capable of producing a tsunami on this side of the Pacific Rim as the other. Diablo and

its hazards imposes a huge burden of anxiety on our communities. It puts us in extreme jeopardy---not merely us but generations to come. Life is full of risks--but this one can be sidestepped if you put human safety and welfare first. (0609-3 [Leon, Vicki])

Comment: Indian Point is less than 30 miles from Wall Street and is located on the banks of the historic Hudson River. George Washington defeated the British here. Washington and his soldiers was aided by the narrowness of the Hudson above Buchanan and the impossibility of escape from lower Hudson Valley without going through the narrow Ramapo pass along the Appalachian Trail. The geography of this region remains unchanged. Then, and now evacuation from this region is impossible. (0611-1 [Shapiro, Susan])

Comment: Indian Point also has the infamous distinction of being named by the NRC the #1 plant in the nation most likely to be severely damaged by earthquake. Indian Point is located on two intersecting earthquake faults (the Ramapo and Stamford faults) and has two 36" natural gas pipeline within 500 feet from the facility, without on-site shutoff valves. In addition in 2013 the Congressional Government Accountability Office ("GAO") reported that Indian Point is the nation's reactor site with the most safety violations. (0611-2 [Shapiro, Susan])

Comment: Indian Point currently has 2700 tons of high level radioactive waste and more being produced everyday, even with an expired license. According to physicist Michio Kaku, the average 1000 MW reactor produces about 30 tons of high-level nuclear waste in one year. If the NRC grants Entergy's application for a new 20 year license for each reactor will produce an additional 600+ tons of radioactive waste, including high burn up waste. (0611-3 [Shapiro, Susan])

Comment: There is no comprehensive, continuous, independent monitoring or on-going capture species studies even though strontium-90 has been found in the majority of fish sampled and at a pilot desalination plant, the Haverstraw Desalination Plant, located 3.5 miles downriver, 6 out of 10 samples of finished water have measurable levels of strontium-90. (see Exhibit C: attached except from DEIS; Exhibit D: aerial photograph of Desal intake; and, Exhibit E: Thermal heat plume Aerial Photograph Indian Point/Desal). (0611-36 [Shapiro, Susan])

Comment: Local authorities depend on Entergy to report and radioactive leaks. This is clearly the fox watching the hen house and does not provide adequate monitoring. (0611-37 [Shapiro, Susan])

Comment: Indian Point is not an 805 plant. Currently Indian Point continues to use defective fire insulation, which has degraded fire protection at Indian Point from 1 hour to only 24 minutes, in a location where all other mandated fire safety requirements had already been degraded. At Indian Point the spent fuel pools are so overly packed that there is a very real threat of a spent fuel fire which will melt the zirconium cladding. Aging Zircolloy cladding suffers from creep, erosion, corrosion, embrittlement and pyrophoricity. (0611-40 [Shapiro, Susan])

Comment: The Nuclear Regulatory Committee does not operate as an ordinary federal regulatory government body, as its name suggests. Rather, historically, though it is funded by federal taxation, it functions as a body that forwards the interests of the nuclear energy business. Unfortunately, as a result, in the state of Illinois, this has resulted in the highest number of nuclear reactors being built. The oversight of the power plants in the state of Illinois has been such that in the past decade, that with just one reactor, millions of gallons of radioactive water has been released into the public water ways. The mop-up operation of Braidwood's performance and also its state and federal response at the time of the radioactive

release shows that there is much danger in the protocol and functioning of both the engineers of the plant as well as state and federal response. (0612-1 [Takarabe, Tamae])

Comment: In particular, the chance of an earthquake causing ground motion at Diablo Canyon greater than 0.75g is 3.9×10^{-3} per year (NRC 2011). Put another way, such an earthquake is likely to happen once every 256 years. To put this value in context, the Diablo Canyon reactors are more than 10 times more likely to experience an earthquake larger than they are designed to withstand than the average U.S. reactor. Of the 100 reactors currently operating in the U.S., the two at Diablo Canyon top the NRC's list as being most likely to experience an earthquake larger than they are designed to withstand.... [T]he chance such a large earthquake will occur at Diablo Canyon over the 40-year lifetime of the plant is 40 divided by 256, or about 1 in 6--which is a toss of a die.¹ [footnote 1 text: "Seismic Shift: Diablo Canyon Literally and Figuratively on Shaky Ground," UCS, http://www.ucsusa.org/assets/documents/nuclear_power/diablo-canyon-earthquake-risk.pdf] The GEIS states that the NRC in March 2012 requested information from all U.S. nuclear power plants, and "these assessments may make use of new consensus seismic hazard estimates for the power plants in the central and eastern United States." This is of little use to residents in the vicinity of a nuclear plant on the coast of California. Nor does the accompanying statement -- "In the 2010 assessment, the NRC chose seismic core damage frequency as the appropriate risk metric to changes in the seismic hazard" -- offer reassurance on the issue of seismic hazard to spent fuel pools, which, as seen at Fukushima, present a risk of disaster as great or greater than a core meltdown. (0614-2 [Christie, Andrew])

Comment: This criteria, the basis of seismic risk assessment in the GEIS, does not apply to our reactor community. Alone among U.S. nuclear facilities, Diablo Canyon has been allowed to operate outside its design basis. In 2008, the NRC was informed of a previously unknown earthquake fault line that runs as close as 2,000 feet from Diablo Canyon's reactors and could cause more ground motion during an earthquake than the plant was designed to withstand.² [footnote 2 text: "Several other important aspects of the Shoreline fault remain poorly characterized and therefore subject to uncertainty. These uncertainties include (1) the surface or subsurface rupture length of the fault, (2) structural relationships of the Shoreline fault to other faults, in particular the faults of the San Luis Bay fault zone, and (3) whether the Shoreline fault is capable of producing large enough earthquakes to affect the hazard at the DCP." Confirmatory Analysis of Seismic Hazard at the Diablo Canyon Power Plant from the Shoreline Fault Zone, NRC, Oct. 2012.] Since this fault was discovered, the NRC has not demonstrated that the reactors meet NRC safety regulations. Per UCS, "At other facilities, the NRC enforced its safety regulations and protected Americans from earthquake threats. Today, in the case of Diablo Canyon, the NRC is ignoring its regulations, unfairly exposing millions of Americans to undue risk." (0614-4 [Christie, Andrew])

Comment: When the PIN GP was originally licensed in the 1970s, it was assumed that the spent nuclear fuel would be sent to the Department of Energy's ("DOE") West Valley facility for reprocessing (at that time it was called the Nuclear Fuel Services Processing Plant.² [footnote 2 text: Final Environmental Statement Related to the Prairie Island Nuclear Generating Plant, US Atomic Energy Commission, May 1973, Docket Nos. 50-282,50-306, page V-37.] There was no other mention of PINGP spent nuclear fuel in the May 1973 Final Environmental Statement Related to the Prairie Island Nuclear Generating Plant. When the ISFSI at Prairie Island was initially proposed, in the early 1990s, it was to be temporary measure, only for a few years, to keep the plant running and plant personnel working, until the national repository (legislatively mandated to be at Yucca Mountain) could be opened. The Tribe, along with countless others, expressed concerns regarding the *long-term* storage of spent fuel in dry casks and the possibility that the waste would never leave Prairie Island. We understood then that the ISFSI

was to be an *interim or temporary* solution until the national repository could begin accepting waste. The NRC's EA for the Prairie Island ISFSI states that the TN-40 dry casks are designed to provide storage for spent nuclear fuel for at least 25 years.³ [footnote 3 text: US NRC, Environmental Assessment Related to the Construction and Operation of the Prairie Island Independent Spent Fuel Storage Installation, July 1991. Docket 72-10. ML090260415 at page 2.] The Purpose and Need (of the NRC action) was to allow the PIN GP 1 and 2 to operate until 2013 and 2014 by approving on-site spent nuclear fuel storage. The implication in the EA was that the ISFSI was for a short duration. Minnesota law requires approval from the Public Utilities Commission ("PUC") and the State Legislature before a utility can use on-site dry cask storage. During the process to evaluate NSP's application for a Certificate of Need ("CON") for the Prairie Island dry cask storage facility by the PUC, hearings were held before Administrative Law Judge Allan Klein in November and December 1991. In April 1992, Judge Klein recommended that the PUC deny the CON because of the likelihood that the Prairie Island ISFSI would not be temporary. In his Findings of Fact, Conclusions, and Recommendations, ALJ Klein stated that the essentials of the Findings and facts of the CON could be summarized as:

1. If we knew that the dry cask storage would be temporary, then it is a reasonably safe and cost effective way to deal with the storage problem, and would be eligible to receive a Certificate of Need. In particular, the radiation from the casks would be negligible, and would not pose a health risk to any person.
2. Unfortunately, the past delays in federal siting efforts raise questions about whether the dry casks storage will be temporary or will end up being permanent.
3. There has not been any substantial attempt to evaluate the Prairie Island storage site as a permanent location, nor has there been any comparison of this site with other sites in the state to determine which could be the preferable location for a permanent storage facility. The same is true for the method of storage-dry cask storage has not been evaluated as a permanent method.
4. The likelihood that the dry cask storage would become permanent is so great that it is appropriate to require legislative authorization if the project must go forward immediately. Neither the Commission nor NSP can control the timing or direction of the federal siting effort. Once the casks are in place, the path of least resistance is to leave them there indefinitely.
5. A reasonable alternative would be to wait and see whether the federal government can, in fact, progress its effort to the point that the Commission can be satisfied that the dry cask storage will be only temporary. It is possible to stretch-out Prairie Island and use other alternatives to meet energy needs while we wait and see how the federal effort is progressing. However, the cost of this wait and see approach is greater than the dry cask approach, but that cost has not been fully developed in this record.⁴ [footnote 4 text: State of Minnesota, Office of Administrative Hearings, In the Matter of the Application of Northern States Power Company for a Certificate of Need for the Construction of an Independent Spent Fuel Storage Facility. Findings of Fact, Conclusions, and Recommendations. April 10, 1992. 6-2500-5462-2, E-002/CN-91-9.](0619-1-2 [Mahowald, Philip R.]])

Comment: Despite these findings and conclusions, the Public Utilities Commission rejected Judge Klein's recommendation and ruled that NSPM could store the waste, but the MN Legislature reduced the number of casks allowed from 48 to 17 (NSPM initially sought a CON for 48 dry casks, the amount of casks permitted by its current NRC license). Subsequent Legislative action in 2003 lifted the 17-cask limit. The 1992 legislative hearings for the Prairie Island ISFSI were highly contentious and divisive. It is highly doubtful that NSPM would have received state approval then if legislators and the public believed that the waste would be on-site for an additional 60 or 100 years after reactor operations cease, or indefinitely, as the draft GEIS now contemplates. As mentioned previously, NSPM has filed an application seeking a 40-year license extension for the PINGP ISFSI. A draft EA was issued in November of 2013. The

stated purpose and need of the proposed action (i.e., the PINGP ISFSI license renewal) "is to provide an option (emphasis added) that allows for the continued temporary storage of spent nuclear fuel generated by the PIN GP Units 1 and 2."⁵ [footnote 5 text: US NRC Draft Environmental Assessment for the Proposed Renewal of the Prairie Island Independent Spent Fuel Storage Installation, November 2013. Docket 72-0010. ML13205A120.] Given that the Yucca Mountain national repository has all but been abandoned, and that there seems to be no action on siting and developing a different repository location, the Tribe does not believe that the continued storage of spent nuclear fuel at Prairie Island is either optional or temporary. (0619-1-3 [Mahowald, Philip R.]

Comment: Prairie Island is the Tribe's homeland, and the Tribe is unwilling to now or in seven generations bear the risks and costs associated with a nuclear waste dump it has never supported. (0619-2-10 [Mahowald, Philip R.]

Comment: As a citizen of San Clemente, and a professional hydrogeologist, I am concerned about the proposed long-term storage of spent nuclear fuel rods at the closed San Onofre nuclear power generating station. Storage of the spent fuel rods is not a safe long-term location, but simply the result of the inability of the United States and California government agencies to decide upon and implement a long-term storage location for spent nuclear fuel within the United States. Long-term storage of the spent rods at San Onofre was not planned when the nuclear power plant was constructed, and long-term storage should not be implemented at San Onofre just because another permanent nuclear storage site has not been identified. The citizens of San Clemente should not be subjected to the potential health risks of radiation release and loss of property value due to radiation release from an unexpected event such as an earthquake, tidal wave, or terrorist attack. If the U.S. does not plan on constructing a long-term storage facility for spent nuclear fuel within the continental U.S., then an intermediate storage facility should be identified somewhere in California that is not so close to a population center. San Clemente should not bear the risk of potential radiation release that could occur from an unforeseen event. (0632-1 [Dolegowski, John])

Comment: No Fukushima's in southern California! We DO NOT want the nuclear waste of San Onofre stored on site! It is the worst possible place to store radiation. On a fault line and at the ocean's edge. You are public servants & need to put the public's safety first. Costs to industry pale in comparison to costs of a nuclear accident in the backyard of 8 million people. (0658-1 [Jennings, Stephanie])

Comment: We are grateful that the City Council of San Clemente with its 60,000+ residents; and encouraging nearby Emergency Zone cities, did Approve and Pass their Resolution No. 13-53 requesting that the Nuclear Regulatory Commission; D.O.E. and responsible agencies prioritize San Onofre nuclear plant's radioactive waste storage and removal, when safe to do so. (0665-1 [van Thillo, Grace])

Comment: Likewise, to carry out San Clemente's SAFETY MANDATE, with the decommissioning plant in its front yard, the City MUST be financially supported, along with independent expert assistance to be included in the decommissioning process. Through the years, so-called utility and industry "experts" talked about safety BUT it has been many informed citizens, the on-going horror of Fukushima, the NRC, the CPUC, GAO & Congressional Investigations, which ALL exposed San Onofre's realities - TODAY THE NUCLEAR PLANT IS CLOSED, and we the people are LEFT with the radioactive WASTE! (0665-6 [van Thillo, Grace])

Comment: NO FUKUSHIMA IN SAN CLEMENTE OR CALIFORNIA! GET THIS NUCLEAR WASTE OUT OF HERE! YOU CREATED IT, PUT IT IN YOUR BACK YARD! HOW WOULD YOU LIKE THAT! THINK ABOUT IT! (0668-2 [Gordon, Mark] [Gordon, Michelle])

Comment: IF THERE WERE TO BE AN ACCIDENT OR ATTACK OR FORCE OF NATURE AT SAN ONOFRE RESULTING IN A MELTDOWN TOTAL DEVASTATION WOULD FOLLOW FOR THE PEOPLE AND THE ECONOMY OF CALIFORNIA. OUR LIVES, WEALTH & HEALTH REST ON YOUR DECISIONS. PLEASE DO WHAT IS RIGHT FOR THE PEOPLE. (0673-2 [Massey, Jennifer])

Comment: We are concerned for our safety due to the lack of responsible decisions by the NRC. *The report from the Union of Concerned Scientists ("Seismic Shift") states the lack of enforcement by the NRC of the Safe Shutdown Earthquake requirement found in Diablo Canyon's license. As the Union of Concerned Scientists report points out, of the 100 reactors currently operating in the U.S., the two at Diablo Canyon top the NRC's list as being most likely to experience an earthquake larger than they are designed to withstand. (0678-2 [Georgi, Carol])

Comment: The approximately 600 tons of highly radioactive spent fuel generated at our local nuclear plant [Seabrook Nuclear Generating Station], most of which is still underwater, is expected to end up in casks behind a simple chain-link fence in a former parking lot, across from the plant's visitors center and no more than 100 yards from the shoreline. With sea level rising and our coastline being increasingly eroded away, this existing arrangement appears woefully inadequate to secure these deadly wastes many decades into the future. Your GEIS and rulemaking should at the very least acknowledge and address these sort of shortcomings in existing waste management. (0680-2 [Bogen, Doug])

Comment: Diablo Canyon NPP needs to close immediately. (0686-12 [Malboeuf, Simone])

Comment: It is true that if DCNPP were closed, those employees would be out of work. I submit that if PG&E should stop promoting the continuation of an outdated system of the production of nuclear power, and started becoming a leader in solar, wind and wave power. Let them lead the way not just in the US but in the world to a new and better standard of producing needed electrical power for the world's population that is not as toxic and potentially dangerous as nuclear power. This discourse is wasting valuable time. It is time now to take our heads out of the sand. Admit the shortcomings and negatives of the nuclear power industry. Step up to the opportunity to become leaders with a bold mission to develop renewable energy sources that hold real promises for the future. The time is NOW. If PG&E cannot accomplish this on their own, then the courts and the NRC need to order them to do this. (0686-20 [Malboeuf, Simone])

Comment: Direct PG&E to also begin the process of finding the safest possible process of way of dealing with the radioactive waste. The only "safe" nuclear power plant is one that is not operational. As long as the radioactive waste is still at the site, it needs to be taken care of and monitored by PG&E, whether its cost effect or not. These costs should be absorbed by PG&E's corporation/share holders and not pushed upon the tax payers of California or the United States. (0686-22 [Malboeuf, Simone])

Comment: [I] recommend the decommissioning and closing of Diablo Canyon Nuclear Power Plant in San Luis Obispo, CA immediately. (0686-7 [Malboeuf, Simone])

Comment: We already have ongoing leaking radioactive tanks leaking directly into groundwater near the Columbia River, one of the most radioactive rivers in the world. (0690-8 [Eisman, Val])

Comment: From 1985 through 1987, the state of New Hampshire was one of seven eastern states embroiled in a public debate with the U.S. Government's Department of Energy over the site selection and characterization for a high-level nuclear waste repository in a portion of the Cardigan Pluton, a crystalline rock body that runs under seven towns in "The Granite State." The federal government dumpsite selection and characterization effort coincided with the ongoing federal effort to issue an operating license to the Seabrook nuclear power station in New Hampshire, then a would-be nuclear waste generator. A broad and significant portion of the New Hampshire public reasonably recognized and duly acted upon the hazardous environmental and unacceptable societal impacts from generating high-level nuclear waste and the creation of dubious national sacrifice areas for nuclear waste management. The New Hampshire public reasonably demonstrated their objection and their lack of confidence in government policy and efforts with the adoption of identical town warrant articles in local town meetings throughout the state in March 1986 "to oppose the burial, storage, transportation and production of high-level nuclear waste in the town of _____ and the State of New Hampshire." The identical warrant article popularly appeared in town meetings such as Article 21 of the March 10, 1986 Town Meeting of Rye, NH¹ [footnote 1 text: Town Report for 1986, Rye, New Hampshire, March 10, 1986, p.78

http://www.archive.org/stream/annualreportofto1986ryen/annualreportofto1986ryen_djvu.txt] and similarly Article 29 in the March 11, 1986 Town Meeting of Stoddard, NH where, "After much debate Art. 29 carries unanimously".² [footnote 2 text: Town Report for 1986, Stoddard, New Hampshire, March 11, 1986, p. 45

http://www.archive.org/stream/annualreportsoft1986stod/annualreportsoft1986stod_djvu.txt] Throughout New England, the debate over the inclusion of reviewing the production of nuclear waste into the management of nuclear waste received much media attention. As an example, the Boston Globe reported the popular public opposition and the subsequent "no confidence" vote in a March 12, 1986 article entitled "NEW HAMPSHIRE TOWN SPEAKS OUT AGAINST STUDY ON NUCLEAR DUMP SITE."³ [footnote 3 text: "NEW HAMPSHIRE TOWN SPEAKS OUT AGAINST STUDY ON NUCLEAR DUMP SITE John Milne, Boston Globe, Metropolitan Section, p. 25] (0691-10 [Gunter, Paul])

Comment: The Associated Press wire service similarly reported on the disingenuous political effort by promoters of nuclear power to disassociate the hazards of nuclear waste generation from the unresolved and long-lived adverse environmental impacts once the nuclear waste is generated. The AP news report, "Sununu Says Seabrook and Dump Not Linked", points out "Sununu, an opponent of a New Hampshire dump but a proponent of nuclear power, had urged voters to amend the resolution to delete the word 'production.' Seabrook plant officials backed the governor."⁵ [footnote 5 text: "Sununu Says Seabrook And Dump Not Linked," Michael Mokrzycki, AP, Concord Monitor, March 27, http://www.beyondnuclear.org/storage/waste/waste-confidence-decision/geis-comments-12202013/nhdump_sununnu.JPG] The Seabrook nuclear power proponents were saying that linking nuclear waste production to unresolved adverse environmental consequences with waste management was a "mistake" and "clouding the issue." However, Governor John Sununu and the nuclear industry were unsuccessful in persuading New Hampshire Town Meetings to disassociate waste generation from waste management. The news article reports that at least 92 of 137 towns adopted identical language "to oppose the burial, storage, transportation and production of high-level radioactive waste" in New Hampshire. (0691-11 [Gunter, Paul])

Comment: •TVA does not currently use MOX fuel at any of its nuclear plants, but TVA has considered possible future use of MOX fuel. (0694-2-19 [Shea, Joseph])

Comment: Please reread you own Special Inspection Report On ANO One[.] They dropped 250 ton Management job was Dumb dumb dumb dumb[.] (0699-2 [Lee, Michel])

Comment: (Tune: "Rocking Around the Christmas Tree") Rocking Around the Reactor Core[.] Rocking around the reactor core At the Indian Point power plant Nuke waste lovers just adore The nuclear power plant[.] Rocking around the reactor core At the Indian Point power plant Nuke waste lovers just adore The nuclear power plant[.] A new nuke dump is being built To hold the overflow The spent fuel pool is so tightly packed The water is aglow[.] You will get a sentimental feeling when you hear The NRC saying Just keep a praying For 20 more year[.] Rocking around the reactor core Have a radioactive day Everyone fleeing hysterically When the core starts to melt away! (0699-7 [Lee, Michel])

Comment: The Diablo Canyon Nuclear Power Plant is near two faults. The plant is built over the Hosgri Fault and is near the San Andreas Fault. The plant is built to withstand the expected earthquakes and the spent fuel is stored near by. That could be hazardous at times in the short term, but for long term storage the spent fuel should be moved a short distance to the east of the San Andreas Fault. The Pacific Plate is sliding north along the San Andreas Fault. No one can predict what will happen to the spent fuel in the distance future. The Hosgri Fault was an unknown fault until it had an earthquake. Diablo Canyon should be shutdown, mothballed and decommissioned. (0701-10 [Wilson, Greg])

Comment: The movie "San Andreas Fault" is on the series "How The Earth Was Made" on The History Channel. This movie explains the fault line that all of the West Coast Nuclear Power Plants are built on. The San Andreas Fault runs right under the San Onofre Power Plant. The movie explains how two bends in a dry river bed is evidence that the Pacific Plate is moving north at one inch per year as it slides against the North American Plate. The sliding occurs during earthquakes in a very dramatic manner. The next quake is coming soon and it may be a huge earthquake, the narrator said Huge! The Pacific Plate moves one inch per year. The last San Andreas fault earthquake was 300 years ago. The Pacific Plate could slide 300 inches or 25 feet north. Whatever part of the plant that is on the Pacific Plate could move 25 feet north and away from the other half of the plant. Both parts of the plant will collapse during a very powerful earthquake and first responders may not be able to respond to the tragedy. Many of the bridges and roads may be destroyed. Los Angeles could be devastated in the next San Andreas quake. Where the fault line runs in a straight line a shock wave is produced that

spreads off the fault in a cone shape, just like a jet plane breaking the sound barrier and creating a sound wave. The cone shaped shock wave spreads the fault line shock wave out covering a much larger area as demonstrated during the Great 1906 San Francisco Earthquake. (0701-7 [Wilson, Greg])

Comment: But Illinois has even more in common with Fukushima than just four Fukushima twin reactors that need to be shut down for safety inspections. At the same time that Fukushima is about to start the high-risk, high-level radioactive-waste fuel transfers out of Unit 3, the Zion Nuclear Generation Plant, 40 miles north of Chicago and midway between Chicago and Milwaukee, is about to start its own fuel transfer operation. In 2014 over 1,000 tons of radioactive waste, two and a half times the 400 tons being transferred at Fukushima, will be transferred to dry casks at Zion, Illinois. This is the largest scale decommissioning in history. (0708-3 [Lewison, Linda])

Comment: 4. *Seismic Conditions at Indian Point*[.] A 2008 study by seismologists at Columbia University's Lamont Doherty Earth Institute revealed that the area around Indian Point is not an inactive seismic area, as previously thought. Instead, the study found that, in addition to the Ramapo earthquake fault that Indian Point sits directly on top of, there is another, previously unknown earthquake fault, labeled the Stamford-Peekskill seismic line, that runs just slightly north of Indian Point. The study concluded that the area where Indian Point is located is susceptible to an earthquake of up to 7.0 in magnitude,²³ [footnote 23 text: Lynn R. Sykes, John G. Armbruster, Won-Young Kim, & Leonardo Seeber, Observations and Tectonic Setting of Historic and Instrumentally Located Earthquakes in the Greater New York City–Philadelphia Area, *Bulletin of the Seismological Society of America*, Vol. 98, No. 4, pp. 1696–1719, August 2008; see also The Earth Institute, Columbia University, “Earthquakes May Endanger New York More than Thought, Says Study: Indian Point Nuclear Power Plant Seen as Particular Risk,” Press Release Posted on The Earth Institute website, August 21, 2008, *available at*, <http://www.earth.columbia.edu/articles/view/2235> (last visited December 19, 2013).] even though the plant was not built to withstand an earthquake of this magnitude.²⁴ [footnote 24 text: The Environmental Impact Study conducted for Indian Point's original construction and operation presumed that the site was located in an inactive seismic zone, and thus was built to withstand an earthquake from 3.0 to 5.0 on the Richter scale.] Furthermore, an NRC report from August 2010 (in conjunction with supplemental data regarding power plants not reviewed in the report) indicated that Indian Point Unit 3 has the *highest* risk of seismic related core damage than any other nuclear power plant in the country.²⁵ [footnote 25 text: See Generic Issue 199 (GI-199), Implications of Updated Probabilistic Seismic Hazard Estimates in Central and Eastern United States on Existing Plants Safety/Risk Assessment, August 2010, at Appendix D (Seismic Sore-Damage Frequencies), *available at*, ADAMS Accession Nos. ML100270639, ML100270756; Bill Dedman, *What are the odds? US nuke plants ranked by quake risk*, March 17, 2011, *available at*, http://www.msnbc.msn.com/id/42103936/ns/world_news-asia-pacific/ (last visited Dec. 19, 2013).] (0710-6 [Brancato, Deborah] [Musegaas, Philip])

Comment: From a safety and security perspective, Indian Point is a highly mismanaged plant that poses an incredible risk to the region. Indian Point consistently operates in an unsafe manner, including pursuant to many regulatory exemptions, such as fire safety exemptions, which reduce critical safety margins at the plant. Notably, Indian Point was recently determined to be the plant with the highest number of violations of any operating reactor in the country.²⁶ [footnote 26 text: Associated Press, *Report: NY Plant Had Most Nuclear Violations in US* (Oct. 15, 2013), <http://online.wsj.com/article/AP5fc1534dab524315b3ccdf1ec8ec79cc.html> (last visited Dec. 19, 2013).] The plant is highly degraded, with components consistently succumbing to breakdown and malfunction: in 2001 a steam generator tube ruptured causing Indian Point

Unit 2 to remain shut down for almost a year; in 2007 a degraded transformer of Unit 3 exploded and just two years later in 2010, a Unit 2 transformer exploded;²⁷ [footnote 27 text: See NRC Information Notice 2009-10: Transformer Failures-Recent Operating Experience, *available at*, <http://pbadupws.nrc.gov/docs/ML0905/ML090540218.pdf> (“Indian Point, Unit 3—On April 6, 2007, while operating at 92-percent power, a fault occurred on the No. 31 main transformer resulting in an automatic reactor trip and transformer fire.”); NRC Event Notification Report 46400 (November 7, 2010), *available at*, <http://pbadupws.nrc.gov/docs/ML1101/ML110190640.pdf> (“At 1849 EST, the licensee declared an Alert due to an explosion in the 21 Main Transformer. As a result of the loss of the transformer, Unit 2 experienced a reactor trip.”).] and over the past twelve years both reactors have suffered numerous unplanned shutdowns. As the plant continues to operate, aging related degradation will continue to occur and, in accordance with the bathtub curve principle, actually accelerate. Security at the plant is, likewise, abysmal. Recent analyses have adjudged Indian Point to be vulnerable to and inadequately protected against intentional terrorist attacks.²⁸ [footnote 28 text: See, e.g., Lara Kirkham & Alan Kuperman, Protecting U.S. Nuclear Facilities from Terrorist Attack: Re-assessing the Current “Design Basis Threat” Approach, Nuclear Proliferation Prevention Project (Working Paper #1 August 15, 2013), *available at*, <http://blogs.utexas.edu/nppp/files/2013/08/NPPP-working-paper-1-2013-Aug-15.pdf>; (acknowledging “that NRC licensees might be unable to provide adequate security measures to satisfy” design basis threats “due to economic or statutory constraints” and arguing that the government needs to “provide the necessary supplementary security, which currently does not occur in many cases, rather than to reduce artificially the posited threat as now is done.”).] A 2007 Report by Gordon Thompson, Ph.D. related to the risks of continuing to operate Indian Point explains the vulnerability of the spent fuel pools at Indian Point to intentional attacks, the credible threat environment, and the likelihood of acts of malice occurring at Indian Point.²⁹ [footnote 29 text: Gordon Thompson, Risk-Related Impacts from Continued Operation of the Indian Point Nuclear Power Plants (Institute for Resource and Security Studies, 2007), *available at*, <http://pbadupws.nrc.gov/docs/ML1209/ML120970089.pdf> ((hereinafter “Thompson, Risk-Related Impacts”).] Likewise a 2004 report by Edwin Lyman, Chernobyl on the Hudson: the Health and Economic Impacts of a Terrorist Attack at the Indian Point Nuclear Plant, explains the justified concerns about a potential terrorist attack at Indian Point.³⁰ [footnote 30 text: Edwin S. Lyman, Chernobyl on the Hudson? The Health and Economic Impacts of a Terrorist Attack at the Indian Point Nuclear Plant (September 2004), *available at*, http://www.ucsusa.org/assets/documents/nuclear_power/indianpointhealthstudy.pdf (hereinafter “Lyman, Chernobyl on the Hudson”).] Importantly, Indian Point faces a uniquely high probability of attack due to the location of the plant.³¹ [footnote 31 text: For example, the 9/11 Commission Report revealed that the mastermind of the 9/11 attacks had originally planned to hijack additional aircrafts to crash into targets, including nuclear power plants, but wrongly believed the plants were heavily defended. See Nat’l Comm’n on Terrorist Attacks Upon the U.S., *The 9/11 Commission Report* (2004), *available at*, <http://www.9-11commission.gov/report/911Report.pdf>, at 154. This report indicates that the terrorists were considering attacking a specific nuclear facility in New York, most likely Indian Point, which one of the pilots had seen during a familiarization flight near New York. *Id.* at 245.] (0710-7 [Brancato, Deborah] [Musegaas, Philip])

Comment: In addition, numerous current and former Indian Point employees, including security staff, have come forward as whistleblowers recently, highlighting inadequate training and deficient security systems and procedures that clearly leave the plant susceptible to human error as well as malicious acts. Repeated reports of faulty security systems, failed security exercises, and overworked guards found asleep at their posts raise grave concerns about the susceptibility of the facility, particularly the unhardened spent fuel pools, to terrorist attack.³² [footnote 32 text: See My Fox New York Staff, *Guards raise concerns about security at Indian*

Point (Nov. 14, 2013), <http://www.myfoxny.com/story/23975312/guards-raise-concerns-about-security-at-indian-point> (last visited Dec. 19, 2013); Roger Witherspoon, *NRC Probes Security Failings at Indian Point* (Nov. 22, 2013), <http://www.newjerseynewsroom.com/science-updates/nrc-probes-security-failings-at-indian-point-power-plant> (last visited Dec. 19, 2013); Shawn Cohen, *Second Indian Point worker charged in copper wire theft* (Jan. 26, 2013), <http://www.lohud.com/article/20130127/NEWS02/301250115/Second-Indian-Point-worker-charged-copper-wiretheft> (last visited Dec. 19, 2013).] In addition, there have been several instances of Entergy employees being prosecuted for theft and falsification of records related to the safe operation of the plant.³³ [footnote 33 text: For example, see the following: Shawn Cohen, *Second Indian Point worker charged in copper wire theft* (Jan. 26, 2013), <http://www.lohud.com/article/20130127/NEWS02/301250115/Second-Indian-Point-worker-charged-copperwire-theft> (last visited Dec. 19, 2013); *Ex-supervisor at Indian Point nuclear plant charged with fabricating fuel tests*, NY Daily News, July 23, 2013, <http://www.nydailynews.com/new-york/ex-supervisor-indian-point-nuclearplant-charged-fabricating-fuel-tests-article-1.1406963>; *Indian Point Nuclear Plant Worker Pleads Guilty After Attempt To Cover Up Diesel Fuel Contamination*, AP, Oct. 17, 2013, http://www.huffingtonpost.com/2013/10/17/indian-point-nuclear-diesel-cover-up_n_4115227.html, also <http://www.justice.gov/usao/nys/pressreleases/July13/WilsonDanielComplaint.php>; *NRC: Indian Point Worker Falsified Background Check Letter*, Hudson Valley Reporter, Nov. 21, 2013, <http://hudsonvalleyreporter.com/westchester/buchanan/2013/11/nrc-indian-point-worker-falsified-backgroundcheck-records/>.] (0710-8 [Brancato, Deborah] [Musegaas, Philip])

Comment: Instead I have had to study, participate in public meetings, write, and worry about just one radioactive waste site --- here in St. Louis --- namely, the West Lake Landfill. West Lake contains what many people recognize as some of the oldest radioactive waste of the Atomic Age. The landfill is located in the floodplain of the flood-prone Missouri River, just upstream from the Missouri/Mississippi rivers' confluence --- and upstream from the drinking water intakes for many St. Louisans and others farther downstream. And most recently, to the surprise and concern of the St. Louis public, we have learned that the West Lake Landfill contains not only historically significant and highly radioactive nuclear weapons wastes, but it is also the site of an advancing "underground smoldering event" --- that is, a fire. Starting in April 1942, engineers, scientists, and other workers at the Mallinckrodt Chemical Works (MCW), a mile from Downtown St. Louis, began to generate tons of extremely radiotoxic, long-lived uranium and thorium wastes for the Manhattan Project. MCW processed uranium and generated radioactive waste at the Downtown plant for fifteen years, and then for another ten years at the Weldon Spring plant, across the Missouri River, in St. Charles County. Amazingly enough, it had taken MCW only fifty days in 1942 to figure out how to purify the requisite tonnage of highly pyrophoric uranium that was then used for the world's first self-sustaining nuclear chain reaction. On December 2, 1942, in the Fermi reactor, under the University of Chicago's football field --- using Belgian Congo uranium purified here in St. Louis --- the Atomic Age was born. (0715-2 [Drey, Kay])

Comment: The decommissioning of the nuclear reactor in Zion, Illinois, is the largest decommissioning of a nuclear reactor in history with almost a billion-dollar budget. The project is scheduled to start the fuel transfer of the irradiated waste into dry casks next month. One thousand metric tons of irradiated fuel will be transferred into dry casks over the course of the next twelve months. HARDENED ONSITE STORAGE hasn't even been on the table. This fuel transfer of 1,000 metric tons of radioactive waste is TWO AND HALF TIMES the 400 metric tons currently being transferred at Unit 3 at Fukushima, Japan. Since the Zion decommissioning began, there have been two license transfers approved through the NRC. Now Zion Solutions,

LLC, a privately held company, has been granted authority by the NRC to manage the decommissioning. As a privately held company, Zion Solutions is legally entitled to take a profit. When I, along with others ConEd ratepayers, contributed to the public funding of this project, through a charge on our monthly electric bills, we expected that, if there were any funds left over, they would be rebated back to the public. There are precedents for this in the last twenty years when, through the assistance of Citizens Utility Board, millions of dollars were rebated back to the ratepayers in a settlement negotiated with ConEd.. According to the NRC, the NRC's only responsibility is to see that there is enough money to cover the cost of the project. At this point, those costs include a profit margin. Even if it turns out there is no profit to be made from the Zion decommissioning, the precedent is set for a privately held company to manage public funds and build a profit into the budget. As a ConEd ratepayer, I did not agree to this "public-private ownership" model. As a ConEd ratepayer, I did not agree that the public could legally be prohibited from access to the records of a privately held entity. There is already one lawsuit in the courts challenging the Zion project. There may be more in the future. At the last sham of a public meeting of the Zion Community Action Panel (a group of local people appointed by Zion Solutions who were not elected in a public process, and whose backgrounds do not encompass the expertise required for the oversight of a billion-dollar radioactive waste decommissioning project), Pat Daly, who has been managing this decommissioning up until now for Zion Solutions, announced that he was leaving the post and going back to Tennessee. He introduced the new executive, who will be starting now. Pat Daly, having made all the arrangements over the past eight years for this fuel transfer, is leaving at the most critical and vulnerable time, when the fuel transfers are due to start and when we, the millions of people who live in the Chicago/Milwaukee metropolitan areas within 50 miles of the reactor, will be at the most risk. How can we possibly have CONFIDENCE in the government agency, the NRC, that is charged with protecting the public, when it allows these things to happen? Whatever the next executive's fine credentials may be, it is not "best practices" to change management at this critical time.. This is not the best way for this decommissioning to occur, and by not intervening and postponing the fuel transfers, the public is put at needlessly higher risk. (Maybe Daly knows something we don't and we should all leave town!!) We do not oppose the fuel transfers; we oppose the process that is going on at Zion. And we are very concerned about the role (or the lack of role) of the NRC. We are all in clear and present danger here. It is the NRC's job to protect and safeguard the public, not turn a deaf ear. (0717-1 [Lewison, Linda])

Comment: QUESTIONS FOR NRC: •How was this budgetary figure arrived at? •How can we see the evidence supporting this budget at the NRC? •What contingencies (such as the different characteristics of high burn up fuel and if the fuel rods drop and an "inadvertent criticality" event occurs and there is a partial or complete drainage of the pool, unexpected power outage, and more) have been considered during the fuel transfer? •What are the preparations, emergency plans, extra boron on hand, and more that have been made to respond to them? •Since there only a few dry cask manufacturers and since there is a history of some defective casks, what was the process of testing and quality control for these dry casks? •Was this an open bid process? Was there an open bid process for the rest of the contracts let out – since such large sums of money are being spent – at Zion? If not, what was the process and what were the criteria used to select the contractors? •Why was HARDENED ONSITE STORAGE not considered as part of the decommissioning – when it is seen as "best practices" by so many experts? •What were the damages of the fuel rods – 1,500 of them – that were reported to have been repaired at Zion? What were the repairs? Why is it a good idea for the damages/repaired fuel rods to be in the same dry casks as the other fuel rods? •What is the amount and age of the high burnup fuel at Zion? •What special arrangements are being made in the fuel transfer? It is my understanding that high burn up fuel CANNOT BE MOVED!! It is too dangerous. It is my understanding that HIGH BURNUP FUEL needs to be stored in fuel pools for much longer

periods than the rest of the fuel rods. What special arrangements are being made with these constraints in mind? •What is the plan and time frame for keeping these dry casks onsite at Zion? •What is the plan for the safe monitoring of them 24/7? •What is the plan to keep terrorists away? To provide camouflage from the many flights going over Zion, which is on the flight path to and from O'Hare airport to the East Coast? (0717-4 [Lewison, Linda])

Comment: Questions for the NRC: •Why did the NRC allow for these license transfers from Exelon to Energy Solutions and Zion Solutions as part of the Zion decommissioning project? What was the process that allowed this to occur? What was the rationale behind the arrangements? •What is the authority of the NRC that allowed it to hand over almost a billion dollars of public trust fund money to a privately held entity? •How does it protect the public, to legally prohibit public oversight, accountability and transparency from the operation? •What is the profit? •What is the story behind the \$200 million dollar "line of credit" which was taken out of Northern Trust bank and put in a bank in New York? Why does this project even need such a line of credit – on which the public is paying a fee (of millions of dollars/year)? What funds have been paid out to Exelon - as part of the decommissioning •expenses? What have they done to earn these fees? Where is the documentation? •Will the NRC, let alone the public, ever see the financial statements? •Zion Solutions – in the third year of the project – brought in a public auditor. Where are the auditor's reports? Will the NRC, let alone the public, ever see them? •Do we need to file a FOIA to do so or can you make them available on the NRC website? •What is the NRC's plan and what is the NRC's responsibility 1) if the funds run out before the project is completed and 2) in the case of an inherent criticality event or unexpected events causing mega-catastrophic damages - past the caps of the Price Anderson Act? (0717-5 [Lewison, Linda])

Comment: Questions for the NRC: •What is the profit in actual amount and the profit margin on the Zion decommissioning project? Who gets it? How is it paid out? Questions for the NRC: •What are the guidelines for fiscal matters for a decommissioning project? •Who owns the R& D and intellectual property – as well as the actual physical new equipment and tools that may need to be developed for the decommissioning? •Why should public funds pay for development expenses and then allow the private company to profit from their "proprietary" intellectual property rights? •How does the NRC evaluate what is proprietary? Questions for the NRC: •Does the NRC have any recourse in this matter? Can Pat Daly be forced to remain at Zion and manage the fuel transfers? Does the NRC have the power to postpone the fuel transfers until such time as there is a public trustee and public oversight of the project? Who does? Who can stop it? What role does the NRC play in the process? (0717-6 [Lewison, Linda])

Comment: Throughout this proceeding, New York has requested that NRC conduct a transparent, objective, and comprehensive site-specific severe accident mitigation alternatives analysis of spent fuel pool accidents at Indian Point – and conduct a site-wide analysis of severe accidents at Indian Point. (0718-1-1 [Sipos, John])

Comment: Fires[.] When fuel is removed from a nuclear reactor, it is extremely hot and continues to generate large amounts of energy. It must be submerged in cold water for five years so that it does not spontaneously ignite. The figures below, taken from a report prepared by Sandia National Laboratories,²⁸ [footnote 28 text: Sandia National Laboratories, *Mitigation of Spent Fuel Pool Loss-of-Coolant Inventory Accidents and Extension of Reference Plant Analyses to Other Spent Fuel Pools*, at 54 ("2006 Sandia Report") (Nov. 2006).] show that spent fuel can generate close to 10 MW of energy when it is first removed from a reactor and placed in a spent fuel pool. To put this amount of energy in perspective, one megawatt of capacity produced by a conventional generator (such as a coal plant) will produce enough electricity to provide for the annual electric needs of 400 to 900 homes.²⁹ [footnote 29 text: Bob Bellemare,

What is a Megawatt? (June 24, 2003). Available at: <http://www.utilipoint.com/2003/06/what-is-a-megawatt/>.] This considerable amount of residual or "decay" heat causes the temperature of the pool water to increase rapidly, and cooling water is required to constantly refresh the pool and replenish the water lost through evaporation so that the fuel assemblies do not overheat. [Figures inserted] Assuming that a reactor has a 23-month refueling cycle, the scenario depicted by the above figures could take place ten times during a twenty year operating license authorized by a renewed reactor operating license. For sites, such as Indian Point, that have two operating power reactors, this scenario could occur approximately twenty times during the additional twenty year operating period. (0718-1-13 [Sipos, John])

Comment: NRC Staff has already ordered that certain measures be taken at nuclear reactors in an attempt to address some of the environmental and safety problems associated with spent fuel storage. In its March 12, 2012 Status Report on Implementation of the Near-Term Task Force Recommendations Based on Insights from the Fukushima Dai-ichi Accident, NRC announced it had ordered that "strategies shall be developed to add multiple ways to maintain or restore core cooling, containment and spent fuel pool (SFP) cooling capabilities in order to improve the defense in depth of licensed nuclear power reactors" and "[l]icensees are ordered to install enhanced SFP instrumentation." *Id.* at 2-3. These recently- announced, first steps underscore the fact that NRC has now recognized that spent fuel pools represent a potential source of significant adverse environmental impacts for which corrective actions are needed. However, NEPA requires analysis of a full range of site specific alternatives and mitigation measures. Such a full range of alternatives has not been developed or analyzed for Indian Point. The State is aware of ongoing efforts by NRC to begin to address problems with the spent fuel storage, including the above-mentioned Orders regarding recommendations from the Fukushima Daiichi Near Term Task Force. It is not a satisfactory answer to the State's concerns for NRC to indicate that those efforts should be a substitute for consideration at this time in major federal rulemaking proceeding of the serious environmental damage that can be caused by the spent fuel pool use and alternatives to mitigate that damage. (0718-1-21 [Sipos, John])

Comment: We write to request additional information regarding NRC's examination of potential aqueous releases following a severe accident, both for the Indian Point facilities and on an agency-wide basis. As we discussed on our conference call yesterday, the severe accident mitigation alternatives ("SAMA") analysis for Indian Point does not consider aqueous releases. Significant new information shows that, in light of the ongoing aqueous releases at Fukushima, aqueous releases should be considered in both the analysis of the impacts associated with a severe accident at Indian Point and the SAMA analysis for Indian Point. On April 27, 2013, the State submitted supplemental comments on the draft supplement to the December 2010 Final Supplemental Environmental Impact Statement ("FSEIS").¹ [footnote 1 text: The State had previously submitted comments on March 28, 2012 and August 20, 2012.] The State's April 2013 supplemental comments identified and discussed new and significant information. The State requested that NRC Staff examine the new and significant information in the supplement to the environmental impact statement. The State's April 2013 comments cited a presentation by the Director of NRC's Research Office from NRC's March 2013 Regulatory Information Conference. Based on that presentation, it is clear that the MACCS2 computer code used to examine severe accidents lacks the ability to analyze the impacts to water resources and the environment resulting from aqueous radiological releases accompanying such an accident. International Session - Post-Fukushima Research, Brian Sheron, Director, NRC Office of Nuclear Regulatory Research (March 13, 2013).² [footnote 2 text: The document is available at https://ric.nrc-gateway.gov/m/Docs/Abstracts/sheronb_rev1-hv-w15.pdf.] In slide 7 of that presentation (reproduced below), NRC notes (1) aqueous releases occurred during Fukushima accident, and (2) current models do not address aqueous release pathways. The term "current

models," as used in the slide, would include computer codes such as MACCS2, which Entergy and NRC Staff used to analyze severe reactor accidents in connection with the applications for renewed operating licenses for the Indian Point facilities. (0718-6-1 [Sipos, John])

Comment: In addition to the March 2013 presentation, the State's April 2013 comments also included recent reports regarding continuing radiological aqueous releases at the Fukushima site—two years after the start of the severe accidents that damaged four of the Dai-ichi nuclear facilities. The State's comments explained that, although these releases had not been reflected yet in publically-available NRC documents, according to news articles, the receptacles holding radiation contaminated fluids at the Fukushima site have leaked and have released radiological material to the environment. See, e.g., *Damaged Nuclear Plant in Japan Leaks Toxic Water*, Martin Fackler, New York Times (April 6, 2013); *Japan Nuclear Plant Finds New Leaks*, Mari Iwata, Wall Street Journal (April 7, 2013); *Nuclear Plant in Japan Has Leak in Other Tank*, Hiroko Tabuchi, New York Times (April 9, 2013); *Fukushima Nuclear Plant is Still Unstable*, Japanese Official Says, Hiroko Tabuchi, New York Times (April 10, 2013). More recently, on August 1, 2013, NRC made the transcript of a December 2012 Advisory Committee on Reactor Safeguards ("ACRS") subcommittee meeting publicly available. July 30, 2013 Memorandum to ACRS Members regarding Certified Minutes of the ACRS Reliability and PRA Subcommittee Meeting on Level 3 PRA on December 4, 2012 (ML13211A477) (*ACRS Transcript"). At that meeting Alan Kuritzky from NRC's Office of Research, Division of Risk Analysis, explained [""]Aqueous transport and dispersion of radioactive materials, this is something very big given the Fukushima event, but something we simply are not going to address in our study, but the Agency as a whole is looking into it.[""] ACRS Transcript at 43:17-21. An article appearing in today's New York Times further underscores the importance of the issue. *Fukushima Plant Has 300-Ton Water Leak*, Associated Press, New York Times (Web Edition) (August 20, 2013) ("The operator of Japan's tsunami-crippled nuclear power plant said Tuesday that about 300 tons (300,000 liters, 80,000 gallons) of highly radioactive water have leaked from one of the hundreds of storage tanks there—its worst leak yet from such a vessel."). Aqueous releases following a severe accident would be of particular concern at Indian Point, which sits on the Hudson River. Aqueous releases have the potential to contaminate the Hudson River's waters, riverbanks, riverbed and sediment, adjacent freshwater tidal wetlands, and fish and other aquatic organisms and impacts to the environment and human health could exceed the impacts flowing from the aqueous releases into the Pacific Ocean at Fukushima. The unique, site-specific conditions at Indian Point warrant an analysis of the aqueous release issue in the context of the SAMA analysis. (0718-6-2 [Sipos, John])

Comment: NRC's acknowledgement of the continuing aqueous releases at Fukushima and the importance of analyzing aqueous release pathways in the context of severe accidents constitutes new and significant information. Under 10 C.F.R. § 51.92(a)(2), NRC Staff is obligated to "prepare a supplement to a final environmental impact statement . . . if . . . [t]here are new and significant circumstances or information relevant to environmental concerns and bearing on the proposed action or its impacts." See also 40 C.F.R. § 1502.9(c)(1)(ii); *Marsh v. Oregon Natural Res. Council*, 490 U.S. 360, 370-78 (1989) (even after initial approval of an environmental impact statement (*EIS"), an agency must continue to evaluate the environmental consequences of the project and supplement the EIS as necessary). The information is new because the presentation was made publically available after NRC Staff issued its FSEIS in December 2010. It is significant because an analysis of aqueous releases would lead to an increase in severe accident costs, which could lead to the consideration of mitigation measures designed specifically to address aqueous releases or render additional mitigation measures cost-beneficial in the SAMA analysis. NRC Staff's failure to identify and analyze the impacts and costs associated with aqueous release following a severe accident and the alternatives to

mitigate such impacts in the FSEIS supplement is not consistent with the National Environmental Policy Act. We appreciate your cooperation and look forward to receiving a description of NRC's analysis of aqueous releases in the wake of the Fukushima accidents. Please also indicate whether NRC plans to supplement the FSEIS for the renewal of the operating licenses for the Indian Point facilities to include a site-specific analysis of the impacts of aqueous releases flowing from a severe accident and the means to mitigate such impacts. Based on our conversation yesterday, we trust that you will forward this letter and our request to the appropriate individuals including Brian W. Sheron, Director, Office of Nuclear Regulatory Research and John Lubinski, Director, Division of License Renewal. (0718-6-3 [Sipos, John])

Comment: The State writes to request additional information regarding NRC's oversight and funding of offsite decontamination in the event of a severe accident at Indian Point. As we discussed on our conference call yesterday, it is not clear which federal agency is responsible for decontaminating the area surrounding Indian Point or whether the Price Anderson Act covers such decontamination costs. On March 20, 2012, NRC Staff announced that it was going to supplement its examination of the environmental impacts of the issuance of proposed operating licenses for the Indian Point Unit 2 and Indian Point Unit 3 facilities in the December 2010 Final Supplemental Environmental Impact Statement ("FSEIS"). 77 Fed. Reg. 16278 (Mar. 20, 2012). On March 28, 2012, the State sent a letter to NRC Staff regarding the proposed scope of the FSEIS supplement. See March 28, 2012 letter from J. Sipos to S. Turk (NRC), ML12090A609. In its scoping comments, the State urged NRC Staff to address, in a proactive way, the issue of how it deals with severe nuclear events that lead to significant environmental impacts including land contamination. *Id.* at 13. In Attachment I to the State's letter, the State raised the issue of funding for decontamination costs, noting that "according to documents prepared by staff at the U.S. Environmental Protection Agency ("EPA")" the NRC recently informed the EPA and the Federal Emergency Management Agency ("FEMA") that the industry-funded account established under the Price Anderson Act would likely not be available to pay for offsite decontamination in the event of a severe accident at a nuclear plant. *Id.*, Attachment I at 59 (discussing Douglas P. Guarino, *Agencies Struggle To Craft Offsite Cleanup Plan For Nuclear Power Accidents*, Inside EPA (Nov. 10, 2010), and attached emails disclosed pursuant to Freedom of Information Act ("FOIA") Request). On June 26, 2012, NRC Staff informed the public that the draft FSEIS supplement was available for public comment, however, the draft did not address the State's scoping comments. See Notice of Availability of Draft Supplement to Final Plant Specific Supplement 38 to the Generic Environmental Impact Statement for License Renewal of Nuclear Plants, Regarding Indian Point Nuclear Generating Unit Nos. 2 and 3, June 26, 2012, ML12178A660; Generic Environmental Impact Statement for License Renewal of Nuclear Plants, Supplement 38 Regarding Indian Point Nuclear Generating Unit Nos. 2 and 3, Draft Report for Comment, June 2012, ML12174A244. (0718-7-1 [Sipos, John])

Comment: On August 20, 2012, the State submitted comments on the draft FSEIS supplement to the NRC, identifying and discussing the issue of funding for environmental restoration following a major radiological release at Indian Point. See Comments by the New York State Office of the Attorney General on the Draft Supplement to Supplement 38 to the Generic Environmental Impact Statement For License Renewal of Nuclear Plants, Regarding Indian Point Nuclear Generating Unit Nos. 2 and 3, Draft Report for Comment Dated June 26, 2012 ("State Comments") at 4, Aug. 20, 2012, ML12235A409. The State's comments cited a presentation by NRC Commissioner William D. Magwood, IV at the Health Physics Society Mid-Year Meeting on February 6, 2012. See Commissioner Magwood, Nuclear Issues in the Post Fukushima World - Presentation at the Health Physics Society Mid-Year Meeting ("Magwood Presentation"), Feb. 6, 2012, *available at*: <http://www.nrc.gov/about->

nrc/organization/commission/comm-william-magwood/testimonyspeeches.html. In the presentation, Commissioner Magwood noted that "[t]here is no regulatory framework for environmental restoration following a major radiological release." *Id.* at slide 15 (reproduced below). [figure inserted] Based on this information, the State commented that "it [is] not clear that NRC has the desire, capability, or financial resources to respond to a serve accident at Indian Point and ensure the thorough decontamination of the New York metropolitan area including, but not limited to, its water resources—and drinking water resources—in the wake of such an accident." State Comments at 4. In response to the State's comments, NRC Staff stated that "NRC has technical leadership for the Federal government's response to the event," but it also listed eight other federal agencies "who may respond to an event at an NRC-licensed facility, or involving NRC- licensed material." Generic Environmental Impact Statement for License Renewal of Nuclear Plants, Supplement 38 Regarding Indian Point Nuclear Generating Unit Nos. 2 and 3 Final Report, Supplemental Report and Comment Responses ("June 2013 FSEIS Supplement") at A-32, June 2013, ML13162A616. Staff's response did not address Commissioner Magwood's statement regarding the lack of a regulatory framework for environmental restoration following a major radiological release. Nor did Staff explain which agency is responsible for decontaminating the New York metropolitan area following a severe accident at Indian Point, or which agency's decontamination standards will apply to a cleanup. Staff noted that "[c]osts associated with nuclear incidents are governed by the Price- Anderson Nuclear Industries Indemnity Act" and that "[t]he main purpose of the Act is to provide prompt and orderly compensation to the public who may incur damages from a nuclear incident, no matter who might be liable." *Id.* Staff added that there is a combined level of protection under the Price Anderson Act of \$12 billion, and if a nuclear accident involves damages in excess of this amount, the Act "includes a provision that obligates Congress to take appropriate action to provide compensation for public liability claims." *Id.* at A-33. However, while Staff's response explains how the public will be compensated for damages incurred as a result of an accident, such as hotel stays, lost wages and property replacement costs, it does not explain how decontamination costs will be funded in the event of a severe accident at the Indian Point reactors or spent fuel pools. (0718-7-2 [Sipos, John])

Comment: Given the unique characteristics of Indian Point, the State believes it is especially important that the public have access to this information. The Indian Point reactors are located 24 miles north of New York City. More than 17 million people live within 50 miles of Indian Point, a total that is projected to grow to over 20 million by 2035. According to the Atomic Energy Commission, the NRC, and FEMA, more people live within 10 and 50 miles of the Indian Point reactors than at any other operating power reactor in the nation. The communities within the 50-mile radius around Indian Point also contain some of the most densely-developed and expensive real estate in the country, critical natural resources, centers of national and international commerce, transportation arteries and hubs, and historic sites. Thus, the decontamination costs of a severe accident at Indian Point have the potential to be larger than an accident at any other reactor in the country. Documents disclosed by the NRC and other federal agencies indicate that there are conflicting responsibilities of multiple federal agencies for offsite restoration after a nuclear incident and that NRC may not lead cleanup oversight in the event that an accident at a nuclear power plant dispersed radioactive contamination off the reactor site and into the surrounding area. See Douglas P. Guarino, *Agencies Struggle To Craft Offsite Cleanup Plan For Nuclear Power Accidents*, Inside EPA (Nov. 10, 2010), and attached emails disclosed pursuant to FOIA Request (reproduced in part below). [figures inserted] These documents also indicate that money set aside by the Price Anderson Act would not be available to fund decontamination. *Id.* If there is no regulatory framework or source of funding in place to decontaminate the New York metropolitan area in the event of a severe accident at Indian Point, that fact should be disclosed by NRC Staff to the public. Therefore, in light of Commissioner

Magwood's statements and NRC's statements to EPA, the State requests that the U.S. Nuclear Regulatory Commission answer the following questions: 1. Which federal agency is responsible for decontaminating radiation released offsite by a severe accident at the Indian Point reactors and spent fuel pools? 2. Would the Price Anderson Act fund decontamination in the event that that an accident at Indian Point caused radioactive contamination to be dispersed off the reactor site and into the surrounding area? We appreciate your cooperation and look forward to receiving additional information regarding NRC's oversight and funding of offsite decontamination in the event of a severe accident at Indian Point. Based on our conversation yesterday, we trust that you will forward this letter and our request to the appropriate individuals, including James Wiggins, Director, Office of Nuclear Security and Incident Response, and Robert Lewis, Director, Division of Preparedness and Response, Office of Nuclear Security and Incident Response. (0718-7-3 [Sipos, John])

Comment: In terms of our local nuclear power plant, Diablo Canyon... I am a rancher living only seven miles from the facility, so I have everything at stake here. I love this county and am very supportive of our community. I know many residents are happy with PG&E but I believe they can be providing jobs and electricity in much, much better ways. There are plenty of natural resources available (and many untapped) -- solar, wind, tidal -- that would make this county, and country, far safer. Let's not wait until a disaster occurs!! Let's take the lessons from Fukushima to heart. (0734-8 [Hisasue, Carole])

Comment: Please do not store this nuclear waste at San Onofre. Earthquakes happen frequently and could have a disastrous effect on waste not stored well and properly. It would be far preferable to have it gone somewhere. We live about 20 miles from there and we are very glad you shut that crippled reactor down, but we are left with all of the waste to continue to pollute our beautiful area. Help us to get rid of it, please. (0749-1 [Horne, Shari])

Comment: You allowed the plant to operate...Now it is time to get rid of the dangerous waste ASAP. Its presence puts millions at risk. Therefore, San Onofre waste should be put as a top priority for clean up. (0769-1 [Worthington, Juniel])

Comment: Nuclear waste at SONGS should be removed from this site, because of the threat of a tsunami or earthquake. With millions of people living within a 50 mile radius, this should be done ASAP. (0782-1 [Schlegel, Ed])

Comment: In addition, as outlined below, the actual ISFSI is located within the boundaries of the City [Red Wing, MN]. Thus, the City is and will continue to be impacted by the spent fuel that is located in the ISFSI. (0783-1-3 [Harlan, Thomas])

Comment: I am concerned about the thought of storing nuclear fission waste material indefinitely at San Onofre, CA, The reactor is no longer to be used, and the stored waste is just that, waste with no functional purpose. It must be constantly monitored. The material is within 5 miles of populated neighborhoods who have already been exposed to gaseous emitted radioisotopes for the duration of the operation of the former facility and have contaminated groundwater from the tritium water emissions that have been ongoing here. (0793-1 [Sauerheber, Richard])

Comment: We need to again become a green, organic Nation. By correcting this, cleaning the land in San Onofre and figuring out how to store the waste away from a population center or water source, is precisely how this return to a clean and well kept country begins. (0793-4 [Sauerheber, Richard])

Comment: Spent nuclear fuel should be removed from this ecologically sensitive coastal zone. The beaches and communities near SONGS are some of America's finest. Please do everything in your power to protect our future, America's future. (0795-1 [Carey, Kevin])

Comment: Please find a safe solution to the waste at San Onofre. Southern California (from San Diego County to Orange County to LA county and Riverside) is such a hugely populated area and beautiful area that it would be very irresponsible to leave the nuclear waste at the plant . Please act with this in mind. (0799-1 [Powers, Jim])

Comment: Your first target should be San Onofre. Please head the San Clemente City Counsel resolution. (0800-2 [Renzoni, Dante])

Comment: I'm a resident of Southern California; I urge you to responsibly, safely and as quickly as possible remove, and safely store long term the radioactive waste from the decommissioned San Onofre Nuclear Generating Station. Its location on a earthquake fault and at risk of Tsunami, - and with US Marines practicing day and night in the area at Camp Pendleton! - makes it absolutely too vulnerable, dangerous and too risky for millions of residents and future generations. I won't stop monitoring and voicing my concerns until it will be done. I haven't used my time and energy to pressure the decommissioning of the nuclear power plant in the past 2 years to allow nuclear waste to remain here and haunt us and our children. Thank you for your prompt attention to this matter[.] (0804-1 [Colfi, Alessandra])

Comment: it is absolutely vital to this region, the nation and the world, that you find ways to encapsulate all the necessary parts of Indian Point the absolute best way you know and close the plant down now[.] (0807-2 [Krimsky, Pam])

Comment: It is ludicrous. It is insanity. It is insulting to listen to you, the NRC, bulldoze forward with your lies and false assumptions that there will be a safe place to store the radioactive mess you have created and are not taking responsibility for. Diablo Canyon nuclear power plant must stop producing waste immediately. (0811-1 [Paulsen, Carol])

Comment: It is time to shift your focus toward safe, renewable energy. It is time to close Diablo Canyon because there is no safe storage on a multiple, active earthquake fault. (0811-4 [Paulsen, Carol])

Comment: I am opposed to relicensing the Diablo Canyon facility. (0817-2 [Munson, Marcia])

Comment: Certainly TVA is unlikely to exist 100 years from now. TVA is reeling from the apparently permanent decline in energy intensity and in TVA sales due to increased efficiency. As electricity costs rise, private actions to reduce consumption will increase, causing a permanent loss of demand even as population may grow. Likewise, the external investment in grid connected distributed renewable solar and the availability of inexpensive wind generated electricity are making TVA's model of centrally generation outmoded. This is true whether the generation is from coal or nuclear. (0821-12 [Paddock, Brian])

Comment: Moreover Sequoyah is still under scrutiny as to flood safety in the event of failure of one or more of TVAs upriver dams. TVA and NRC continue the checklist process for license renewal which looks only at the longevity of reactor parts and refuses to consider that these reactors are now directly adjacent to a large and fast growing (and greening) city. This is a risk and accident consequence factor that should cause both TVA and the NRC to consider decommissioning the reactors in light of the reduced need for electricity within the TVA fence

that has occurred steadily over the last eight years and is projected to last into the 2020's according to TVA. (0821-4 [Paddock, Brian])

Comment: In Wisconsin, the NRC granted license extensions to Point Beach nuclear plant's 2 reactors in Manitowoc County as well as to the Kewanee nuclear plant 27 miles south of Green Bay on the shores of Lake Michigan. Kewanee has recently closed due to financial costs. Kewanee has spent fuel rods stored in an on-site pool. The NRC granted both Point Beach and Kewanee license extensions, after dismissing, as inappropriate, citizen testimony that both plants were leaking tritium. The NRC did not mandate any stoppage of the leaks. Wisconsinites who knew about this causal acceptance found it unacceptable that some people have become, so to speak, sacrificial lambs to be harmed at the altar of nuclear power. This blatant causal acceptance consisted of a breach of the very safety that the NRC's oversight authority should have corrected, but it didn't. A test reactor exists at the University of Wisconsin-Madison. There is another closed plant south of LaCrosse, Wisconsin near the shores of the Mississippi River. Prairie Island is on an island between Wisconsin and Minnesota. (0823-10 [Michetti, Susan])

Comment: In one example, Prairie Island reactors are situated on an island that floods in the Mississippi River between Wisconsin and Minnesota. Public testimony prior to the licensing of Prairie Island reactors expressed grave concern about the vulnerability of that location on an island in the Mississippi River with a history of past flooding. Grave concern was expressed about that location's wetness in terms of its inability to hold back contamination from waters. Native Americans stated that licensing a nuclear power plant on Prairie Island would put into place the likelihood that their sacred drinking water would become contaminated with radioactivity. The NRC failed to scientifically assess and analyze this vulnerability correctly after the very environmental vulnerabilities were stated during public testimony as concerns with the potential to contaminate the Mississippi River with radiation. Today, contaminated drinking water has become a reality. The NRC's license approval process inadequately protects environmental and human safety when the environmental conditions present contain unique vulnerabilities, such as this location on a small island that periodically floods. The NRC did not deny that Prairie Island reactor license. The Prairie Island license warranted denial based on environmental vulnerability that predicted drinking water contamination in time. This [the licensing of the Prairie Island Nuclear Generating Plant] is an example of the harm being caused by failures and distortions occurring in the decision-making. Native American trust lands require being provided protection for their water sources, particularly their drinking water. All water runs together in uncontained ways. All water connects. Any water contamination reaches other water sources over time. (0823-33 [Michetti, Susan])

Comment: Washington's Columbia reactor is close to Columbia River and unacceptably contaminates drinking water[.] The Columbia reactor in Washington is located close to the Columbia River. It was predictable scientifically that Columbia would contaminate drinking water sources, and this has happened. This type of unscientific oversight and decision-making at the NRC is unacceptable. (0823-34 [Michetti, Susan])

Comment: Indian Point is unacceptably close to Hudson River which threatens safety[.] Indian Point reactors are located close to the eastern shore of the Hudson River near a huge population. This has unique environmental vulnerabilities. (0823-35 [Michetti, Susan])

Comment: Turkey Point is unacceptably next to fragile aquifers and Everglades National Park and threatens environmental safety[.] The Turkey Point reactors are located close to fragile aquifers next to Everglades National Park with unique environmental vulnerabilities. (0823-36 [Michetti, Susan])

Comment: Diablo Canyon unacceptably is in an earthquake zone that threatens safety[.] Diablo Canyon is located in a known earthquake zone with high seismic risk for a nuclear power plant with unique environmental vulnerabilities. (0823-37 [Michetti, Susan])

Comment: San Clemente is a very different place from what it was when SONGS 2 & 3 were approved. Our population then was about 25K, whereas today it is over 65K. Additionally, all surrounding communities have grown exponentially as well. We wouldn't have been able to successfully evacuate in 1980, and we certainly couldn't evacuate today. Terrorism was unheard of in 1980. Today, with political unrest and growing tensions around the world, and an influx of radical elements residing within the United States, it is of constant concern and a very real reality as evidenced by 9-11. Having a nuclear waste storage facility amidst such a highly populated area and not far from the border of Mexico that holds the potential to be an attack the United States would never forget, is daunting to even consider. When you now factor that the area is riddled with fault lines, a few holding the potential for very large seismic events, as well as tsunamis, the stark reality of this areas incompatibility for spent fuel storage is blatant. We have lived with the risks associated with having a now aging nuclear power plant at our back door for more than 30 years. The time has come to find a site that isn't near a major population hub, isn't on the coast with fragile ecosystems and is away from major fault lines. PLEASE...make the people and families of San Clemente and the surrounding communities your top priority. Relocate the spent fuel to another, more suitable, more sensible area. A San Clemente resident (0837-1 [Korsen, G])

Comment: We'd like to see the complete decommissioning of all nuclear power plants. Further we strongly oppose the storage of nuclear waste at San Onofre, California. We don't want that crap stored here! They've already proven they can't be trusted. (0848-2 [Whiting-Broeder, Pamela])

Comment: The decommissioned San Onofre generating station is but one of many such facilities in the U.S. Even if each and every unsafe reactor were to be decommissioned, we'd still be left with the problem of nuclear waste, an extreme hazard in and of itself. For that reason, which seems sufficient, I want to be assured by your Office that the nuclear waste problem isn't allowed to percolate and sit like a time bomb waiting to go off. (0857-2 [Anonymous, Anonymous])

Comment: I live in a Chicago suburb, I receive my water from Lake Michigan. We are being poisoned by bp dumping chemicals in Lake Michigan. Now another corporation wants to bury RADIOACTIVE waste under another Great Lake. Why do corporations get to abuse the privilege of being the earth's stewards by fouling our drinking water, air & soil? They ruin it for the common man while they laugh all the way to the bank! The Great Lakes are under assault by these corporations, & the government who is paid for by the peoples tax dollars keep buckling under to these corporations that take no ones rights into consideration! We do not want any more waste radioactive or other wise to be placed in or under or by these national treasures! The Great Lakes belong to everyone & should not be allowed to be fouled by these for profit corporations! Lets keep the integrity of the Great Lakes intact. Have you not seen what has happened to the Pacific Ocean because of radioactive water from the fukishama nuclear plant being released into the ocean? Wake up & smell the coffee this could happen to our great lakes, they could become a dead zone! Believe me these corporations will be long gone with their cash & won't take anyresponsibility for clean up. How many super fund sites are in this country already? that the peoples taxes cannot afford to clean up because the corporations skipped out on their responsibilities? I mean what could possibly go wrong? RIGHT?<http://thinkprogress.org/climate/2013/12/20/3096231/chevron-illegally-dumping-toxic-drilling-waste/>. (0858-1 [Selesky, Laura])

Comment: Although I have long been aware of environmental issues, once Indian Point opened I did not pay too much attention to it. Recently, however (even before the tsunami, earthquake, and meltdown at Fukushima Daiichi), I have begun to learn more about the Indian Point nuclear facility, and frankly what I have learned scares me. (0864-1 [Gellert, Sally Jane])

Comment: Indian Point lies on 2 fault lines; it is considered by some to be in the least safe site of any reactor in the country. We in the Hudson Valley and New York City metropolitan area, including northern New Jersey, live with possible disaster as a remote yet frightening possibility. In addition, of course, Indian Point leaks invisible radiation constantly, as well as heating the river water that it draws in vast quantity in everyday operation of the reactors and to cool the ever-increasing number of irradiated fuel rods. These day-to-day dangers are outside the scope of this hearing, but are affecting us every day, whether or not we acknowledge it publicly. (0864-3 [Gellert, Sally Jane])

Comment: NRC COULD TAKE ACTION AND DEMAND ALL SPENT FUEL RODS BE PUT INTO DRY STORAGE AND SHUT DOWN DIABLO. (0887-1 [Chappellet, Carissa])

Comment: As there is not much more one could say to this presently - paid NRC puppereria concerning the continuous catastrophic Devil's Armageddon which has destroyed & doomed our central coast, California & the Pacific Ocean. You must immediately shut down the Devil's bank account. (0905-1 [Schmidt, Otto])

Comment: The grave risks of DCR outweigh all arguments in favor. The risks are not only contamination by the ever-increasing, unprotected stores of spent fuel, but even more so the threat of a catastrophic meltdown when (not if) the active fault moves, on which DCR is built. You in Washington are safe from all this, Mr. Secretary. We, who live in DCR's shadow, are not. We will gladly pay more for our electricity to have the threat of a radiation catastrophe --brought on by an earthquake, a terrorist plane strike or simple operator error--removed from us. Please side with the people and not with PG&E, and have DCR closed down now. (0907-3 [Bethlenfalvay, Marina])

Comment: PETITION TO UPGRADE HEALTH AND SAFETY MEASURES AT INDIAN POINT The ongoing crisis at the Fukushima Daiichi Nuclear Power Plant in Japan brings home the disastrous consequences of a catastrophic release of high-level radiation from nuclear reactors or from spent fuel storage Indian Point Nuclear Power Plant. The measures embodied in this petition, if acted upon, would make us all safer, and are appropriate whether the plant is closed and decommissioned or is relicensed and continues to operate. Therefore, we, the undersigned, request that the following actions be implemented as soon as possible with regard to Indian Point Nuclear Power Plant: 1. Move spent fuel rods into hardened dry cask storage as soon as is safely possible 2. Provide full containment for the spent fuel pools and establish independent back up electricity and cooling for the spent fuel pools 3. Perform a comprehensive evaluation of the faulty inflatable gasket used in the exchange canal between the reactor and storage in fuel pool. 4. Extend the evacuation zone from 10 to 50 miles as the Nuclear Regulatory Commission recommended for Americans in Japan 5. Remedy the flaws and deficiencies regarding emergency evacuation raised by the James Lee Witt report; consider lessons learned from Fukushima and Hurricane Sandy in evacuation planning. Congress should hold hearings on the viability of evacuation around nuclear plants. 6. Consider all seismological data and upgrade infrastructure accordingly for continued operation. (0918-3 [Church of New York, The Riverside])

Comment: Because so much uncertainty surrounds the Yucca Mountain dump proposal, as well as other high-level radioactive waste proposals, Petitioners-Intervenors contend that waste generated at Palisades during the 20 year license extension could very well be stored at Palisades *indefinitely*, a scenario inadequately addressed by the applicant and NRC. [emphasis added; note that "Indefinite Storage" is exactly what NRC refers to in the WC DGEIS, on Page 1-12, as: "Assumes no repository becomes available; Indefinite storage and handling of spent fuel."] (0919-1-11 [Kamps, Kevin])

Comment: The more casks loaded on the storage pads at Palisades, the more risk of erosion to the sand supporting the pads, given the large weight of the casks themselves (well over 100 tons each), weather related erosion of the sand dunes, as well as the erosion that will occur due to more severe weather impacts from the global climate crisis and climate de-stabilization. Arresting erosion at both pads is important to safety and radiation containment over the long haul, given the proximity of the waters of Lake Michigan. The State of Michigan and the U.S. Army Corps of Engineers have designated the sand dunes upon which the older pad is located - so close to the waters of Lake Michigan -as a high-risk erosion zone. The Lake Michigan dunes are subject to "blow outs" where entire dunes are blown out during wind storms and lightning strikes. See F. Nori, P. Sholtz, and M. Bretz (Department of Physics, The University of Michigan), "Sound-Producing Sand Avalanches," Scientific American, Vol. 277, No. 3 (September 1997). (0919-1-12 [Kamps, Kevin])

Comment: The Palisades dunes could, in a wind storm or lightning strike, shift, blow and cover the dry cask storage area. As weather patterns intensify (as anticipated) this potential for erosion will increase. Additionally, the dunes and shore line are geologically prone to sand avalanche. A sand avalanche coupled with a seismic event could compromise the integrity of one or more casks at Palisades." (the entire REQUEST FOR HEARING AND PETITION TO INTERVENE is posted online at <http://www.nirs.org/reactorwatch/licensing/petition.pdf>) (0919-1-13 [Kamps, Kevin])

Comment: The contention regarding Consumers Energy's Palisades dry cask storage (now owned and operated by Entergy Nuclear) violating NRC earthquake safety regulations was prompted by a warning from NRC dry cask storage inspector for the Midwest Region, Dr. Ross Landsman, dating back to February 17, 1994. Dr. Landsman wrote to NRC's Chairman, Ivan Selin, warning him about the risk at Palisades that an earthquake could result in high-level radioactive waste storage casks falling into Lake Michigan, or being buried in loose sand. Dr. Landsman wrote: "Actually, [it's] the consequences that might occur from an earthquake that I'm concerned about. The casks can either fall into Lake Michigan or be buried in the loose sand because of liquefaction "It is apparent to me that NMSS [NRC's Nuclear Materials Safety and Safeguards department] doesn't realize the catastrophic consequences of their continued reliance on their current ideology." (0919-1-14 [Kamps, Kevin])

Comment: The Palisades reactor has no place to store its overflowing irradiated nuclear fuel inventory within NRC regulations. The indoor irradiated fuel storage pool reached capacity in 1993. But the outdoor dry cask storage pads at Palisades, both the older one nearer Lake Michigan and the newer one further inland, are in violation of NRC earthquake regulations. 10 CFR § 72.212(b)(2)(i)(B) requires that: Cask storage pads and areas have been designed to adequately support the static and dynamic loads of the stored casks, considering potential amplification of earthquakes through soil-structure interaction, and soil liquefaction potential or other soil instability due to vibratory ground motion. . . . According to Petitioners' anticipated expert, Dr. Ross Landsman, former U.S. Nuclear Regulatory Commission Region III dry cask storage inspector, the older pad violates the liquefaction portion of this regulation, and the new

pad violates the amplification portion of the regulation. Petitioners contend that neither the older nor new dry cask storage pads at the Palisades plant were designed in consideration of the factors contained in the cited regulation. (0919-1-6 [Kamps, Kevin])

Comment: In 1993, Consumers Power (now Consumers Energy) assured a federal district judge that if it encountered problems with loaded dry casks at Palisades, it would simply reverse the loading procedure and return the high-level radioactive waste to the storage pools. But the fourth cask loaded at Palisades, in June 1994, was shortly thereafter admitted by Consumers Power to be defective, having faulty welds. However, eleven years on, Consumers has yet to unload the defective cask, because it cannot. Petitioners state that Consumers perpetrated a fraud upon the court and the public, with the complicit support by the NRC, and has critically undermined its credibility as to any pledges about the safety of dry cask storage. The significance of this problem with cask #4 is considerable. For example, the configuration of the 18 to 19 dry casks currently stored on the older pad nearer Lake Michigan is such that the casks furthest back cannot be moved or unloaded until all other casks in front of them have been moved out of the way first. This configuration increases the risks, making it very difficult to address emergencies involving certain casks in the configuration in a timely manner. (0919-1-7 [Kamps, Kevin])

Comment: In the case of Vermont Yankee, NRC and industry eventually just assumed that the lost irradiated fuel was mistakenly shipped away, and buried in a ditch at Barnwell, South Carolina, mistaken for "low-level" radioactive waste, to dose workers, shippers, and residents downstream of the leaking dumpsite. At Humboldt Bay, NRC and industry eventually just assumed that the missing irradiated nuclear fuel was simply crushed beneath waste transfer casks weighing a hundred tons, and pulverized into particles which dissolved into the high-level radioactive waste storage pool cooling water, to clog filters and dose workers. (0919-2-16 [Kamps, Kevin])

Comment: Re: NRC's mention of "reinforced concrete pads" at line 35--At Palisades in MI, the pads are "reinforced" with 55 feet of loose sand underneath. That is, although they are three feet thick themselves, the pads are not anchored to anything. They are "floating" on top of 55 feet of loose sand. They are located right next to Lake Michigan, source of drinking water, and so much more, for tens of millions of people. This is a violation of NRC earthquake safety regulations, and a major risk to Lake Michigan. At Dresden in IL, the pads are "reinforced" with dirt, next to the river, thanks to an NRC regulatory exemption due to a bad pad pour. During a tour of nuclear industry and government regulatory officials conducted of Dresden's ISFSI in September 2001, as part of the PATRAM [Packaging and Transportation of Radioactive Materials] conference I attended, an Exelon spokesman overseeing the ISFSI pad admitted that NRC had granted an exemption do to the bad cask pour. (0919-4-21 [Kamps, Kevin])

Comment: On Page 2-26 (lines 32-35) to 2-27 (lines 1-2), NRC states: "The kinds of aging effects managed under an aging management program include, but are not limited to: concrete cracking and spalling; loss of confinement; loss of material; and reduction in heat transfer (e.g., by blocked air duct screens). The application of aging management programs may include structure monitoring; monitoring of protective coating on carbon steel structures; ventilation surveillance; welded canister seal and leakage monitoring programs; and bolted canister seal and leakage monitoring programs (DOE 2012b). It was just such meaningful oversight on aging degradation issues at Palisades ISFSIs that environmental interveners were seeking during the license extension proceeding, particularly in regards to the defective cask already identified there. But the interveners were rebuffed by NRC's ASLBP. (0919-4-3 [Kamps, Kevin])

Comment: I just hope that the new ownership, General Electric-Hitachi, decides to keep the heat turned on at its Morris ISFSI facility (well, the heat in the building, and the cooling water circulation in the pool storing the 772 tons of irradiated nuclear fuel, that is!). For just a half-mile away, at Dresden nuclear power plant, Commonwealth Edison decided to turn the heat off at Unit 1 after its permanent shutdown. Eventually this led to the freezing of pipes on service water systems in the winter time, leading to a large flood in the basement. Had vulnerable pipes and other systems, structures, and components frozen on the storage pool for high-level radioactive waste at Dresden 1, a pool drain down and high-level radioactive waste fire could have taken place, causing a radioactive catastrophe for Chicago downwind. It's interesting that even with 20 employees, GE Morris seemed unaware of a radioactive hot spot on the pool walkway that I discovered with a handheld RadAlert monitor in September 2001, on the same tour where I learned that NRC had granted Commonwealth Edison/Exelon an exemption due to the bad pad pour at the Dresden ISFSI. I was the only person on the GE Morris tour who had a real-time radiation monitor, although we all wore film badges. My RadAlert alarmed, revealing a reading of some 4,500 counts per minute, as I stood about midway down the walkway alongside the GE Morris pool. Others on the tour were surprised and even alarmed at the radiation levels my RadAlert was revealing. One of those 20 GE Morris employees, the one leading the tour, then rushed us along. My point is, I hope those 20 workers at GE Morris, and their counterparts at Dresden right next door, are very good at what they do. Between the two immediately adjacent nuclear facilities, there are some 3,000 metric tons of irradiated nuclear fuel, one of the biggest such concentrations in the entire country. This is a mother lode of radioactive risk, upwind of millions in the metro Chicago area. (0919-5-10 [Kamps, Kevin])

Comment: Re: Page 3-6, line 29 and following, it is disconcerting to learn that a mere 35 workers watch over more than 50 casks at the Maine Yankee site. It is even more disconcerting to learn that only 10 workers watch over 240 casks holding high-level radioactive waste at the Fort St. Vrain site in CO. Only a small number of whom, presumably, are security guards. How many on those teams are PR officials? What role do they play in securing and safeguarding the high-level radioactive wastes? (0919-5-11 [Kamps, Kevin])

Comment: At Page 3-15, in Section 3.5, Geology and Soils, NRC speaks confidently about earthquake preparedness and seismic safety. But what about Palisades' dry cask storage near Lake Michigan? What about its violation of NRC earthquake safety regulations, described above? (0919-5-12 [Kamps, Kevin])

Comment: I'd like to here finish a comment I was making that was interrupted by NRC's strict three minute rule at the Perrysburg, OH public comment meeting. I had pointed out that the War of 1812 had also raged in the Toledo area 200 years ago, begging the question, what does the next 200 years have in store for the high-level radioactive wastes stored on the surface at nearby Davis-Besse atomic reactor? And I was going to close with a comment about seismic risks in the area. Tecumseh, the great Shawnee War Chief who led a broad Native American confederation, and fought in alliance with the British against the Americans in the War of 1812, is reported to have predicted the New Madrid earthquakes of 1811 to 1813. Based on historical records of the time, such as news accounts in the eastern U.S., personal journal entries, etc., as well as physical evidence, the monster quakes have been calculated to have been around 8.0 in magnitude on the Richter scale, which would make them the largest quakes in North American recorded history. Epi-centered in New Madrid, MO, the powerful quakes reversed the flow of the Mississippi River; rang church bells as far away as Maine; and created giant waves on the Great Lakes; among many other impacts. Has the NRC analyzed the seismic risks of 8.0 magnitude, or larger, earthquakes on pool and dry cask storage in the New Madrid zone region? 200 years after those quakes struck, some seismologists are concerned they are overdue to

strike again. Of particular concern are the ISFSIs at Palisades, in violation of NRC earthquake safety regulations, and immediately adjacent to Lake Michigan, part of the Great Lakes drinking water supply for 40 million people in 8 U.S. states, 2 Canadian provinces, and a large number of Native American First Nations. (0919-5-13 [Kamps, Kevin])

Comment: Re: NRC's statement on Page 3-16, beginning at line 11, that "Commercial mining or quarrying operations are not allowed within nuclear power plant boundaries (NRC 2013a)"...this is odd, because it seems that natural gas fracking is being allowed, by NRC, and other decision making bodies, within a mere ¼ mile from the Beaver Valley nuclear power plant in Shippingport, PA. What are the seismic risks of this? On New Year's Eve, 2011, a nearly 4.0 quake struck Youngstown, OH. Fracking activities were suspected immediately, for Youngstown had never experienced such a quake before in recorded history. The Governor of Ohio acknowledged immediately that fracking activities were likely to blame. This has recently been confirmed to be the case: <http://www.nbcnews.com/science/fracking-practices-blame-ohio-earthquakes8C11073601>. (0919-5-14 [Kamps, Kevin])

Comment: Also at one New Jersey plant, a ground water cleanup of a diesel fuel leak was never required to monitor for radionuclides even though the cone of drawdown from the fuel cleanup was down gradient of a major plume of tritium contamination. The ground water pumped from the cleanup was discharged to the local sanitary sewer without any analysis. (0920-21 [Foster, Ruth])

Comment: At Oyster Creek there was an ongoing diesel fuel ground water cleanup which was down-gradient of the tritium leak. Neither NRC nor the plant sampled the effluent from the diesel fuel cleanup for tritium even though the effluent was being discharge to a sanitary sewer. (0920-46 [Foster, Ruth])

Comment: In the area of the Northeast that I live in, around the PNPS, there were major storms that were never seen in the recent history of the area because of the rising level of the ocean and were never taken into consideration in the original plan or presently, the building of a storage pad-----which was started without any proper permitting approval. The Entergy Corporation up to that time had to have a permit to build storage buildings and reception tents but not for the beginning of permanent waste storage. Nor is there to be allowed any public participation where the environment has been proven to be compromised. (0933-5 [Anonymous, Janet])

Comment: I want to address my remarks to bring attention tot what is going on 40 miles up the road at the Zion Nuclear Power Generation Plant, the site of the largest dismantling or decommissioning of a nuclear reactor in history. In 2014, over 1,000 tons of high-level radioactive waste is going to be transferred into dry casks, as reported by Pat Daley of Zion Solutions in August 2013. At Fukushima, Japan, the same fuel transfer of over 400 tons of radioactive waste is being carried out. What we have here is a situation where we who live in the Chicago-Milwaukee Metropolitan Area, over six million of us, are going to be exposed to comparative or greater risk - from a larger and dirtier radioactive waste fuel transfer than what is taking place at Fukushima. Both projects are expected to take a year to complete. Although everyone is doing their best at Zion Solutions, a shell company created for the express purpose of managing the Zion decommissioning, and funded by public trust funds of almost a billion dollars, this scale of decommissioning has never been attempted before. We, the people who live within a 50-mile radius of Zion, remain deeply concerned about our safety and we are aware that there really is no "safe" way to manage and isolate radioactive waste. Fuel transfer represents the "safest of the unsafe" solutions to this impossible problem. (0934-1 [Lewison, Linda])

Comment: Forty years ago in the suburbs of St. Louis, Missouri, the NRC allowed the unlicensed dumping in a now residential area of the largest amount of Thorium-230 in any actual nuclear waste disposal site in the country. It remains there today, one of the NRC's waste sites that cannot be delegated the proper remediation due to legal maneuverings at a time, the 1970s, when every aspect of the Federal nuclear program knew the risks to the public and yet allowed itself to transfer ownership of its waste in an intentional loopholed irradiation of a large population. (0935-1 [Uhls, Agnes])

Comment: Specific to this region and Lake Erie, is flooding potential. There is what is known as a seiche where you have straight line winds which blow the water out to Buffalo, and the water sloshes back. One specific concern that applies to Fermi, Davis-Besse, Perry is Lake Erie susceptibility to Seiche / flooding. Lake Michigan and Lake Huron have also had Seiche events. Pasted below are a just a handful of links to Lake Erie Seiche reports. Lake Erie flooding May 31, 2012 - Lake County - Madison, Ohio[;] Lake Erie 1942 - 8 people killed [;] Lake Erie 1882 - Tidal Wave [http://www.wkyc.com/video/1668105962001/1/3-teenagers-pulled-in-Lake-Erie-by-rareseiche-wave\[;\]](http://www.wkyc.com/video/1668105962001/1/3-teenagers-pulled-in-Lake-Erie-by-rareseiche-wave[;]) 2003 Seiche in Monroe at Fermi [http://www.glerl.noaa.gov/seagrant/glw/photos/Seiche/1113Storm/November2003.html\[;\]](http://www.glerl.noaa.gov/seagrant/glw/photos/Seiche/1113Storm/November2003.html[;]) 1848 Lake Erie Seiche [http://oceanservice.noaa.gov/facts/seiche.html\[;\]](http://oceanservice.noaa.gov/facts/seiche.html[;]) [http://www.dnr.state.oh.us/OhioGeologicalSurvey/tabid/23637/Default.aspx\[;\]](http://www.dnr.state.oh.us/OhioGeologicalSurvey/tabid/23637/Default.aspx[;]) [http://downtown.wgrz.com/news/people/71936-lake-erie-seiche-disaster-1844\[.\]](http://downtown.wgrz.com/news/people/71936-lake-erie-seiche-disaster-1844[.]) (0945-2 [Keegan, Michael J.]

Comment: In 1972, the Davis-Besse site was flooded for over a month. If the plant had been operating at that time, it would have been a disaster. (0945-3 [Keegan, Michael J.]

Comment: Kevin Kamps with Beyond Nuclear has expressed the following concerns, I enter our working communications into the record. Kevin Kamps writes: Fukushima scale releases (or order of magnitudes larger) into Lake Erie, from Fermi 2 (or 3) or Davis-Besse, due to a high-level radioactive waste storage pool fire, would be bad, at least for those millions downstream (including in the connecting rivers, Lake Ontario, the St. Lawrence River) who drink its water, boat or swim its waters, eat its fish, etc. Being so shallow, Lake Erie can't really "dilute" the radioactivity, like the Pacific Ocean can This is a site specific risk at Fermi and D-B. (0945-5 [Keegan, Michael J.]

Comment: In addition a 40 foot wave off of Lake Huron, due to the White Hurricane of Nov. 1912, one hundred years ago. The 1811-1812-1813 New Madrid quakes -- estimated as Magnitude 8 on the Richter scale, the largest in North American history could happen again. These earthquakes created giant waves on the Great Lakes. Even Superstorm Sandy created large waves on Lake Michigan - 30 footers -- which fortunately hit Michigan City, IN, and not Covert, MI (Palisades), Bridgman, MI (Cook), Charlevoix, MI (Big Rock Point, HLRW still there), or Zion, IL (two reactors permanently shutdown, but waste still there). If on Lake MI, why not Lake Erie. With climate destabilization, hurricanes on the Great Lakes could become more common. Then there are tornadoes: water spout near Zion a few weeks back [<http://www.beyondnuclear.org/nuclear-power/2013/9/12/water-spouts-on-lake-michigan-close-to-zion-hlrw-storage-poo.html>]; Davis-Besse of June 1998; Fermi 2 of June 2010. All risks to unleashing the HLRWs into the environment. (0945-7 [Keegan, Michael J.]

Comment: Also site-specific: both Fermi 2's Mark I containment, and Davis-Besse's cracked and cracking worse containment, are no containment whatsoever. Look what happened to the Mark Is at Fukushima Daiichi. Davis-Besse's containment could completely fail during a meltdown. These reactor risks are HLRW risks as well -- if the reactors meltdown, that could

directly cause the wastes to unleash into the environment, as well. Fukushima Daiichi Unit 4 is such a case in point -- the explosion at the non-operating Unit 4 reactor building could yet lead to a collapse of that reactor building, including the HLRW storage pool, as due to another large quake there. If that were to occur, and the cooling water was lost, then the radiological releases would dwarf what has already occurred to date due to the 3 reactor core meltdowns. Our pools - as at Fermi 2, as at Davis-Besse -- contain much more waste than Fukushima Daiichi Unit 4. (0945-8 [Keegan, Michael J.]

Comment: Indian Point's a nucle.ar power plant near here [SOLO SHOUT] Nineteen miles! That makes 50 tons of spent fuel every year. That waste is stored in poo-ools And because we are not foo-ools We know we have good reasons to be scared. If Entergy keeps spinning what it's spun, And their fight for relicensing is won, Fifteen million on the roads May flee their doomed abodes, A fifty-mi-ile race they'll have to run. A terrorist could hit it with a bomb. The earthquake in Japan gave us some qualms. Where will we find the answer To protectingfolks from cancer, Who haven't yet been blown to Kingdom Come? Bring us solar, bring us hydro, bring us wind. Bring us energy from sources that won't end. [SLOW] Before we could trust uranium, We'd need holes in our cranium. [RESUME SPEED] We haven't yet gone that far 'round the bend! (0959-1 [Grannies, Raging])

Comment: Oh, we are a gaggle of grannies Urging you off of your fannies. Indian Point Is a dangerous joint. Shut it down! With all that Entergy's spending To keep their license from ending. You'd think they'd go broke, With mirrors and smoke. Shut it down! The NRC approves of Waste storage by Entergy [SLOW] The NRC is a lapdog To the nuclear in -dus -try. So, we may be a gaggle of grannies, But we've gotten off of our fannies. Stop Entergy's spin! If they lose we win! Shut it down! We really mean it. Shut it down! And we mean business. Shut -it - down! (0959-2 [Grannies, Raging])

Comment: Oh, Entergy says not to worry. 'Cause earthquakes can't happen here, no. But under the Indian Point plant Lurks the fault zone that's called Ramapo Look at routes for evacuation If Indian Point should melt down. Go test-drive those roads for escapin' And learn you can't get out of town. CHORUS: Shut it down! Shut it down! Indian Point is unsafe, we know! Shut it down! Shut it down! Indian Point has to go! The nuclear waste that is stored here Is cause for us all to unite. If only we knew how to do it, We'd shut Indian Point down tonight. CHORUS Oh, NRC, rule as you ought to! You know you should issue a ban To save New York State from such horrors As the tragic events in Japan. (0959-3 [Grannies, Raging])

Comment: How will !!!leave town If Indian Point melts down? Hi-ho, if that place blows, We'll wind up underground. Imagine crowded roads When we leave our abodes. Hi-ho, this plant must go Before the thing explodes. (0959-4 [Grannies, Raging])

Comment: As a resident of Aiken, South Carolina, I know only too well the dangers of the waste that comes from the nuclear industry. Recently, the Savannah River Site Citizens Advisory Board voted no to storage of spent nuclear fuel, 70,000 tons that was supposed to be headed to Yucca Mountain. (0965-1 [Hall, Christopher])

9. Comments Concerning the Proposed Action & Purpose and Need

Comment: In the Scoping Decision, Staff rejected both of these alternatives: Interested parties submitted hundreds of comments that suggested the NRC should consider a cessation of all licensing activities or cessation of all nuclear power plant operations as an alternative. A variety

of other scoping comments suggested that the NRC should require the implementation of HOSS [hardened onsite storage] as an alternative. The NRC considered but ultimately dismissed these suggested alternatives for the purposes of this GEIS. Cessation of licensing activities and overall reactor operations does not satisfy the purpose and need for the GEIS. With regard to HOSS, the NRC is already considering implementing revised security requirements as part of the ongoing ISFSI security rulemaking effort. The rulemaking effort is described in the December 16, 2009, Federal Register notice (74 FR 66589), "Draft Technical Basis for Rulemaking Revising Security Requirements for Facilities Storing SNF and HLW; Notice of Availability and Solicitation of Public Comments." Staff Scoping Decision at 12. The Staff's conclusions directly conflict with well-established legal precedents and, most importantly, ignore the mandate of the Court of Appeals in *New York v. NRC*, 681 F.3d 471 (D.C. Cir. 2012). (0001-13 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: Although the Commission kept moving the date by which it was confident there would be a permanent and operational nuclear waste disposal facility, the existence of such a date-and thus a finite date for storage of spent fuel at the site following plant shutdown-was the key component of the Commission's confidence that there would be minimal environmental impacts of spent fuel storage at plant sites following cessation of plant operations. By concluding that there was no reasonable possibility of long-term, much less indefinite, storage of spent fuel at reactor sites, NRC concluded it never needed to consider alternatives to its plan to continue to authorize generation of more nuclear waste. All this changed when the Commission came to the realization that it was no longer possible to determine a date certain by which a permanent nuclear waste repository would be available. Thus, over 30 years after *Minnesota* was decided, the Court in *New York v. NRC* once again directed the Commission to consider the environmental impacts associated with there never being a permanent, safe, and adequate waste disposal facility: "We further hold that the Commission's evaluation of the risks of spent nuclear fuel is deficient in two ways: First, in concluding that permanent storage will be available 'when necessary,' the Commission did not calculate the environmental effects of failing to secure permanent storage-a possibility that cannot be ignored." *New York*, 681 F.3d at 473 (emphasis added). This holding effectively adopted what Judge Tamm said over 30 years earlier: "[I]f the Commission determines it is not reasonably probable that an offsite waste disposal solution will be available when the licenses if the plants in question expire, it then must determine whether it is reasonably probable that the spent fuel can be stored safely onsite for an indefinite period." *Minnesota*, 602 F.2d at 419-20 (Tamm, J., concurring) (footnotes omitted). By restricting consideration of alternatives and explicitly excluding the alternative of postponing further spent fuel generation until a permanent, safe, and adequate waste disposal facility exists, and excluding use of dry cask storage in lieu of spent fuel pools after spent fuel is 5 years old, the Staff is failing to provide the full environmental review mandated by the federal court. (0001-15 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: The Staff's failure to include all reasonable alternatives in its Scoping Decision stems initially from its failure to focus more precisely on the underlying reason for the GEIS. According to the Staff Scoping Decision, the GEIS will be used to update the Waste Confidence rule (Staff Scoping Decision at 38), the purpose of which "is to develop and implement a regulatory approach that efficiently evaluates the environmental impacts of spent nuclear fuel after the licensed life for operation of a commercial nuclear reactor and prior to ultimate disposal" (Staff Scoping Decision at 2). That description tends to obfuscate the true purpose of the GEIS, which is to provide a basis for NRC to determine whether to issue or renew licenses and, if it issues or renews a license, what conditions should be imposed in the license. As the D.C. Circuit recognized, NRC is required to analyze the environmental impacts of the temporary storage of spent fuel before it licenses or relicenses the operation of a nuclear reactor because

that operation will generate spent fuel for which there as yet is no permanent repository. New York, 681 F.3d at 473 (holding that the fact that permanent storage may never be achieved is "a possibility that cannot be ignored"); *see also id.* at 477 ("It is not only reasonably foreseeable but eminently clear that the WCD will be used to enable licensing decisions based on its findings."). If, as the D.C. Circuit held in *New York v. NRC*, the major environmental impacts that must be assessed are the impacts of long-term and indefinite storage of spent fuel at reactor sites, then the focus of the study of alternatives in the GEIS must be the alternatives that will reduce those impacts. And the Commission must look at "*all* reasonable alternatives." 40 C.F.R. § 1502.14(a) (emphasis added). (0001-16 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: Given the breadth and weight of scientific support for the proposition that there are significant environmental benefits from dry cask storage for all fuel that it is more than 5 years old, this reasonable alternative must be studied in the Commission's review of "*all* reasonable alternatives." 40 C.F.R. § 1502.14(a) (emphasis added). Although the Staff does not directly reject the advantages of dry cask storage, it seeks to avoid consideration of that option by noting that: NRC is already considering implementing revised security requirements as part of the ongoing ISFSI security rulemaking effort. The rulemaking effort is described in the December 16, 2009, Federal Register notice (74 FR 66589), "Draft Technical Basis for Rulemaking Revising Security Requirements for Facilities Storing SNF and HLW; Notice of Availability and Solicitation of Public Comments." Staff Scoping Decision at 12. This attempt to avoid addressing the mitigation potential of the dry cask storage alternative fails for several reasons. First, it is inconsistent with the Commission's directive in its Staff Requirements COMSECY-12-0016. Second, it violates NRC's regulations implementing NEPA. Third, it is contrary to well-established federal law which has been applied to the NRC in an analogous situation. (0001-18 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: There is also no indication that the rulemaking, if it proceeds, will include an environmental analysis of the impacts of the proposed action and alternatives to mitigate those consequences. In short, the pending potential rulemaking is not a viable substitute for the obligations imposed on NRC to conduct a thorough environmental review, including consideration of all reasonable alternatives, of the proposed action of allowing the generation of spent fuel to continue when there is not in place a permanent, safe, and adequate waste disposal facility. (0001-22 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: The sole basis offered in the Staff Scoping Decision for rejecting, as an alternative, cessation of further generation of spent fuel until a permanent, safe, and adequate nuclear waste disposal facility exists, is that "[c]essation of licensing activities and overall reactor operations does not satisfy the purpose and need for the GEIS." Staff Scoping Decision at 12. However, as already noted, this narrow view of the purpose and need for the GEIS stems from the misperception that it will become the basis for a "regulatory approach" to the temporary storage of spent fuel, rather than a prerequisite to licensing decisions that will result in the continued generation of spent fuel in the absence of any permanent repository for that fuel. *New York*, 681F.3d at 473. (0001-25 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: This rule has only ever served one purpose, which has been to streamline the licensing process for nuclear facilities and particularly nuclear power plants, and in fact that's stated very clearly in the documents that we're here to comment on today. And I want to, you know, sort of begin with the stated purpose of the proposed action and the Waste Confidence rule. And I'm reading from the generic environmental impact statement, although nearly verbatim statements are made in the other documents as well. "The purpose and need for the

proposed action are threefold: (1) To improve the efficiency of the NRC's licensing process by generically addressing the environmental impacts of continued storage; (2) to prepare a single document that reflects the NRC's current understanding of these environmental impacts; and (3) to respond to the issues identified in the remand by the court in the New York v. NRC decision." Now, to address these it was entirely unnecessary for the Commission to go back and re-institute the Waste Confidence rule. First of all, the second stated purpose here, to prepare a single document that reflects the NRC's current understanding of nuclear waste storage, doesn't require a rulemaking. That could be done in any other kind of technical document or environmental impact statement. And the third one, to respond to the issues identified in the remand by the court, the court did demand that the NRC do a more thorough credible evaluation of the consequences of nuclear waste storage after a reactor license expiration. That doesn't require the reinstitution of a Waste Confidence rule. The court was clear that it didn't say that the NRC shouldn't do that, or wouldn't be allowed to do that, but it's certainly not a necessary implication of the court rule. (0030-17-3 [Judson, Tim])

Comment: But, instead, you're taking away the environmental impacts and making them generic. The NEI representative was saying that you are not making decisions with this; we are only setting -- you know, it's not a licensing decision. But, actually, it's forcing the licensing decisions to not discuss all sorts of things. So it's very much a huge part of licensing. (0030-4-6 [Hoffman, Ace])

Comment: Have mitigation measures for these costs, risks, and impacts been explored in this GEIS? ---- Again, they have not. NRC's draft GEIS is completely devoid of such issues. Thus, the draft GEIS makes a mockery of NEPA, as well as the federal appeals court ruling in New York versus NRC. (0034-3 [Wagner, Jim and Virginia])

Comment: The Draft GEIS itself is overall a dishonest document: it is dishonest in structuring the alternatives considered to avoid real solutions to the issues of spent nuclear fuel. Its purpose really seems to be (and is so stated by NRC) grease to accelerate licensing and relicensing, and avoidance of site specific environmental analysis of SNF. (0059-9 [Andrews, Richard])

Comment: In addition, by asserting that the environment around spent nuclear fuel storage facilities is well understood and can be reasonably predicted, the Waste Confidence only provides generic determination on continued storage of spent nuclear fuel, instead of complex site-specific evaluations. The argument is merely based on excessive confidence in the U.S. operation experience of nuclear power plants and that the environment impacts are sufficiently understood. When it comes to safety, we should take a more skeptic attitude. (0210-4 [Individual, Anonymous])

Comment: The DGEIS has two responsibilities: (1). Analyze the human environment in a procedural manner for nuclear waste storage of spent fuels after license expiration and (2). Fulfill the order by the U.S. Appeals Court before a proposed rule on waste confidence can be made. (0219-2 [Olmstead, Stan])

Comment: My review determines that the purpose and need of the document should not be the improved efficiency of the NRC's licensing and that the document does not address the deficiencies of the U.S. Court of Appeals ruling by completing an appropriate Environmental Impact Statement. (0219-5 [Olmstead, Stan])

Comment: And then from there, the Executive Summary of the Impact Statement, the Purpose and Need for the Proposed Actions. Number 1: To improve the efficiency of the NRC's licensing process. Improve the efficiency of the licensing process? What's the purpose of the NRC? And Preliminary Conclusion is to provide because the efficiencies will be gained and reactor and spent fuel storage licensing reviews. We're not here for your efficiency -- licensing and reviews, we should be here to try to make us safe from these things. NRC should not be facilitating licensing of new or existing plants. (0244-6-3 [Steorts, Tim])

Comment: On February 18, 2011, Blue Ridge Environmental Defense League; Riverkeeper, Inc.; and Southern Alliance for Clean Energy filed a petition in U.S. District Court to reverse decisions by the U.S. Nuclear Regulatory Commission on Waste Confidence. As a result, in 2012, the U.S. Court of Appeals nullified the Nuclear Regulatory Commission's Waste Confidence Rule because it did not satisfy the National Environmental Policy Act. The Court's decision cleared the way for challenges at scores of commercial nuclear power reactors in the United States because it invalidated a broad Federal regulation which supports all U.S. nuclear power plant licenses. The old Rule presumed that waste stored at reactors would go to a waste dump someday. Following the landmark legal decision, many groups petitioned the NRC to ensure that the new environmental analysis is properly incorporated into the licensing of nuclear power plants. Blue Ridge Environmental Defense League has raised the Waste Confidence issue at several NRC licensing proceedings, namely, Bellefonte, North Anna, William States Lee, Vogtle, and Sequoyah, but until the court ruled in our favor, the Commission refused to even discuss this issue. (0246-7-1 [Zeller, Lou])

Comment: I think that there's an incorrect assumption that the NRC's mission is to enable licensure in an efficient manner, or to make licensure easy, efficient, or desirable for for-profit entities. I'm opposed, and I think that I speak for many people that we're opposed, to any aspect of this rulemaking which would facilitate, or make more efficient, or enable licensure of any new facilities, or the extension of any licenses at existing facilities. (0327-14-2 [Ellison, David])

Comment: The adoption of a Waste Confidence Rule will allow the NRC to operate more efficiently. Both fuel pools and dry storage systems have repeatedly been shown to have no impact on the local environment. Thus, it makes little sense to delay licensing or renewal of licensing of nuclear facilities by requiring environmental impact statements for every plant and storage facilities. (0327-31-4 [Dorans, Rob])

Comment: That's why our tribe has been actively involved in the Waste Confidence activities. We joined a Coalition of States in a successful challenge last year to the Waste Confidence Decision and temporary storage rule in the United States Court of Appeals for the District Court of Columbia. That successful challenge is why the NRC prepared the Waste Confidence Draft Generic Environmental Impact Statement, and why we're all here today. I'm proud of our Tribe's efforts to go forth with this. I'm also thankful for the invitation from the State of New York to join into this challenge. I'd also like to take this time to encourage the State of Minnesota to also get involved. (0328-1-5 [Johnson, Ron])

Comment: [T]he DGEIS claims that the cessation of licensing and operation of nuclear reactors would not satisfy the stated purpose and need for the DGEIS. This argument is without merit for several reasons. First, the purpose and need as contemplated by NEPA is the purpose and need for the proposed Federal action, not the purpose and need of the EIS. The proposed Federal action in this case is the promulgation of the Waste Confidence Rule, not the issuance of the DGEIS. Therefore, the purpose and need for the Federal action is to promulgate a rule that ensures that reactors are licensed so as not to be inimical to public health as the

statute requires, and that there is reasonable assurance that the activities authorized by the operating license can be conducted without endangering the health and safety of the public according to your own regulations. Because radioactive spent fuel is extremely dangerous and no one knows what to do with it, the purpose and need for the Waste Confidence Rule must include the alternative of making no more radioactive waste. (0328-4-6 [Taylor, Wallace])

Comment: Deep within the pages of the GEIS is this little ditty: "As described in Section 1.4 of this draft GEIS, the proposed action is for the Commission to issue a revised rule, 10 CFR 51.23, that generically addresses the environmental impacts of continued storage. This revision would adopt into regulation the environmental impact analyses in this draft GEIS. Further, the revision would state that because the impacts of continued storage have been generically assessed in the draft GEIS and codified in a rule, the NEPA analyses for future reactor and ISFSI licensing actions would not need to separately consider the environmental impacts of continued storage." (GEIS, 8-10) This is a highly suspect attempt to use a limited-scope (and severely flawed) GEIS to drastically alter the nuclear regulatory scheme. It has the appearance of an attempt to promote nuclear power and effectively shackle the nation to continued nuclear power as an energy source and the endless buildup of nuclear waste. (0341-2-16 [Mermelstein, Richard])

Comment: This flawed framing of Alternatives in the Draft GEIS precludes the GEIS from taking a "hard look" at environmental consequences. There are multiple issues associated with this flawed decision framework of the Draft GEIS: * Second, if the environmental impacts are assumed to be the same across Alternatives, the level of environmental effect (small, moderate, or large) does not influence selection of an Alternative. Even if the Draft GEIS identified a large or very large environmental impact (e.g., of postulated accidents), there would be no clear implication on NRC decision-making regarding continued storage under the current decision framework. This is because the impacts would be large regardless of whether they codify the findings of the Draft GEIS (Proposed Action) or undertake a site-specific analysis (No Action and Policy Statement Alternatives). The NRC asserts that, because a GEIS approach is more cost-effective administratively and there is no change in environmental consequences, development of a GEIS is the preferred approach. This rationale could be applied regardless of the findings with respect to the level of environmental consequences, makes meaningless the evaluation of environmental consequences and, and circumvents the purpose of evaluating environmental impacts of alternatives under NEPA.; This rationale also calls into question whether the Alternatives evaluated by NRC in the Draft GEIS encompass the full range of reasonable alternatives, given that the benefits under the NRC's Alternatives do not vary. The NEPA regulations require that an EIS examine "all reasonable alternatives" to the proposed action (40 CFR Part 1502.14). "Reasonable alternatives include those that are practical or feasible from the technical and economic standpoint and using common sense, rather than simply desirable from the standpoint of the applicant."¹ [footnote 1 text: 1 Executive Office of the President, Council on Environmental Quality. March 1981. Memorandum to Agencies: "Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulations."] NRC's structuring of the Alternatives such that environmental consequences of continued storage do not affect decision-making regarding the selection of an Alternative (as the consequences do not vary across Alternatives), indicates that the NRC avoided its responsibility to assess environmental consequences of the proposed action. (0473-1-10 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: This flawed framing of Alternatives in the Draft GEIS precludes the GEIS from taking a "hard look" at environmental consequences. There are multiple issues associated with this flawed decision framework of the Draft GEIS: * Third, while we understand the NRC's point

that the actual impact of an activity on the environment or economy does not change based on the method used to evaluate it, this is not the appropriate way to frame the question in comparing alternatives within NEPA. The appropriate framing of that inquiry would be whether the NEPA evaluation method for a particular activity (e.g., site-specific or generic) affects the level and quality of analysis such that it could change decision-making. The Draft GEIS does not address this question, assuming away the need to investigate. For example, more information, as obtained through site-specific evaluations, would support identification and implementation of the best approaches to mitigation. Site-specific information on locations of potentially affected populations, utility structures, and transportation infrastructure could improve mitigation strategies such as preparation and planning for evacuations at a given site in the case of a severe event. The Draft GEIS does not contain or consider such site-specific information that may be used to guide analysis of consequences and mitigation strategies. (0473-1-11 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The NRC structures the Proposed Action and the Alternatives such that they are entirely disassociated from the consideration of environmental consequences in the Draft GEIS. As noted above, the NRC's Proposed Action is to rely on the information in the GEIS to codify that continued storage is safe until a repository is available. An appropriate framing of Alternatives to the Proposed Action may therefore include different methods of managing spent fuel and mitigating environmental impacts in order to support a conclusion that it is safe. The only variation across the Alternatives, as they are defined by the NRC, however, is with respect to the level of administrative effort to comply with environmental analysis and reporting requirements (e.g., NEPA). Even in the case that the NRC's framing of the Alternatives around developing generic or site-specific NEPA documents were meaningful, the evaluation of environmental consequences in the Draft GEIS provides no real analysis of the relative benefits of across these Alternatives. (0473-1-3 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: This flawed framing of Alternatives in the Draft GEIS precludes the GEIS from taking a "hard look" at environmental consequences. There are multiple issues associated with this flawed decision framework of the Draft GEIS: * First, as noted above, as the NRC frames Alternatives and applies assumptions such that the evaluation of environmental impacts does not vary across Alternatives, the entire discussion of environmental impacts in the report serves no purpose. The D.C. Circuit Court would not have vacated the NRC's 2010 Waste Confidence Decision due to improper analysis of environmental effects if it didn't intend for the NRC to properly consider these potential effects in weighing relative impacts of Alternatives. The evaluation of environmental consequences, and identification of appropriate mitigation strategies are a central purpose of NEPA. As described in the regulation, the evaluation of environmental consequences requires discussion of means to mitigate adverse environmental impacts (40 CFR 1502.17). As it is, the additional information provided in the Draft GEIS to address environmental consequences is entirely symbolic and does not weigh into decision-making regarding the selection of an Alternative or identification of potential mitigation strategies across Alternatives or plant sites. (0473-1-9 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: THE DGEIS INCLUDES NO MITIGATION MEASURES AT ALL, IN VIOLATION OF NEPA AND NRC REGULATIONS: An EIS must also contain a detailed discussion of possible mitigation measures and the extent to which adverse effects can be avoided. *Robertson v. Methow Valley Citizens Council*, 490 U.S. 332, 351-52 (1989). CEQ regulations require a discussion of mitigation measures. 40 C.F.R. § 1500.2(f) ("Federal agencies shall to the fullest extent possible . . . use all practicable means, consistent with the requirements of the Act and

other essential considerations of national policy, to restore and enhance the quality of the human environment and avoid or minimize any possible adverse effects of their actions upon the quality of the human environment"); see also 40 C.F.R. §§ 1502.14(f); 1502.16(h), 1508.25(b)(3). NRC's own regulations also require discussion of mitigation measures, referred to as "alternatives available for reducing or avoiding adverse environmental effects." 10 C.F.R. § 51.71(d). The mitigation of impacts must be considered whether or not the impacts are significant. Forty Most Asked Questions and Answers on the CEQ Regulations, Number 19a. The "omission of a reasonably complete discussion of possible mitigation measures would undermine the 'action-forcing' function of NEPA. Without such a discussion, neither the agency nor other interested groups and individuals can properly evaluate the severity of the adverse effects." Robertson, 490 U.S. at 351-52.; But NRC has included no mitigation measures at all to offset any of the environmental impacts identified in the DGEIS. In a number of instances, however, NRC appears to assume that mitigation measures will be taken but without evaluating their likelihood or alternative mitigation measures that might work better or be more certain, including measures to prevent the adverse consequence from occurring. See, e.g., DGEIS at 3-12 ("Based on EPA's determination, the NRC recognizes that GHGs contribute to climate change, climate change can affect health and the environment, and mitigation actions are necessary to reduce impacts."); 3-19 ("Timely detection of leakage will allow licensees to identify and repair leaks and employ mitigation measures, as necessary, to minimize or eliminate any environmental impacts that would result from leaks."); 4-36 ("The severity of impacts associated with impingement and entrainment is dependent upon several factors including the amount of water withdrawn relative to the size of the cooling-water source, location and configuration of intake structures, type of waterbody from which water is withdrawn, conditions within that waterbody, proximity of withdrawal structures to sensitive biological habitats (e.g., spawning and nursery habitats), sensitivity of populations of impinged and entrained organisms to potential losses of individuals, and mitigation measures in place to reduce impingement and entrainment."); 5-15 ("For an away-from-reactor ISFSI, the NRC assumes that, if necessary, any site-specific permits would include appropriate mitigation to ensure that impacts would not be destabilizing to local air quality."); Despite acknowledging potential impacts in these areas (climate change, aquatic impacts, air pollution) and others, such as severe accidents including spent fuel pool fires, the DGEIS offers no mitigation measures at all. (0473-11-1 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: THE DGEIS SHOULD HAVE DIRECTLY EXAMINED EXPEDITED FUEL TRANSFER TO DRY CASKS AS A MITIGATION MEASURE OR AN ALTERNATIVE: The NRC has made a number of inconsistent statements about the expedited fuel transfer to dry casks. In the DGEIS, it says: Imposing new regulatory requirements, such as requiring licensees to ... reduce the density of spent fuel in pools, or expedite transfer of spent fuel from pools to ISFSIs, is outside the scope of this proposed action, which includes alternatives that improve the efficiency of the NRC's licensing process by generically addressing the environmental impacts of continued storage. ... [T]he NRC cannot impose new requirements or regulations on the duration of spent fuel storage in pools through this proposed action. In separate proceedings, the NRC is considering implementing revised security requirements as part of the ongoing ISFSI security rulemaking effort. The rulemaking effort is described in the December 16, 2009, Federal Register notice (74 FR 66589), "Draft Technical Basis for Rulemaking Revising Security Requirements for Facilities Storing SNF [spent nuclear fuel] and HLW [high-level waste]; Notice of Availability and Solicitation of Public Comments." This position is problematic for three reasons. First, this position is only potentially tenable if the federal action was properly cast as guiding agency efficiency, which, as discussed above, it is not. Second, the NRC is confusing its AEA obligations with its obligations under NEPA. Third, the NRC is, in fact, evaluating the

expedited transfer of spent fuel to dry casks in a document they intend to cite in the DGEIS; they are simply not doing it at the draft stage such that all parties can comment on it or by applying the NEPA standards for evaluating the alternative provided in 10 C.F.R. Section 51.103(a)(4). (0473-11-10 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The reasons why the federal action, Statement of Purpose and Need, and alternatives are artificially limited have been discussed above. A proper evaluation of the federal action and the impacts and alternatives to that action would lead to a discussion of alternatives and mitigation measures to address spent fuel pool fire risk that would naturally include moving fuel out of pools. (0473-11-11 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The NRC's justifications for not including this alternative are unpersuasive. First, the NRC insists "that additional requirements on spent fuel storage would not meet the purpose and need." DGEIS at xxvi. The NRC goes to state that "the draft GEIS is a NEPA review and not a licensing action; therefore, this draft GEIS would not be the appropriate activity in which to mandate new spent fuel storage requirements." *Id.* One purpose of a properly conducted NEPA review is to provide the agency with complete information "to ensure that the agency does not act upon incomplete information, only to regret its decision after it is too late to correct." *Duke Energy Corporation (McGuire, Units 1 and 2; Catawba, Units 1 and 2) CLI-02- 17, 56 N.R.C. 1 (July 23, 2002) at 10.* (0473-11-14 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The analysis of alternatives, 42 U.S.C. § 4332(2)(C)(iii), is the "heart" of an EIS and "should present the environmental impacts of the proposal and the alternatives in comparative form, thus sharply defining the issues and providing a clear basis for choice." 40 C.F.R. § 1502.14. Alternatives to be considered include the "no action" alternative, other reasonable courses of action, and mitigation measures (not in the proposed action). 40 C.F.R. § 1508.25(b). The alternatives that must be examined are bounded by the "purpose and need" for the proposed agency action. See 40 C.F.R. §§ 1502.13, 1508.9(b). By unreasonably limiting its purpose and need to paperwork reduction, the NRC impermissibly frames the alternatives in terms of paperwork also, avoiding the *Minnesota v. NRC* question of whether the NRC can continue to license nuclear power plants. The DGEIS's alternatives are: (1) GEIS-only; (2) Policy-Statement Alternative. The only comparison of these alternatives in the DGEIS is a cost-benefit comparison focused on the cost of paper used and staff time expended. There is no evaluation whatsoever of the relative environmental impacts of each alternative, as is required under NEPA. (0473-11-3 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: This is not an alternatives analysis. Case law is clear that an "agency may not define the objectives of its action in terms so unreasonably narrow that only one alternative from among the environmentally benign ones in the agency's power would accomplish the goals of the agency's action, and the EIS would become a foreordained formality." *Citizens Against Burlington, Inc. v. Busey*, 938 F.2d 190 (D.C. Cir. 1991). This is precisely what NRC has done here. For example, by stating that "[t]he NRC also determined that additional requirements on spent fuel storage would not meet the purpose and need" (DGEIS at xxvi), the DGEIS explains one way the NRC used the unreasonably narrow purpose and need to artificially limit alternatives (0473-11-5 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: To remedy this deficiency, as discussed above, the DGEIS must identify the true federal action here, licensing and relicensing of reactors or storage installations that result in the generation and management of nuclear waste. Once the true federal action is correctly defined, the true purpose and need of the DGEIS can also be defined: analyzing the environmental impacts of continued fuel storage absent a permanent repository. Only then can the reasonable range of alternatives be adequately evaluated under NEPA -- including the non-generation of waste, as well as alternatives that mitigate the potential impacts of a severe accident, which the DGEIS acknowledges could be "significant and destabilizing." DGEIS at 4-68. These alternatives include the accelerated transfer of spent fuel to dry storage, which would reduce the risk of fire during the short-term timeframe and beyond (since, as discussed below, there is no basis for assuming that waste will be removed from pools by 60 years after the licensed life of a reactor) and beyond, as well as banning the use of high burnup fuel. (0473-11-6 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The NRC appears to believe that it is without authority to analyze the true no-action alternative of ceasing to license and relicense plants until a permanent repository is available. See, e.g., DGEIS at 1-9 ("Through the Atomic Energy Act, Congress has mandated that the NRC establish criteria to allow the licensing of nuclear power plants. Therefore, without Congressional direction to do so, the NRC may not deny a reactor license unless it determines that a license applicant has not met the NRC's regulatory standards for issuance of a license." (emphasis added)). That cannot be so. First, this sets up precisely the type of "foreordained" conclusion that the courts have rejected. 938 F.2d at 196; see also, e.g., *California v. Block*, 690 F.2d 753, 767 (9th Cir. 1982) ("[I]t is troubling that the Forest Service saw fit to consider from the outset only those alternatives leading to [its] end result."); *Calvert Cliffs' Coordinating Committee, Inc. v. U.S. Atomic Energy Commission*, 449 F.2d 1109, 1114 (D.C. Cir. 1971) ("Congress did not intend [NEPA] to be such a paper tiger.") (0473-11-7 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Second, even if the NRC were correct that the Atomic Energy Act somehow trumped the requirements imposed by a later Congress through NEPA, the NRC would still have to at least study the no-action alternative to provide a baseline for evaluating the environmental impacts of the proposed action. See, e.g., *Se. Alaska Conservation Council v. Fed. Highway Admin.*, 649 F.3d 1050, 1058 (9th Cir. 2011) (rejecting a " cursory" three-paragraph explanation of the no-action alternative). (0473-11-8 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Third, Congress' authorization to NRC to license nuclear plants is conditioned on the issuance of the license providing adequate protection for the public health and safety. Atomic Energy Act, § 182 (42 U.S.C. § 2232) (0473-11-9 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Finally, the DGEIS fails to identify the reasonably available alternatives to the storage of spent fuel at reactor sites or to assess the different environmental consequences that would arise from each of those alternatives. By failing to properly identify the major federal action and failing to properly identify the purpose and need for the proposed action, the DGEIS has failed to properly consider alternatives. (0473-12-6 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: In general, the DGEIS's complete lack of analysis regarding mitigation measures is wholly inadequate under NEPA. Although the DGEIS does not so much as include a section discussing ways to mitigate the present-day severe accident impacts the DGEIS discloses, the

DGEIS does, confusingly, discuss NRC's past efforts at "mitigation." Under DGEIS Section 4.18.2.1, the DGEIS states that "[i]n the event of even a long-term loss of normal pool makeup water capability at U.S. power plants, measures that were installed in response to the September 11, 2001 terrorist attacks, plus additional measures that are required as a result of the post-Fukushima March 12, 2012, mitigating strategies order, would ensure additional defense-in-depth protection for cooling of the spent fuel." The DGEIS, however, fails to (1) identify which specific post-September 11 and post-Fukushima "measures" it is referring to, (2) acknowledge that not all of these measures were implemented at all plants, and (3) quantify what "additional defense-in-depth protection" these unidentified measures provide, either generically or on a site-specific basis. Furthermore, it fails to identify, discuss, and evaluate other alternative measures that would mitigate the impacts of a severe accident at a spent fuel pool. Indeed, contrary to NEPA, it excludes the consideration of such other readily available mitigation alternatives. (0473-14-3 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: As the preceding comments demonstrate, the DGEIS fails to assess the environmental impacts of the proposed action and weigh the costs and benefits of that action. See *Robertson v. Methow Valley Citizens Council*, 490 U.S. 332, 350-351 (1989). The DGEIS is deficient due to its failure to properly frame the federal action being proposed, its failure to identify the appropriate purpose and need for the proposed action, its failure to properly evaluate the adverse environmental consequences that are likely to occur if the proposed action is taken and its failure to consider any substantive measures to mitigate those adverse impacts. Given the extensive nature of the deficiencies, NRC must issue a new draft DGEIS for public comment and cannot merely respond to the concerns raised here by issuing a final GEIS which will then foreclose any further meaningful public participation in the NEPA process. See, e.g., *Marsh v. Oregon Natural Resources Council*, 490 U.S. 360 (1989); 10 C.F.R. § 51.72. Thus, the States and the Tribe request that NRC's response to these Comments be published in the form of another DGEIS, with site specific supplements as discussed above, which includes a reasonable opportunity for public comment. (0473-18-6 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Under NEPA, the NRC is required to consider the full range of reasonable alternatives to the Proposed Action, as follows: a) Rigorously explore and objectively evaluate all reasonable alternatives, and for alternatives which were eliminated from detailed study, briefly discuss the reasons for their having been eliminated. b) Devote substantial treatment to each alternative considered in detail including the proposed action so that reviewers may evaluate their comparative merits. c) Include reasonable alternatives not within the jurisdiction of the lead agency. d) Include the alternative of no action. e) Identify the agency's preferred alternative or alternatives, if one or more exists, in the draft statement and identify such alternative in the final statement unless another law prohibits the expression of such a preference. f) Include appropriate mitigation measures not already included in the proposed action or alternatives (40 CFR 1502.14). The Proposed Action is a revision to the Waste Confidence Rule. In addition to the Proposed Action, the Draft GEIS considers three Alternatives, as described above. However, the Alternatives do not consider alternate ways of modifying the Waste Confidence Rule, as one may expect of the scope of reasonable Alternatives. For example, Alternatives could be structured around the best ways to manage storage of spent fuel at given sites in order to support the NRC's decision to codify that continued storage is "safe" over the analytic timeframes. This would allow for a meaningful analysis of relative environmental consequences of the different Alternatives. Instead, the Alternatives (including No Action) center around the NEPA process employed to evaluate environmental consequences without revising the Waste Confidence Rule, with no variation in

the approach to managing spent fuel across Alternatives. The result is that the only difference in Alternatives is the administrative effort required to implement the NEPA process. As described above, this framework does not provide a foundation for a purposeful Alternatives analysis of measures to mitigate or eliminate the environmental consequences of continued and increased storage of spent fuel in spent fuel pools over indefinite periods of time. The Proposed Action incorporates the findings of the GEIS into future licensing decisions for plants in order to codify that continued storage is safe. In this way, the Proposed Action establishes that further discussion of environmental impacts of spent fuel storage is not required in connection with the issuance or amendment of an operating license for a nuclear power reactor. However, the Draft GEIS considers only limited methods of managing spent fuel. For example, it does not consider the potential for transferring the fuel to dry casks within the short-term time frame. While the NRC leaves open the possibility of evaluating other methods of managing spent fuel outside of the context of the Waste Decision Rule GEIS, codifying that continued storage is safe across indefinite time frames indicates the NRC is disinclined to fully explore the relative merits of different storage scenarios for given sites and in general. (0473-3-3 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Consistent with NEPA and the Court's remand, the NRC thus must address in this proceeding foundational questions, including whether the generation of further nuclear waste should be allowed and, if allowed, what mitigation measures are available to reduce environmental impacts, and what alternatives exist to the current practice of permitting nuclear wastes to be stored at individual reactor sites indefinitely and in spent fuel pools never designed for that purpose. (0473-5-2 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: However, the DGEIS and draft rule, as presented, fail to address these core issues as required by NEPA and the Court's remand by, among other means, miscasting the purpose and need for the DGEIS to focus on agency efficiency rather than environmental protection, by failing to consider a reasonable range of alternatives, including dry cask storage, to mitigate environmental impacts, and by failing to provide the States, the Tribe, and the public with a meaningful opportunity for site specific review of these issues in violation of the Court's mandate. (0473-5-3 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The NRC states that "[t]he Waste Confidence rulemaking is a major Federal action that requires a NEPA review." DGEIS at xxiii. While the States and the Tribe do agree that the development, justification, and promulgation of regulations are "federal actions" requiring NEPA review, here, the analysis of the storage of nuclear waste relates back to major federal actions resulting in the generation and storage of nuclear waste: the licensing and/or relicensing of nuclear power plants and waste storage installations, and the ongoing storage of nuclear waste at facilities no longer operational. (0473-9-1 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: In 1979 the preferred solution was reracking of spent fuel to allow more spent fuel to be stored at the reactor sites in spent fuel pools. NUREG-0575 evaluated that proposed action and considered a number of alternatives including dry cask storage and ending the further production of spent fuel. Today NRC's preferred solution is to allow more spent fuel to be generated and stored at reactor sites in spent fuel pools and for longer periods of time. It is that proposed action that the DGEIS must evaluate, including an analysis of alternatives to that proposed action, as well as measures to mitigate the environmental consequences of the proposed action. (0473-9-12 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: NRC faces the same type of issues it faced in 1979, when it explicitly recognized that it must analyze whether to allow the continued production of spent fuel and the continued storage of spent fuel at reactor sites in spent fuel pools. NRC must still answer, in the context of NEPA, the same question the Court ordered it to answer in the remand in *Minnesota v. NRC*: the court contemplates consideration on remand of the specific problem isolated by petitioners determining whether there is reasonable assurance that an off-site storage solution will be available by the years 2007-09, the expiration of the plants' operating licenses, and if not, whether there is reasonable assurance that the fuel can be stored safely at the sites beyond those dates.; *Minnesota v. N.R.C.*, 602 F.2d at 412. The Waste Confidence decision in 1984 was a direct outgrowth of that mandate, and NUREG-0575 was the principal basis for the NRC's conclusion that spent fuel could be safely stored at reactor sites in either spent fuel pools or dry casks: The Commission is confident that the regulations now in place will assure adequate protection of the public health and safety and the environment during the period when the spent fuel is in storage ("Final Generic Environmental Impact Statement on Handling and Storage of Spent Light Water Power Reactor Fuel," NUREG-0575, August 1979: Vol. 1, pp. ES-12, 4-10 to 4-17). 49 Fed. Reg. 34658, 34682, Final Waste Confidence Decision (Aug. 31, 1984). (0473-9-13 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Today, utilities continue to struggle with what to do with spent fuel, and NEPA requires that the NRC evaluate whether to let spent fuel continue to build up at reactor sites and remain in spent fuel pools. In addition to fully exploring the environmental consequences of such action, the NRC must examine all the reasonably available alternatives to that action, as well as mitigation measures if the proposed action is to go forward. Such alternatives and mitigation measures include not producing spent fuel, alternative methods for producing spent fuel (e.g., banning the use of high burnup fuel) and alternative methods for storing spent fuel (e.g., in dry casks after five years of pool storage) (0473-9-14 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Thus, contrary to the DGEIS's characterization of the proposed action and the statement of purpose and need, this DGEIS is the continuation of a process begun in 1979 to examine the environmental consequences of not having a permanent repository for spent fuel. The DGEIS must examine the full range of those previously examined issues in light of all the current available information if it is to fully examine the major federal actions NRC is considering, as well as alternatives and mitigation measures. (0473-9-16 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: While NUREG-0575 recognized the broad scope of environmental issues raised by the presence of spent fuel at reactor sites, at no time since 1979 has NRC undertaken a comprehensive look at the environmental implications of onsite spent fuel storage. Yet, if anything, the need for a comprehensive look is all the greater now due to: (1) increased amounts of fuel that is (2) more volatile because it is high burnup fuel and (3) may remain onsite indefinitely. Rather than undertake a comprehensive update to NUREG-0575, NRC has engaged in a handful of narrow examinations of some of the issues raised by the changes since 1979, several of which have occurred outside the procedural and substantive rights created by NEPA, without ever combining its analyses into a single environmental impact statement that addresses anew the now outdated analysis contained in NUREG-0575. (0473-9-17 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The issue of whether and how spent fuel should be stored at reactor sites and alternative ways to accomplish such storage is inexplicably intertwined with the issue of waste confidence. Whether the Commission ultimately concludes that it has a date certain by which a

waste repository will likely be available, as the current Staff prepared DGEIS proposes, or not, the Commission must still address the question of potential environmental impacts of spent fuel storage at reactor sites both during and following plant shutdown and must examine alternatives to mitigate those potential impacts. 10 C.F.R. §§ 51.30(a)(1)(ii) and (iii), 51.103(a)(4) and 42 U.S.C. §§ 4332(2)(C)(iii) and (E). In fact, a number of reactors are already shutdown and storing spent nuclear fuel at the reactor site. See 2013-2014 Information Digest, NUREG-1350 Vol. 25 (August 2013) APPENDIX C U.S. Commercial Nuclear Power Reactors Undergoing Decommissioning and Permanently Shut Down Formerly Licensed To Operate. (0473-9-18 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Under CEQ regulations, the EIS "shall briefly specify the underlying purpose and need to which the agency is responding in proposing the alternatives including the proposed action." 40 C.F.R. § 1502.13. Given that the NRC has miscast the federal action, it has necessarily also miscast the Statement of Purpose and Need. (0473-9-3 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The purpose and need relates back to the NRC's ongoing attempts, for more than three decades now, to address the safety and environmental impacts of nuclear waste storage when it licenses reactors. In 1977, NRC declared, in its denial of a petition filed by NRDC, that it "would not continue to license reactors if it did not have reasonable confidence that the wastes can and will in due course be disposed of safely" (42 Fed. Reg. 34391) (July 5, 1977). As Judge Tamm of the D.C. Circuit stated in 1979, "if the Commission determines it is not reasonably probable that an offsite waste disposal solution will be available when the licenses of the plants in question expire, it then must determine whether it is reasonably probable that the spent fuel can be stored safely onsite for an indefinite period. Answers to these inquiries are essential for adequate consideration of the safety and environmental standards of the relevant statutes." *Minnesota v. NRC*, 602 F.2d 412, 419 (D.C. Cir. 1979) (Tamm, J. concurring). Thirty-four years later, the NRC has still not made these determinations; the DGEIS is its latest attempt. (0473-9-4 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The NRC in the DGEIS states that it is "evaluating the continued storage of commercial spent fuel." DGEIS at xxiii. The proposed action the DGEIS purports to support is the issuance of a rule, 10 C.F.R. 51.23, that "generically addresses the environmental impacts of continued spent fuel storage by incorporating into rule the conclusions" of the DGEIS. DGEIS at ES.3, xxii. Accordingly, the NRC presents its Statement of Purpose and Need as follows: 1. to improve the efficiency of the NRC's licensing process by generically addressing the environmental impacts of continued storage; 2. to prepare a single document that reflects the NRC's current understanding of these environmental impacts; 3. to address the deficiencies in the 2010 Waste Confidence rule identified by the U.S. Court of Appeals for the D.C. Circuit. DGEIS at xxii. To begin with, the purpose of the federal action here is not to improve efficiency. Such a purpose and need turns NEPA on its head. It focuses on the impact of the NEPA review process on the agency staff instead of focusing on the environmental impacts of what the agency is authorizing--licensing and relicensing decisions that will result in continued generation and storage of spent fuel in the absence of a permanent repository. While NRC may certainly discuss the convenience of the federal agency, it cannot be the purpose of the NEPA analysis itself. (0473-9-5 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The NRC's job here is still to meet the requirements laid out by the D.C. Circuit in 1979 - the DGEIS needs to determine "whether there is reasonable assurance that an off-site solution [for spent fuel] will be available by 'the expiration of the plants' operating licenses, and if not, whether there is reasonable assurance that the fuel can be stored safely at the sites

beyond those dates." *New York v. NRC*, 681 F.3d at 474-75, quoting *Minnesota* 602 F.2d at 418. Insofar as the D.C. Circuit has ever expressed an opinion about the efficiency of the NRC's process, it has been secondary to the primary question of whether waste can be stored safely: [A]n agency may not define the objectives of its action in terms so unreasonably narrow that only one alternative from among the environmentally benign ones in the agency's power would accomplish the goals of the agency's action, and the EIS would become a foreordained formality. *Friends of Southeast's Future v. Morrison*, 153 F.3d 1059, 1066 (9th Cir. 1998) (quoting *Citizens Against Burlington, Inc. v. Busey*, 938 F.2d 190, 196 (D.C. Cir.1991)). While it is true that courts afford the NRC and other agencies "considerable discretion" in defining statements of purpose and need (See e.g., *Friends of Southeast's Future*, 153 F.3d at 1066-67), courts have also made clear that an agency's discretion in defining a purpose and need statement is "not unlimited." See *Westlands Water Dist. v. U. S. Dep't of Interior*, 376 F.3d 853, 866 (9th Cir. 2004); *New York v. U. S. Dep't of Transp.*, 715 F.2d 732, 742 (2d Cir. 1983) ("An agency's selection of alternatives . . . is not insulated from review"). (0473-9-6 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The Waste Confidence DGEIS is required to provide an analysis of waste generation and storage that has been lacking from environmental analyses of proposed NRC actions since 1984, when the original waste confidence findings were issued, blocking any discussion of nuclear waste for the period after the licensed life of a facility. The States submit that the NRC's goal in promulgating 10 C.F.R. § 51.23 is to ensure, after considered notice and comment rulemaking, that onsite storage of nuclear waste in the period after the licensed life of a facility is safe and without significant environmental impacts, such that continued generation of spent fuel through the operation of commercial nuclear power facilities is warranted. NRC believes its goal to be precluding consideration of such issues on a site by site basis in the name of administrative efficiency. Even if promulgation of the regulation was the proper federal action, the statement of purpose and need is still inadequate and unreasonably narrow for the above stated reasons. (0473-9-7 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Statement Three of the Statement of Purpose and Need is Too Vague and Fails to Satisfy NEPA's Public Information Purpose: In addition to the above, the Statement of Purpose and Need is also impermissibly vague and fails to satisfy NEPA's public information purpose. In stating that it "address[es] the deficiencies in the 2010 Waste Confidence rule identified by the U.S. Court of Appeals for the D.C. Circuit," it does not provide sufficient information such that adequate alternatives can be framed. The Statement of Purpose and Need is critical to the EIS because it frames the range of reasonable alternatives the agency must consider or such that the public can understand the action NRC is undertaking in the DGEIS. (0473-9-8 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: NEPA has twin aims: it "places upon an agency the obligation to consider every significant aspect of the environmental impact of a proposed action," *Baltimore Gas & Elec. Co. v. Natural Res. Def. Council, Inc.*, 462 U.S. 87, 97 (1983). "[I]t ensures that the agency will inform the public that it has indeed considered environmental concerns in its decisionmaking process." *Id.* "Grudging, pro forma compliance will not do." *Lathan v. Brinegar*, 506 F.2d 677, 693 (9th Cir. 1974). Both the CEQ and NRC's own NEPA regulations underscore that EISs should be written for the public: Ultimately, of course, it is not better documents but better decisions that count. NEPA's purpose is not to generate paperwork—even excellent paperwork—but to foster excellent action. The NEPA process is intended to help public officials make decisions that are based on understanding of environmental consequences, and take actions that protect, restore, and enhance the environment. 40 C.F.R. § 1500.1(c); see also 40 C.F.R. §

1500.2(b) ("Federal agencies shall to the fullest extent possible . . . emphasize real environmental issues and alternatives."); 10 C.F.R. § 51.70(b): The draft environmental impact statement will be concise, clear and analytic, will be written in plain language with appropriate graphics, will state how alternatives considered in it and decisions based on it will or will not achieve the requirements of sections 101 and 102(1) of NEPA and of any other relevant and applicable environmental laws and policies, will identify any methodologies used and sources relied upon, and will be supported by evidence that the necessary environmental analyses have been made.) In framing the purpose of this DGEIS by referencing a federal appellate court decision, NRC has failed to satisfy NEPA's public information purpose. (0473-9-9 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The purpose of NRC's Waste Confidence rule is to streamline nuclear plant licensing by ignoring the permanent, multi-billion dollar problem of what to do with radioactive waste. The only problem Waste Confidence solves is how to permit nuclear plants to continue making this waste when there is no solution for it. (0552-1-9 [Macks, Vic])

Comment: The NRC incorrectly changed the purpose of the GEIS from what the court ordered. The DC Circuit ordered NRC to do a GEIS as a prerequisite to licensing decisions that will result in the production of more spent fuel in the absence of a permanent repository (Ibid at 473). *It ordered a specific and narrow focus. NRC changed and broadened it to a need to do the GEIS so that it will become the basis for a regulatory approach to temporary storage of spent fuel.* (0556-1-6 [Lampert, Mary])

Comment: It seems to me that there is an irrational, CIRCULAR LOGIC being applied by the regulator. The NRC repeatedly emphasizes that the "Waste Confidence rulemaking is not a licensing action. It [(the rulemaking)] does not permit a nuclear power plant or any other facility to operate or store spent fuel. Every nuclear power plant or specifically licensed spent fuel storage facility must undergo an environmental review as part of its site-specific licensing process." (DGEIS, Executive Summary, p. xxvi). However, the point of the rulemaking is to apply the generic determinations of the DGEIS to individual licensing actions in order to help facilitate the approval of future license applications. So, the circular logic is clearly evident. True, the proposed Rule is not a licensing action or authorization for "continued storage," and, yes, site-specific reviews are still required as part of license applications; BUT, "the potential environmental impact of continued storage" would "not be considered in those proceedings -- due to the generic determination in 10 CFR 51.23(a)." (78 FR 56781 - 56782, Section III, A11). The generic determinations of the DGEIS which are codified in the proposed Rule are intended to fulfill the NEPA requirements for individual licensing decisions with regard to assessing foreseeable environmental impacts from "continued storage" of spent nuclear fuel. Therefore, it is reasonable to argue that the DGEIS is absolutely intended to be applied as a regulatory basis for supporting the expedited APPROVAL of all major relevant licensing applications in the future. In other words, the disingenuous and circular logic being applied by the NRC has all the appearances of a "con." The NRC has attempted to rationalize its paradigm of generic assessments in the Federal Register (78 FR 56781, Section III, A9). Unfortunately, the NRC's argument is ludicrous and lacking in credibility despite the research studies cited. Apparently, the NRC fails to see the madness and circular logic involved in relying on (global disasters) "lessons learned and knowledge gained from operating experience" in order to understand the "environmental impacts of operation" of "spent nuclear fuel storage facilities" for "continued storage" of spent nuclear fuel beyond the licensed life for operation of a reactor. How naive for the NRC to suggest that "[c]hanges in the environment . . . are sufficiently gradual and predictable to be addressed generically." A staggering degree of hubris accompanied with astounding recklessness form the foundation of any attempt to rationalize or justify such

determinations. Therefore, on behalf of the public interest and consistent with the Mission of the regulating agency, there is no rational basis for continuing to pursue the mistaken historical tradition of applying generic rules and criteria in order to address specific and unique situations. (0603-11 [Schonberger, David])

Comment: It is not clear why the NRC included licensing process efficiency improvements in the scope of the draft GEIS. As we understand, each licensing action must still meet the requirements of the National Environmental Policy Act (NEPA), either through an EIS or an EA during licensing actions (0619-1-7 [Mahowald, Philip R.])

Comment: In the GEIS Executive Summary, the stated purpose of this ruling is for the efficiencies that would be gained, minimizing expenditures and avoiding delays in licensing reviews. This apparent bias towards the industry seems to contradict the sole purpose of the NRC in protecting the public and the environment. (0660-2 [Headrick, Gary])

Comment: The purpose and need of the draft GEIS is too narrowly focused on improving the efficiency of the NRC's licensing process. This is to the detriment of encouraging public involvement and effectively conveying environmental information to the public and decision makers about potential effects of continued storage of spent fuel. (0669-1 [Walter, Joan])

Comment: NEPA requires agencies to follow a particular process in making decisions and to disclose the information and data that was used to support those decisions. Tiering⁵ [footnote 5 text: Tiering refers to the coverage of general matters in broader EISs with subsequent narrower environmental documents incorporating by reference the general discussions and concentrating solely on the issues specific to the subsequent project specific action. 40 C.F.R. Sections 1500 through 1508.28.] is appropriate when a sequence of EISs progresses from a general NEPA analysis to a site-specific NEPA analysis. Accordingly, the draft GEIS states that while some site-specific information is used in developing the generic impact determinations, the NRC does not intend for this draft GEIS to replace the NEPA analysis associated with any individual site licensing action. Notwithstanding, as a programmatic environmental document, the draft GEIS would be more effective if it included a meaningful discussion of the means to mitigate adverse environmental impacts⁶ [footnote 6 text: 40 C.F.R. Section 1502.16 (h).] to ensure that the environmental effects of the proposed Action are fairly assessed, and if it provided a summary of mitigating actions relied upon from other NEPA documents to reach conclusions about the significance of environmental effects resulting from the proposed Action. NRC regulations⁷ [footnote 7 text: 10 C.F.R. Part 51 entitled "Environmental Protection and Regulations for Domestic Licensing and Related Regulatory Functions, Appendix A to Subpart A, Item 7.] describe what should be included in an environmental impact statement, including a discussion of environmental consequences and mitigating actions, and specifically, the means to mitigate adverse environmental impacts. Yet mitigating actions are not provided in the draft GEIS. (0669-7 [Walter, Joan])

Comment: For example, Tables 8-1 through 8-3 summarize levels of environmental impacts, including unavoidable adverse impacts, for each resource area but the draft GEIS does not include any corresponding discussion of the means to reduce or avoid these impacts. The draft GEIS provides a figure illustrating a process for tiering off NEPA analyses for other NRC activities (Figure 1-2) and list of NEPA documents used in the draft GEIS preparation, but does not reference any mitigating actions from those documents. The draft GEIS states that it generically addresses the likely impacts of continued storage and that other aspects of spent fuel storage will either be addressed in site-specific analyses or are addressed generically elsewhere. However, it is unclear how the environmental consequences and mitigating actions

from the draft GEIS are supported by the numerous other generic EISs that the draft GEIS tiers off of. Under NEPA, environmental documents are provided to inform the public and other agencies who may be interested or affected by the proposed Action.⁸ [footnote 8 text: 40 C.F.R. Section 1506.6(b).] The lead agency must determine the proposed Action's full extent and may not divide it into smaller segments to avoid presentation of its full environmental effects. The draft GEIS fails to disclose information about or adequately identify mitigating actions for the likely impacts of continued spent fuel storage by relying on unspecified mitigating actions addressed generically elsewhere or by deferring mitigating actions to assumed future activities which "may" require monitoring programs or mitigation measures (see Attachment A for examples). (0669-8 [Walter, Joan])

Comment: NRC staff have repeatedly described nuclear waste management as "a small piece of the puzzle." On the contrary, nuclear waste could be the undoing of our civilization. It is quite obvious to those who are well-informed that the Nuclear Regulatory Commission (NRC) MUST assess the environmental impacts of nuclear plant operation in general in order to fulfill the requirements of the Waste Confidence Decision, as well as to fulfill the requirements of common sense and our common humanity. (0679-1 [Sorgen, Phoebe])

Comment: NIC concurs with the NRC intent of addressing Waste Confidence generically, through rulemaking, rather than on a site-specific, case-by-case basis. To do otherwise would be unnecessary, extremely inefficient and an inappropriate use of limited NRC budgetary resources. (0685-6 [Davis, Ed])

Comment: The DGEIS claims that the cessation of licensing and operation of nuclear reactors would not satisfy the stated purpose and need for the DGEIS. This argument is without merit for several reasons. First, purpose and need as contemplated by NEPA is the purpose and need for the proposed federal action, not the purpose and need of the EIS. The EIS evaluates the environmental impact of the proposed federal action. The EIS is not the federal action. (0688-10 [Taylor, Wallace])

Comment: Secondly, the federal action involved here is the promulgation of the Waste Confidence Rule. See, DGEIS § 1.4. The proposed rule, amending 10 C.F.R. § 51.23, states that the GEIS for waste confidence precludes the need for discussion of environmental impacts of spent nuclear fuel storage following the term of the reactor license or amendment thereof in any environmental report, EIS or EA in connection with the issuance or amendment of a reactor license. Therefore, the purpose and need for the federal action is to promulgate a rule that ensures that reactors are licensed so as not to be "inimical" to public health, 42 U.S.C. § 2133(d), and that "[t]here is reasonable assurance . . . that the activities authorized by the operating license can be conducted without endangering the health and safety of the public . . .," 10 C.F.R. § 50.57(a)(3). Because radioactive spent fuel is extremely dangerous and no one knows what to do with it, the purpose and need for the Waste Confidence Rule must include the alternative of making no more radioactive waste. (0688-11 [Taylor, Wallace])

Comment: An EIS must discuss reasonable alternatives "to the proposed action." 42 U.S.C. § 4332(2)(C)(iii). The alternatives analysis is the "heart of the environmental impact statement." 40 C.F.R. §1502.14. NEPA demands that the agency "rigorously explore and objectively evaluate all reasonable alternatives" so the agency can "sharply define the issues and provide a clear basis for choice among options by the decision maker and the public." 40 C.F.R. §1502.14. The "existence of a viable but unexamined alternative renders an environmental impact statement inadequate." Resources Ltd. v. Robertson, 35 F.3d 1300, 1307 (9th Cir. 1994). And the main point of examining alternatives is to avoid environmental harm. So even if an

alternative might be superior in non-environmental terms, an alternative can be reasonable if it avoids the environmental harm better than another alternative. Surfrider Foundation v. Dalton, 989 F.Supp. 1309 (S.D. Cal. 98), *aff'd per curiam*, 196 F.3d 1057 (9th Cir. 1999). (0688-5 [Taylor, Wallace])

Comment: •The deficiencies in the 2010 Waste confidence rule identified by the Court should have been the primary purpose of the GEIS-- environmental analysis of the failure to secure a repository, and of spent fuel leaks and of fires. (0693-3-11 [Warren, Barbara])

Comment: •A key problem with the NRC analysis is that it sought to fulfill another purpose: improving the efficiency of the NRC licensing process by generically addressing the environmental impacts of continued storage. We believe it would be more accurate to say improving efficiency by ignoring or avoiding analysis of the environmental impacts, based on what we see in the draft GEIS. On p. xxvi, NRC describes its efforts to elevate efficiency by minimizing expenditures on site-specific reviews and limiting the potential for lengthy project delays. In fact the Regulatory Analysis in the Federal Register Notice states there is no burden on licensees associated with this proposed action. (0693-4-2 [Warren, Barbara])

Comment: Separate from the agency's AEA obligations, NEPA requires that before licensing or re-licensing nuclear power plants, NRC must evaluate the environmental impacts of its licensing decision in an EIS. 42 U.S.C. § 4332(C); 10 C.F.R. § 51.20(b)(2). An EIS must address the environmental impacts of the proposed action and connected actions, including cumulative impacts. 10 C.F.R. § 51.71(d). It must also weigh the costs and benefits of a reasonable array of alternatives for avoiding or mitigating the consequences of the proposed action. *Id.* Thus, in proposing to license or re-license nuclear power plants, NRC must examine the environmental impacts of the SNF and radioactive waste generated by the plants. It must also evaluate the relative costs and benefits of alternatives for avoiding or mitigating those impacts, including denying or amending licenses so that the radioactive waste is either not produced or there will be some future limitation. *Id.* The environmental impacts that must be examined by NRC include the risks posed by SNF interim storage, permanent disposal and the failure to secure permanent disposal. With regard to the latter, the NRC is obligated to examine the potential environmental impacts should institutional control over surface storage of SNF be lost for an extended period of time. Since there is uncertainty regarding when loss of institutional control might occur, how often and for how long, this portion of the analysis should examine the impacts for a range of dates and time periods for loss of institutional control. (0706-1-11 [Fettus, Geoffrey])

Comment: In order to comply with these controlling precedents, as noted earlier, we ask NRC to withdraw the existing Waste Confidence Draft GEIS and commence with publishing a Scoping Notice with a clear description of the NRC action that leads to SNF storage and disposal impacts: licensing nuclear reactors. (0706-1-12 [Fettus, Geoffrey])

Comment: In short, *New York et al.* was the natural successor to a lawsuit NRDC brought in 1977 to force NRC to address the public health and environmental impacts of SNF and high-level radioactive waste ("HLW") storage and disposal. See *NRDC v. NRC*, 582 F.2d 166, 169 (2nd Cir. 1978). While NRDC's and Minnesota's original lawsuits had a measure of success as a policy matter by forcing the compromise embodied in the Waste Confidence decision – NRC will not license reactors without "reasonable confidence" in the progress and development of a permanent disposal facility and the ability to safely store SNF—at no point over the last 40 years had NRC prepared an EIS regarding the environmental impacts of SNF and high-level radioactive waste disposal. Moreover, NRC continued to assume in its licensing decisions that

SNF and HLW disposal caused no public radiation doses and had no appreciable environmental impacts, long after those assumptions were proven wrong. After years of work by NRDC and many others, those assumptions have now been vacated by the D.C. Circuit. However NRC has issued a first draft of a NEPA analysis of the environmental impacts of SNF storage and disposal where the agency inadequately contemplates the possibility that a final disposal solution may never be found. Unfortunately, NRC has gotten off on the wrong foot and must: (1) withdraw this first draft and the proposed rule; and (2) commence work on a draft EIS that complies with federal law. The agency must then present reasonable alternatives and subject them to NEPA's "hard look requirements" and rely on reasonable projections, forecasts and assumptions to formulate its alternatives and examine their reasonably foreseeable environmental impacts. (0706-1-14 [Fettus, Geoffrey])

Comment: Page 1-5. "*Proposed Federal Action*. The Commission proposes to issue a revised Rule, 10 CFR 51.23, that generically addresses the environmental impacts of continued storage. This revision would adopt into regulation the environmental impact analyses in this draft GEIS. Further, the revision would state that because the impacts of continued storage have been generically assessed in this draft GEIS and codified in a Rule, NEPA analyses for future reactor and spent fuel storage facility licensing actions would not need to separately consider the environmental impacts of continued storage." NRDC Comment[:]. As NRDC will describe in detail below, the impacts of continued storage have not been generically assessed in this Draft GEIS and NRC will in any event have to consider certain site specific impacts of long-term storage at nuclear facilities in future "tiered" NEPA analyses. The Draft GEIS misconstrues NRC's NEPA obligation to properly define the nature and scope of the "major federal action" – in this instance a rulemaking – that NRC proposes as a fundamental predicate to all pending and future licensing actions authorizing the production and storage of spent nuclear fuel. In so doing, the Draft GEIS ignores the DC Circuit's unambiguous language vacating *en toto* the Commission's 2010 iterations of the WCD and TSR – "we are invalidating the Commission's conclusions as a whole." *New York et al.*, at 482. Indeed, the DC Circuit rejected the very argument – "the WCD/TSR is not a licensing action" – NRC now employs to arrive at its cramped, unreasonable description of the Commission's purpose and need in seeking to readopt the now vacated WCD and TSR: "(1) to improve the efficiency of the NRC's licensing process by generically addressing the environmental impacts of continued storage; (2) to prepare a single document that reflects the NRC's current understanding of the environmental impacts; and (3) to respond to the issues identified in the remand by the Court in the *New York v. NRC* decision." Draft GEIS at 1-6. (0706-1-17 [Fettus, Geoffrey])

Comment: The failure to analyze meaningful alternatives is a direct result of an improperly framed proposed action and its cramped, unreasonable purpose and need section. Following the Court's guidance and a common sense reading of NEPA and its implementing regulations, a legally compliant definition of the proposed action would be the following: *The NRC proposes to reinstate, as a pre-determined stage of its individual licensing actions for nuclear reactors and Independent Spent Fuel Storage Installations, a binding rule that generically considers, and determines for the purposes of future licensing, reasonably foreseeable and cumulative environmental impacts of continuing to store on the surface of the earth for extended periods, including indefinitely, all spent fuel previously generated and requiring storage pursuant to past Commission licensing actions, and any spent fuel that would be generated pursuant to pending and reasonably foreseeable licensing actions the Commission may undertake in the future.* But in defiance of the DC Circuit's directions, NRC's Draft GEIS continues present its WCD and TSR decisions as "separate from the individual licensing decisions it enables," and even includes a special box in the Executive Summary to this effect, headlined, "The Waste Confidence rulemaking is not a licensing action." This box then asserts, "Every nuclear power

plant or specifically licensed spent fuel storage facility must undergo an environmental review as part of its site-specific licensing process," when the NRC knows full well adoption of the Draft GEIS conclusions would, as the DC Circuit noted, actually *preclude* further NEPA consideration of spent fuel storage issues at the licensing stage! Draft GEIS at xxvi. NRDC notes in passing that we find such mind-numbing doublespeak, on behalf of a Commission charged with safeguarding the public interest, to be regrettable. (0706-1-18 [Fettus, Geoffrey])

Comment: NRC's Proposed Action thus becomes "to adopt into regulation the environmental impact analyses in this Draft GEIS," and the alternative of No Action involves not codifying generic environmental findings at 10 CFR 51.23 and instead "addressing the environmental impacts from continued storage in each of its nuclear power plant and ISFSI initial licensing and license renewal proceedings." Draft GEIS at 1-6. Since addressing environmental impacts in the licensing proceedings has not been the agency's practice to date, and is therefore not part of the environmental status quo, this cannot lawfully comprise the "No Action Alternative." Despite the vast radionuclide inventories, geographic dispersion, temporal sweep, and potential hazards involved in the nuclear waste storage problem, there are just two "[O]ther Reasonable Alternatives" considered in this GEIS: (1) "Develop a GEIS without incorporating the results into a rule...allow[ing] the NRC to adopt these Draft GEIS findings into environmental reviews for future licensing activities, but without the effect of a rule;" and (2) "...issue a policy statement [that] would not bind licensees and applicants like a rule, but would provide notice of the Commission's intent to incorporate the findings of the GEIS into environmental reviews for future licensing activities." *Id.* at 1-7. We discuss the inadequacies of the presented alternatives below. (0706-1-19 [Fettus, Geoffrey])

Comment: Page 1-6. (Purpose of and Need for the Proposed Action) "The purpose and need for the proposed action are threefold: (1) to improve the efficiency of the NRC's licensing process by generically addressing the environmental impacts of continued storage; (2) to prepare a single document that reflects the NRC's current understanding of these environmental impacts; and (3) to respond to the issues identified in the remand by the Court in the *New York v. NRC* decision. The NRC intends to codify the results of its analyses in this draft GEIS at 10 CFR 51.23. NRC licensing proceedings for nuclear reactors and ISFSIs will continue to rely on the generic determination in 10 CFR 51.23 to satisfy obligations under NEPA with respect to the environmental impacts of continued storage." NRDC Comment[:] The Purpose and Need of NRC's "proposed" action under NEPA are improperly defined, as is the major federal action at issue. As the DC Circuit and the NRC have acknowledged, an EIS is necessary. See *New York et al.* at 476-477 (explanatory brackets inserted, emphasis added, citations omitted), ("Under NEPA, each federal agency must prepare an Environmental Impact Statement ("EIS") before taking a "major Federal action[] significantly affecting the quality of the human environment." 42 U.S.C. § 4332(2)(C). ... The issuance or reissuance of a reactor license is a major federal action affecting the quality of the human environment... the WCD rulemaking is a major federal action requiring either a FONSI or an EIS. *The Commission's contrary argument treating the WCD as separate from the individual licensing decisions it enables fails under controlling precedent.*"). So what is the purpose at issue here and why is an EIS necessary? An EIS is necessary not just because the Court directed there be one. An EIS is necessary to address the environmental impacts identified by the Court as necessary for evaluation under NEPA. We now explain what a proper purpose and need section might look like. (0706-1-20 [Fettus, Geoffrey])

Comment: As a result, the notice failed to give the public sufficient information on which to develop comments on the appropriate scope of the EIS proposed by the NRC, and not surprisingly, the Agency has brought forth a Draft GEIS with a scope of analysis that is woefully deficient. (0706-1-4 [Fettus, Geoffrey])

Comment: We are unclear how the Court could have been more direct in its language. The NRC action - licensing nuclear power plants - leads to the environmental impacts associated with SNF storage and a lack of disposal options and that is what must be considered under NEPA.⁸ [footnote 8 text: NRDC also responded at length in its scoping comments to the Chairman's assertion that scoping notices prepared under the Commissioners' discretionary authority found in § 51.20(a)(2) impliedly have no such obligations as those found in §51.27(a), as such restrictions apply only to scoping notices that are prepared under §51.26. First, nothing in § 51.20(a)(2) removes the Commissions' responsibility to comply with the whole of NEPA. Second, the Chairman's assertion conflicts with the agency's own Waste Confidence Scoping Notice—which at no point references §51.20 – but does, in fact, reference §51.26. 77 Fed. Reg 65138.] To comply with the Court's opinion and NEPA, we see no alternative but for the Commission to withdraw this Draft EIS and reissue it with a properly defined proposed action and reasonable alternatives for achieving the agency's purpose and need for action that are consistent with the purpose of NEPA to foster not "paperwork" but "excellent agency action" that "protect(s) the environment." 40 CFR § 1500.1 (c). In pursuit of this objective, the Agency must publish a new Scoping Notice that clearly articulates the scope of reasonably foreseeable environmental impacts flowing from all future agency actions that critically depend on the Proposed Action to license the production and storage of SNF. In the abundance of caution we will nevertheless comment in detail on the many manifest deficiencies in the current Draft GEIS. (0706-1-6 [Fettus, Geoffrey])

Comment: In its response to the scoping comments filed by NRDC and many others, NRC managed to both misconstrue and disregard them. We could belabor the point for pages, but we will cite the way one of our own comments was handled. First, NRC misconstrued NRDC's following observation regarding the major federal action and reasonable alternatives for implementing it: [NRC must] determine whether or how much additional SNF may be generated when there is no permanent, safe and secure waste disposal facility, no date certain by which such a facility will exist and the significant possibility that such a disposal facility may never exist. Further, if such additional SNF is allowed to be generated, what alternatives exist to the current practice of allowing nuclear wastes to be generated and stored at individual reactor sites indefinitely and in spent fuel pools for as long as the licensee chooses? And finally, regardless of how much new SNF may or may not be allowed to be generated, what are the long term storage alternatives and associated environmental impacts for the SNF and high-level radioactive waste that are already in existence? 10 C.F.R. § 51.27(a)(2). If one examines the "Alternatives" section of NRC's scoping summary document, at no point does NRC even acknowledge, much less respond in a substantive fashion to observations regarding the major federal action and reasonable alternatives for implementing it. Rather, NRC nonsensically suggested parties had submitted "alternatives to the Waste Confidence rulemaking ... such as stopping all NRC licensing activities, halting any further production of spent nuclear fuel, and shutting down all existing nuclear power plants." NRC Scoping Summary Document at 26-27 (emphasis added). Such a response trivializes and distorts the important NEPA compliance issues NRDC and others introduced. At issue is the arbitrary and contrived manner in which the agency has defined the scope of its Proposed Action for NEPA analysis, and the range of reasonable alternatives for avoiding, reducing, and mitigating environmental impacts it must consider before arriving at a final agency decision to pursue a particular course of action. (0706-1-7 [Fettus, Geoffrey])

Comment: As a result of all of the above, the agency must evaluate the environmental effects of all reasonable alternatives for on-site and off-site storage of waste during and after the period of extended operation; offsite land, water, and air use impacts of continued operations and the storage of additional spent fuel on the surrounding areas; evaluation of the long term impacts

and safety of the generation and long-term storage of radioactive waste; the comparative impacts of spent fuel storage in pools versus in dry casks; the implications of on-site storage of waste for decommissioning; the effects of spent fuel disposal and the effects of spent fuel storage and disposal in the event of extended delay or if no final disposal option or repository is ever identified; and alternatives to mitigate these impacts, among other issues. Many of these issues appear to be site specific and cannot be dealt with generically, but in any event we suggest a legally compliant definition of the proposed action in the next comment. (0706-2-1 [Fettus, Geoffrey])

Comment: In place of the required comparative NEPA analysis of reasonable alternatives for implementing the proposed action and mitigating environmental harms, like the one outlined above, we find instead a "Cost-Benefit Analysis" (Draft GEIS Section 7.0) confined to reviewing the legal, financial, and "public perception" costs and benefits of the four agency administrative options that could in some fashion render an the required analysis of the long-term impacts of prolonged surface storage of spent fuel. However, according to the Draft GEIS, these costs and benefits *"do not include the environmental impacts of continued storage, an activity that will occur regardless of the alternative that the NRC selects to consider its impacts."* Draft GEIS at 7-1, emphasis added. But NRC's NEPA obligation cannot be nonsensically reduced to the mere selection of a paperwork alternative for *considering* environmental impacts. Rather the Draft GEIS must analyze the environmental consequences of reasonable alternatives for actually *implementing* continued storage of spent fuel the Commission may authorize in future commercial power reactor and spent fuel facility licensing actions. (0706-2-16 [Fettus, Geoffrey])

Comment: And as a final matter, putting aside for a moment the broader question whether NRC's Draft framework used in this GEIS for analyzing its NEPA obligations complies with the statute and applicable regulations—it doesn't—and focusing on the narrower question whether these are even distinct and cognizable "alternatives" with discernible environmental impacts, NRDC is hard pressed to detect any meaningful difference between the proposed alternatives as all but one involve preparation of a Draft GEIS, but not its subsequent adoption into a proposed rule. However, "reasonable alternatives" are, by definition, alternative means (with greater and lesser environmental impacts) for *accomplishing the agency's purpose and need for action*—that is what makes them "reasonable"—and NRC's purpose and need is defined in this Draft GEIS as "improve[ing] the efficiency of the NRC's licensing process by generically addressing the environmental impacts of continued storage." Since neither of the two "reasonable alternatives" deemed worthy of detailed NEPA analysis could culminate in a discernible agency Record of Decision supporting an agency action that generically determines impacts to "improve the efficiency of the NRC's licensing process," they do not meet the threshold standard of being reasonable alternative means for achieving the agency's stated purpose and need for action. Both alternatives would leave NRC with "Draft GEIS findings" that have no have no legal status, which, if used, would be subject to challenge in site-specific licensing proceedings. In short, the NRC Staff is leading decision-makers and the public through a convoluted, rhetorical hall of mirrors in this Draft GEIS that has nothing to do with good-faith compliance with NRC's legal obligations. (0706-2-17 [Fettus, Geoffrey])

Comment: The Framing of the Proposed Action Leads to An Absurd Comparison of Alternatives. As established above, the issuance or reissuance of a reactor license is a major federal action affecting the quality of the human environment." *New York et.al. at 7*, (citing *New York v. Nuclear Regulatory Comm'n*, 589 F.3d 551, 553 (2d Cir.2009)). The instant DC Circuit ruling further held, "[w]e agree with petitioners that the WCD rulemaking is a major federal action requiring either a FONSI or an EIS. The Commission's contrary argument treating the WCD as separate from the individual licensing decisions it enables fails under controlling

precedent. ...The WCD makes generic findings that have a *preclusive effect in all future licensing decisions*—it is a *pre-determined 'stage' of each licensing decision*. NEPA..." *Id.* at 8, emphasis added. In this connection, the Court also noted, "It is not only reasonably foreseeable but eminently clear that the WCD will be used to enable licensing decisions based on its findings.... [the WCD] renders uncontestable general conclusions about the environmental effects of plant licensure that will apply in every licensing decision. See 10 C.F.R. § 51.23(b)." The failure to analyze meaningful alternatives is a direct result of an improperly framed proposed action. As we suggested above, following the Court's guidance and a common sense reading of NEPA and its implementing regulations, a legally compliant definition of the proposed action would be the following: *The NRC proposes to reinstate, as a pre-determined stage of its individual licensing actions for nuclear reactors and Independent Spent Fuel Storage Installations, a binding rule that generically considers, and determines for the purposes of future licensing, reasonably foreseeable and cumulative environmental impacts of continuing to store on the surface of the earth for extended periods, including indefinitely, all spent fuel previously generated and requiring storage pursuant to past Commission licensing actions, and any spent fuel that would be generated pursuant to pending and reasonably foreseeable licensing actions the Commission may undertake in the future.* (0706-2-2 [Fettus, Geoffrey])

Comment: Page 1-10. Comparison of Reasonable Alternatives. NRDC Comment[:] See Comment #5 above. NRC's inadequate paper alternatives result in the same minimal environmental impacts because the agency has failed to (1) identify the major federal action at issue – licensing nuclear reactors and allowing the production of spent nuclear fuel – and (2) evaluate a set of meaningful alternatives and potential strategies for mitigating the harms. As noted, the analytical framework adopted in this Draft GEIS blatantly subverts the essential purposes of NEPA. (0706-2-20 [Fettus, Geoffrey])

Comment: An understandable and coherent proposed action would result in meaningful NEPA process. By contrast, in the instant case the failure of this Draft GEIS to take account of the Court's finding the WCD/TSR represents a "predetermined stage of each licensing decision" is evident not only from the wide gap between the Court's plain language and the analytical constructs employed in the Draft GEIS, but also from the fact that the resulting analysis violates a fundamental principle of statutory interpretation: longstanding legal precedent admonishes us not to interpret a statute - NEPA in this instance - in a manner that yields futile results with little or no meaning.¹⁹ [footnote 19 text: See *Absurdity And The Limits Of Literalism: Defining The Absurd Result Principle In Statutory Interpretation*, Veronica M. Dougherty, *The American University Law Review*, Vol. 44:127 (1994) at 127, ("[I]t is a venerable principle that a law will not be interpreted to produce absurd results."), <http://digitalcommons.wcl.american.edu/cgi/viewcontent.cgi?article=1523&context=aulr>.] (0706-2-3 [Fettus, Geoffrey])

Comment: Specifically, NRC Staff has produced a Draft GEIS that, contrary to statute and regulation, fails to consider and compare the environmental impacts (and mitigation options) of a representative range of reasonable alternatives for ensuring prolonged but safe surface storage of spent fuel generated as a direct consequence of past, pending, and reasonably foreseeable future licensing actions of the Commission. The Draft GEIS thus yields, *in its own words*, the following "absurd and futile" result: "The environmental impacts of these three [NEPA] alternatives are substantially the same, and the *licensed activities under all three alternatives remain the same*. The alternatives *merely propose alternative means of analyzing* the environmental impacts of continued storage." Draft GEIS at 1-10, emphasis added. In other words, with a circular reasoning worthy of the famous BBC comedy series "Yes, Minister," this Draft GEIS sets its task as "analyzing alternative means of analyzing" the environmental

impacts of continued storage, rather than considering reasonably foreseeable *action* alternatives for *implementing* continued storage that could potentially minimize environmental risks and impacts, as the agency is required to do by law. "NEPA's purpose is not to generate paperwork -even excellent paperwork-but to foster excellent *action*." 40 CFR § 1500.1 (c). We are aware of no comparable instance in which a Federal Agency proposing a major federal action - much less one responding to specific NEPA direction from a Federal Court - has sought to substitute a *cost-benefit comparison of alternative procedural pathways for NEPA analysis* in place of the required substantive and searching *environmental impact comparison of reasonable alternatives* required under NEPA. See NEPA, 42 U.S.C. § 4321, *et seq.*; see also 40 C.F.R. § 1502.14 and 10 C.F.R. 51.85 and § 51.10-125 and App A. CEQ's regulations governing implementation of NEPA direct that Federal agencies "shall to the fullest extent possible....(b)...emphasize *real environmental issues and alternatives*...(e) Use the NEPA process to identify and assess the *reasonable alternatives to proposed actions that will avoid or minimize adverse effects of these actions* upon the quality of the human environment." 40 C.F.R. §1500.2 (emphasis added). (0706-2-4 [Fettus, Geoffrey])

Comment: NRC Has Not Plausibly Defined the Alternative of No Action, or Provided Reasonable Alternatives for Comparison. In setting out the fundamental purpose of an EIS, CEQ's regulations also state, "It [the EIS] shall provide full and fair discussion of significant environmental impacts and shall inform decisionmakers and the public of the *reasonable alternatives which would avoid or minimize adverse impacts or enhance the quality of the human environment*. Agencies shall focus on *significant environmental issues and alternatives*..." 40 C.F.R. §1502.1(emphasis added). Satisfying these requirements is a non-discretionary duty of the NRC's NEPA process and obligations under the law. But the analysis of reasonable alternatives in this Draft GEIS fails to meet these requirements. It fails to consider "real environmental issues" *in the context* of "reasonable alternatives to proposed actions that would avoid or minimize adverse impacts," and instead compares the *non-environmental* costs and benefits of codifying its environmental analysis with three alternative procedural pathways for completing NEPA review, an approach fails to comply with NEPA's basic requirements, and *delivers the absurd result of literally performing NEPA analysis on ways to carry out NEPA analysis*. Since NRC's framework for NEPA analysis fails at this fundamental level, it stands to reason that this Draft GEIS fails many other specific regulatory standards for a legally sufficient EIS. The analysis of "alternatives, including the proposed action...is *the heart of the environmental impact statement*....it should present *the environmental impacts of the proposal and the alternatives in comparative form*, thus *sharply defining the issues and providing a clear basis for choice among options* by the decisionmaker and the public..." agencies *shall rigorously explore and objectively evaluate all reasonable alternatives ... and devote substantial treatment to each alternative considered in detail* including the proposed action so that *reviewers may evaluate their comparative merits*." 40 CFR §1502.14 (emphasis added). These requirements affecting the environmental analysis of the proposed action and reasonable alternatives are substantially echoed in the Commission's own regulations at § 51.71 (d) and § 51.125, Appendix A paras (5) and (7). (0706-2-5 [Fettus, Geoffrey])

Comment: But in this Draft GEIS, the required rigorous and objective exploration of all reasonable alternatives, providing an environmental evaluation of their "comparative merits" to identify those that "would avoid or minimize adverse impacts," is reduced to less than 2 pages, *none of which actually describe or compare environmental impacts!* See Draft GEIS Subsection 1.6.2 "Other Reasonable Alternatives," p. 1-7. The subsection comparing "reasonable alternatives" is comprised of two short paragraphs, barely 10 lines of text in total. Draft GEIS Subsection 1.6.4 , "Comparison of Reasonable Alternatives§ at 1-10. This is cursory treatment for the supposed "heart of the environmental impact statement." This Draft GEIS is unable to

provide such comparative environmental analysis, because it fails to define, consider, and compare the environmental consequences of a range of reasonable alternatives for implementing continued and potentially indefinite storage of spent fuel arising from future licensing actions, including the mandated alternative of No Action. Logically, the latter should be defined in this Draft GEIS, as in thousands of other federal NEPA documents, as the *continuation of the policy and environmental status quo assuming the Agency does not undertake the Proposed Action, or any of the action alternatives assessed in detail and determined to be reasonable.* (0706-2-6 [Fettus, Geoffrey])

Comment: In contrast to the above posited scenario, NRC's Draft GEIS arbitrarily and capriciously defines its "No-Action Alternative" as one in which "the NRC would take no action to *generically address the environmental impacts* of continued storage." Draft GEIS at 1-6, line 24. The agency is literally stating that it is comparing the environment impacts arising from not preparing a "generic analysis" to the impacts of preparing one! As if this were not sufficiently absurd by itself, the bogus character of this alternative is further exposed by the fact that preparation of the Draft GEIS *is obviously itself an action* that "generically address[es] the environmental impacts of continued storage." In other words, even within its cramped and noncompliant NEPA decision framework, this purported "No Action Alternative" already embodies a major component of the agency's Proposed Action, which by law and judicial precedent it is barred from doing. The Draft GEIS then compounds its NEPA noncompliance by noting that under the No Action Alternative, which by law must assume the absence of the Proposed Action, the Commission would nonetheless be "likely" to pursue the *same objective* (of making a generic environmental determination) by "first construct[ing] complete analyses of the issues previously addressed by earlier Waste Confidence proceedings resulting in the adoption and revision of 10 CFR 51.23 [i.e. the WCD/TSR] for use in site-specific NEPA reviews, and then incorporat[ing] by reference the applicable findings from the first few published environmental documents that used the analyses. This approach could ultimately lead the NRC *to consider the issue through a generic and replicable analysis.*" Draft GEIS at 1-6, line 32 (emphasis added). In short, this capricious and self-interested framing of the "No Action Alternative," which already fails for being devoid of environmental content, also turns out to be a bureaucratic ruse, and just another route to achieving a "a generic and replicable analysis" of spent fuel storage that can be invoked at will into future licensing actions. (0706-2-8 [Fettus, Geoffrey])

Comment: The Alternatives Analyzed In the Draft GEIS Are Arbitrary and Capricious. By statute, a "major federal action" warranting preparation of an EIS is one "significantly affecting the quality of the human environment." 42 U.S.C. § 4332(2)(c). The minor bureaucratic act of selecting among four alternative pathways for completing NEPA documentation on continued spent fuel storage obviously does not, in and of itself, rise to the level of a "major federal action significantly affecting the quality of the human environment," and therefore it cannot legitimately serve as the appropriate decision analysis framework for this Draft GEIS. Not surprisingly, the Draft GEIS tacitly reaches the same conclusion by failing to quantify, compare, contrast, and qualitatively discuss the environmental impacts (including mitigation) of its two supposed "reasonable alternatives." Indeed, in place of the required comparative NEPA analysis of reasonable alternatives for implementing the proposed action and mitigating environmental harms, we find instead a "Cost-Benefit Analysis" (Draft GEIS Section 7.0) confined to reviewing the legal, financial, and "public perception" costs and benefits of the four agency administrative options that could in some fashion render an the required analysis of the long-term impacts of prolonged surface storage of spent fuel. However, according to the Draft GEIS, these costs and benefits *"do not include the environmental impacts of continued storage, an activity that will occur regardless of the alternative that the NRC selects to consider its impacts."* Draft GEIS at

7-1, emphasis added. But NRC's NEPA obligation cannot be nonsensically reduced to the mere selection of a paperwork alternative for *considering* environmental impacts. Rather the Draft GEIS must analyze the environmental consequences of reasonable alternatives for actually *implementing* continued storage of spent fuel the Commission may authorize in future commercial power reactor and spent fuel facility licensing actions. This analysis must embrace a range of reasonable surface storage alternatives with greater or lesser environmental impacts, over a relevant range of time periods extending from an initial 20-year license renewal to indefinite storage. For more distant time periods, the analysis must consider the consequences for the human and natural environment in the absence of institutional controls. (0706-2-9 [Fettus, Geoffrey])

Comment: The problem is that the NRC's expressed confidence that there would soon be a permanent disposal site has repeatedly been empirically disproven. In 1977, a couple years after its establishment, NRC issued a finding that it was confident that the wastes produced by reactors "can and will *in due course* be disposed of safely."¹ [footnote 1 text: 42 FR 34391, 34393; July 5, 1977, *pet. for rev. dismissed sub nom., NRDC v. NRC*, 582 F.2d 166 (2d Cir.1978)), as cited in 78 FR 56776,78, Proposed Waste Confidence Rule.] (emphasis added) With no such facility having opened or even under construction underway by 1984, NRC issued a waste confidence rule that said there would be a functioning HLW disposal facility open and operating by 2007-2009. When it was clear that wouldn't happen, it revised its confidence statement in 1990 with a new expected date of the first quarter of the 21st century. When that also turned out not to be in the cards, NRC stopped giving dates by which it was confident there would be such a site and instead found that the Commission was confident there would be a HLW geological repository open "when necessary." The Court of Appeals for the District of Columbia struck down that rule, concluding that it was not clear such a disposal site would in fact ever open, and directed NRC to prepare an Environmental Impact Statement analyzing the environmental impacts of high level radioactive waste if no geological repository became available.² [footnote 2 text: This history is summarized in the NRC notice of the Proposed Waste Confidence Rule, 78 FR 56776.] (0738-5 [Hirsch, Daniel])

Comment: Under section ES.2, page xxiv, lines 5-7, the Draft GEIS needs to include a mitigation analysis (including emergency preparedness) to meet its NEPA requirements. The failure to do so is an assumption that there will not be an incident at any storage facility, wet or dry, for which a response will be required. This assumption is not appropriate in an environmental impact statement and, fundamentally, defies common sense. There must be a mitigation analysis. (0783-1-13 [Harlan, Thomas])

Comment: Under section ES.16 .2, page lix, lines 15-35, there is no reference whatsoever to any mitigation, emergency response or emergency preparedness. All of these factors must be included within in an analysis of the spent fuel fire – or any other analysis of an incident or threatened incident. To merely rely on general statements of the robustness of the container or "mitigation measures implemented by licensees as a result of NRC orders" are insufficient. This does not analyze any impact of the proposed action because it assumes there will be no impact of the proposed action. This assumption, then, foregoes any analysis under NEPA. The Draft GEIS should set out the necessary mitigation to control or contain any incident. (0783-1-19 [Harlan, Thomas])

Comment: In order for the EIS to meet NEPA, an analysis of mitigation through emergency preparedness and/or emergency response must be included. The core concept of NEPA is to evaluate a certain activity and its potential impact on the human and natural environment. As part of that, there are a number of alternatives that are examined including how certain adverse

impacts may be avoided. The inclusion of possible mitigation measures serves one of NEPA's basic functions. See *Robertson v. Methow Valley Citizens Council*, 490 U.S. 332, 351-52, 109 S.Ct. 183 (1989). Mitigation is defined as measures that are intended to avoid and, minimize, rectify, reduce, or compensate for environmental impacts. See 40 CFR § 1508.20. Not only is a federal agency, or in this case, the NRC, obligated to discuss possible mitigation measures as part of the scope of its Draft GEIS but it should discuss alternatives to the proposed action and the consequences of the same and as alternatives. In other words, it needs to address how mitigation plays out in the Draft GEIS. See 40 CFR § 1505. (0783-1-7 [Harlan, Thomas])

Comment: The purpose of the Draft GEIS is to evaluate the impact of continued storage over the stated periods of time. It is also to evaluate, as it does to a great extent with spent fuel pools, the impact of potential release into the environment and the impact it would have on the human and natural environments. The general discussion of the robust nature of the storage systems is not a substitute for evaluating mitigation. Indeed, it is the systems themselves that must be evaluated for release and potential release-and then mitigation as a result of that activity. Mitigation here comes in the sense of a response and effort to contain or potentially stop any release. The emergency preparedness of any first responder is required as part of the reasonable assurance that each is required to provide annually. Accordingly, the failure to include a complete discussion and analysis of mitigation, which would include emergency preparedness and certain base levels for the same, defeats the very goal the NRC set out to accomplish: the creation of an EIS that meets NEPA qualifications.³ [footnote 3 text: It could be said regarding the new Waste Confidence Rule that is being proposed: the only true measure of confidence is to include an analysis about what will happen in the event of an incident, whether radiological or non-radiological, at a storage facility. To be confident that nothing is going to happen and no response will be needed is not confident or reassuring at all. It is naïve. The probability may be small but if there is an incident and no appropriate response, the results will be catastrophic.] Mitigation and an evaluation of emergency preparedness need to be included in the Draft GEIS. (0783-1-8 [Harlan, Thomas])

Comment: Under section 1.3, page 1-5, lines 16-21, the Draft GEIS should add that past licensing has been based, in part, on the Waste Confidence Rule. This Waste Confidence Rule was done or completed without the benefit of an EIS or any determination of long-term impact. There was simply the assumption that continued storage was safe. As it currently exists, the Draft GEIS is exactly the same. The City [Red Wing, MN] hopes its comments are appropriately weighed so that any final report avoids this flaw. (0783-2-2 [Harlan, Thomas])

Comment: The Draft GEIS, on page 3-41, should include a new section on mitigation. Mitigation is a specific and necessary requirement for an appropriate NEPA analysis. This section would include, but not be limited to, a general description of the necessary emergency preparedness steps and requirements. This can relate back to the impact of the ISFSI or storage system on the host community. The failure to include any analysis, mitigation efforts, or even to address it, is a fatal shortcoming of the Draft GEIS. (0783-2-23 [Harlan, Thomas])

Comment: Under section 6.4.16 and 6.4.17, running from pages 6-53 – 6-57, an analysis of mitigation needs to be set forth. Mitigation is a necessary NEPA component that must be addressed. A failure to do so is a flaw that may result in a challenge to the Draft GEIS or the GEIS in its final form. (0783-3-15 [Harlan, Thomas])

Comment: The summary of environmental impacts, overall, needs to be modified to include the City's [Red Wing, MN] recommended modifications to the Draft GEIS. In addition, the summary should, as a separate section under the same, include an analysis of mitigation. (0783-3-16 [Harlan, Thomas])

Comment: Under section 8.7, page 8-12, the Draft GEIS, and the NRC recommendation, is to select the proposed action. The City [Red Wing, MN] agrees with this recommendation. However, the necessary changes in the Draft and Final GEIS, as described by the City, should be included. (0783-3-19 [Harlan, Thomas])

Comment: Under section 4.17, starting on page 4-64 and carrying over to page 4-66, the Draft GEIS addresses public and occupational health. The Draft GEIS should be modified to include an analysis regarding mitigation. There is nothing to establish or support that there would be any mitigation in the event of an incident. The inclusion of this must be analyzed in order to meet NEPA requirements. (0783-3-7 [Harlan, Thomas])

Comment: The following Analytic Assumptions are asserted: Institutional controls, i.e. the continued regulation of spent nuclear fuel, will continue. • A DTS will be built (and used) at each ISFSI location • A 100 year replacement cycle for spent fuel canisters and ISFSI • Aging management and maintenance will continue • "Sufficient low-level waste disposal capacity will be made available when needed[.] Asserting these Assumptions in order to avoid -- rather than engage - mitigation strategies is wholly incompatible with both the court order and with NEPA: "The purpose of environmental Mitigation must be considered for all impacts, regardless of their significance". The failure to provide mitigation for the required analysis is in direct defiance of NEPA and the CEQ Guidance document on Mitigation adopted in January, 2011: http://energy.gov/sites/prod/files/NEPA-CEQ_Mitigation_and_Monitoring_Guidance_14Jan2011.pdf (0820-10 [Eide-Tollefson, Kristen])

Comment: Furthermore, the construction of the GEIS Assumptions, undermines the very pre-conditions that would ensure safe storage over indeterminate periods of time. This makes it impossible for states to implement planning or require utilities to fund mitigation strategies for indeterminate storage. This is stated as one of the express purposes of the GEIS, to avoid Implementing Additional Regulatory Requirements (1.6.3.2) (0820-11 [Eide-Tollefson, Kristen])

Comment: Mitigation development: The GEIS-only alternative could provide the NRC with a mechanism through which to develop a set of mitigation strategies to address the unknown, and unknowable future of nuclear waste. For this to happen, NRC would need to reformulate the "Analytic Assumptions" as a set of "Pre-Conditions" for storage which would protect the public health and safety. And proceed to review, adapt and develop tools*, frameworks and strategies, as in the recommendations following. *Hazardous Substances Pollution Contingency Plan and Community Right to Know provisions. <http://www.gpo.gov/fdsys/pkg/CFR-2001-title40-vol24/pdf/CFR-2001-title40-vol24-chap1-subchapJ.pdf> International Radiation Protection Association - recommendations for Public Stakeholder involvement in radiological education and protection. <http://www.ncbi.nlm.nih.gov/pubmed/21979548> Health Physics Society endorsement of Guiding Principles for Radiation Protection Professionals on Stakeholder Engagement developed by the IRPA - Adopted January, 2010. http://hps.org/documents/stakeholder_engagement_ps024-0.pdf (0820-14 [Eide-Tollefson, Kristen])

Comment: The NRC has defined the proposed action as a rule (a revised TSR) that codifies the agency's generic determination on the environmental impacts of continued (i.e., interim) storage of spent nuclear fuel at, or away from, reactor sites beyond a reactor's licensed life, pending disposal at a repository. This definition accurately characterizes the proposed action. The D.C. Circuit itself concluded that the "*rulemaking* at issue here constitutes a major federal action."³⁶ [footnote 36 text: "*New York v. NRC*, 681 F.3d at 473 (emphasis added).] The TSR has always been based upon the Findings of the NRC's WCD and, as discussed below, should continue to reflect the conclusions from the GEIS and supporting record. The present

amendment to the rule would incorporate the results of the NRC's GEIS, which specifically includes the issues identified by the Court of Appeals. (0827-1-8 [Ginsberg, Ellen])

Comment: Page 1-11, Line 16-17. Interesting that you are using the guidance of NUREG-1748 regarding "LICENSING ACTIONS" when you have already said this document has nothing to do with licensing. Again, this underlines our assertion that indeed you are considering a change in the license, but are doing it in such a way to avoid the scrutiny of the license amendment process. Shame on you. (0836-34 [Davis, Anonymous])

Comment: The DGEIS overlooks the central problem by using a purpose and need statement that sidesteps the analytical issues raised by the task it is obligated to undertake. (0867-3-19 [Griffin, William])

Comment: After reading through the draft EIS document, my understanding is that the document acts as a template of continuity to ensure individual licenses will be evaluated consistently. With this continuity in place, will the final draft GEIS be as soft on facts and science? (0881-1 [Szymanowski, Jennifer])

Comment: In fact, the DGEIS flouts both NEPA and the Court's application of NEPA in *New York*, 681 F.3d 481 (D.C. Cir. 2012) in multiple ways: In violation of NEPA, the DGEIS makes no attempt to show how the environmental impacts associated with the proposed rule will be quantified and incorporated into cost-benefit analyses for nuclear reactors. Although spent fuel disposal and long-term storage costs are high enough to tip the balance of a cost-benefit analysis for reactor licensing away from licensing, nowhere does the NRC explain how it will take these costs into account in reactor licensing decisions. (0897-1-12 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: In fact, the DGEIS flouts both NEPA and the Court's application of NEPA in *New York*, 681 F.3d 481 (D.C. Cir. 2012) in multiple ways: The NRC has splintered the analysis of environmental impacts associated with storage and disposal of spent fuel into an array of safety findings and environmental analyses. While the issues covered by these separate findings and analyses overlap and involve cumulative impacts, the NRC refuses to integrate them. The NRC also refuses to correct inconsistencies between them. (0897-1-13 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The attached declaration of Mark Cooper shows that these costs are not only significant, but they may tip the balance of a cost-benefit analysis away from licensing or re-licensing reactors to energy efficiency and other energy alternatives. (0897-1-16 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Finally, the DGEIS must show how the significant risks and costs of siting a reactor or failing to do so, plus the risks and costs of spent fuel storage, will be integrated into the cost-benefit analyses for individual reactors. (0897-1-17 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The proposed rule and DGEIS come at a critical juncture for the U.S. energy future. The costs of clean energy alternatives such as wind and solar are declining at the same time that costs of building new reactors and maintaining aging existing reactors are going up. Spent reactor fuel inventories, along with their storage costs and environmental risks, are also mounting at every U.S. reactor site -- and the prospect of a permanent repository grows more distant and costly with each passing decade. Under the circumstances, as demonstrated in the attached declaration of Mark Cooper, the costs of spent fuel management could tip the balance away from new or re-licensed nuclear reactors toward energy efficiency or clean

alternative energy sources. Thus it is important for the NRC to ensure that these energy choices are well-informed by full consideration of environmental risks and a weighing of reasonable alternatives, as required by NEPA. But the NRC has not even acknowledged its obligation to make that analysis, let alone shown how it plans to carry it out. (0897-1-18 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The Organizations respectfully request the NRC to revise and integrate all regulations that relate to the environmental impacts of spent fuel storage and disposal. Issues related to spent fuel storage and disposal impacts are now balkanized into separate rulemakings for spent fuel disposal impacts (Table S-3), safety and impacts of spent fuel storage and disposal from fuel generated during the license renewal period (Table B-1), safety and impacts of spent fuel storage after license termination (proposed 10 C.F.R. § 51.23), and safety and feasibility of siting a spent fuel repository (proposed 10 C.F.R. § 51.23). While the NRC has divided consideration of environmental impacts into piecemeal decision-making, they are in fact related. By considering them separately, the NRC ignores the interaction of impacts, cumulative impacts, and inconsistencies in safety and environmental analyses conducted in the separate decision-making processes. In order to comply with NEPA, the NRC should conduct a comprehensive review of these regulations and environmental studies, revise them to be consistent with the current state of knowledge, and integrate them into one cohesive regulatory framework. (0897-1-20 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: In fact, the DGEIS flouts both NEPA and the Court's application of NEPA in *New York*, 681 F.3d 481 (D.C. Cir. 2012) in multiple ways: The DGEIS fails to acknowledge that the proposed rule is a licensing action, and therefore it distorts the statement of purpose and need for the proposed rule as relating to administrative rather than environmental concerns. As a result, the DGEIS also mischaracterizes the alternatives that must be considered. Instead of evaluating alternatives related to storage and disposal of spent fuel, the DGEIS examines alternatives related to the administrative question of how to prepare an environmental impact statement (EIS). The result is a farcical cost-benefit analysis that utterly fails to address alternatives for avoiding or mitigating the environmental impacts of storing spent fuel or siting a repository. (0897-1-8 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: In other words, the purpose and need for the proposed action, as described in the DGEIS, is to justify a generic approach to the analysis of the environmental impacts of spent fuel storage, in lieu of a reactor-specific analysis. (0897-2-2 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Instead of avoiding or diminishing physical environmental impacts of spent fuel, the alternatives considered in the DGEIS "provide different approaches that the NRC could apply to future licensing activities that can satisfy the agency's responsibility to consider the potential environmental impacts of continued storage in deciding whether to issue certain licenses." DGEIS at 7-1. (0897-2-3 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The rationale offered by the DGEIS for failing to evaluate the costs of continued spent fuel storage is that this activity "will occur regardless of the alternative that the NRC selects to consider its impacts." DGEIS at 7-1. (0897-2-4 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The DGEIS lists a set of alternatives, proposed for consideration by members of the public, that could avoid or mitigate the adverse environmental impacts of spent fuel storage, but the NRC refuses to analyze them in the DGEIS: During the scoping period for the draft GEIS,

the NRC received many suggested alternatives to the Waste Confidence rulemaking, including calls for halting NRC licensing activities and shutting down operating reactors or imposing new requirements on nuclear power plants, such as storing spent fuel in special hardened onsite storage, reducing spent fuel pool density, and accelerating the transfer of spent fuel from pools to dry casks. The NRC determined that halting NRC licensing and closing nuclear reactors would not meet the purpose and need of the proposed rulemaking action. The NRC also determined that additional requirements on spent fuel storage would not meet the purpose and need. Further, the draft GEIS is a NEPA review and not a licensing action; therefore, this draft GEIS would not be the appropriate activity in which to mandate new spent fuel storage requirements.

DGEIS at xxvi. The DGEIS provides the additional rationale that: Although cessation of nuclear power plant licensing and operations would halt the future generation of spent fuel, other environmental impacts could result from the required development of replacement power sources or demand reductions. Even then, the environmental impacts of continued storage would not cease until sufficient repository capacity becomes available. (0897-2-5 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: THE DGEIS VIOLATES NEPA BY MISSTATING THE PURPOSE AND NEED FOR THE PROPOSED RULE AND THEREBY PROVIDING A MEANINGLESS ALTERNATIVES AND COST-BENEFIT ANALYSIS (0897-3-1 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Compounding the absurdity of the DGEIS' identification of alternatives as a choice among analytical methods, the DGEIS' cost-benefit analysis consists of meticulous cost estimates and comparisons of the human hours and quantity of paper required for each method. DGEIS at 7-3, H-2. The results are absurd, giving no information whatsoever about the relative costs and benefits of measures to avoid or mitigate the environmental impacts of the spent fuel that will be generated through future licensing decisions. These impacts are potentially significant and the costs of mitigating them are potentially great, as discussed in Sections V.F, VI.E, and VII below. (0897-3-11 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The NRC should have clarified that the proposed rule would not allow the shutdown of operating reactors and therefore it is not a viable alternative for consideration under NEPA. (0897-3-13 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The NRC Must Evaluate a Reasonable Array of Alternatives for the Avoidance or Mitigation of Spent Fuel-Related Environmental Impacts, Either in the DGEIS or Reactor-Specific EISs[.] NEPA requires that the NRC must analyze a reasonable set of alternatives for the avoidance or mitigation of the significant impacts of generation of spent fuel, and integrate those considerations into individual licensing decisions. *See Robertson v. Methow Valley Citizens Council*, 490 U.S. 332, 351 (1989) (explaining that the “requirement that an EIS contain a detailed discussion of possible mitigation measures flows both from the language of the Act and, more expressly, from CEQ’s implementing regulations”); *see also* 10 C.F.R. § 51.71(d) (an EIS must include an analysis of “alternatives available for reducing or avoiding adverse environmental effects”). Whether the NRC performs that analysis generically or on a reactor-specific basis is entirely up to the NRC’s discretion. *Baltimore Gas & Electric*, 462 U.S. at 96. But NEPA requires that it must be done. (0897-3-14 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: First and foremost, the NRC must consider the no-action alternative, i.e., the alternative of not permitting further generation of spent fuel through the licensing of new reactors and the re-licensing of existing reactors. *Calvert Cliffs*, 449 F.2d at 114 (the

alternatives requirement “seeks to ensure that each agency decision maker has before him and takes into proper account all possible approaches to a particular project (including total abandonment of the project) which would alter the environmental impact and the cost-benefit analysis”). As demonstrated in the attached declarations of Dr. Arjun Makhjani (Exhibit A), Dr. Gordon Thompson (Exhibit C), and David Lochbaum (Exhibit B), spent fuel storage and disposal have significant environmental impacts, and measures for mitigation of those impacts involve significant costs. As further demonstrated in the attached declaration of Mark Cooper (Exhibit D), the costs of managing spent fuel could be great enough to tip the balance against reactor licensing or re-licensing. NEPA requires a full analysis of the environmental impacts of spent fuel generation, as well as a weighing of the relative costs and benefits of alternative energy sources in relation to the significant costs associated with nuclear power generation and spent fuel management. NEPA requires such an analysis before the NRC can promulgate a final version of 10 C.F.R. § 51.23. (0897-3-15 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The NRC must also consider the relative costs and benefits of mitigation alternatives to reduce adverse environmental impacts. For instance, numerous options are available to reduce the radiological risk arising from management of spent fuel, including options for providing enhanced protection of ISFSIs from attacks. Thompson Declaration, par. XI-8. Use of such options at ISFSIs across the United States would also support a national strategy of protective deterrence. *Id.* Whether these alternatives are considered generically or in individual licensing cases, they must be carried out under NEPA. (0897-3-16 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: In the DGEIS, the NRC purports to fulfill the key preliminary requirements for structuring the DGEIS and ensuring the completion of a meaningful analysis: defining the proposed action, describing the purpose and need of the proposed action, and identifying a range of alternatives to the proposed action. But the NRC taints the process by beginning it with the same legally erroneous premise rejected by the Court of Appeals in *New York v. NRC*: that proposed 10 C.F.R. § 51.23 is not a licensing action. Leading from this faulty premise, the DGEIS makes the absurdly circular assertion that the purpose and need for the DGEIS is to decide whether to address the environmental impacts of spent fuel storage generically or on a site-specific basis. The NRC then compounds its legal error to an even more absurd effect, by identifying a range of alternatives for *thinking about* the environmental impacts of spent fuel storage. The NRC conducts a comically detailed comparison of the costs and benefits of these alternative methods for analyzing environmental impacts of spent fuel storage, and finds that although none of these modes of thought have any adverse physical impacts on the environment, the generic mode of analysis is the “preferred alternative” for reasons of administrative efficiency. Thus, based on the NRC’s grossly erroneous structuring of the DGEIS, the DGEIS de-couples the environmental impacts of spent fuel from reactor licensing decisions and ensures that concerns about spent fuel storage or disposal impacts will never stop the issuance of a reactor license or result in the alteration of its terms. In short, the DGEIS is rendered meaningless. (0897-3-2 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: In order to comply with NEPA, the NRC must correctly define the proposed action and its purpose and need, and must conduct a meaningful analysis of a reasonable array of alternatives. See 10 C.F.R. Part 51, App’x A (in an EIS, the NRC must “briefly describe and specify the need for the proposed action”), 10 C.F.R. § 51.71(d) (an EIS must include an analysis of “alternatives available for reducing or avoiding adverse environmental effects,” including “consideration of the economic, technical, and other benefits and costs of the proposed action and its alternatives”). See also 40 C.F.R. §§ 1502.13, 1502.14 (in an EIS, an agency must describe the “purpose and need for the proposed action” and “[r]igorously explore

and objectively evaluate all reasonable alternatives”). These alternatives must include the option of denying new reactor license applications and license renewal applications for existing reactors, as well as alternatives for mitigating the adverse environmental impacts of spent fuel storage and disposal such as prohibition of the use of high burnup fuel. Whether the NRC performs this analysis in a generic EIS or reactor-specific EISs is a matter for the NRC’s discretion, but NEPA requires that it must be done. *Baltimore Gas & Elec. Co. v. NRDC*, 462 U.S. 87, 97-101 (1983). (0897-3-3 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The DGEIS’s Description of the Proposed Action is Incomplete and Fails to Acknowledge that Proposed 10 C.F.R. § 51.23 is a Licensing Action[.] The DGEIS provides only a partial description of the proposed regulatory action in 10 C.F.R. § 51.23. The DGEIS defines the proposed action as: issu[ing] a revised Rule, 10 CFR 51.23, that generically addresses the environmental impacts of continued storage. . . . Further, the revision would state that *because the impacts of continued storage have been generically assessed in this draft GEIS and codified in a Rule, NEPA analyses for future reactor and spent fuel storage facility licensing actions would not need to separately consider the environmental impacts of continued storage*. DGEIS at 1-5 (emphasis added). In other words, proposed Section 51.23 generically resolves, for individual reactor licensing and re-licensing decisions and spent fuel storage facility licensing decisions, the question of whether storage of spent fuel would have significant impacts on the environment. While this definition of the proposed action is correct as far as it goes, it is incomplete. The DGEIS fails to acknowledge that the proposed rule makes other environmental findings generically applicable to all individual reactor licensing and re-licensing decisions and spent fuel storage facility licensing decisions. These findings are the following: • Proposed 10 C.F.R. § 51.23 makes generic safety findings with respect to the feasibility of safely storing spent fuel for an indefinite period and the feasibility of siting a repository for spent fuel disposal within 60 years. • Proposed Table B-1 makes an environmental impact finding that spent fuel disposal impacts are not large enough to require “that the option of extended operation under 10 CFR part 54 should be eliminated.” • Proposed Table B-1 makes an environmental finding that the NRC “has not assigned a single level of significance for the impacts of spent fuel and high level waste disposal.” (0897-3-4 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Equally important, the DGEIS fails to acknowledge that all of the provisions of proposed 10 C.F.R. § 51.23 and proposed Table B-1 listed above constitute licensing actions, because they enable the creation of spent fuel by resolving safety and environmental issues that are necessary to the licensing and re-licensing of reactors. As was true of the 2010 Waste Confidence Decision that was vacated by the U.S. Court of Appeals, the “action” of the 2013 proposed rule is to “allow the licensing of nuclear plants.” *New York v. NRC*, 681 F.3d 471, 478 (D.C. Cir. 2012). See also *id.* at 476 (finding that the waste confidence decision is a “pre-determined ‘stage’ of each licensing decision”). There is no doubt that if carried out, these proposed actions will result in adverse impacts to the environment through the creation of spent reactor fuel. Not only does the DGEIS fail to acknowledge the fact that the proposed regulations constitute licensing actions, it denies that fact: The Waste Confidence rulemaking is not a licensing action. It does not permit a nuclear power plant or any other facility to operate or store spent fuel. Every nuclear power plant or specifically licensed spent fuel storage facility must undergo an environmental review as part of its site-specific licensing process. DGEIS at xxvi (emphasis in original). (0897-3-5 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The DGEIS’ Statement of Purpose Violates NEPA Because it Bears No Relationship to the Environmental Harm Caused by the Proposed Action[.] Compounding the NEPA violation caused by the DGEIS’ defective description of the proposed action, the DGEIS’ description of the “purpose and need for the proposed action” strays even further off course into

the realm of the utterly fallacious. The statement of purpose and need bears no relationship to any physical effects on the environment and absurdly contemplates the relative merits of *thinking and writing about* environmental impacts in different ways. According to the DGEIS: The purpose and need for the proposed action are threefold: (1) to improve the efficiency of the NRC's licensing process by generically addressing the environmental impacts of continued storage; (2) to prepare a single document that reflects the NRC's current understanding of these environmental impacts; and (3) to respond to the issues identified in the remand by the Court in the *New York v. NRC* decision. DGEIS at 1-6. Thus, instead of addressing the purpose and need for licensing decisions that allow harm to the environment through the generation of spent fuel, the DGEIS addresses the purpose and need for making a licensing decision generically instead of on a reactor-specific basis. But the question of how to prepare an EIS has no bearing on what will be the physical environmental impacts of the NRC's decisions to allow reactors to generate spent fuel. Thus, the statement of purpose and need blatantly violates NEPA. The DGEIS' additional statement that the purpose and need for the proposed action is "to respond to the issues identified in the remand by the Court" does not bring the NRC any closer to complying with NEPA, because elsewhere the DGEIS clearly rejects the Court's decision that the safety and environmental findings in 10 C.F.R. § 51.23 constitute a licensing decision. As discussed above, the DGEIS asserts that "the Waste Confidence Rulemaking is not a licensing action." DGEIS at xxvi. Indeed, this repudiation of the Court of Appeals' decision is written in bold and placed in a text box for emphasis. Thus, the DGEIS' statement of purpose and need is impermissible under NEPA, because it fails to address the purpose or need for NRC to allow the environmental harm that would be permitted by the proposed action. See *Baltimore Gas & Elec. Co. v. NRDC*, 462 U.S. 87, 96 (1983) ("The key requirement of NEPA . . . is that the agency consider and disclose the actual environmental effects in a manner that will ensure that the overall process . . . brings those effects to bear on decisions to take particular actions that significantly affect the environment."). As a result, as further discussed below, the environmental harm caused by generation of spent fuel is "foreordained" and the DGEIS becomes a mere "formality." *Citizens Against Burlington*, 938 F.2d at 195. (0897-3-6 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The DGEIS Violates NEPA by Failing to Identify or Compare the Costs and Benefits of Reasonable Alternatives to Avoid or Mitigate the Adverse Environmental Impacts of Spent Fuel Generation[.] Not surprisingly, because the DGEIS' purpose and need statement bears no relationship to the actual physical environmental impacts of the proposed action, the range of alternatives identified in the DGEIS also bears no relationship to the physical impacts of the proposed action or their avoidance or mitigation. The NRC's failure to identify a meaningful array of alternatives violates NEPA. *Calvert Cliffs*, 449 F.2d at 1128 ("NEPA requires that an agency must -- to the fullest extent possible . . . consider alternatives to its actions which would reduce environmental damage."). (0897-3-7 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Instead of considering alternatives for avoiding or mitigating the environmental impacts of spent fuel that will be generated as a result of future licensing decisions, the NRC presumes that spent fuel production will continue and then considers alternative methods for analyzing the impacts of this spent fuel production. See DGEIS at 7-1 (each alternative "provides a means for the NRC to address, in its environmental review documents, the environmental impacts of continued spent fuel storage (continued storage) at a reactor site or at an away-from-reactor storage facility."). Thus, the two main alternatives considered in the DGEIS are whether to prepare a generic impact analysis or a set of reactor-specific impact analyses. DGEIS at 1-6. The NRC observes, without irony, that neither of these alternatives "noticeably alter the environmental impacts from continued storage." DGEIS at 7-1. In fact, the NRC's failure to identify any actual physical environmental effects from these alternatives is just

the "foregone conclusion" of the NRC's faulty analysis. *Citizens Against Burlington*, 938 F.2d at 195. (0897-3-8 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The NRC admits that commenters demanded consideration of actual alternatives to the proposed action, but the NRC refused, relying on its misplaced purpose and need statement: (0897-3-9 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: In addition, the NRC fails to provide decisionmakers and the public with a reasonably comprehensive analysis of environmental impacts and how they could be avoided or mitigated through the avoidance of licensing or the imposition of reasonable alternatives. *Baltimore Gas & Elec. Co. v. NRDC*, 462 U.S. 87, 96 (1983) ("The key requirement of NEPA . . . is that the agency consider and disclose the actual environmental effects in a manner that will ensure that the overall process . . . brings those effects to bear on decisions to take particular actions that significantly affect the environment."). (0897-7-19 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Page 1-11, Line 16-17. Interesting that you are using the guidance of NUREG-1748 regarding "LICENSING ACTIONS" when you have already said this document has nothing to do with licensing. Again, this underlines our assertion that indeed you are considering a change in the license, but are doing it in such a way to avoid the scrutiny of the license amendment process. Shame on you. (0930-2-8 [Lutz, Ray])

Comment: The following are my comments on the Waste Confidence Generic Environmental Impact Statement. This is a pathetically vague document in its own bureaucratic reality. The GEIS is a document whose clear purpose are Points 1 and 2 under "Purpose and Need", basically to allow for rubber-stamping of further nuclear operation licenses while not offering a sufficient range of alternatives -- and offering no alternatives which can be useful in helping to gauge relative safety due to different methods and locations for storing radioactive waste. (0937-1 [Campbell, Bruce])

Comment: It is appalling, as indicated on page xxvi of the Generic EIS' Executive Summary, that alternatives such as "halting NRC licensing and closing nuclear reactors would not meet the purpose and need of the proposed rulemaking action." This may be the case, but only because the NRC came out with their purposes (in their points one and two under Purpose and Need) which was essentially to assist the nuclear industry in making it easier to obtain licenses. As stated before, those "purposes" have nothing to do with satisfying the remand by the D.C. Circuit Court of Appeals, but are just pandering to a sleazy disreputable industry. Halting NRC licensing and closing nuclear reactors should be offered as an alternative since it meets the "need" of the document -- which is to try to adequately address the remands from the court. Just because the desperate industry comes up with "purposes" to grease the skids for the nuclear industry does not mean that they are valid or legal purposes to pursue in the Generic EIS or otherwise. (0937-12 [Campbell, Bruce])

Comment: Once again, this document is highly inadequate, it does not meet the remand called for by the D.C. Circuit, its "purpose and need" is faulty and pandering to industry, it does not offer a reasonable range of alternatives, and it means close to nothing in the real world of radioactive waste impacting celled organisms. (0937-18 [Campbell, Bruce])

Comment: It is quite clear that the "Need" which precipitated this Generic EIS is the 3rd point under "ES.4 What is the Purpose and Need for the Proposed Action?" on page xxiv of the Executive Summary. This 3rd point reads, "3. to address the deficiencies in the 2010 Waste

Confidence rule identified by the U.S. Court of Appeals for the D.C. Circuit". Would this document have been prepared without the remand from the D.C. Circuit(?) -- of course not! Please note that the first point identified is aiming to streamline and allegedly "improve the efficiency" of the NRC's licensing process. This is the primary objective of the nuclear industry and their enabling rubber-stampers at the Nuclear Regulatory Commission. Since before the AEC became the NRC, promoting nuclear power has definitely been a larger concern for the agency than serious regulations of some impacts of this inherently dangerous energy source. So, that point 1 reads (under Purpose and Need): "to improve the efficiency of the NRC's licensing process by generically addressing the environmental impacts of continued storage". While some industry members may be pleased that the document is paving the way for many NRC rubber-stamps of nuclear proposals to come, yet there was no real assessment of environmental impacts of continued storage (and comparative risks) in the GEIS. (0937-5 [Campbell, Bruce])

Comment: Note that point 2 (under Purpose and Need) says, "to prepare a single document that reflects the NRC's current understanding of these environmental impacts". This is a sham assessment (which does not reflect the NRC's current understanding of environmental impacts of varying kinds of radwaste storage) which aims to grease the skids for approving poorly analyzed nuclear licenses in the future. (0937-6 [Campbell, Bruce])

Comment: Exelon supports the NRC's decision to continue its long-standing and Court-sanctioned practice of addressing waste confidence issues generically, rather than on a site-specific basis. This practice maximizes administrative efficiency, while ensuring that the environmental impacts of spent fuel storage are fully considered and disclosed prior to licensing or relicensing nuclear power reactors. Exelon agrees that a comprehensive general analysis is sufficient to examine onsite risks that are essentially common to all plants, particularly given the NRC's use of conservative bounding assumptions and the opportunity for concerned parties to raise site-specific differences at the time of a specific site's licensing. (0942-3 [Helker, David P.]

10. Comments Concerning Alternatives – General

Comment: In the current proceedings, inclusion of major alternatives in the environmental analysis, such as alternatives that can substantially mitigate the potential adverse environmental impacts of long-term or indefinite spent fuel storage at the sites of formerly operating nuclear reactors, will present an entirely different picture of the environmental consequences of long-term or indefinite spent fuel storage at reactor sites. In the case of license renewal proceedings, a grant of the proposed extension would often increase the amount of spent fuel stored by approximately 50%, an increase that would be avoided if the alternative of prohibiting spent fuel generation until an adequate, safe, and permanent repository was in place, and the impacts of which could be substantially mitigated if the spent fuel were stored in dry casks after 5 years. These alternatives could either eliminate any long-term or indefinite spent fuel stored at the site after plant shutdown by requiring that an available, safe, permanent, and adequate waste disposal facility be in existence before authorizing generation of new spent fuel, or substantially mitigate the environmental consequences of post operation onsite storage by requiring that all spent fuel that is more than 5 years old be placed in dry cask storage. Thus, absent immediate review of the erroneous Staff Scoping Decision, if it is ultimately determined that exclusion of these alternatives from the GEIS was an error, that error will only be correctable by the issuance of a supplemental draft GEIS. However, by promptly accepting review of the issues raised by Petitioners, the Commission can take corrective steps in a timely manner that will allow the Staff to modify its analyses and incorporate these further analyses into its draft GEIS. Since the draft

GEIS is not expected until September, there should be time for the Staff to make the necessary changes to the draft GEIS to meet that deadline. (0001-11 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: During the scoping process, Petitioners and others urged Staff to ensure that the NEPA alternatives analysis would include the alternative of requiring all spent nuclear fuel to be placed in dry cask storage rather than left in spent fuel pools and the alternative of suspending the further creation of spent fuel until such time as there is an available, safe, permanent, and adequate nuclear waste storage facility for the spent fuel to be generated. See, e.g., Comments Submitted by the Office of the Attorney General of the State of Vermont with the State of Vermont Department of Public Service, and by the Office of the Attorney General of the State of New York Concerning Scope of Consideration of Environmental Impacts of Temporary Storage of Spent Fuel After Cessation of Reactor Operation (Jan. 2, 2013) at 15-16 & Letter from Matthew Brock to Sarah Lopas on behalf of the Commonwealth of Massachusetts joining in the Vermont and New York Comments (Jan. 3, 2013) (collectively, "States' Written Scoping Comments")². [Footnote 2 text: In this regard, Petitioners raise two concerns about the Staff Scoping Decision. First, the Staff Scoping Decision excludes recognition of even the existence of viable mitigation alternatives that the States have identified, such as the transfer of spent nuclear fuel from spent fuel pools to dry cask storage. Second, the Staff Scoping Decision does not explicitly recognize that-given the Staffs decision to exclude certain mitigation alternatives, such as the transfer of spent fuel from densely packed spent fuel pools to dry storage casks, and given the differences among plants and their siting profiles-those mitigation alternatives should be considered and evaluated as part of a site-specific environmental impact statement. During the initial public scoping meeting at NRC headquarters in Rockville, the State of New York raised this issue and requested that NRC undertake a site-specific severe accident mitigation alternatives analysis for the continued storage of spent nuclear fuel at the Indian Point nuclear site similar to the Severe Accident Mitigation Alternatives ("SAMA") analysis that NRC conducts for severe reactor accidents. See Oral Comments of State of New York Assistant Attorney General J. Sipos at Public Scoping Meeting for the Environmental Impact Statement to Support an Updated Waste Confidence Decision and Rule, November 14, 2012 1:00 P.M. EST, Transcript of Proceedings at 37-40 & State of New York November 14, 2012 Presentation Slides, ML12331A347. Such a spent nuclear fuel SAMA analysis would identify site-specific environmental impacts and site-specific mitigation alternatives to minimize or eliminate those impacts. See States' Written Scoping Comments at 16-18. (New York raised this issue again during the recent March 2013 NRC Regulatory Information Conference. See 2013 RIC Session TH30, Insights to the Future of High Level Waste Management.) Thus, in addition to identifying the alternative of requiring all spent nuclear fuel to be placed in dry cask storage rather than left in spent fuel pools and the alternative of suspending the further creation of spent fuel until such time as there is an available, safe, permanent, and adequate nuclear waste storage facility for the spent fuel, the scope of the GEIS must be expanded to identify and specifically reserve for further site-specific analysis, all reasonable alternatives to long-term or indefinite spent fuel storage at reactor sites, including alternatives that will mitigate the environmental impacts of that storage such as by placing all spent fuel in dry storage casks at particular sites. See *infra* Part II.] (0001-12 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: Proceeding with the GEIS without considering all viable alternatives to mitigate the adverse consequences of the proposed action, also violates long-standing NRC regulations. NRC requires that all reasonable alternatives be explored as part of the NEPA process: State whether the Commission has taken all practicable measures within its jurisdiction to avoid or minimize environmental harm from the alternative selected, and if not, to explain why those measures were not adopted. Summarize any license conditions and monitoring programs

adopted in connection with mitigation measures. 10 C.F.R. § 51.103(a)(4). By never addressing alternatives that could mitigate the adverse impacts of long-term or indefinite spent fuel storage at reactor sites after plant shutdown, the GEIS would not have considered, and NRC would not have taken, "all practicable measures within its jurisdiction to avoid or minimize environmental harm." The Staff's limited analysis of reasonable mitigation alternatives also violates federal case law. In *NRDC v. NRC*, 539 F.2d 824 (2d Cir. 1976), *vacated on grounds of subsequent mootness sub. nom. Allied-General Nuclear Services v. NRDC*, 434 U.S. 1030 (1978), NRC sought to rely on a draft generic impact statement on the use of mixed oxide fuels ("GESMO") to grant interim licenses even though the "draft GESMO did not fully address alternatives." 539 F. 2d at 842. NRC argued, as the Staff does here, that the rest of the analysis would be completed as part of an additional analysis at a later time. The Court rejected NRC's reliance on the draft GESMO as a basis for interim licenses, ruling that the draft GESMO was "a legally insufficient environmental impact statement" because "the consideration of alternatives and of special hazards to the public health, safety and welfare are vital to *any* impact statement." *Id.* (emphasis in original). Here, as well, the GEIS will be legally insufficient unless it fully considers all alternatives to the long-term use of spent fuel pools, rather than leaving the analysis of dry cask storage for a later date. (0001-23 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: I'm going to focus on a more narrow, but I think fundamental portion of the staff's analysis, and that's the definition of the proposed action in consideration of alternatives, particularly the staff's decision not to consider the cessation of reactor licensing or operation or the imposition of additional requirements as alternatives to the proposed action. The NEI agrees with the NRC's definition of the proposed action as promulgation of a rule that generically addresses the environmental impacts of used fuel storage making such consideration largely unnecessary in individual licensing proceedings. We also agree with the NRC's characterization of the alternatives to the proposed action which generally consists of different methods of assessing the impacts of used fuel storage during a continued storage period. (0030-16-1 [Bonanno, Jerry])

Comment: With respect to the alternatives involving imposition of new or additional regulatory requirements, NEI supports NRC's conclusion that imposition of such requirements is outside of the scope of the proposed action, which again is to explore alternatives that improve the efficiency of the licensing process through generic examination of safety and environmental implications of continued storage. (0030-16-5 [Bonanno, Jerry])

Comment: The NRC must now thoroughly review Environmental Impacts of onsite storage, and consider safer alternatives to nuclear when licensing decisions come up. (0143-2 [Arauz, Jorge])

Comment: Thirdly, I call on you to convene a gathering of experts in the fieldto include engineers, scientists, seismologists, meteorologists, non-governmental organizations, concerned citizens to study and discuss the safest methods for storing this poison for the long term ...for forever (0177-4 [Craig, Anne])

Comment: The US Court of Appeals for the District of Columbia DC ruled that the NRC's analysis was "not thorough enough" to support the waste confidence rule at 10 CFR 51.23. Yet on remand, the NRC has elected to pursue generic rule, a decision we believe is unwise. The NRC must account for the consequences of specific risks at varied sites. Therefore, all reactor sites must be included whether seaside, riverside, inland, etc. It is impractical for this to be done adequately to cover all sites and be completed within 24 months. And to artificially limit the alternatives is in contravention of the law. In order to satisfy the National Environmental Policy

Act (NEPA), the NRC must address the original agency action that caused the production of irradiated nuclear fuel and the resulting impacts: i.e., the licensing of nuclear reactors. (0222-8 [Zeller, Lou])

Comment: One good thing about the reporter in Fukushima. He has said that there is bacteria, a fungus of some kind growing on the reactor buildings that have been blown up, and that is a very hot, radioactive environment, and maybe the people that are looking at what to do with spent fuel rods can find out what kind of growth that is and use it to eat up the spent fuel rods. (0244-13-7 [Wilson, Greg])

Comment: So, I would propose, NRC, you make this a military issue. I would propose that you nationalize this issue. (0328-16-3 [Bonniwell, Colleen])

Comment: The third claim by the NRC to avoid examining this alternative is to say that the cessation of reactor licensing and operations would prevent the production of radioactive waste. Other environmental impacts could result from the required development of alternative power sources, or demand reductions. Significantly, however, the NRC does not even hint at what those other environmental impacts might be, that would still be there if nuclear plants are shut down. The NRC should still be considering how to mitigate the environmental impact of there being no solution to the storage of even more waste. (0328-4-8 [Taylor, Wallace])

Comment: And there is one reporter in Fukushima that is posting videos all the time. And Fukushima has lost three reactors three-quarters down into the ground, which is spewing out radiation. And I saw one video that has some kind of algae or mold or something growing in the area in this high-radioactive zone. And that could be possibly used to reduce the radioactivity in the spent fuel rods. I'm not real sure. You know, that is something that someone will have to investigate and see if it could be used to basically render spent fuel rods back to a safe level. (0329-24-2 [Wilson, Greg])

Comment: The second thing that is wrong with the GEIS, a second thing, is also in the alternatives. And clearly the fact that the NRC is proposing indefinite aboveground storage shows that it has essentially abandoned the fantasy of geologic storage. And engineered geologic storage has always been the preference of probably everyone who has looked at this, but, for whatever political, economic, geologic, engineering reasons, this has been abandoned, it seems to me. And the failure to treat it as an alternative to be fully and carefully analyzed really shows that we have an industry that is making a highly dangerous waste product, which cannot be managed and which there really is no way to manage. (0329-25-3 [Paddock, Brian])

Comment: In addition, NRC's draft EIS also fails to properly analyze all reasonable alternatives and all feasible mitigation measures that could reduce safety risks associated with on-site nuclear waste storage. For example, NRC has not considered, but should have, the possibility of not relicensing operating reactors so that no additional nuclear waste is produced. NRC has also improperly failed to examine how the expedited transfer of spent fuel from dangerously overcrowded pools to dry casks would substantially reduce safety and accident risks. (0465-7 [Commenters, Multiple])

Comment: Reconsider, re-scope and reformulate a technically feasible and economically, politically and ethically viable alternative that fully and genuinely complies with the official Mission of the NRC embodied by the official slogan "Protecting People and the Environment." (0603-6 [Schonberger, David])

Comment: [The NRC must] consider all feasible alternatives in order to adequately review the risks and environmental impacts of storing spent fuel centuries into the future. (0604-13 [Pisha, Gayla])

Comment: The draft GEIS is intended to provide an evaluation of the environmental impacts that may occur as a result of continued storage of spent fuel at or away from reactors, including the possibility that spent fuel may be stored for 60 years, 100 years or indefinitely. Because these time frames contemplate continued storage for generations to come, the NRC should seriously consider alternatives to the proposed Action that do not include a binding rule, which potentially serves to limit public involvement and the introduction of new information in future decisions. (0669-16 [Walter, Joan])

Comment: The draft GEIS should fully disclose mitigating actions that support conclusions about the significance of environmental effects resulting from the proposed Action, identify mitigating actions relied upon through incorporation by reference, and specify activities that will require further site-specific environmental evaluation. (0669-17 [Walter, Joan])

Comment: The purpose and need of the draft GEIS should be expanded to give equal importance to facilitation of public involvement in decisions and to provide meaningful analysis and consideration of alternatives that do not include a binding rule. (0669-6 [Walter, Joan])

Comment: In order to be an effective programmatic environmental document, the draft GEIS should be revised to: 1) fully disclose specific, tangible mitigating actions that reduce physical environmental effects to support conclusions about the significance of environmental effects resulting from the proposed Action, 2) clearly identify and summarize mitigating actions that are being relied upon through incorporation by reference from environmental documents, and, 3) specify and summarize those activities which would require further environmental evaluation in plant-specific supplemental EISs. (0669-9 [Walter, Joan])

Comment: The NRC claims that although cessation of reactor licensing and operations would prevent the production of radioactive waste, other environmental impacts could result from the required development of alternative power sources or demand reductions. Significantly, however, the NRC does not even hint at what those other environmental impacts might be. (0688-16 [Taylor, Wallace])

Comment: In this same vein, the NRC makes the snide comment that even if no more radioactive waste is produced, the environmental impact of continued storage of the existing waste would still be present. That may be true, but the NRC must still consider how to mitigate the environmental impact of there being no solution to the storage of even more waste. That is especially true when there is no foreseeable solution to the presently existing waste. (0688-17 [Taylor, Wallace])

Comment: Two weeks after the issuance of the EIS Scoping Notice, NRDC counsel and counsel for several other environmental groups wrote NRC Chairman Macfarlane requesting the withdrawal of the Waste Confidence Scoping Notice because it failed to satisfy two of the most basic requirements of NRC's regulations for notices of intent to publish an EIS: (1) the Scoping Notice failed to provide a "description of the proposed action;" and (2) the Scoping Notice failed to provide "to the extent sufficient information is available, possible alternatives." See 10 CFR § 51.27(a)(2) ("Notice of Intent") and Att. 3, November 8, 2012 letter from NRDC et al. to NRC Commissioners. As explained in our letter, NRC's Waste Confidence Scoping Notice gave no hint of the proposed agency action(s) that give rise to the risk of SNF storage environmental

impacts, and thus it required commenters to guess at the nature of the agency's proposed action and the reasonable alternatives it was contemplating to implement it. Moreover, we stated that what little factual information was presented in the Scoping Notice was likely to mislead commenters into viewing the proposed action and its alternatives as merely the generic assessment of some combination of methods for storing SNF, irrespective of the underlying agency actions authorizing creation of intrinsically hazardous SNF requiring safe storage for millennia. Such a truncated scope of alternatives is far too narrow to satisfy NEPA because it fails to address the underlying agency action—the licensing of nuclear reactors—that causes the production of spent reactor fuel and its associated environmental impacts. Therefore, as we stated in the letter, the scoping process would not lead to any analysis of some of the most obvious alternatives for the avoidance or reduction of SNF storage impacts: limitations on or cessations of reactor licensing until there is reasonable assurance of the availability of permanent disposal in a geologic repository. Nor did the scoping notice describe any proposed alternative configurations for prolonged surface storage of the reasonably foreseeable amounts of SNF that the NRC may authorize production of in the future. (0706-1-3 [Fettus, Geoffrey])

Comment: NRDC's Description of a Representative Range of Reasonable Alternatives. *Figure 1* presents an illustrative matrix of reasonable alternatives and the various factors for considering the impacts of each alternative. This matrix is intended to be neither definitive nor exhaustive, but rather indicative of the range of reasonable alternatives NRC must by law consider pursuant to its proposal to determine in advance the environmental impacts of future licensing actions that would authorize continued production and surface storage of SNF for extended periods, including indefinitely. It can hardly be stressed enough that under NEPA, *it is the agency's most important task to formulate a set of reasonable alternatives with greater and lesser environmental impacts that fairly represent the domain of plausible agency actions that could achieve its purpose and need for action while furthering the aims of NEPA*. Despite being made aware, during and immediately after the public scoping process, of its failure to define a representative range or indeed any reasonable alternatives for detailed environmental analysis, the agency rejected or ignored all these comments and in this Draft GEIS persists in its failure to subject a range of reasonable alternatives for agency action to detailed environmental analysis. In order to ensure NRC cannot claim commenters did not sufficiently describe the nature of the reasonable alternatives they believe must be considered and subjected to detailed analysis under NEPA, NRDC offers the following narrative descriptions of the alternatives outlined in *Figure 1*, beginning with the appropriate definition for the statutorily mandated evaluation of the consequences of taking "No Action." Each potential reasonable action alternative, whether these or others the agency may belatedly define after considering public comments on this Draft GEIS, must consider all the major factors that could cumulatively or collectively have a bearing on that alternative's environmental impacts. The range of such factors is indicated in *Figure 1* at page 32, and includes at a minimum consideration of the following: *Relevant timescales*, which are the "Licensed Lifetime of Facilities," "Short-Term Storage" for up to 60 years after license expiration; "Long-term Storage" for up to 160 years after License Expiration; and "Indefinite Storage." Detailed analysis may reveal technical limitations in surface storage technology and fuels that make other specific timescales relevant - for example, some fuels types may not maintain their cladding integrity for the full term of so-called "Short-Term Storage," which already implies a maximum irradiated fuel age of 140 years, and lesser terms will thus need to be considered, or specific mitigation actions proposed. (0706-2-10 [Fettus, Geoffrey])

Comment: *Reasonable Alternative One ("RA" #1)* is a "License Extension Only" alternative, based on current-licensed Spent Fuel Pool (SFP) and independent at-reactor dry cask storage installation capacities. It assumes the availability of a government-provided geologic repository

whenever the maximum license extension for each at-reactor surface storage facility, safely supportable within current NRC regulations, runs out. This time period can be expected to vary across facilities, and thus in analyzing this alternative, the NRC must construct a time vs tonnage profile of how much SNF would need to be transferred and when. Transfer to a Regional Consolidated Dry Storage (RCDS) or National Consolidated Dry Storage (NCDS) facility would not be possible under this alternative, as these would be new facilities requiring new licensing actions. Cask storage and transport options for each of the relevant fuel classes must be discussed with this timeframe in mind. Detailed analysis of this option could serve to identify future critical decision points and vulnerabilities built into the current spent fuel management structure that need to be addressed if extended surface storage is going to be implemented safely with minimal environmental impacts. If analysis of this option reveals a disconnect between the earliest plausible date for repository availability and expiring surface storage capacity, it could serve to guide NRC, DOE, other decision-makers, and the public to an understanding of how much RCDS or NCDS will be needed, and when. The agency could reasonably explore variants of this alternative, such as new licensing actions for at-reactor dry storage facilities only, to facilitate transfer of spent fuel to safer storage configurations than current SFP's. (0706-2-12 [Fettus, Geoffrey])

Comment: *Reasonable Alternative Two (RA #2)* is a "Near-Term Nuclear Growth" that extends and builds upon the analysis in RA #1 by considering the environmental impacts of SNF storage proceeding from new reactor and storage facility licensing actions based on the proposed revised WCD/TSR, with defined by the universe of COL application requests received by the NRC as of 12/31/2012 and assumed, for the purpose of NEPA analysis, to be granted before the end of 2030. This alternative requires analysis of the extended safe storage requirements and storage technology/facility options for the amount and types of SNF produced under a scenario that assumes a 60-year licensed lifetime for each newly licensed reactor and the same short-, long-, and indefinite storage terms already adopted for the DGEIS truncated analysis of environmental consequences, although in the course of detailed analysis the NRC staff may well uncover the technical and environmental significance of additional relevant timeframes, intermediate between those pre-selected for analysis. For example, certain types of fuel and cask combinations may have limited sharply lifetimes when it comes to preserving the "defense-in-depth" barrier against radionuclide leakage provided by preserving both continued fuel cladding integrity and the structural integrity of cask containment barrier. This option would also go beyond RA #1 in considering the safety and environmental requirements for, and impacts of new licensing actions authorizing the creation of one or more RCDS facilities, or a single NCDS site, and additional at-reactor storage sites. The analysis should seek to identify the environmentally superior configurations or combination of these options for extended surface storage. It would also generically describe the necessary, functions, capacities and technical features that would likely be common to all such facilities of a given type, discuss plausible alternative definitions of the geographic regions that might be served by each such facility (e.g. a single national RCDS site, two RCDS sites covering the Eastern and Western halves of the country, multiple RCDS sites geared to the different specific geotechnical, climate, and weather environments that prevail in different parts of the country, e.g. "Northeast/Mid-Atlantic," "Southeast" "Midwest" and "Western U.S." This analysis would identify those aspects of continued surface storage that are most sensitive to particular regional or site-specific conditions, such as seismicity, humidity, salinity, peak, low and average temperature ranges, flood-risk, tornado risk, hurricane risk, etc., and thus define the limits of environmental issues subject to resolution in a "Generic EIS," versus those that would need to be further considered in a tiered "regional" and/or site-specific EIS. (0706-2-13 [Fettus, Geoffrey])

Comment: Because the time frames and options for agency action are broader than the previous two alternatives, it will need to consider a wider range of cask/fuel combinations, SNF transport options, and alternative consolidated storage configurations, to identify the environmentally preferred sequence and combination(s) of extended pool storage, on-site drycask storage, and offsite consolidated interim storage that appropriately balance the prospective cost, complexity and technical risk of various continued surface storage options with their prospective benefits for public health and the environment. *Reasonable Alternative Three (RA #3)*: This alternative is based on the "Constant Nuclear Market Share Scenario," a widely perceived minimum nuclear growth scenario among proponents of nuclear energy and de-carbonization that posits nuclear power generation will grow at least enough to maintain its longstanding share of total U.S. grid-connected power generation at 20%. It assumes the RA #1 baseline inventory of SNF plus an added SNF inventory corresponding to a 20 % nuclear share of US power generation for the next 60 years. In connection with all modest-to-major nuclear growth scenarios occurring within the constraint of no geologic repository availability (this option and RA#4 below), it may prove both cost-effective and environmentally beneficial to consider a "Direct to RCDS" option that promptly transfers SNF five years after irradiation from Spent Fuel Pools directly to an RCDS or NCDS, skipping the intermediate step of on-site dry cask storage, which today is focused on freeing-up space in densely-packed SFP's to accept scheduled discharges of irradiated fuel from the reactor. It should also examine an "at-reactor storage only variant" that could prove cost-effective if a geologic repository is developed on a timeframe that makes interim consolidated storage unnecessary or uneconomic. Analysis of this alternative must also consider the potential impacts of new fuels and fuel cycles (examples are listed in the Table) on SFP, transport cask and long-term storage cask performance, in both normal storage conditions and accidents. (0706-2-14 [Fettus, Geoffrey])

Comment: *Reasonable Alternative Four (RA#4)*: This alternative, an aggressive "Major Nuclear Growth" scenario, represents a reasonably foreseeable upper bound on the amount of SNF that might be generated by a doubling of present annual nuclear output (measured in terawatt-hours of electricity produced) achieved by 2040, with 60 years of SNF discharges assumed for each new licensed reactor. Thus this scenario envisions sharply increasing nuclear fuel discharges in need of continued surface storage until the year 2100, followed by extended surface storage for periods of 60 and 160 years after this date. As shown in the Figure, analysis requirements are similar to RA#3, and this alternative, and indeed all extended storage alternatives beyond 30 years, must be subjected to the plausible constraint that institutional controls may begin to fail relatively soon after termination of an operating license for a variety of historically plausible reasons – financial incapacity, corporate dissolution or managerial malfeasance, institutional neglect, political gridlock, war, civil strife, etc. We suggest the historical record suggest 20 years following reactor license termination is an appropriately conservative figure - as noted, some stored fuel will be 80 years old at this point and in need of special measures that may not be forthcoming. But given that the minimum period for continued storage post-licensing considered in the current DGEIS is 60 years, the choice whether to set the dividing line for requiring consideration of partial-to-total "loss of institutional controls" at 30, 40, or 50 years is not crucial to the overall analysis, as long as this remains a significant component of the analysis for each extended storage option. (0706-2-15 [Fettus, Geoffrey])

Comment: Once NRC recognizes the potential significant environmental impacts that spent fuel storage will have at Indian Point, there are a wide array of mitigation measures and alternatives that it is obligated to consider as part of the NEPA review. First, NRC is obligated to assure that: ["the Commission has taken all practicable measures within its jurisdiction to avoid or minimize environmental harm from the alternative selected, and if not, to explain why those measures were not adopted."] 10 C.F.R. § 51.103(a)(4). Second, where, as here no legally

sufficient prior analysis of spent fuel pool severe accident mitigation alternatives has been completed, NRC is obligated to assure that such an analysis has occurred and that all reasonable severe accident scenarios and mitigation measures have been evaluated. On occasion NRC and its consultants have publicly recognized the much greater potential risk from events occurring in a spent fuel pool including criticality accidents and fire hazards. By way of example, the Sandia National Laboratories have recently acknowledged that reducing the volume of spent fuel in spent fuel pools would mitigate the risks posed by dense storage. See, e.g., *Investigations of Zirconium Fires During Spent Fuel Pool LOCAs* (Slideshow) (Feb. 7, 2012); see also *Responding to Fukushima-Daiichi* (Speech) (Jan. 31, 2012); *Responding to Fukushima-Daiichi* (Slideshow) (Jan. 31, 2012); *On Site Spent Fuel Criticality Analyses*, NRR Action Plan (September 19, 2011) ML11251A210; Sandia National Laboratories, *Mitigation of Spent Fuel Pool Loss-of-Coolant Inventory Accidents and Extension of Reference Plant Analyses to Other Spent Fuel Pools* (Redacted) (November 2006); NUREG-1738, *Technical Study of Spent Fuel Pool Accident Risk at Decommissioning Nuclear Power Plants* (Feb. 2001); NRC Reactor Safety Team (RST), *Assessment of Fukushima Daiichi Units*, ML11216A018 (Mar. 26, 2011, 2100h) (discussing ejection of fuel and damage to Daiichi facilities). There are a wide-range of alternatives and mitigation alternatives that should be considered to the current plan to continue to crowd more spent fuel into the spent fuel pools and to maintain their current configuration including suggestions from the National Academy of Sciences, *Safety and Security of Commercial Spent Nuclear Fuel Storage: Public Report*, The National Academies Press (2006), and by well-respected experts in nuclear power plant safety such as Robert Alvarez, et. al., *Reducing the Hazards from Stored Spent Power-Reactor Fuel in the United States*, Science and Global Security, Vol. 11:1-51. Among the many feasible and easily implemented measures that could significantly mitigate the environmental impacts of routine operation of spent fuel pools at Indian Point as well as significantly reduce the consequences of severe accidents are the immediate off-loading of all spent fuel that is at least 5 years old to dry cask storage, installation of safety grade spray systems in the spent fuel enclosures to ensure replacement water in the event of loss of coolant accident, re-arrangement of the spent fuel in the pools to allow for better circulation in the event of loss of coolant, to mention only a few of the recommendations contained in the reports identified in the Attachments to this letter. (0718-1-9 [Sipos, John])

Comment: NEPA requires a federal agency to prepare "to the fullest extent possible" an environmental impact statement ("EIS") regarding proposed "major Federal actions significantly affecting the quality of the human environment."¹³³ [footnote 133 text: 42 U.S.C. § 4332(2)(C).] An EIS must discuss, among other things, the adverse environmental impacts of the action and alternatives to the action.¹³⁴ [footnote 134 text: *Id.*; 40 C.F.R. §§ 1502.2, 1502.14, 1507.2, 1508.9.] "[O]ne important ingredient of an EIS is the discussion of steps that can be taken to mitigate adverse environmental consequences."¹³⁵ [footnote 135 text: *Robertson v. Methow Valley Citizens Council*, 490 U.S. 332, 351 (1989).] This directive that federal agencies meaningfully consider alternatives and mitigation measures to the proposed action is one of NEPA's hallmarks.¹³⁶ [footnote 136 text: 42 U.S.C. § 4332(2)(C),(E).] The requirement that alternatives be studied, developed, and described both guides the substance of agency environmental decision making and provides evidence that the mandated decision making process has actually taken place.¹³⁷ [footnote 137 text: *Calvert Cliffs' Coordinating Committee, Inc. v. United States Atomic Energy Comm'n*, 449 F.2d 1109, 1114 (D.C. Cir. 1971).] NEPA is not intended to simply confirm or insulate previous agency decisions or assumptions. Rather, NEPA forces federal agencies with discretionary regulatory authority to confront and publicly evaluate the environmental impacts of proposed action, the alternatives to that action, and the means to mitigate or minimize the adverse impacts of the final agency action.¹³⁸ [footnote 138 text: *Dep't of Transportation v. Public Citizen*, 541 U.S. 752, 768-69 (2004).] As discussed above

(p.15), if the water in a spent fuel pool boils or drains away, the zirconium cladding that forms the spent fuel rods may melt or catch on fire, potentially causing a major release of radiation. NRC does not dispute that a spent fuel pool fire could have catastrophic environmental impacts. Indeed, it has acknowledged that "a zirconium fire event can have public health and safety consequences similar to a severe core damage accident with a large off-site release."¹³⁹

[footnote 139 text: Nuclear Regulatory Commission, Policy Issues Related to Safeguards, Insurance, and Emergency Preparedness Regulations at Decommissioning Nuclear Power Plants Storing Fuel in Spent Fuel Pools (WITS 200000126), NRC SECY-01-0100, at 5 (June 4, 2001).] Therefore, NRC must consider alternatives to the current storage scheme that reduce the risk of a zirconium fire. Moreover, these issues must be considered on a site-specific Category 2 basis, since plant-specific factors may make facilities more or less vulnerable to such fires, may require different mitigative measures, and may lead to different environmental impacts.¹⁴⁰

[footnote 140 text: This fact was recognized by Congress when it directed NRC to implement the recommendations of the 2006 NAS Report on spent nuclear fuel storage. In particular, Congress asked NRC to prepare site-specific models to mitigate the risks associated with spent fuel storage. U.S. Congress, Conference Report 108-792, *Making Appropriations for Foreign Operations, Export Financing, and Related Programs for the Fiscal Year Ending September 30, 2005, and For Other Purposes*, at 982 (Nov. 20, 2004). Former NRC Commissioner Victor Gilinsky also recommended that spent fuel storage be examined on a site-specific basis in his *Separate Views Regarding Proposed Amendments to 10 CFR Parts 50 and 51, Waste Confidence Proceeding*, 48 Fed. Reg. 22730 (May 20, 1983) ("While I agree that there is no obstacle in principle to extended on-site storage, I think it is clear that each power reactor site will have to be examined in detail.")]. The State recommends that the following alternatives be considered in a site-specific review of a facility's spent fuel pool. (0718-2-16 [Sipos, John])

Comment: NEPA requires that NRC consider safer storage alternatives such as the thinning of spent fuel pools and the use of dry cask storage. These alternatives must be considered in a site-specific analysis that evaluates the unique features of each fuel pool and its surrounding environment. The State further urges NRC to ensure that the severe accident mitigation alternatives analyses rely on site-specific cost estimates and are reanalyzed at each operating licensing milestone. Moreover, given the importance of these issues, the NRC should revise the GEIS and implementing regulations as requested by these comments and apply the GEIS, as revised, to all license renewal applications that are currently pending. (0718-3-7 [Sipos, John])

Comment: Likewise, although an "informed and meaningful consideration of alternatives" is an "integral part" of the NEPA statutory scheme,²⁵ [footnote 25 text: *Bob Marshall Alliance v. Hodel*, 852 F.2d 1223, 1228 (9th Cir. 1988).] EISs need not discuss the environmental effects of alternatives that are "deemed only remote and speculative possibilities."^y [footnote 26 text: *Vermont Yankee Nuclear Power Corp. v. Natural Res. Def. Council*, 435 U.S. 519, 551 (1978).] Viable alternatives must be examined,^y [footnote 27 text: *Citizens for a Better Henderson v. Hodel*, 768 F.2d 1051, 1057 (9th Cir. 1985).] but to be considered viable alternatives must meet the purpose and need of the proposed action. (0827-1-5 [Ginsberg, Ellen])

Comment: Under NEPA, the definition of the proposed action dictates the alternatives that the NRC must consider. NEI concurs with the three alternatives to the proposed rulemaking evaluated by the NRC: (1) no-action, (2) GEIS-only (no TSR), and (3) policy statement. (0827-1-9 [Ginsberg, Ellen])

Comment: NEI agrees with NRC's determination that the rule would not impose any requirements on industry or have any "cumulative effect." NRC correctly states, "Adoption of a revised 10 CFR 51.23, supported by this draft GEIS, is not a licensing action, and does not

impose new requirements on licensees or applicants."¹⁰⁷ [Footnote 107 text: Draft GEIS, Section 1.6.3.2, Implementing Additional Regulatory Requirements, pp. 1-9, lines 29-31.] NRC's proposed action is to issue a revised rule, 10 CFR 51.23, that generically addresses the environmental impacts of continued storage. Whether or not the impacts are evaluated generically, in connection with a specific licensing action, or through some other alternative, the environmental effects remain the same. Because the proposed action is to make an administrative decision regarding how to evaluate environmental effects (i.e., generic evaluation), there are no cumulative environmental effects of implementing the proposed action or any alternative. As stated in Section 1.6.4, Comparison of Reasonable Alternatives, p. 1-10, lines 10 and 11, "The alternatives merely propose alternative means of analyzing the environmental impacts of continued storage." NRC's efforts simply improve efficiency of the licensing process without instituting any new requirements on licensees. (0827-5-7 [Ginsberg, Ellen])

Comment: A third option, use of the pre-existing WIPP facility, has not been addressed by the NRC. That facility is included in the discussion below to show how, if motivated, the NRC could have addressed the purpose and need by analyzing viable alternatives. (0867-1-15 [Griffin, William])

Comment: NPP were not designed to host and accommodate unlimited amounts of SNF inventory. They were not designed in this way because the original assumption was that the SNF would be removed from the power plant and reprocessed (EPRI p. 1-1). Since the United States has chosen to abandon reprocessing as an option, the only viable alternatives are to stop production of nuclear power or for storage of the by-products like SNF, first at the production site in wet storage and thereafter at a geological or dry storage facility. The problem then becomes the increasing inventories of SNF at the reactor sites. (0867-1-17 [Griffin, William])

Comment: The Waste Isolation Pilot Plant (WIPP) east of Carlsbad, New Mexico is currently accepting transuranic wastes, a by-product of the weapons production cycle. This salt basin based geological repository does not accept SNF but it may be an alternative to the failed Yucca Mountain project or PFS facility. Consideration of such an alternative was not part of the DGEIS and would require analysis of site specific characteristics if such an alternative was to be analyzed by the NRC. The use of such a pre-existing geologic repository site would overcome some of the objections to siting that would arise - it already exists, its environmental impacts are fairly well known and the political/social opposition to its existence has been addressed to date. Methodologically the technical issues of long term storage of the SNF would be easier to analyze since analogous wastes are currently stored at the facility, it is licensed to accept similar wastes and its operational characteristics are known. WIPP would be an interesting case study for the NRC to analyze since it has many of the characteristics needed for long term geological storage. The assumptions used by the DGEIS precluded analysis of such an alternative and thus that choice limited the viability of alternatives analyzed by the NRC. Those assumption choices likewise limit the DGEIS ability to address the courts desire for a purpose and need study. Ultimately, the ongoing failure of these various efforts to construct a permanent SNF site repository has led to the issues that should be addressed in the DGEIS. The study of an alternative like WIPP has not been done and thus another opportunity for alternatives was not explored. (0867-1-21 [Griffin, William])

Comment: The NRC fails in their choice of alternatives in the DGEIS and as discussed further on, the NRC fails to consider an appropriate range of conditions for those alternatives. This failure to take a hard look at the issues is evidenced by several examples that will act as a running commentary in this review of the DGEIS. (0867-1-4 [Griffin, William])

Comment: Because of these assumptions, the NRC did not examine a realistic set of alternatives or a realistic set of potential future conditions and the environmental consequences they would produce. (0867-3-23 [Griffin, William])

Comment: In addition the NRC fails to consider viable alternatives to on-site storage - for example, the WIPP geologic repository in New Mexico. Inclusion of such an alternative would have been reasonable. In other words, the assumptive choices made by the Commission and agency staff do not represent a hard look at the issues and thus NRC fails to meet its obligation under NEPA. (0867-3-28 [Griffin, William])

Comment: If there was a serious evaluation of a reasonable range of alternatives and actual proposals where one could evaluate relative risk from various methods of storage, it could be helpful material. There should be extensive discussion on how waste from "high burn-up fuel" complicates matters while a commercial nuclear reactor is operating, while the facility has an operating license and is storing radwaste, while a reactor is going through decommissioning phases, and when it is decommissioned. Yet, there is no serious addressing of alternatives nor of how radioactive waste can impact many aspects of real life for celled organisms such as human beings. (0937-16 [Campbell, Bruce])

Comment: we certainly need a thorough EIS with a reasonable range of alternatives -- rather than a skimpy Environmental Assessment. This current draft generic document shows that one can churn out a reasonable number of pages while purposefully saying very little about comparative risks of various modes of storage or otherwise. (0937-20 [Campbell, Bruce])

Comment: There needs to be a Full EIS of any waste storage alternative, particularly Transport and CIS Sites before Waste Confidence can be assured. (0938-15 [Sondheim, Steven])

11. Comments Concerning Alternatives – No Action/Site-Specific

Comment: Numerous participants in the GEIS and rulemaking proceedings publicly expressed their concern about the need for site-specific treatment of certain issues. *See, e.g.,* Staff Scoping Decision at 8-9, 14; States' Written Scoping Comments at 4-5, 16-18; *see also* discussion of New York's comments cited in footnote 2 *supra*. The Staff Scoping Decision recognizes that such issues may exist and states that "[t]he GEIS and Waste Confidence rule will identify those impacts that cannot be analyzed generically and therefore must be analyzed on a site-specific basis." Staff Scoping Decision at 50. But the Staff Scoping Decision says nothing about the need to amend §§ 51.23(b), 51.53(c)(2), and 51.95(c)(2). As noted, without amendments to those provisions, the opportunity to raise site-specific issues will be meaningless and will compel a party to go through the laborious and uncertain process of seeking a waiver of §§ 51.23(b), 51.53(c)(2), and 51.95(c)(2). Further, the Staff Scoping Decision offers no guidance on what criteria will be used to determine which issues are for site-specific consideration. Rather it merely states: The NRC received a comment requesting that the Commission establish a new procedure by which the public would have an opportunity to raise site-specific impacts of continued storage before the ASLB. The GEIS will generically analyze the environmental impacts of continued storage. The GEIS and Waste Confidence rule will identify those impacts that cannot be analyzed generically and therefore must be analyzed on a site-specific basis. Staff Scoping Decision at 50. Because the Staff Scoping Decision does not include any criteria that are to be applied in determining which issues will receive site-specific consideration, public participation is severely limited by the lack of an opportunity to develop evidence and arguments on issues that should be considered site-specific or should be

considered generic. The Staff Scoping Decision should have disclosed NRC's intentions regarding the criteria to be used for deciding whether an issue will be considered site-specific or generic. (0001-28 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: In my case I am particularly concerned about the generic aspects that the NRC wants to bring to this process. Each reactor site has its own unique signature and needs to be treated individually. In my case the Columbia Generating Station is in the agricultural center of Washington State. An accident threatens \$9.5 billion worth of products in Washington, and another \$6 billion in Oregon. This is besides having the populations of Seattle, Spokane, and Portland downwind based on what direction the wind blows. We also have the risk of contaminating the Columbia River, a national treasure, and we have the double jeopardy of having the Hanford Reservation next door where we have confidence in particular storage tanks that are now leaking. Safe storage of spent fuel needs to consider all of these risks for each one of the individual sites. There are also seismic and flood issues that need to be considered. (0030-12-4 [March, Leslie])

Comment: So when it comes to waste confidence, one of the gentlemen here mentioned it's a clear path to generic waste confidence. I don't understand. It's not very clear at all actually. And dealing with North Anna is very not site-specific. So I have problems with this. (0030-15-5 [Gray, Erica])

Comment: Cost and benefits and alternatives to nuclear plant licensing, including not issuing licenses or license renewals, is fully considered in the environmental reviews for individual plants; that is, consideration of not licensing a plant or allowing continued operation under a renewed license is appropriately addressed in the NEPA reviews conducted when licensing those specific facilities. As clarified in the Statement of Consideration published with the proposed rule, although the Waste Confidence EIS may inform these analyses, it's not the appropriate context to consider these types of no-action alternatives. (0030-16-3 [Bonanno, Jerry])

Comment: So, but the basis on which the NRC would reaffirm a Waste Confidence rule for issuing new licenses going forward is completely unrealistic and doesn't speak to the reality. And in fact, you know, in the proposed or the considered alternatives to the proposed action the first one is taking no action, not re-instituting a Waste Confidence rule. And what's the consequence of that? Not that the NRC couldn't license reactors anymore, as is its mandate under the Atomic Energy Act, but just that it would have to evaluate the impact of generating nuclear waste at each and every one of those proceedings. And NIRS feels that that is the appropriate course of action to be taken. We don't know what to do with this waste. There's no guarantee that there's any way to dispose of it and the risks that have been identified are so great that that would be the best course of action. (0030-17-7 [Judson, Tim])

Comment: All nuclear reactors and reactor sites are not created equal. A generic environmental impact statement for evaluating waste and waste storage at all reactors is an irresponsible and unscientific response to the challenges posed by long-term irradiated waste storage. Each reactor site has its own unique environment. Stated issues can range from those from being close to large population centers, being in a floodplain, and having seismic issues. A Generic EIS cannot paint a true picture of the impacts of waste generation and storage on a highly-radioactive spent fuel. Because the NRC generically rules it has confidence that there would be a solution for high-level nuclear waste, the dangers were never allowed to be considered at each site. (0030-21-9 [Carberry, Mike])

Comment: In my case, I am concerned about the generic aspects that the NRC wants to bring to this process. Each reactor site has its own unique signature and needs to be treated individually. (0045-11-6 [March, Leslie])

Comment: As a Generic EIS, NRC's current draft largely ignores site-specific risks. This must be fixed to ensure safety for each specific site. (0054-2 [Kurland, Miriam])

Comment: How can the NRC expect a generic environmental Impact Statement and Proposed Rule to apply to all of the 104 reactors in the United States? You are wasting the taxpayers' money with such an approach. The nuclear reactor sites all have different concerns and must be dealt with as a unique impact with rules that fit each site. (0063-1 [Magda, Marni])

Comment: SONGS would never have been approved for construction by the NRC with today's understanding of the dangers and the realization that the Federal Government has failed to remove the nuclear spent fuel to a safe location. In the 1960's we believed a way to use the spent fuel would be invented. It hasn't. MOX is unstable and not accepted for commercial use. California is an earthquake zone, with SONGS on a new fault, and we have yearly danger of out of control wild fires and global warming predicting rising ocean levels. Maps have been made. How far is the ocean at SONGS predicted to rise in the next 30 years? A new study has shown an Alaska tsunami could destroy the ocean areas of Newport Beach, Laguna Beach and San Clemente. We cannot afford to let the spent fuel stay at Songs for 30 years until the Cesium 137 has lost it power. That is only 45% of the spent fuel. What about the other 55%? Plutonium has a 24,000 year half-life. What is being done to protect 8.4 million people from a cooling pool accident? (0063-12 [Magda, Marni])

Comment: NRC needs a paradigm shift. Instead of wasting our tax dollars trying to convince us that a small risk outweighs an unacceptable consequence, maybe they should begin to regulate with the understanding that sometimes consequences are so unacceptable to the people and the environment that they outweigh even the smallest theoretical risk. That said, of the three alternatives presented, the No Action Alternative is the one I support. Decisions regarding highly irradiated fuel assemblies should be made on a site-by-site basis, with full transparency and maximum input from the public and the affected community. (0089-19 [Shaw, Sally])

Comment: The NRC must protect our communities and environment from radioactive waste. The NRC must adopt rules that will look at each nuclear plant closely. No nuclear plant should get an easy rubber stamp. (0091-1 [Capozzelli, J.])

Comment: I'd like to comment on the generic nature of this Environmental Impact Statement and urge the NRC to undertake a site-specific review of reactors seeking to continue to store spent fuel onsite. There are reactors like Pilgrim that should not be included in a Generic EIS because site-specific conditions make long-term fuel storage an incredible risky undertaking. (0112-13-1 [Byrne, Genevieve])

Comment: In the United States we have reactors located on major freshwater rivers, the Great Lakes, the Atlantic and Pacific Oceans, and in the Gulf of Mexico in 31 different states. The environmental impacts of long-term dry cask storage, or any fuel storage for that matter, are not essentially the same in each of those locations. (0112-13-3 [Byrne, Genevieve])

Comment: I support the no-action alternative decisions regarding highly irradiated fuel assemblies should be made on a site-by-site basis with maximum public input. (0112-18-8 [Shaw, Sally])

Comment: Although much has been made tonight and previously of the need for individualized determinations, the Supreme Court and the Court of Appeals have already said that the feasibility of interim or ultimate nuclear waste disposal solutions is one that is essentially common to all nuclear facilities. In our [Nuclear Energy Institute] view, it is most sensibly treated as such. (0112-19-6 [Ginsberg, Ellen])

Comment: I'm a little disappointed in this particular rule in a number of aspects. First, let's start off with the idea that it's generic. Having spent a little time in a dictionary today, generic, to most people, means that something applies equally to all members of the class. I would strongly doubt that anybody in this room in their heart of hearts believes that everything that's said in this draft GEIS or in the NUREG applies equally across the board to every nuclear power plant. Can you say it applies equally to every PWR and every BWR? Can you say it applies equally to a plant that is operating perhaps efficiently and certainly making money? And, also, to a plant like Pilgrim that is losing approximately \$30 million every year? That has had ten times as many shutdowns this year as the national average? That has had close to 20 unusual, quote, "events," closed quote? I doubt that every plant generically in this country is having this type of trouble. (0112-2-1 [Lampert, Jim])

Comment: Pilgrim Watch supports the no-action alternative obviously and for two principal reasons. First, as my husband talked about, it should be site-specific, not generic. The other reason is the foundation of the GEIS of the final document rests on the draft GEIS and the -- what I call the earthquake study that looks into pool fires [NRC-2013-0136]. (0112-3-3 [Lampert, Mary])

Comment: So it's impossible to ignore site-specific criteria and move them over to rulemaking and still protect public safety. (0112-31-5 [Johanson, Birgit])

Comment: I'm here to suggest that we need site-specific solutions. Nothing generic. (0112-34-5 [Chichester, Ben])

Comment: You know, at Seabrook we have about 600 tons of this high-level radioactive waste stored in a spent fuel pool and some in waste casks. We do not feel that it is secure in either of those locations. This waste cask storage site is a former parking lot. It's surrounded by a chain-link fence. It's across from the visitor's center so I guess you can all see it on your way into the place. But we don't think that's a secure location. It's a few feet higher than the plant, itself. We are on the coast, of course, in Seabrook. But it's still too close to the ocean. With the seas rising, storm surges are increasing, we really question whether that site would be good for another 100 years or even more. So, it's highly doubtful. (0112-5-2 [Bogen, Doug])

Comment: In the Indian Point community, the result of a spent fuel fire would put at risk the NYC water supply at the Kensico and Croton reservoirs. And if the financial capital of the world suffers a partial evacuation from which there is no return, what happens to the US economy? So let's just roll the dice and say the Waste Confidence approach is "probably good enough." (0136-13 [Shaw, Gary])

Comment: In terms of your one size fits all GEIS approach, how can you rationalize that the magnitude of risk is equal and that policy standards and protocols should be the same at all nuclear plants regardless of size, age and physical environment across the US nuclear fleet,

stretching from the Pacific Coast to the flooded Midwest to the East Coast stretching from Florida to New England. In terms of Indian Point, we have an intersection of two seismic faults, two large high pressure natural gas pipes between the faults and the plant, and during Superstorm Sandy, the plant came close to flood level from the Hudson River surge. It would seem to me that these characteristics might not be universal, so why should there not be site specific EIS perspectives rather than one universal policy paper? (0136-8 [Shaw, Gary])

Comment: Another element that makes Indian Point unique is that Indian Point has been ordered to install closed cycle cooling. If that order is affirmed by the courts and a large structure must be built, what impact does that have on the ability to expand cask storage space for what would be a 60 year accumulation of fuel assemblies? What procedures will be in place to conduct dry transfer of degraded fuel assemblies from the Holtec casks when they expire in 100 years or less? What about 200 years? What about 300 years? That is about how long it takes for Cesium137 to become benign? What about 240,000 years? That is the amount of time it takes for plutonium, the deadliest element known to man, to lose its ability to mutate human cells. (0136-9 [Shaw, Gary])

Comment: This proposed analysis concerns one of the most dangerous materials on the planet and a long-term storage of that material and spent fuel pools here in Westchester County and at other nuclear power plants around the nation. The Westchester storage site has the highest surrounding population of any site in the nation. More than 17 million people live within 50 miles of Indian Point, and there are critical water resources and infrastructure developments close to the site. (0163-1-2 [Schneiderman, Eric])

Comment: Generic review of accident risk at Indian Point is inappropriate because the consequences of spent fuel pool accidents in the densely populated area surrounding Indian Point are significantly greater than in the rural or less populated areas in which the reference plants are located. Either the NRC must conduct site-specific analysis of environmental impacts of a severe accident at the Indian Point spent fuel pools or use the Indian Point site and not less populated sites as its baseline for spent fuel pool accident risk nationwide. (0163-1-4 [Schneiderman, Eric])

Comment: The third point is the NRC assumes that the risks and the impacts are the same at all plants. We all know Indian Point is unique. We know why. I don't need to remind you all why. (0163-2-6 [Musegaas, Philip])

Comment: Indian Point lies on two fault lines and this goes to the fact that you can't do a Generic Environmental Impact Statement because not -- they don't all lie on fault lines. They don't all lie in an area as crowded as we are. (0163-20-2 [Gellert, Sally Jane])

Comment: In terms of -- in terms of a one-size-fits-all GIS -- GEIS, how can you rationalize that the magnitude of risk is equal so that policy standards and protocols should be the same at all nuclear plants regardless of size, age, physical environment across the U.S. nuclear fleet stretching to the Pacific Coast to the flooded Mid-West to the east coast stretching from Florida to New England. (0163-22-4 [Shaw, Gary])

Comment: In terms of Indian Point, we have an intersection of two seismic faults. We have two large, high-pressure natural-gas lines between the faults and the plants. During Sandy -- Super Storm Sandy, the plant came close to flood level from the Hudson River surge. It would seem to me that these characteristics might not be universal, so why would there be a Generic EIS. (0163-22-5 [Shaw, Gary])

Comment: [A]nother element that makes Indian Point unique is that it's been ordered to install closed-cycle cooling. If that order is affirmed by the courts and a large structure must be built, what impact does that have on the ability to expand cask-storage space for what would be a 60-year accumulation of fuel assemblies. (0163-22-6 [Shaw, Gary])

Comment: Indian Point contains almost three times the amount of radioactive material in the spent fuel pools that are causing so much trouble from Fukushima. Three times as much radiation in the spent fuel pools. But, on the other hand, Indian Point is number one. We're -- Indian Point is number one in safety violations of any plant in the United States. It's number one in the risk of earthquake damage of any plant in the United States. It's number one in the risk of flooding of any plant in the United States. It's number one in the most impossible evacuation plant -- plan of any plant in the state. It's number one in the most risk to the most people of any plant in the United States. And it's number one in risk to the United States economy of any plant in the United States. World Series night, Yankees alone is an over three billion dollar economic industry within this -- within the 50 miles, within 20 miles. There is nothing generic about Indian Point and if any of this rulemaking should address the worst-case scenario at Indian Point, what you do with this waste? Staying on the theme of waste, just segue way into "S*T happens." (0163-40-1 [Dengler, Allegra])

Comment: [T]here cannot be a Generic Environmental Impact Statement. It is not sufficient when there's a broad variety of different risks at different locations, so I reject the very basis of it..It's like the old -- what they used to say about computers, garbage-in, garbage-out. And when I look at this Generic EIS and I see line after line of small risk, small risk, small risk, it's their unsubstantiated assertions and conclusions based on those unsubstantiated assertions are necessarily false. (0163-42-1 [Fry, Mark])

Comment: I'm really shocked by the audacity that you have presented such a general document for Indian Point. (0163-51-2 [DeCrescenzo, Jocelyn])

Comment: The GEIS cannot be generic for a hundred plants throughout this nation who have different regional issues, different concerns, different populations, different operating histories, different geological issues, multiple different issues cannot be issued. Each plant must have its own evaluation. The postulation in Appendix S -- H is that this will be cost-effective. In fact, it will be the opposite of cost-effective. (0163-7-4 [Shapiro, Susan])

Comment: The NRC ignores the differences between reactors (in terms of age, type, site location, ownership, history of problems, accidents, violations). These differences should prohibit the NRC from taking a generic approach to a spent nuclear fuel storage proposal. Throughout the country, all the operating reactors present spent nuclear fuel management risks. These have been identified and described by numerous people commenting. However, the statements made and the evidence cited have been ignored. Each reactor should be considered in terms of its own problems. (0174-9 [Thomas, Ellen] [Thomas, Ruth])

Comment: In addition to many frightening past incidents and accidents, Indian Point came dangerously close to being flooded by Hurricane Sandy. My home is located approximately 12 miles north of Peekskill, NY and Indian Point. My house and lands are not only my most valuable single asset. It is where my children were born and raised. It is where I live and breathe clean country air and drink clear fresh untainted water from my well. It is an extremely valuable and unique property. I could not replace it, nor could I ever afford to, if it were to be made worthless due to a nuclear disaster at Indian Point NY. The fact is that in the event of a failure at Indian Point, NY, countless surrounding homes and properties would become uninhabitable.

Where could all those people live then? Where would their business go? The costs of such an event would be astronomical and are simply not worth the risk presented by relicensing Indian Point. Indian Point is environmentally destructive and runs afoul of various coastal policies. New York State should object to Entergy's proposed consistency certification and to the NRC Draft Generic Environmental Impact Statement (DGEIS) as part of the process of replacing the NRC's Waste Confidence Rule. In particular, the State of New York and the NRC must consider and address: --The utter impossibility of evacuating and relocating the exceedingly dense population area surrounding Indian Point in the event of an emergency. --The 1.2 billion fish and other aquatic organisms killed annually by Indian Point's once-through-cooling water intake system, and the devastating impacts on the aquatic biota of nearby State and Federally designated Significant Coastal Fish and Wildlife Habitat in Haverstraw Bay. --The effect of rampant and ongoing radioactive leaks from Indian Point that indisputably release to the Hudson River and will continue to do so for decades. --The safety risks of storing thousands of tons of highly radioactive nuclear waste for decades if not centuries in overly crowded leaking spent fuel pools and temporary dry cask storage structures. (0194-1 [Gerstein, Bill])

Comment: I don't think that there should be a general plan for the waste from the nuclear reactors, every site is different and located in different environmental areas so there should be plans for each of these. (0200-2 [Individual, Anonymous])

Comment: There isn't much of a place for emotions in government, which isn't lost on me, but the ability to put a blanket over a larger issue isn't lost on me either. Each of the waste sites need different regulations based on what materials they handle. Handing out one answer for many questions won't suffice. (0203-1 [Louise, Tiffany])

Comment: On September 13, 2013, the U.S. Nuclear Regulatory Commission (NRC) submitted a proposed rule concerning the current and future storage of spent nuclear waste. This rule is proposing a few changes to 10 CFR 51.23 including having a generic environmental impact statement (EIS) for all nuclear waste storage sites that supports the continued on-site storage of wastes until a nuclear waste repository is found within the next 60 years. This would be an improvement because, in the past, the NRC did not require an EIS at nuclear waste storage sites. Having a generic EIS available will ease and simplify the licensing process for nuclear reactors in the country. (0205-2 [Lyons, Laura])

Comment: In order to refine the determination of continued storage, the Commission should adopt site-specific methods as a supplement to the generic evaluation. At least some sites, such as research reactors, MOX fueled reactors, and high-temperature gas-cooled reactor (HTGR) should be evaluated using site-specific method. (0210-5 [Individual, Anonymous])

Comment: Without a federal repository for spent nuclear fuel, we are left with tons of high level nuclear waste for decades to come, sitting in our communities. A federal court said the EPA's environmental impact studies must be done on storage, which forced the NRC to halt new reactor licensing and relicensing "until it established a technical basis for its belief that high-level radioactive waste will always be safely stored." Do not create generic rules that treat all sites alike, whether the waste is on the banks of a river, lake, ocean, or on an earthquake fault. (0215-1 [Matsuda, Thomas])

Comment: As a resident of Escondido, CA., I am among at least 8.4 million other highly vulnerable citizens located within 50 miles of San Onofre (SONGS) reactors, who would realistically be exposed to far greater public safety risks, as well as being unwilling victims of a much more probable catastrophic scenario than the extent which was projected, analyzed, and

used as the basis in NRC's Proposed Generic Assessment of Risks of Storing Nuclear Waste in Our Communities, and NRC's Proposed Rulemaking. It's extremely important for NRC to recognize that conditions in reactor communities surrounding San Onofre (SONGS) are extremely UNLIKE the conditions assessed at the two nuclear reactor sites in rural, or low population areas where impacts of spent fuel pool fires, and a series of other significant public safety risks were either analyzed generically in NRC's proposed Draft EIS, or where large quantities of high burn-up spent fuel risks were unanalyzed, or ignored, or where spent fuel assemblies here are stored in spent fuel pools with overly dense fuel assembly rack configurations containing 4 or 5 times greater volume of spent fuel than the design basis, conditions which are more prone to pool leaks, cause thermal irregularities, and require greater separation and cooling for safe storage. In contrast, the population density of communities surrounding San Onofre (SONGS) in southern California are much more similar to the high population communities surrounding New York's Indian Point reactors. (0218-1 [Borchmann, Patricia])

Comment: A Generic Environmental Impact Statement (GEIS) is NOT acceptable for California ! (0218-5 [Borchmann, Patricia])

Comment: The NRC should completely eliminate the waste confidence rule. Because it is a general rule, it cannot apply to the 65 different commercially operated nuclear plant sites across the US. Each site is different and should be treated as such. There should be individual plant environmental impact statements. (0222-1 [Zeller, Lou])

Comment: The NRC's one-size-fits-all generic approach is unjustified. The Commission is abrogating due process required under the Constitution by abandoning its responsibility to allow public to participate in decisions which affects them. The NRC's summary of the proposed rule proposed waste confidence rule states: If this proposed rule is adopted as a final rule, the NEPA analyses for future reactor and spent-fuel storage facility licensing actions would not need to consider the environmental impacts of continued storage on a site specific basis. A generic decision to allow the creation of additional irradiated nuclear reactor fuel and other radioactive waste associated with the uranium fuel cycle should be accompanied by 65 well-supported and well-documented plant-specific safety findings. And it would need scores of credible, plant-specific environmental impact statements that fully assesses the health and environmental impacts of the uranium fuel cycle with a reasonable array of alternatives. (0222-5 [Zeller, Lou])

Comment: NRC staff has said it would take 7 years to properly complete the GEIS. Given varied power station designs, geographic features such as rivers, oceans, dams, flood zones, population, flight paths, SFPs inside or outside of containment, containments that cannot contain, et cetera, each reactor is unique. Therefore there should be no GEIS. Rather, every storage site should require a properly completed site-specific Environmental Impact Statement (EIS). (0230-6 [Garb, James])

Comment: The consequences of a loss of electricity would be catastrophic. We can't say that just because a tsunami is unlikely, a Fukushima disaster is unlikely here. Peachbottom to Baltimore's north is at risk of a sudden dam failure, like 34 reactors in our fleet (2). Calvert Cliffs is 3 miles from the largest liquid natural gas terminal on the east coast where a huge fire or explosion could occur. (0233-3 [Dubois, Gwen L])

Comment: What is this question of why not evaluate all the impacts on a site-specific as opposed to a generic basis? And this is where the question of efficiency comes in. Well, the

easy answer is the Court upheld NRC's right to do that, so, end of story. NRC does not need to reverse Court. But that -- that's an answer only a lawyer can love. (0244-11-5 [McCullum, Rod])

Comment: As experienced in Nebraska during the summer of 2011 at Fort Calhoun and Cooper Nuclear Stations, NRC must begin to focus upon reactors in a site-specific manner with scientifically based analysis. (0244-14-9 [Prescott, Lisa Marie])

Comment: For instance, several reactor sites in our region are in ecologically sensitive areas, including FP&L's Turkey Point near Miami, which is situated between the Everglades National Park and Biscayne Bay. Given Turkey Point's location, sea level rise and storm surges are real threats that must be considered. Can the NRC ensure that spent nuclear fuel can safely sit at Turkey Point even for 100 years, let alone indefinitely? Likewise, Southern Company's Plant Vogtle in Georgia is located on the endangered Savannah River. In addition to being in a sensitive ecosystem, Plant Vogtle, it is also located across the river from Savannah River site, yet no consideration was given to the cumulative impacts of having reactors and corresponding nuclear waste in such close proximity to a highly contaminated DOE radioactive waste site. Additionally, both Vogtle and Turkey Point are slated for more reactors and thus, if built, even more toxic radioactive waste would be generated. The NRC cannot turn a blind eye to the unique characteristics of each site and each community. (0244-3-5 [Hancock, Mandy])

Comment: I don't believe that the EIS is adequate to address the individual characteristics of, you know, individual sites across the country. Taking Turkey Point, because that's what I'm currently involved in, as an example, and as Mandy spoke earlier about. (0244-8-1 [Totoiu, Jason])

Comment: Miami is ground zero for that, Homestead. And so it's really surprising to me that a lot of money is being spent to put two more reactors in Homestead, and coupled with the long-term indefinite storage of spent fuel, within ten miles of two National Parks and Everglades National Park, which the country is spending billions, with a "B," to restore. And all the while we're proceeding right along, almost as business as usual. Additional issues. I don't think the EIS really -- you know, going back to this individual, you know, the consideration of some individual site-specific things. I think Florida has a unique geography and it has unique hydrology, especially South Florida, it can vary within just a few miles. I'm not sure if that's really adequately looked at in this Environmental Impact Statement, and how fuel leakage and how the interaction and the resulting effects. (0244-8-3 [Totoiu, Jason])

Comment: So, how can we ever capture one moment in time with something called GEIS and presume that it will capture what is happening in this ever-changing reality? Every reactor site is unique. If they were to drop one cask out at Zion, you could punch a hole in the bottom of the pool. It would partially drain and, in a worst case scenario, set fuel on fire in a few hours in an order of magnitude greater than Chernobyl. These are catastrophic risks and we cannot address them through this absurdity of a generic impact statement. And these are site-specific impacts in this very densely populated area that we need to take into consideration as we make our future plan. (0245-10-3 [Lewison, Linda])

Comment: So, the NRC incorporates the draft GEIS into every reactor license, the conclusion that spent fuel, excuse me, with the conclusion that spent fuel can be safely stored aboveground indefinitely with future analyses of spent fuel and reactor licensing actions like ours, silencing the concerns of growing populations around nuclear reactors. (0245-19-5 [Smith, Ed])

Comment: As all those involved in facilitating nuclear power seek to extend the time that nuclear waste stays in our communities, they also seek to reduce their own liability and responsibility to the public. Worse yet is they seek to silence us by including this Generic Environmental Impact Statement into the reactor licensing and effectively preventing the public from raising concern and being able to question the storage of nuclear waste forever onsite at individual nuclear reactor facilities in our home communities. (0245-30-3 [Snyder, Gail])

Comment: I work as a volunteer with Peoria Families Against Toxic Waste. We normally work with hazardous waste on heavy metals and PCBs and other things that stick around for a long time, but, boy, all of that pales in comparison with nuclear. When I reviewed the draft EIS, the first thing that I was taken aback by was the fact that it was a generic EIS and at some point we authorized that we can have one EIS that would cover what really is a relatively small number of nuclear plants, a discrete hundred or so. (0245-31-1 [Fox, Tracy])

Comment: I find the term "generic environmental" an oxymoron. Environment is the essence of site variability. So, I find the proposition absurd and reject any GEIS for nuclear waste. (0245-46-2 [Craig, Evan])

Comment: And if it [the NRC] is going to proceed with that [rulemaking], it needs to look at these on a site-specific basis. (0246-2-9 [D'Arrigo, Diane])

Comment: Absent a legitimate GEIS that fully evaluates the environmental impacts of failing to secure permanent spent fuel disposal, the NRC must not exclude consideration of the environmental impacts of nuclear waste from individual license proceedings in the future moving forward. (0246-22-5 [Fisher, Allison])

Comment: [T]here are so many different kinds of plants, there is plants with pools in the air, there is plants of different designs, there are plants near earthquake faults, near water. There is no way not to have to look at each situation when it comes around in order to judge things. (0246-26-3 [Sondheim, Steven])

Comment: And furthermore, the idea that this is a Generic EIS. Every reactor is located in vastly different -- they are vastly different from each other. I mean the San Onofre reactors are so different they put one in backwards because they didn't realize that the two reactors were opposite. One of them failed and they never really did figure out what was different about the other one. Populations are different. Egresses are different, the transportation, the roads, and so forth. The seismic situation, the tornado, the earthquake, the size of the airplanes. There might be slightly different reactors. The size of airplanes that were expected when the reactors were built versus what they are flying now, the viciousness of the terrorists. These are all things that have changed. Our own viciousness as soldiers when we go out and fight. The real effect of a generic EIS is to inhibit later on public discussion because that is what is decided in a generic EIS. We can't revisit it. And yet, we are talking about indefinite storage. I would say that indefinite is a terrible word to use with a generic EIS. (0246-29-7 [Hoffman, Ace])

Comment: One, the Nuclear Regulatory Commission should abandon the Waste Confidence Rule. Because it is a general rule, it cannot apply to the 65 different commercially operated power plant sites across the nation. Each site is different and should be treated as such. There should be individual plant Environmental Impact Statements for all 65. (0250-1-1 [Zeller, Lou])

Comment: One of the most distressing things in this Environmental Impact Statement is the fact that it is generic. This is a term which flies in the face of the facts of the matter, as I've just outlined. (0250-1-4 [Zeller, Lou])

Comment: First, it makes sense to evaluate generic issues on a generic basis. It's the most efficient use of our regulatory resources and we should use those resources efficiently. (0250-15-3 [Rodack, Tom])

Comment: We know the real risks of nuclear energy and its waste, and that is why we are asking you to abandon this general ruling and instead draft individual EISs for each location. (0250-28-7 [Embrey, Monica])

Comment: The draft GEIS does not address water safety issues as reactor site-specific, and does not include the necessary data collection needed to take a realistic look at our situation. The nuclear power stations Catawba and McGuire give us four nuclear reactors located on drinking water reservoirs within 20 miles of downtown Charlotte. They are the largest water users on the Catawba River, a river that has been ranked the fourth most stressed river in the United States by the Union of Concerned Scientists, and made the Southern Environmental Law Center's list of the top ten most endangered places in the southeast. Other reports have quoted by 2040 there will not be enough water in the Catawba River to meet all the water demands. Most people don't realize that more water is used to generate power for their home than is directly used in a household. The Oconee Nuclear Station shut down October 24th due to water issues. This plant faces serious dam issues, and has had 14 high-level violations since 2000. For those of you who don't know, that's a heck of a lot. It took an NRC whistle blower for Duke and the NRC to do anything about it. That doesn't give me confidence. And the proposed W.S. Lee Nuclear Plant in Gaffney; they have to really compensate for the small Broad River. That dries up in the summer. You can just walk across it. Yet, Duke and the NRC think it's okay to just build 20 miles downstream in Cliffside, then down to the south you've got three reactors at V.C. Summer and Jenkinsville. (0250-45-1 [Sorenson, Laura])

Comment: The NRC ignores the differences between reactors in terms of age, type, site location, ownership, history of problems, accidents, violations. These differences should prohibit the NRC from taking a generic approach to a spent nuclear fuel storage proposal. Each reactor should be considered in terms of its own problems. (0250-51-6 [Thomas, Ellen])

Comment: The American people do not accept the generic shortcut approach to environmental impact statements as equivalent to individual environmental impact statements for each license application. The Generic Environmental Impact Statement fails to provide detailed information concerning significant environmental impacts of proposed individual reactors. I'm speaking to a matter of public policy. Though less burdensome on the bureaucracy, the generic approach does not consider regional differences of scattered nuclear waste storage sites, preventing acquisition of complete and thorough information for the NRC to base key nuclear license decisions. And, more important, the GEIS process creates a swim upstream against the bureaucracy for communities with regional concerns that it becomes very difficult for a community to express their individual concerns. (0250-63-4 [Kasher, Brian])

Comment: If future nuclear plants are approved, then there will be between 8 and 10 nuclear reactors surrounding the City of Charlotte within 70 miles, 10 nuclear reactors surrounding the City of Charlotte within 70 miles. A generic Waste Confidence Rule that doesn't take into consideration these particular circumstances of our city, of our environment is not acceptable. We need to address that. (0250-64-2 [Gupton, William])

Comment: And I have just come to speak briefly in opposition to what I see as a one size fits all generic EIS for what we have is really a variety of plants in a variety of locations, a variety of environments. And I don't think you can have a one size fits all solution or a one size fits all environmental thing for that. (0250-69-1 [Rundle, Steve])

Comment: I question this idea of a one-size-fits-all impact statement . In South Carolina, we have such a diversity of reactors, with so many different conditions. For example, up at Oconee, which is in the northwestern part of the state, the NRC has determined that there's a safety risk there, because it sits on the edge of a lake that has an earthen dam. If there was an earthquake, and South Carolina is an earthquake-prone state - we just had one the other day actually - that dam would break, and a Fukushima-type event would happen. Oconee would be swamped. So I don't know how you can do a one-size-fits-all when you have so many different reactor sites and things going on. (0250-7-3 [Corbett, Susan])

Comment: As I look at what we're calling this, a G-E-I-S, and I like to take it personally. I say that because I left at home my lovely wife, who just had a total knee replacement. But thank God I didn't ask him for a generic doctor. I didn't ask him to send me to a generic pharmacy, and I didn't ask him to send me to anybody but the best. That's the same way I feel about this proposal. You're asking the future to live up to something that's going to fit everybody, doesn't matter where they live, who they are, where they come from or where they're going. You and I both know that is impossible. Savannah River site has leaking taking place as I stand. Camp Vogtle shut down last week and it was reported on national television, but locally, they said "Oh, it just shut off." Yet we're going to consider what I would call in kindergarten a pattern to fit all, when you cut one little cookie pattern, and it will fit everybody. (0250-8-1 [Uitley, Charles])

Comment: I have been concerned about the storage of nuclear waste at the DCNPP since before retirement I was the County Fire Chief in charge of emergency response to the plant. I also served on the County Nuclear Waste Management Committee chaired by a member of the Board Of Supervisors. The draft Waste Confidence Generic EIS is a troubling euphemism. We here in San Luis Obispo, feel risk not confidence. We feel there is unacceptable risk for several reasons. (0255-2 [Frank, Fred])

Comment: 1) A generic rule is inappropriate for the DCNPP because of unknown seismic risks. The plant is located on a web of known and perhaps unknown faults. The plant is now being operated under questionable seismic assumptions. 2) The spent fuel pools now contain over 1800 assemblies, many times the original design. The EIS stated that dry storage was the option of choice for safe storage but cost concerns dictated pools storage. 3) About 80% of the fuel stored in the pools are high burnup assemblies prone to cladding failure. 4) An accident, beyond design basis earthquake or terrorist attack could release orders of magnitude more radiation from the pools than from dry the casks. 5) All spent fuel will need to be moved to dry casks anyway, so the cost of early transfer will be offset to some degree, even if high burnup fuel dictate fewer assemblies per cask. Considering the above we feel that cost should not override safety and the NRC must rule that spent fuel assemblies be transferred from the pools to dry casks as soon as possible regardless of cost. (0255-3 [Frank, Fred])

Comment: I live in the state of Washington, where we have a very serious problem with nuclear waste here at Hanford Reservation. The tanks that supposedly were going to contain this virulent mess are leaking and eventually this radioactivity will reach the ground water and the Columbia River, if it hasn't already. Given the secrecy of this entire operation, it is likely there are already more problems than have been admitted with this reservation. While this is an example of something (creating atomic weapons) that we are probably not doing any longer, there are similar issues with the storage of wastes from commercial nuclear power plants around the country. (0269-1 [Gale, Maradel])

Comment: I was born and raised on the shore of Lake Michigan, part of the Great Lakes -- one of the greatest and largest inland, freshwater lake systems in the world . A nuclear incident on one or all of these lakes would have an unimaginable and irreparable impact. In your documents, you believe that one-size fits all -- that all of these nuclear power plants are the same or similar; and therefore, do not require site specific rules. However, the Palisades Nuclear Power Plant inspectors this past spring identified safety injection refueling water tank weld failures which caused a tritium leak into our precious Lake Michigan. Previously, the NRC staff had repeatedly insisted that the plant was taking "adequate" steps to ensure its safe operation. Then, we learn of weld failures. And, that brings into question the quality of the welds that have occurred on the spent fuel storage casks. How many of those welds were performed by the same contractors who did not know how to properly weld the safety injection refueling water tank? What kind of leaks may be occurring with the onsite high-level radioactive waste storage or any other storage or crucial infrastructure for that matter? (0277-7 [Pierman, Bette])

Comment: How can the NRC expect a generic environmental Impact Statement and Proposed Rule to apply to all of the 104 reactors in the United States? You are wasting the taxpayers' money with such an approach. The nuclear reactor sites all have different concerns and must be dealt with as a unique impact with rules that fit each site. (0280-1 [Magda, Marni])

Comment: SONGS would never have been approved for construction by the NRC with today's understanding of the dangers and the realization that the Federal Government has failed to remove the nuclear spent fuel to a safe location. In the 1960's we believed a way to use the spent fuel would be invented. It hasn't. MOX is unstable and not accepted for commercial use. California is an earthquake zone, with SONGS on a new fault, and we have yearly danger of out of control wild fires and global warming predicting rising ocean levels. Maps have been made. How far is the ocean at SONGS predicted to rise in the next 30 years? A new study has shown an Alaska tsunami could destroy the ocean areas of Newport Beach, Laguna Beach and San Clemente. We cannot afford to let the spent fuel stay at Songs for 30 years until the Cesium 137 has lost its power. That is only 45% of the spent fuel. What about the other 55%? Plutonium has a 24,000 year half-life. What is being done to protect 8.4 million people from a cooling pool accident? (0280-12 [Magda, Marni])

Comment: As a resident of Escondido, CA., I am among at least 8.4 million other highly vulnerable citizens located within 50 miles of San Onofre (SONGS) reactors, who would realistically be exposed to far greater public safety risks, as well as being unwilling victims of a much more probable catastrophic scenario than the extent which was projected, analyzed, and used as the basis in NRC's Proposed Generic Assessment of Risks of Storing Nuclear Waste in Our Communities, and NRC's Proposed Rulemaking. It's extremely important for NRC to recognize that conditions in reactor communities surrounding San Onofre (SONGS) are extremely UNLIKE the conditions assessed at the two nuclear reactor sites in rural, or low population areas where impacts of spent fuel pool fires, and a series of other significant public safety risks were either analyzed generically in NRC's proposed Draft EIS, or where large quantities of high burn-up spent fuel risks were unanalyzed, or ignored, or where spent fuel assemblies here are stored in spent fuel pools with overly dense fuel assembly rack configurations containing 4 or 5 times greater volume of spent fuel than the design basis, conditions which are more prone to pool leaks, cause thermal irregularities, and require greater separation and cooling for safe storage. In contrast, the population density of communities surrounding San Onofre (SONGS) in southern California are much more similar to the high population communities surrounding New York's Indian Point reactors. (0284-1 [Borchmann, Patricia])

Comment: A Generic Environmental Impact Statement (GEIS) is NOT acceptable for California ! (0284-5 [Borchmann, Patricia])

Comment: No one will be allowed to raise the question of whether the creation of additional wastes could be justified, even though there is no way of safely storing it. (0287-3 [Swanson, Jane])

Comment: [I urge that] the EIS be redone, with comprehensive and site-specific analysis of the conditions, problems, and risk associated with different reactor locations (0303-13 [Lamberts, Frances])

Comment: The Commission should perform a new environmental impact study. This should reflect site-specific conditions and risks, such as from possible evacuation need where reactor facilities are in densely populated areas. It should comprehensively meet NEPA standards of scientific impact assessment of all resources and operations involved, such as water and its potential scarcity; fail-save, longer-duration off-site electricity provision for spent-fuel cooling in case accidents; transportation hazards; aquatic and terrestrial species, and others. (0303-8 [Lamberts, Frances])

Comment: Also, considering the variables at each nuclear plant, this document needs to be site-specific rather than generic. (0309-8 [Green, Jeanne])

Comment: Anyway, as a resident in Escondido, I'm among at least 8.4 million other highly vulnerable citizens located within 50 miles of San Onofre reactors who will realistically be exposed to far greater public safety risks, as well as being unwilling victims of a much more probable catastrophic scenario than the extent which has been projected and analyzed in this Generic Environmental Impact Statement. The Draft Generic EIS has used as their basis of risks of storing nuclear waste in communities in Southern California and for NRC's proposed rulemaking. It's extremely important for NRC to recognize that there are conditions in reactor communities surrounding San Onofre that are extremely unlike those conditions that were assessed at the two nuclear reactor sites in rural and low population areas, where impacts of spent fuel pool fires, or a series of other potential safety risks were either analyzed generically, or where impacts were unanalyzed, or impacts were under-estimated. In contrast, the population density here in communities surrounding San Onofre, Southern California are much more similar to high population areas surrounding New York's Indian Point reactors. In 2012, New York's Attorney General successfully argued and led to a challenge on NRC's Rule which led to this Draft Environmental Impact Statement. (0325-11-1 [Borchmann, Patricia])

Comment: Please stop wasting our time and energy and your great minds on something that's generic. Generic won't work anywhere in this country. We have 104 reactors, we have to have a special solution for each place. (0325-12-7 [Magda, Marni])

Comment: I just want to say that the concept that you can reasonably assess the environmental impacts of 104 nuclear reactors across this country in a Generic EIS is laughable on its face. It's ludicrous. How can you possibly, possibly consider that the impacts at San Onofre on an eroding seashore adjacent to two known earthquake faults, adjacent to the major transportation artery between Los Angeles and San Diego, adjacent to one of the largest military installations on the West Coast, which also happens to be a military target, how can you possibly consider the impact that you generically identify for all nuclear reactors can adequately assess the impact at that location versus an impact in the middle of Nebraska? It's absolutely ludicrous, and I'm sorry but the NRC should be ashamed of itself. I certainly would be if I was a professional. (0325-20-1 [Sullivan, Martha])

Comment: San Onofre is not a generic nuclear power plant. I don't think there is such a thing, but we are not generic. We're graced with three earthquake faults, the plant is on the beach, we have really no real way to evacuate people. And right now with freeway construction coming up, it's going to close down the I-5 for two years due to a widening thing. Our beach communities are more vulnerable than ever for radioactive disasters. This planned major construction on the I-5 will be from 2014 through 2017. The widening is going to start from San Juan Creek Road and finish just south of Avenida Pico. The I-5 is our lifeline to evacuation. Should, God forbid, any natural or terrorist disaster occur to disrupt the tons of thermonuclear waste stored at San Onofre, we are trapped. It's bad enough when the freeway is open and running, but with it narrowing down, we haven't a chance. That freeway is the only possible way of escape from disasters to our stored nuclear waste, if any is possible, for people living in and visiting our beach communities, so it's up to the locals to stop any further freeway construction that would hinder evacuation from this power plant. And to call our situation generic is ridiculous. It's inhumane. I don't think any other plant has as many earthquake faults to contend with, and the other dangers. We need that waste out of here as soon as possible. We didn't ask for it to be there. We don't want it there. It's endangering all of us. (0325-23-1 [Kernahan, Mel])

Comment: I think everyone has made it plain that generic is not a word we like. And this one line in your additional issues for public comment, I would like to point out. "The Proposed Rule codifies the conclusions from the Draft Generic Environmental Impact Statement so that those determinations do not need to be made in individual actions." And I think those things need to be looked at very carefully because we do consider ourselves very special and significant. (0325-25-1 [Welty, Delores])

Comment: If you were to go back in time to when that plant was being designed and to when it was being proposed, I wonder if you could have gotten anyone in the community, anywhere in this state, anyone to say yes, we will be happy to have an atomic waste dump on our beautiful shore of California for 60 years, 100 years, 300 years, we don't know. And, also, we're going to give you a generic plan when we get to that point. Well, we're not a generic community. My kids are not generic, my family is not generic. (0325-27-2 [Davis, Patti])

Comment: The other word I'd like to speak about is the very first word we got stuck on at the first question, that's generic. The lady asked a question about this to the NRC and it was not answered, so we're stuck on the first part. So, here's a report which makes no distinction between storing nuclear waste in the middle of a metropolitan area, and storing it in the middle of an Arizona desert. It's a report that makes no distinction between storing nuclear waste on top of an earthquake fault, and one someplace that never has any earthquakes, same with tsunamis. So, this report is automatically suspect. It's not a serious report. This report is a whitewash. It's not considering the true facts, and as long as it's a generic report, this report is worthless. I think you better start all over and get rid of all the generic stuff. I think that's the message you should take home with you, revise the whole report and get rid of any generic analysis. (0325-31-2 [Johnson, Roger])

Comment: So, we've got airplane strikes, we've got terrorists, we've got 8 million people here in this county who have no benefit whatsoever from this nuclear waste and yet we've got it sitting here. And then what do they want to do? They want to make a generic, a Generic Environmental Impact Statement which means that anything unique about our situation, such as that we don't even have a reactor running, is going to be ignored. And not only that, but because it's generic, anything that doesn't get said now is going to be ignored. You're not going to be able to change anything. (0325-7-6 [Hoffman, Ace])

Comment: It shouldn't be a generic report at all. It should be a site and issue-specific. (0325-8-3 [Von Thillo, Grace])

Comment: I suggest that you use EISs for each nuclear power plant individually[.] (0326-15-7 [Schumann, Klaus])

Comment: The Draft Waste Confidence Generic EIS is a troubling euphemism. We here in San Luis Obispo County feel risk, not confidence. We feel this is an unacceptable risk for several reasons. Number one, a generic rule is inappropriate for Diablo because of unknown seismic risk. The plant is located on a web of known, and perhaps unknown, faults. The plant is now being operated under questionable seismic assumptions. Number two, the spent fuel pools now contain over 1900 assemblies, many times the original design. The EIS stated that dry storage was an optional choice for safe storage, but cost concerns dictated pool storage. Three, about 80 percent of the fuel stored in the pools are high-burnup assemblies prone to cladding failure; they are much higher temperature and higher radiation levels than conventional fuels. Cladding failure could release radioactive gases into the environment, since there is no containment over the pools. An accident beyond design basis earthquake, a terrorist attack, could release orders of magnitude more radiation than the pools -- from the pools than from dry casks. Five, all spent fuel pools will be needed to move to dry cask, so the cost of early transfer would be substantially offset, even if the high-burnup fuel dictates using more casks. Considering the above, we feel that the costs should not override safety and the NRC must rule that spent fuel assemblies be transferred to the pools to dry cask as soon as possible, regardless of cost. (0326-28-1 [Frank, Fred])

Comment: Now the most important thing that I wish to say is that the creation, the artificial creation of composite generic non-existent nuclear sites, is inherently flawed to perform qualitative analysis. You see, the geological, socio-political, geographic, environmental, and epidemiological considerations are unique to each site. Moreover, the mechanical operation of each of these plants and storage facilities is also unique. So you cannot make a generic plan based on things that are so inherently unique. There is not one generic nuclear power plant in the United States. They're all unique. So the people of San Luis Obispo reject this because it is scientifically invalid. (0326-56-7 [Homick, Nick])

Comment: I think it's a flawed GEIS. I'm very concerned about a generic approach with no chance to revisit at individual site re-licensing hearings. That makes no sense whatsoever. None. If that made sense then I would get to just have my business wherever I wanted it in San Luis, because there was one business they said was okay, so it must be okay for me to do it at my house. It's okay if they do it over there. It doesn't make sense for anyone. Why would it make sense for a nuclear power plant? (0326-61-6 [Henry, Anita])

Comment: So I agree with the two or three speakers talking about the generic issue. You know as well as I do that many U.S. nuclear power facilities are very unique. These are not cookie cutter facilities. Thus, you need specific site analysis for each nuclear power facility. (0326-63-1 [Campbell, Bruce])

Comment: [W]ithdraw the generic beast. And then also, obviously, facilities are unique as far as seismicity. A tornado hits a uranium enrichment facility in Paducah, Kentucky in the last few days and then there's flooding along the Missouri River. (0326-63-7 [Campbell, Bruce])

Comment: No one will be allowed to raise the question of whether the creation of additional radioactive waste should be allowed at any given site if this waste rule is adopted, so we object to it on that ground. (0326-8-3 [Swanson, Jane])

Comment: In your Draft GEIS, you say, "Storing highly radioactive spent fuel out onsite at Diablo Canyon is just the same as storing it at Prairie Island Nuclear Power Plant in Minnesota." Except, Diablo Canyon is built on the intersection of 13 earthquake faults on a fragile coastline on the ocean. Prairie Island is built on an island in the middle of the Mississippi River where there's been terrible flooding in the past few years. (0326-9-3 [Seeley, Linda])

Comment: 10 CFR 61, which deals with low-level radioactive waste has much more site-specific requirements than anything that is contained in these documents, either the GEIS or the rulemaking. (0327-11-8 [Kline, Connie])

Comment: In the Pandora myth, she ended up keeping hope. She did not release hope from her jar when she let out all the consequences, the punishments that were held inside that jar. And there's always been some ambiguity in interpretation of what it means that the hope was not released. Does it mean that hope has been held captive, or does it mean that there is hope to be had in that jar still? I would say that when the NRC, which is tasked to protect people and the environment, does things like saying that the environmental impacts of continued storage are generically addressed and will not be revisited in future site-specific licensing proceedings, that is holding hope captive in ways that we'll still be regretting and suffering from generations upon generations from now. And so Pandora is still with us. (0327-24-2 [Rivers, Alicia])

Comment: What these series of hearings indicate to me is that the NRC has finally come our way, that confidence is an importance in this process, confidence of the general public to make policy work, okay? So in policy, this rule that we're looking at, the rule changes are about making it more efficient to relicense operating nuclear reactors and plants, okay? So in all policy formations, you have to not just think of efficiency, but you must think of effectiveness and economy. So I would suggest that we have a no action, no action, no action in this process. The change is not good. The alternatives do not provide any increased efficiency or effectiveness. It may be more cheap, but the cheap is always bad. (0327-38-1 [Stansberry, Mark])

Comment: Now, when we started talking about the changes that are coming up, if this change would go through, any future licensing, any future licensing of a reactor would not have to have an EIS, an environmental impact statement. They would go from this generic non-site specific. So if you would just throw something out, we've been talking about Fukushima today, but, you know, Davis-Besse, all the other site-specific concerns would not be brought into the impacting or influencing the decision for future licensing, which we're talking about future 80 years of operation of already several decade-old facilities that we're talking about. (0327-38-2 [Stansberry, Mark])

Comment: I'm glad the NRC is starting to think about confidence as being part of this process and help build the confidence. Confidence building is very important, so thank you and let's go no action on this one. (0327-38-4 [Stansberry, Mark])

Comment: It's been stated, it's stated in the PowerPoint that you presented earlier that this GEIS is what it is, and we're not going to have environmental assessment, environmental review of individual storage facilities. That's an absurd position, and absurd conclusion because as various people have already pointed out, these facilities vary greatly one from another. The city in its comments has pointed out that the Red Wing nuclear parking lot is at such a level that it's

likely at some point in the future to be inundated by the Mississippi River. Now, I don't know whether the design basis of those casks makes provision for them to be flooded without significant harm occurring, but that's certainly something that would need to be looked at. A desert facility might have other issues, such as the degradation of elastomeric parts due to high heat. So, this is -- you need, in my opinion, to abandon the claim that any GEIS can be sufficiently adequate to give us comfort with regard to individual nuclear waste storage facilities. (0328-11-5 [Muller, Alan])

Comment: I think that cost should not be the measure. When you look at site-specific detail that should be required for every facility across this country... cost. (0328-6-1 [Foushee, Lea])

Comment: I think trying as hard as I can to be constructive to the attempt to protect society from the destruction associated with irresponsible or mismanaged irradiated fuel, in my attempt to be as respectful as I can to this process you're going through to try and make a rule to deal with the utter absurdity; well, I would encourage you to recognize that generic is out of the question. There is no generic here. There is no generic. (0328-7-7 [Crocker, George])

Comment: Every one of these sites, every one of these casks, every one of the fuel assemblies in the casks, every single fuel rod in every single assembly is unique with a unique set of stressors that have been acting on it over whatever period of time you care to assume. And those stressors on every rod, in every cask will cause every rod in every cask potentially to act differently than the others. And you need to account for that, or your rule is bullshit. (0328-7-8 [Crocker, George])

Comment: But the difficulty with this waste storage and the thought of permanent aboveground storage at reactor sites like Sequoyah is very troubling, and the Sequoyah re-licensing, which is pending, of course, is now suspended in terms of the possible issuance because of the process we're currently going through about whether we could have any confidence about the management and isolation from the environment of high-level radioactive waste resulting from the continued operation of the reactors. One of the difficulties with the proposal is that the regulation would essentially say that this is good enough to give us confidence for every reactor at every site, and it will no longer be an issue with respect to re-licensing of these reactors. That, I think, that's an unjustifiable step. (0329-12-2 [Paddock, Brian])

Comment: The Sequoyah site is still under investigation, and TVA is under directions from the NRC to be investigating both the seismic stability and the potential for destruction by flooding of the Sequoyah site. And for anyone to adopt a document that says, without even completion of those, we know that surface storage indefinitely, for hundreds of years perhaps, past the lifetime of the operation of the reactors is simply unsustainable and unjustifiable and contrary to all common sense. (0329-12-3 [Paddock, Brian])

Comment: I want to reiterate that a Generic EIS is just not wise or prudent. There are entirely too many idiosyncrasies of situations like some of the past people I've mentioned. (0329-14-3 [Sondheim, Steven])

Comment: And the next thing is that this is a generic, and it boggles the mind that any other state would be willing to let their requirements be the same as California's, which are bound to be much more strict because of our tsunami dangers and our earthquake dangers. Maybe that's a good thing if it really is going to be bounded by the worst possible case, but I just have a lot of trouble believing that that's going to happen. I think California is going to get shorted, that the protection is not going to be as good as we need. (0329-16-2 [Hoffman, Ace])

Comment: Right now, today, the Marine Corps is testing bombing runs on Camp Pendleton, and we're talking about storing waste at San Onofre essentially permanently. And we've been in wars almost permanently, which means the Marines are going to be testing bombing runs on the same area where San Onofre is going to store its waste permanently. Permanently. And I think this is all wrong. (0329-16-6 [Hoffman, Ace])

Comment: I just really wanted to briefly talk about generic EIS. Generic is just -- when you are talking with nuclear power, generic is a really dangerous thing. We all live in different areas of the country. All of these nuclear power plants with all their spent fuel, they all have different challenges, some of them weather-related, some of them -- just to name a few, we have flooding disasters, tornadoes, earthquakes, tsunamis, hurricanes, super storms, heatwave, drought. All of this spent fuel is really tied to water. And as we move into a climate change world, generic just isn't going to cut it. I happen to live in Iowa. I live downstream from, 33 miles from, Duane Arnold Energy Center Nuclear Power Plant. They have had issues of flooding. We have had three 100-year floods in the last 20 years. Fort Calhoun borders Iowa. We still have Fort Calhoun shut down. It was almost a major disaster there, almost a station blackout because of the Flood of 2011 on the Missouri River, which if you look into that, there are 7 dams on the Missouri River upstream of Fort Calhoun and also Cooper Station. A disaster like we had in Colorado this past year, where there was so much rain that deluged the Colorado Rockies and just basically tore away a few towns. If that were to happen on the upper Missouri River Basin, we could see a cascading dam failure that would send a wave of water down the Missouri River that would be unprecedented. And Fort Calhoun, some estimates say, would be 30 feet underwater, which would create a station blackout and a disaster of unimaginable proportions with spent fuel. So generic EIS does not cut it. I think we need environmental impact statements of all 100 existing reactors and all the reactors that have been recently closed or were scheduled to close. (0329-18-3 [Carberry, Mike])

Comment: [I support] Kevin's [Kamps'] comments and Steve's [Sondheim's] comments about the fracking issues. And there is no way that a generic environmental impact statement can cover this in one statement for each separate reactor. The point I want to leave you with is that in this new universe that we are entering of decommissioning, each site is different. And each arrangement to do the decommissioning in each site is different. And there is no way that that can be covered through one generic environmental impact statement. (0329-23-4 [Lewison, Linda])

Comment: I actually would like to provide a couple of specifics to support the speakers who request a separate environmental impact statement at each nuclear plant. For some reason, I actually consider it regulatory malpractice for NRC to have done this, but they have excluded Limerick Nuclear Plant from the outcome of NRC's nuclear waste study and new rules. Now, here are two reasons that we put on the record that that is really, really terrible. NRC's own, you know, documents for Limerick relicensing confirm that Limerick's fuel pool liners are corroding at up to ten times faster than what were anticipated. NRC told Exelon to recoat them immediately and then caved into Exelon in allowing them to wait for a decade to do that. Also, the actual storage, aboveground storage, there are also corrosion concerns about that. For example, in these documents for Limerick relicensing for nuclear plants that have cooling towers, they confirm that the steel onsite can corrode in 4 to 52 weeks. That's in NRC's own documents. They're overlooking all of these things. There could be times that we would have to pull some of those, some of the waste out of the cask. That might be impossible to do that because of the corrosion issues. We have been raising this with NRC since 2006. They have ignored, you have ignored, all of it. It's really frightening to us from the standpoint of what could happen here. (0329-26-1 [Cuthbert, Donna])

Comment: And we certainly encourage NRC to do these separate environmental impact statements at each nuclear plant and have every nuclear plant benefit from any protective decisions that are made after this study is completed. (0329-26-2 [Cuthbert, Donna])

Comment: [B]ased on the evidence that we've compiled, we are requesting that the NRC conduct a site-specific nuclear waste study at Limerick Nuclear Plant prior to completing the court-ordered nuclear waste study nationally. Our analysis is that this is about the public's long-term health and financial risks in terms of what needs to be considered. We would suggest that it would be safer to stop producing waste for which there is no current safe solution and for which financial responsibility has been passed off largely to the public, to taxpayers and ratepayers. (0329-3-2 [Cuthbert, Lewis])

Comment: So in conclusion I would respectfully suggest to the NRC that it is extremely important that you not exclude Limerick Nuclear Plant from the outcome of the nuclear waste study and new rules, as I believe is currently planned. And based on our investigation of Limerick's deteriorating and structurally deficient fuel pools and questionable casks with numerous design flaws and unanswered viability questions, it's imperative that you take a site-specific look and address a lot of the questions that we've previously put on the record and will continue to place on record. There is no safe solution to the problem of high-level radioactive waste, and we need to have a site-specific nuclear waste study done on Limerick before any decision is made. (0329-3-9 [Cuthbert, Lewis])

Comment: The draft GEIS is really kind of ludicrous. I have been reading it since you were here. I picked up a copy, and I have been reading it. And, you know, the whole idea of a generic environmental impact study for over 100 nuclear plants is absurd, to say the least. And other people have told you why. You have heard it from us. (0329-32-3 [Seeley, Linda])

Comment: I would like to expand my comments regarding the generic structure of the proposed rule as being perhaps the most insidious and alarming aspect of the policy. Apparently taking the lead from the NRC, the State of Michigan is demonstrating how establishing generic rules can be a game changer for the corporate stakeholders. I would like to read a few passages from a regulatory impact statement and cost-benefit analysis published in October 2013 by the State of Michigan Department of Environmental Quality pertaining to proposed generic rules governing environmental contamination response activity and cleanup criteria requirements for response activity, also known as remediation and redevelopment of brownfields, contaminated sites, and facilities. My comments are very applicable today, regardless of whether we are discussing the Rocky Flats facility in Colorado or the Waste Confidence Rule for continued storage of spent fuel. On page 4, part 3, number 2, it says, "Other states do not have generic cleanup criteria. A site-specific risk assessment must be conducted to determine environmental conditions and develop cleanup standards for each site. Generic criteria in Michigan provide a mechanism to quickly determine environmental concerns and provide information to parties involved in property transfers. Generic criteria facilitate property transactions, allowing financial institutions to make loan decisions regarding contaminated properties, allowing liability protection for a party not liable for the contamination." Now, on page 6, part 3, number 5, it says, "Purchasers of properties would not be able to limit their liability for cleanup of past environmental concerns if criteria are not available to assess the risk posed at a property and, therefore, would be less likely to purchase the property." Now, on page 9, part 3, number 18, it says, "An environmental assessment report to provide the information necessary to utilize the generic cleanup criteria is estimated to cost 5,000 to 20,000 dollars. If generic criteria were not an option, the cost of an environmental assessment report to provide the information necessary to develop site-specific cleanup criteria

would be 50 to 100 thousand dollars or more depending on the circumstances and nature of the site." And, finally, on page 9, part 3, number 21, "The proposed rules are designed to be less burdensome than the effort and costs to evaluate the Environmental concerns . . . in the absence of generic cleanup criteria." (0329-36-1 [Schonberger, David])

Comment: Perhaps the most insidious and alarming aspect of the Proposed Rule is its generic structure. If Michigan is any indication of emerging trends, citizens should be forewarned to expect generic rules and criteria coming to a state near you. (0329-7-4 [Schonberger, David])

Comment: The United States Forest Service (USFS) court challenges require only site-specific assessments of a timber sale at the time of project rather than the initial designation and establishment of entire forest plan. The USFS have utilized the deregulation of EA/EIS analysis for projects on national forest; however such postponed site-specific analysis letting overall plans stand as is have profound effects on the culpability of agency management and disguise the whole-picture plan of how each site may impact the human environment. This is the impact of a Forest Management Plane requiring an EIS only when a site-specific project occurs to cut and sell timber. This management regime in the nuclear waste sector is far more detrimental, far-reaching and uncertain. Though, NRC's determination was to improve agency efficiency, this management proposal poses greater question to NRC's thoroughness of safe storage and future prevention of ecological harm. (0339-1 [Wilmott, Emily])

Comment: The Waste Confidence rule and subsequent alterations, though applicable only to the period following the expiration of a licensed reactor, is a part of the EA for agency decision making on the relicensing of the nuclear reactor and independent spent fuel storage installations. These broader analyses may be appropriate for agency efficiency efforts when dealing with resources lacking such monumental consequences; however dealing with the wastes of nuclear power plants in this manner seeks to deregulate licensed reactors without updating the assessment of their waste impacts or informing the endangered public. (0339-3 [Wilmott, Emily])

Comment: Let's play it safe, look at each site carefully, individually. (0340-2 [Case, Ed])

Comment: Failing a national repository, the NRC has not studied the issue of waste storage for each individual reactor (age, type, site location, ownership, history of problems, accidents, violations) but instead has created a generic wish list for waste storage, lacking workable specifics. Each reactor must be considered on its own. (0348-3 [Agnew, David] [Roscoe, Lee])

Comment: Failing a national repository, the NRC has not studied the issue of waste storage for each individual reactor (age, type, site location, ownership, history of problems, accidents, violations) but instead has created a generic wish list for waste storage, lacking workable specifics. Each reactor must be considered on its own. (0352-3 [Roscoe, Lee])

Comment: I suggest, in the alternative, that the Commission not attempt to provide a "generic environmental impact statement" as each reactor site may very well contain different land use and socioeconomic features capable of being impacted disparately. (0354-1 [Oeser, Robert])

Comment: It is clear that the nuclear waste stored at Indian Point poses a unique risk, which warrants site-specific examination. The long term storage of waste so close to a major population center seems unwarranted. 1950s/1960s era technology needs to be updated. Please issue rules which bring this site into the 21st century - or close it entirely. (0356-1 [Klepner, Lou])

Comment: Do not use a GEIS but rather work with individual EIS' for each NPP. (0358-11 [Schumann, Klaus])

Comment: Failing a national repository, the NRC has not studied the issue of waste storage for each individual reactor (age, type, site location, ownership, history of problems, accidents, violations) but instead has created a generic wish list for waste storage, lacking workable specifics. Each reactor must be considered on its own. (0373-3 [O'Malley, Brian])

Comment: The draft GEIS ignores the obvious fact that each site is unique. The one-size-fits-all plan is especially irresponsible for Diablo Canyon given that it is underlain by multiple fault lines. (0375-1 [Wilvert, Calvin])

Comment: ACE made a list of requests. This includes a request for NRC to do a site-specific radioactive waste study at Limerick and for NRC to NOT exempt Limerick (as planned) from NRC's new waste rules. Over the past few years, NRC has failed to take responsible action regarding Limerick's on-site deadly radioactive wastes, and has even failed to respond to our specific questions and concerns. (0377-1-3 [Cuthbert, Lewis])

Comment: 1. Conduct a site-specific nuclear waste environmental impact study at Limerick Nuclear Power Plant, prior to completing this court-ordered nuclear waste study, based on all serious threats and concerns summarized in these written comments and other still unresolved waste concerns raised previously with NRC. (0377-1-6 [Cuthbert, Lewis])

Comment: NRC INEXPLICABLY IGNORES UNPRECEDENTED RISKS FROM LIMERICK'S FUEL POOLS AND REFUSES TO DO AN UPDATED REVIEW FOR LIMERICK'S SPENT FUEL STORAGE, DESPITE COMPELLING EVIDENCE PRESENTED TO NRC THAT CLEARLY IDENTIFIES THE NEED. Comprehensive evidence of Limerick's fuel pool risks was submitted in written testimony by ACE for NRC's public hearing record for Limerick's EIS 11-26-13, and updated in written testimony for NRC's public hearing record 6-24-13. Summaries were also provided in correspondence to NRC Commissioner Borchardt 8-5-13. In 2012, the federal court said NRC should consider potential environmental effects of leaks and fires involving spent fuel pools. Despite the inherent risks from Limerick's fuel pools identified and summarized by ACE, NRC is ignoring the order to re-think the environmental impact of storing radioactive wastes in Limerick's fuel pools. In 2013 NRC's Neil Sheehan said in an e-mail to the Mercury newspaper, that NRC's new rules about spent fuel storage are not likely to affect Limerick's Environment Impact Statement. He said: "There is no expectation that Exelon would have to conduct a new review of spent fuel storage at Limerick" (Mercury - March 8, 2013). "Limerick nuke plant relicensing unlikely to be affected by new spent fuel rules" (Mercury - March 13, 2013) (0377-3-14 [Cuthbert, Lewis])

Comment: WE CONSIDER IT REGULATORY MALPRACTICE FOR NRC TO EXCLUDE LIMERICK FROM THE OUTCOME OF NRC'S NUCLEAR WASTE STUDY AND NEW RULES: Given the extreme dangers and destruction faced by the entire Greater Philadelphia Region from storage of massive amounts of all of Limerick's deadly high-level radioactive wastes in fuel pools and casks on the Limerick site, NRC would be negligent to ignore these unprecedented long-term risks to the environment and dense population in Limerick's Environment Impact Statement. Risks at Limerick will continue to grow as Limerick produces 2 tons more of high-level radioactive wastes every year Limerick continues to operate. (0377-5-6 [Cuthbert, Lewis])

Comment: NRDC petitioned the Atomic Licensing and Safety Board, arguing, among other things, that the reactors should not be re-licensed without a new, site-specific environmental

impact review; IT IS INDEFENSIBLE FOR NRC TO USE A GENERIC EIS IN NRC'S DRAFT, WHEN THIS NEGLIGENTLY IGNORES THE KINDS OF SITE-SPECIFIC RISKS WE IDENTIFIED ABOVE FOR LIMERICK NUCLEAR PLANT; IT IS INDEFENSIBLE FOR NRC TO EXCLUDE LIMERICK FROM NEW RULES AS A RESULT OF NRC'S NUCLEAR WASTE STUDY; NRC CANNOT JUSTIFY IGNORING LIMERICK SPECIFIC ENVIRONMENTAL IMPACTS FROM MASSIVE AMOUNTS OF HIGH-LEVEL RADIOACTIVE WASTES STORED AT LIMERICK[.] (0377-5-8 [Cuthbert, Lewis])

Comment: WE ASK NRC TO DO A SITE-SPECIFIC NUCLEAR WASTE STUDY FOR LIMERICK'S HIGH-LEVEL RADIOACTIVE WASTE STORAGE, PRIOR TO NRC'S COMPLETION OF THE COURT-ORDERED NUCLEAR WASTE STORAGE STUDY (0377-6-8 [Cuthbert, Lewis])

Comment: NRC staff has said it would take 7 years to properly complete the GEIS. Given varied power station designs, geographic features such as rivers, oceans, dams, flood zones, population, flight paths, SFPs inside or outside of containment, containments that cannot contain, et cetera, each reactor is unique. Therefore there should be no GEIS, every storage site should require a properly completed site-specific Environmental Impact Statement (EIS). (0419-11 [Agnew, David])

Comment: The NRC must change its nuclear reactor licensing process to require an individual Environmental Impact Statement for each site determining the impact of creating and storing radioactive waste on each reactor site. The health and safety effects on communities and the environment in proximity to each site needs to be carefully considered in a site specific manner. (0421-8 [Clemons, Victoria])

Comment: It is urgent for the NRC to look into best practices for each specific site and not try to apply a convenient and unscientific solution to all nuclear power plants. (0423-3 [Graves, Caryn])

Comment: Moreover, as a generic statement, the analysis makes no distinctions among the dozens of sites covered by the EIS with regard to such factors as levels of seismic risk (earthquakes and tsunamis), regional population levels, size of site and isolation of site, and proximity to transportation corridors. Rather, it assumes an identical level of risk at all sites regardless of specific characteristics. (0431-11 [Pascall, Glenn] [Watland, George])

Comment: unsuitability of and failed utility of a generic EIS for over 100 unique and site specific situations involving SNF (0447-1-8 [Andrews, Richard])

Comment: This issue of management of SNF is site specific to each reactor and ISFSI. (0447-2-9 [Andrews, Richard])

Comment: I ask the Commissioners to step out of their shoes to view this issue as a citizen whose daily life is threatened by proximity of a nuclear facility, that perhaps they might see the absurd science fiction scenario of electricity produced by nuclear fission, and in particular, by the Diablo Canyon Nuclear Power Plant situated amid 13 earthquake faults within a ring of fire. Generic does not apply here. Here is my thinking as a citizen living 10 miles from Diablo Canyon. (0450-1 [Bast, Nancy])

Comment: The Waste Confidence Rule in the NRC Draft Generic Environmental Impact Statement (GEIS) is clearly inadequate to address the unique safety issues which exist at the Diablo Canyon plant. We doubt that it is adequate to address the safety issues at any number of

US plants as it is written as a generic one-size fits all plan for some fictional plant site. This is an extremely flawed approach to considering safety needs at nuclear power plants within this country--each with its own unique set of conditions which impacts the safety of each plant. This "cookie cutter" way of planning to deal with the nuclear waste in this country is grossly inadequate. (0451-2 [Rippner, Sharon] [Rippner, Thomas])

Comment: To be meaningful, waste storage plans must be uniquely written for each nuclear plant and this generic plan should be rejected in its entirety. (0451-5 [Rippner, Sharon] [Rippner, Thomas])

Comment: As a Registered Civil Engineer, I am baffled by your decision to even consider submitting a Generic Environmental Impact Statement (EIS). Proposing the same safeguards for stockpiled nuclear waste at all of the nuclear facilities throughout the country is irresponsible and unsafe! Establishing identical safety requirements for an isolated facility in a sparsely populated area in New Mexico, for instance, and the San Onofre facility, located within fifty miles of over 8.5 million people, next to known off-shore earthquake faults capable of 8.0 magnitude earthquakes and situated on eroding bluffs in a potential tsunami zone is reckless. The only evacuation route is Interstate 5, situated adjacent to the plant. It is even more frightening considering that the San Onofre nuclear facility is adjacent to Camp Pendleton, one of the largest military installations on the West Coast, a potential target for terrorists. This is madness! (0453-1 [Feathers, Jösan])

Comment: The proposed new Rule on Waste Confidence is deficient in the following three fundamental respects: 1. It does not require a site specific Waste Storage Plan for each existing or proposed nuclear power generating station. (0454-1 [Waldstein, Joe])

Comment: The operating assumption behind the new proposed rule is that Waste Storage at individual sites is intrinsically safe for as long as necessary (multiple generations) regardless of the environmental conditions and population density surrounding each plant. This seems to be an arbitrary assumption, conveniently concocted to deny risk and save money. The focus of any rule which speaks confidently to a given population should be the safety of the community. (0454-4 [Waldstein, Joe])

Comment: Environmental impacts are shown as "generic," no distinction is made of added risks at sites such as San Onofre that are in earthquake and tsunami zones on small and valuable pieces of land near major population centers and transportation corridors. (0464-4 [Nelson, Pam])

Comment: Importantly, the NRC should perform site-specific risk assessments and environmental impact statements for each U.S. reactor. The reason for this is perfectly exemplified by the Indian Point nuclear power plant, which is unique in several ways:

- Indian Point sits in a more densely populated area than any other U.S. plant, with more than 20 million people living within 50 miles.
- The plant sits adjacent and nearby to State designated significant fish and coastal wildlife habitats.
- Since at least the 1990s, radioactive toxins such as tritium and strontium-90 have been leaking from at least two spent fuel pools at Indian Point into the groundwater and the Hudson River. The pools at Indian Point are already compromised and are sure to continue causing environmental impacts in the future. For example, in January 2007 Strontium-90 was detected in four out of 12 Hudson River fish tested.
- Parts of New York City's drinking water supply, which provides 9 million New Yorkers with

unfiltered drinking water, are less than 15 miles away from Indian Point.

- Indian Point sits at the intersection of two active earthquake faults; these faults could produce upwards of a 7.0 magnitude earthquake, which Indian Point was not initially built to withstand.

- Indian Point's spent fuel pools, which were never designed to hold the nearly 2,000 tons of toxic waste now stored at the plant, are highly vulnerable to terrorism and accidents.

It is clear that the nuclear waste stored at Indian Point poses a unique risk, which warrants site-specific examination. (0465-8 [Commenters, Multiple])

Comment: It is urgent for the NRC to look into best practices for each specific site and not try to apply a convenient and unscientific solution to all nuclear power plants. (0472-3 [Sheridan, Paul])

Comment: 2. Even if the framework used were correct, the Draft GEIS provides no evidence for the assertion that environmental consequences do not vary across Alternatives. The NRC states that environmental impacts of continued storage scenarios will be the same regardless of which of the Alternatives described above is selected. The rationale provided is that because, under each Alternative, the NRC would analyze the environmental impact of continued storage (either site-specific or generically), the Alternatives provide for the same level of environmental protection (Draft GEIS, pg. xxvi, lines 5-11). Limited discussion is offered in the Draft GEIS to support this assertion; in fact, elements of the document suggest that site-specific information could improve decisions related to continued storage, as described below. The NRC's criteria for determining that a generic analysis is appropriate are, in this case, flawed. The rationale provided by NRC is that continued storage of spent fuel is a generic activity that is similar for all commercial nuclear power plants and storage facilities and, therefore, a generic analysis is an appropriate method of evaluating the environmental impacts of continued storage (Draft GEIS, pg. xxiv). The Court's standard for a generic evaluation is quite different, however, specifying that a general analysis would be sufficient, "...to examine on-site risks that are essentially common to all plants." (New York v. NRC, 681 F.3d 471 (D.C. Cir. 2012), pg. 16) Here, the Court describes that the appropriate comparison across sites to justify a generic analysis is the risk, whereas the NRC relies on a comparison of fuel-handling activities. While the design and regulation of continued storage facilities and activities may be similar across sites, the affected environment, and therefore relative resources at risk due to a severe event, may differ. For example, the setting of a given power plant, including its proximity to people, development, economic activities, and ecological and cultural resources, is an important consideration in evaluating environmental consequences of continued storage. Given this variation across sites, the public will likely raise site-specific issues associated with continued storage during licensing decisions that will need to be addressed. The GEIS does not include sufficient information to address concerns regarding site-specific risks and associated mitigation strategies, thus limiting its usefulness as a generic evaluation. An unequivocal example of the site-specific nature of environmental consequences considers the effects of postulated accidents or catastrophic events across sites. Environmental consequences of accidents and events in the Draft GEIS are calculated in part based on human health and mortality effects (as described in Appendix F), which are directly related to the magnitude of the population exposed. However, the Draft GEIS includes only limited discussion of the variability across sites with respect to the number of people residing in proximity to the plants. (0473-1-13 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The Draft GEIS states that the population density for a 50-mile radius surrounding more than 50 percent of the plants is fewer than 200 persons per square mile. In contrast, the largest population density, surrounding Indian Point Nuclear Generating Station in Westchester County, New York, is an order-of-magnitude greater than this, with 2,138 persons per square

mile within the 50-mile radius (Draft GEIS, pg. 2-4). The consequences of a catastrophic event would therefore be measurably greater at the Indian Point site than a rural site due to the size of the population exposed. The Draft GEIS identifies another example of the site-specific nature of impacts of continued storage. As described further below, following the earthquake and tsunami incident at the Fukushima Dai-ichi nuclear power plant in Japan, the NRC requested that all U.S. plants identify and address vulnerabilities and adequacies of monitoring and maintenance procedures, and re-evaluate the flooding and seismic hazards of the plants (Draft GEIS, pg. 2-11). This example indicates that the NRC does not have all of the information it requires to determine that environmental consequences are small across Alternatives, and that site-specific information is imperative to properly evaluate and address safety concerns and environmental impacts. According to the NRC's framing of Alternatives, under the No Action Alternative or Policy Statement Alternative, a site-specific evaluation of continued storage would weigh specific issues or vulnerabilities at a given site (such as discussed in these examples); on the other hand, the Proposed Action and GEIS-Only Alternatives would not. Therefore, even under the NRC's framework, the No Action or Policy Statement Alternative may lead to a different conclusion with respect to environmental impacts at a given site (e.g., large or moderate as opposed to small for postulated accidents), and promote consideration of appropriate site-specific management or mitigation needs. In this way, a site-specific approach to NEPA compliance has the potential to lead to improved environmental outcomes. Because the Draft GEIS has not demonstrated either that: a) consequences, probability of those consequences, are therefore risks, are common to all plant sites; or b) that site-specific analyses would not lead to different outcomes than a generic analysis, the NRC has not supported its proposal to follow a GEIS approach to evaluating impacts of continued storage (with no issues identified as requiring site-specific analysis). While this does not necessarily indicate that all sites would require site-specific analysis, generically codifying that continued storage is equally safe across all sites across all time frames would effectively preclude the need for careful consideration of important site-specific conditions, vulnerabilities, and mitigation needs. (0473-1-14 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The Draft GEIS fails to demonstrate that site-specific evaluations would not result in different findings than the GEIS with respect to environmental consequences. This demonstration is required to support the decision to follow a GEIS approach with no issues identified as requiring site-specific analysis. (0473-1-4 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The Draft GEIS only considers environmental impacts of limited storage scenarios and does not specify whether, and in what context, additional scenarios may be considered at a given site or in general. In short, while the Draft GEIS appears to conclude that site specific factors can be considered at a later time, the overall conclusion is that no such site specific analyses would be required with respect to environmental impacts of continued storage. (0473-1-6 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: THE DRAFT GEIS FAILS TO DEMONSTRATE THAT SITE-SPECIFIC EVALUATIONS WOULD NOT RESULT IN DIFFERENT FINDINGS THAN THE GEIS WITH RESPECT TO ENVIRONMENTAL CONSEQUENCES. THIS DEMONSTRATION IS REQUIRED TO SUPPORT THE DECISION TO FOLLOW A GEIS APPROACH WITH NO ISSUES IDENTIFIED AS REQUIRING SITE-SPECIFIC ANALYSIS. (0473-1-7 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: In response to the Court decision, the NRC incorporated additional timeframes (long-term and indefinite) into its Draft GEIS, and included additional discussion of high-consequence events (e.g., spent fuel pool fires, earthquakes, and acts of terrorism). This additional discussion in the 2013 Draft GEIS is, however, entirely ineffectual and plays no role in any real analysis. 1. The framework for and selection of Alternatives in the Draft GEIS does not provide a legitimate basis for evaluating environmental consequences. The Draft GEIS assumes that environmental impacts do not vary across Alternatives. Specifically, the NRC asserts that environmental impacts of continued storage scenarios will be the same regardless of whether the evaluation method is site-specific or generic. The conclusion that is reached in the Draft GEIS follows from this assertion: environmental impacts are not affected by the method of evaluation (i.e., whether generic or site-specific). In other words, the NRC asserts that the extent to which accidents at plants affect people and the environment is not influenced by the way NRC evaluates them. Importantly, however, the NRC's and the public's understanding of the nature and magnitude of impacts at a given site may be influenced by the method of evaluation. By not recognizing and evaluating the potential value of more information (e.g., on relative risk and socioeconomic context), the NRC assumes away any benefits of the Action Alternatives that would call for site-specific analysis. For example, as detailed later in this review, the probability of a seismic event or terrorist attack during the continued storage timeframes is variable by plant site. Site-specific information on the relative probability of such an accident and event, combined with information on the vulnerable population at the site, is required for an adequate evaluation of environmental impacts of such events. Because the Alternatives evaluated in the GEIS revolve simply around the decision to conduct or not to conduct site-specific analyses (as opposed to a real consideration of storage options), and the NRC simply assumes no benefit to integrating site-specific information, the consideration of environmental impacts in the Draft GEIS is rendered irrelevant to the selection of an Alternative. (0473-1-8 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: In the Revised GEIS for License Renewal issued earlier this year, NRC Staff states that: For severe accidents, the probability-weighted consequences of atmospheric releases, fallout onto open bodies of water, releases to groundwater, and societal and economic impacts from severe accidents are SMALL for all plants. However, alternatives to mitigate severe accidents must be considered for all plants that have not considered such alternatives. This is a Category 2 issue. NUREG-1437, Rev. 1 (Mar. 2013), ML13106A241 at S-17. This finding applies to nuclear power plants during their licensed life. And yet the Waste Confidence DGEIS treats this issue generically for the post-operation time period, with no indication why it is treating severe accident mitigation alternatives differently than the License Renewal GEIS does during a facility's licensed life. In addition, as noted earlier, in all previous analyses of spent fuel storage at reactor sites -- most notably NUREG-0575 and NUREG-1738 -- the NRC has concluded that there are factors that are inherently site-specific and require site-specific consideration. The DGEIS does not recognize these site-specific factors and does not provide for addressing them in future individual licensing proceedings. (0473-13-1 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: NRC has also historically treated severe accidents related to a spent fuel pool differently than severe accidents at an adjacent reactor. Early analyses of severe accidents focused exclusively on reactor accidents. WASH-740 (1957); WASH-1400 (1975). At the time these studies were developed, the Atomic Energy Commission's and the Nuclear Regulatory Commission's stated policy was that spent nuclear fuel would be quickly removed from the reactor sites and transported to a reprocessing or disposal facilities. The federal agencies told the public that reactor sites would not become radioactive waste storage sites. Given this policy there was no need for large spent fuel pools or dense storage of spent fuel in the pools. As a

result, given the minimal inventory anticipated for the existing spent fuel pools there was little perceived need to examine severe accidents in spent fuel pools. Even if that dichotomy in the approach to severe accidents was reasonable decades ago when a permanent repository was expected in some reasonable timeframe, it is no longer appropriate given the fact that fuel storage is occurring at different plants and different sites.²⁵ [footnote 25 text: 25 Limerick understood that generic analysis for permanent spent nuclear fuel disposal was only appropriate because there would be a permanent repository. *Limerick Ecology Action, Inc. v. NRC*, 869 F.2d 719, 738 (3d Cir. 1989) ("Given that the NRC's long-term storage plans did not provide for permanent storage at each individual site, the common storage of the wastes in bedded-salt repositories provided a generic basis for the regulation because the effect of long-term storage could be expected to arise from the situs of the waste, rather than from the particular characteristics of the plants at which the waste was generated."). Twenty five years after Limerick, the Nation is no closer to an operating permanent repository. At various sites, including, for example, Indian Point and Pilgrim, the spent fuel pools that are outside containment hold more potential source term of radiation than do the adjacent reactors that are inside the containment shell.] NRC's spent fuel pool exception to the requirement that mitigation of severe accidents be handled on a site-specific basis is no longer rational. *Limerick Ecology Action, Inc. v. U.S. Nuclear Regulatory Comm'n*, 869 F.2d 719 (3d Cir. 1989), requires a site-specific analysis of mitigation of severe accident risk. There, the Third Circuit held that NEPA requires NRC to examine the environmental effects of significant accidents at nuclear power plants and measures to mitigate those effects. The Limerick court recognized that "the potential consequences [of a severe accident] will largely be the product of the location of the plant." *Id.* at 738. "[T]he same probability of the same accident in a plant such as Limerick will produce a higher risk than that produced by the same accident at a plant not located within twenty-five miles of a major metropolitan area. Therefore, it is unlikely that severe accident mitigation can be treated as a generic issue. In fact, in its conclusion that severe accidents pose "no undue risk," the [NRC's] Final Policy Statement did not take into account the added risks of a plant located in a densely populated area." *Id.* at 738-39 (emphasis added). (0473-13-2 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Former NRC Commissioner Victor Gilinsky recommended that spent fuel storage be examined on a site-specific basis in his *Separate Views Regarding Proposed Amendments to 10 CFR Parts 50 and 51, Waste Confidence Proceeding*, 48 Fed. Reg. 22730 (May 20, 1983) ("While I agree that there is no obstacle in principle to extended on-site storage, I think it is clear that each power reactor site will have to be examined in detail."). Allan S. Benjamin et al., *Spent Fuel Heatup Following Loss of Water During Storage* (Sandia National Laboratory, NUREG/CR-0649, SAND77-1371) at 50 ("1979 Sandia Report") (Mar. 1979) ("The high density holders ... are the least well-suited to heat removal, as expected, particularly if the spent fuel is packed wall-to-wall so as to preclude a down-comer space at the edge of the pool."); see 2006 Sandia Report at viii ("[D]ispersed configurations [of spent fuel assemblies] provided additional time for mitigative actions before the release of fission products versus a non-dispersed configuration."); see also NAS Report at 103 ("[M]odifying the storage racks to provide for closer spacing of the fuel assemblies ... can make it more difficult to cool the freshly discharged fuel if there is catastrophic loss of the fuel pool water.") (0473-13-3 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: For example, they ignore the unique, site-specific consequences that would occur as a result of a severe accident at Indian Point. The ISR Report details why Indian Point needs to be examined on a site-specific basis, but some of the general conclusions are summarized here. * In the reference case of Peach Bottom used in the Spent Fuel Pool Consequence Study, the total population within a 50-mile radius is 5.7 million. By comparison, the total population

within a 50-mile radius surrounding the Indian Point site is 17 million. * The wind rose (i.e., probability of wind directions) of the site has a direct correlation to the probability of certain areas being contaminated and thus requiring mitigative actions. In the Spent Fuel Pool Consequence Study, the reference plant's wind rose was such that the predominant wind directions were towards lower population areas (Spent Fuel Pool Consequence Study, Section A.2). By comparison, the predominant wind directions at the Indian Point site are to the North/North-Northwest and to the South; the latter would affect the New York City metropolitan area, one of the most populated areas in the United States. * The value of nonfarm wealth (VALWNF) includes all public and private property not associated with farming that would be unusable if the region was rendered either temporarily or permanently uninhabitable. This value should include the cost of land, buildings, infrastructure, and the cost of any non recoverable equipment or machinery (MACCS2 manual). The value chosen for the Consequence Study, which uses the Peach Bottom site as the reference case, is \$210,000/person (2012 USD). By its definition, this value is site-specific. As a comparison, in its submission for a license renewal for Indian Point Units 2 and 3, Entergy calculated VALWNF to be \$209,000 (2004 USD). In 2012 USD, this value is approximately \$250,000, which is 20% higher than the value used in the Spent Fuel Pool Consequence Study. * The per capita cost of long-term relocation (POPCST) takes into account both personal and corporate income losses, as well as moving expenses, for a transitional period. The value chosen for the Spent Fuel Pool Consequence Study is \$12,000/person (2012 USD). This value is site-specific. For example, in the state of New York, the average per capita income is approximately \$32,000 (2011 USD). Using an interdiction period of 140 days as recommended in NUREG/CR-4551, the total amount of lost wages is \$12,600/person (2012 USD). With the addition of corporate income losses and moving expenses, this amount is expected to be higher than the value used in the Spent Fuel Pool Consequence Study. * The cost and time for decontamination, CDNFRM and TIMDEC respectively, are not site-specific, and do not take into account the differences in decontamination efforts required for varied land use surrounding the site (e.g., rural, semi-urban and urban). Table 1: Summary of site-specific MACCS2 input parameters relevant to Indian Point (0473-13-9 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: In many instances, NRC is not able to predict the environmental impacts of spent fuel pool leaks because these impacts are dependent on site-specific factors. The following are several examples of statements from the DGEIS where NRC indicates that impacts can be determined only on a site-specific basis: • "The impacts of a spent fuel pool leak on offsite groundwater depend on many factors, including the volume and rate of water released from the spent fuel pool, the radionuclide content and concentration and water chemistry of the spent fuel pool water, the direction of groundwater flow, the distance to an offsite groundwater receptor, the velocity or transport rates of radionuclides through the subsurface, and radioactive decay rates." DGEIS at E-16. • "Contaminants may enter an aquifer system and be transported with the hydraulic gradient. The direction and rate of contaminant transport will depend on the site-specific properties of the aquifer." DGEIS at 3-18 to 3-19. • "The concentrations of radionuclides in offsite surface waters will depend on the rate of release from the spent fuel pool, direction and rate of groundwater flow, the distance to nearby offsite surface waters toward which groundwater flows, the velocity of transport rates of radionuclides through the subsurface, and radioactive decay rates." DGEIS at E-17. • "The degree of offsite soil contamination will depend on the rate of release from the spent fuel pool, direction of groundwater flow, the distance to offsite locations, the velocity or transport rates of radionuclides through soils, and radioactive decay rates." DGEIS at E-18. Simply listing the site-specific factors that determine the impact of spent fuel pool leaks does not allow NRC or the public to reasonably anticipate what those impacts will be. Impacts may only be analyzed generically if they "do not involve particularized

situations." *Minnesota v. NRC*, 602 F.2d 412, 416 (D.C. Cir. 1979)) and only if they involve "on-site risks that are essentially common to all plants" (*New York v. NRC*, 681 F.3d at 480). NRC's inability to generically determine what the impacts of spent fuel pool leaks will be shows that this is a particularized situation that necessitates site-specific review. NRC must review the impacts of spent fuel pool leaks on a site-specific basis both because the consequences of such leaks vary from site to site but also because the probability of such leaks vary based on the specific characteristics of the spent fuel pool and spent fuel in the pool. Some factors that should be examined for each individual plant include: the geological landscape underlying the reactor and the spent fuel pool (including the composition of the subsurface, direction of groundwater flow, etc); the nature and uses of nearby resources (such as the proximity of wells supplying drinking water and the classification of local water bodies); the degree to which already existing groundwater contamination from past radiological leaks may affect the impact of new leaks; the ecology of local water bodies; the presence of nearby significant habitats and endangered species; and possible site-specific causes of leaks (tornados, earthquakes, flooding, etc). Factors relevant to the characteristics of the pool and its contents include the rack configuration used in the pool, the types of equipment and devices used to provide boron to offset the potential for criticality accidents, and the vulnerability of the fuel to leaks due to the presence of high burnup fuel in the pool. (0473-15-7 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Finally, as they did with severe accidents as discussed above, the NRC has taken internally inconsistent positions on whether leaks should be evaluated on site-specific or generic basis, evaluating them on a site-specific basis during the licensed life of a facility in the GEIS for License Renewal, but proposing to evaluate them generically here for the post-licensed life period of time. See NUREG-1437, Rev. 1 (Mar. 2013), ML13106A241 at 1-24 (stating that despite comments requesting generic review of leaks, "[r]adionuclides released to groundwater" remains a Category 2 issue). Neither DGEIS provides a basis for this inconsistent treatment of the same issue. (0473-15-8 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Overall, a more reasoned and informed approach would be for the NRC to consider site-specific event scenarios (e.g., seismic events, aircraft crashes, tornado missiles, spent fuel fires, cask drops, terrorist attacks, etc.), and describe the consequences of these events. While information on probabilities of these events may be important, the NRC has indicated that they do not have enough information to assess these probabilities across all event types and sites. However, site-specific analysis would allow NRC to gather and consider helpful information, such as site-specific vulnerabilities (as they have recently requested regarding seismic risks), and reference available site-specific information (e.g., locations of populations) in making determinations regarding environmental consequences. (0473-2-5 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: THE DRAFT GEIS ONLY CONSIDERS ENVIRONMENTAL IMPACTS OF LIMITED STORAGE SCENARIOS AND DOES NOT SPECIFY WHETHER AND IN WHAT CONTEXT ADDITIONAL SCENARIOS MAY BE CONSIDERED AT A GIVEN SITE OR IN GENERAL. IN SHORT, WHILE THE DRAFT GEIS APPEARS TO CONCLUDE THAT SITE SPECIFIC FACTORS CAN BE CONSIDERED AT A LATER TIME, THE OVERALL CONCLUSION IS THAT NO SUCH SITE SPECIFIC ANALYSES WOULD BE REQUIRED WITH RESPECT TO ENVIRONMENTAL IMPACTS OF CONTINUED STORAGE. (0473-3-2 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Overall, the Draft GEIS does not frame the Alternatives to the Proposed Action in a manner that promotes meaningful analysis of the environmental impacts of continued storage either at a site- specific level or in general. In structuring the Alternatives around the approach to complying with NEPA (i.e., developing a generic or site-specific analyses), and assuming away any benefit of site-specific evaluations, the NRC has reduced the comparison of Alternatives to the relative level of administrative effort required. Furthermore, the Draft GEIS does not sufficiently support the driving assumption in the document that there is no benefit to developing site-specific analyses of continued storage. As described in this review, site-specific evaluations can provide more and better information on relative risk of high-consequence events and appropriate mitigation strategies across sites, thus leading to improved environmental outcomes. (0473-4-1 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Finally, the Tribe expressed its concern during the December 4, 2013 public meeting in Minnetonka, Minnesota, that due to its close proximity to the PINGP and its ISFSI, its reservation homeland could be rendered uninhabitable by a spent fuel accident in the PINGP's spent fuel pool or dry cask storage installation. See Testimony of Tribal Council Member Ronald Johnson during the December 4, 2013; Waste Confidence Public Meeting in Minnetonka, MN December 4, 2013, Transcript of Proceedings at 17-22 (ML13344B149). The Tribe stated that this potential site- specific impact implicates the NRC's trust responsibility to federally-recognized Indian tribes, and cannot possibly be assessed generically. Id. (0473-6-3 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The DGEIS simply does not provide an environmental analysis that is sufficient to justify eliminating consideration of spent fuel disposal impacts or storage impacts from every licensing proceeding. (0531-1-14 [Morgan, Sally])

Comment: To continue to pursue licensing on the basis of Waste Confidence -- despite the new Generic Environmental Impact Statement and Rule -- is illegal and immoral. CWFNC calls to scrap the GEIS and hold the NRC accountable for individual EIS for each reactor that do not underestimate the likelihood and environmental damage of nuclear waste leakage. (0531-1-16 [Morgan, Sally])

Comment: The new GEIS does not properly analyze the environmental effects of permanent disposal. It continues to look in a generic fashion at risks across the board at nuclear plants, rather than by conducting a site-by-site analysis of each specific nuclear plant. A site-by-site analysis is necessary, because risks of leaks and fires, especially over the long term, are affected by site-specific factors, such as pool configuration, leak detection systems, and the location of the pool within the plant. (0531-1-6 [Morgan, Sally])

Comment: The DGEIS simply does not provide an environmental analysis that is sufficient to justify eliminating consideration of spent fuel disposal impacts or storage impacts from every licensing proceeding. (0531-2-24 [Morgan, Sally])

Comment: To continue to pursue licensing on the basis of Waste Confidence -- despite the new Generic Environmental Impact Statement and Rule -- is illegal and immoral. CWFNC calls to scrap the GEIS and hold the NRC accountable for individual EIS for each reactor that do not underestimate the likelihood and environmental damage of nuclear waste leakage. (0531-2-26 [Morgan, Sally])

Comment: The new GEIS does not properly analyze the environmental effects of permanent disposal. It continues to look in a generic fashion at risks across the board at nuclear plants, rather than by conducting a site-by-site analysis of each specific nuclear plant. A site-by-site analysis is necessary, because risks of leaks and fires, especially over the long term, are affected by site-specific factors, such as pool configuration, leak detection systems, and the location of the pool within the plant. (0531-2-6 [Morgan, Sally])

Comment: And because environmental impacts are shown as "generic," no distinction is made of added risks at sites such as San Onofre that are in earthquake and tsunami zones on small and valuable pieces of land near major population centers and transportation corridors. (0540-4 [Watland, George])

Comment: Overall, the proposed NRC Statement underrates risks at all sites, blurs or eliminates the fact of higher risk at some sites, and seeks to walk away from the search for less hazardous sites. (0540-7 [Watland, George])

Comment: The U.S. Court of Appeals rejected the current Waste Confidence Rule noting that, after decades of failure to site a repository, the NRC has no long-term plan other than hoping for a geologic repository. It is hence possible that the highly radioactive spent fuel will be stored at reactor sites on a permanent basis. The NRC must examine the environmental consequences of storing radioactive waste at reactor sites into the indefinite future. The NRC Draft Generic Environmental Impact Statement relies on the assumption that all reactor sites are alike. This flawed assumption makes one wonder how reliable the other parts of the GEIS are. Each site has unique geographical, environmental, geological, and epidemiological considerations. To wit, Diablo Canyon Power Plant on the central coast of California sits on many earthquake faults, a condition no other nuclear plant in the US faces. The creation of a one-size-fits all plan is scientifically invalid. (0541-1 [Justesen, Evelyn])

Comment: Start all over again by addressing each nuclear power plant as a separate identity each with its own unique problems. (0541-8 [Justesen, Evelyn])

Comment: The health risk assessment for a spent fuel fire was done using only three different nuclear power plants (Ginna, Surry and Zion), ignoring the idiosyncratic nature of each reactor in the US. Reactor sites all have different amounts of irradiated fuel that gives off different amounts of radioactivity. Fermi 2 has 600 tons of spent fuel in one overcrowded pool. The surrounding human populations are not equal nor are they distributed in the same way-- the dose calculations couldn't possibly be the same for all reactors. Realistic recognition of population numbers, local infrastructure, access roads, possible destinations, facilities for displaced populations, vary with each location of reactors. (0552-2-15 [Macks, Vic])

Comment: The seismic risks for the spent fuel pools in highly earthquake-prone areas are ignored. The seismic risk for Diablo Canyon, San Onofre and Columbia fuel pools were deliberately glossed over, by the NRC's own admission, since the one reactor used in the NRC's "Consequences Study" is in Pennsylvania (Peach Bottom). (0552-2-16 [Macks, Vic])

Comment: Because of the major variations in climate, geologic, and other conditions of the various elements and "activities" related to continued-storage sites across coterminous U.S., generic descriptions of environmental impacts can at best provide only a framework for selected types of impacts. The procedures for establishing a generic basis for impact assessment omit some critical sources of potential environmental impact and rationalize the safety of others on the basis of very limited data. (0553-2 [Wilshire, Howard])

Comment: The approach is stated in the Abstract, p. iii as follows: "For the resource areas considered, this draft GEIS attempts to establish generic impact determinations that would be applicable to a wide range of existing and potential future spent fuel storage sites," using "some site-specific information in developing the generic impact determinations..." And further, a goal is stated to "...identify the types and assessing the magnitude of environmental impacts where generic findings can be established." Comment: These statements provide no information on exactly what characteristics/activities/properties of all elements of ISFSIs do not qualify for generic findings, and how many sites have such disqualified characteristics. These must be specified as they may (and do for some known characteristics) represent sources of environmental impacts that are of overriding importance in establishing and maintaining integrity and safety of continued storage. Information should be supplied on the number of sites, including all time frames, to which the chosen set of generic findings do not apply [the language quoted above "...establish generic impact determinations that would be applicable to a wide range of existing and potential future spent fuel storage sites" implies that the determinations are not universal]. (0553-3 [Wilshire, Howard])

Comment: Most of the identified elements of affected environment are described as widely ranging, variable, many are site-specific, or occur only at certain sites. This being the case how can environmental impacts be reduced to generic assessment? (0553-5 [Wilshire, Howard])

Comment: The DGEIS treats environmental impacts generically. They should be evaluated on a site-specific basis. The potential impact on different reactors varies widely. The potential impact on a reactor like Pilgrim is far greater, in both consequences and likelihood, than NRC's "generic" conclusion. (0556-1-10 [Lampert, Mary])

Comment: The purpose of the proposed action according to NRC is "to improve the efficiency of the NRC's licensing process by generically addressing the environmental impacts of continued storage." (DGEIS, ES.4) However, efficiency is not NRC's AEC mandate; instead it is to protect public health and safety. PW shows that the potential environmental impacts vary from site to site and must be considered on a site-specific basis, not generically. If they were addressed on a site by site basis, PW shows that the impact would be far from small. *No two reactors are alike - they vary on likely environmental impact after license termination; 1.* Reactors vary in Location requiring site specific analysis: Whether reactors are located in regulated or deregulated electric markets; their susceptibility to natural events, impact of climate change on each reactor; impact proximity to a marine environment; groundwater issues; proximity to high population centers; susceptibility to acts of malice; proximity to cultural and historic resources; accessibility to LLRW disposal; number safety violations varies regionally; likely impact on public and occupational health. (0556-1-14 [Lampert, Mary])

Comment: Reactors vary from one another and individually over time in the likelihood of a severe earthquake. They should be examined individually. Pilgrim, for example, was once rated the second least likely to be damaged by seismic activity, but in August 2011 it was re-ranked as the second most likely. Therefore the damage analyses from an earthquake made when the pool and its structures were built underestimate the risk after operations cease. NRC Chair, Dr. Macfarlane said to the New York Times¹ [footnote 1 text: For New Nuclear Chief, Concerns Over Plant Safety, Matthew Wald, NYT, August 13, 212] that: "As a geologist, I also know that geological knowledge is constantly changing...The American industry recently began a re-evaluation of its earthquake vulnerability after the United States Geological Survey released a new estimate of the prospects for earthquakes in the eastern United States. And there may be more revisions in the future." Matthew Wald reported that "she considers the industry's

evaluation of earthquake vulnerability -- an issue that was once believed to be settled when a nuclear power plant was licensed -- to be inadequate." (0556-1-16 [Lampert, Mary])

Comment: Some reactor sites are in environments that are particularly vulnerable to adverse effects of groundwater contamination. Groundwater contaminations from spent fuel pool leaks may affect known drinking water sources and impinge on Native American trust lands. Examples are Prairie Island and Columbia. (0556-1-22 [Lampert, Mary])

Comment: A historically well-maintained reactor is likely to age better than one neglected and present less environmental risk over the 60 years after the license ends. For example, Pilgrim was poorly maintained in its early years. It was forced to shut down from 1987- 1990. In its later years, Entergy, unable to compete in a deregulated market with cheaper sources of electricity, cut maintenance and personnel. In 2013 alone Pilgrim had 18 event reports and 10 times more shutdowns than any other reactor. On November 6, the NRC announced that it had dropped Pilgrim's performance rating because of shutdowns with complications, placing it among 15 plants in the country requiring more oversight. And only a few days later, the NRC told Entergy that Pilgrim's rating is likely to drop again next month, placing it among the 8 worst performers. Therefore leaks and malfunctioning of systems required to maintain the water in the spent fuel pool have a much higher probability of failure than a reactor that does not have a history of financial distress, cut backs in maintenance/ personnel, and mismanagement. (0556-1-33 [Lampert, Mary])

Comment: Leakage from spent fuel pools varies from site to site; and at many sites, it is significant, especially when taken together with leakage from other parts of the reactor. These cumulative impacts must be evaluated on a site-specific basis. NUREG/CR-7111¹¹ [footnote 11 text: <http://www.nrc.gov/reading-rm/doc-collections/nuregs/contract/cr7111/>] provides a summary of aging effects and their management in reactor spent fuel pools. It lists (at 7.1.2) 10 sites that have *identified leaks*. At 7.2.1 it says that repairs in the reactor refueling cavity and spent fuel pool structures are difficult and sometimes impractical. Also, environmental impacts of leaks are likely to be more severe at reactors where NRC oversight has been weak or erratic. The NUREG shows the necessity to evaluate each individual reactor to determine the environmental impact from leaks. [THERE ARE THREE TEXT BOXES INSERTED HERE. ONE CONTAINS THE FIRST PART OF SECTION 7.1.2 SPENT FUEL POOL LEAKAGE FROM NUREG/CR-7111 THE SECOND ONE CONTAINS THE SECOND PART OF SECTION 7.1.2 AND THE THIRD IS SECTION 7.2.1] [Images of Text Boxes Submitted with Correspondence ML13354A021] (0556-1-34 [Lampert, Mary])

Comment: PW supports the need for NRC to address the environmental impacts of continued storage for the period after plant shutdown in site-specific licensing reviews, as discussed above. The rationale is simple. Reactors vary in location, design, history, and oversight by the responsible parties. (0556-5-10 [Lampert, Mary])

Comment: This conclusion is bolstered by the fact that a number of coastal nuclear plants are located in densely populated areas. Although the DGEIS states that the majority of U.S. nuclear power plant sites are located in relatively sparsely populated areas (DGEIS at 2-4), the Indian Point plant in New York, located on the tidal Hudson River and subject to storm surge from coastal storms, has the largest nearby population density in the United States, and among the highest in the world. Id.; Declan Butler, "Reactors, residents, and risk," *Nature*, Apr. 21, 2011, available at <http://www.nature.com/news/2011/110421/full/472400a.html>. Moreover, the DGEIS's blanket statements about low population density obscures the fact that many low-lying, potentially vulnerable plants are located in densely populated areas. For instance, several U.S.

coastal or riparian reactors located below ten meters in elevation have surrounding populations between 2 and 10 million people within 75 km, and one (Indian Point), has nearly 20 million.⁵ [footnote 5 text: Center for International Earth Science Information Network (CIESIN), Columbia University, Low Elevation Coastal Zone (LECZ) Urban-Rural Population and Land Area Estimates, Version 2, Palisades, NY: NASA Socioeconomic Data and Applications Center (SEDAC), available at <http://beta.sedac.ciesin.columbia.edu/data/set/lec2-urban-rural-population-land-area-estimates-v2>, accessed Dec. 17, 2013; Declan Butler, "Reactors, residents, and risk," *Nature*, Apr. 21, 2011, available at <http://www.nature.com/news/2011/110421/full/472400a.html>. See also Bobby Magill, "Sandy a Warning Rising Seas Threaten Nuclear Plants," *Climate Central*, Oct. 21, 2013, available at <http://www.climatecentral.org/news/sandy-a-warning-that-nuclear-plants-threatened-by-rising-seas-16622>] (0558-6 [Strell, Ethan])

Comment: In June 2012, the Court of Appeals for the DC Circuit ruled that the 2010 Waste Confidence rulemaking by the Nuclear Regulatory Commission did not satisfy the Commission's National Environmental Policy Act or NEPA obligations, identifying deficiencies in the 2010 Waste Confidence rule. Specifically, the Court stated: "...In determining that spent fuel can safely be stored onsite at nuclear plants for sixty years after the expiration of a plant's license, (and here I add emphasis), the Commission failed to properly examine future dangers and key consequences". This Draft Generic Environmental Impact Statement is the Commission's response to the Court's ruling and an attempt to address NEPA shortcomings in the 2010 Waste Confidence rule. However, as the DGEIS states, the responsibilities of Federal agencies under NEPA is to "Consider the environmental impacts in making decisions" and subsequently "Assess the environmental impacts of major Federal actions." Thus, the Commission cannot assess the environmental impact of its Waste Confidence rule if it doesn't consider all environmental impacts in making its decisions. Producing a Generic Environmental Impact Statement neither fulfills it NEPA obligations nor addresses the Court's concerns over "...future dangers and key consequences". Only by analyzing each individual nuclear site can the Commission ever hope to adequately address the unique aspects of the various sites and thus properly determine all environmental impacts the Waste Confidence rule will have. And only then can the Commission say it has: "...properly examined future dangers and key consequences." So, go back and review all environmental impacts the Waste Confidence rule will have on each and every site. (0576-1 [Blackburn, Lee])

Comment: in June 2012, the Court of Appeals for the DC Circuit ruled that the 2010 Waste Confidence rulemaking by the Nuclear Regulatory Commission did not satisfy the Commission's National Environmental Policy Act or NEPA obligations, identifying deficiencies in the 2010 Waste Confidence rule. Specifically, the Court stated: "...In determining that spent fuel can safely be stored onsite at nuclear plants for sixty years after the expiration of a plant's license, (and here I add emphasis), the Commission failed to properly examine future dangers and key consequences". This Draft Generic Environmental Impact Statement is the Commission's response to the Court's ruling and an attempt to address NEPA shortcomings in the 2010 Waste Confidence rule. However, as the DGEIS states, the responsibilities of Federal agencies under NEPA is to "Consider the environmental impacts in making decisions" and subsequently "Assess the environmental impacts of major Federal actions." Thus, the Commission cannot assess the environmental impact of its Waste Confidence rule if it doesn't consider all environmental impacts in making its decisions. Producing a Generic Environmental Impact Statement neither fulfills it NEPA obligations nor addresses the Court's concerns over "...future dangers and key consequences". Only by analyzing each individual nuclear site can the Commission ever hope to adequately address the unique aspects of the various sites and thus properly determine all environmental impacts the Waste Confidence rule will have. And only

then can the Commission say it has: "...properly examined future dangers and key consequences." So, go back and review all environmental impacts the Waste Confidence rule will have on each and every site. (0578-2 [Blackburn, Lee])

Comment: The stated purpose of the Draft GEIS is to generically analyze environmental impacts of spent nuclear fuel storage so that the NRC may revise its waste confidence rule, 10 C.F.R. § 51.23, to eliminate the need to conduct NEPA analyses for continued storage during future reactor and spent fuel facility licensing actions.⁷ [footnote 7 text: Draft GEIS at 1-5] To justify the implementation of the waste confidence rule, the Draft GEIS states that implementing the waste confidence findings as a GEIS only alternative or as a policy statement "could result in the considerable expenditure of public, NRC, and applicant resources" and that "licensing boards could be required to hear nearly identical contentions [on generic issues]."⁸ [footnote 8 text: Draft GEIS at 1-7.] The desire to improve the efficiency of NRC's licensing process by generically addressing environmental impacts is laudable. Nevertheless, irrespective of the amount of resources expended, it is NRC's statutory obligation to consider the environmental, safety and licensing aspects of individual storage proposals. Moreover, affected parties must have an the opportunity to participate in site specific licensing proceedings. Based on our experience in the PFS licensing matter, Utah recommends that the Commission take substantial precautions in determining what environmental impacts, if any, are eliminated from future consideration in site specific reviews. (0579-3 [Smith, Amanda])

Comment: Regarding the San Onofre nuclear power plant and waste storage, please make site specific approaches to storing nuclear waste and site-specific environmental reports and recommendations that take local conditions into account. Please take into account short term, long term, and very long term approaches to waste storage. Please apply the most strict and cautionary standards. (0585-1 [Marks, Lisa])

Comment: One subject of significant concern particularly to residents of Michigan and the Great Lakes Region is the issue of wet storage solutions for spent nuclear fuel, that is, actively managed pools. Appendix G "Spent Fuel Storage Facilities" (Pages G-1 to G-15) of the DGEIS specifically mentions Fermi, Unit 2 on Pages G-1 and G-4. The Fermi, Unit 2 nuclear fission reactor is located within a fifty-mile radius of Metro Detroit (MI), Ann Arbor (MI), Toledo (OH), Windsor (Ontario), and a large section of Lake Erie. Fermi, Unit 2's design is the notorious U.S. GE Mark 1 Boiling Water Reactor (BWR), and Appendix G notes that Fermi, Unit 2 has the largest spent fuel pool capacity of any operating BWR in the country -- hence, the potentially greater magnitude of consequences of severe leaks, fires, or other structural breaches of the pool. Why, then, does the NRC apply a generic analysis to "continued storage" in spent fuel pools for up to 60 (sixty) years after the end of the licensed operating life of a reactor? I submit that sixty years is a long time to live "on the edge." (0603-12 [Schonberger, David])

Comment: [T]he NRC must fully consider site-specific concerns[.] (0604-11 [Pisha, Gayla])

Comment: The most important problem with the GEIS is that it "considers the continued storage of spent fuel a generic activity that is similar for all commercial nuclear power plants and storage facilities." (Executive Summary, p. xxiv) It is vital that each plant have its own evaluation, even though that will result in a higher cost, as discussed in Chapter 7 of the GEIS. (0604-2 [Pisha, Gayla])

Comment: Under the proposed action of preparing a GEIS and revising 10 CFR 51.23, the "NRC does not undertake site-specific reviews of the continued storage issue in the course of individual licensing proceedings." (ES, p. lvii) However, sites such as Indian Point have unique

characteristics which bear on the environmental impacts of continued spent fuel storage. (0604-3 [Pisha, Gayla])

Comment: It is important that NRC consider plant specifics when assessing the environmental impact of waste storage. Various site specific factors can alter environmental impact, including a plant's proximity to hazards, sensitive ecosystems, and densely populated areas. A one-size-fits all approach, using an average plant, is simply inadequate for attaining a comprehensive understanding of environmental impact. (0607-2 [Messinger, Michael])

Comment: The No-Action alternative should not rely on the No-Action Alternative of the Yucca Mountain EIS for its conclusions or analysis. Among other things, the environmental impacts in the Yucca Mountain EIS No-Action Alternative were deliberately underestimated by the DOE. In the case the NRC does not issue a generic Waste Confidence rule, the No-Action Alternative should not presume that sufficient information exists to resume site-by-site licensing decisions. It does not. (0610-10 [Brechin, Vernon])

Comment: The No-Action Alternative as described in three paragraphs above should be the preferred alternative. (0610-11 [Brechin, Vernon])

Comment: Each of the nation's 103 nuclear plants have unique issues, are located in unique regions of the nation with different geological issues, have different operating histories, have different environmental considerations, and have different surrounding population densities and evacuation challenges. (0611-17 [Shapiro, Susan])

Comment: Therefore, supplemental EIS will be required at every site in the nation to address a multitude of site specific issues which are not and cannot be addressed in a generic review. (0611-20 [Shapiro, Susan])

Comment: A Generic EIS cannot adequately analyze seismic risk. The 100+ commercial nuclear reactors in the U.S. differ in their design, age, and siting. The GEIS offers a single analysis to assess the probability of an earthquake anywhere in the U.S. and its effects on a reactor, spent fuel pools or dry casks and the release of nuclear materials. The inadequacy of this approach is illustrated in a recent report by the Union of Concerned Scientists[.] (0614-1 [Christie, Andrew])

Comment: Should a comparable incident occur at the Diablo Canyon Nuclear Power Plant, California, the world's seventh-largest economy, would undergo a severe disruption and displacement of the population, with attendant environmental impacts, and suffer losses to the fishing, agriculture and tourism sectors of its economy measured in the billions of dollars.³ [footnote 3 text: The omission of any analysis of impacts to California's agriculture as the result of a radiological release is particularly unhelpful in light of the agricultural impacts of the Fukushima disaster, per Physicians for Social Responsibility: "80,000 farms in the Fukushima prefecture have been contaminated by the nuclear disaster, and crippling the local agriculture sector worth 250 billion yen. As of March 1, 2012, 25 percent of Japanese agriculture production or about 58 billion yen (\$694 million) had been lost. In 2011, the agriculture ministry reported that the cost of imported farm products jumped 16 percent to 5.58 trillion yen."] The omission of analysis of such impacts points up both the insufficiency of the GEIS and the error in considering a generic environmental review to be a substitute for the necessity of preparing a specific EIS for each facility. (0614-6 [Christie, Andrew])

Comment: The plan should be site-specific, not generic. The failure of the GEIS plan to make important distinctions based on particular situations is particularly troubling. How can the NRC write a report which states that earthquakes, tsunamis, human error, breakdowns, and terrorist vulnerability are trivial issues not worth worrying about? (0618-12 [Johnson, Roger])

Comment: Site-specific reviews (during subsequent licensing actions) would more accurately reflect NRC's current understanding of the environmental impacts of continued storage (at the time of the licensing action, rather than 60-100 years in the past). Rather than dismissing site-specific reviews because of the costs, the final GEIS should also include some discussion regarding the benefits of site-specific reviews. The environment of each ISFSI is unique and the benefits of evaluating the site-specific environmental impacts to these unique sites must be evaluated. (0619-1-21 [Mahowald, Philip R.])

Comment: Finally, if the potential health and environmental impacts associated with the storage of spent nuclear fuel in a permanent repository cannot be assessed generically, and therefore will necessitate a site-specific environmental impact statement, then the NRC ought not be allowed address generically the potential health and environment impacts of de facto permanent storage at multiple facilities around the country. Site specific analysis must be performed. (0619-1-22 [Mahowald, Philip R.])

Comment: Utilizing a "generic" environmental impact assessment, rather than requiring site-specific assessments, serves to further understate those risks. That it does not even require a site-specific prerequisite such as hardened on-site storage ("HOSS") containers with features known to safely extend their safe status and using "efficiency" (code word for "industry cost concerns") reflects the Commission's lack of independence from the industry it is supposed to oversee. (0620-7 [Rivera, Evelyn])

Comment: The impacts on tourism and commercial uses are not fully assessed in Sections 4.2 and 4.18 of the DGEIS. Tourism and commercial uses vary widely at reactor sites across the nation - a generic EIS cannot properly assess the impacts of long-term storage or of postulated accidents related to storage of spent nuclear fuel at all U.S. reactor sites. For example, Entergy's dry cask storage project at the Pilgrim plant in Plymouth, MA is being built approximately 100 feet from the shore of Cape Cod Bay (CCB). Marine based tourism in Massachusetts is largely dependent on CCB; it is an important economic driver for the state and for Plymouth and Barnstable counties in particular, which directly border the Bay.¹ [footnote 1 text: Massachusetts Department of Business and Technology. 2003. Massachusetts toward a new prosperity: Building regional competitiveness across the commonwealth.; Haughton J, Giuffre D, and Barrett J. 2003. Blowing in the wind: Offshore wind and the Cape Cod economy. Beacon Hill Institute at Suffolk University. ISBN-1-886320-19-5. 53 pp.] Marine tourism includes recreational fishing, boating, diving, swimming, sight-seeing, and whale watching. Stellwagen Bank National Marine Sanctuary, located about 3 miles (4.8 km) north of CCB, is a major destination for recreational fishing, boating, and whale watching. Several whale watching companies operate throughout CCB -including vessels out of Barnstable, Plymouth and Provincetown harbors. In 1996, it was estimated that the whale watching industry made US\$21 million in revenue for the state of Massachusetts.² [footnote 2 text: Massachusetts Ocean Management Task Force Technical Report (MA OMTFTR). 2004. Estuarine and Marine Habitat. 101-127.] Approximately six million tourists visit Cape Cod each year and Massachusetts is the eighth most popular U.S. destination for international travelers.³ [footnote 3 text: Massachusetts Department of Business and Technology. 2003. Massachusetts toward a new prosperity: Building regional competitiveness across the commonwealth.] Total annual output of the marine economy state-wide, based on 2004 data, was US\$14.8 billion with tourism accounting for US

\$8.7 billion of that total.⁴ [footnote 4 text: Coastal Zone Management, Massachusetts Office of (C.M). 2006. Report I - An assessment of the coastal and marine economies of Massachusetts. RFR #: ENV 06 CZM 09.] CCB is also important to commercial fishing operations (fin fishing, lobster fishing, and fishing charters), since a variety of commercially valuable species are found in the bay. To a lesser extent, CCB is also used for commercial ferry services, aquaculture operations, and for transportation for vessels going to and from the Cape Cod Canal.⁵ [footnote 5 text: Executive Office of Energy and Environmental Affairs (EOEEA). 2009. Draft Massachusetts ocean management plan. Volume 1. 141 pp] Impacts of continued spent fuel storage on tourism and commercial uses like those discussed above should be assessed by the NRC. (0622-1-15 [Vale, Karen])

Comment: This is extremely concerning and must be addressed with an individual EIS immediately. We support the "no action" alternative and at the very least believe that the NRC should perform site-specific reviews of the environmental impacts of continued storage at each facility in the nation. In particular, Pilgrim is located on the coast of Cape Cod Bay. The impacts of continued, long-term and/or indefinite spent nuclear waste storage and postulated accidents associated with an ISFSI or a spent fuel pool on such a unique and invaluable resource such as Cape Cod Bay - including its many diverse habitats and wildlife species upon which the region depends - needs to be properly assessed by the NRC. This has not been done with the subject generic EIS. (0622-1-3 [Vale, Karen])

Comment: The generic nature of the DGEIS results in a flawed assessment of environmental impacts associated with continued nuclear waste storage at individual plants. Our concern regarding the generic nature of the GEIS is discussed throughout this document. Plants have different equipment, differing ages of infrastructure, different environmental conditions and changes - it's much more complicated than could be covered by a generic EIS. For example, the Fukushima Daiichi disaster occurred largely as a result of location and elevation relative to the sea. Nowhere in the DGEIS does the NRC consider specific locations of individual plants. (0622-1-4 [Vale, Karen])

Comment: The DGEIS attempts to address globally significant superfund sites without consideration of site-specific challenges. To better understand the risks, the NRC should address questions such as: 1) Which reactors are within three miles of the east coast at an elevation below 100 MSL?, 2) Which facilities are on rivers with upstream dam/impoundments that could cause flooding if breached?, 3) Which facilities are on the west coast Pacific fault line?, 4) Which facilities could experience warming water temperatures, therefore cooling water failure?, and 5) Which facilities deal with corrosive salt water and air? (0622-1-5 [Vale, Karen])

Comment: Entergy has already started construction of its dry cask facility, without review of any external party, which raises many concerns. Knowing that Entergy's facility is being built with little oversight, and no apparent assessment of its vulnerability to sea level rise and other climate change effects, and before the NRC finishes addressing environmental impacts of continued spent fuel is very concerning and must be addressed with an individual EIS for Pilgrim right away. If the NRC's assessment of environmental impacts of continued storage of spent fuel does not apply to Pilgrim, then where is the EIS for Pilgrim's storage? If the NRC's DGEIS does apply to Pilgrim, then what specific aspects of the DGEIS would apply to its unique location? (0622-1-8 [Vale, Karen])

Comment: Furthermore, sea level rise and other climate change effects will likely cause changes to groundwater systems in coastal areas; sea level rise will affect groundwater level and flow, increase the fresh water table in many areas, and influence the chemical properties of

groundwater. However, no site-specific investigations on how these issues will affect contamination leaks at coastal nuclear plants have been done. A generic EIS certainly cannot assess these issues. For example, there is limited knowledge about the hydraulic gradient at Pilgrim's site. Existing contamination as a result of construction and other activities on the site over the past 40 years, as well as future contamination, must be evaluated in relation to the influence of Cape Cod Bay and the PCA on the groundwater as well as the capacity of the groundwater to migrate to the Bay and throughout the PCA. (0622-2-13 [Vale, Karen])

Comment: The construction of spent fuel storage sites, including earth clearing and foundation laying, could contribute to coastal erosion for plants located near the coast. According to a 2011 USGS study,⁶ [footnote 6 text: Hapke CJ, Himmelstoss EA, Kratzmann M, List JH, and Thieler ER. 2010. National assessment of shoreline change; historical shoreline change along the New England and Mid-Atlantic coasts. U.S. Geological Survey Open-File Report 2010-1118. 57 pp.] on average, the beaches in New England and the mid-Atlantic are eroding at about 1.6 ft/year. However, erosion was much worse in the southern Virginia area (60 ft/year). This shows that while the problem of coastal erosion is widespread in New England and the mid-Atlantic, erosion can vary widely depending on the location. A generic EIS cannot accurately assess the potential impacts of an ISFSI (and related construction) on erosion. (0622-2-2 [Vale, Karen])

Comment: Pilgrim should be required to file a site-specific environmental impact statement for public review immediately. (0622-3-6 [Vale, Karen])

Comment: Based on our comments above, we support the "no action" alternative, or at the very least request a supplemental EIS be done to address site specific concerns at Pilgrim and other facilities across the nation. We strongly believe that the NRC should perform site-specific reviews of the environmental impacts of continued storage. Given the fact that Pilgrim's spent fuel storage is located on the coast of Cape Cod Bay, the impacts on this irreplaceable resource -including its many diverse habitats and wildlife species upon which the region depends - needs to be properly assessed by the NRC. (0622-4-14 [Vale, Karen])

Comment: Only site-specific reviews can inform the NRC whether mitigation strategies - such as chillers -would be required to sustain the temperature of wet pools during extended heat waves. (0622-4-5 [Vale, Karen])

Comment: An EIS that is generic in nature cannot address how individual plants would be affected by climate change and other issues (sea level rise, flooding and storm surges, warming water temperature, increasing storm intensity, ocean acidification, etc.). Plants have different equipment, differing ages of infrastructure, different environmental conditions and changes: even coastal plants are located with differing vulnerabilities-some are behind barrier beaches, some nestled in salt marsh estuaries, but Pilgrim is on Cape Cod Bay facing northeast toward the ocean - these issues are much more complicated than could be covered by a generic EIS. (0622-4-8 [Vale, Karen])

Comment: The NRC should not implement a generic "one size fits all" approach to storing nuclear waste, but rather should make site-specific environmental reports and recommendations that take local conditions into account. (0632-2 [Dolegowski, John])

Comment: Each site has differences, so a blanket/generic plan may seem a cost-saver upfront but prove disastrous later. Each site needs a specific plan. (0636-4 [Bluestein, Bonnie])

Comment: In addition, the NRC considers the continued storage of spent fuel a generic activity that is similar at all commercial nuclear power plants and storage facilities. It fails to take into account individual considerations for individual sites such as reactors sited in geologically sensitive areas, coastal sites vulnerable due to sea level rise or those located near other sites housing nuclear waste, such as Department of Energy nuclear weapons facilities. The cumulative effects and unique characteristics of each site should be considered. A generic analysis is not appropriate or effective in evaluating the full range of environmental impacts from waste storage. (0646-18 [Hanson, Courtney])

Comment: Protecting the public means conducting a professional analysis of the individual site conditions and determining safety in light of hazards such as the possibility of earthquakes, potential dangers to populations in the area, to public transportation close to the facility, and other factors. You are supposed to do your due diligence in this regard, and I am appalled that you have not done so! Be prepared for lots of legal actions against you! We do not want you to jeopardize our children's future! DO YOUR JOB! (0649-2 [Imhoof, Christina])

Comment: It is just plain foolish to generically say there will be minimal environmental impact: 1. regardless of the site. Site specific EA and EIS need to be undertaken. (0652-1 [Maurer, William])

Comment: The analysis makes no distinctions among all of the nuclear power plants covered by the GEIS with regard to levels of seismic risk (earthquakes and tsunamis), regional population levels, proximity to transportation corridors, etc. (0660-1 [Headrick, Gary])

Comment: Abandon the generic "one size fits all" approach and instead, make site-specific environmental reports and recommendations[.] (0660-7 [Headrick, Gary])

Comment: [E]ach nuclear reactor has specific geographic, geologic and population realities. San Onofre's unique realities--its sensitive earthquake/tsunami zones; dense surrounding populations; major transportation corridors; and the Department of Navy's essential installation of USMC, Camp Pendleton, make such a "generic" statement impossible! (0665-3 [van Thillo, Grace])

Comment: Abandon the generic "one size fits all" approach to storing nuclear waste and instead, make site-specific environmental reports and recommendations that take local conditions into account. (0668-1 [Gordon, Mark] [Gordon, Michelle])

Comment: The draft GEIS recommends the proposed Action as the preferred alternative and rules out as inefficient² [footnote 2 text: Based on a lesser level of efficiency than the NRC would gain through a binding generic analysis measured by Council on Environmental Quality guidance for achieving efficiency and timeliness under NEPA.] other alternatives that would enable parties in licensing proceedings to raise contentions challenging the conclusions in the draft GEIS. (0669-3 [Walter, Joan])

Comment: As a binding rule, the proposed Action places an unfair burden on the public to show special circumstances through the waiver process³ [footnote 3 text: 10 CFR 2.335(b)] that the generic environmental determination doesn't adequately address impacts at a specific site. Important new information that could affect future NRC decisions may not be considered because of an inability of affected parties to meet this test. (0669-4 [Walter, Joan])

Comment: As a result, the two major purposes of the NEPA process, creating the opportunity for better informed decisions and promoting citizen involvement, are thwarted by the preferred alternative. Council on Environmental Quality regulations 4 state that EISs should highlight reasonable alternatives that would minimize adverse impacts and should be used to inform decisions -not to justify already-made decisions. Here, it appears that the presentation of alternatives is made solely to justify the preferred alternative.⁴ [footnote 4 text: 40 CFR Sections 1500-1508] (0669-5 [Walter, Joan])

Comment: Duke Energy concurs with the NRC intent of addressing Waste Confidence generically, through rule making, rather than on a site-specific basis. To do otherwise would be unnecessary and extremely inefficient. (0672-5 [Jamil, Dhiaa])

Comment: Site-Specific Analysis of Environmental Impacts of Waste Storage at New York Sites: The proposed rule and the proposed draft GEIS purport to examine some environmental impacts associated with the storage of spent nuclear fuel at reactor sites - and to do so on a generic, nation-wide basis. If the NRC proceeds with the proposed rule and draft GEIS as currently worded, NRC will preclude the State of New York as well as its citizens from raising site specific concerns in site specific licensing proceedings for nuclear reactors and storage facilities located in or near the State. Instead of relying on a generic analysis, the State requests that NRC conduct a site specific environmental impact statement and examine the environmental impacts that would result from a severe accident at the spent fuel pools or the dry storage cask facilities. (0681-9 [Peterson, Alyse])

Comment: I am writing as a concerned U.S. citizen affected by the environmental, economic, and public health and safety risks associated with operating and closed nuclear power plants across the nation. A problem at any of these plants has the potential to affect the entire nation, although adequate protection against such problems requires site-specific analysis and measures. As a resident of Raleigh, NC, I am particularly affected by the risks at the nearby Shearon Harris plant, which houses a massive inventory of used nuclear fuel posing clear and present radiological risks. Any transportation of those materials would entail further risks. (0684-1 [Kinsella, William])

Comment: Attempting to address any of these complex sociotechnical systems by way of a generic environmental impact analysis and a generic regulatory rule is grossly inadequate to the task. The specificities of particular sites are essential to understanding the risks. Without such specificity, the proposed regulatory framework is only a thin simulation; the risks are too great to leave the local particularities unexamined. (0684-3 [Kinsella, William])

Comment: This perennial problem is made worse by a generic approach to rulemaking and other regulatory procedures. Assessing sites individually, case by case, with broad-based participation by local communities is one way to address this disjunct between affected parties and parties engaged in the regulatory conversation. (0684-5 [Kinsella, William])

Comment: Accordingly, I disagree with the statement in the draft GEIS that the no-action alternative "is not consistent with Council on Environmental Quality guidance for achieving efficiency and timeliness under NEPA." (0684-7 [Kinsella, William])

Comment: The U.S. Court of Appeals rejected the current Waste Confidence Rule noting that, after decades of failure to site a repository, the NRC "has no long-term plan other than hoping for a geologic repository." Therefore it is possible that spent fuel will be stored at reactor sites "on a permanent basis." The NRC must examine the environmental consequences of storing

radioactive wastes at reactor sites into the indefinite future. The NRC Draft Generic Environmental Impact Statement (GEIS) relies on the fundamentally flawed assumption that all reactor sites are the same. On the contrary, they each have unique geographic, environmental, geological, climactic, and epidemiological considerations. The creation of a one-size-fits-all plan is scientifically invalid. (0686-1 [Malboeuf, Simone])

Comment: In this case, the public is deprived through a "generic" environmental impact statement that averts a public and expert review of the adverse environmental impacts of expanded nuclear generation and denies the impacted communities their due process under the National Environmental Policy Act (NEPA) and the Atomic Energy Act. This effort runs contrary to the principles of democracy and the legal process, exacerbating and aggravating the lack of public confidence in government and industry siting policy and environmental management practices for radioactive waste. (0691-13 [Gunter, Paul])

Comment: [T]he nuclear waste generators do not have site specific environmental impact statements as required under the National Environmental Policy Act for indeterminate on-site storage. (0691-3 [Gunter, Paul])

Comment: This lack of public confidence and societal objection is made more "reasonable" given that under the current reframing of the Waste Confidence Decision and the associated rulemaking the public hearing rights for site-specific issues raised by the expansion and extension of nuclear waste generation would be forfeited. (0691-9 [Gunter, Paul])

Comment: IV. We support only the No Action Alternative, described in the GEIS for the following reasons: •The No Action Alternative is the only alternative that ensures that there will be site-specific analysis of continued storage of spent fuel. Site-specific information and analysis is essential to making sound decisions about safe storage of spent fuel. •Other alternatives allow for NRC to substitute its judgment for detailed factual analysis[.] (0693-2-13 [Warren, Barbara])

Comment: •Lessons learned from Fukushima are only beginning to be addressed by NRC. Future site-specific analyses are the only means to ensure that these lessons will be incorporated into storage plans. (0693-2-15 [Warren, Barbara])

Comment: The Fukushima lessons learned about spent fuel and any new analyses should provide information for site-specific environmental analyses in the future that this deficient GEIS cannot provide. (0693-2-17 [Warren, Barbara])

Comment: There is nothing in the draft GEIS or the rule that includes an appropriate opportunity for the public to be involved in decisions related to how on-site storage of spent fuel would be managed at specific sites and for what time periods. In fact NRC does not adequately describe the methods or protections that would be provided, instead deferring to licensees in a laissez-faire approach. (0693-3-8 [Warren, Barbara])

Comment: •The NRC states its preference for generic analyses of environmental impacts despite what the Fukushima Near Term Task Force had to say: Because the regulatory framework has evolved over time, "the licensing bases, design and level of protection from natural phenomena differ among the existing operating reactors in the US, depending on when the plant was constructed and when the plant was licensed for operation." (p. 28 The Near Term Task Force Review of Insights from the Fukushima Dai-Ichi Accident, July, 2011) Given this information related to licensing it is pretty clear that there is no uniformity for the existing

reactors and thus generic analysis for spent nuclear fuel will be inadequate. (0693-4-7 [Warren, Barbara])

Comment: Turkey Point, St. Lucie, and the closed Crystal River Nuclear Power Plants in Florida are a completely different scenario from the Nuclear Power Plants in the other 47 states and their spent fuel must be dealt with in a different manner. South Florida is all flat land with an aquifer under the swamp. High ground is north of Lake Okeechobee which contains densely populated areas...Crystal River is not in the range of the Cumbre Vieja tsunami but an asteroid strike in the Gulf of Mexico or a methane gas bubble could cause a devastating tsunami that will destroy the short term storage at the power plant. (0701-13 [Wilson, Greg])

Comment: There is not any one solution that can be applied to every Nuclear Power Plant. (0701-9 [Wilson, Greg])

Comment: 3. Federal Register Vol. 78, pp. 56780-81. Oh! And there you answer my last question for me. Or rather the NRC does not. It does tell all about the technical ways and means of spent nuclear waste, but not a single mention of the environmental impact that happens in the existing facilities. The problem with using a generic formula for nuclear issues -- the nature of nuclear science. When exposed to radiation, EVERY single eco-system is going to respond soooooo differently based on material compounds of the water -- I mean, seriously, has anyone taken a sample of the #Fukushima #nuclearizedwater and mixed it with some of that #NorthAtlantic #radioactivewater? I mean, seriously, what is going to happen up there in the Arctic Ocean?! I hope someone else really smart who studies the impact of nuclear waste radiation on the things like viruses and fungi in specific locations near different radioactive sites has submitted some thoughts on this whole Generic Thing. I completely understand the need for it, the Generic Rule, but the question I have is: Has the NRC really gotten to the root issues for implementing a Generic Rule that does not undermine the Common Defense? I would have to say, based on the fact that I could not find in all of those words in the Federal Register anything that gave me confidence that THIS industry here in the United States of America would not do the same thing their peer did in Japan. In which case, this NRC Generic Rule MUST be way more detailed in the specifics than it currently is. (0703-14 [Vandel, Nikohl] [Vandenberg Clermont, Elaine])

Comment: Federal Register Vol 78, p. 56776, "The analysis in NUREG 2157 ..." I guess the only problem with the generic environmental approach is the reality of emergencies, and I think that is what everyone outside of the industry is objecting to -- how do you have a generic approach to such different realities? And, the truth is, every nuclear facility is unique. But I do think that the NRC did its best to associate apples with apples and oranges with oranges in order to make generic the consistent ways nuclear waste imposes its threat on the natural environment. However, when the generic level of waste management parameters are so low as to pose such a considerable risk across the board, not even broaching into the emergency realm, this is where the NRC does disservice to its mission, the industry and most definitely the Stakeholders. The quality acceptable to the Commission is simply too dependent on industry self-regulation, and in our current corporate climate, that is too hazardous for history to say "we did it right." (0703-9 [Vandel, Nikohl] [Vandenberg Clermont, Elaine])

Comment: Defining and Evaluating the Alternative of "No-Action:" NRDC's example. Logically, and as a matter of law, the alternative of "No Action" should be defined in this Draft GEIS (as it is in thousands of other federal NEPA documents) as the continuation of the policy and environmental status quo assuming the Agency does not undertake the Proposed Action, or any of the action alternatives assessed in detail and determined to be reasonable. In the instant

case, the environmental status quo already includes substantial continued surface storage of spent fuel generated pursuant to previous NRC licensing actions and licenses that remain in force, but does not include the storage of spent fuel arising from pending and future licensing actions that would be enabled by the proposed reinstatement of a revised WCD/TSR. Thus a NEPA compliant analysis of the No-Action Alternative would encompass the environmental consequences of continuing to store on the surface for various terms the different extant types, ages, and "burn-ups" of spent fuel that fit within this bounding condition, based on the existing licensed pool storage and dry cask capacities and currently licensed technologies required to responsibly manage this amount of spent fuel under existing licenses and allowable amendments thereto. Such an analytically meaningful No Action Alternative would delineate quantitatively the current and projected types, characteristics and volumes of spent fuel that have been and will be produced over time under the authority of existing operating licenses until their currently applicable dates of expiration, the environmental risks and reasonably foreseeable impacts of continuing the current practice of transferring older spent fuel to dry casks only when pool storage capacity is on the verge of being exceeded, and options for mitigating these impacts that the Agency could reasonably be expected to take under its existing rules in the absence of implementing its Proposed Action. Under current law the Federal government will hold nominal title to this spent fuel. Thus, NRC must consult with other agencies (e.g. DOE EPA, and DOT)²⁰ [footnote 20 text: Indicative of NRC's haste to finalize this proposed rulemaking and GEIS, NRDC notes with significant surprise that NRC notes "there are no formal cooperating agencies identified in the Waste Confidence Environmental Review." Draft GEIS at xxvii. Given the major roles assigned to DOE, EPA and DOT in the management, storage, transportation and standard setting for SNF we find such lack of formal cooperation nothing short of astonishing.] and describe the range of reasonably foreseeable actions that these agencies could undertake that could alter the environmental risks and impacts from future storage of this spent fuel prior to its transport and disposition in a permanent geologic repository. Under No Action the DGEIS must evaluate the environmental impacts of the storage of SNF authorized by existing licenses. The no action alternative assumes the agency undertakes no further new licensing actions or license extensions, and instead relies solely on its existing regulatory authorities to approve license amendments and require installation of safety upgrades. (0706-2-11 [Fettus, Geoffrey])

Comment: The "No Action Alternative" is Not a "No Action Alternative" And It Leads to An Arbitrary and Capricious Result. As a first point, the environmental status quo already *includes* substantial continued surface storage of spent fuel generated pursuant to previous NRC licensing actions and licenses that remain in force, but *not* the storage of spent fuel arising from pending and future licensing actions that would be enabled by the proposed reinstatement of a revised WCD/TSR. Thus a NEPA compliant No-Action Alternative would encompass the environmental consequences of continuing to store on the surface the different extant types, ages, and "burn-ups" of spent fuel that fit within this bounding condition, based on the existing pool storage and dry cask capacities and currently available technologies required to responsibly manage this amount of spent fuel under existing licenses and allowable amendments thereto. This analytically meaningful No Action Alternative would delineate quantitatively the current and projected types, characteristics and volumes of spent nuclear fuel that have been and will be produced over time *under the authority of existing operating licenses until their currently applicable dates of expiration*, the environmental risks and reasonably foreseeable impacts of continuing the current practice of transferring older spent fuel to dry casks only when pool storage capacity is on the verge of being exceeded, and options for mitigating these impacts that the Agency could reasonably be expected to take in the absence of implementing its Proposed Action. Since the Federal government now legally holds nominal title to this spent fuel, NRC must consult with other agencies (e.g. DOE and EPA) and describe

the range of reasonably foreseeable actions these agencies could undertake that would alter the environmental risks and impacts from future storage of this spent fuel prior to its disposition in a permanent geologic repository. (0706-2-7 [Fettus, Geoffrey])

Comment: In particular, the operation of the Indian Point nuclear power plant implicates a variety of site- specific concerns that have not been adequately accounted for or analyzed in the DGEIS. The Indian Point facility faces a unique set of circumstances and challenges which exacerbate concerns related to nuclear waste storage at the site. Yet, such issues have not been adequately “bounded” or otherwise accounted for by the discussion in the DGEIS. A. Site-Specific Considerations at Indian Point[.] 1. Plant Location[.] Indian Point is located in Buchanan, Westchester County, NY just 24 miles north of New York City proper and 35 miles north of midtown Manhattan. The 50-mile radius around the plant encompasses NYC, which has a population of over 8 million people.⁸ [footnote 8 text: See Generic Environmental Impact Statement for License Renewal of Nuclear Plants: Regarding Indian Point Nuclear Generating Unit Nos. 2 and 3 (NUREG-1437, Supplement 38), *available at*, <http://pbadupws.nrc.gov/docs/ML1033/ML103350405.pdf>, at p.2-1 (“The area within a 50-mi (80-km) radius of the site includes parts of New York, New Jersey, and Connecticut. New York City, located approximately 24 mi (39 km) south of the plant, is the largest city within 50 mi (80 km) with a 2006 population of approximately 8,214,426 (USCB 2006).”).] With over 17 million people living within the 50-mile radius of Indian Point, the plant has, by far, the, highest surrounding population density of all the nuclear power reactors in the United States.⁹ [footnote 9 text: Generic Environmental Impact Statement for License Renewal of Nuclear Plants: Regarding Indian Point Nuclear Generating Unit Nos. 2 and 3 (NUREG-1437, Supplement 38), *available at*, <http://pbadupws.nrc.gov/docs/ML1033/ML103350405.pdf>, at p.2-124 (“Approximately 16,791,654 people live within 50 mi (80 km) of IP2 and IP3”); See also Bill Dedman, *Nuclear Neighbors: Population Rises Near US Reactors*, NBC New.com, http://www.nbcnews.com/id/42555888/ns/us_news-life/t/nuclear-neighbors-populationrises-near-us-reactors/#.UrNSx8Kx7IU (last accessed Dec. 19, 2013).] Thus, Indian Point is situated just minutes from one of, if not, the world’s leading financial, cultural, and socio-economic centers. Various affluent areas surround or are in the vicinity of the plant, which command high property values. In addition, two of New York City’s most important drinking water reservoirs are located less than ten miles and approximately twenty one miles from Indian Point.¹⁰ [footnote 10 text: The New Croton Reservoir is approximately 9.4 miles from Indian Point, and is the primary reservoir for the “East of Hudson” water supply for New York City. The Kensico Reservoir, which serves as the terminus surface water storage reservoir for the entire East and West of Hudson water systems for New York City, is approximately 21 miles from Indian Point. See NYC DEP, Kensico, http://www.nyc.gov/html/dep/html/watershed_protection/kensico.shtml (last accessed Dec. 20, 2013).] Nine million people depend on the safety of that water supply every day. (0710-2 [Brancato, Deborah] [Musegaas, Philip])

Comment: The GEIS on “Waste Confidence” (NUREG 2157) does not pass the laugh test: the federal court ordered NRC to assess the environmental impact of extended waste storage, not environmental impact of writing a GENERIC document; yet NRC focuses on the cost of writing one document vs many. Even if a summary is in a report, there is zero rational basis to exclude highly radioactive waste storage impacts from specific licensing actions. We reject the Generic approach whole-cloth. Use of a “reference” site has further reduced the public’s confidence in the NRC, if that was possible. A final decision from NRC that it “has confidence” in a generic approach to the existing waste or confidence in continued generation, management and storage of highly radioactive spent nuclear fuel by energy corporations, will confirm our conclusion that this is nothing more than a “Waste CON;” as in a “CON game.”ⁱ [footnote I text: From Wikipedia:

A confidence trick (synonyms: confidence scheme and scam) is an attempt to defraud a person or group after first gaining their confidence, in the classical sense of trust. A confidence artist (or con artist) is an individual, operating alone or in concert with others, who exploits characteristics of the human psyche such as dishonesty, honesty, vanity, compassion, credulity, irresponsibility, naïveté, or greed... A confidence trick is also known as a con game, a con, a scam, a grift, a hustle, a bunko (or bunco), a swindle, a flimflam, a gaffe or a bamboozle. The intended victims are known as "marks" or "suckers", and when accomplices are employed, they are known as shills.] Radioactive waste is far from a "game;" and NRC's failure to fully engage with the site-specific and technical bases of this problem is potentially fatal to us and our progeny. (0711-2 [Olson, Mary])

Comment: Do you understand that if there is a future reactor, the purpose of this GEIS is to ensure that the people who would be impacted by any fuel pool fire if their "number came up" will have no right to raise any concerns about that possibility during the licensing of that reactor? (0711-26 [Olson, Mary])

Comment: [A]mend the NRC licensing and re-licensing process to require an individual Environmental Impact Statement for waste at every individual nuclear plant. (0712-4 [Schimmelpfennig, Pamela Y.])

Comment: *The above discussion demonstrates that the local variability of circumstances among US reactors argues against a generic policy, and generic assumptions on the part of NRC regarding spent fuel management.* At the Oak Brook, IL NRC Waste Confidence hearing on November 12th, 2013, Sierra Club group chair Evan Craig made a critical observation to NRC, which we are sure went totally ignored. He said (we paraphrase) that "generic environmental" is an oxymoron. There is NOTHING generic about the environmental, which is a dynamic, constantly changing and evolving set of near infinite interactions and possibilities. As such, he dismissed the NRC's "generic environmental" impact statement as an exercise in both futility and unreality. It would describe nothing but severely limited self-fulfilling prophecies, not the real world. NRC would be wise to understand this fundamental flaw in issuing a DGEIS. (0716-17 [Kraft, Dave])

Comment: There is no way that a generic environmental impact statement can address the unique and ever-changing realities of each reactor and site in one blanket statement for all reactors. Even the seemingly "common elements" have different ways of wearing out at each site. As one philosopher has put it: You never put the same foot in the same river twice. All the factors of any given situation and at any reactor site are constantly changing. That is the law of the physical universe as well. Things are constantly changing and breaking down - ultimately into entropy and chaos. Eventually even good machines wear out, and this is certainly true of complex systems like nuclear reactors.. The point I want to leave you with is that in this new universe of decommissioning, each reactor site is different. And each arrangement to do the decommissioning is different and will require its own GEIS, more than one, at different points in time. There is no way that such ever-changing realities can be covered through one generic environmental impact statement. (0717-2 [Lewison, Linda])

Comment: Spent fuel pools have different designs and liners, and some are located at ground level while others are located above the ground. The design and placement of spent fuel racks, air circulation and convection mechanisms, type of reactor, and amount of heat generated by the fuel itself also differ from plant to plant. Unlike nuclear power reactors, which are located within containment shells, spent fuel pools are not protected by thick concrete domes,²⁶ [footnote 26 text: *NAS Report* at 40.] making them susceptible to radiological release as a result

of fires or leaks. Their susceptibility, however, is affected by the site-specific differences between the pools.²⁷ [footnote 27 text: *Id.* at 8, 31, 40-43.] (0718-1-12 [Sipos, John])

Comment: Concerned about the implications of the Alvarez article and NUREG-1738, the United States Congress directed NRC to seek independent technical advice from the National Academy of Sciences ("NAS") on the safety and security of spent fuel storage.⁴⁴ [footnote 44 text: U.S. Congress, Conference Report 108-357, *Making Appropriations for Energy and Water Development for the Fiscal Year Ending September 30, 2004, and for Other Purposes*, at 191 (Nov. 7, 2003).] In response, NAS confirmed the potential for a pool fire that could result in the release of a substantial portion of a fuel pool's radioactive inventory.⁴⁵ [footnote 45 text: *NAS Report* at 1. NRC actions delayed the release of the public version of the report. *Agencies Fight Over Report on Sensitive Atomic Wastes*, New York Times (Mar. 30, 2005). The public version of the NAS Report was release on April 6, 2005.] The NAS report also agreed with NUREG-1738 that the risk of spent fuel pool fires cannot be determined on a generic basis: "[t]he potential vulnerabilities of spent fuel pools to terrorist attacks are plant-design specific. Therefore, specific vulnerabilities can be understood only by examining the characteristics of spent fuel storage at each plant."⁴⁶ [footnote 46 text: *NAS Report* at 8.] The NAS report also found that sabotage of spent fuel pools is possible and that under some conditions, a terrorist attack that partially or completely drained a spent fuel pool could lead to a zirconium cladding fire that would "propagate"—i.e., spread from the spent fuel rod or assembly that initially caught fire to other assemblies—and cause the release of large quantities of radioactive materials to the environment.⁴⁷ [footnote 47 text: *Id.* at 38-39, 48.] Following the completion of the NAS Report, Congress directed NRC to develop site-specific mitigation models for different spent fuel sites.⁴⁸ [footnote 48 text: U.S. Congress, Conference Report 108-792, *Making Appropriations for Foreign Operations, Export Financing, and Related Programs for the Fiscal Year Ending September 30, 2005, and For Other Purposes*, at 982 (Nov. 20, 2004).] (0718-1-16 [Sipos, John])

Comment: There is substantial new evidence that there is earthquake risk that NRC did not take into consideration when approving operation licenses for existing reactors and spent fuel storage facilities. In 2004, United States Geological Survey ("USGS") told NRC that earthquake hazards in the Central and Eastern United States ("CEUS"), the portion of the lower 48 states east of the Rocky Mountains, were higher than previously understood. In May 2005 NRC staff acknowledged that earthquake risk for reactors and spent fuel storage in CEUS may be greater than NRC assumed when it approved operating licenses for these facilities. See, e.g., May 26, 2005 NRC Staff memorandum re: Identification of a Generic Seismic Issue (available at ML051450456). NRC staff's response to the new USGS earthquake hazard information was to consider issuing a "generic letter" on the subject of "Implications of Updated Probabilistic Seismic Hazard Estimates in Central and Eastern United States." June 9, 2005 NRC staff memorandum Generic Issue 199, "Implications of Updated Probabilistic Seismic Hazard Estimates in Central and Eastern United States" (available at ML051600272). This memorandum contained an estimate that "the initial screening technical analysis will be completed within three months of receipt of the necessary information from [NRC's Office of Nuclear Reactor Regulation]." *Id.* The summary of the February 6, 2008 NRC staff public meeting relates that a seismologist working on Generic Issue 199 stated that for some CEUS areas the current earthquake frequency estimates were several times larger than those used in the 1980's, and that revised ground motion predictive equations generally produced higher estimates of uncertainty about the effect of earthquakes at these sites. February 8, 2008 NRC staff memorandum Subject: Summary of February 6, 2008, Category 2 Public Meeting with the Public and Industry to Discuss Generic Issue 199, "Implications of Updated Seismic Hazard Estimates in Central and Eastern United States on Existing Plants," p. 2 (available at ML080350189). ⁴ [footnote 4 text: The summary also related that a representative of the Electric

Power Research Institute ("EPRI"), a private organization funded by the electric power industry, stated that it had "calculated mean seismic spectra for the 28 sites used in [NRC Regulatory Guide] 1.165." *Id.* However, EPRI has prevented public review of information and has delayed NRC's reassessment of earthquake hazards. See, e.g., February 1, 2008 Screening Analysis for GI-199, "Implications of Updated Probabilistic Seismic Hazard Estimates in Central and Eastern United States on Existing Plants," p. 2 (available at ML073400477) (EPRI unwilling to share a report with NRC contractor.).] (0718-1-5 [Sipos, John])

Comment: Need for Objective Site-Specific Analysis. Given the combination of site-specific characteristics, the decontamination costs and resource replacement costs following a severe accident at Indian Point have the potential to be substantially larger than an accident at any other reactor in the country. Furthermore, in light of the site-specific characteristics and the considerable costs associated with a severe nuclear accident in the New York metropolitan area, mitigation alternatives are likely to be more cost effective at the Indian Point facilities. (0718-1-6 [Sipos, John])

Comment: Lack of Site-Specific Analysis of Severe Spent Fuel Pool Accident. Given their regulatory history, the three power reactors and their spent fuel pools located at Indian Point were not subjected to a severe accident mitigation alternatives analysis when AEC and NRC issued the construction permits and operating licenses for those facilities. According to AEC and NRC documents, the Consolidated Edison Company ("ConEd") received the following construction permits and operation licenses on the following dates: [Table inserted] Source: Federal Register and NRC Information Digest.⁵ [footnote 5 text: See 21 Fed. Reg. 3,085 (May 9, 1956); 31 Fed. Reg. 13,616-17 (Oct. 21, 1966); 34 Fed. Reg. 13,437 (Aug. 20, 1969); NUREG-1350, Volume 20, 2008 - 2009 Information Digest, at 103, 113 (Aug. 2008).] When ConEd announced its selection of the Indian Point site back in March 1955 and filed an application for the necessary construction permit, the AEC did not have site selection regulations that addressed population or seismic issues. To place this initial siting decision in perspective, ConEd selected, and AEC approved, Indian Point as the site for a power reactor before the Windscale - Sellafield (1957), Three Mile Island (1979), Chernobyl (1986), and multi-unit Fukushima (2011) events. The 1955 selection of Indian Point also came before the enactment of NEPA (1970), the promulgation of CEQ regulations (1978), the Third Circuit's *Limerick* decision (1989), and NRC promulgation of the 10 C.F.R. § 51.53 regulation (1996) that collectively require an analysis of ways to mitigate the impacts of severe accidents at nuclear facilities. In addition, AEC approved the construction of the first reactor and spent fuel pool before Congress enacted in the Price Anderson Act (1957). (0718-1-7 [Sipos, John])

Comment: NRC confirms that severe accidents and consequences were not taken into account when selecting and approving the Indian Point site. In its 1979 Siting Study Report, NRC stated: [image] NRC, Report of the Siting Policy Task force, NUREG-0625 (Aug. 1979) at p. 10, ML12187A284. Moreover, severe accidents to spent fuel pools were not considered by AEC or NRC at the initial licensing stages for Indian Point -- and were not analyzed in the Siting Study Report. Storage and Accumulation of Spent Nuclear Fuel at Indian Point. When the federal government first licensed the operation of Indian Point Unit 2 and Indian Point Unit 3 it authorized each unit's single spent fuel pool to hold 241 spent fuel assemblies. NRC subsequently authorized the pools to hold five times (5x) the original limit. The following charts summarize how NRC has authorized increasing amounts of spent nuclear fuel to be stored in the spent fuel pools for Indian Point [table for Unit 2 inserted] ⁶ [footnote 6 text: Consolidated Edison, *Final Design Report for Reracking the Indian Point Unit No. 2 Spent Fuel Pool*, at 1, ML100200292 (May 1980); Consolidated Edison, *Supplemental Spent Fuel Safety Analysis*, at 3-1, ML100350310 (Nov. 1985); and Consolidated Edison, *Indian Point Unit 2 Spent Fuel Pool*

Increased Storage Capacity Licensing Report, at 1-2, ML100200114 (June 1989).] [table for Unit 3 inserted] ⁷ [footnote 7 text: USAEC, *Safety Evaluation Report by the Directorate of Licensing U.S. AEC In the Matter of Consolidated Edison Co. of New York, Inc. Indian Point Nuclear Generating Unit No. 3*, at 4-1, 9-2, ML072260465 (Sept. 21, 1973); USNRC, *Indian Point, Unit 3, Amendment 13, Authorizing Modifications to the Spent Fuel Pool, Increasing Capacity from 264 to 840 Fuel Assemblies*, attached to *Letter from A. Schwencer, NRC to New York State Power Authority*, ML003778668 (Mar. 22, 1978); and USNRC, *Indian Point, Unit 3, Amendment 90, Allowing for the Expansion of the Spent Fuel Pool Storage Capacity*, attached to *Letter from Joseph Neighbors, NRC to New York Power Authority*, ML003778816 (Oct. 12, 1989).] Indian Point currently has – and is expected continue to have – substantial amounts of radioactive spent nuclear fuel waste on site. During the May 8, 2012 site visit to the Indian Point facilities by the Atomic Safety and Licensing Board, Entergy representatives made the following statements about Entergy's plans for spent nuclear fuel at Indian Point: (A) All of the spent fuel generated during since the start of commercial operation of Indian Point Unit 3 remains in the Indian Point Unit 3 spent fuel pool (as of the date of the May 2012 site visit); (B) Entergy has no current plans to construct an additional dry cask storage area (in addition to the existing dry cask storage area); and (C) At the end of operation under any 20-year extension of the current operating licenses, Entergy estimates that the existing dry cask storage area would be filled to capacity and that the Indian Point Unit 2 spent fuel pool and the Indian Point Unit 3 spent fuel pool would be filled to capacity as well. This means that under Entergy's plan the site's two operating spent fuel pools will continue the site's dense pool storage practices into the future. All of these unique characteristics of the Indian Point site demonstrate why it is essential that a site-specific analysis of the potential environmental impacts from the storage of spent fuel at the Indian Point facilities and measures to mitigate those potential impacts must be addressed. (0718-1-8 [Sipos, John])

Comment: North Anna, Virginia[.] On August 23, 2011, a 5.8 magnitude earthquake occurred in Virginia with the epicenter located approximately 11 miles from the North Anna Power Station. The earthquake exceeded the spectral and peak ground accelerations that the plant was built to withstand and the plant temporarily lost power.¹²⁹ [footnote 129 text: Nuclear Regulatory Commission, *NRC Technical Audit Report of North Anna Post-Seismic Fuel Inspections*, at 3, ML11305A239 (Oct. 27, 2011).] The tremor was felt in various northeast cities, including Washington and New York. While initial review by North Anna's owner concluded that there was no major damage to the reactors or spent fuel pools, the incident highlighted the fact that U.S. nuclear facilities are also subject to beyond-design-basis earthquakes. As indicated by the figures below, many nuclear reactors in the U.S. are located in areas with potentially dangerous seismic activity. The first figure is the U.S. Geological Survey National Seismic Hazard Map, updated in 2008, showing the earthquake ground motion (peak acceleration or PGA) for a 2% probability over 50 years. The second image, from NRC, shows the locations of nuclear reactors in the U.S. [Figures inserted] On January 31, 2012, NRC, DOE, and EPRI released a new seismic study, revealing significantly higher earthquake risks in the central and eastern United States. According to NRC, "Calculations with the new model are expected to result in a higher likelihood of a given ground motion compared to calculations done using previous models."¹³⁰ [footnote 130 text: Nuclear Regulatory Commission, Press Release: New Seismic Model Will Redefine Hazard Analysis at U.S. Nuclear Plants, No. 12-010 (Jan. 31, 2012).] Nuclear power plants will use the new model to re-evaluate their seismic risk. The State urges NRC to change the draft revised DGEIS and proposed rule to allow seismic risks to be taken into consideration by conducting a site-specific review of seismicity risks for spent fuel pools. (0718-2-13 [Sipos, John])

Comment: No provision allowing site specific review is made in the DGEIS and the proposed rule. Given this absence, the DGEIS and the proposed rule should be revised to allow for such a site specific and site wide review. (0718-2-15 [Sipos, John])

Comment: San Onofre by the sea seems a poor choice for nuclear waste disposal. Abandon the generic "one size fits all" approach to storing nuclear waste and instead, make site-specific environmental reports and recommendations that take local conditions, such as earthquakes, into account. (0726-1 [Allerton, George])

Comment: Please review each site individually to determine how waste should be handled. A one size fits all is dangerous and will not protect health or safety, as you are entrusted to do. (0727-1 [Peinado, Susan])

Comment: "Generic Address"--One cannot "generically address" the environmental impacts of spent nuclear fuel. One must be precise and far-sighted. A term like "generically address" does not specify future plan and/or historical repercussions on environment due to "spent nuclear fuel". Please be precise, clear, historically-accurate on future plans for environmental impact. (0728-1 [Anonymous, Anonymous])

Comment: Abandon the generic "one size fits all" approach and instead, make site-specific environmental reports and recommendations[.] (0728-5 [Anonymous, Anonymous])

Comment: Abandon the generic "one size fits all" approach and instead, make site-specific environmental reports and recommendations[.] (0741-2 [Giese, Mark M.])

Comment: [I believe the NRC must:] Abandon the generic "one size fits all" approach and instead, make site-specific environmental reports and recommendations[.] (0757-13 [Lynch, Laura])

Comment: Problems exist specific to the Indian Point Nuclear Power Plant that cannot be addressed by a "generic" set of regulations. For example, the Indian Point Nuclear Power Plant is 35 miles from the most densely populated area of the northeast - New York City. (Some areas of NYC are closer than 35 miles.) As Manhattan is an island with limited points of egress, evacuation on short notice would be impossible. Altogether, 20 million people live within a 50 mile radius of Indian Point. In addition, a new word is needed to describe this potentially necessary emergency process, as the word "evacuation" implies "return;" and, with nuclear contamination, as we have learned from past experience, there is no "return" (as in Chernobyl). For this reason, a "generic" set of regulations cannot be accepted. (0762-1 [Skopic, Catherine])

Comment: Generic Environmental Impact Statement – NOT acceptable for California. •California didn't "sign up" for permanent (100+ years) nuclear waste dumps. (0764-3 [Gilmore, Donna])

Comment: The NRC needs to abandon the generic "one size fits all" approach to storing nuclear waste and instead, make site-specific environmental reports and recommendations that take local conditions into account. (0767-1 [Harris, Kate])

Comment: I am very concerned that the waste confidence plan does not adequately address the specific risks at the San Onofre site, especially considering the proximity to major population, the large amount of waste material, and the extended period for containing special highly radioactive fuel. Coastal Southern California is one of the worst places to store nuclear waste. (0770-1 [Maher, Ed])

Comment: The analysis makes no distinctions among all of the nuclear power plants covered by the GEIS with regard to levels of seismic risk (earthquakes and tsunamis), regional population levels, proximity to transportation corridors, etc. (0774-11 [Revilla, Oscar])

Comment: Abandon the generic "one size fits all" approach and instead, make site-specific environmental reports and recommendations. (0774-7 [Revilla, Oscar])

Comment: Protecting the public means conducting a professional analysis of the individual site conditions and determining safety in light of hazards such as the possibility of earthquakes, potential dangers to populations in the area, to public transportation close to the facility, and other factors. You are supposed to do your due diligence in this regard, and I am appalled that you have not done so! Be prepared for lots of legal actions against you! We do not want you to jeopardize our children's future! DO YOUR JOB! (0776-2 [Kuttler, Eugen])

Comment: We have a unique geographical problem with limited egresses and no way out for a population of over 8 million people. We must have a separate EIR. (0785-2 [Korsen, Alan])

Comment: Abandon the generic "one size fits all" approach and instead, make site-specific environmental reports and recommendations[.] (0789-2 [Salto, Don])

Comment: You must treat nuclear waste disposal on a case by case basis. Separate EIRs, take into account earthquake fault lines, aquifers[.] There is no one size fits all. (0794-1 [Amthony, Elizabeth])

Comment: Because of the major variations in climate, geologic, and other conditions of the various elements and "activities" related to continued-storage sites across coterminous U.S., generic descriptions of environmental impacts can at best provide only a framework for selected types of impacts. The procedures for establishing a generic basis for impact assessment omit some critical sources of potential environmental impact and rationalize the safety of others on the basis of very limited data. (0805-2 [Wilshire, Howard])

Comment: The approach is stated in the Abstract, p. iii as follows: "For the resource areas considered, this draft GEIS attempts to establish generic impact determinations that would be applicable to a wide range of existing and potential future spent fuel storage sites," using "some site-specific information in developing the generic impact determinations..." And further, a goal is stated to "...identify the types and assessing the magnitude of environmental impacts where generic findings can be established." Comment: These statements provide no information on exactly what characteristics/activities/properties of all elements of ISFSIs do not qualify for generic findings, and how many sites have such disqualified characteristics. These must be specified as they may (and do for some known characteristics) represent sources of environmental impacts that are of overriding importance in establishing and maintaining integrity and safety of continued storage. Information should be supplied on the number of sites, including all time frames, to which the chosen set of generic findings do not apply [the language quoted above "...establish generic impact determinations that would be applicable to a wide range of existing and potential future spent fuel storage sites" implies that the determinations are not universal]. (0805-3 [Wilshire, Howard])

Comment: Most of the identified elements of affected environment are described as widely ranging, variable, many are site-specific, or occur only at certain sites. This being the case how can environmental impacts be reduced to generic assessment? (0805-5 [Wilshire, Howard])

Comment: The GEIS would not take into account any site-specific concerns that have arisen such as the lack of confidence in the NRC to correct structural conditions of existing a nuclear power plant operator's ability to store safely waste material and spent fuel rods, especially in the case of operational malfunction, natural disaster, or deliberate malfeasance. (0816-2 [Stansberry, Mark])

Comment: The GEIS would not take into account any site-specific concerns that have arisen such as the lack of confidence in the NRC to fully disposition future license applications without a site-specific Environmental impact Study incorporated into the process. (0816-3 [Stansberry, Mark])

Comment: In the 2011 IRP, TVA included construction of one or more nuclear reactors at the Bellefonte (Scottsboro, AL) site to start in a specified time frame simply because the reactors otherwise could not be completed within the time allowed by (NRC restored) Construction Licenses. Since that time TVA has effectively abandoned plans to construct any reactors at Bellefonte though it has not relinquished either of the two construction licenses or the two COL licenses for AP1000 units. This history at Bellefonte and related issues at every other TVA reactor demonstrate the inappropriateness of applying the final DGEIS to all sites and all reactors as the actual waste generation to be dealt with is unpredictable. When the time and scale of actual reactor operations and spent fuel generation is complicated by issues like the (DOE proposed) use of MOX, the use of "high burn-up" fuel, and individual reactor designs and with varying lengths of refueling cycles, it is clear that a reactor by reactor EIS should be required under any plan for long term onsite irradiated fuel storage. (0821-1 [Paddock, Brian])

Comment: This need for a site by site and reactor by reactor EIS is re-enforced by the question of the suitability of each specific site. The example within TVA's ambit is Sequoyah. TVA has contracted for cask storage of irradiated fuel at Sequoyah. It is unclear whether this processing and detention is to serve only the two reactors located there or may involve transfer of irradiated fuel from Watts Bar and/or Browns Ferry. (0821-2 [Paddock, Brian])

Comment: As I mentioned in my oral comments, NRC cannot assume the security of stored irradiated fuel. The security performance for each reactor site must be considered. TVA's abysmal lack of reactor reservation site security is a matter of record. TVA has proven unable to provide consistent security from intrusions under both systems of use of contractors and use of TVA employed staff. (0821-8 [Paddock, Brian])

Comment: Leakage from spent fuel pools and from various other parts of each reactor contain cumulative impacts which require a physical site-specific evaluation with data maps for each site. Generic evaluation is inapplicable to physical world reality. (0823-40 [Michetti, Susan])

Comment: It is unacceptable for the Draft Generic EIS to depend upon regulations and guidelines created for other purposes without going through the full rigorous process of scientific thinking, assessment, methods, analysis, and practices in terms of spent fuel monitoring in on-site pools at each and every specific location with unique differentiating characteristics. This is another violation of scientific principles. (0823-49 [Michetti, Susan])

Comment: Overview analysis to determine any inadequacies in NRC's regulatory program for future leak detection requires a better tool than the Draft Generic EIS. As a conceptual tool, not a physical world tool, Draft Generic EIS fails to address unique, differentiating factors that arise from the full set of characteristics at a specific physical location. As a result, it is inappropriate to determine safety. (0823-51 [Michetti, Susan])

Comment: The Draft Generic EIS is seriously flawed by not addressing the actual specific unique circumstances of individual reactors. The "generic" concept fails to address the actual Physical World in which individual reactor sites are distinct, unique, and differentiated in assorted ways that contradict inaccurate broad sweeping generalized conceptualizations made in the Draft Generic EIS. The Draft Generic EIS is unscientific for these reasons, by definition. (0823-54 [Michetti, Susan])

Comment: The Physical World requires physical assessments for physical world rules, decisions, and solutions, which become not possible when using an imaginary "generic" concept. It is impossible to physically measure and test a conceptualized "generic" location which lacks actual specific measurable physical location because it is not part of the Physical World. The thought world is perceived under different laws that govern its much lesser density. The attributes of the Physical World has its own laws that do not tend to operate practically outside of the Physical World. The same applies to the thought world. The laws that operate within the Physical World emerge from its greater density. This very density lends itself to precision measurements upon which all knowledge about the physical world is based. Only by measuring and testing the facts pertaining to physical world density to the widest and deepest extent possible will we as a society begin to assess any case for safety for any specific nuclear waste storage solution location and its parameters. This happens because the unique, differentiating reality located in space and time with unique physical realities must be assessed first for its ability to maintain isolation of these most lethal substances on earth. It is impossible to skip this step and to claim "safety" with far too many unknowns with the most dangerous substances on earth. Integrity of safety claims must be supported by reliable facts derived from reliable, dependable research conducted with transparent open honesty and peer-reviewed. We expect that safety claims contain full integrity, particularly for the most lethal substances on earth. We expect that what has not been problem-solved remains out in the open, so to speak, on the table for discussion. (0823-57 [Michetti, Susan])

Comment: Generic conceptualization for safety is inappropriate and unacceptable. Physical storage and disposal remain an integral part of the safety case. Storage and disposal is an integral part of any solution. Generic conception does not lend itself to physical observation, measurement, and analysis of all unique, differentiating, surrounding environmental factors through the complete timeline of impacts. (0823-58 [Michetti, Susan])

Comment: Each specific operation has a location that requires its own unique EIS with scientific analysis that includes all impacts of any and all ionizing isotopes found on-site throughout their ionizing life spans. This analysis is required, particularly, in order to sufficiently identify "the potential environmental effects" of storing spent fuel onsite "on a permanent basis" at each nuclear power reactor site in the USA or any other proposed location, interim or permanent. (0823-64 [Michetti, Susan])

Comment: Each specific actual physical world location, as compared to a generic conceptualization with missing physical variables, is required to be scientifically assessed, measured, tested, and analyzed in terms of its complete set of physical properties, specifically including those which are unique and differentiated, particularly in terms of safety to the full environment and all living organisms. Scientific assessment requires thorough safety data: pertaining to actual physical sites for each individual reactor or repository; pertaining to physical interactions of each and all elemental isotopes emitting ionizing radiation with the various interactions among the various attributes and parameters of each specific physical site; pertaining to full identification of the full timeframe of all impacts within the complete parameters of the specific physical site including atrophy and interaction with specific elemental isotopes

emitting ionizing radiation over the complete life span required to expire all the cumulative half-lives involved; pertaining to radioactive and toxic leakage from structural weaknesses and other atrophy observed or predicted at that sited repository, including migration off-site, for the complete timeframe required to expire all the cumulative half-lives at that site; and pertaining to predicted or observed public health and environmental damages emerging from any leakage or non-containment of ionizing isotopes from that repository. This is not a complete list. (0823-66 [Michetti, Susan])

Comment: For accurate safety overview as well as safety assessments and safety analyses, separate rigorous and thorough full EISs are required to be conducted for the actual physical world's characteristics at each unique individual and differentiated nuclear plant, particularly including spent fuel disposal or storage impacts, in order to determine if any physical world feasibility actual exists to justify the continuation of operations generating these lethal toxins. Full identification of impacts, including cumulative impacts, through the entire timeline of ionizing radiation of each identified isotope, are required for adverse public health impacts; adverse environmental impacts to healthy well-being; adverse reproductive and genetic impacts upon all living organisms, including "race" or "species" survival impacts; social and economic impacts upon various populations; financial impacts; adverse impacts to water forms and water quality, atmospheric issues and air quality, landforms and soil quality, climate changes and/or impacts, and adverse impacts to property and its values. The value of human life and environmental criteria is required to be equal in value to that used by other federal agencies. (0823-67 [Michetti, Susan])

Comment: Specific on-site independent rigorous assessments strictly using scientific analysis, methods, and practices are required at each reactor site to thoroughly identify each site's unique attributes and parameters identified in its specific physical location, size, and volume on planet earth to discover critical safety information that is impossible to discover with any generic conceptualization. Differentiated, tested, and measureable site attributes and parameters are required for each reactor site and for each storage site to quantify any "safety" claim. This is not a complete description of all variables to be assessed for safety. By inaccurately shifting actual physical location to a "generic" conception, information that belongs to the actual physical world but missing in the "generic" thought world introduces unacceptable distortions, or suppressions, of the actual facts. These distortions that arise from generic conceptualization convert all dependent assessments, conclusions, and rule-making into that which is unreliable, undependable, and untrustworthy. By definition, suppressed information does not qualify to be considered as open and transparent, rigorous, thorough scientific methods that can be peer-reviewed or studied by any academic. (0823-68 [Michetti, Susan])

Comment: This low prediction of fatalities does not compare with the huge quantities of stored spent fuel in each pool at San Onofre. According to a report authored by Robert Alvarez entitled "Reducing the hazards of high-level radioactive waste in Southern California" published by Friends of the Earth, if only 30% of one of the San Onofre spent fuel pools was released by a fuel pool fire, the resulting fall out dead zone could be more than 10 times the size of the Chernobyl accident resulting in a dead zone five times the size of the state of New Jersey, where people would never return to Southern California. In light of Mr. Alvarez's estimations of the impact of a spent fuel fire of one of the San Onofre spent fuel pools, the 55 Billion dollar economic impact stated in Draft NUREG-2157's Table F-1 would not even come close to the real estate losses of a successful terrorist aircraft attack on a San Onofre spent fuel pool. Yet alone the personal loss of time, economic loss of industrial production or the impact on the world economy. The NRC needs to be more realistic in their fatality predictions as a service to

the public and to begin to acknowledge the severe impact one fully fueled jet aircraft could have on our nation. (0826-24 [Morgal, Rick])

Comment: Because the WCD and the related TSR do not in themselves authorize individual licensing actions, the NRC need not consider alternatives to licensing, or renewing licenses for, nuclear power plants in this GEIS. A "no licensing" alternative is not reasonable under NEPA for the present rulemaking because that approach is beyond the scope of the proposed action (which does not involve licensing a plant) and would not serve the purpose of the proposed action. Although the Court of Appeals found the WCD rulemaking to be a major federal action, the TSR and WCD comprise just one element in the agency's NEPA analysis for operating licenses, combined licenses, and renewed licenses. Alternatives to specific proposed licensing actions (including "no action") are considered separately in site-specific environmental reviews for the particular proposed projects or proposed actions. (0827-1-10 [Ginsberg, Ellen])

Comment: With respect to the alternatives considered, NEI agrees that the "no-action" alternative is not preferred to the proposed action. No action would require the NRC to perform site-specific reviews of the issues identified by the Court. As discussed in Section 7.0 of the draft GEIS, repetitive reviews of continued storage issues would be time-and resource-intensive, and extremely inefficient. The environmental impacts of continued spent fuel storage can readily be resolved on a generic basis. The generic approach is also consistent with the Council on Environmental Quality (CEQ) guidance for achieving efficiency and timeliness under NEPA.⁴² [footnote 42 text: See Memorandum from N. Sutley, Council on Environmental Quality, to All Heads of Federal Department and Agencies, "Improving the Process for Preparing Efficient and Timely Environmental Reviews Under the National Environmental Policy Act" (March 6, 2012).] (0827-1-13 [Ginsberg, Ellen])

Comment: Although the GEIS-only alternative would provide limited additional efficiency when compared to the no action alternative, it would still leave open the issue for individual licensing actions. Hence, the environmental impacts of continued storage would be subject to site-specific consideration, and could be challenged by petitioners in individual cases without a waiver under 10 C.F.R. § 2.335. As discussed in the draft GEIS, the temporary storage issues can and should be resolved through a rulemaking. Furthermore, NEI agrees with the NRC that site-specific analyses of these impacts would likely not reveal any new information that cannot be addressed in a generic analysis.⁴³ [footnote 43 text: Draft GEIS at 7-10.] (0827-1-14 [Ginsberg, Ellen])

Comment: Should new and significant information arise for a particular site, it still could be presented in a petition under Section 2.335. (0827-1-15 [Ginsberg, Ellen])

Comment: The NRC's generic approach to the environmental review of a discrete set of issues common to all reactors will obviate duplicative and inefficient site-specific reviews of continued spent fuel storage issues. Certainly, as is discussed further below, the issue of the "no repository scenario" affects all sites similarly. The GEIS includes well-supported bounding analyses for these issues that encompass all reactor sites and operations.³⁵ [footnote 35 text: Bounding analyses have also been previously accepted for NEPA reviews. See, e.g., *Baltimore Gas & Elec. Co. v. NRDC*, 462 U.S. at 107; *Natural Res. Def. Council v. NRC*, 685 F.2d 459, 486 (D.C. Cir. 1982).] Moreover, no evidence has been presented that would require that potential spent fuel pool leaks or fires necessitate site-specific consideration. The GEIS includes well-supported bounding analyses for these issues that encompass all reactor sites and operations. (0827-1-7 [Ginsberg, Ellen])

Comment: There is not enough consideration for those site-specific issues which may be different at specific NWO sites. We expect explicit enumeration of issues that will need to be considered at each site to deal with site-specific issues. There is no section of this type, although throughout the document, you say that the situation may vary at each plant. All of these variances should be summarized in a list such that users of the GEIS will know exactly what areas they will likely need to resolve for their site-specific situation. For example, section 3.15 "Transportation" on 28 page 3-37 says in Lines 12-16 that "Local and regional transportation networks in the vicinity of nuclear power plant sites may vary considerably depending on the regional population density, location, and size of local communities, nature of economic development patterns, location of the region relative to interregional transportation corridors, and land surface features, such as mountains, rivers, and lakes." You go on to say that most have only one access road. We note that San Onofre has a 10-lane freeway going through the exclusion zone, however. Now, this is just one example where it is likely that the term "generic" does not encompass all situations, and the GEIS must be supplemented with a site-specific EIS to be complete. For this document to be most useful to practitioners and so that the public will know what issues actually DO vary (outside of the term "generic") these should be enumerated explicitly. (0836-14 [Davis, Anonymous])

Comment: We reject the notion that this GEIS can adequately address the needs of each specific site situation, and therefore, the assertion that 10 CFR 51.23 could be revised to "state that because the impacts of continued storage have been generically assessed in this draft GEIS and codified in a Rule, NEPA analyses for future reactor and spent fuel storage facility licensing actions would not need to separately consider the environmental impacts of continued storage."¹ [footnote 1 text: Waste Confidence Draft GEIS Page 1-5] -- NO! NEPA analyses must still occur because the GEIS addresses only GENERIC concerns! (0836-25 [Davis, Anonymous])

Comment: There is no enumeration of issues that are likely to need to be resolved on a site-by-site basis. This must be included. (0836-67 [Davis, Anonymous])

Comment: A generic answer covering all nuclear power plants cannot be found for a question so complex, diverse and dangerous. Concerns such as earthquake faults, proximity to oceans and waterways, etc. must be considered with each and every relicensing request. (0846-2 [Wells, Gerald])

Comment: Abandon the generic "one size fits all" approach to storing nuclear waste and instead, make site-specific environmental reports and recommendations that take local conditions into account. (0860-1 [Headrick, Gary])

Comment: Abandon the generic "one size fits all" approach and instead, make site-specific environmental reports and recommendations (0860-7 [Headrick, Gary])

Comment: We know that the risk of a serious problem at a nuclear reactor is small, but the consequences can be so severe that it would be dangerous and irresponsible to ignore them. I realize that the courts have ruled that it is acceptable to create a Generic Environmental Impact Statement; to me, this implies not a reactor in a perfect, low-population rural area, but considering a worst-case scenario-which Indian Point embodies in many ways. If-and it is a big IF-we can be confident about nuclear waste at Indian Point, then (and only then, in my opinion) can we be confident about nuclear waste at other nuclear power plants. (0864-2 [Gellert, Sally Jane])

Comment: The Mayor and City Council from City of San Clemente just recently adopted a Resolution on December 17, 2013 which resolves : "City of San Clemente appreciates information in 2013 Waste Confidence Generic Environmental Impact Statement, however City requests a site specific study be done for SONGS (San Onofre) that recognizes; a) the geographic conditions unique to SONGS, B) the dense population surrounding SONGS, and c) that SONGS is being decommissioned. City of San Clemente formally requests the Energy Department create a dry cask storage facility in an area remote from high populations areas to provide safe storage of nuclear waste. Once complete City of San Clemente requests that spent fuel rods stored onsite at SONGS be relocated to the repository as soon as it is safe to do so. City of San Clemente requests to be included in the SONGS decommissioning process, and also requests NRC to conduct a SITE SPECIFIC IMPACT STUDY at SONGS. San Clemente believes such a study would demonstrate the need for the accelerated removal of nuclear waste to a permanent repository." (0866-2 [Borchmann, Patricia])

Comment: Each site has unique geological, socio-political, geographic, environmental and epidemiological features. Moreover, each nuclear reactor has a unique construction and mechanical operation - not a generic design. (0869-4 [Homick, Nick])

Comment: Also, a generic EIR is crazy give that Diablo is underlain by multiple fault lines! Conditions vary from plant to plant. (0872-8 [Wilvert, Calvin])

Comment: THE GENERIC WASTE CONFIDENCE DRAFT IS A JOKE. YOU CAN'T HAVE A GENERIC DOCUMENT TO REPORT ON ALL NUCLEAR PLANTS. (0887-2 [Chappellet, Carissa])

Comment: DIABLE IN AN INDIVIDUAL CASE AND SHOULD BE LOOKED AT INDIVIDUALLY. (0887-3 [Chappellet, Carissa])

Comment: NRC's SFP leaks impact analysis violates NEPA and the Court's decision in *New York v. NRC* because the bounding parameters used by NRC are not broad enough to cover a number of site-specific concerns[.] Although the Court in *New York v. NRC* found that a generic analysis of environmental impacts of spent fuel storage may be appropriate, whether generic or site-specific, the analysis must be "thorough and comprehensive." *New York v. NRC*, 681 F.3d 471, 481 (D.C. Cir. 2012). The Court accepted the NRC's bounding assumptions in the 2010 waste confidence rule, considering them to be "conservative" and finding the risks associated with the waste confidence decision to be "essentially common." *Id.* at 480. However, in the DGEIS, the NRC fails to use conservative bounding assumptions and as a result, the NRC fails to fully consider several site-specific concerns.²⁴ [footnote 24 text: 24 Bounding estimates are especially important here, where in its proposed rule, NRC states that site-specific concerns regarding future reactor and SFP storage facilities cannot be brought up during individual licensing actions. See Waste Confidence- Continued Storage of Spent Nuclear Fuel 78 Fed. Reg. 56804 (Sept. 13, 2013) (amending 10 C.F.R. pt. 51); see also Proposed Regulation 10 C.F.R. § 51.23(b).] (0897-6-1 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: NRC's generic analysis of radioactive contamination in groundwater from spent fuel pool leaks is deficient because that issue is most appropriately addressed in a site-specific manner as explained in the recently finalized update to the License Renewal Generic Environmental Impact Statement. There, the NRC determined that impacts surrounding "radionuclides in groundwater" should be addressed as a site-specific, rather than generic basis because: This new Category 2 issue evaluates the potential contamination and degradation of groundwater resources resulting from inadvertent discharges of radionuclides into groundwater from nuclear power plants. Within the past several years, there have been numerous events at

power reactor sites which involved unknown, uncontrolled, and unmonitored releases of radionuclides into the groundwater. The number of these events and the high level of public controversy have made this issue one that the NRC believes needs a “hard look” as required by NEPA. *As a voluntary action, NEI 07-07 [Industry Ground Water Protection Initiative— Final Guidance Document; NEI 2007] cannot be enforced by the NRC.* As such, no violations can be issued against a licensee who fails to comply with the guidance in NEI 07-07. Furthermore, *the NRC cannot rely on a voluntary initiative as a basis to ensure that the nuclear power industry will have adequate information available for the NRC to determine whether a documented leak or spill does or does not have an adverse impact on groundwater resources.* Regarding the magnitude of impact, the NRC bases its determination of SMALL to MODERATE impact on a review of existing plants have had inadvertent releases of radioactive liquids. Even though the NRC expects impacts for all plants to be within this range, a conclusion of LARGE impact would not be precluded for a future license renewal review based on new and significant information if the data support such a conclusion. As reflected in the final GEIS and rule, “Radionuclides released to groundwater” remains a Category 2 issue. Generic Environmental Impact Statement for License Renewal of Nuclear Plants, at 1-24, NUREG-1437, Volume 1, Revision 1 (June 2013) (emphasis added).²⁵ [footnote 25 text: 25 Additionally, this provides another example of how NRC’s reliance on inappropriate, inapplicable, and voluntary programs fails to satisfy NEPA as discussed in Section VI.D.2.b of these comments. While in its June 2013 License Renewal GEIS, NRC found that reliance on a voluntary program could not serve as a basis for ensuring information will be available for NRC to determine whether a leak did or did not have significant impacts, here, in its waste confidence DGEIS, NRC relied on that exact same document to support the conclusion that leaks will not have significant impacts. See DGEIS at E-5–E-6. This is completely illogical and at a minimum, NRC must explain this discrepancy.] But here, in the DGEIS, NRC relies on that same voluntary initiative in support of its generic determination that SFP leaks will not cause significant impacts. DGEIS at E-5-E-7. NRC provides no explanation of why it deems the issue of radionuclides in groundwater site-specific in the license renewal context, but not in the waste confidence assessment of spent fuel pool leaks into groundwater and its generic treatment here is inconsistent with its recent License Renewal GEIS and illogical. (0897-6-2 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: And further, the NRC should have considered a number of other site-specific concerns that fall outside of its current bounding estimates. For example, it should consider SFP sites where multiple reactors and SFPs exist (e.g., Turkey Point nuclear plant in Florida). The NRC should have also considered SFP sites where other nuclear facilities or waste sites are in close proximity, such as Plant Vogtle and its proximity to the Savannah River Site. In addition, the NRC should have considered sites that are particularly vulnerable to flooding, such as the Oconee and Fort Calhoun nuclear plants. Dam Failures and Flooding at U.S. Nuclear Plants, Union of Concerned Scientists (October 2012); Perkins, Richard, et al., Screening Analysis Report for the Proposed Generic Issue on Flooding of Nuclear Power Plant Sites Following Upstream Dam Failures (July 2011). (0897-6-3 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Generally, in order to assess the probability of future SFP leaks, a consideration of site-specific factors is critical. For example, particular sites’ susceptibility to natural disasters including earthquakes, hurricanes, floods, etc., may affect the integrity of SFPs, and the probability that such events may occur can lead to or exacerbate existing SFP degradation and leaks. That is, NRC must take into account current information regarding seismicity in regions where nuclear power plants are located,²⁶ [footnote 26 text: In 2007, the NRC began examining new earthquake hazard information and found that various seismic hazard estimates have increased and required further analysis; NRC is currently continuing to update earthquake risk hazard estimates for U.S. nuclear power plants in light of newer information and seismic

models. See Generic Issue 199 (GI-199), Implications of Updated Probabilistic Seismic Hazard Estimates in Central and Eastern United States on Existing Plants: Safety/Risk Assessments, August 2010, ADAMS Accession No. ML100270639; Memo from P. Hiland to B. Sheron Re: Results of Safety/Risk Assessment of Generic Issue 199, September 2, 2010, ADAMS Accession No. ML100270598. Site-specific consideration of such new information and analyses concerning regional seismology and hazards posed therefrom is necessary for determining risks of future SFP leaks at particular nuclear power plants. For example, a study by Columbia University seismologists in 2008 concluded that the area surrounding the Indian Point nuclear plant was not, as previously thought, an area of low seismic activity, and that, in fact, it was “quite possible” the region could experience upwards of a 7.0 magnitude earthquake, which the owner of the plant has admitted Indian Point is not designed to withstand. See Lynn R. Sykes, John G. Armbruster, Won-Young Kim, & Leonardo Seeber, Observations and Tectonic Setting of Historic and Instrumentally Located Earthquakes in the Greater New York City–Philadelphia Area, *Bulletin of the Seismological Society of America*, Vol. 98, No. 4, pp. 1696–1719, August 2008; The Earth Institute, Columbia University, “Earthquakes May Endanger New York More than Thought, Says Study: Indian Point Nuclear Power Plant Seen as Particular Risk,” Press Release Posted on The Earth Institute website, August 21, 2008, available at, <http://www.earth.columbia.edu/articles/view/2235> (last visited December 13, 2012). Any such new information must be considered in relation to the risk of future SFP leaks at particular plants as waste is stored in such pools during post-operation timeframes.] as well as the most current scientific knowledge regarding sea level rise and other impacts of climate change, including the increased frequency of severe weather events that result in storm surges, flooding, and extended power outages that could compromise safe storage of spent fuel at reactor sites.²⁷ [footnote 27 text: See, e.g., NRC Event Notification Report #48452 for Oyster Creek (October 29, 2012), available at, <http://www.nrc.gov/reading-rm/doc-collections/event-status/event/2012/20121030en.html> (Notice of unusual event declared due to high intake structure water level).] Site-specific review related to these kinds of external circumstances is necessary since new information reveals such issues can be problematic and since different regions in the U.S. face different geological conditions and weather patterns. (0897-6-4 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Moreover, in relation to foreseeable impacts to surface waters from SFP leaks NRC should consider the following: the nature of the affected surface water (that is, is it an estuary that flows back and forth versus a static man-made pond?); the presence of nearby significant habitats and endangered species in surface waters affected by SFP leaks; the relevant status of the aquatic ecology in a given waterway, such as whether the waterway is already degraded or contains stressed fish populations, such as the Hudson River;²⁸ [footnote 28 text: For example, in the Hudson River, which is adjacent to the Indian Point nuclear facility, study has shown that 10 out of 13 critical fish species are in long-term decline, largely as a result of entrainment, impingement, and thermal impacts from power plant cooling water intake structures. See *The Status of Fish Populations and the Ecology of the Hudson*, Pisces Conservation Ltd., April 2008, available at, <http://www.riverkeeper.org/wpcontent/uploads/2009/06/Status-of-Fish-in-the-Hudson-Pisces.pdf>; NYSDEC Hudson River Power Plants FEIS (June 25, 2003), Public Comment Summary at 57, http://www.dec.ny.gov/docs/permits_ej_operations_pdf/FEISHRPP5.pdf. NRC must consider how long-term exposure to radiological contamination from SFP leaks may impact already troubled fish populations.] the degree to which already existing radiological contamination of surface waters resulting from prior SFP leaks may affect the level and degree of exposure to future SFP leaks; how site-specific susceptibility to severe weather events and earthquakes, may affect the behavior, fate, and effect of radiological contamination in surface waters resulting from future SFP leaks; and the degree to which radiological contamination of surface waters

“threatens a violation of Federal, State, or local law or requirements,” (40 C.F.R. § 1508.27(b); 10 C.F.R. § 51.71(d)) such as whether and the extent to which radiological contamination of surface waters results in violations of applicable state water quality standards adopted pursuant to the Clean Water Act or state environmental protection laws (including prohibitions and limitations on the discharge of radiological materials to State surface waters,²⁹ [footnote 29 text: For example, New York State law contains a provision that prohibits discharges of high-level radioactive waste as well as any discharges not permitted by NYS rules and regulations. See New York State Environmental Conservation Law § 17-0807(1), (4).] designated best usages of surface waters, and other established surface water standards.)³⁰ [footnote 30 text: For example, it is common for designated best usages established pursuant to the CWA to include recreational activities such as swimming, fishing, boating, etc.; in New York, the Hudson River directly adjacent to the Indian Point nuclear power plant has been designated as suitable for recreational activities, including swimming and boating; State standards require that the discharge of deleterious substances shall not impair the waters for such best uses. 6 NYCRR § 701.11; 6 NYCRR § 700.1(a)(49); 6 NYCRR 700.1(a)(56); 6 NYCRR § 703.2. NRC must consider the degree and extent to which future SFP leaks may interfere with such designated uses of impacted surface waters. In this regard, NRC cannot narrowly examine compliance with NRC dose limits; as such limits do not necessarily reflect the pathways of exposure contemplated by water protection standards. For example, at Indian Point, the plant owner only considers one exposure pathway, i.e., the consumption of fish and invertebrates from the Hudson River, when calculating NRC-doses. Entergy Nuclear Operations, Inc. (Indian Point Unit 1, 2, and 3 Nuclear Power Plants Docket Nos. 50-03, 50-247, and 50-286), Radioactive Effluent Release Report: 2010, at page 33 of 49, *available at*, ADAMS Accession No. ML11124A031 (“Liquid offsite dose calculations involve fish and invertebrate consumption pathways *only*”) (emphasis added). This fails to capture exposure resulting from recreational uses of the waterway.] (0897-6-5 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: In relation to foreseeable impacts to groundwater resources, NRC should consider site-specific factors as they bear upon the likely behavior, fate, and effect of radiological contamination plumes resulting from future SFP leaks, including the following: the varying geological landscapes underlying reactors and SFPs at different sites (e.g., the nature of the bedrock and the hydraulic gradient underneath and surrounding the site); the nature of nearby resources (including the presence of significant habitats and endangered resources); the degree to which already existing groundwater contamination resulting from past radiological leaks may affect the behavior, fate, and effect of any new groundwater contamination resulting from new SFP leaks; and how site-specific susceptibility to severe weather events and earthquakes, may affect the behavior, fate, and effect of radiological contamination plumes resulting from future SFP leaks. In addition, NRC must consider whether and the extent to which radiological groundwater contamination results in violations of applicable state water quality standards adopted pursuant to the Clean Water Act (“CWA”) or state environmental protection laws. See 40 C.F.R. § 1508.27(b); 10 C.F.R. § 51.71(d). This includes designated best usages of state groundwaters,³¹ [footnote 31 text: For example, the State of New York has designated the best use of the groundwater beneath the Indian Point nuclear power plant to be “as a source of potable water supply,” and requires that the discharge of deleterious substances shall not impair the groundwaters for such best uses. See 6 NYCRR § 701.18; 6 NYCRR § 701.15; 6 NYCRR § 703.2. This is regardless of whether such groundwaters are actually used for potable purposes.] and any other established groundwater standards. (0897-6-6 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Because NRC's bounding parameters are not broad enough to encompass a number of site-specific concerns NRC's DGEIS is insufficient. (0897-6-7 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: In license renewal cases, the NRC refuses to consider the no-action alternative, which includes energy conservation. 61 Fed. Reg. 28,467, 28,471-73 (June 5, 1996). Yet, as described in the Cooper Declaration, energy conservation may be more cost-effective than paying for spent fuel storage and disposal. But the NRC's regulatory system provides no method for evaluating the effects of spent fuel storage and disposal costs on the choice of the no-action alternative. (0897-7-14 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Impacts on river systems may be bounded by sites that are quite different in character. For instance, large scale dispersal of radioactivity from spent fuel storage at Prairie Island could create long-term damage to the entire Mississippi River system, including agricultural lands around it, cities that are vulnerable to flooding on its shores, barge traffic that is a major artery of commerce, and so on. Agricultural impacts alone may be bounded by sites like Fort Calhoun in Nebraska or Duane Arnold in Iowa. Such impacts would be especially important to evaluate in the case of long-term storage and indefinite storage accompanied by loss of institutional control. (0898-5-11 [Curran, Diane] [Makhijani, Arjun])

Comment: It is impossible to bound critical ecological impacts in a generic manner. They will require site specific discussion. For instance, the Calvert Cliffs reactors in Maryland are situated in one of the most sensitive and unique ecosystems of the United States – the Chesapeake Bay. The impacts of a major radioactivity release into the Chesapeake Bay ecosystem are likely to be quite different than those of a similar release at Turkey Point in Florida, which has barrier islands and Biscayne National Park a few miles away or Diablo Canyon, in California, where a major release could severely impact oceanic ecosystems. It is important to remember in this context that the inventory of long-lived radioactivity in spent fuel pools in the United States is generally far larger than that in Chernobyl Unit 4, which had a severe accident and radioactivity releases in 1986. It is essential for the waste confidence GEIS to analyze critical ecosystem impacts on a site specific basis unless it can classify sites based on types of ecosystems and address bounding impacts for similar sites. (0898-5-12 [Curran, Diane] [Makhijani, Arjun])

Comment: From the above examples, it is clear that the NRC should create a list of site-specific issues that are excluded from the purview of the GEIS and therefore could be brought up in individual licensing cases. In the alternative, it must show that it has bounded the impacts in a generic manner for each type of impact. This is especially important for long-term storage and indefinite storage with loss of institutional control. A GEIS must include bounding estimates for (i) the number of cancers attributable in case of a worst case release of radionuclides; (ii) the worst case damage to riverine ecosystems, such as the Mississippi River or the Columbia River; (iii) the worst case loss of agricultural land and production; (iv) the ecosystem damage to each unique ecosystem, including the Chesapeake Bay, the Mississippi River Delta, the Columbia River, and oceanic ecosystems, and (v) the worst case property damage. These evaluations should include not just today's source terms but the projected source terms based on the dates of the expiry of the licenses and the total accumulated spent fuel at that time. (0898-5-13 [Curran, Diane] [Makhijani, Arjun])

Comment: While some storage impacts can reasonably be addressed on a generic basis, there are many that cannot. At the very least, it is essential for the NRC to group incommensurate site-specific impacts by category, such as high population density areas,

reactors on rivers that could affect large populations living along those rivers, and so on. (0898-5-23 [Curran, Diane] [Makhijani, Arjun])

Comment: I have also concluded that it will be necessary to carve out a number of issues for site specific consideration unless the NRC considers groups of sites and specific types of impacts in this GEIS. No single generic analysis can cover the issues presented by indefinite storage onsite. The facts presented above are true to the best of my knowledge and the opinions contained herein represent my best professional judgment. (0898-5-29 [Curran, Diane] [Makhijani, Arjun])

Comment: THE EIS SHOULD ACKNOWLEDGE THAT CERTAIN IMPACTS CANNOT BE ANALYZED IN A GENERIC MANNER. (0898-5-5 [Curran, Diane] [Makhijani, Arjun])

Comment: The Draft GEIS claims to have considered site specific issues sufficiently to draw generally applicable conclusions regarding waste confidence so that such issues could not be brought up during reactor or specific storage facility licensing cases.¹³⁶ [footnote 136 text: NRC 2013a, p. xxiv] 9.2. I would agree that some impacts are generic and can, given adequate data, be bounded on that basis. This is the case, for instance, with the on-site impacts of transferring spent fuel from one cask to another. But other issues cannot be analyzed in a generic manner. This is because different kinds of impacts are incommensurate with each other. Therefore, it is necessary to have a bounding analysis for each major type of impact. I provide several examples in the following paragraphs. (0898-5-6 [Curran, Diane] [Makhijani, Arjun])

Comment: Take the example of the storage of spent fuel at the Columbia Generating Station in Washington State. A realistic analysis, including loss of institutional control, indicates that there would likely be catastrophic impacts that would contaminate Columbia River and its fish, including salmon. Indefinite storage would have devastating cultural and environmental justice impacts that could no longer be brought up for that site once a generic determination is made regarding the safety of indefinite storage. The tribes who have Columbia River-related rights would be precluded from bringing up the issue for any future new reactor or storage licenses or license extensions. The Draft GEIS does mention plants of special significance in the vicinity of the Prairie Island reactors, but provides no specific impact analysis in case of indefinite storage and dispersal of radioactivity or in case of severe accidents with high burnup failed spent fuel bundles. (0898-5-8 [Curran, Diane] [Makhijani, Arjun])

Comment: The U.S. Court of Appeals rejected the current Waste Confidence Rule noting that, after decades of failure to site a repository, the NRC "has no long-term plan other than hoping for a geologic repository." Therefore it is possible that spent fuel will be stored at reactor sites "on a permanent basis." The NRC must examine the environmental consequences of storing radioactive wastes at reactor sites into the indefinite future. The NRC Draft Generic Environmental Impact Statement (GEIS) relies on the fundamentally flawed assumption that all reactor sites are the same. On the contrary, they each have unique geographic, environmental, geological, climatic, and epidemiological considerations. The creation of a one-size-fits-all plan is scientifically invalid. (0908-1 [Mikkelsen, Sara])

Comment: People in our community feel that the spent fuel pools at Indian Point pose a grave risk to our health and safety. This assessment is backed up with solid scientific evidence from many sources. We do not understand how the NRC can conclude that a generic study can address the highly unique impacts of Indian Point. (0918-1 [Church of New York, The Riverside])

Comment: NRC's dismissive remarks about rural economies, at Page 3-4, line 17 and following, leaves a bad taste. After all, it was the local concerned farmer at Clinton, IL, who not only educated me about NRC's Nuclear Waste Con Game, but prompted NRC's meeting facilitator, Chip Cameron, to have to remind his colleagues about the policy's existence. Of course, the impacts of nuclear power - including, relevantly here, its forever deadly highlevel radioactive wastes - are of LARGE significance to agricultural areas of this country that have the dubious "honor" of "hosting" them - from Clinton, IL to Kewaunee, WI and many other sites. (0919-5-2 [Kamps, Kevin])

Comment: At line 23, NRC's describing the Indian Point, NY and Limerick, PA areas as "semi-urban" is puzzling? There are 21 million people within 50 miles of Indian Point! That is the most urbanized geographical area surrounding any nuclear power plant in the U.S.! And Limerick has some of the highest casualty figures on the CRAC-2 charts! Again, the 50 mile radius surrounding Limerick's two reactors, and on-site irradiated nuclear fuel storage facilities, is amongst the most urbanized areas in the entire country! By the way, CRAC-2 refers to Calculation of Reactor Accident Consequences. The report is also known as the 1982 Sandia Siting Study or as NUREG/CR-2239. I specify this, because at the Davis-Besse license extension oral argument pre-hearings held in Port Clinton, OH on March 1, 2011 (yes, ten days before the Fukushima Daiichi nuclear catastrophe was to begin), FirstEnergy Nuclear's attorneys, as well as NRC's attorneys and staff, as well as the ASLB panelists themselves, claimed not to know what CRAC-2 referred to. (0919-5-3 [Kamps, Kevin])

Comment: In some cases, the environmental impacts of continued storage can be addressed through a generic environmental impact statement (EIS). In other cases, there may be site specific environmental issues that are not adequately addressed by the Generic EIS. Therefore, the NRC should require the licensees to verify that the Generic EIS adequately addresses the environmental impacts of continued storage at their facility, and if that is not the case, require them to provide a supplement to the Generic EIS that addresses the site specific issues. (0920-1 [Foster, Ruth])

Comment: It is indicated that "If the proposed Rule is adopted, the site-specific NEPA analyses for future commercial power reactor and spent fuel storage facility actions would not need to consider the environmental impacts of continued storage." The problem with this statement is that environmental impacts are extremely site and even time specific. Also, demographics around a facility can change significantly from the time the plant was originally being licensed until even the first license renewal. (0920-11 [Foster, Ruth])

Comment: Lines 9 to 11 indicate that revising the Waste Confidence rule would provide the same level of protecting the environment as a site specific EIS would. This is difficult to accept since each facility's impact on the environment would be different depending on the local geology, physiography, ecology and area water use. Also over time climate change due to global warming can alter a regions' water use, storm frequency and, as sea level rises, there will be impacts on coastal and estuarine facilities. (0920-12 [Foster, Ruth])

Comment: According to NRC's proposed Waste Confidence rule as indicated on p. xxiv of Section ES.3 a " ... site-specific NEPA analyses for future commercial power reactor and spent fuel storage facility actions would not need to consider the environmental impacts of continued storage." This storage could be anywhere from 60 years after the end of the license and two license extensions (short term), to 160 years after the license extensions (long term) or possibly forever (indefinite). If the facilities are not required to consider any future impacts of continued storage on the environment then any new or better understanding of geology, aquifers or

ground water resources near and under the facility does not have to be considered. (0920-15 [Foster, Ruth])

Comment: This section [1.3, p. 1-5] implies that by use of this GEIS site specific consideration of continued storage of spent fuel, the environmental impacts will not have to be considered for any continued operation of the facility. They justify this by 40 years of generic considerations of continued storage in proceedings and by the operating experience of spent fuel storage and licensing dating back to the 1950's, which they say supports the assessment. According to Table G-1, the first two reactors went on line December 1, 1969, so essentially the operating experience of spent fuel storage did not start until 1970, not the 1950's. Also, due to the fact that 17% of the spent fuel pools already have developed leaks, continued storage is not just a simple issue that can be decided by a generic GEIS, especially since one of their main premises is that spent fuel pools do not leak. The impacts of leaks at an individual site depend on the local climate conditions, demographics, water use (both ground and surface) and the geologic interpretations for the facility and area. All these can and will change over the life of the facility. (0920-23 [Foster, Ruth])

Comment: Under a provision in the Nuclear Waste Policy Act of 1982, the NRC can approve ISFSI's under a nuclear plant's general operating license. This means even the nominal safeguards for protecting the environment and involving the public --normally required for licensing a nuclear facility --are done away with no site-specific study is required, no environmental impact statement (EIS) is made, and no adjudicatory public hearing process is allowed. The original EIS for the reactor itself-prepared decades earlier, long before ISFSI's were even envisioned--is relied upon for licensing the dry cask storage site. An environmental assessment is issued by the NRC which automatically finds no adverse impacts on the environment based upon the earlier EIS. (0929-8 [Kamps, Kevin])

Comment: Concerned citizens and community groups regard this "generic licensing process" as a meltdown of democracy. Michigan's Palisades nuclear plant was the first in the U.S. to receive the go-ahead from NRC to set up an ISFSI under the reactor's general operating license. In May, 1993 NRC allowed Consumers Energy Company to install a dry cask storage site on a sand dune identified by the Michigan Department of Natural Resources, the Army Corps of Engineers, and the University of Michigan as a "high risk erosion zone" just 150 yards uphill from the waters of Lake Michigan, the source of drinking water for tens of millions of people. Whereas the Palisades reactor itself is anchored to bedrock, its two dozen dry storage casks fully loaded with irradiated nuclear fuel (each one weighing 120 tons) sit on a three foot thick concrete storage pad, anchored to nothing but shifting sand. In early 1994, an NRC inspector stated "it's the consequences that might occur from an earthquake that I'm concerned about. The casks can either fall into Lake Michigan or be buried in the loose sand because of liquefaction." He concluded "It is apparent to me that NMSS [NRC's office of Nuclear Materials Safety and Safeguards] doesn't realize the catastrophic consequences of their continued reliance on their current ideology," the generic licensing process. Over a decade later, these concerns have not been addressed. NRC continues to generically license ISFSI's, rubberstamping nuclear utility applications at an accelerating rate. (0929-9 [Kamps, Kevin])

Comment: We reject the notion that this GEIS can adequately address the needs of each specific site situation, and therefore, the assertion that 10 CFR 51.23 could be revised to "state that because the impacts of continued storage have been generically assessed in this draft GEIS and codified in a Rule, NEPA analyses for future reactor and spent fuel storage facility licensing actions would not need to separately consider the environmental impacts of continued

storage."[Waste Confidence Draft GEIS] -- NO. NEPA analyses must still occur because the GEIS addresses only GENERIC concerns. (0930-1-18 [Lutz, Ray])

Comment: There is not enough consideration for those site-specific issues which may be different at specific NWO sites. We expect explicit enumeration of issues that will need to be considered at each site to deal with site-specific issues. There is no section of this type, although throughout the document, you say that the situation may vary at each plant. All of these variances should be summarized in a list such that users of the GEIS will know exactly what areas they will likely need to resolve for their site-specific situation. For example, section 3.15 "Transportation" on 28 page 3-37 says in Lines 12-16 that "Local and regional transportation networks in the vicinity of nuclear power plant sites may vary considerably depending on the regional population density, location, and size of local communities, nature of economic development patterns, location of the region relative to interregional transportation corridors, and land surface features, such as mountains, rivers, and lakes." You go on to say that most have only one access road. We note that San Onofre has a 10-lane freeway going through the exclusion zone, however. Now, this is just one example where it is likely that the term "generic" does not encompass all situations, and the GEIS must be supplemented with a site-specific EIS to be complete. For this document to be most useful to practitioners and so that the public will know what issues actually DO vary (outside of the term "generic") these should be enumerated explicitly. (0930-1-7 [Lutz, Ray])

Comment: There is no enumeration of issues that are likely to need to be resolved on a site-by-site basis. This must be included. (0930-3-19 [Lutz, Ray])

Comment: The idea that the GEIS can be proposed as a GENERIC plan is absurd to begin with. Several plants in the NE and New York State area each have problems unique unto themselves. At Seabrook in New Hampshire, there is concrete degradation and perhaps not occurring in other places because of the type of concrete that is used (and there the corporate owners applied for a license renewal in 2012 from 2032, when it is set to expire, to 2052!). At Vermont Yankee in Vernon, VT there has tritium leaking for years and years, at Plymouth NPS, the water temperature of the Cape Cod Bay increase necessitated the plant be shut for days and the numerous plant shutdowns heads the list of number of unplanned shutdowns in the U.S. It was also cited as the second highest chance of earthquake occurrence in the U.S. This an example of another factor that has changed with the passing years of improved technology and geology study. (0933-6 [Anonymous, Janet])

Comment: So, how can we ever capture one moment in time with something called a Generic Environmental Impact Statement, and presume that it will capture what is happening in this ever-changing reality? Every reactor site is unique. If they were to drop one cask out at Zion, you could punch a hole in the bottom of the pool. It would partially drain and, in a worst-case scenario, set fuel on fire in a few hours in an order of magnitude greater than Chernobyl. These are catastrophic risks and we cannot address them through the absurdity of a generic impact statement. And these are site-specific impacts in this very densely populated area that we need to take into consideration as we make our future plan. (0934-3 [Lewison, Linda])

Comment: A Generic EIS is inherently ridiculous when one considers not only that each nuclear power facility and radwaste storage area is in a unique geographical, seismic, hydrologic, demographic, and other settings. Not only should there be thorough real world analysis of licensing actions at individual nuclear power facilities by developing a sufficient EIS for each of them, but these studies must also evaluate various options for storing fuel onsite and

beyond the site (including the complications involved with "high burn-up fuel"). (0937-10 [Campbell, Bruce])

Comment: Thus, the No-Action Alternative (Alternative 1) is the only alternative which appears that it may involve a thorough analysis before the NRC acts again with their well-worn "rubber-stamp" to approve various licensing actions at nuclear power facilities. This is the one sensible alternative offered which could actually involve adequate analysis of real world situations and alternatives. The "No Action Alternative" reads: "The NRC would take no action to generically address the environmental impacts of continued storage in individual, site-specific license reviews." (0937-11 [Campbell, Bruce])

Comment: Returning to the point mentioned under "E." in regards to UNIQUENESS of nuclear power facilities in the USA. Certainly each site at which there is a nuclear reactor and/or radwaste is unique. Yet in the USA, there are no cookie-cutter nuclear power facilities. There are many different configurations of nuclear power facilities (even if there is a similar type of reactor installed as at other sites) in the USA. Thus, it defies logic to claim that any sort of generic determination can be made when we are referring to uniquely sited facilities as well as unique facility determination and equipment being used. (0937-13 [Campbell, Bruce])

Comment: Let's examine the claim on page xxiv of the WC Generic EIS that, "The NRC considers the continued storage of spent fuel a generic activity that is similar for all commercial nuclear plants and storage facilities." How many licensed NRC facilities have received permission to store a greater concentration of radioactive waste than was originally intended? How many of these (and how many others) have their radwaste situation complicated by "high burn-up fuel"? Thus, there are many differences in radwaste storage configuration and timing (such as timing of putting some radwaste in dry casks, so the NRC's conclusion defies logic and, once again, is designed to help this highly toxic and beleaguered industry. (0937-14 [Campbell, Bruce])

Comment: Thus, the No-Action Alternative is the only alternative which could possibly involve sufficient analysis of alternatives for radwaste storage -- through site-specific EISs of individual nuclear reactor and radwaste storage sites. (0937-19 [Campbell, Bruce])

Comment: The GEIS risk analysis is not credible or adequate -- both in regards to "generic" risk and failures to differentiate between different sites even in regards to such basics as geography, seismicity, and proximity to large population centers and vital agricultural regions. It strains common sense that there appears to be no distinction drawn in the WC Generic EIS document between spent fuel in a region with millions of people in the immediate region versus the spent fuel being stored or permanently repositied / deposited at a site quite remote from population centers. (0937-23 [Campbell, Bruce])

Comment: Clearly there is not serious analysis of alternatives that could help contend with radioactive wastes in the real world. So, since this document is so vague and does not offer a reasonable range of alternatives, thus we need the more site-specific documents for a licensing action to be very thorough. Unfortunately, both the Nuclear Energy Institute (in their advice to the NRC during scoping comments for this Generic EIS) and the NRC have left open the possibility that such site-specific documents would be relatively skimpy Environmental Assessments rather than the often more thorough (in many cases -- yet this Generic EIS is neither thorough in analysis nor in offering a reasonable range of alternatives). (0937-7 [Campbell, Bruce])

Comment: The Waste Confidence Generic EIS has insufficient analysis and offers a pathetic range of alternatives, so this document was be seriously re-written in a "real world" way which offers a reasonable range of alternatives as NEPA calls for. So, not only do we need an adequate rather than this joke of a Waste Confidence Generic EIS, but all site-specific documents seeking nuclear licenses and permits need to go through the more thorough EIS process rather than merely undertaking an Environmental Assessment on these situations. (0937-9 [Campbell, Bruce])

Comment: All nuclear reactors and reactor sites are not created equal. A generic environmental impact statement for evaluating waste and waste storage at all reactors is an irresponsible and unscientific response to the challenges posed by long-term irradiated waste storage. Each reactor site has its own unique environment. Site issues can range from being close to large population centers, being in a flood plain and having seismic issues. A generic EIS cannot be a true picture of the impacts of the waste generation and storage of highly radioactive spent fuel. Because NRC generically ruled it had confidence that there would be a solution for high level nuclear waste, the dangers were never allowed to be considered at each site. (0938-12 [Sondheim, Steven])

Comment: And because environmental impacts are shown as "generic," no distinction is made of added risks at sites such as San Onofre that are in earthquake and tsunami zones on small and valuable pieces of land near major population centers and transportation corridors. (0944-6 [Pascall, Glenn] [Watland, George])

Comment: Overall, the proposed NRC Statement underrates risks at all sites, blurs or eliminates the fact of higher risk at some sites, and seeks to walk away from the search for less hazardous sites. (0944-8 [Pascall, Glenn] [Watland, George])

Comment: Abandon the generic "one size fits all" approach to storing nuclear waste and instead, make site-specific environmental reports and recommendations that take local conditions into account. (0947-1 [Abbott, Sandra] [Anonymous, Anonymous] [Anonymous, Jill] [Bandfield, Gary] [Bennett, Mary] [Clancy, Stephan] [Clig, George] [Evans, Michael W.] [Faunce, Stephanie] [Ferreira, Raul] [Foster, William] [Hafer, Sarah] [Kalama, Laura] [Pratt, Curtis] [Turner, D] [Van Leekwijck, Natalie] [Wigglesworth, Marilyn] [Yarrobino, Erin])

Comment: The U.S. Court of Appeals rejected the current Waste Confidence Rule noting that, after decades of failure to site a repository, the NRC "has no long-term plan other than hoping for a geologic repository." Therefore it is possible that spent fuel will be stored at reactor sites "on a permanent basis." The NRC must examine the environmental consequences of storing radioactive wastes at reactor sites into the indefinite future. The NRC Draft Generic Environmental Impact Statement (GEIS) relies on the fundamentally flawed assumption that all reactor sites are the same. On the contrary, they each have unique geographic, environmental, geological, climactic, and epidemiological considerations. The creation of a one-size-fits-all plan is scientifically invalid. (0951-1 [Commenters, Multiple])

Comment: I was an outreach/education specialist working for the Washington State Department of Health in a cooperative agreement partnership with the Agency for Toxic Substances and Disease Registry for five years. I specialized in fish advisories. If radioactive waste leaks into the Columbia River it will be an environmental disaster of epic proportions. The impact on human health and the fishing industry will run into billions of dollars. Please heed this message. Future generations are counting on you. (0993-2 [Henning, Marcia])

12. Comments Concerning Alternatives – GEIS Only

Comment: I am speaking almost exclusively to the third point that was made by the court of the need to evaluate the environmental effects of failing to secure permanent disposal. I'm very specifically addressing that. And I have an opinion about the alternatives, whether or not that the GEIS would be useful in creating a framework for scoping, and for addressing site-specific long-term storage issues. I'm confused about the fact that the GEIS-only alternative appears to do this but is named GEIS-only alternative. I have an enormous number of questions about this, but I think that a positive use of the GEIS process would be to begin to scope and establish some very essential parameters for addressing -- for responsible waste storage. (0328-12-2 [Eide-Tollefson, Kristen])

Comment: This comment supports the GEIS-Only Alternative for the following reasons: • It would not become part of the Waste Confidence rule, but would be used as a guidance document to support site specific license review; • This may prevent the GEIS from becoming an impediment to rational decision-making and effective planning and implementation of mitigation strategies; • It does not prevent the filing of contentions; • The GEIS findings and conclusions would remain open to challenge in site-specific review. • It would provide a middle ground of efficiency in review. Given the uncertain future of nuclear waste storage this alternative is a middle ground, that would allow for common features of analysis to be addressed by the GEIS, but would not inappropriately prejudice or bind site specific concerns to the conclusions of the GEIS. In addition, the GEIS-Only alternative would mean that the document would remain a tool, not a rule. This is appropriate, again, given the uncertainty of the future of nuclear waste storage. (0820-12 [Eide-Tollefson, Kristen])

Comment: COPS supports only the GEIS-only alternative, and require that any NWO that is to extend licensing past the decommissioning period of 60 years, must first accomplish a license amendment process, if not before. WE DO NOT SUPPORT THE NOTION THAT THESE ARE SAFE ENOUGH FOR USE AFTER THE 60-year DECOMMISSIONING PERIOD! (0836-26 [Davis, Anonymous])

Comment: Section 7.4 GEIS-Only Alternative. COPS supports ONLY this option, and than only for the short-term (decommissioning time) for each plant. This GEIS should not be used to allow unlimited and permanent ISFSI operation! (0836-63 [Davis, Anonymous])

Comment: COPS does not support a policy-statement approach, which will, without any site-specific review, hearing or study, allow NWOs to 4 persist on a permanent basis. We support only the use of a GEIS-Only alternative, and that, we support he approval of the use of co-located NWOs ONLY FOR THE SHORT TERM (60-year) decommissioning period. At that point, the canisters should be transported off-site to either a below- ground deep geologic repository or a surface repository in lower-risk areas, and allow plants to fully decommission and remove all traces of the ISFSI, and then return any balance of decommissioning funds to ratepayers. (0836-65 [Davis, Anonymous])

Comment: COPS supports only the GEIS-only alternative, and require that any NWO that is to extend licensing past the decommissioning period of 60 years, must first accomplish a license amendment process, if not before. WE DO NOT SUPPORT THE NOTION THAT THESE ARE SAFE ENOUGH FOR USE AFTER THE 60-year DECOMMISSIONING PERIOD. (0930-1-19 [Lutz, Ray])

Comment: Section 7.4 GEIS-Only Alternative. COPS supports ONLY this option, and than only for the short-term (decommissioning time) for each plant. This GEIS should not be used to allow unlimited and permanent ISFSI operation. (0930-3-15 [Lutz, Ray])

Comment: We support only the use of a GEIS-Only alternative, and that, we support the approval of the use of co-located NWOs ONLY FOR THE SHORT TERM (60-year) decommissioning period. At that point, the canisters should be transported off-site to either a below-ground deep geologic repository or a surface repository in lower-risk areas, and allow plants to fully decommission and remove all traces of the ISFSI, and then return any balance of decommissioning funds to ratepayers. (0930-3-17 [Lutz, Ray])

Comment: It is sad that page xxv of the Executive Summary under "2. The GEIS-Only Alternative" leaves the door open for more skimpy Environmental Assessments rather than thorough site-specific EISs on licensing reviews. (0937-21 [Campbell, Bruce])

13. Comments Concerning Alternatives – Policy Statement

Comment: Therefore, Utah strongly recommends that the Commission proceed according to the Draft GEIS proposed "policy alternative" - by issuing a policy statement that the finding of the GEIS could be incorporated into the environmental reviews of future licensing actions. Staff acknowledges that If the matter is truly a generic issue that the GEIS has adequately addressed, then, the GEIS could be incorporated into a site specific licensing proceeding.⁹ [footnote 9 text: Draft GEIS at 1-6] By proceeding with a policy statement, instead of a rule, the decision whether an environmental impact is truly generic will consider site specific licensing facts. While a party with standing may still file a contention raising a generic issue, Commission and licensing board case law and precedence would eliminate the rehearing of truly generic issues. Importantly, whether an issue is in fact generic would be considered along with site specific information and not be presupposed years, if not decades, in advance. Under a policy alternative, the Commission, indeed, will still achieve its desired goal of improving the efficiency of licensing proceedings if the issues are truly generic. (0579-4 [Smith, Amanda])

Comment: Lastly, the policy statement alternative, like the no-action alternative, would be inefficient in that it also would necessitate costly and time-consuming site-specific reviews. Therefore, NEI supports the recommendation in Section 8.7 of the draft GEIS that the proposed action - a rulemaking accompanied by a GEIS - is the preferred alternative. (0827-1-16 [Ginsberg, Ellen])

Comment: COPS does not support the "Policy-statement alternative," as described above, due to the fact that this circumvents site-specific public oversight, and assumes incorrectly, that a generic EIS is sufficient to deal with site-specific issues, which abound (but you conveniently forget to enumerate and acknowledge exist). (0836-27 [Davis, Anonymous])

Comment: COPS does not support the "Policy-statement alternative," as described above, due to the fact that this circumvents site-specific public oversight, and assumes incorrectly, that a generic EIS is sufficient to deal with site-specific issues, which abound (but you conveniently forget to enumerate and acknowledge exist). (0930-2-1 [Lutz, Ray])

Comment: COPS does not support a policy- statement approach, which will, without any site-specific review, hearing or study, allow NWOs to persist on a permanent basis. (0930-3-22 [Lutz, Ray])

Comment: The 3rd and last of the alternatives offered in the WC Generic EIS is "3. The Policy Statement Alternative" and is quite disturbing. It appears that the nuclear industry wants to leave the door open for an option where the inadequate joke of the environmental impact analyses in this generic EIS document can be incorporated into site-specific NEPA documents in order to avoid a more thorough site-specific evaluation. (0937-22 [Campbell, Bruce])

14. Comments Concerning Alternatives – Considered but Eliminated

Comment: One obvious and reasonable alternative that must be considered in the GEIS is dry cask storage as an option to storage in spent fuel pools. Although Staff may believe there is no environmental impact difference between spent fuel that is closely packed and stored in pools and spent fuel that is placed in dry cask storage once it is 5 years old, there is ample and technically competent disagreement with that conclusion. See, e.g., Robert Alvarez, Jan Beyea, Klaus Janberg, Jungmin Kang, Ed Lyman, Allison Macfarlane, Gordon Thompson, Frank N. von Hippel, *Reducing the Hazards from Stored Spent Power-Reactor Fuel in the United States* (Science and Global Security, 11:1-51, 2003)³ [footnote 3 text: This article was cited in a filing in these proceedings. See Comments by Alliance for Nuclear Accountability, et. al. (Jan. 2, 2013), Declaration of 2 January 2013 by Gordon R. Thompson: Recommendations for the US Nuclear Regulatory Commission's Consideration of Environmental Impacts of Long-Term, Temporary Storage of Spent Nuclear Fuel or Related High-Level Waste, Appendix A.]; Robert Alvarez, *Spent Nuclear Fuel Pools in the U.S.: Reducing the Deadly Risks of Storage* (Institute for Policy Studies, May 24, 2011). (0001-17 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: Petitioners [The State of Vermont with the Vermont Department of Public Service, the State of Connecticut, the State of New York, and the Commonwealth of Massachusetts] request that the Commission reverse the following errors that were made in the Staff Scoping Decision: Refusing to consider the alternative of requiring dry cask storage of spent fuel rather than continued use of spent fuel pools for spent fuel that is more than 5 years old. (0001-2 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: Another obvious and reasonable alternative that must be addressed in the GEIS is the option of not allowing additional spent fuel to be generated until a permanent, safe, and adequate nuclear waste disposal facility exists.⁴ [Footnote 4 text: [T]his alternative should be analyzed for all plants that are not yet licensed, that are up for relicensing, or that received operating licenses or license extensions on or after December 23, 2010, when the Commission formally abandoned the position that it could establish a date by which a permanent nuclear waste repository would be available. See 75 Fed. Reg. 81032.] The alternative of ceasing generation of additional spent nuclear fuel until a permanent, safe, and adequate nuclear waste disposal facility exists is not only a "reasonable alternative" that must be analyzed to meet the requirements of 40 C.F.R. § 1502.14(a), but is also required by 40 C.F.R. § 1502.14(d), which states that agencies such as NRC must include in their environmental analysis "the alternative of no action." The "no action" alternative must be analyzed before NRC can license the generation of additional spent nuclear fuel (and the resulting environmental impacts of such additional generation) at any nuclear facility. Because the GEIS is intended to support the environmental review of licensing actions and license renewal actions regarding environmental impacts of storing spent nuclear fuel, NEPA mandates that NRC examine the cessation of further generation of spent fuel until a permanent, safe, and adequate nuclear waste disposal facility exists. Indeed, the D.C. Circuit has already identified this alternative as a reasonable one by noting that it may be unreasonable to do anything else: "The lack of progress on a permanent repository has caused considerable uncertainty regarding the environmental effects

of temporary SNF storage and *the reasonableness of continuing to license and relicense nuclear reactors.*" *New York*, 681 F.3d at 474 (emphasis added). (0001-24 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: Petitioners [The State of Vermont with the Vermont Department of Public Service, the State of Connecticut, the State of New York, and the Commonwealth of Massachusetts] request that the Commission reverse the following errors that were made in the Staff Scoping Decision: Refusing to consider the alternative of not allowing further production of spent fuel until NRC determines that there is a safe and environmentally acceptable permanent waste repository to receive the additional spent fuel—a consideration that the U.S. Court of Appeals for the D.C. Circuit explicitly recognized to be reasonable in *New York v. NRC*, 681 F.3d 471, 474 (D.C. Cir. 2012). (0001-3 [Griffin, William] [Sipos, John] [Snook, Robert] [Springer, Darren])

Comment: [T]he EIS should consider the option of not making any nuclear waste at all in the future by comparing the environmental footprint of nuclear from mining to long term waste disposal to that of renewables and energy efficiency. (0003-5 [Commenters, Multiple])

Comment: I really would like to see this Environmental Impact Statement looking at alternatives, alternatives like not making the waste at all. (0030-12-11 [March, Leslie])

Comment: I'm asking that the EIS thoroughly discuss spent fuel impacts for each reactor, following NEPA by considering alternatives for creation of future waste, including the alternative to continue the moratorium on relicensing and licensing reactors with the goal of phasing out all reactors by 2020 or sooner. If the Germans can do it, we can. (0030-12-5 [March, Leslie])

Comment: The EIS needs to look at renewables and energy efficiency as being an alternative to creating more nuclear waste. (0030-12-7 [March, Leslie])

Comment: As the Agency has consistently clarified, several people have mentioned today the waste confidence rulemaking is not a licensing decision, does not authorize construction or operation of nuclear power plants or the continued storage of used fuel at any specific site. Importantly the staff has correctly concluding that stopping nuclear reactor licensing or operations is not an alternative required to be addressed under NEPA in the waste confidence proceeding. It's not an alternative that serves the purpose of the present rulemaking, which are: (1) To improve the efficient of the NRC licensing actions through generic consideration of environmental impacts of continued storage; (2) to capture the review in a single comprehensive document; and (3) to respond to the court's remand. Consideration of halting reactor licensing or operation wouldn't further the NRC's ability to consider analyzing the environmental impacts of extended storage of used fuel at or away from reactor sites, nor does it necessarily reflect the environmental benefits of continued operation of nuclear power plants. (0030-16-2 [Bonanno, Jerry])

Comment: Unless and until permanent isolation of existing radioactive waste from the biosphere has been demonstrated, there should be no confidence in licensing waste production and the NRC should stop licensing new reactors and relicensing old ones. The NRC does not have the authority to license making more waste until it has proven that the waste can be isolated from the environment. We have no current working process to isolate or remove radioactive waste at all levels of our environment. The NRC is too closely involved with the nuclear industry to make an objective decision regarding waste generation. There should be no more licensing or relicensing of nuclear reactors until the permanent disposal of radioactive waste becomes a proven reality. Why should we condone continued licensing of new reactors

and renewing licenses from old reactors while we're facing the dilemma of not being able to safely dispose of 70,000 metric tons of commercial high-level waste already generated and the 2,000 metric tons being produced each year by the nuclear power reactors in the United States? The EIS should consider and analyze the option of not generating any additional waste. It should consider and evaluate phasing out nuclear reactors in the near future. Creating additional waste when there is no identifiable solution for its permanent disposition cannot be justified. There are other methods of generating electricity that do not generate radioactive waste. (0030-21-2 [Carberry, Mike])

Comment: Finally, the EIS should consider the option of not making any nuclear waste at all in the future by comparing the environmental footprint of nuclear from mining to long term waste disposal to that of renewables and energy efficiency. (0039-8 [Littlejohn, Nick])

Comment: The EIS needs to look at renewables and energy efficiency as being an alternative to creating more nuclear waste. (0045-11-10 [March, Leslie])

Comment: I am asking that the EIS thoroughly discuss spent fuel impacts for each reactor, follow an EPA by considering alternatives for creation of future waste including the alternative to continue the moratorium on re-licensing and licensing reactors with the goal of phasing out all reactors by 2020 or sooner. (0045-11-8 [March, Leslie])

Comment: We must look at the option of NOT generating any additional waste. We must evaluate phasing out nuclear reactors in the near future. (0065-2 [Payne, Gail])

Comment: Unless and until permanent isolation of existing radioactive waste from the biosphere has been demonstrated, there should be no confidence in licensing waste production, and the NRC should stop licensing new reactors and relicensing old ones. The NRC does not have the authority to license making more waste until it is proven that the waste can be isolated from the environment. We have no current working process to isolate or remove radioactive waste of all levels from our environment. The NRC is too closely involved with the nuclear industry to make an objective decision regarding waste generation. There should be no more licensing or re-licensing of nuclear reactors until the permanent disposal of radioactive waste has been determined, proven and funded. Why should we condone continued licensing of new reactors and renewing licenses from old reactors while we are facing the dilemma of not being able to safely dispose of the 70,000 metric tons of commercial high level nuclear waste already generated and the ~ 2000 metric tons being produced each year by nuclear power reactors in the US? The EIS should consider and analyze the option of not generating any additional waste. It should consider and evaluate phasing out nuclear reactors in the near future. Creating additional waste when there is no identifiable solution for its permanent disposition cannot be justified. Any EIS regarding nuclear waste storage must first and foremost consider alternatives to nuclear waste generation. There are other methods of generating electricity that do not generate radioactive waste. (0072-1 [Black, Ryan])

Comment: Nuclear plants are deadly. Considering the problem with the plant in Japan and that a number plants here in the United States use the same system, we are placing thousands of people in harms way. The cost of nuclear plants from the subsidies to build them, damage to the environments where the material is mined, cost of transportation, disposal of waste to the decommissioning of these reactors need to be compared to less dangerous alternative energy sources such as solar and wind. We do need to transition from fossil fuels and lets do so with a system that cost less and is safe for our communities. (0110-2 [Wolf, Ann])

Comment: I think NRC, at least, should implement a rule to nuclear power plant operators that unless the operators are capable of moving their spent fuel into dry casks from fuel pools, they cannot operate the reactors. (0141-1 [Tonohira, Yuko])

Comment: Any EIS regarding nuclear waste storage must first and foremost consider alternatives to nuclear waste generation. Creating additional waste when there is no identifiable solution for its permanent safe storage is not justified. (0143-4 [Arauz, Jorge])

Comment: [T]he first one is that this is an environmental review that the court ordered the NRC to do under -- under what's called NEPA. And when you do an environmental review under this Federal Law, you're supposed to look at the action that's taken, and here the action is how do we look at the -- look at the storage of nuclear waste and how do we allow licensing and nuclear reactors and the re-licensing of reactors like Indian Point to continue while this waste piles up with no solution in sight. The most obvious alternative to that, and they have to look at a whole range of alternatives, is to stop producing waste. (0163-2-3 [Musegaas, Philip])

Comment: Finally, the EIS should consider the option of not making any nuclear waste at all in the future by comparing the environmental footprint of nuclear from mining to long term waste disposal to that of renewables and energy efficiency. (0198-6 [Cerrito, Robert])

Comment: Require a low-density, open-frame layout for fuel pools: Fuel pools were originally designed for temporary storage of a limited number of irradiated fuel assemblies in a low density, open frame configuration. As the amount of waste generated has increased beyond the designed capacity, the pools have been reorganized so that the concentration of fuel in the pools is nearly the same as that in operating reactor cores. If water is lost from a densely packed pool as the result of an attack or an accident, cooling by ambient air would likely be insufficient to prevent a fire, resulting in the release of large quantities of radioactivity to the environment. A low density, open-frame arrangement within fuel pools could allow enough air circulation to keep the fuel from catching fire. In order to achieve and maintain this arrangement within the pools, irradiated fuel must be transferred from the pools to dry storage within five years of being discharged from the reactor. (0222-15 [Zeller, Lou])

Comment: The NRC's generic approach to the environmental assessment and rulemaking remains utterly inadequate to satisfy the requirements of both the Atomic Energy Act and the National Environmental Policy Act for the licensing decisions necessary for nuclear power plants. And the Commission fails to give due consideration to the alternative of shutting down nuclear plants and not producing any additional radioactive waste, an approach now taken by other advanced industrial nations. (0222-22 [Zeller, Lou])

Comment: In fact, within the context of the DGEIS, the most practicable alternative for preventing or mitigating high-level nuclear waste storage impacts is the cessation of further reactor licensing. (0222-9 [Zeller, Lou])

Comment: I recommend the Energy Reader, an anthology of informative and academic writings on energy and society, edited by Laura Nader. This tome elucidates many of the complex issues surrounding energy production and would be a fantastic resource to utilize when considering energy policy. Finally, the EIS should consider the option of not making any nuclear waste at all in the future by comparing the environmental footprint of nuclear throughout the production chain--from mining to long term waste disposal--to that of renewables and energy efficiency by design. These technologies already exist--and should be promoted, utilized and further developed. Let's make the United States the leader and envy of the world, by becoming

the most sustainable, and sustainably profitable country in the world. Imagine the possibilities: re-making our country to be efficient and ecologically sustainable is an enormous project that would generate countless jobs and billions of dollars. Many small start up companies are already innovating green product and service solutions-and this is a fast growing sector of the economy. Taking a stand on nuclear would send a clear message: the future has arrived, we will no longer stay the course with policies and technologies that are sending us into environmental disaster. Send the social and market signal that the time for green innovation and green bottom-lines, is here. (0241-4 [Nixon, Kerry])

Comment: The NRC should stop licensing new reactors and relicensing old ones until it has proven that the waste can be isolated from global ecosystem with long-term storage and sites secured. Only then can we truthfully express and experience waste confidence. The methodology by which our current society generates electricity must be managed in a responsible manner with health and stability of future generations in mind. NRC has the purpose and the responsibility of protecting public health. The NRC should provide clear, focused, site-specific analysis of nuclear plants as it determines adequate storage methods for spent fuel. (0244-14-12 [Prescott, Lisa Marie])

Comment: Should NRC be licensing and relicensing plants based on their grossly inadequate GEIS? The answer is a resounding NO! They must not be allowed to just say they are confident that waste will be safely stored without any basis in fact. NRC's response in their GEIS is not any better than their past position of just stating they were confident that waste could be safely stored. I don't feel safe. (0245-15-4 [McComb, Sandy])

Comment: It's not that I'm in favor of these things but I'm supportive of these alternatives. The first one is to implement dry spent fuel storage in hardened onsite casks, which was mentioned earlier. Immediate efforts should be made to transfer spent fuel sufficiently cooled from wet pool storage to onsite at-reactor dry storage and so-called hardened casks. This approach would avoid the need to have additional away-from-reactor interim spent fuel installations. And as recommended by Dr. Arjun Makhijani, the Federal government should purchase land adjacent to reactor sites to accommodate this process. (0245-29-1 [Shineflug, Marilyn])

Comment: It really is that simple. If you can't transform it, don't produce it. Radioactivity from atomic power will pose a threat to life on the Earth for the next million years. We are confident that NRC and the waste generators can never contain this waste for as long as it poses a hazard. But to continue making more of it is not just insane, it is irresponsible and should be illegal. NRC must abandon its waste confidence policy and stop using it to license nuclear power plants. There is no safe dose of radiation and to pursue licensing it on the basis of waste confidence is immoral. (0245-37-5 [Bilenko, Stephanie])

Comment: Without a waste solution, like everybody else has said, I oppose the creation of more nuclear waste. I see few in this room who will be around to fulfill the promises to replace casks in the 60 or 100 years, let alone 250,000 years. I've seen promises to protect the public abandoned in the face of extreme events, like the increasingly extreme weather events we can expect or more frequently -- gives me pause. NRC should stop jeopardizing future citizens without their consent and should not be allowed to issue new licenses or extensions. (0245-46-3 [Craig, Evan])

Comment: One of the things, when you look at engineering projects, and this is fundamentally what the argument here is, that we can engineer our way out of this issue. And as was stated before, in any engineering project there's a number of assumptions when you build something

to a particular set of specifications. And I think that with this particular issue, you can't set the assumptions at a point that's strong enough for us to have confidence that you could come up with, really, a solution that would justify keeping new plants being licensed. (0245-8-2 [Fox, Rick])

Comment: So the real issue here is whether or not to license new reactors, to extend the licenses of old reactors, and the preferred alternative in this EIS should be stop licensing reactors, stop making high-level radioactive waste, for which there is no solution. (0246-32-3 [Kamps, Kevin])

Comment: The only solution for nuclear waste is to stop producing it. We oppose this EIS, and any new operating licenses for nuclear plants (0250-28-8 [Embrey, Monica])

Comment: All plants should be shut down, so we need to get -- the confidence that we need is to get rid of operating nuclear plants, number one, because we have a big problem. We have to lie about the fact that all these problems are small. (0325-19-4 [Lutz, Ray])

Comment: So I've created this five-point plan. The five-point plan would be, number one, stop production. Don't go find a place to put nuclear fuel. That'll only let them keep making it. First, stop production. Second, move it all into dry cask storage. Third, remove that dry cask storage spent fuel from the Pacific Rim of fire. Then, number four, weld shut the sea water cooling intake pipe and save our sea life. And then five, prosecute all those responsible for this hideous crime against the future. (0326-12-2 [Racano, Joey])

Comment: You should withdraw the Draft Generic EIS immediately. But due to this generic situation I don't think it makes sense to even do a revision. But anyway, it should be withdrawn and if a revision is done I hope that these are two of the alternatives considered. One is analyze an alternative which halts the generation of additional radioactive waste from U.S. commercial nuclear power facilities. Another analyzed alternative should be a phase-out of nuclear reactors beginning with the west coast reactors along the Pacific Rim of Fire, while also including Vermont Yankee and other GE Mark I reactors, plus Salem, New Jersey and Indian Point, New York. And then move on to shut more reactors down. (0326-63-2 [Campbell, Bruce])

Comment: So make no mistake, folks, this is about a solution now when we are the most information-rich and resource-rich for all time, because I have a feeling future generations will not live as well, nor be as educated, and be as understanding about what to do with this enormous problem. There's one alternative that wasn't discussed, isn't being discussed, in the proposed Environmental Impact Statement. That is the alternative of stopping now. It's the only sane alternative, and it's not being considered. My strong recommendation is that the NRC go back to the drawing board, get real, and treat us like adults, and treat as though this is a democracy. (0327-13-4 [Lodge, Terry])

Comment: An accounting of public costs of reactors, from uranium mining through shielding and monitoring of nuclear waste forever, has not been done and must be included in the Generic EIS. That will demonstrate the better alternative: energy efficiency, conservation, wind, solar, and hydro. (0327-27-7 [Macks, Vic])

Comment: Even if the decision was to phase out all existing nuclear reactors in the United States today, we've still set ourselves up into eternity to require a technical and military elite whose job it will be to guard the 70,000-plus ton mountain of high-level radioactive waste. Isn't that enough of a job for the NRC to oversee into the future? (0327-39-5 [Izant, Carol])

Comment: [F]or all those reasons, we believe that the DGEIS in this case should thoroughly examine the alternative of making no more nuclear waste. (0328-4-10 [Taylor, Wallace])

Comment: We believe the DGEIS in this case fails to evaluate an important alternative that must be considered in the analysis of environmental impacts of radioactive spent nuclear fuel. That alternative is to stop licensing any new nuclear reactors and decommissioning all existing reactors so we are not creating any more radioactive waste. The important point to be understood, also, is that the Waste Confidence decision and rule are an integral part of the licensing process of nuclear reactors. Statutes, rules, and court decisions have said that an EIS must discuss reasonable alternatives to the proposed action. The alternatives analysis is the heart of the Environmental Impact Statement. NEPA demands that the agency rigorously explore and objectively evaluate all reasonable alternatives so the agency can sharply define the issues and provide a clear basis for choice among options by the decision maker and the public. The existence of a viable but unexamined alternative renders the Environmental Impact Statement inadequate. The main point of examining alternatives is to avoid environmental harm, so even if an alternative might be superior in non-environmental terms, an alternative can be reasonable if it avoids the environmental harm better than another alternative. (0328-4-2 [Taylor, Wallace])

Comment: The Sierra Club and others commented during the scoping process for this DGEIS that the DGEIS must consider the alternative of stopping the production of any more radioactive waste, but the DGEIS has eliminated this proposed alternative from consideration. In eliminating this alternative, the DGEIS posits three arguments in support of the decision to eliminate this alternative. (0328-4-5 [Taylor, Wallace])

Comment: The NRC's next argument in its attempt to avoid considering the alternative of terminating licensing and reactor operation is that the Atomic Energy Act requires the NRC to license nuclear reactors unless there is a threat to public health and safety, but as presented by the NRC this is a circular argument. The NRC states that it already has regulations in place to provide reasonable assurance of public health and safety, and consideration of the environment, but the regulation allegedly providing this assurance is the Waste Confidence Rule, which is the rule that's being amended and evaluated by the DGEIS. Therefore, the NRC's argument is circular and self-serving. It's important to note that the NRC has the authority to stop licensing or relicensing plants, and also to revoke the license of reactors already licensed and relicensed. 10 CFR Section 100 authorizes the NRC to revoke a license for conditions which would warrant the Commission to refuse to grant a license for an original application, and that would include any reason that would make it inimical to public health or that there's no assurance that the activities authorized will not endanger the public health, safety, and the environment. (0328-4-7 [Taylor, Wallace])

Comment: So, really, the NRC is complicit in allowing the industry to carry on for many, many years with no solutions. So I think it's just wrong. And so I do not believe that the NRC should allow the industry to continue until there's some real solution. And, frankly, I just reject this whole generic ruling. You guys needs to go back to the blackboard, and you all need to really get down to it and look at what we're going to do. But no new licenses, no renewals. I mean, North Anna got a renewal way ahead of time before its renewal was even up. We had a 1.9 earthquake a few miles down from the plant the other day. No. We don't need more plans for new reactors when you guys still haven't figured out what to do with 70,000 plus toxic waste that's already been created. (0329-17-4 [Gray, Erica])

Comment: [N]obody has any idea what we are going to do with the waste. And the draft GEIS does not address that. It is only sensible and logical and practical. From the eyes of anyone who just looks at the world in practicable ways that the only logical thing you can do is stop making the waste. There is nowhere to put it. Saying that we can safely store it onsite for the next 300 to 10 million years is the most, one of the most, absurd things that I have ever heard in my life. (0329-32-5 [Seeley, Linda])

Comment: One of the things that I would ask you to add to the EIS is the alternative that 175 environmental groups have been advocating for over the last couple of years. It's called the hardened onsite storage principles. And I think that probably most people are familiar with this document already. It was signed off in March of 2011. And 175 environmental groups who put public health and safety and environmental protection as number one have looked at the situation of waste management and have decided that the only thing that we can do that is possibly safe for people and for the environment is to keep it where it is, hardened onsite storage as close as possible to the site of generation as possible, until we have a final disposal plan ready to put into place. Interim storage doesn't do that for us. It just doesn't. It has too many risks involved in it. And the hardened onsite storage plan is missing from your EIS. I have emphasized a couple of times 135 environmental groups have signed onto these hardened onsite storage principles because they are independent of industrial concerns. They are independent of steam-making concerns. They are looking at public health and safety and environmental protection. And as an EIS, it should look at that as an alternative so that we can go into that alternative or whatever alternative we want to pursue with open eyes as to the pluses and minuses of every single alternative that is open to us. (0329-33-1 [Feldman, Jane])

Comment: Because there is no known safe storage for this toxic by- product, the only meaningful action for the NRC to take would be to adopt a rule that prevents any nuclear power plant from producing this waste until a safe means of disposal is achieved. Sadly, there is no language in this rule that proposes any such action. (0330-3 [Beccia, John])

Comment: [T]he GEIS should consider the option of not making any nuclear waste at all in the future by comparing the environmental footprint of nuclear from mining to long term waste disposal to that of renewables and energy efficiency. (0336-13 [Lish, Christopher])

Comment: Ending radioactive waste generation is the single most important step we can take to minimize the risks surrounding its storage, and the NRC should revise its Waste "Confidence" document to ensure the speediest possible end to that generation. (0336-15 [Lish, Christopher])

Comment: I would contest shutting down nuclear energy production cold turkey would be very problematic if not impossible and would kill more dreams than to let nuclear power companies continue operations as normal. (0347-3 [Morrow, Jon Paul])

Comment: Very real also, although perhaps hard to quantify, is the public health toll attributable to NRC's errant decisions. Any delay in deploying additional nuclear power stations necessarily means prolonged use of fossil fuel combustion for large-scale electricity generation. The resulting effluents translate directly to some number of additional cases of heart and lung diseases, cancers, prenatal neurological development problems owing to exposure to mercury in the womb, early onset asthma attributable to ozone, etc. Some fraction of these additional cases will result in premature deaths. Senator Jeffords' comments on the Senate floor on June 26, 2002 (see in the Congressional Record for that date, pp. S6052-S6053), provide a good summary of these untoward, power-plant-related health effects. (0355-4 [Skov, Jeff])

Comment: There should be no more licensing or re-licensing of nuclear reactors until the permanent disposal of radioactive waste has been determined, proven and funded. Any EIS regarding nuclear waste storage must first and foremost consider alternatives to nuclear waste generation. Creating additional waste when there is no identifiable solution for its permanent safe storage is not justified. (0357-2 [Daily, G. Allen])

Comment: I would like the following to be considered as my comments on the GEIS/Waste Confidence Plan: Please add a scenario in which there is no safe way to store nuclear waste. If this scenario is added to the plan, it would allow for the possibility of needing to wean our country from using nuclear fuel and work toward a less potentially dangerous substance for our energy needs. Considering the long-term effects that nuclear waste can have on the environment and human health and to be fair to the American people, we should propose this as an option. (0371-1 [Baker, Anna])

Comment: The NRC should consider alternatives to minimize the risks of storage of spent nuclear fuel and high level waste, including placement below ground level, elimination of the current practice of high-density storage of spent fuel in pools, and more robust designs for storage casks. (0377-5-20 [Cuthbert, Lewis])

Comment: We developed nuclear energy facilities without adequate thought regarding the potential consequences and making assumptions regarding safety that have proven invalid. Yet the NRC again fails give adequate thought to potential consequences and continues with these assumptions. It would compound the present dangers and problems by continuing to license more facilities to endanger even more populations and generate even more waste. There is no logic to such a proposal, and there is no such thing as safe nuclear energy regardless of design changes. (0402-4 [Gross, Cheryl])

Comment: For future safety, I urge the NRC to revise its Waste Confidence document to ensure the quickest possible end to the generation of radioactive waste. There should be no more licensing or re-licensing of nuclear reactors and existing facilities should be phased out as quickly as possible, replaced by truly clean, safe, sustainable energy sources. (0402-6 [Gross, Cheryl])

Comment: Ending radioactive waste generation is the single most important step we can take to minimize the risks surrounding its storage, and the NRC should revise its Waste "Confidence" document to ensure the speediest possible end to that generation. (0405-5 [Dugan, Pat])

Comment: Similarly, the NRC should not be allowed to issue licenses for new nuclear reactors or expansions of existing reactors until a permanent, deep-geological, high-level radioactive waste disposal facility is build and operating. (0406-2 [Gerleman, Douglas])

Comment: Until there is a proven, safe, and sound nuclear waste management system, the NRC should advocate the ending of radioactive waste generation. The NRC should revise its Waste "Confidence" document to ensure the speediest possible end to that generation. (0443-9 [Sabo, Betty])

Comment: In addition, no further licensing for new nuclear plants should be granted or current licenses renewed, until the waste storage problems--short, medium and long term/off site storage--are solved. If the NRC were primarily concerned about the safety of the public, it would curtail all further generation of nuclear energy immediately until these "nuclear waste" storage

problems were addressed and a permanent storage site identified and approved. (0451-6 [Rippner, Sharon] [Rippner, Thomas])

Comment: The GEIS fails to consider the need to: Reduce spent fuel pool density to design basis standards, without exemptions; (0490-5 [Chin, Rebecca])

Comment: Not only is there no long-term solution for atomic waste in hand or on the horizon, the shorter-term programs now in place are inadequate from a public safety standpoint, and do not offer the requisite confidence to allow continued generation of radioactive waste. (0491-2 [Commenters, Multiple])

Comment: Ending radioactive waste generation is the single most important step we can take to minimize the risks surrounding its storage, and the NRC should revise its Waste "Confidence" document to ensure the speediest possible end to that generation. (0491-6 [Commenters, Multiple])

Comment: No-action Alternative isn't Even Afforded Serious Considered: NRC does not even seriously consider the alternative of no-action (halting nuclear reactor operation) -- a legal requirement. The WCGEIS pays little more than brief "lip service" to this option. The WCGEIS needs to be revised to address this alternative particularly in terms of the reduced emissions, reduction in spent fuel and radioactive waste, and reduction in radioactive emissions, and enhanced safety. (0496-7 [Batobato, Alicia])

Comment: There should be no more licensing or re-licensing of nuclear reactors until the permanent disposal of radioactive waste has been determined, proven and funded. Any EIS regarding nuclear waste storage must first and foremost consider alternatives to nuclear waste generation. Creating additional waste when there is no identifiable solution for its permanent safe storage is not justified. (0507-1 [Giese, Mark M.])

Comment: The GEIS fails to consider the need to [r]educe irradiated/spent fuel pool density to design basis standards, without exemption[.] (0537-5 [Commenters, Multiple])

Comment: We are confident that NRC and the waste generators can never contain this waste for as long as it poses a hazard. NRC must abandon its Waste Confidence policy and stop using it to license nuclear power plants. (0552-1-5 [Macks, Vic])

Comment: PW disagrees with NRC's finding that spent fuel can be stored safely in pools over the short term, 60 years after the license to operate ends - when some fuel may be 160 years old. Instead, PW supports the alternative of requiring dry cask storage of spent fuel rather than the continued use of spent fuel pools for spent fuel that is more than 5 years out of reactor. There is an abundance of technically competent documents supporting this alternative, ignored by NRC's draft³⁴ [footnote 34 text: See, for example: Robert Alvarez, Jan Beyea, Klaus Janberg, Jungmin Kang, Ed Lyman, Allison Macfarlane, Gordon Thompson, and Frank N. von Hippel, *Reducing the Hazards from Stored Spent Power-Reactor Fuel in the United States* (Science and Global Security, 11:1–51, 2003) [deleted superscript 3]; Robert Alvarez, *Spent Nuclear Fuel Pools in the U.S.: Reducing the Deadly Risks of Storage*. Institute for Policy Studies, May 24, 2011; Environmental Impacts of Storing Spent Nuclear Fuel and High-Level Waste from Commercial Nuclear Reactors: A Critique of NRC's Waste Confidence Decision and Environmental Impact Determination, by Dr. Gordon Thompson, February 6, 2009; Report to the Massachusetts Attorney General on the Potential Consequences of a Spent Fuel Pool Fire at the Pilgrim or Vermont Yankee Nuclear Plant, by Jan Beyea, PhD., May 25, 2006; Risks and

Risk Risk-Reducing Options Associated with Pool Storage of Spent Nuclear Fuel at the Pilgrim and Vermont Yankee Nuclear Power Plants: A report for the Office of the Attorney General Commonwealth of Massachusetts, by Dr. Gordon Thompson, May 25, 2006.] Given the breadth and weight of scientific support for the proposition that there are significant environmental benefits from dry cask storage for all fuel more than 5 years old, this reasonable alternative must be studied more thoroughly in the Commission's review of "all reasonable alternatives." 40 C.F.R. § 1502.14(a). NRC's finding that storage in either spent fuel pool or dry cask was safe for 60 years after the termination of a license failed to consider that spent fuel pools vary in density, geometry, vulnerability, mitigation capabilities and consequences. NRC ignored or seriously downplayed the following. (0556-5-2 [Lampert, Mary])

Comment: PW supports NRC studying the alternative of not allowing continued production of spent fuel until NRC sufficiently shows that there is a safe and environmentally acceptable permanent waste repository to receive additional fuel generated. This consideration was found reasonable by the U.S. Court of Appeals for DC. The Circuit Court explicitly recognized it as reasonable in *New York v NRC*, 681 F.3d 471, 474 (D.C. Cir.2012). It said, "The lack of progress on a permanent repository has caused considerable uncertainty regarding the environmental effects of temporary SNF storage and the reasonableness of continuing to license and relicense nuclear reactors." Because the GEIS is intended to support the environmental review of licensing actions and license renewal actions regarding environmental impacts of storing spent nuclear fuel, NEPA requires that NRC examine the cessation of further generation of spent fuel until a permanent, safe, and adequate nuclear waste disposal facility exists. What NRC did instead was simply assume, with no factual basis, that all nuclear waste will be removed from the nation's nuclear power plants within 60 years after the plants are closed. (0556-5-9 [Lampert, Mary])

Comment: I would also love it if you could stop this "short term thinking" and put a moratorium on construction of any new operating facilities until you figure out a way to safely dispose of its waste, that would never ever put the future generations of humanity in danger. (0569-3 [Hulstrunk, Matt])

Comment: No more operating permits or extensions until us humans can safely control our waste stream. (0572-2 [Fisher, Peter])

Comment: The NRC has also improperly failed to examine how the expedited transfer of spent fuel from dangerously overcrowded pools to dry casks would substantially reduce safety and accident risks. Both of these possibilities certainly have a bearing on the environmental impacts of long-term storage of spent fuel, and should be considered as options. (0604-10 [Pisha, Gayla])

Comment: Finally, the NRC has not considered the possibility of not relicensing operating reactors so that no additional nuclear waste is produced. (0604-9 [Pisha, Gayla])

Comment: Our communities' safety and security also depend on implementing safe strategies that reduce the number of spent fuel rods stored in fuel pools. The use of spent fuel pools beyond their intended timeline or design capacity significantly increases risks of tragedy from plant failure, terrorism, natural disaster, or other hazards. We must move safely but swiftly to remove rods from pools to reduce our exposure. As one option, we strongly encourage the NRC to consider the environmental impact of requiring dry cask storage of spent fuel older than 5 years. (0607-5 [Messinger, Michael])

Comment: In the absence of an adequate EIS review, the NRC should have no choice but to continue to suspend all Licensing and re-licensing action for U.S. nuclear reactors. All licensing and re-licensing actions were previously suspended by the NRC until an EIS and revised Wasted Confidence Decision have been issued. (0610-2 [Brechtin, Vernon])

Comment: The EIS should have a no-action alternative that would be the non-issuance of a waste confidence decision and rule and a continued suspension of new reactor licensing and existing reactor license extension actions until data to make scientifically valid impacts estimates of the consequences of long-term storage of high burnup spent fuel are collected and analyzed. (0610-9 [Brechtin, Vernon])

Comment: --[The NRC has failed to fully examine] the mitigation alternative of ceasing production of additional nuclear waste, if and until, safe, secure and affordable nuclear waste storage solutions are identified, tested, sited and constructed. (0611-14 [Shapiro, Susan])

Comment: The GEIS improperly excludes reasonable mitigation alternative of cessation of production of additional waste, therefore the GEIS review is inherently fatally flawed. To satisfy NEPA standards the NRC is required to identify impacts, take a "hard look" at impacts and seriously consider alternatives and public comments. Public comments overwhelming call for the inclusion of the consideration of mitigation measure to cease nuclear waste production. (0611-22 [Shapiro, Susan])

Comment: The NRC's decision to eliminate consideration of the alternative to cease of production of more nuclear waste in the GEIS is arbitrary and capricious and without scientific support, and seems to be wholly based on the NRC's desire to continue to produce more nuclear waste. This failure to consider a realistic alternative makes it clear the NRC is not the proper agency to determine Waste Confidence since it's allegiance is solely with the nuclear industry to protect its continued profits without unbiased consideration of protecting public health, now and in the future. (0611-33 [Shapiro, Susan])

Comment: Require reliable, sustainable back up power for spent fuel pools including but not limited to solar or wind systems with battery back to insure against loss of power which would result in an uncontrollable spent fuel fire. (0611-54 [Shapiro, Susan])

Comment: Most importantly the NRC needs to deny any new licenses to prevent continue accumulation of unmanageable nuclear waste. The reality of a long term solution to nuclear waste does not exist, and may very likely never exist. Since the GEIS fails address the need to stop making more nuclear waste, as an alternative it cannot be relied upon to comply with NEPA. (0611-58 [Shapiro, Susan])

Comment: The GEIS does not calculate the level of risk from the ongoing production of nuclear waste vs. the cessation of waste production. The NRC attempts to dispense with its obligation to analyze this scenario by relegating it to the alternatives analysis as the "Cessation of Licensing or Cessation of Reactor Operation," classifying it as an alternative to the proposed action to address the environmental impacts of continued storage, and dismissing it on the basis of the argument that "Abandonment of reactor licensing and the closure of existing plants is not a reasonable alternative to the proposed action because these actions would not meet the NRC's stated objectives in proposing to revise 10 CFR 51.23." (0614-7 [Christie, Andrew])

Comment: This argument does not exempt the GEIS from analyzing all aspects of the environmental effects of continued waste storage, including the potential difference in impacts

from the ongoing re-racking of spent fuel pools and expansion of ISFSI sites and all activities attendant upon these actions, versus the lack of a requirement for same. (0614-8 [Christie, Andrew])

Comment: [I respectively urge the Commission to] Continue the moratorium on issuing new and renewal licenses for all reactors[.] (0620-12 [Rivera, Evelyn])

Comment: The Waste Confidence Decision cannot be interpreted as so limited in scope that the lunacy of producing more waste is not even considered. (0640-4 [Geary, B.])

Comment: One mitigation alternative not examined in the draft GEIS is the transfer of spent nuclear fuel from spent fuel pools to dry storage casks to reduce the density of spent nuclear fuel in the pools. The transfer of spent fuel from a pool to a cask would reduce the inventory of radionuclides and radiation source term in the pool. It would also reduce the environmental impacts from an off-site release of radiation following a severe accident at a spent fuel pool. The State of New York recommends that the NRC require nuclear licensees to remove spent fuel from on-site storage pools to dry cask storage as soon as possible. (0681-6 [Peterson, Alyse])

Comment: *On this basis, I wish to register my strong opposition to all the alternatives included in the draft GEIS. I believe the no-action alternative is the best of those included, but not sufficient, and I especially oppose the exclusion of an alternative that would continue the current moratorium on new reactor licensing and license extensions. I urge the USNRC to revise the draft GEIS to include the option for such an alternative, and in doing so to take full account of the issues that have been raised by citizens and public interest groups throughout the public involvement process.* (0684-10 [Kinsella, William])

Comment: I also disagree with the statement in section 1.6.3.1 that "the Commission has already established criteria that provide reasonable assurance of public health and safety and due consideration of environmental impacts in the construction and operation of nuclear power plants, including facilities for continuing storage of spent fuel." (0684-8 [Kinsella, William])

Comment: Furthermore, the ultimate purpose of the Waste Confidence Rule is to inform the NRC's licensing and relicensing decisions. Analyzing the alternative of producing no more waste will require the NRC to consider whether to cease issuing licenses for new reactors, to deny relicensing applications, and to revoke existing licenses. (0688-12 [Taylor, Wallace])

Comment: The NRC's next argument in its attempt to avoid considering the alternative of terminating licensing and reactor operation is that the Atomic Energy Act requires the NRC to license nuclear reactors unless there is a threat to public health and safety. But as presented by the NRC, this becomes a circular argument. The NRC states that it already has regulations in place to provide reasonable assurance of public health and safety and consideration of the environmental impacts of storing spent fuel. But the regulation allegedly providing such assurance is the Waste Confidence Rule, which is the rule that is being amended and evaluated with the DGEIS. Therefore, the NRC's argument is circular and self-serving. It is also important to note that the NRC has the authority to revoke a nuclear reactor license. 10 C.F.R. § 100 authorizes the NRC to revoke a license for "conditions . . . which would warrant the Commission to refuse to grant a license on an original application." Based on the August 7, 2012, Order of the NRC refusing to grant pending licenses and license renewals because of the court decision vacating the Waste Confidence Decision, the Waste Confidence Decision would be a "condition[] . . . which would warrant the Commission to refuse to grant a license on an original application," requiring the NRC to revoke the relicensing decisions described above. The Atomic

Energy Act, 42 U.S.C. § 2133(d), states that the NRC cannot issue a reactor license if it would be "inimical" to public health. The NRC, by its own regulations, cannot issue a license unless "[t]here is reasonable assurance . . . that the activities authorized by the operating license can be conducted without endangering the health and safety of the public" 10

C.F.R. § 50.57(a)(3). The essence of the decision in New York v. NRC was that spent nuclear fuel is a danger to public health and safety and that there is no reasonable assurance that a permanent repository will ever be established. And as the court in New York v. NRC found, spent nuclear fuel "poses a dangerous, long-term health and environmental risk. It will remain dangerous 'for time spans seemingly beyond human comprehension.'" (0688-13 [Taylor, Wallace])

Comment: Based on the foregoing, the NRC has the authority to refuse to issue new reactor licenses and renewals and to revoke existing licenses when public health and safety and the environment are impacted. (0688-15 [Taylor, Wallace])

Comment: Furthermore, in response to the NRC's argument that there will still be existing waste on site even if production of waste is halted, a discussion of the alternative of discontinuing production of radioactive waste should include the feasibility of hardened on site storage (HOSS). Although HOSS is not the perfect solution to the radioactive waste problem, it is the best solution to a bad situation. There actually is no permanent solution to the existence of approximately 70,000 tons of radioactive waste currently stored at reactor sites. But HOSS is a much better alternative than the groundless hope expressed in the DGEIS that this waste can be stored in pools and dry casks essentially forever. Therefore, a discussion of HOSS in the DGEIS is required. (0688-18 [Taylor, Wallace])

Comment: In discussing the alternative of discontinuing production of spent fuel, the EIS should consider how renewable energy can replace whatever current or future energy needs would have been supplied by nuclear power if nuclear power is discontinued as an energy source. Numerous studies have shown that we can generate all the energy we need from renewable sources with a comprehensive transmission and distribution grid if we will adopt policies supporting that vision. See, e.g., Archer and Jacobson, Supplying Baseload Power and Reducing Transmission Requirements by Interconnecting Wind Farms, *Journal of Applied Meteorology and Climatology* (v. 46, Nov. 2007); Jacobson and Delucchi, Providing All Global Energy with Wind, Water, and Solar Power, Part I: Technologies, Energy Resources, Quantities and Areas of Infrastructure, and Materials, *Energy Policy* (v. 39, p. 1154-1169); Jacobson and Delucchi, Providing All Global Energy with Wind, Water, and Solar Power, Part II: Reliability, System and Transmission Costs, and Policies, *Energy Policy* (v. 39, p. 1170-1190); Jacobson and Archer, Saturation Wind Power Potential and Its Implications for Wind Energy, found at www.pnas.org/cgi/doi/10.1073/pnas.1208993109. See also, The Energy Report: 100% Renewable Energy by 2050, prepared for the World Wildlife Fund by Ecofys and found at www.worldwildlife.org/climate/energy-Report.html; Big Risks, Better Alternatives, prepared for Union of Concerned Scientists by Synapse Energy Economics, Inc. and found at www.ucsusa.org/assets/documents/nuclear_power/Big-Risks-Better-Alternatives.pdf. Another important source is Arjun Makhijani, Carbon-Free and Nuclear-Free: A Roadmap For U.S. Energy Policy (2007), available for download at www.ieer/carbon-free/. (0688-19 [Taylor, Wallace])

Comment: We believe that the DGEIS fails to evaluate an important alternative that must be considered in the analysis of environmental impacts of radioactive spent nuclear fuel. That alternative is to stop licensing any new nuclear reactors and decommissioning all existing reactors so we are not creating any more radioactive waste. (0688-2 [Taylor, Wallace])

Comment: The electric utilities and energy companies assert that in order to provide baseload power they have to use coal, natural gas or nuclear energy. But baseload as viewed by the utilities and power companies is an outdated concept. They are stuck with the narrow view of electric power coming from power plants. But rather than referring to the term baseload we are really talking about energy and capacity. Energy is the total amount of electricity that is being supplied to consumers. Capacity is the highest level of electricity that can be supplied at any one time to meet peak demand. Renewable energy can meet the energy and capacity demands of the country, combined with a program of energy efficiency and conservation and expansion of the transmission grid. Most states have energy efficiency programs subject to public utility regulation. Likewise, many states have renewable electricity standards requiring that a certain amount of the energy consumed in the state be from renewable sources. There are other policies, including feed-in tariffs, tax credits, loan programs, etc., that should be adopted to encourage the expansion of renewable energy. The DGEIS should analyze all of these issues in examining the alternative of stopping the production of spent fuel by not permitting new nuclear reactors and closing existing reactors. This would lead us to a renewable energy future and away from the production of more radioactive nuclear waste. (0688-20 [Taylor, Wallace])

Comment: The storage and disposal of radioactive nuclear waste from spent fuel is a long-term problem posing grave risks to public health and the environment for which there is no solution. One alternative to this conundrum-- the Sierra Club believes it is the most important alternative --is to stop producing any more radioactive waste. For the reasons stated above, NEPA and common sense require that the DGEIS analyze this alternative. (0688-23 [Taylor, Wallace])

Comment: The only sensible course of action is to stop making more spent fuel. Therefore, the DGEIS must include an analysis of the alternative of discontinuing production of spent nuclear fuel by not licensing any new reactors and decommissioning all existing reactors. (0688-8 [Taylor, Wallace])

Comment: The Sierra Club and others commented during the scoping process for this DGEIS that the DGEIS must consider the alternative of stopping the production of any more radioactive waste. But the DGEIS has eliminated this proposed alternative from consideration. See, DGEIS § 1.6.3.1. (0688-9 [Taylor, Wallace])

Comment: •Very real also, although perhaps hard to quantify, is the public health toll attributable to NRC's failure to abide by the NWPA. Any delay in deploying additional nuclear power stations necessarily means prolonged use of fossil fuel combustion for large-scale electricity generation. The resulting effluents translate directly to some number of additional cases of heart and lung diseases, cancers,¹⁸ [footnote 18 text: See, e.g., "IARC: Outdoor air pollution a leading environmental cause of cancer deaths," International Agency for Research on Cancer, Press Release No. 221, dated October 17, 2013 ("the risk of developing lung cancer is significantly increased in people exposed to air pollution. . . . The predominant sources of outdoor air pollution are transportation, stationary power generation, industrial and agricultural emissions, and residential heating and cooking." (emphasis added)); "Smoggy Beijing sees lung cancer cases soar," BBC News, November 9, 2013 ("The number of lung cancer cases in the Chinese capital Beijing has soared over the last decade. . . . According to figures published by the state-run Xinhua news agency, they have increased by more than 50%. . . . Correspondents say Chinese people are becoming increasingly worried about the health problems caused by the thick air pollution that often blankets much of their country.".)] prenatal neurological development problems owing to exposure to mercury in the womb, early-onset asthma attributable to ozone, etc. Some fraction of these additional cases will result in premature

deaths. Senator Jim Jeffords' comments on the Senate floor on June 26, 2002 (see in the Congressional Record for that date, pp. S6052-S6053), provide a good summary of these untoward, power-plant-related health effects.¹⁹ [footnote 19 text: 148 Cong. Rec. S6052 ("Studies show that 30,000 Americans die every year due to powerplant pollution—30,000 deaths from powerplant pollution alone. Incredible. . . . Powerplant pollution results in 20,000 hospitalizations each year, 600,000 asthma attacks, 5 million days of lost work due to pollution-related illness, and 18,000 cases of bronchitis. . . . Powerplant pollution has resulted in mercury advisories in 44 of the 50 States. In these 44 States, our citizens are asked not to eat the fish caught in the lakes and streams. . . . Because of powerplant pollution, 6 million American women and children are exposed to mercury levels well above those considered safe by Federal health authorities. . . . According to the CDC, the Centers for Disease Control and Prevention, 10 percent of women in the United States have mercury levels above those considered protective of newborns. As a result, as many as 390,000 children are born each year at risk for neurological development problems due to exposure to mercury in the womb. The March issue of the Journal of the American Medical Association found that millions of people who live in areas polluted by fine particles have about the same increased risk of dying from heart or lung disease or lung cancer as people who live with a cigarette smoker. . . . This is simply the beginning of my list regarding the impacts of powerplant pollution. . . . There is acid rain, smog, lung disease, heart disease, asthma, on and on. . . . Just this year, a respected public health journal published the first study showing a direct connection between the onset of asthma in young, healthy children and their exposure to ozone. The journal found that children exercising outdoors are more likely to contract asthma if they live in areas polluted with high ozone concentrations. This dangerous ozone is created by pollution from old power plants.".)] (0692-9 [Skov, Jeff])

Comment: The most obvious problem with the approach NRC adopted by the rigged analysis is that the nuclear industry continues to produce enormous quantities of nuclear waste. NRC refused to consider reducing or stopping the production of nuclear waste by limiting new permits. In fact, the federal government continues to subsidize the nuclear industry with millions of dollars. The primary purpose of an EIS is to examine environmental impacts, yet the Agency substituted another purpose for the EIS: to improve the efficiency of the licensing process. This will result in more applications, more reactors and more waste. (0693-1-10 [Warren, Barbara])

Comment: Page 1-9. "Cessation of licensing activities and cessation of reactor operations do not satisfy the stated purpose and need for this draft GEIS, which is to improve the efficiency of NRC's licensing process, to prepare a single source that reflects the NRC's current understanding of the environmental impacts of continued storage, and to comply with the remand in the New York v. NRC decision. Abandonment of reactor licensing and the closure of existing plants is not a reasonable alternative to the proposed action because these actions would not meet the NRC's stated objectives in proposing to revise 10 CFR 51.23." NRDC Comment[:] This is an inaccurate restatement of the import of NRDC's comments offered during scoping. We address this issue above in our discussion of Scoping. Moreover, since licensing activities may not be resumed absent a Waste Confidence rule, the cessation of licensing activities and reactor operations must necessarily be analyzed under the No Action alternative. Suggesting that this is what NRDC demanded misconstrues the point of NEPA compliance we sought to make the agency understand. Thus, with the above text, NRC inappropriately restricts the alternatives that must be analyzed to comply with NEPA. By any measure, NRC will need to conduct an analysis of spent nuclear fuel either stored permanently at reactor sites or at other above ground (non-repository) site(s), or in various combinations of distributed and consolidated surface storage, as existing stores of spent nuclear fuel and spent fuel yet to be produced from lawfully licensed reactors will continue to pile up. But an analysis that omits an obvious

alternative and subset of alternatives directly related to the environmental harms under review is arbitrary and capricious. (0706-2-18 [Fettus, Geoffrey])

Comment: Page 1-9. "Imposing new regulatory requirements, such as requiring licensees to implement hardened at-reactor storage systems, reduce the density of spent fuel in pools, or expedite transfer of spent fuel from pools to ISFSIs, is outside the scope of this proposed action, which includes alternatives that improve the efficiency of the NRC's licensing process by generically addressing the environmental impacts of continued storage." NRDC Comment[:]
Consistent with comment #5 above, NRC fails to provide any reasonable basis for not analyzing alternatives that might increase public safety and reduce potential environmental harms by speeding removal of spent nuclear fuel from the pools when appropriately cooled. Moreover, the scope of NEPA does not extend to "imposing new regulatory requirements," and no one is suggesting that it does. But a proper NEPA analysis may uncover *the agency's need to consider* such requirements. (0706-2-19 [Fettus, Geoffrey])

Comment: *Alternative Storage Modes & Configurations* (Spent Fuel Pools with At-Reactor Dry Storage (ARDS); Upgraded Spent Fuel Pools and License-Extended/Expanded ARDS; Regional Consolidated Dry Storage (RCDS); and a Single National Consolidated Dry Storage Facility (NCDS). Various sequences and combinations of these storage modes need to be evaluated and compared in the alternatives analysis. (0706-2-21 [Fettus, Geoffrey])

Comment: Stop licensing new nuclear reactors, and stop relicensing aging reactors as the first alternative: This will at least provide some assurance to citizens that the problem of storing vast amounts of dangerous nuclear waste, often on the shores of fragile water bodies, including our Great Lakes, won't continue to grow. Creating additional waste without an identifiable solution for its permanent, safe storage is not rational or responsible to future generations. (0707-3 [Werner, Shahla M.]

Comment: Laws that created NRC and enable licensing of atomic fission to energy corporations were passed in error by a body that was either sorely misled, delusional, or had no care for the future. Production of massive quantities of radioactivity was legalized while there is no possible way to ensure that this radioactivity could, or would be isolated from the living systems of our planet. Even though it is clear that there is no safe dose of radiation, the production of massive amounts from radioactivity from 24 / 7 fission has not stopped, and today more than 95% of the radioactivity in radioactive waste in the USA is from the licenses that NRC issues. The court ordered moratorium on licensing of nuclear fission is the first rational step in curing this situation. The NRC has the option to join in correcting this situation: the nuclear licensing moratorium should be maintained and further expanded to a phase-out of operating reactors. We should, as a society, stop making more radioactive waste. NUREG 2157 declares the "need for nuclear energy" outside its scope; the "need" for this waste is not outside scope: we don't need any more radioactive waste. (0711-4 [Olson, Mary])

Comment: *CCNR recommends that the current suspension of licensing decisions by the NRC should be continued indefinitely until the NRC has established detailed plans for the long term management of irradiated nuclear fuel that is not based on the unwarranted assumption that a safe permanent walk-away disposal method will become available within a few decades.* (0714-1-6 [Edwards, Gordon])

Comment: CCNR [Canadian Coalition for Nuclear Responsibility] recommends that the current suspension of licensing decisions by the NRC should be continued indefinitely until the NRC has established detailed plans for the long term management of irradiated nuclear fuel that is

not based on the unwarranted assumption that a safe permanent walk-away disposal method will become available within a few decades. (0714-2-4 [Edwards, Gordon])

Comment: NEIS believes that the moratorium on licensing of new and relicensing of currently operating reactors should remain in place until such time as a permanent, deep-geological high-level radioactive disposal facility is designed, licensed, built and in operation. We ask NRC to maintain this moratorium until this condition is reached; and ask that the moratorium be extended to include the siting and licensing of any temporary, away from-reactor high-level radioactive waste "storage" facilities, such as those referred to as "centralized interim storage" facilities. It is irresponsible to continue the production of such wastes without a demonstrated and operational means of disposal. (0716-2 [Kraft, Dave])

Comment: *The NRC moratorium on licensing of new and relicensing of currently operating reactors should remain in place until such time as a permanent, deep-geological high-level radioactive disposal facility is designed, licensed, built and in operation. We ask NRC to maintain this moratorium until this condition is reached; and ask that the moratorium be extended to include the siting and licensing of any temporary, away-from-reactor high-level radioactive waste "storage" facilities, such as those referred to as "centralized interim storage" (CIS) facilities.* (0716-6 [Kraft, Dave])

Comment: The Blue Ribbon Commission recommended that the National Academy of Sciences ("NAS") conduct its own separate assessment of the lessons learned from Fukushima and the implications of these lessons for the conclusions reached in earlier NAS studies on the safety and security of spent nuclear fuel.¹¹³ [footnote 113 text: *Blue Ribbon Commission Report* at 44.] As part of this assessment, the Commission suggested that NAS conduct "an analysis of the advantages and disadvantages of moving spent fuel from densely packed pools to on-site dry cask storage to facilitate low-density packing in the pools."¹¹⁴ [footnote 114 text: *Id.*] However, the Near-Term Task Force report did not address this issue. When asked by Commissioner Ostendorff why this issue was not included, Task Force members replied that it was not clear what exactly happened to the spent fuel pools at Fukushima, that there was no "overwhelming evidence that the fuel would be safer outside of the pool than in it," and that their recommendations enhance pool safety more than removing fuel would.¹¹⁵ [footnote 115 text: Nuclear Regulatory Commission, Briefing on the Task Force Review of NRC Processes and Regulations Following the Events in Japan, Transcript of Proceedings, at 36-37, ML112020051 (July 19, 2011).] However, Task Force members failed to acknowledge that dry cask storage has numerous safety advantages over pool storage¹¹⁶ [footnote 116 text: *NAS Report* at 70.] and that some of the safety measures they recommended are necessary because of the dense-storage of fuel in U.S. spent fuel pools. In short, the recommendations deal with symptoms of the problem (e.g., the rapid heat up of densely packed spent fuel once water is removed from the pool) but do not offer alternatives or solutions to the problem itself. Even NRC Staff recognized that the transfer of spent fuel to dry cask storage has "a clear nexus to the Fukushima Daiichi event [and] may warrant regulatory action but [was] not included with the NTTF recommendations."¹¹⁷ [footnote 117 text: Nuclear Regulatory Commission, SECY-11-0317: Prioritization of Recommended Actions to be Taken in Response to Fukushima Lessons Learned, at 5, ML11269A204 (Oct. 3, 2011).] It also appears that the Commissioners were not informed that Sandia National Laboratories has recently acknowledged that reducing the volume of spent fuel in spent fuel pools would mitigate the risks posed by dense storage. On February 7 and 8, 2012, NRC Staff made publically available three documents discussing the safety of spent fuel pools. The first is a slideshow explaining the findings of a study conducted by Sandia National Laboratories, which investigated zirconium fires during spent fuel pool loss of coolant accidents ("LOCAs").¹¹⁸ [footnote 118 text: Samuel G. Durbin and Eric R. Lindgren of

Sandia National Laboratories, investigations of Zirconium Fires During Spent Fuel Pool LOCAs (Slideshow), ML120380359 (Feb. 7, 2012).] The study found that low density racking is the spent fuel configuration that is least vulnerable to zirconium fires.¹¹⁹ [footnote 119 text: *Id.* at slide 15.] [Figure inserted] The disclosure of this study and its conclusion constitute significant new information because it is now clear that federal laboratories recognize that safer options are available for the storage of spent nuclear fuel. This recognition and the alternative of reducing the volume of waste stored in pools must be considered when NRC Staff examines the alternatives to the proposed federal action authorizing a 20-year extension of a facility's operating license. NRC should revise the Waste Confidence DGEIS and proposed rule and require the review of such alternatives[.] (0718-2-10 [Sipos, John])

Comment: Thinning of Spent Fuel Pools and Use of Dry Cask Storage[.] One alternative that should be considered is the thinning of spent fuel pools. Densely packed spent fuel heats up faster in the event of the loss of cooling water than more loosely packed fuel,¹⁴¹ [footnote 141 text: Allan S. Benjamin et al., *Spent Fuel Heatup Following Loss of Water During Storage* (Sandia National Laboratory, NUREG/CR-0649, SAND77-1371) at 50 ("1979 Sandia Report") (Mar. 1979) ("The high density holders . . . are the least well-suited to heat removal, as expected, particularly if the spent fuel is packed wall-to-wall so as to preclude a down-comer space at the edge of the pool.".)] giving workers and emergency crews less time to respond to prevent fire or other damage to the fuel assemblies.¹⁴² [footnote 142 text: *See 2006 Sandia Report* at viii ([D])dispersed configurations [of spent fuel assemblies] provided additional time for mitigative actions before the release of fission products versus a nondispersed configuration.); *See also NAS Report* at 103 ("[M]odifying the storage racks to provide for closer spacing of the fuel assemblies. . . . can make it more difficult to cool the freshly discharged fuel if there is catastrophic loss of the fuel pool water.".)] [Figure inserted] Alvarez et al. recommend moving away from the current "dense-pack" configurations and returning to open-rack configurations, for which the spent fuel pools were originally designed.¹⁴³ [footnote 143 text: *Reducing the Hazards* at 23.] The figures below illustrate the different designs.¹⁴⁴ [footnote 144 text: First figure: *Reducing the Hazards* at 17. Second figure: *1979 Sandia Report* at 20.] [Figure inserted] In the original design for pressurized-water reactor spent fuel pools, fuel assemblies were packed 53 cm apart, allowing the cooling water to channel between them.¹⁴⁵ [footnote 145 text: *Reducing the Hazards* at 17.] In the densely packed design, fuel assemblies are only 23 cm apart (close to the 21.4 cm spacing in reactor cores),¹⁴⁶ [footnote 146 text: *Id.* at 16.] allowing about five times as many assemblies to be stored in the pool.¹⁴⁷ [footnote 147 text: *NAS Report* at 43.] To keep these closely packed fuel rods sub-critical, they are placed in metal boxes containing neutron-absorbing boron.¹⁴⁸ [footnote 148 text: *Id.*] In a loss of coolant accident, where pool water is lost, these boxes would prevent the horizontal circulation of cooling air.¹⁴⁹ [footnote 149 text: *Id.* at 17.] A 1979 Sandia report¹⁵⁰ [footnote 150 text: *1979 Sandia Report.*] prepared for NRC found that with an open frame storage configuration in a well-ventilated facility, spent fuel in a drained storage pool would not overheat if it was cooled for five days before being transferred to the pool.¹⁵¹ [footnote 151 text: *Reducing the Hazards* at 23.] Also, as mentioned above on pages 54-55, Sandia recently released the results of a study finding that low density racking is the spent fuel configuration that is least vulnerable to zirconium fires.¹⁵² [footnote 152 text: Samuel G. Durbin and Eric R. Lindgren of Sandia National Laboratories, *Investigations of Zirconium Fires During Spent Fuel Pool LOCAs* (Slideshow), ML120380359 (Feb. 7, 2012).] If there is not enough room in the pool to permit open frame storage—because too much fuel is unloaded from a reactor during a given five year period—Alvarez et al. recommend considering: "(1) an arrangement where one fifth of the fuel assemblies are removed in a pattern in which each of the remaining fuel assemblies has one side next to an empty space; (2) an arrangement where alternate rows of fuel assemblies are removed from the rack."¹⁵³ [footnote 153 text: *Id.*] The first suggestion is illustrated in the figure

below.¹⁵⁴ [footnote 154 text: Figure is taken from: *Damages From a Major Release* at 133.] [Figure inserted] If this suggestion is found to be effective at allowing spent fuel in a drained pool to be convectively air cooled, it would reduce the amount of spent fuel that would need to be removed from pools in the U.S. in 2010 from 35,000 tons (under an open frame storage plan) to 9,000 tons.¹⁵⁵ [footnote 155 text: *Id.*] However, Alvarez et al. recommend that all spent fuel be removed from pools and placed in dry cask storage after it has cooled for five years. Similarly, the NAS report recommended that, space permitting, empty slots be arranged throughout the pool to promote natural air convection in the event that the pool is completely drained.¹⁵⁶ [footnote 156 text: *NAS Report* at 55.] That report also found that spent fuel is less at risk from accident or attack in dry cask storage than in a fuel pool.¹⁵⁷ [footnote 157 text: *NAS Report* at 68.] This is because the spent fuel stored in dry casks has been cooled for at least five years, and is therefore, not prone to zirconium cladding fires.¹⁵⁸ [footnote 158 text: *NAS Report* at 69.] Moreover, the dry cask system divides the spent fuel between many different casks—each cask stores only 10 to 15 tons of fuel, as opposed to a pool, which stores hundreds of tons—so if an individual cask is compromised, there is less potential radiation to be released. Additionally, since dry cask storage relies on natural air circulation for cooling, a breach would not release contaminated water into the environment and emergency crews would not need to find an alternative source of water with which to fill them. (0718-2-17 [Sipos, John])

Comment: In the wake of the Fukushima nuclear disaster, nuclear plant operators are beginning to consider thinning spent fuel pools as a safety precaution. For example, in April 2011, the Tennessee Valley Authority issued a nuclear program update that said it was considering moving spent fuel out of pools and into dry cask storage.¹⁵⁹ [footnote 159 text: Tennessee Valley Authority, “Fact Sheet: Nuclear Program Update” (Apr. 14, 2011). *Available at:* http://www.tva.gov/news/releases/aprjun11/pdf/nuclear_programupdate_fact_sheet.pdf. The Tennessee Valley Authority owns and operates various nuclear power reactors and is an agency of the United States.] Although TVA attended the January 11, 2012 public meeting, this initiative was not discussed. Others have called for the removal of spent fuel that is more than five years old from storage pools. In March 2011, David Lochbaum, of the Union of Concerned Scientists, stated before the U.S. Senate Energy and Natural Resources Committee, “A better strategy would be to reduce the inventory of irradiated fuel in the pools to the minimum amount, which would be only the fuel discharged from the reactor core within the past five years.”¹⁶⁰ [footnote 160 text: Statement by David Lochbaum, Director of Nuclear Safety Project, Before the U.S. Senate Energy and Natural Resources Committee, at 2 (March 29, 2011). *Available at:* http://www.ucsusa.org/assets/documents/nuclear_power/lochbaum-senate-energy-3-29-2011.pdf.] This, he said, would lower the risk of fire by decreasing the heat load of the pool, giving workers more time to respond in the event of the loss of cooling water. Also, if radiation was released, it would be significantly lower in a less densely packed pool. That same month at a meeting on Capital Hill, Energy Secretary Steven Chu recognized that the storage of spent nuclear fuel in dry casks is much safer than storage in pools.¹⁶¹ [footnote 161 text: Hearing on the Fiscal Year 2012: Department of Energy and Nuclear Regulatory Commission Budgets, House of Representatives, Subcommittee on Energy and Power joint with the Subcommittee on Environment and the Economy Committee on Energy and Commerce, at 77 (March 16, 2011). *Available at:* http://democrats.energycommerce.house.gov/sites/default/files/image_uploads/031611%20EPEE%20Fiscal%20Year%202012%20DOE%20and%20NRC%20Budgets.pdf (Chu stated: “After you take the fuel rods out of the reactor, immediately you put them in a pool of water for a period of time where they are actually still dissipating a considerable amount of heat. But then after that, the next stage is that you can put them in dry cask storage, which is much safer.”).] In May 2011, the Institute for Policy Studies released a report authored by Robert Alvarez, also recommending that all spent fuel that has been in pools for five years be removed and placed in dry storage.¹⁶²

[footnote 162 text: Robert Alvarez, *Spent Nuclear Fuel Pools in the U.S.: Reducing the Deadly Risks of Storage*, at 21 (May 2011).] Additionally, in April 2011, U.S. Senator Diane Feinstein called upon the NRC Commissioners to enact regulatory policies that reduce the amount of spent fuel stored in pools.¹⁶³ [footnote 163 text: Letter from Senator Feinstein to NRC Chairman Jaczko, ML11108A038 (April 8, 2011).] In August 2011, Chairman Jaczko acknowledged the benefits of transferring spent fuel to dry cask and said the Commission should consider this alternative: ["I also believe the Commission should consider in the long term if there should be new regulations to require licensees to move spent fuel to dry cask storage within a specific timeframe. This step, recognizing the inherent safety benefits of dry storage and combining that knowledge with the new ISFSI security regulations under development, may provide a safer and more secure disposition for spent fuel. I also believe that an NRC-developed pilot probabilistic risk assessment provides additional supporting evidence of the benefits of having more of the spent fuel held in dry storage."]¹⁶⁴ [footnote 164 text: Nuclear Regulatory Commission, Commission Voting Record: Near-Term Report and Recommendations for Agency Actions Following the Events in Japan, at PDF page 9, ML112310746 (Aug. 19, 2011).] (0718-2-18 [Sipos, John])

Comment: While removing spent fuel and placing it in dry cask storage remains the safer alternative, there are other steps that can also contribute to reducing the risk of zirconium cladding fires in spent nuclear fuel pools. For example, the fuel assemblies in pools can be arranged in a checkerboard pattern so that newly discharged fuel is surrounded by older, cooler fuel. The cooler fuel will act as heat sink, absorbing the heat from the newer fuel.¹⁶⁵ [footnote 165 text: *NAS Report* at 54.] Similarly, newly discharged fuel can be placed near the walls of the pool, which will also act as a heat sink. Water spray systems can be installed to cool fuel in the case of loss of pool coolant and pool walls can be reinforced to prevent their damage.¹⁶⁶ [footnote 166 text: *NAS Report* at 55.] Also, limiting the frequency of full core offloads into pools and delaying the transfer of fuel into a pool after a reactor shutdown would reduce the heat-load in the pool.¹⁶⁷ [footnote 167 text: *NAS Report* at 55.] What is possible at each facility will vary, and therefore, a site-specific evaluation must be conducted. Although the recent Near-Term Task Force report does not call for the transfer of fuel to dry storage, Recommendation 7 of the report addresses some concerns about enhancing the safety of spent fuel pools. The Task Force recommends that licensees be required to install or enhance equipment that will allow workers to better monitor spent fuel pools in emergencies, as well as improve the ability of workers to get water to the pools if necessary.¹⁶⁸ [footnote 168 text: *Near-Term Task Force Report* at 45-46.] The State urges NRC to include such requirements for relicensing, in addition to requiring the thinning of spent fuel pools.¹⁶⁹ [footnote 169 text: In the briefing on the proposed GEIS, held on January 11, 2012, Chairman Jaczko indicated that license renewal is an opportunity to get requirements implemented at nuclear facilities. *January 2012 GEIS Briefing Transcript* at 86. The State recommends that license renewal be made conditional upon the implementation of the requirements recommended by the Near-Term Task Force. This will ensure that the changes are implemented by licensees prior to license renewal.] (0718-3-1 [Sipos, John])

Comment: NRC should stop issuing reactor licenses until a real repository is determined. That would be a repository situated on bedrock that would be stable for thousands of years. (0739-3 [Quartermann, John S.]

Comment: AREVA agrees with the NRC conclusion that a moratorium on reactor and Independent Spent Fuel Storage Installation (ISFSI) licenses is not a reasonable or equitable alternative to the proposed rulemaking. A "no licensing" approach would not successfully achieve the intent of the proposed rulemaking, which is to catalogue the NRC's conclusion of the environmental impacts of continued safe storage of nuclear fuel. In addition, as NEI has

indicated, a licensing moratorium is not legally required by the National Environment Policy Act (NEPA) or the Atomic Energy Act (AEA). AREVA agrees that a licensing cessation is not a permanent solution. Such an act would be detrimental to the economic infrastructure of the industry, would not achieve the goals set forth by the proposed rulemaking, and is not legally bound by NEPA or the AEA. (0745-5 [Kelley, Devin])

Comment: NRC should not be allowed to issue new reactor licenses, nor grant license extensions to old operating reactors until a permanent, deep-geological high-level radioactive waste disposal facility is built and operating. (0757-7 [Lynch, Laura])

Comment: It should be clear by now that, unless we can deal with the waste products, nuclear energy is probably doomed. Shouldn't we just grow up and accept that and move on to more viable solutions to our energy need. (0758-2 [Kuchnia, Margaret])

Comment: I believe NRC should not be allowed to issue new reactor licenses, nor grant license extensions to old operating reactors until a permanent, deep-geological high-level radioactive waste disposal facility is built and operating. (0763-3 [Freeman, Susan])

Comment: NRC should not be allowed to issue new reactor licenses, nor grant license extensions to old operating reactors until a permanent, deep-geological high-level radioactive waste disposal facility is built and operating. (0791-3 [Mierzwicki, Tony])

Comment: In conclusion, the moratorium on issuing new reactor licenses and renewing existing ones must remain in place. The DGEIS and Proposed Rule are completely unacceptable. Further, because there is absolutely no solution for the more than 80,000 tons of current waste which will grow to more than 150,000 tons by 2050, the NRC must finally act responsibly and phase out nuclear power as quickly as possible and attempt to manage this deplorable mess as diligently as possible. The mantra must be "mitigate don't exacerbate." (0819-23 [Kline, Connie])

Comment: We disagree that abandonment of reactor licensing and the closure of existing plants is not a reasonable alternative. This should be INCLUDED as an option. We believe this is the only prudent and reasonable option, which responsibly acknowledges the severe danger of nuclear substances, the fact that no permanent geologic repository exists, and the fact that the NWO DO NOT measure up to the deep geologic repository alternative. No new licensing should be allowed unless and until the permanent solution for the waste is determined, and no plant licenses should be extended. (0836-28 [Davis, Anonymous])

Comment: The NRC does have the authority to pull licenses if they decide the plant is not safe, period. It does not matter if the licensee has some vested interest. We see this as the key and disheartening reality... the NRC is now a toothless lapdog instead of being a watchdog, and it has been co-opted by the industry to the point that it truly believes that the right thing to do is to continue to grant and extend licenses WHEN NO SOLUTION EXISTS TO DEAL WITH THE WASTE! (0836-29 [Davis, Anonymous])

Comment: Page 1-9, lines 19-20, you are right that cessation of nuclear power plant licensing and operations would halt the future generation of nuclear fuel. That is as far as your analysis should go. You are not responsible for regulating every form of energy or option. You have no analysis of "other environmental impacts that may result." etc. We believe that if done responsibly, this is the best course of action. (0836-30 [Davis, Anonymous])

Comment: Regarding Page 1-9, Lines 25-29, you say that requiring hardened storage systems, etc. are outside the scope of the GDEIS. Of course it is, because this is not a licensing action. But the GDEIS CAN state that these would be necessary if any site were to become truly safe under certain accident scenarios. To eliminate these concerns out of hand by stating that they are "out of scope" is truly ridiculous. THESE CONCERNS MUST BE ADDRESSED AND YOU CAN'T SWEEP THEM UNDER THE RUG BY SAYING THEY ARE OUT OF SCOPE!! There are differences between a deep geologic repository and surface NWOs... YOU MUST DISCLOSE THESE DIFFERENCES! (0836-32 [Davis, Anonymous])

Comment: Page 1-10, Line 1: the expedited transfer of fuel from fuel pools to ISFSI did not consider plants that were not operating. So their conclusions cannot be directly adopted by your group. You did not mention that, and then the implications that the scope of that project explicitly did not consider the scope you are considering. The fact is that the expedited fuel transfer project ASSUMES that the fuel will not necessarily need to be placed in dry storage on site, and could potentially be shipped directly from the fuel pools. Thus, by not moving fuel from the pools as soon as practicable into dry casks, they envision avoiding this cost. However, in the scenario you are promoting here, all fuel from the fuel pools will be moved into the ISFSI prior to being transported off site, and therefore, there is NO SAVINGS, and the conclusion of that project should be REVERSED, i.e. expedited transfer is WISE, PRUDENT, and COST EFFECTIVE, and the safest thing to do, based on the fact that there is a safety difference between dry casks and fuel pools. If you have to transfer it to dry casks anyway, why not do it as quickly as practicable, to avoid the safety differences between the ISFSI and FUEL POOLS? Answer: there is no reason, and thus the conclusions of the expedited transfer are now moot. (0836-33 [Davis, Anonymous])

Comment: I find it difficult to comment on a safe alternative to spent nuclear fuel when the very premise that ANY nuclear fission, fuel or waste can be deemed safe is seriously, intrinsically flawed. Nevertheless, the grim reality is that we do, in fact, have thousands of tons of highly lethal of spent nuclear fuel on site in at virtually all United States nuclear power plants. These aging nuclear power plants should NOT be granted operating extensions beyond their "safe" and originally approved lifespans. I believe that ALL nuclear power plants should be shut down, decommissioned, with no new nuclear reactors developed as this is an unsafe, economically and ecologically unsustainable technology. (There are other, less deadly viable energy alternatives.) There needs to be an end to the production and/or reprocessing of spent nuclear fuel. This will in turn, make finite the total amount of spent nuclear fuel to be stored. (0843-1 [Davis, Cherie])

Comment: There are better, cheaper and safer ways to fight global warming and provide electricity. While it will be expensive and unpopular to take care of the existing spent nuclear fuel, we must stop adding to the problem of spent nuclear fuel. The NRC needs to make prudent decisions regarding safety: it must expedite the thinning of overcrowded spent fuel pools and expedite the transition to dry cask storage. And, the NRC must not be allowed to license new nuclear reactors or relicense existing reactors. (0851-13 [Thatcher, Tami])

Comment: And further, the NRC admitted that not licensing and re-licensing nuclear power would stop the production of waste. However, NRC shied away from consideration of a no-action alternative that would stop licensing, by stating: Although cessation of nuclear power plant licensing and operations would halt the future generation of spent fuel, other environmental impacts could result from the required development of replacement power sources or demand reductions. Even then, the environmental impacts of continued storage would not cease until sufficient repository capacity becomes available. DGEIS at 1-9. This

statement is simply irrational, and reflects a complete lack of analysis. The fact that other energy sources may have environmental impacts does not render them unworthy of consideration. NEPA requires that the entire array of reasonable alternatives must be analyzed. *Calvert Cliffs*, 449 F.2d at 1128. In addition, consideration of the no-action alternative of not licensing and re-licensing reactors that would generate spent fuel is explicitly required under NEPA and NRC implementing regulations. (0897-3-10 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The GEIS should have a no-action alternative of not issuing any further licenses or license extensions for reactors or for spent fuel storage at least until the basis to do a scientifically valid GEIS exists in the area of high burnup fuel. At present the NRC lacks the factual and analytical basis to do so in a number of areas. This should be the preferred alternative. (0898-5-25 [Curran, Diane] [Makhijani, Arjun])

Comment: (X-16) The potential for a pool fire became clear in 1979. From the beginning, the means of addressing this threat was also clear. The radiological risk of a pool fire could be dramatically reduced by abandoning the use of high-density racks in pools, and reverting to low-density, open-frame racks.⁹⁹ [footnote 99 text: In the case of BWR spent fuel, removal of channel boxes from the fuel could also be appropriate.] Figure X-1 shows the two types of rack. Since 1979, numerous parties have intervened in license proceedings and pursued other avenues, seeking to persuade NRC to order the elimination of high-density racks. A corollary of that action would be the transfer of a substantial portion of the US inventory of spent fuel from pools to dry casks. NRC has consistently and vigorously opposed the elimination of high-density racks. (0916-2-10 [Curran, Diane] [Thompson, Gordon R.]

Comment: The draft GEIS does not consider options for reducing the radiological risk arising from management of spent fuel. However, numerous options of this kind are available. For example, options are available for providing enhanced protection of ISFSIs. Use of such options at ISFSIs across the United States would support a national strategy of protective deterrence. (0916-3-24 [Curran, Diane] [Thompson, Gordon R.]

Comment: An ounce of prevention is worth a pound of cure. The U.S. must stop generating radioactive waste. NRC estimates that 52,000 metric tons of irradiated nuclear fuel will be stored at commercial reactors in the U.S. by 2005. If currently operating reactors continue generating waste until the end of their 40 year licenses, the mountain of waste will more than double in size. If NRC continues to allow old reactors to extend their operating lifetimes from 40 to 60 years, the amount of waste will increase still more. If new nuclear reactors are built, yet more waste would be produced. Nuclear power must be phased out and replaced with safer, cheaper, cleaner ways to meet our electricity needs; conservation, efficiency, and renewable sources such as wind, solar, and fuel cells. (0929-18 [Kamps, Kevin])

Comment: We disagree that abandonment of reactor licensing and the closure of existing plants is not a reasonable alternative. This should be INCLUDED as an option. We believe this is the only prudent and reasonable option, which responsibly acknowledges the severe danger of nuclear substances, the fact that no permanent geologic repository exists, and the fact that the NWO DO NOT measure up to the deep geologic repository alternative. No new licensing should be allowed unless and until the permanent solution for the waste is determined, and no plant licenses should be extended. (0930-2-2 [Lutz, Ray])

Comment: We see this as the key and disheartening reality... the NRC is now a toothless lapdog instead of being a watchdog, and it has been co-opted by the industry to the point that it

truly believes that the right thing to do is to continue to grant and extend licenses WHEN NO SOLUTION EXISTS TO DEAL WITH THE WASTE. (0930-2-3 [Lutz, Ray])

Comment: Page 1-9, lines 19-20, you are right that cessation of nuclear power plant licensing and operations would halt the future generation of nuclear fuel. That is as far as your analysis should go. You are not responsible for regulating every form of energy or option. You have no analysis of "other environmental impacts that may result." etc. We believe that if done responsibly, this is the best course of action. (0930-2-4 [Lutz, Ray])

Comment: Regarding Page 1-9, Lines 25-29, you say that requiring hardened storage systems, etc. are outside the scope of the GDEIS. Of course it is, because this is not a licensing action. But the GDEIS CAN state that these would be necessary if any site were to become truly safe under certain accident scenarios. To eliminate these concerns out of hand by stating that they are "out of scope" is truly ridiculous. THESE CONCERNS MUST BE ADDRESSED AND YOU CAN'T SWEEP THEM UNDER THE RUG BY SAYING THEY ARE OUT OF SCOPE.. There are differences between a deep geologic repository and surface NWOs... YOU MUST DISCLOSE THESE DIFFERENCES. (0930-2-6 [Lutz, Ray])

Comment: Page 1-10, Line 1: the expedited transfer of fuel from fuel pools to ISFSI did not consider plants that were not operating. So their conclusions cannot be directly adopted by your group. You did not mention that, and then the implications that the scope of that project explicitly did not consider the scope you are considering. The fact is that the expedited fuel transfer project ASSUMES that the fuel will not necessarily need to be placed in dry storage on site, and could potentially be shipped directly from the fuel pools. Thus, by not moving fuel from the pools as soon as practicable into dry casks, they envision avoiding this cost. However, in the scenario you are promoting here, all fuel from the fuel pools will be moved into the ISFSI prior to being transported off site, and therefore, there is NO SAVINGS, and the conclusion of that project should be REVERSED, i.e. expedited transfer is WISE, PRUDENT, and COST EFFECTIVE, and the safest thing to do, based on the fact that there is a safety difference between dry casks and fuel pools. If you have to transfer it to dry casks anyway, why not do it as quickly as practicable, to avoid the safety differences between the ISFSI and FUEL POOLS? Answer: there is no reason, and thus the conclusions of the expedited transfer are now moot. (0930-2-7 [Lutz, Ray])

Comment: Position: Stop making nuclear waste for any number of reasons including a Lack of Waste Confidence > --Unless and until permanent isolation of the existing radioactive waste from the biosphere has been demonstrated, there should be no confidence in licensing waste production, and the NRC should stop licensing new reactors and relicensing old ones. The NRC does not have the authority to license making more waste BECAUSE the waste canNOT be isolated from the biosphere. There is no current working process to isolate or remove radioactive waste of all levels from our biosphere. (0938-1 [Sondheim, Steven])

Comment: There should be no more licensing or re-licensing of nuclear reactors FOR MANY REASONS INCLUDING THE FACTS THAT METHODS FOR permanent disposal AND ISOLATION of radioactive waste have NOT been determined, proven and funded. Why should we condone continued licensing of new reactors and renewing licenses from old reactors while we are facing the dilemma of not being able to safely dispose of the 70,000 metric tons of commercial high level nuclear waste already generated and the ~ 2000 metric tons being produced each year by nuclear power reactors in the US? > --The EIS should consider and analyze the option of not generating any additional waste. It should consider and evaluate phasing out nuclear reactors in the near future. Creating additional waste when there is no

identifiable solution for its permanent disposition cannot be justified. > --Any EIS regarding nuclear waste storage must first and foremost consider alternatives to nuclear waste generation. There are other methods of generating electricity that do not generate radioactive waste. Prevention and precaution are the responsibility of the NRC. (0938-16 [Sondheim, Steven])

Comment: New potentially less dangerous methods such as Hardened ON- Site Storage (HOSS) should be fully evaluated in the EIS. (0938-5 [Sondheim, Steven])

Comment: NRC should not be allowed to issue new reactor licenses, nor grant license extensions to old operating reactors until a permanent, deep-geological high-level radioactive waste disposal facility is built and operating. (0939-3 [Marschak, Cheryl])

Comment: Please suspend licensing of nuclear Power plants until the radioactive waste can be stored safely. There is no confidence in your current policy. Also the current power plants are aging and need onsite inspections. Our nation and planet depend on you. (0940-1 [Doyle, Rosemary])

Comment: The EIS for "waste confidence" should consider and analyze the option of not generating any additional waste. It should consider and evaluate phasing out nuclear reactors in the near future. Renewables and energy efficiency are more climate responsible and do not come with a legacy of generations of radioactive waste. (0950-1 [Commenters, Multiple])

Comment: NUCLEAR POWER GENERATION SHOULD BE PUT TO REST BECAUSE THERE IS NO REASONABLE EXPECTATION OF STORING SPENT FUEL SAFELY. WE HAVE ENOUGH WASTE TO LAST MILLIONS OF YEARS, AS IT IS, AND WE ARE ALL CONTAMINATED. (1004-2 [Dimondstein, Carla])

Comment: Ending radioactive waste generation is important to minimize these societal risks. The NRC should revise its Waste "Confidence" document to ensure the speediest possible end to that generation. (1007-3 [Diamond, Jim])

15. Comments Concerning Alternatives – Costs

Comment: In addition, the limited attempt to distinguish Alternatives through comparing costs and benefits in Chapter 7 of the Draft GEIS is meaningless. Because the NRC determines in the Draft GEIS that the environmental consequences are not variable across Alternatives, the costs that do differ are limited to administrative costs (e.g., to develop site-specific NEPA reviews, rulemaking costs, policy statement costs, and costs to develop the GEIS). Such administrative costs are not typically the focus of NEPA analyses. Furthermore, the manner in which these costs were evaluated is inappropriate. While the Draft GEIS states that the costs of each Alternative are projected from fiscal year 2015 through fiscal year 2044 (Draft GEIS, pg. 7-2), the actual calculations of costs also include those incurred in years 2013 and 2014 to develop the GEIS for the three Action Alternatives (this cost is not relevant to the No Action Alternative). These past costs (referred to as "sunk" costs) can no longer be avoided and, therefore, should not be included in the document. (0473-1-12 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The Draft GEIS does not include discussion of the intergenerational impacts of high consequence events and associated discounting methods over the long-term and indefinite time frames. Because the Draft GEIS does not monetize environmental impacts of accidents or events, it does not include discussion of discounting impacts to estimate a present value over

time. In the context of economic analysis, discounting is the process of determining the relative worth today of costs incurred in the future (i.e., calculating "present values" of future costs of benefits). In other words, discounting reflects people's preference for receiving a dollar today over the promise of receiving a dollar ten years from now; the dollar received ten years from now is worth relatively less. In economic analysis, we apply a discount rate to future costs and benefits to reflect this preference. The cost benefit analysis in section 7 of the Draft GEIS, which evaluates only administrative costs of the Alternatives over 30 years, applies discount rates of three percent and seven percent to evaluate future costs. For these types of costs over this short period of time, this approach is consistent with best practices for Federal agencies as described by the U.S. Office of Management and Budget (OMB).³ [footnote 3 text: Office of Management and Budget, Circular A-4, September 17, 2003]. However, OMB's guidance suggests considering lower but positive discount rates (economists commonly assume values as low as one percent) to evaluate costs and benefits over intergenerational timeframes, such as presented in the Draft GEIS for consideration of environmental impacts.⁴ [footnote 4 text: Ibid] Lower discount rates over long analytic time frames better reflect the public's view of intergenerational tradeoffs (for example, in trading off current consumption for avoidance of future adverse events), and thus provide a more reliable measure of the present value benefit of such policies. (0473-2-2 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Specifically, in considering intergenerational costs or benefits, economists generally agree a lower or declining discount rate is appropriate. The lower or declining rate reflects the current population's consideration of the well-being of future generations, as well as increased uncertainty regarding the appropriate discount rate over longer time frames. A recent article by prominent economists highlights the importance of the selection of a discount rate for policies that have implications for centuries. This study specifically cites the relevance of policies related to the disposal of nuclear waste, and establishes the importance of relying on low or declining discount rates.⁵ [footnote 5 text: Arrow, K., M. Cropper, C. Gollier, B. Groom, G. Heal, R. Newell, W. Nordhaus, R. Pindyck, W. Pizer, P. Portney, T. Sterner, R.S.J. Tol, and M. Weitzman. July 26, 2013. "Determining Benefits and Costs for Future Generations." *Science*: 341. Pg 349-350.] For example, in the context of severe events, a lower discount rate applied over a long time frame reflects both ethical considerations of the current population with respect to the welfare of future generations, and increasing uncertainty over time about the level of risk for such events. (0473-2-3 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Exhibit 1 illustrates the significant difference in the cumulative present value costs of high- consequence events over long time frames depending on the discount rate assumption.⁶ [footnote 6 text: Absent an estimated magnitude for the risk (probability multiplied by consequence) in each year, as described above, this exhibit can only be illustrative; thus, the vertical axis is unitless. For the purposes of this demonstration, we model a declining discount rate assuming linear decline in the assumed rate between three percent and one percent between years one and 300.] That is, the points along the curve represent the present value costs of a future environmental impact each year into the future applying varying discount rate assumptions to reflect declining values of dollars over time. The vertical axis represents the present value impact and the horizontal axis is time. The area under each curve therefore reflects the total present value economic impact (summing across all years) between years 1 and 300. Consistent with the concept of discounting as explained, the present value cost of economic impacts declines in future years but is sensitive to the assumed rate of decline (i.e., discount rate). As suggested by the state-of-the-science, applying a declining discount rate, or a rate of one percent can result in present value impacts more than an order-of-magnitude greater

than a seven percent discount rate. The declining and one percent discount rates appropriately incorporate consideration of the potential for distant future severe events in today's decisions. Exhibit 1: Sensitivity of Impacts to Discount Rate Assumption graphic. Absent: 1) considering the probability and potential adverse consequences of high- consequence events; 2) a discussion of the cumulative costs of such events across future years in the Draft GEIS; and 3) using an appropriate discounting assumption, it is unclear how NRC concludes that environmental impacts are "small" across all of the Alternatives (No Action and the three Action Alternatives), scenarios (varying time frames for continued storage), and sites. (0473-2-4 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: In 2013 President Obama commissioned a study on the costs of "doing nothing" and found that Utilities have already sued the US Gov with 80 victories to recover their storage costs because USA did not come through with a Yucca mountain or similar. Direct payouts around \$2B, and further they estimated that as more plants age and close that the USA taxpayers could be on the hook for \$20B in judgments by the year 2020. And up to an additional 20% could be legal and consultants fees, bringing the tab to \$24B How much more simple can this be? \$14.375B to "pretty darn well" fix to the problem for 50 years and reduce our risk of disaster or terrorist attack, create good jobs, or squander \$24B in judgment fees and lawyer costs and NO PROGRESS? (0484-6 [Olsen, Steven])

Comment: In 2013 President Obama commissioned a study on the costs of "doing nothing" and found that Utilities have already sued the US Gov with 80 victories to recover their storage costs because USA did not come through with a Yucca mountain or similar. Direct payouts around \$2B, and further they estimated that as more plants age and close that the USA taxpayers could be on the hook for \$20B in judgments by the year 2020. And up to an additional 20% could be legal and consultants fees, bringing the tab to \$24B. (0529-3 [Claybourne, Ana])

Comment: GEIS Section 7.6, p.7-15, Table 7-6. "Public perception" costs and benefits should not be included in NRC's cost benefit analysis (Table 7-6, GEIS 7-15). First of all these are entirely speculative and fail to consider that different members of the public have different perceptions. For example, NRC has concluded that there would be a public perception benefit to site specific review and a public perception cost to precluding such review. This could be true for part of the public opposing specific facilities, because it would provide a facility specific opportunity for opposition to the facility. However, among portions of the public who desire efficient use of Federal resources, the opposite would be true. This part of the public would not want the facility specific licensing of facilities to undergo unnecessary and duplicative environmental reviews. So, whose perception does NRC ascribe a given cost or benefit and what is the basis for NRC's determination? The Table 7-6 perceived benefits and costs are merely a declaration without basis. Such speculation should not be included in the GEIS. Avoiding speculation about perceived benefits and costs is consistent with the approach DOE took in the Yucca Mountain FEIS that cited a consensus among social scientists that a quantitative assessment of the potential impacts from risk perceptions was "impossible at this time and probably unlikely even after extensive additional research" (DOE/EIS-250, Appendix N, page 21). The speculative nature of perceived benefits and costs is recognized in GEIS Section 8.6, p. 8-12, lines 5-10 that first recognizes that perceptions vary among stakeholders, and then cites the same speculative benefits contained in Table 7-6. The tabular information in Table 7-6 and the wording in Section 8.6 regarding perceived benefits and costs should be deleted from the GEIS. (0544-30 [Enriquez, Elizabeth])

Comment: Instead of being cost effective as postulated in Appendix H the reliance on a GEIS will be much more expensive and time consuming. Appendix H does not take into consideration

the costs of endless litigation and the need to conduct supplemental EIS for each reactor site. (0611-21 [Shapiro, Susan])

Comment: Section 1.6 discusses alternatives to the proposed action, including the "No Action" alternative, which if implemented, would require the NRC to perform site-specific reviews of the environmental impacts of continued storage during licensing actions. In dismissing this alternative, the draft GEIS states that the alternative is not viable because of the costs associated with these site-specific reviews (to the public, the agency, and licensee) and that licensing boards would be required to hear nearly identical contentions in each proceeding. The NRC is already required to meet NEPA for licensing actions, either through an EIS or EA; the environmental effects of continued storage would simply be another aspect of those documents. As an organization that has spent considerable sums in participating in the NEPA process (EIS for the PINGP 1 and 2 license renewal and EA for the ISFSI renewal) and litigating environmental and safety issues, the Tribe does not believe that "costs" justify the dismissal of this Alternative. The licensee will simply pass the costs of the review on to the ratepayers and the NRC currently recovers most of its costs from the licensee/applicant (current estimate is that 90 percent of the NRC's budget is from licensee fees). As far as the costs to the public, that decision is best left to the tribes, states, cities, or communities impacted by continued spent fuel storage. Not everyone impacted by continued storage is aware of the draft GEIS and how the Waste Confidence Rule affects their communities and prevent them from raising issues related to continued storage during subsequent licensing actions. According to the January 2012 report, issued by the Blue Ribbon Commission on America's Nuclear Future (BRC or Commission), the Nation's taxpayers are currently financially responsible for the numerous partial breach of contract lawsuits filed by the utilities on behalf of its ratepayers. If the Government begins accepting waste in 2020 (close to 6 years from now), the government liability is estimated to be \$16.2 Billion (in 2012). The Government's partial breach of contract liability increases by \$500 Million for each year of delay. Of course, this is in addition to the estimated \$15 Billion already spent to develop the now-abandoned Yucca Mountain site. The additional costs of site-specific reviews are nothing compared to the money already wasted developing and abandoning the Yucca Mountain site. The Nation's ratepayers have willingly paid licensing fees, Nuclear Waste Fund fees, and their taxes, with the expectation that they would get something for their money-a national repository for the spent fuel generated in their communities and states and assurances that the environmental impacts of these spent fuel storage facilities will be evaluated with respect to their unique site and not some generic "reference site." The additional costs of site specific environmental reviews are nothing more than a legal device to shield the NRC and licensees from litigation related to long-term storage. (0619-1-10 [Mahowald, Philip R.]

Comment: "Public perception" costs and benefits should not be included in NRC's cost benefit analysis (Table 7-6, GEIS 7-15). As a legal matter, public perception is, we believe, too far removed from the physical environment to be an appropriate consideration in NEPA reviews. As the Supreme Court stated in *Metropolitan Edison Co. v. People Against Nuclear Energy*,⁹⁹ [footnote 99 text: 460 U.S. 766, 7777 (1983).] the operation of the facility is an event in the physical environment, but the alleged psychological health damage in that case was "too far removed from the event to be covered by NEPA." So too is "public perception." Further, these costs are entirely speculative and fail to consider that different segments of the public have different perceptions. For example, NRC has concluded that there would be a public perception benefit to site-specific review and a public perception cost to precluding such review. This assumption is likely to be correct for segments of the public opposing specific facilities, as a site-specific review provides an additional opportunity to voice this opposition. But among segments of the public concerned about the cost and availability of clean reliable electricity, the exact opposite would be true - *i.e.*, this segment of the public would not want the licensing of

generating facilities they support to become protracted by unnecessary and duplicative environmental reviews. The dilemma then becomes: Which group's perception should be credited or assigned a given cost or benefit? If the answer to this question is to be that the perception held by the majority of the public should prevail, then NRC's decision to associate costs and benefits with the views of those who oppose nuclear power plants is most certainly incorrect. According to recent public opinion surveys a majority of the public favor nuclear power. For example, a survey conducted in September 2013 by Bisconti Research Inc. and Quest Global Research found 69 percent of the respondents now favor the use of nuclear energy as one of the ways to produce electricity. Such poll results have been consistent for a number of years. Nonetheless, it is inappropriate for the NRC, an independent safety regulator, to base its cost-benefit analyses on the results of public opinion surveys or its perception of public opinion. Rather, it would be more appropriate for NRC to avoid attempting to quantify perception costs and benefits altogether. This would also be consistent with the conclusion reached by DOE in the Yucca Mountain FEIS that there was a consensus among social scientists that a quantitative assessment of the potential impacts from risk perceptions was "impossible at this time and probably unlikely even after extensive additional research."¹⁰⁰ [footnote 100 text: DOE/EIS-250, Appendix N, page 21.] (0827-5-1 [Ginsberg, Ellen])

Comment: Exelon suggests that the NRC reconsider including "public perception" costs and benefits in the NRC's cost benefit analysis. Exelon believes that these costs might be speculative and fail to consider that different segments of the public have different perceptions. For example, the NRC has concluded that there would be a public perception benefit to site-specific review and a public perception cost to precluding such review. Indeed, among segments of the public opposing specific facilities, this is most likely a correct assumption, as a site-specific tool provides another opportunity for this opposition to be considered. However, among segments of the public concerned about the cost and availability of clean reliable electricity, the exact opposite would be true; this segment of the public would not want the licensing of generating facilities they support to become protracted by unnecessary and duplicative environmental reviews. The dilemma then becomes to which group's perception does the NRC ascribe a given cost or benefit. If the answer to this question is to be that the perception held by the majority of the public should prevail, then the NRC's decision to associate costs and benefits with the views of those who oppose nuclear power plants is considered to be incorrect, according to recent public opinion surveys. Exelon reviewed a recent survey noting that 69 percent now favor the use of nuclear energy as one of the ways to produce electricity. But even though such poll results have been consistently typical for a number of years, it is probably not appropriate for the NRC, an independent safety regulator, to base its cost benefit analyses on the results of public opinion surveys. Rather, it would seem more appropriate for the NRC to avoid attempting to quantify perception costs and benefits altogether. (0942-6 [Helker, David P.]

16. Comments Concerning GEIS Assumptions and Analysis

Comment: Proposals by the NRC -- including a 2050 repository, institutional control forever, replacing storage containers -- are impossible and fanciful, or just plain lies. (0023-5 [Bridges, Martha])

Comment: I appreciate the fact that you have your data and references in the report, but the actual engineering calculations, the actual computer source codes are not available. Lawyers I hear call it work product. But what I'm trying to say is, yes, we do have very good results

reported in this 2157, however, the source code that generated those results, the engineering calculations by hand are not available. It brings a question to my mind. (0030-14-5 [Lewis, Marvin])

Comment: I went through the documents and every time there was a risk -- you know, summary of environmental impacts on continued storage at reactor storage, reactor storage, small, small, small, small. You know, away from storage. You know, away from reactors, small, small, small. You know, no water. You know, everything's small. But you know, I've been attending these meetings for two years between the North Anna issues and when we restarted there without actually doing a lot of checking. Everything's always downplayed. I mean we're talking about some serious issues here. I mean lessons learned from Fukushima. I went to one of the Blue Ribbon Commission meetings and these are serious issues. It seems like this document is so generic, it was put together in a rush. (0030-15-6 [Gray, Erica])

Comment: And we're talking about a 100-year changeout; that is mentioned several times in the document. And a 100-year changeout is going to cost -- well, let's see, we've got 1,500, roughly, dry casks nationally right now. And that means in 100 years, if they last that long, we're going to have to start changing them out at the same rate that we're making them. And if we had all of the fuel that we -- we would like to accelerate the rates that we're making them, and we'll have nearly 10,000 dry casks, just by the time we get all of the fuel that has already been made put into dry casks. That's an awful lot of dry casks, but that's only the beginning. That's only what they're going to have to do in 100 or 110 years, or whatever it takes us to get it all in. And then the other, oh, 100,000 dry casks that have been built in the meantime are all going to also need to be replaced over and over and over again. (0030-4-2 [Hoffman, Ace])

Comment: So we're talking about licensing and relicensing. That was Andy's opening statement. And 10 years ago, 15 years ago, when they were given this dry cask -- I have the documents, I was looking at them just a day or two ago, and the word "temporary" was always in the dry cask phraseology, that this was a temporary solution. But he didn't say "and relicensing and relicensing and relicensing" for 300 years, 500 years, and that's with changing them out. Just calling it licensing/relicensing is not going to be good enough. It could be quite a bit longer than that. (0030-4-4 [Hoffman, Ace])

Comment: There is a lot here to have confidence in. There is a lot more that will be said. But -- and I do think that, you know, these 100-year scenarios and repackaging, NEI may have some things to say about that. We don't think we are going to be repackaging every 100 years. (0030-6-9 [McCullum, Rod])

Comment: Though not required by NEPA, the GEIS makes very conservative assumptions. In other words, the GEIS makes assumptions that tend to overstate the environmental impacts of used fuel storage. For example, the GEIS assumes that used fuel will be moved to new casks every 100 years under the long-term storage scenario, even though current science and experience shows that cask replacement need not necessarily occur that frequently. (0030-7-6 [Matthews, Tim])

Comment: In the GEIS, To guide its analysis, the NRC relied upon certain assumptions regarding the storage of spent fuel. These included two assumptions that have no basis in experience or reality, never having been accomplished in the US. These are: Spent fuel canisters and casks would be replaced approximately once every 100 years. Independent spent fuel storage installation (ISFSI) and dry transfer system (DTS) facilities would also be replaced approximately once every 100 years. Given that NRC has ignored both past experience and staff recommendations to implement the lessons learned from experience (such as when they

went against the recommendation of their staff scientists to require hardened filtered vents in Mark 1 BWRs to prevent the explosions and massive release of radiation that occurred at Fukushima); to make assumptions based on NO evidence at all, no experience or confidence that such transfers of fuel from dry casks to new storage casks will occur without damaging embrittled fuel cladding, or that the technology will exist to safely transfer damaged fuel assemblies over unimaginable time frames is yet another example of NRC hubris and pattern of substituting wishful thinking for scientific integrity. (0089-10 [Shaw, Sally])

Comment: However, casks such as the Holtec High Storm 100 have leaked, even before their 20 year license expired. How then can NRC assume with confidence that they will not leak in the future, over 100 years to 1,000,000 years, and that these leaks will not have environmental impacts. Such assumptions are wishful thinking, not science. (0089-9 [Shaw, Sally])

Comment: Page 8-8 lines 19-22: For both at-reactor and away-from-reactor ISFSIs, there would be no irreversible and irretrievable commitments of resources during continued storage for most resources. However, impacts on land use, aesthetics, historic and cultural resources, waste management, and transportation would result in irreversible and irretrievable commitments. You say there is no irreversible and irretrievable commitments of resources for most resources. But the resources that are affected are significant. Also you fail to mention that the resources utilized to maintain the waste facilities will then not be available for alternative non-polluting, renewable, energy development. Maintenance of these waste facilities represents an irreversible and irretrievable commitment of resources that could otherwise be available for development of renewable energy sources. THIS IS SO IMPORTANT AS A VERY SIGNIFICANT IMPACT OF NUCLEAR ENERGY DEVELOPMENT AND MUST BE STATED SOMEWHERE IN THIS DOCUMENT. (0093-8 [Dennis, Harold E.B.])

Comment: So while our legislative and executive branches take their time trying to stay up with France on geologic disposal, our judicial branch has directed the Nuclear Regulatory Commission here to look at the what ifs. What if we don't dispose for these incredibly long periods of time? And they have done a credible job at looking at those ifs. We all need to understand these are what ifs. These are bounding scenarios. They've talked about things like 60 years in pools. Since dry cask storage was invented the average plant goes to dry cask storage 11 years after it shuts down. They've talked about putting dry-transfer facilities at every site. That won't happen. We'll use portable systems and every 100 years we will continue to license them well beyond 100 years. (0112-25-4 [McCullum, Rod])

Comment: Plutonium-239, just one of the poisons that radiate from spent fuel pellets, will remain hazardous for at least 240,000 years. Therefore your NRC assumption that "indefinite storage" at reactor sites can go on literally forever must end now. It has also been shown by the catastrophic release of nuclear fuel at Fukushima, that irradiated nuclear fuel will degrade with age, and will also degrade the materials with which the containers are built. Therefore NRC's assumption that dry cask storage - cask pads, inner canisters, and the dry casks themselves - will be replaced once every 100 years is seriously deficient. The fuel transfer operations must be undertaken whenever monitoring shows any danger of cask decomposition, no matter what the cost. (0127-2 [Lee, Catherine])

Comment: The proposed changes to the Waste Confidence Rule appear to assume that long-term storage of SNF will be in casks, and that the effects of long-term storage should be based upon this assumption. However, the NRC has no rule or policy that requires movement of SNF from wet storage to dry storage, and thus any analysis of long-term storage pool should analyze the possibility of SNF remaining in a densely configured elevated spent fuel pool (such as the pool

at the Vermont Yankee Station) for at least fifty years after cessation of operations, and perhaps longer because the NRC allows a licensee to request an extension of the period of SAFSTOR beyond 60 years. Absent a clear regulatory mandate from the NRC for movement of SNF from wet to dry storage, there is no basis for limiting analysis of the effects of the rule change to dry storage options. (0146-2 [Buchanan, Tom])

Comment: The assumptions the NRC used in the EIS are reasonable and conservative, and I believe the conclusions reached are correct. I know from personal experience that nuclear power plant owners have safely managed spent nuclear fuel for decades, and the continue to do so today. (0163-11-2 [Gutherman, Brian])

Comment: I looked at the Generic Draft -- the Generic Environmental Impact Study. I looked at that draft and in print it seems very solid. The pages are there. It's all lined out. And you know, it doesn't exactly seem as ambiguous as I found out it was when I talked to the people from the NRC out in the hall. Not only are there exceptions and exemptions, but it's for the purpose of an analysis. It's for the purpose of creating a model, which means that it's not really for us. It's not real. It's for a plant that doesn't exist. A perfect plant and a perfect world if there could be such a thing. (0163-21-1 [Elie, Marilyn])

Comment: I was here about two years ago, and at the time, my mind was blown by the presentation from the NRC that they had issued, that year, 1100 exemptions from safety procedures. So today while I was waiting before this began, I was encouraged to speak with the staff outside and there was graph. And it was a generic graph, which I didn't understand, so I asked for clarification, and I was curious about how much of the waste at Indian Point was in dry cask storage. The person told me they didn't know. They had no clue. There was a graph showing 60 years, 160 years, for dry cask storage, for open fuel ponds, whatever it was. It didn't make any sense. So I began to ask some questions and again, no clues. (0163-33-2 [Geist, Sheila])

Comment: There are three basic assumptions which this document is based upon which are false and misleading and inaccurate, and therefore, the GEIS is fatally flawed. (0163-7-5 [Shapiro, Susan])

Comment: It is my understanding that the NRC did not do the 'full analysis' required by the Court of Appeals. Instead of examining what would happen if spent fuel remained unprotected on the earth's surface indefinitely, the NRC assumed that spent fuel would be safely managed in surface storage for an indefinite period. The Court required NRC to examine the risks of spent fuel storage and did not allow NRC to merely assume that storage would be safe. (0177-5 [Craig, Anne])

Comment: Full knowledge of each of the Final EIS documents for each nuclear power facility would certainly have been beneficial, and I contend that a summary of this information should be within the DGEIS to quantify and to provide a summation of cause and effect specifics. (0219-1 [Olmstead, Stan])

Comment: The draft document draws the reader away from nuclear plant licensing and plant specific locations. The document for analysis is extremely general without any specifics and fails to be analytical. It is a "Trust Me Document." I can accept the concept of generic analyses. I cannot accept general analyses without specifics. The document is fraught with constant assumptions, short-term experience and has an industry-based analysis. Not one specific species is mentioned in the document for federally listed species, special status species or other

terrestrial species. No specific water bodies are analyzed that may become contaminated by the stored material whether on Eastern state waterways, Midwestern farming areas or the Pacific coast. Each existing facility has a unique environmental and geological situation and the assumption is made if it was adequately analyzed for a 40 year license with two 20 year renewals at the power plant then it is adequate for short term, long term and indefinite storage. Not true! I accept the attributes within the document's analyses, but do not accept the analyses. The DGEIS is a waste storage document. It has two essential and almost insurmountable problems: The serious nature of the waste to be stored and the vast length of time (millenniums beyond millennia) the waste must be safely stored. (0219-7 [Olmstead, Stan])

Comment: Despite each NRC commissioner's seemingly impressive academic credentials, the assumptions it makes regarding safe storage of nuclear waste are so flawed, any D grade high school student can see the dangers involved. (0239-1 [Rasmussen, Kenneth])

Comment: It's also heartening to see the four students get up here and talk about what they're doing, because one of the big flaws in the EIS is it assumes that every 100 years is going to be the same 100 years over and over again. I know better, I know these young people are going to do a way better job than my generation did. So, you know, again, that's where -- an example of where its bounding. (0244-11-8 [McCullum, Rod])

Comment: Why does the NRC rely on assumptions rather than directly implement specific and measurable expectations? How can the nuclear industry and U.S. society have confidence in such a system for managing waste, waste associated with detrimental biological effects when inappropriately handled? (0244-14-5 [Prescott, Lisa Marie])

Comment: Regarding the environment. According to the NRC, changes in the environment around spent nuclear fuel storage facilities are sufficiently gradual and predictable to be addressed generically. I beg to differ. (0244-14-6 [Prescott, Lisa Marie])

Comment: You say that this is the Waste Confidence Generic Environmental Impact Statement, so the key word would be confidence. And, to me, confidence comes from knowledge, so just a couple of suggestions. In this report the word "small" in capitalized font appears more than 119 times. However, there's no actual outline of what small really means. There's no numbers, there's no science, no actual graphs to really assess what the word small really means in this study. Also, it would just be nice to have, like, a copy of the data in which that was based upon. (0244-15-1 [Zuccarini, Ana])

Comment: So it's just -- for a nuclear, you know, very science-based, you know, PhD's, there's not a lot of science to these, it's just a lot of capital letters, small, moderate, large. So, you know, I'd appreciate, since this is up for the community and you are providing us a chance to really be acquainted with what you are doing, if you would just provide that kind of science for us to assess, even if somebody may not grasp completely what is written on there, it would just be like a good -- indicative of, you know, how much the study -- like how in depth it went, you know, many might be able to recognize some, you know, maybe some pollutants that are already in the environment that could maybe interact with some that might leak or whatnot. So, you know, even if I -- I'm not going to use this for anything, it would just be appreciated if you would provide that. (0244-15-6 [Zuccarini, Ana])

Comment: And then, also it says here that these -- the overall contributor, human health and environmental effects from continued short-term spent fuel storage would be limited in scope

and small for all populations. However, what are the limiting factors of the scope? (0244-15-8 [Zuccarini, Ana])

Comment: Just as we cannot assume that long-term geologic storage will be secured, we cannot assume that indefinite storage onsite will be safe. To act under these assumptions is inconsistent with the Nuclear Waste Policy Act and violates NRC's own regulations. Instead of these some assumptions the NRC should draft a new GIS to examine the probability that a geologic repository will be successfully sited, the probability that a successfully sited repository will actually contain radiation, the degree to which a repository may leak radiation, and the public health and environmental consequences that may occur if a repository is not sited or if it ineffectively contains radioactivity. (0244-3-3 [Hancock, Mandy])

Comment: From the onset I think the fundamental flaw here is just what Mandy said that, you know, instead of really following what the Court had ordered, which was an examination of the environmental effects, instead it works off this assumption that things will be okay, it's safe indefinitely.

And I think NEPA demands more, and I think, you know, the law over the last 40 years is -- you know, you see that in court decisions after court decisions. It's not a tool to justify a predetermined outcome.

And these effects that we speak of, I mean it's not speculative. I mean there's at least two events that, strangely enough, were not identified in this Generic Impact EIS, there being Yankee Rowe then the high flux beam reactor, issues from years ago. (0244-8-6 [Totoiu, Jason])

Comment: The NRC was -- I'm sorry, I didn't mean to -- okay. The spent fuel pools are more crowded than Japan's. The NRC was to find a permanent site for spent fuel. With Yucca off the map and our nuclear waste growing to 70,000 tons, a Federal court ruled in 2012 that the NRC could not proceed with new licenses or extensions until they completed an environmental study to show the environmental and health effects over time if spent fuel is not stored in a repository. (0245-14-3 [Kurz, Carol])

Comment: As a generic report, we understand the use of bounding assumptions. These types of assumptions result in a conservative approach being used on a generic basis. But it also may not be fully representative of what will occur at a site with fuel storage in the future. For instance, the report assumes that a dry transfer facility will be built at all dry cask storage facilities, and that all dry casks will be replaced every one hundred years. While the conditions of the casks will of course be closely monitored over their lifetime and a rigorous aging management program is already in place, it is unlikely that wholesale replacement of all casks would be required and the transfer facility may not be needed at all sites. (0245-20-3 [Dunlap, Jeff])

Comment: So, pool breakdown -- comprised of natural end state for which nuclear -- are naturally drawn by the great fact of the natural course of things. Only through the ongoing interventions of dutiful employees has it been forestalled like jugglers -- for reasons of their own. Where are the NRC's thorough, comprehensive, and informed analyses of the future? Should we expect to find such dutiful employees six decades after the nuclear supply business has gone bust? I'll just make a casual reference to Michael Burn, the convicted masked gunman, car-jacking senior operator with the six years unescorted access to Dresden, it's a big waste policy, licensing and relicensing -- (0245-24-6 [Conn, Corey])

Comment: This GEIS has one scenario where there is no repository at all becoming available. Again, why do we generate more waste when we're not going to have storage facility as one possibility? And changing out these casks every hundred years, I mean a thousand years from now, what kind of shape are these casks going to be in if we have to change them all, you know, every hundred years? (0245-27-2 [Ower, Douglas])

Comment: I opened up the big document and started to page through it. And I expected to see tables and charts that might tell me here is where we're at as far as filling up these spent fuel pools, here is where we are using dry casks, and here are some guidelines for best practices. And I didn't find any of that. I found that kind of quirky. And then I thought, well, we're going to have certainly some best practices and some guidelines that are going to underlie these assumptions. But I didn't find any of that. (0245-31-2 [Fox, Tracy])

Comment: The third point I have is actually in the EIS, which I partake a lot in my career when I worked at Argonne, uncertainty of the generic EIS, there's a lot of assumptions coming into that. But every assumption has a lot of uncertainty involved. So, I'm not too sure of how exactly uncertainty has been analyzed much more specifically. And maybe the last one would be the site-specific management part of that, how that ties into the uncertainties I mean here would be very important. (0245-5-3 [Chen, S.Y.])

Comment: As I said, the intent of the Court order was for the NRC to conduct a comprehensive analysis of the impacts of storing spent fuel onsite at nuclear plants indefinitely. The NRC has not done this. They have not provided a complete analysis but rather are assuming that spent fuel would be safely managed for an indefinite period of time. For example, the study assumes waste will not leak radioactivity because the fuel will be safely managed essentially forever, including the assumption that waste will be transferred into new storage casks every 100 years. This is a tough assumption to justify[.] (0246-22-2 [Fisher, Allison])

Comment: I would encourage the NRC to provide more details in the GEIS that are similar to these that I have just laid out regarding package robustness so that the public, in fact, can understand exactly what the NRC truly knows. (0250-27-4 [Pennington, Charlie])

Comment: In the GEIS, this draft, it says it's a potential environmental -- it analyzes potential environmental impacts that could occur as a result of the continued storage of spent nuclear fuel. I don't see that in here. I see a whitewash. I see the murdering of logic in the assumptions, that the storage of this fuel, the institutional control, the canisters being replaced every hundred years, the independent spent fuel storage installations, the dry transfer system. All of that stuff going on forever? Really? (0250-5-6 [Safer, Don])

Comment: Today at this hearing, we are considering the promise of safety by a) a repository available by 2050; b) institutional control forevermore; c) replacing storage containers every 100 years forevermore. Have we learned nothing from the hubris of humans in history? Are we promising the impossible? Do we dare? (0250-52-4 [Amos, T.J.])

Comment: One of the unintended consequences of the Nuclear Waste Policy Act is that it fomented the perception that nuclear waste, which by law must be permanently disposed underground, is so dangerous and unmanageable that it must be buried underground or otherwise permanently removed from the human environment. Unfortunately a comprehensive, accessible public education/information campaign to effectively address these fears, does not exist. Unchallenged and uncorrected, the public's misunderstanding of the risks and benefits of spent fuel will impede the country's ability to develop nuclear energy, and as a result, prolong

our reliance on carbon-based fuels. The fact that some members of the public fear a technology that has time and again been proven safe is no reason to banish the technology. We suggest to the NRC that the technical basis for the conclusions in the GEIS, and the numerous studies supporting the safety of spent fuel storage systems, drive the rulemaking and that the NRC expansively address in lay terms the evaluated risks associated with spent fuel storage. (0262-12 [Patterson, Karen])

Comment: We find that NRC's "finding of no significant impact" regarding: 1.) spent fuel pool fires; 2.) spent fuel pool leaks; 3.) vulnerability of spent fuel pools and dry cask sites to natural disasters and terrorist assaults; and 4.) NRC's belief in the adequacy of generic findings at reactors--to be unfounded, inadequate to the protection of the public health and safety (0274-5 [Kraft, David])

Comment: The NRC's draft Waste Confidence GEIS skirts the issue of long time storage safety by assuming fuel in dry casks can be managed indefinitely for 100's of years. It does not consider the possibility of terror attacks, nor mention the impacts of pool leaks, especially tritium, where there's a significant history of such accidents, nor show concern for earthquakes, tornadoes, floods which grow stronger with climate change. (0276-5 [Kurz, Carol])

Comment: I am extremely disturbed by NRC's methodology used to define how although consequences would be high, probability is extremely low. It is interesting to observe that in the Executive Summary, Tables ES-3 and 4, with few exceptions typically concludes probability of high consequence impacts are low. (But are significantly underestimated). (0284-14 [Borchmann, Patricia])

Comment: The Rule did not have the benefit of a full, comprehensive study of the potential public-health and environmental effects of long-term SNF storage at reactor sites, as mandated by the Court. Indeed, it implicitly acknowledges this (p. 56788): The DGEIS analyses are based only, it stated, "on current technology and regulations," instead of on detailed and rigorous scientific study, as the seriousness of the issue demands and as the Court has mandated. (0303-7 [Lamberts, Frances])

Comment: The Federal Circuit Court agreed with the New York Attorney General, required NRC to provide a thorough analysis of public health, safety, and environmental impacts about storage-- the impacts that storage would pose before allowing long-term storage to occur. (0325-11-2 [Borchmann, Patricia])

Comment: I'd like to bring to your attention now one section here, Section 8.4, Survey of Environmental Impacts and the section heading is "Relationship Between Short-Term Uses of the Environment and the Maintenance and Enhancement of Long-Term Productivity." And it goes on to say, "In addition, the long-term productivity period evaluated in this chapter is the time period beyond continued storage (i.e., based on the NRC guidance in NUREG-1748, the period beyond the action under review.) As discussed in Chapter 1 in this draft GEIS, the NRC believes that the most likely outcome is that a repository will become available to accept the spent fuel generated by a reactor by the end of the short-term time frame, or 60 years after the end of the reactor's licensed life for operation." And I won't continue, but I read this page several times trying to understand what, if anything, it actually meant, and I still don't know what it means. And if this was a sort of hearing where one was allowed to summon a witness and question that witness, I would like to ask somebody from the Commission staff just what this does mean, because with all due respect, I don't think it means anything. (0328-11-2 [Muller, Alan])

Comment: The Draft Generic Environmental Impact Statement sidesteps the Circuit Court directed analysis with several assumptions, including an assumption that the spent fuel storage installation will be rebuilt, and that every cask will be reloaded every 100 years. In other words, the NRC purports to analyze the potential impacts of long-term onsite storage of spent nuclear fuel by assuming that there will be no long-term onsite storage of spent nuclear fuel. (0328-3-1 [Mahowald, Philip])

Comment: Now, to say that none of these impacts are anything but small in all of the work in this Generic Environmental Impact Draft, it's not credible, it's not credible. On the one hand you say it needs to be put into a deep geologic repository for 10,000 years or more, and then you say the impact is small. Somebody's lying. Somebody's lying, and it's not the children, and it's not the water, and it's not all the living things. I think it's the Nuclear Regulatory Commission, and I think it's the nuclear industry. (0328-6-3 [Foushee, Lea])

Comment: I think nobody is contending here that whatever pools or casks we design will last forever, we do think that the assumption that casks need to be repackaged every hundred years is conservative. (0329-10-4 [McCullum, Rod])

Comment: But one area I did want to focus on today, and it kind of picks up right where Rod McCullum from NEI just left off, was this notion of contents, I guess. Rod spoke about replacing the dry cask storage infrastructure once every hundred years, and he called that a conservative thing to do because I guess he thinks that the dry casks and supporting infrastructure are going to last longer than that in most likelihood. But I'd have to challenge that at its face. I mean, there have been problems with the dry cask storage at Surry, for example. There have been leaks of the inert gas through seals. Supposedly, it has not completely leaked out, which would introduce air and oxygen into the dry casks and, combined with the heat, could corrode the dry casks prematurely. So I think something that a commenter or a concerned citizen in Chicago at the Oak Park, Illinois hearing said was right on, which is a false confidence when it comes to technology is a technological arrogance. (0329-11-1 [Kamps, Kevin])

Comment: It's about the absurdity of assuming dry cask storage be maintained forever into the future with once-per-century replacement of the entire kit and caboodle. (0329-20-1 [Kamps, Kevin])

Comment: The Draft Generic Impact Statement has been challenged several times here. I don't see -- as an attorney who has read many EISs and litigated with others in the area of NEPA -- can't understand how you could possibly have a finding of no significant impact on the human environment. If nothing else, the pattern and history of leaks from existing aboveground storage, which supposedly had leak monitoring in compliance with NRC regulations, shows that one cannot say that there will not be significant releases of radioactivity to the human environment from aboveground storage. (0329-25-2 [Paddock, Brian])

Comment: And yet, the NRC in this GEIS has determined that the above and all other major risks attendant to high level nuclear waste should be entirely discounted, written out of the equation, because each is unlikely and the foresight and powers of the NRC are so remarkable, that it will be able to prevent the occurrence of any and all major problems. With knowledge of the future that is vast and precise, the NRC has determined that continued storage of nuclear waste in aging spent fuel pools for the next 100 years is nothing to worry about. And holding large amounts of nuclear waste at dozens, perhaps even hundreds of sites throughout the nation for 200 years is no problem either. Indeed, the NRC's omniscience is such that, rest

assured, having large amounts of high level nuclear waste on these sites is safe for millennia. (0341-1-18 [Mermelstein, Richard])

Comment: For 100 years, 200 years, tens of thousands of years: All environmental and human health impacts the NRC proclaims in the GEIS will be "SMALL." Impacts from major natural disasters, major earthquakes, raging wildfires, floods and massive storm surges, with all the possible consequences that could ensue, are also "SMALL." Impacts relating to accidents, the GEIS attests, will be "SMALL." Even impacts from terrorist attack directed at nuclear sites or materials in transport, the GEIS assures, will be "SMALL"! How, we wonder, did the NRC arrive at these patently preposterous conclusions? (0341-1-19 [Mermelstein, Richard])

Comment: The GEIS suffers at its very foundation from a flawed risk model. The GEIS states: "NRC's concept of risk combines the probability of an accident with the consequences of that accident. In other words, the NRC examines the following questions: * What can go wrong? * How likely is it? * What would be the consequences?" (GEIS, at xxx). "What can go wrong?" begs the answer: Fukushima and Chernobyl. And this illuminates the reality that embodied in any evaluation is a value system. The value system expressed in the GEIS clearly does not elevate human health, the protection of the environment, or the security of the nation above the goal of enabling the additional accumulation of high level nuclear waste.⁵[Footnote 5 text: A value system that focuses on public health, preserving the integrity of essential natural systems, averting climate change, making energy generation more democratic, and reducing homeland security risks and geopolitical conflict would, in contrast, promote expansion of efficiency technologies, advance transmission system modernization, and strive towards transition to energy systems which are renewable and sustainable. Energy policy encompasses a host of policy objectives.] It is exceptionally disingenuous for the risk formulation in the GEIS to be proffered as if some sort of objective mathematical equation drives the analysis. Each of the three bullet point questions posited involves human beings making judgment evaluations based on what they subjectively deem worthy of attention and consideration.⁶ [Footnote 6 text: The very quirky exception made in the GEIS findings of no impact being "LARGE" is the area of "Historic and Cultural Resources." Apparently the GEIS authors view the potential destruction of things like a historic graveyard to be more problematic than the despoliation of the lands of a Native American reservation or the pollution of a National Heritage river. In the GEIS, the impact of loss of historic buildings and cultural assets is admitted may be "LARGE" with the explanation that such loss is permanent. Yet the impacts of "Public and Occupational Health" (i.e., illness and loss of human life due to radiation exposure) is deemed "SMALL." One would think death to also be a rather permanent condition. The sole additional finding of other than small is the concession that nonradioactive waste might have impacts that are "MODERATE." This is rather bizarre, given the determination that all impacts relating to highly radiotoxic material are "SMALL."] Each involves a subjective decision as to what specific selection of sets of data to use and how to weight each component of available evidence. And, with respect to very long term holding of nuclear waste, each step involves - at best - an educated guess based on limited data. (0341-2-1 [Mermelstein, Richard])

Comment: Radiation is Not a Major Health Risk. This assumption is implicit. Reading the GEIS, if one did not know what spent fuel was, the reader would conclude the material was a minor pollutant presenting minimal health risk.¹² [footnote 12 text: It is worthy of note that none of the individuals in the GEIS Table 9-1 List of Preparers put forth as having public and occupational health expertise are medical doctors. It is also perplexing that the GEIS determines nonradiological waste to be more of a health concern than radiological waste. Moreover, as earlier noted, the GEIS concedes that the impacts of nuclear waste might be "LARGE" with respect to historic and cultural resources, because the effects could be

permanent, yet deems the impacts upon public and occupational health to be "SMALL." This is a rather bizarre given the fact that chronic illnesses and certainly loss of human life caused by radiation exposure would normally be seen as pretty permanent conditions.] (0341-2-12 [Mermelstein, Richard])

Comment: The following point mandates emphasis: Models are models, not reality. A model's equations are a limited and partial representation of a limitlessly complex series of systems. And when dealing with extraordinarily complex systems that interact with multiple other highly complex systems - as is the case here, where nuclear installations with massive numbers of constituent parts interact with complex, constantly changing, ambient environmental conditions, weather behaviors, geologic events, human actions (both benign and malevolent), and the behaviors and capabilities of other infrastructure - modeling is a particularly inadequate mechanism of prediction. The very best a model can do is pick out some relevant variables relating to the machine and its structures and tie them through different algorithms to dynamic equations relating to selected sets of models for other systems. Probabilistic risk modeling may be useful and acceptable for NRC institutional use in assessing the odds of certain specified outcomes for certain specific systems, components, or dangers. But it is an invalid and unacceptable model to use when, as here, a vast number of factors are unknown, and the potential outcomes are catastrophic. (0341-2-2 [Mermelstein, Richard])

Comment: The NRC cannot seriously contend, for example, that climate change would not exert a multiplier effect on the aging mechanisms applicable to spent fuel assemblies, spent fuel pools, or ISFSIs. Yet such analysis is absent. For a wide assortment of risks - flooding risk, dam failure risk, earthquake risk, site structure hazard risk, construction accident risk, landslide risk, hurricane risk, tornado risk, site fire risk, wildfire risk, malevolent insider risk, terrorism risk, human error, acts of nature, you name it - small risks can grow pretty exponentially when combined and when the time periods are long. Take just seismic risk. Accepting that the seismic risk is numerically (albeit not qualitatively) small for any given year to the current existing nuclear plant infrastructure, that does not mean risk will remain small as more spent fuel is created, more nuclear sites are built, and the decades and centuries pass. Not only does the GEIS not consider this, but IPSEC is aware of no existing seismic study which has conducted such analysis. Most astonishingly, given the nuclear events of recent years,⁷ [footnote 7 text: Fukushima at least had emergency generators designed to operate for 8 hours. The NRC has allowed Indian Point and many other plants in the U.S. to operate with generators designed for only 4 hours. Notably, just this year, a supervisor, the Chemical Manager, at Indian Point was indicted and pled guilty on charges of falsifying tests relating to emergency diesel operation.] there is no analysis which connects the potential consequences of a protracted station blackout (or SBO) to the risks presented by extreme weather, other infrastructure vulnerabilities, earthquakes, terrorism, sabotage, the aging transmission grid and just plain inept operation.⁸ [footnote 8 text: The large-scale, broad geographic region power outages in the U.S. include those from Superstorm Sandy and the nor'easter which struck 3 days later in 2012 and the East Coast-Canada blackout of 2003 (during which, incidentally, Indian Point's emergency communications systems and emergency diesel generators failed. See NRC, Special Inspection Report, 2003).] The entirety of problems which may impact spent fuel both during and after reactor license periods is particularly relevant to sites with multiple reactors where continuing reactor operation overlaps with the "short-term" storage period. Sites with more than one spent fuel pool also mandate scrutiny because of the multiplier effects which inevitably result should several pools be affected by one event. The methodology employed in the GEIS thus disregards the entire discipline of disaster science. More astoundingly, the GEIS also appears to have no institutional memory of nuclear accident and incident history. (0341-2-5 [Mermelstein, Richard])

Comment: Obviously the NRC is eager to justify an end to the Court-imposed moratorium on reactor licensing and renewal procedures. Yet it attempts to do so without addressing the actual issues or providing proposals to deal with potential scenarios that could result in a release of materials. The draft seeks to rely on claims of low potential for problems, a claim that is without scientific validity given recent events, and which avoids rather than addresses the potential impacts should a problem arise. (0402-1 [Gross, Cheryl])

Comment: As for dry cask storage, the NRC has proposed basically two scenarios to deal with the political impasse over the Yucca Mountain repository; and to inspire "confidence" that nuclear power plants will be able to continue to produce and dispose of their nuclear waste into the foreseeable future. These scenarios are: (1) continued on-site storage of spent fuel in cooling pools for the first 60 years after reactor shutdown, after which the fuel will be transferred to dry cask storage on-site, placed on concrete pads in the open air where they are effectively parked for the next 100 years or indefinitely with pad and cask replacement each additional 100 years; and (2) away-from-reactor dry cask storage at independent spent fuel storage facilities yet to be determined, on concrete pads in the open air, with the possibility of indefinite storage by replacing the pad and containers every 100 years. Facilities for dry transfer of fuel assemblies between casks would need to be constructed in both of the above scenarios. The away-from-reactor analysis in the case of scenario (2) smacks a bit of desperation as the NRC repeatedly uses another politically failed depository as an example of and "proof of concept" that an away-from-reactor consolidated independent fuel storage facility is both feasible and practical. The example used is that of a withdrawn license application by Private Fuel Storage, Ltd., to build a depository on the Goshute Indian reservation in Skull Valley, Utah. Basically, the proposal amounted to relocation of the politically failed national underground repository at Yucca Mountain to an above-ground, open-air, indefinite, storage facility, built to accommodate 40,000 metric tons of the nation's accumulated high level nuclear waste, just 35 miles from Salt Lake City. Not surprisingly this proposal met with considerable resistance. PFS, Ltd. wanted the Goshute land because it was not subject to state environmental regulations. They approached the tribal leaders and made them an "offer they couldn't refuse," namely, give every member of the tribe a million dollars and let them all move away from their reservation, en masse. Some members of the tribe declined the recommendation of their elders and because they refused to leave the reservation, the deal fell through. The Governor of Utah also weighed in on this controversy and threatened to block road and rail transport of high level waste across State transportation corridors into the depository. The proposal became a poster-child for environmental injustice, until it was eventually abandoned. (0410-20 [Nelson, Dennis])

Comment: You have assumed that cask pads, inner canisters, and the dry casks will be replaced once every 100 years, for hundreds of millennia. Since Spent Fuel Pools (SFP) will have been dismantled by, at most, 60 years after permanent reactor shutdown, you further assume that dry transfer systems will be built and replaced every 100 years. Will degradation of irradiated nuclear fuel prevent the proper execution of such transfer operations? No one knows and you don't care. (0419-10 [Agnew, David])

Comment: A continuing issue is the spent fuel will need new containers every century or two. Will the NRC determine the likelihood that time will treat these containers gently or what will be the likelihood and effects of failure of these containers? (0430-2 [Lewis, Marvin])

Comment: The key risk analysis makes almost no distinction between levels of risk involved in on-site and remote storage. Table E-4 applies the methodology used in E-3 to remote storage, using the same three timeframes and 24 environmental factors. The levels of environmental impact for spent fuel storage at remote (away-from-reactor) sites are shown as identical to on

site-storage, with one exception: Aesthetic impacts rate as "Small" for on-site storage and "Small to Moderate" for remote storage. In summary, the draft Generic EIS finds essentially no difference between on-site and remote storage from an environmental impact perspective, and rates impacts as "Small" in over 80 percent of the data points. (0431-12 [Pascall, Glenn] [Watland, George])

Comment: The findings of the GEIS appear to seriously understate (a) generic levels of risk in storing spent nuclear fuel on-site at decommissioned reactors; (b) specific risk factors arising from characteristics of specific sites; (c) risk differentials of long term or indefinite storage on-site rather than at a remote geologic repository; (d) added risks of on-site storage created by the use of high burn-up fuel. (0431-2 [Pascall, Glenn] [Watland, George])

Comment: The GEIS risk analysis of on-site storage is not credible regarding either the generic level of risk or site-specific factors affecting risk. Table ES-3 in NUREG 2157 summarizes the likely at-reactor impacts on 24 environmental factors during short-term, long-term, and indefinite storage of spent nuclear fuel. Applying the time scenarios (3) to the environmental factors (24) results in 72 assessment points. Five of every six impacts - 60 out of 72 - are rated as Small, including all impacts on land use, climate change, geology and soils, surface-water quality and use, groundwater quality and use, aquatic ecology, noise, waste management of low-level, mixed and non-radioactive waste, public health, accidents, and sabotage or terrorism. "Small to Moderate" impacts are projected for short-term air quality, short-term terrestrial resources, and traffic during short, long, and indefinite storage. "Small to Large" impacts are projected on historical and cultural resources; i.e. disruption at sites that have these values. "Large" impacts are projected in only one case - beneficial socioeconomic impacts. Such low levels of estimated impact do not square with widely held concerns of both the public and experts regarding indefinite on-site storage of waste. These concerns arise from the inherently higher risk levels related to accidents, terrorism or sabotage at sites that are neither isolated nor remote from urban areas or water. (0431-8 [Pascall, Glenn] [Watland, George])

Comment: The Waste Confidence Draft GEIS itself is overall a dishonest and inappropriate assessment of the environmental impacts of spent nuclear fuel. A broad brush generic assessment, even if done well, cannot deal with individual plant site specific issues. The time frames defined in alternatives of the DGEIS are totally unresponsive to the needs to protect the environment and human health. It is flawed in structuring the alternatives which avoid real solutions to the issues of the extreme hazards and consequences of spent nuclear fuel. Its purpose really seems to be (and was so stated by NRC in its public hearings) to grease and accelerate licensing and relicensing, and avoidance of site specific environmental analysis of SNF. This is subverting the purpose and utility of the NEPA process. Each of the more than 100 nuclear power facilities and ISFSIs is unique and this document cannot possible provide legitimate or accurate assessment of the site specific environments and impacts where these facilities occur. (0447-2-1 [Andrews, Richard])

Comment: However, Dry Cask Storage is not a long term or permanent solution by any means. The original licenses for the nation's reactors did not envision long term storage of nuclear waste on site as a responsible or necessary option. That said, the NRC is now asserting that storage indefinitely in dry casks will be safe & reliable for generations so long as the casks are replaced every 100 years by those who follow. This is another unreasonable assumption since human beings are notoriously fickle & irrational. (0454-6 [Waldstein, Joe])

Comment: Storing nuclear fuel waste on-site at closed nuclear power plants for decades or even longer, with no requirement to move the waste at any point to a less hazardous location is irresponsible and an accident waiting to happen. (0464-3 [Nelson, Pam])

Comment: The NRC's flawed environmental study is based on a number of unrealistic assumptions that must be reconsidered. The NRC assumes all the waste will be moved from the spent fuel pools into dry casks within 60 years of the reactors' permanent shutdown, despite the fact that NRC regulations allow plant owners to ask for an exemption from the 60 year cleanup requirement. Due to this unfounded assumption, NRC has inappropriately ignored the potential impacts of storing nuclear waste in unsafe pools, which are highly vulnerable to accidents and terrorist attacks, long-term. (0465-3 [Commenters, Multiple])

Comment: It is imperative for NRC to conduct a legally sound and complete environmental review as mandated by the U.S. Court of Appeals. This review must not generically waive off critical risks and impacts associated with the prospect of centuries of nuclear waste storage and individual reactor sites, and must fully consider site-specific concerns, as well as all feasible alternatives and mitigation measures, including not licensing/relicensing plants in order to avoid the production of any additional waste, and requiring the expedited removal of spent fuel from pools and into dry casks to reduce safety risks of pool storage. (0465-9 [Commenters, Multiple])

Comment: We conclude that the Draft GEIS fails to take a "hard look at environmental consequences" as would be expected of such a decision document. In particular, the document assumes away any site-specific differences in risks associated with continued storage of spent fuel and fails to provide sufficient basis for the conclusion that the environmental impacts are likely to be "small." (0473-1-1 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: It is our professional opinion that the Draft GEIS fails to adequately support its findings that the environmental impacts of continued storage of spent nuclear fuel at at-reactor and away-from-reactor sites until a repository is available are "small" across all timeframes, and that the environmental consequences do not differ across Alternatives. (0473-1-2 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: NRC Staff attempts to justify its decision not to perform this analysis by indicating that if a licensee made a request under § 50.82(d) to extend decommissioning, NRC Staff would conduct "any appropriate site-specific NEPA analysis" at that time. Presumably most, if not all, licensees will seek to employ § 50.82's decommissioning extension since there is currently no estimate of repository availability within the 60-year timeframe contemplated by these regulations, which would mean many site-specific spent fuel pool fire analyses would be done many decades from now.²⁰ [footnote 20 text: As the GEIS notes in footnote 3, "the Commission's regulations provide that renewed operating licenses may be subsequently renewed, although no licensee has yet submitted an application for such a subsequent renewal." This would mean that no spent fuel pool fire analysis would be done for another potentially 80 years for plants nearing the end of their license now but that obtain a second license renewal. The Court clearly did not authorize this approach.] Simply put: the Court did not permit the NRC to opt out of doing a long-term analysis of spent fuel pool risk because the probability of such an occurrence is not zero. That analysis needs to be done before plants are licensed or relicensed, thus generating spent fuel which may remain on- site beyond 60 years post-operating life if neither dry cask storage or a permanent repository is available. (0473-12-12 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The DGEIS does not establish that independent spent fuel storage installations are a viable possibility at every reactor site such that generic review is appropriate. Additionally, the DGEIS explicitly assumes that each reactor will have an at-reactor ISFSI or DTS by the end of a reactor's life, in doing so assuming that every nuclear power plant has the capability of accommodating an ISFSI or DTS if they don't already have one. DGEIS at 4-5. The DGEIS does not establish that this is true at each plant site, to support a generic finding. The States submit that in order to rest a generic finding on the assumption that ISFSIs and DTS facilities will be constructed at every facility, the NRC must examine every facility and make an affirmative finding that indeed each and every power plant site can accommodate these new facilities. The DGEIS offers only a sample of the total site area vs. land area developed for ISFSIs for seven locations around the country (Table 3-1, DGEIS at 3-4), and does not include a site-by-site list of facilities that were assessed for ISFSI viability. This does not support a generic finding for all locations around the country. (0473-12-20 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The D.C. Circuit in its decision concluded that the NRC was required to examine the consequences of pool fires unless their probability was zero. 681 F.3d at 482. Yet in response to this directive, in the DGEIS the NRC again opted not to offer any analysis of the consequences of spent fuel pool fires and leaks after the short-term time frame, citing without basis the NRC's belief that all waste will be moved from pools to dry cask by the end of 60 years after licensed life. This position is clearly inconsistent with the Court's order. The Court gave the NRC one option only for concluding that no analysis of consequences was necessary: "Only if the harm in question is so 'remote and speculative' as to reduce the effective probability of its occurrence to zero may the agency dispense with the consequences portion of the analysis." 681 F.3d at 482 (emphasis added). (0473-12-7 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: An agency's use of a model is arbitrary if that model "bears no rational relationship to the reality it purports to represent." *American Iron & Steel Inst. v. EPA*, 115 F.3d 979, 1005 (D.C. Cir. 1997) (quotation marks and citations omitted). Models need not fit every application perfectly, nor need an agency "justify the model on an ad hoc basis for every chemical to which the model is applied." *Chemical Mfrs. Ass'n v. EPA*, 28 F.3d 1259, 1265 (D.C. Cir. 1994). If, however, "the model is challenged, the agency must provide a full analytical defense." *Eagle-Picher Indus., Inc. v. EPA*, 759 F.2d 905, 921 (D.C. Cir. 1985); see also *Natural Resources Defense Council, Inc. v. Herrington*, 768 F.2d 1355, 1385 (D.C. Cir. 1985). Furthermore, an agency "retains a duty to examine key assumptions as part of its affirmative burden of promulgating and explaining a non-arbitrary, non-capricious rule." *Small Refiner Lead Phase-Down Task Force v. EPA*, 705 F.2d 506, 534 (D.C. Cir. 1983). Here, the NRC knows that "key assumptions" underlying Sample Problem A/NUREG-1150 MACCS2 code inputs are wrong and yet has offered no defense of its continued reliance on those inputs. C.f., *Columbia Falls Aluminum Co. v. EPA*, 139 F.3d 914, 923 (D.C. Cir. 1998). By failing to account for the differences between spent fuel pool sites and the effects of those differences on the impacts of an accident, the DGEIS fails to perform a conservative bounding analysis. NRC Staff has failed to ensure that the DGEIS contains accurate information. See *Native Ecosystems Council v. U.S. Forest Serv.*, 418 F.3d 953, 964-65 (9th Cir. 2005) (NEPA requires that agencies rely on high quality data and accurate scientific analysis); 40 C.F.R. § 1500.1(b) (same), § 502.24 ("Agencies shall insure the professional integrity, including scientific integrity, of the discussions and analyses in environmental impact statements"); Entergy Nuclear Operations, Inc. (Indian Point, Units 2 and 3), LBP-11-17, at 11-12 (citing *ShieldAlloy Metallurgical Corp. v. NRC*, 624 F.3d 489, 492-93 (D.C. Cir. 2010)) ("NRC would be acting arbitrarily and capriciously if it did not look at relevant data and sufficiently explain a rational nexus between the facts found in its

review and the choice it makes as a result of that review."); see *Nw. Ecosystem Alliance v. Rey*, 380 F. Supp. 2d 1175, 1196 (W.D. Wash. 2005) (the fact that older data had been used for a previous NEPA analysis is not a justification for its continued use where more recent data dictated a different result) (citing *Friends of the Clearwater v. Dombek*, 222 F.3d 552, 557 (9th Cir. 2000) ("The agency must be alert to new information that may alter the results of its original environmental analysis")). Administrative convenience or tradition do not justify use of obsolete or inapplicable information. The ISR Report also addressed site-specific characteristics for the configuration of spent fuel pool and seismicity. These are also crucial to a conservative bounding analysis and should also be corrected. (0473-13-10 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: In leaving the decision of whether to perform a site-specific or generic analysis to NRC, the D.C. Circuit conditioned the Commission's discretion to utilize generic analysis on the "Commission's use of conservative bounding assumptions and the opportunity for concerned parties to raise site-specific differences at the time of a specific site's licensing." *New York v. NRC*, 681 F.3d 471, 480 (D.C. Cir. 2012). The NRC has not employed a conservative bounding analysis for spent fuel pool fires, and the NRC has not provided a meaningful opportunity for concerned parties to raise site-specific differences at the time of a specific site's licensing (see discussion of waiver below). (0473-13-5 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Although the DGEIS acknowledges in passing that "the economic impacts would vary for different facilities," and notes that "[f]or example, higher total population or population density could result in higher relocation costs, and land use (e.g., whether land is used as farmland or not) could also impact decontamination and condemnation costs" (DGEIS at F-7), there is absolutely no acknowledgement of the disparity in impacts at Indian Point and other plants as compared to the sites used by NRC in the documents it relies upon--chiefly Surry, which is surrounded by farmland in rural Virginia, and Peach Bottom, via the Spent Fuel Consequence Study, which is surrounded by a much lower population density. (0473-13-6 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The D.C. Circuit found that a comprehensive general analysis of risks is sufficient, particularly "given the Commission's use of conservative bounding assumptions." *New York*, 681 F.3d at 480. However, NRC fails to employ conservative bounding assumptions in examining the impacts of spent fuel pool leaks. For example, its conclusion that groundwater impacts will be small rests on its finding that "the hydrologic characteristics associated with typical nuclear power plant settings . . . will act to impede the offsite migration of future spent fuel pool leakage." DGEIS at 4-26. Relying on the characteristics of typical nuclear plants does not result in a conservative estimation of the impacts of leaks. Such an analysis gives no sense of the groundwater impacts at a plant lacking typical hydrologic characteristics such as proximity to a large water body, shallow water table flow toward that water body, flat hydraulic gradients in the shallow water tables, large distance to local groundwater users, and the likelihood that local groundwater usage is in deeper confined aquifers. *Id.* While NRC states that leaks at sites with different hydrological conditions could have the potential to affect nearby groundwater users (DGEIS at E-14), it simply concludes that in the unlikely event that contamination exceeded Maximum Contaminant Level for a groundwater source, "the EPA could take emergency action under the Safe Drinking Water Act (EPA 1991)." DGEIS at E-16. The DGEIS does not state which plants lack the "typical hydrologic characteristics," what combination of hydrologic characteristics could lead to groundwater contamination, or what the expected groundwater impacts could be (aside from exceeding drinking water standards). NRC does not even explain what emergency actions might be taken by EPA. Such actions might include preventing the

affected population from using their only source of potable water or preventing farmers from using their only source of irrigation. NRC must conduct a conservative bounding analysis that takes a detailed look at the impacts at plants lacking "typical hydrologic characteristics," such as plants where there are nearby groundwater users of shallow groundwater aquifers. (0473-15-4 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Similarly, NRC's examination of surface water impacts lacks conservative bounding assumptions. While NRC acknowledges that a leak could result in "indirect effects on surface-water quality" due to groundwater contamination, it concludes that the effects would be small because the contaminated groundwater would be diluted by the large volume of surface water. DGEIS at E-17. Contrary to NRC's approach, impacts to surface waters should be bounded by sites that are different in character. For example, the impact on a river that is designated for the best uses of surface water will be different than the impact on an ocean that does not have that designation. In addition, plants like Vermont Yankee, which is near a downstream dam where contaminated sediment can accumulate, are different than plants that are discharging to free-flowing rivers. NRC also states that even if a pool leaked into surface waters continuously, the quantities of radioactive material would be comparable to values associated with permitted, treated effluent discharges from plants. However, NRC fails to examine the combined impact of a leak and effluent discharges on sensitive surface waters, including whether state or federal water quality standards could be violated. (0473-15-5 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Nor did NRC employ conservative bounding assumptions to determine the impacts of leaks on soils. Such an analysis would look at the impacts at sites that are in agricultural areas such as Fort Calhoun in Nebraska or Duane Arnold in Iowa. At a minimum, NRC must include such conservative bounding assumptions if it is to conduct a generic analysis of the risks of spent fuel pool leaks. That being said, the findings of the DGEIS indicate that generic analysis is not appropriate for spent fuel pool leaks. (0473-15-6 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The DGEIS often uses vague language that does not adequately describe impacts; for example, it says various occupational activities "may have effects on upland vegetative communities and habitats" (DGEIS at 3-21, emphasis added). The DGEIS claims, with no basis, that the effects of indefinite storage would be the same as the effects of long term storage. The DGEIS frequently refers to the "License Renewal GEIS" determinations, without adequately explaining how the License Renewal GEIS reached that determination or incorporating the License Renewal GEIS's conclusions into this document. The State submits that a reader residing in one of the dozens of nuclear waste storage communities around the country trying to understand the impacts of nuclear waste storage near their home deserves to have all of the relevant information in one place. (0473-16-2 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Failure to address current and future safety conditions: The WCGEIS fails to address current and future safety conditions. The Affected Environment section does not adequately address worker or public dosages, emissions, scrams, or safety violations in terms of either nuclear power plants or the spent-fuel basins. Moreover, no consideration has been given to safety issues such as number or trends in SCRAMS or safety violations and how this may affect future safety operations. The WCGEIS needs to be revised to address the risks and impacts posed by such events in terms of a national fleet of operating reactors and spent-fuel basins. (0496-11 [Batobato, Alicia])

Comment: The "Current Technology" Assumption (1): Storage and Subsequent Transportation: The GEIS states that its analyses are based on "current technology and regulations". Our understanding is that current technology has (in combination with substantial strengths) substantial limitations: e.g. How well are we able to monitor the condition of SNF in pool storage? How well are we able (based on such monitoring) to anticipate hazards such as spent fuel fires or pool leaks? How well does the inspection of spent fuel assemblies when removed from pools provide the basis for long-term storage in sealed canisters? How well can we monitor the condition of spent fuel stored long-term in sealed canisters? Is it realistic to expect utilities to repackage spent fuel if there is a probability (but no assurance) that the current packaging may be safe for extended storage and subsequent transportation? What is the assurance that spent fuel that is safely stored in canisters will also be safe in transport, with its increased temperature (due to the sealed transportation cask) and substantially increased physical stress? We are doubtful that current technology and knowledge regarding the above questions support a conclusion that SNF is assuredly safe in continued storage and (except in the indefinite storage case) subsequent transportation. (0505-6 [Williams, Jim])

Comment: The "Current Technology" Assumption (2): Replacement of Canisters and Casks: The GEIS assumes that, as long as SNF remains on site, all canisters and casks would be replaced every 100 years. The GEIS further assumes that, after all SNF is removed from a pool and the pool is shut down, a dry transfer system would be built at the site, and maintained, and replaced every 100 years, until all SNF is removed. We question this assumption on both institutional and technological grounds. On institutional grounds, utilities may be reluctant to replace all canisters and casks, given the cost and hazard of replacement, as well as the perhaps ambiguous information regarding the need. Continued storage requires assurance that utilities at up to 75 sites can be persuaded to build such facilities. On technical grounds, we question whether site-built hot cells can reliably be used to cut open and repackage large sealed canisters (something that utilities are very reluctant to do in currently operating spent fuel pools), and then do it again 100 years hence, when the facility may be degraded. We also question whether mobile hot cells (current technology) could do the job that the GEIS continued storage assumption presumes. (0505-7 [Williams, Jim])

Comment: The draft GEIS does not do a full analysis of the potential environmental effects of storing spent fuel onsite at nuclear plants, as ordered by the court. (0531-1-3 [Morgan, Sally])

Comment: Adequate proof of no significant environmental impact for long term or indefinite storage of nuclear waste at facilities without a national repository is impossible. The nuclear industry is subject to the same human errors and unpredictable disasters as any other industry, but with hazardous waste that will continue to be a problem for hundreds of thousands of years, there is simply no way to assure a "low" environmental impact. (0531-1-5 [Morgan, Sally])

Comment: The draft GEIS does not do a full analysis of the potential environmental effects of storing spent fuel onsite at nuclear plants, as ordered by the court. (0531-2-3 [Morgan, Sally])

Comment: Adequate proof of no significant environmental impact for long term or indefinite storage of nuclear waste at facilities without a national repository is impossible. The nuclear industry is subject to the same human errors and unpredictable disasters as any other industry, but with hazardous waste that will continue to be a problem for hundreds of thousands of years, there is simply no way to assure a "low" environmental impact. (0531-2-5 [Morgan, Sally])

Comment: The statement by the GEIS Draft that long term - or indefinite - storage has little environmental impact completely disregards the extreme hazards of radioactive wastes and the complete lack of experience of storing these toxins. (0541-2 [Justesen, Evelyn])

Comment: Section 1.8, Analytical Approach, should discuss a scenario of completing the Yucca Mountain repository, as required by Federal law. That scenario would have the least cumulative environmental impacts when compared to the scenarios analyzed in the Draft GEIS. It may be unnecessary to repeat the analysis in the Yucca Mountain EIS, but reference should be made to the Yucca Mountain EIS results. Otherwise, this GEIS would evaluate one scenario that is not allowed by Federal law while ignoring the only scenario that is required by Federal law. Furthermore, in the scenarios analyzed in the Draft GEIS, comparison should be made in the impact assessment sections to show the difference in cumulative impacts between a Yucca Mountain scenario and the other scenarios analyzed. In particular, the comparative analysis should recognize that without Yucca Mountain, or some other repository in the near term, multiple transportation campaigns will be required. It should also be recognized that without Yucca Mountain, all spent fuel will have to be repackaged after it is in dry storage for ultimate repository disposal. In the Yucca Mountain scenario, a significant portion of the spent fuel will be loaded by the utilities in transportation, aging, and disposal canisters and disposed directly without repackaging. It is unlikely (and absolutely unknown) what type of packaging would be required for any alternative repository option, should one ever be developed. The ability to dispose large waste packages may be unique to Yucca Mountain. With the recent writ of mandamus ordering NRC to restart the Yucca Mountain licensing process, it is unclear how NRC can continue to flout Federal law and ignore the Yucca Mountain alternative in any proper NEPA analysis. (0544-12 [Enriquez, Elizabeth])

Comment: The NRC addresses the issue of spent fuel for only 160 years---not its full range of the radioactive time period. The NRC considers 3 alternatives: Indefinite storage at reactor sites, regional consolidated storage sites, central repository. In doing so, the NRC expresses confidence that spent fuel will be managed adequately and safely, with no basis for such assertions or conclusions. (0552-1-6 [Macks, Vic])

Comment: So, how many elements of comparability satisfy a generic assessment? In conclusion, it is my opinion that this DGEIS is premature and establishes an impact rating system solely related to magnitude of very poorly described potential environmental impacts. It is, in the general absence or severe shortage of relevant evidence, model-driven by use of "Reference guides." None of the critical storage items-cask performance in many different environments and tested over a very short time period (14 years, one casket), the potential for catastrophic impacts on storage facilities, which can have far greater environmental consequences than any considered in the GEIS, and the human impact factor that has great potential for environmental harm, but which doesn't fit the format for this GEIS. (0553-16 [Wilshire, Howard])

Comment: The evidence base is so deficient that the indefinite time frame considerations are not credible. I would give pigs a better chance of flying than protocols followed indefinitely would protect the environment. (0553-17 [Wilshire, Howard])

Comment: Since this statement indicates unspecified assessments of unspecified environmental impacts on unspecified resource areas, it is both uninformative and says nothing about how it fits into a generic impact statement. (0553-6 [Wilshire, Howard])

Comment: The draft rests on unsupported assumptions that support its "small impact" finding but it has no basis in reality. (0556-1-11 [Lampert, Mary])

Comment: NRC's DGEIS claims, absent support, that no serious impacts will occur from leaving the spent fuel onsite indefinitely. What NRC simply substituted is its offsite repository fantasy for another fantasy - waste could remain safely onsite in above ground storage indefinitely. This assumption defies commonsense and conflicts with the Nuclear Waste Policy Act (NWPA). (0556-1-3 [Lampert, Mary])

Comment: DOE's *Inventory and Description of Commercial Fuels in the US*, March 31, 2011 ¹² [footnote 12 text: <http://sti.srs.gov/fulltext/SRNL-STI-2011-00228.pdf>] shows how reactors vary. DOE looks at: fuel types; fuel cladding: some better than others (primarily there are 4 cladding alloy types: Zirconium 2, improved Zirc 4, M5, Zirlo, optimized Zirlo [DOE, p. 6, Table 5]). Wet storage, varies by density and geometry; dry storage, varies by location and vendor; license termination dates vary; ranges of burnup vary (DOE, pg., 25, Table 7). Therefore the potential environmental impacts will vary from reactor to reactor. For example: Individual reactors are making increasing use of high burnup fuel. Each reactor varies. High burnup fuel has more tritium, which is notoriously hard to clean up if it contaminates groundwater. The time spent fuel is stored in pools and dry casks varies from one reactor to the next. Therefore NRC's generic assumption about the time the fuel can be stored in the pool and dry casks before it must be moved makes no sense. (0556-1-36 [Lampert, Mary])

Comment: In addition to failing to treat environmental impacts on a site specific basis, the DGIS relied upon false and unsupported assumptions. If you take away the unsupported assumptions, NRC's findings fall apart. (0556-2-1 [Lampert, Mary])

Comment: The unsupported assumptions include: The analyses in the draft GEIS are based on current technology and regulations. (0556-2-3 [Lampert, Mary])

Comment: Analyses in the draft GEIS are based on current technology and management practices. The assumption is wrong on its face. Much of the technology on which it relies does not currently exist; and no one should be foolish enough to assume that management practices principally focused on generating electricity will remain unchanged when current management no longer exists and all that remains is long-term storage of spent nuclear fuel. Whatever minor experience industry might now have is too short to project over the hundreds of years that the DGEIS is projecting. (0556-2-6 [Lampert, Mary])

Comment: Cask storage is far safer than pool storage but not without its pitfalls. PW disagrees with NRC's unqualified finding that spent fuel can be stored safely in dry casks placed on pads both over the short term, 60 years after the license to operate ends and for the interim period (100-300 years) and for the extended period (300 yrs and beyond) by simply changing the casks and pad every 100 years. Instead, PW supports the alternative of requiring specific safety requirements for dry cask storage. For example: • Casks must be required to be located over the short, long, and indefinite periods at higher elevations to avoid flooding, especially along coasts, because of climate change and sea level rise. Placing casks at higher elevations is especially important in marine locations where chloride has the potential of inducing stress corrosion cracking of austenitic stainless steel³⁸ [footnote 38 text: IN 2012-20 Potential Chloride Induced Stress Corrosion Cracking of Austenitic Stainless Steel and Maintenance of Dry Cask storage System Canisters. (ML 1231a440)] and corrosion of concrete, impacting both cask over-packs and pads. • Casks need to be outfitted with monitors for both temperature and radiation, although not required now. • Casks need to be protected from the elements by

placement in buildings, especially in areas with snow and ice storms and a building would limit line of sight attacks, • Offsite emergency planning must be required with compensation for offsite radiological emergency planning expenses while waste is onsite. • There simply is no way to project on a generic basis that casks and pads will last 100 years. There is no history to base it upon. (0556-5-7 [Lampert, Mary])

Comment: NRC assumes that casks (both the inner canister and outer over-pack) and cask pads only need to be replaced every 100 years. This is contradicted by NRC's own statement that, "Dry casks are licensed or certified for 20 years, with possible renewals of up to 40 years. This shorter licensing term means the casks are reviewed and inspected, and the NRC ensures the licensee has an adequate aging management program to maintain the facility³⁹." [footnote 39 text: <http://www.nrc.gov/waste/spent-fuel-storage/faqs.html>] NRC provides no proof that casks can go an additional 60 years before replacement. NRC assumes that there will be Dry Transfer Systems to perform the "change of clothes" since pools will be dismantled during decommissioning 60 years after reactor shutdown. But there is no showing that assemblies will not degrade making transfer unsafe. This is especially true with high-burnup fuel that has spent more time in the reactor core and is more radioactive and thermally hotter. NRC has not provided the cost for the transfer operation nor indicated who will pay. (0556-5-8 [Lampert, Mary])

Comment: Next, if future stakeholders may be precluded from raising site specific issues, it is essential that the Draft GEIS relies on sufficient data and analysis to support its conclusions. However, NRC staff indiscriminately adopts many of the findings from the Final Environmental Impact Statement for the Construction and Operation of an Independent Spent Fuel Storage Installation on the Reservation of the Skull Valley Band of Goshute Indians and the Related Transportation Facility in Tooele County, Utah, NUREG-1714, December 2001 ("PFS FEIS").¹⁰ [footnote 10 text: Utah participated in the NRC licensing proceedings for the PFS facility and is intimately familiar with the PFS proposal] In general, notwithstanding whether Utah agrees with the analysis and conclusion included in the PFS FEIS, barring an adequate explanation of its basis, it is wholly inappropriate to incorporate the site specific details of the PFS FEIS into a generic EIS. Moreover, an earlier version of the waste confidence rule prevented the consideration of any environmental impacts for continued storage beyond the storage licensing period in the PFS FEIS. Now, after the U.S. Court of Appeals, District of Columbia, vacated the waste confidence rule, staff rely, in part, on findings in the PFS FEIS when it did not consider the impacts of continued storage. Without an adequate explanation for the basis of incorporating portions of the PFS FEIS findings into the final GEIS, it is circular logic to rely on an analysis that did not consider the impacts of continued storage when the stated purpose of the Draft GEIS is to "address[] the environmental impacts of continuing to store spent fuel ... at an away-from-reactor storage facility, after the end of a reactor's licensed life for operation until final disposition in a geologic repository ("continued storage").¹¹ [footnote 11 text: Draft GEIS at 1-1] (0579-5 [Smith, Amanda])

Comment: Staff recognize that environmental impacts of constructing and operating an away-from-reactor ISFSI would be evaluated in more detail during a site-specific licensing proceeding. The final GEIS should clarify what potential impacts will not be considered in a site-specific evaluation. (0579-8 [Smith, Amanda])

Comment: Further, the NRC has failed to sufficiently demonstrate (a) that a generic environmental assessment "provides for the same level of environmental protection as the other [Rulemaking] alternatives" (DGEIS, Executive Summary, p. xxvi, lines 10 - 11) and (b) that the quality of a generic environmental assessment inherently meets or exceeds the quality, detail and comprehensiveness of a gold-standard professional site-specific investigation and report. In

fact, the NRC implicitly acknowledges that the primary benefits of a generic regulatory framework accrue predominantly to the private and corporate stakeholders. "The NRC's preliminary conclusion is to revise 10 CFR 51.23 because of the efficiencies that would be gained in reactor and spent fuel storage facility licensing reviews. Revising the Waste Confidence rule minimizes expenditures on site-specific reviews, [and it] limits the potential for lengthy project delays . . ." (DGEIS, Executive Summary, p. xxvi, lines 7 - 10). Indeed, according to the NRC's statements published in the Federal Register (78 FR 56803 - 56804, SUPPLEMENTARY INFORMATION: Section XII -- Regulatory Analysis), the "DGEIS [Chapter 7] contains an estimate that it could cost over \$24 million to address continued storage in site-specific proceedings[.]" and "[l]icensees and license applicants ultimately shoulder the majority of costs incurred { . . . }." The same paragraph in Section XII also notes that a "draft regulatory analysis has not been prepared for this proposed regulation because this regulation does not establish any requirements that would place a burden on licensees." Well, \$24 million is certainly not "small money;" but, it is merely a "rounding error" in relative terms compared to the \$15+ BILLION price-tag on a new reactor facility such as the currently proposed Fermi 3 reactor in Michigan. In other words, the NRC's position is "penny wise and pound foolish," as the saying goes. (0603-10 [Schonberger, David])

Comment: Perhaps the most insidious, alarming and disturbing aspect of the NRC's proposed Waste Confidence Rule is the inherent GENERIC design and application of the Rule, which is based on a fundamentally misguided GENERIC approach to the supporting Environmental Impact Statement. While it is indeed true that the labels "spent nuclear fuel" and "high-level radioactive waste" are relatively generic and simplistic terms, the practical, technical and logistically-unprecedented challenge of properly and responsibly managing such material, which remains distributed across numerous facilities throughout the continent, necessitates a structural and regulatory approach that is SITE-SPECIFIC and not generic in nature. The NRC is evaluating Waste Confidence on a generic basis because the "NRC considers the continued storage of spent fuel a generic activity that is similar for all commercial nuclear power plants and storage facilities. Therefore, a generic analysis is an appropriate, effective, and efficient method of evaluating the environmental impacts of continued storage." (DGEIS, Executive Summary, p. xxiv). I certainly agree that the generic approach is an efficient regulatory concept; however, I disagree that the generic approach is appropriate and effective. As a matter of fact, the State of Michigan has recently proposed revising criteria and requirements for remediation and redevelopment of contaminated facilities (so-called "brownfields") in order to accommodate a GENERIC paradigm. The new regulations are expected and actually intended to be a game-changer for the corporate stakeholders, as new efficiencies and "less burdensome" rules are introduced into the system. (Regulatory Impact Statement and Cost-Benefit Analysis, "Cleanup Criteria Administrative Rules for Part 2 of NREPA," ORR Rule 2013-056 EQ, State of Michigan Department of Environmental Quality, Remediation and Redevelopment Division, 10/10/13). Fundamentally, the NRC has failed to sufficiently demonstrate that the technical process of continued storage of spent nuclear fuel is a generic task rather than a case-by-case challenge which presents unique circumstances requiring site-specific evaluations and analyses in order to properly, appropriately and effectively mitigate risk. (0603-9 [Schonberger, David])

Comment: [The NRC must] re-examine the unrealistic assumptions it makes in the GEIS[.] (0604-12 [Pisha, Gayla])

Comment: The NRC assumes all the waste will be moved from the spent fuel pools into dry casks within 60 years of the reactors' permanent shutdown, despite the fact that NRC regulations allow plant owners to ask for an exemption from the 60 year cleanup requirement. As a result, the NRC has not adequately considered the potential impacts of storing nuclear

waste in unsafe pools for the long-term, a concern because these are more vulnerable to accidents and terrorist attacks. (0604-7 [Pisha, Gayla])

Comment: Furthermore, the NRC should consider the possibility that spent fuel will still be stored on-site more than 60 years after the licensed life of a power plant. There are potentially serious environmental consequences if fuel remains on-site indefinitely. By not addressing this contingency, the DEGIS fails to provide adequate assurances to us or our communities. Currently, no alternative plan exists to storing spent fuel on-site at Pilgrim, and there will not be one for the foreseeable future. People who live in the shadow of Pilgrim deserve information about the environmental impacts of indefinite on-site storage. Moreover, this information will be invaluable during ongoing NRC relicensing decisions. Finally, information about the potential impacts of indefinite on-site storage may spur policymakers to finally develop a suitable off-site storage facility. Every day that passes without a long term strategy to more safely store nuclear waste heightens the exposure for our communities to the destructive forces of a nuclear disaster. (0607-6 [Messinger, Michael])

Comment: Before it can be assumed that spent fuel canisters and casks, ISFSI and DTS facilities will be replaced every 100 years, the ability to actually perform replacement functions must be demonstrated. This means, first, at a minimum, that the Draft GEIS must contain or rely upon a probability assessment regarding the number of waste fuel assemblies that experience each identifiable degradation mode, and the confidence boundaries surrounding that assessment. Second, this means that the protocol for safely managing the identified volume of degraded fuel assemblies must be specified for each identifiable degradation mode. This includes the protocol for safely managing criticality events inside casks during storage periods. The protocols must be detailed and specific enough to give reasonable confidence that if followed, degraded fuel assemblies will not result in unacceptable levels of adverse environmental impact. Third, this means that the additional costs of managing the degraded fractions identified in the probability assessment be quantified, included in the cost of maintaining institutional control as specified earlier in this comment, and accounted for in terms of where the required money will come from. (0608-15 [Crocker, George])

Comment: The Draft GEIS states, in category after environmental impact category, in virtually every instance in each of the timeline scenarios, that the impact will be "small." Such a repeated finding of "small" regardless of the length of storage does not pass the smell test. (0608-16 [Crocker, George])

Comment: NAWO is concerned that there apparently has been no analysis that demonstrates that an available land-base exists, at every reactor site, that is capable of hosting an ISFSI large enough to hold the number of dry storage casks needed to contain the posited 80-years worth of irradiated fuel produced by each reactor. (0608-19 [Crocker, George])

Comment: The Summary of Environmental Impacts provided by Chapter 8 of the Draft Waste Confidence Generic Environmental Impact Statement, which in turn provides the regulatory basis for the NRC's proposed amendment to 10 CFR 51.23, would, NRC Staff asserts, re-establish Waste Confidence regarding the safety and environmental impacts of storing spent nuclear fuel beyond the licensed life for operations of nuclear power plants. Because of numerous untenable assumptions that guide and are essential to the NRC's analysis, and that are specified below, nothing could be further from the truth. (0608-5 [Crocker, George])

Comment: --[The NRC has failed to fully examine] the environmental consequences and costs that may occur if a repository cannot be sited or cannot effectively contain radioactivity; (0611-12 [Shapiro, Susan])

Comment: The findings in the GEIS that basically all environmental impacts with every few exceptions are small is wholly unfounded, not scientifically supported and are self serving, arbitrary, and conclusory. (0611-30 [Shapiro, Susan])

Comment: NRC has failed to do the "full analysis" required by the Court. Instead of examining what would happen if spent fuel remained unprotected on the earth's surface indefinitely, the NRC assumed that spent fuel would be safely managed in surface storage for an indefinite period. But the Court required NRC to examine the risks of spent fuel storage, and did not allow NRC to merely assume that storage would be safe. The GEIS fails provide a scientific and "full analysis" of the potential environmental effects of permanently storing spent fuel on-site, and therefore does not satisfy the Court's order. Instead the NRC has based the EIS on the unproven and unscientific assumption that spent fuel can be stored safely forever without evidence or proof. (0611-9 [Shapiro, Susan])

Comment: No wonder NEI is attempting to convince the NRC to interpret the WCD as being so restricted in scope such that the sheer lunacy of producing more nuclear waste in the first place is ignored! NEI claims that "site-specific and generic" Environmental Impact Statements (EISs) cover all permutations of this basic question: Is what we're doing logical? However, they do not: Invariably, ALL other NRC and DOE EISs assume that the waste problem can be solved, thus relegating the dangers of continued operation, continued production of nuclear waste, and continued mining of uranium to matters which can be assessed through Probabilistic Risk Assessments (PRAs). (0616-6 [Hoffman, Ace])

Comment: The Tribe remains concerned that the environmental impacts long-term and indefinite storage have not been adequately evaluated in this draft GEIS. (0619-2-9 [Mahowald, Philip R.])

Comment: The wealth of truly independent scientific literature indisputably sets forth the harm from radiation and the mass contamination that it has inflicted, and will continue to inflict, on mankind and on our environment. Such evidence is ignored by this and other environmental impact statements and analyses issued by the NRC which I have read. The labeling of "low" and "small" impacts are seen time after time when various assumptions of risk are muddled through proposed mitigation measures and "cost-benefit" analyses used to "balance" the real impacts with industry goals. That a license is granted for the construction and operation of a nuclear reactor to generate electrical power without examining the full environmental impacts and all costs which will be needed beyond the reactor's "end of life" and the "life" of its waste which will last for hundreds of thousands of years is a mockery of this and the entire EIS process. (0620-9 [Rivera, Evelyn])

Comment: Instead of assuming that spent fuel can be stored safely forever at or away from reactor sites, the NRC should examine the likelihood that a federal repository will be successfully sited, and then assess the health and environmental consequences that may occur if a repository is not sited or if accidents occur related to the repository. (0622-1-12 [Vale, Karen])

Comment: In addition, the DGEIS should discuss under what conditions on-site storage is not appropriate, and therefore when off-site storage is preferable to insure safer, long term/indefinite storage of this hazardous waste. (0622-1-13 [Vale, Karen])

Comment: APV opposes the NRC plan, as outlined in this GEIS, to use the Private Fuel Storage (PFS), LLC "centralized interim storage" proposal, targeted at the Skull Valley Goshutes Band of Indians in Utah, as a model for away-from-reactor storage. (0648-8 [Price, Scott])

Comment: The NRC assumes a 100-year replacement cycle for the ISFSI facility, spent fuel canisters and casks, and dry transfer system⁴. [footnote 4 text: Dry Transfer System (DTS): would allow for the retrieval of spent fuel for inspection or repackaging without the need to return the spent fuel to the spent fuel pool. A DTS would be built on site in the long-term storage timeframe.] The NRC provides no background data or material analysis in support of a 100 year replacement cycle. In fact, the NRC refutes its own assumption: "this assumption does not mean that dry cask storage systems and facilities need to be replaced every 100 years to maintain safe storage."⁵ [footnote 5 text: Waste Confidence Generic Environmental Impact Statement Draft Report for Comment. (as n.3 above).] It is clear that the exact lifetime of the spent fuel storage systems is unknown. Furthermore, it should be noted that a Dry Transfer System as envisioned in the draft GEIS has not yet been constructed in this country. (0681-1 [Peterson, Alyse])

Comment: The NRC also assumes that all spent fuel will be removed from fuel pools on site and placed in dry cask storage no later than 60 years after the end of the reactor's licensed life for operation. The assumption that plant owners will do this voluntarily is unrealistic. To begin with, NRC's regulations do not require spent nuclear fuel to be removed from the pools or the site. 10 C.F.R. § 50.82(a)(3) (decommissioning and removal of fuel may be delayed beyond 60 years given "unavailability of waste disposal capacity"). (0681-3 [Peterson, Alyse])

Comment: It is highly improbable that the owner of record will voluntarily spend the money and manpower necessary to move all spent fuel from an on-site spent fuel pool to dry cask storage or increase the current rate of transfer of spent fuel between pool and cask. First, nuclear plants do not generate profits during decommissioning and, similarly, the storage of spent nuclear waste at a nuclear plant is not ordinarily thought of as a profit making activity. Secondly, the current NRC stance is that spent fuel pool and dry cask storage are equally safe and secure: "The NRC believes spent fuel pools and dry casks both provide adequate protection of the public health and safety and the environment. Therefore [according to NRC] there is no pressing safety or security reason to mandate earlier transfer of fuel from pool to cask."⁶ [footnote 6 text: "Spent Fuel Storage is Pools and Dry Casks Key Points and Questions & Answers," Nuclear Regulatory Commission (March 2013) (available at <http://www.nrc.gov/waste/spent-fuel-storage/faqs>. (last viewed 21 Nov. 2013).] New York State staff understand that nuclear licensees in New York currently plan to keep fuel storage pools at maximum capacity (i.e., dense storage) until a means for federal transport and final disposal is available.⁷ [footnote 7 text: See, e.g., State of New York, Riverkeeper, Inc., and Hudson River Sloop Clearwater's Joint Contention NYS-39/RK-EC-9/CW-EC-10 Concerning the On-Site Storage of Nuclear Waste at Indian Point, 32 (Jul. 8, 2012) ML12190A002 (discussing Entergy statement during May 2012 site visit).] (0681-5 [Peterson, Alyse])

Comment: The Draft GEIS claims that the environmental impact of long-term or indefinite storage is small. This is an absurd statement on its face, given the known extreme hazards of radioactive wastes and the lack of any experience of storing these toxins for even a hundred years, let alone hundreds of thousands of years. (0686-2 [Malboeuf, Simone])

Comment: The end result of the faulty analysis in the GEIS is a determination that storage of nuclear spent fuel is incidental and has fewer impacts than reactor operations. Therefore, the agency concludes, long-term or indefinite storage poses no significant environmental impacts. (0693-1-12 [Warren, Barbara])

Comment: V. The Court Decision called for an analysis of the environmental impacts of failing to obtain a permanent repository. (State of NY, et. al., Petitioners v. NRC and the USA, Respondents, US Court of Appeals for the District of Columbia Circuit, June 8, 2012, No. 11-1045.) The GEIS rather than conducting the analysis called for by the court, instead merely adopted the position that few impacts would occur in the short term, long term and even indefinitely, because all this high level nuclear waste fuel would be adequately managed. This is not the analysis the court decision required. (0693-3-1 [Warren, Barbara])

Comment: Tanks at the end of their 50-yr. maximum useful life have not been replaced, calling into serious question the likelihood of cask replacement every 100 years for spent fuel. (0693-4-10 [Warren, Barbara])

Comment: Throughout the GEIS, NRC has told us how unlikely many adverse events are, but nowhere has NRC provided details about how it derived these probabilities. NRC used probabilities to assign small impacts to the majority of environmental impacts, although this was secondary to not properly evaluating the impacts in the first place. (0693-4-6 [Warren, Barbara])

Comment: Here, the NRC has considered a broad spectrum of potential scenarios and made informed scientific judgments based on substantial available data, experience, and analyses about the possible impacts stemming from each storage scenario. Indeed, some assumptions, such as the 100 year replacement assumptions and the need to construct a DTS at every site, are likely very conservative, and add further support for the robust nature of the NRC's response to the D.C. Circuit decision. (0694-2-13 [Shea, Joseph])

Comment: TVA also concurs with the NRC's assumption that "an ISFSI of sufficient size to hold all spent fuel generated during licensed life for operation [will be] constructed during the reactor's licensed life for operation."⁸³ [footnote 83 text: *Id.* at 2-17.] (0694-2-25 [Shea, Joseph])

Comment: TVA's own experience with dry cask storage fully supports the NRC's conclusions that dry cask storage is technically feasible for the timeframes considered in the DGEIS.¹¹⁴ [footnote 114 text: *Id.* at B-11 to B-15.] In fact, TVA believes that the NRC's assumption of replacing dry casks every 100 years of service life is very conservative, and that due to their robust design the casks could last much longer without substantial maintenance. (0694-3-12 [Shea, Joseph])

Comment: The DGEIS states that WBN-1 is not yet eligible to request renewal, but that "[t]he NRC assumes that this facility will undergo a license renewal review for purposes of this analysis."¹⁴⁶ [footnote 146 text: See DGEIS at 7-5 to 7-6 (notes 4 & 5).] This assumption is reasonable; TVA is not aware of any reason that it will not seek license renewal of WBN-1. Additionally, this assumption is intended to lend conservatism to the Staff's environmental impacts analysis for continued spent fuel storage. (0694-3-19 [Shea, Joseph])

Comment: [T]he NRC has considered a broad spectrum of potential scenarios and made informed scientific judgments based on substantial available data, experience, and analyses about the possible impacts stemming from each storage scenario. Indeed, some assumptions, such as the 100 year replacement assumption and the need to construct a DTS at every site,

are very conservative, and add further support for the robust nature of the NRC's response to the D.C. Circuit decision. (0697-1-30 [Bessette, Paul] [Kuyler, Raphael])

Comment: Entergy's own experience with dry cask storage fully supports the NRC's conclusions that dry cask storage is technically feasible for the timeframes considered in the DGEIS.⁹² [footnote 92 text: *Id.* at B-11 to B-15.] In fact, Entergy believes that the NRC's assumption of replacing dry casks every 100 years of service life is very conservative, and that due to their robust design the casks could last much longer without substantial maintenance. (0697-2-21 [Bessette, Paul] [Kuyler, Raphael])

Comment: Entergy also concurs with the NRC's assumption that an ISFSI of sufficient size to hold all spent fuel generated during licensed life for operation will be constructed.⁶⁶ [footnote 66 text: See DGEIS at 2-17.] (0697-2-6 [Bessette, Paul] [Kuyler, Raphael])

Comment: *The Safety-Relevant Classes of Spent Fuel Requiring Continued Storage*, (commercial low-enriched uranium (LEU) oxide "Low Burn-up" SNF, commercial LEU oxide "High Burn-up" SNF, and "Other Fuels" requiring special consideration in a prolonged surface storage scenario, e.g. High Temperature Gas Reactor (HTGR), Plutonium MOX, and Damaged fuels). (0706-2-22 [Fettus, Geoffrey])

Comment: *Storage Cask Technology Options*, including repackaging options for deteriorating fuel and fuel stored in non-qualifying casks for transport or extended surface storage, (e.g., "Storage Only"; "Transport Only"; "Dual-Purpose" storage and transport). The Draft GEIS must discuss new proposed and reasonably foreseeable cask and storage technologies and their implications for prolonged surface storage safety and environmental impacts. (0706-2-23 [Fettus, Geoffrey])

Comment: Page 3-1 to 3-37. Discussion of ISFSIs and need for site specific reviews. NRDC Comment[:] While NRDC has no quarrel with a broad treatment of the affected environment in the an initial generic or programmatic environmental analysis, the description of the affected environment from 3-1 to 3-37 is so cursory so as to be meaningless in terms of the hard look necessary under NEPA. This is especially true for an action of the magnitude of examining the impact of storing spent nuclear fuel in place for potentially long periods of time, past that which one might reasonably rely on the viability of institutional controls. As we explained *supra* at comment #5 in our proposed matrix of reasonable alternatives that could lead to a compliant NEPA analysis, there could be a meaningful examination of environmental impacts at a site specific level or at least a regional level. Once the agency has presented and commenced an evaluation of the diverse range of actual alternatives in terms of snf amounts, storage configurations, spent fuel classes, cask options and institutional control scenarios, the agency can then commence examination of quantitative impacts on realistically portrayed affected environments. It should suffice to say regional and local environments differ – differing climates, peak and average temperatures, moisture content, salinity, natural environment. The cursory descriptions in the Draft GEIS don't reach this important differences and the way the proposed rule is structured, those important differences would never be examined. Thus, the cursory nature of this section illustrates the need for a tiered process, at least on a regional or site-specific level. Only then could then could decision-makers have the proper information before them. (0706-4-2 [Fettus, Geoffrey])

Comment: Page 4-21 - 91. NRDC Comment[:] Consistent with comments #5, #9, and #19 above, the conclusory treatment of the environmental impacts to the affected environment are so NRC's presentation of generic treatment of the affected environment and the reliance on the

arbitrary assumption that institutional controls will last forever ensures the conclusions regarding environmental impact from 4-20 (Geology) to 4-91 fail NEPA's hard look requirement. There are repeated problems and assumptions of no environmental impact where the NRC has provided no basis that challenges DOE's analysis of the environmental effects of failing to develop a repository or even a basis that supplies common sense. Examples include 4-77, DTS, 4-54 (land use), 4-24 surface water quality, 4-28, groundwater quality, etc. (0706-4-3 [Fettus, Geoffrey])

Comment: No wonder NEI is attempting to convince the NRC to interpret the WCD as being so restricted in scope such that the sheer lunacy of producing more nuclear waste in the first place is ignored! NEI claims that "site-specific and generic" Environmental Impact Statements (EISs) cover all permutations of this basic question: Is what we're doing logical? However, they do not: Invariably, ALL other NRC and DOE EISs assume that the waste problem can be solved, thus relegating the dangers of continued operation, continued production of nuclear waste, and continued mining of uranium to matters which can be assessed through Probabilistic Risk Assessments (PRAs). (0709-6 [Wythe Elnagar, Romi])

Comment: The NRC's DGEIS contains a deficiently generic analysis of the impacts of long-term and indefinite onsite nuclear waste storage to purportedly support the proposed rule, which, if adopted, would preclude site-specific NEPA analyses for future nuclear power reactor, reactor license renewal, and spent fuel storage facility licensing actions.⁵ [footnote 5 text: See, e.g., DGEIS at xxiv ("The proposed action is to issue a rule, 10 CFR 51.23, that generically addresses the environmental impacts of continued spent fuel storage by incorporating into rule the conclusions of the final version of this draft GEIS. If the proposed Rule is adopted, the site-specific NEPA analyses for future commercial power reactor and spent fuel storage facility licensing actions would not need to consider the environmental impacts of continued storage.")].] The DGEIS fails to recognize and assess critical site-specific concerns related to the impacts of onsite nuclear waste storage, and as a result does not take the "hard look" required by NEPA. That is, NRC has presented an allegedly conservative bounding assessment, however the bounding parameters used were not broad enough to cover various site-specific concerns. As a result, the DGEIS is fundamentally flawed, and NRC has demonstrably failed to justify the generic proposed rule and future preclusion of the consideration of site-specific issues relating to nuclear waste storage.⁶ [footnote 6 text: See *New York v. NRC*, 681 F.3d at 480-81 (explaining that a generic analysis must be "thorough and comprehensive" and that a generic rulemaking is considered appropriate where "conservative bounding assumptions" are used and there is "the opportunity for concerned parties to raise site-specific differences at the time of a specific site's licensing").] In order to comply with NEPA, the NRC should specifically require site specific review of the impacts of future spent fuel pool leaks, and the risk and consequences of pool fires in all licensing proceedings.⁷ [footnote 7 text: It is critical to note that in the Court Ruling, while not agreeing with Petitioners that site specific review was required, the Court did not specifically prohibit the NRC from conducting site specific analyses in the DGEIS. *Id.* at 480-81. On the contrary, while the Court Ruling states that "a comprehensive general analysis" might be sufficient to "examine onsite risks that are essentially common to all plants," it also states the following; "Nonetheless, whether the analysis is generic or site by site, it must be thorough and comprehensive." *Id.* at 481-82. Moreover, the justification for the Court permitting a generic analysis included the notion that that site specific issues could be raised by intervenors at the time of a specific site's licensing action. *Id.* at 480-81. However, the proposed rule at issue here, supported by the facially deficient DGEIS, would expressly *prohibit* such site specific analysis of the environmental impacts of spent fuel storage in all future licensing proceedings, which clearly undermines the basis for a generic analysis.] (0710-1 [Brancato, Deborah] [Musegaas, Philip])

Comment: If dry storage and recontainerization is used, what is the likelihood that it will exceed the viability of our species? (0711-38 [Olson, Mary])

Comment: NRC mistakenly projects uniformity in parameters such as heat and rate of heat generation, aging and rate of aging, fissile material content and overall "biological effectiveness" (one of the most offensive technical terms for "likeliness to cause disease and death") for different types of fuel with different levels of burn-up, decay and damage. This mistake is unacceptable. If it is not a mistake, the wholesale incompetence it reflects is stunning and if it persists will undermine any remaining ability to ensure that this highly varied material is not released to our biosphere. In addition, NRC fails to factor the changing characteristics of this waste over time. The dominance (heat and high-surface radiation dose) of the intense fission products in the several centuries give way; later the access to the plutonium and other fissile materials will become easier. NRC fails to factor this shift. (0711-9 [Olson, Mary])

Comment: The NRC has not conducted a thorough environmental analysis of spent fuel storage and disposal issues, the costs and risks of storing spent fuel at reactor sites for decades, or even hundreds of years. (0712-1 [Schimmelpfennig, Pamela Y.])

Comment: In particular, it is imprudent for NRC to presume that a geologic repository will become available within a few decades. (0714-1-7 [Edwards, Gordon])

Comment: REQUEST TO NRC: We request that NRC provide these calculations, the model used, the base assumptions, and all pertinent data regarding the projected future water conditions of the Illinois river network in a climate disrupted world, and the effects this will have on Illinois reactor functioning; as well as their effects on the assumptions NRC has made in this DGEIS. Since NRC allowed us 75 days to comment on the DGEIS, we request that the requested information be provided within 75 days of the submittal of these comments. (0716-14 [Kraft, Dave])

Comment: NRC has relied on inadequate, outdated, superceded and at times simply wrong information as the basis for its many opinions. Using the GIGO rule, the DGEIS is totally inadequate to the task of protecting the public health and safety, since NRC has made "predictions" about a world that simply does not exist. (0716-24 [Kraft, Dave])

Comment: As some of the material below will demonstrate, NRC has totally ignored the Court mandate to actually envision future problems – even those NRC feels are not likely – and do real calculations to reach predictions and conclusions about consequences. Instead NRC has merely proclaimed the world flat, and has proceeded to give assurances based on its ill-informed opinion. This is not what the Court required of NRC. (0716-5 [Kraft, Dave])

Comment: The State of New York submits that the Waste Confidence DGEIS and proposed rule are inconsistent with NEPA's objective of forcing federal agencies to examine previously-held assumptions, confront the environmental consequences of their present decisions, and meaningfully weigh reasonable alternatives or conditions to the requested federal action before the federal agency takes action. Staff's approach fails to take the NEPA-required "hard look" at the environmental consequences of from continued dense storage of spent nuclear fuel in spent fuel pools. (0718-2-14 [Sipos, John])

Comment: Event reports and accident precursors[.] In the DGEIS, US-NRC has relied upon a compilation of event reports such as NUREG-1275 Vol. 12 (US-NRC 1997a) to identify relevant spent fuel events. The DGEIS mentions that US-NRC staff also performs annual reviews of U.S.

and international operating experience with spent fuel storage and handling (US-NRC 2013a), although this does not appear to be documented in an official document. (0718-3-17 [Sipos, John])

Comment: As we cannot assess the stability of future society or its similarity to our own, any storage design that requires the active input of either educated human labor or electrical or fossil energy is making too many assumptions. Any study of the recorded history of human society will tell you that the highest probability outcome for the next 10,000 year period is that the world as we know it will change to something unrecognizable to our present day. the people of any future era will likely not have the financial and technical means, the interest, or the knowledge necessary to satisfy the proposed 100 year cycle of indefinite reconstruction of these storage facilities. Thus, the environmental, economic and human safety effects of such storage are incalculable. (0724-5 [Gamble, Dan])

Comment: The National Environmental Policy Act is based on a critical principle: that one should honestly and thoroughly evaluate potential environmental impacts of major federal actions *before* deciding to undertake them. Here, NRC proposes to make licensing decisions that would result in creation of large amounts of additional high level radioactive waste for which no disposal solution exists. Yet NRC has declined to evaluate the environmental consequences of such production, solely on the assumption that institutions will exercise "eternal vigilance" of the waste. (0738-19 [Hirsch, Daniel])

Comment: The Draft GEIS claims that the environmental impact of long-term or indefinite storage is small. This is hypothetical ... given the known extreme hazards of radioactive wastes and the lack of any experience of storing these toxins for even a hundred years, let alone hundreds of thousands of years. The Draft GEIS claims that impact of a severe accident would be small. Such a conclusion cannot be supported by logic or experience. A severe accident would release deadly radioactivity into the environment. Every release of manmade radioactive matter into the environment to date has had serious and long-lasting impacts on humans and other living things within the area affected. (0757-4 [Lynch, Laura])

Comment: The NRC, by court order, has been required to gather public input regarding a Generic Environmental Impact Statement (GEIS) regarding the storage of nuclear waste that is grossly inadequate and leaves over 150 million Americans who live within 50 miles of a nuclear power plant at risk. The NRC has declared that it would only be a SMALL risk to the environment and communities near nuclear power plants to store nuclear waste on-site for 60 years, 160 years or even INDEFINITELY if no permanent repository is established. (0774-1 [Revilla, Oscar])

Comment: The Draft GEIS Lacks any Reference to Manufacturers' Requirements for the Storage Systems. The Draft GEIS assumes that there will be dry cask storage after (or during) the one hundred (100) year period following cessation of plant operations. The Draft GEIS further assumes that these robust systems of storage will be adequate for that time though, after 100 years, they will need to be transferred into a second storage cask or a cask that may be used for transfer.⁴ [footnote 4 text: As noted previously, the confidence expressed in the 100 year timeframe for storage is inconsistent with the base line assumption that storage will start on the day that a plant ceases operation. Storage starts the day the spent fuel assemblies are transferred to the dry cask storage.] Despite these assumptions, there is no reference to any manufacturers' analysis on the useful life of the casks. Nowhere is there any reference to any warranty that is provided or other information that would tend to support the conclusions that are reached within the Draft GEIS on storage. There is no reference to any experiences to date on attempted transfer. There is not a sufficient period of empirical evidence that would otherwise

support the conclusions reached by the Draft GEIS. Simply put, there has not been storage over the stated period times that would support the same conclusions. Rather, the Draft GEIS makes and relies on these assumptions being made without any substantive analysis or support. In order to support the conclusions set forth within the Draft GEIS, manufacturers' information must be included. The Draft GEIS must also set out what historically has been said about storage and the use and limitation of the current storage systems. (0783-1-11 [Harlan, Thomas])

Comment: Under section ES.9, page xxvii, lines 10-21, the Draft GEIS sets forth some of the assumptions that were made in preparing the same. As described below, these assumptions have no empirical or other evidence to support the validity of the same. Rather, the conclusions/assumptions are based upon the experience of the NRC and its continued management of the nuclear industry. However, as the NRC has noted, the Draft GEIS, is in response to the unique set of facts that the NRC is facing relative to spent nuclear fuel. The experience that purportedly is being relied upon is not experience realized through completion of a similar exercise and then repeating that same task but rather is garnered in real time. That is not the definition of experience. Accordingly, any assumption, in keeping with basic NEPA principles, should be supported in an articulable way. (0783-1-14 [Harlan, Thomas])

Comment: An analysis that starts upon cessation of operations of a power plant that generates a spent fuel also provides a false mark for the storage periods being analyzed in the Draft GEIS. For example, at the PINGP storage in dry casks began in 1993. The plant, however, will not cease operations until 2033 and 2034, respectively. Accordingly, storage in dry casks will be ongoing for over forty (40) years prior to the PINGP's cessation of operations. Applying the logic of the Draft GEIS, replacement would not occur until one hundred (100) years after the PINGP's cessation. This would mean that the casks, first filled in 1991, would be over one hundred-forty (140) years old before replacement of the same would occur. This is inconsistent, the presumption that dry casks need to be changed every one hundred (100) years. Accordingly, the best mark to start or use is the timeframe that spent fuel goes into dry cask storage. This timeframe would not include mandatory time it has spent in the spent fuel pool to ensure that the fuel assemblies have sufficiently cooled for handling and radio activity.² [footnote 2 text: This argument assumes, and the NRC should require, that spent fuel is moved to dry storage in a commercially reasonable timeframe after the same has sufficiently cooled in a spent fuel pool. The NRC should limit spent fuel pool storage.] (0783-1-6 [Harlan, Thomas])

Comment: Under section 1.2, page 1-4, lines 17-21, the language regarding the timeframe in which the continued storage should be analyzed must exclude any language relative to the end of a reactors license life for operation. The appropriate timeframe for beginning the analysis on storage is the date in which the spent fuel is actually stored. This analysis shall be separate and distinct from any licensing and further separate and distinct from any operations or decommissioning. (0783-2-1 [Harlan, Thomas])

Comment: On page 1-16, lines 1-4, the Draft GEIS contradicts itself by indicating that storage in a single cask can go beyond the one hundred (100) year cycle. There is no experience or evidence to support this assumption. There is no evidence to support that casks can even last 100 years. This assumption must be removed. (0783-2-10 [Harlan, Thomas])

Comment: On page 1-16, lines 10-12, there is an assumption on aging management. This assumption should be blended into institutional control and measured from the stand point of a generator's ability to provide systems and appropriate funding for age management of the storage systems. Again, this assumption is made without any empirical evidence or support that

generators would have the necessary funds and capabilities to ensure maintenance and safety. (0783-2-11 [Harlan, Thomas])

Comment: On page 1-16, lines 32-36, there is an assumption that a DTS is going to be replaced once during the life cycle of storage. This assumption is premised upon the robustness of the storage casks themselves and the ability of the generator to properly maintain the same. This assumption therefore is faulty because it is built on two other assumptions for which there is no experience or information to support the same. (0783-2-12 [Harlan, Thomas])

Comment: Under section 2.1.1.2, page 2-5, lines 10-13, the assumption regarding decommissioning and removal of spent fuel within sixty (60) years should be modified. Rather, the assumption should be that spent fuel should be moved to dry cask storage as soon as commercially reasonable. In no event, this should exceed five (5) years after the same has sufficiently cooled. (0783-2-14 [Harlan, Thomas])

Comment: This also applies to the various reports the Draft EIS cites to and relies upon. Those reports may be based upon assumptions of experience or that the Commission, as contemplated by the old Waste Confidence Rule, will simply remove the fuel in a stated period of time. Thus, while there is an analysis of some aspect of storage, the equipment or components used and various threats to the same, there is not an inclusion of a specific time element and the natural decay or degradation of the examined equipment or components. The Commission must be careful in its reliance on these types of reports – as well as the assumptions in the Executive Summary or its risks concluding, without analysis, that continued storage need not be analyzed. (0783-2-4 [Harlan, Thomas])

Comment: Under section 1.8.3, starting on page 1-13 and carrying over to 1-17, the Draft GEIS makes a number of assumptions that are then carried forward throughout the document. These assumptions are, in many ways, not supported by any substantive evaluation, analysis or any other empirical evidence. There is no reference to any report, study, or other governmental or non-governmental review. As such, these assumptions, rather than support and provide depth to the Draft GEIS, pull away from it and create opportunities to challenge the same for failure to meet NEPA requirements. (0783-2-6 [Harlan, Thomas])

Comment: The opening section of Chapter 4 should be modified to reflect the prior comments set forth in this letter. This should include, but not be limited to, modification of the timeframe in which the analysis should take place, modification of the assumptions set forth in section 1.8.3 and further expansion of the analysis to include both direct and indirect impacts of the proposed action. Finally, chapter 4 should be amended to include a discussion on mitigation, emergency preparedness, and other impacts that a host community would be facing. (0783-3-1 [Harlan, Thomas])

Comment: Appendix B addresses the technical feasibility of continued storage and repository availability. The technical feasibility of continued storage is based upon a series of underlying assumptions and conclusion about the robustness of the storage facilities. These assumptions, among other things, fail to include any sort of analysis from the manufacturer in the form of warranties or recommended useful life. (0783-3-20 [Harlan, Thomas])

Comment: Under section 4.12, page 4-47, lines 33-37 and carrying over to page 4-48, lines 1 and 2, there is reference to the rule making for certification of the cask design. It describes the various environmental requirements that are met for the same. The reader is left with a distinct impression that there was not, for the cask design, an EIS or EA completed. Despite this, the

Draft GEIS indicates that it is simply relying on the same. This reliance is inappropriate. The cask itself will be the storage vehicle for spent fuel, and as such, the analysis of the cask itself must be included within the Draft GEIS.⁶ [footnote 6 text: This is a bit ironic since there is an underlying assumption that the storage system (i.e. cask) is so sturdy and robust there will not be a release from the same.] As stated before, this analysis should include but not be limited to information from the manufacturers as to warranty and anticipated life, the original estimates for the casks and other information. (0783-3-4 [Harlan, Thomas])

Comment: In conclusion, it is my opinion that this DGEIS is premature and establishes an impact rating system solely related to magnitude of very poorly described potential environmental impacts. It is, in the general absence or severe shortage of relevant evidence, model-driven by use of "Reference guides." None of the critical storage items--casket performance in many different environments and tested over a very short time period (14 years, one casket), the potential for catastrophic impacts on storage facilities, which can have far greater environmental consequences than any considered in the GEIS, and the human impact factor that has great potential for environmental harm, but which doesn't fit the format for this GEIS. (0805-15 [Wilshire, Howard])

Comment: Environmental Impacts At-Reactor Continued Storage of Spent Fuel[:p. 4-3. "In this chapter, the NRC uses the License Renewal GEIS (NRC 2013) to inform some of the impact determinations regarding continued storage. In many of these cases, the analysis in this draft GEIS considers how the environmental impacts of continued storage compare to the impacts considered in the License Renewal GEIS. In the License Renewal GEIS, the NRC evaluated the potential impacts in each resource area by reviewing previous environmental analyses for past license renewal reviews, scientific literature, and other available information. Where appropriate, this draft GEIS also considers analyses and impact determinations made in previous ISFSI licensing and renewal environmental assessments (EA) and environmental impact statements (EISs) and in reactor license renewal and new reactor licensing EISs to inform the impact determinations in this analysis." Comment: Since this statement indicates unspecified assessments of unspecified environmental impacts on unspecified resource areas, it is both uninformative and says nothing about how it fits into a generic impact statement. (0805-6 [Wilshire, Howard])

Comment: The DGEIS defies credulity. Unless the NRC is clairvoyant or omniscient, how can it possibly predict with any assurance that onsite storage will be safe for 100 years, let alone millions or billions that it remains hazardous? (0819-5 [Kline, Connie])

Comment: NRC's conclusions are no more believable or reliable than an online psychic or fortune teller. It is just incredible that the DGEIS dismisses as "Small" virtually every "Environmental Impact of At-Reactor Spent Fuel Storage" including, but not limited to, "Geology and Soils", "Surface and Groundwater Quality and Use", "Aquatic Ecology." Likewise, the environmental impacts of "Postulated Accidents" and "Terrorism or Sabotage" are deemed to be "Small" (i.e inconsequential). (0819-6 [Kline, Connie])

Comment: "Indefinite" at reactor site storage, is an irreversible and irretrievable commitment of resources, and should be analyzed as such. (0820-6 [Eide-Tollefson, Kristen])

Comment: The GEIS Analysis Assumptions at 1.8.3 undermine the purpose of the environmental review, as charged by the Court. NRC cannot simply assert its own purposes or assumptions to over ride and undermine the Court's charge. The need and purposes of 1 and 3 are incompatible. (0820-7 [Eide-Tollefson, Kristen])

Comment: The Court's charge is to examine and evaluate the environmental effects of "indeterminate", permanent at reactor site storage. NRC cannot evade this requirement by assuming or reasserting the premise that prompted the court's challenge: that permanent storage will be available "when needed". (0820-8 [Eide-Tollefson, Kristen])

Comment: Inadequate application of scientific principles, thinking, testing, methodology, and practices in DGEIS and entire oversight process[.] Scientific principles and practices require their thorough application with rigor to every potential point of vulnerability, to every potential point from which lack of safety is introduced: anything less is unacceptable. Safety, which logically assures the protection of the environment and humanity from harmful exposure, requires placement at the top of the scientific decision tree, upon which all else depends. If a point of vulnerability does not have a practical solution when we are dealing with the most lethal substances created on earth, then logically the entire ensuing operation becomes too dangerous. Vulnerabilities with this extreme dangerousness exist; therefore, safety requires that the operation be stopped in order to avoid unsafe situations. (0823-1 [Michetti, Susan])

Comment: We request actual EIS regarding any and all safety issues, including fuel storage pools and casks that pertain to the actual timeframe required for all ionizing radiation isotopes identified as present to expire. The impossibility of safe actual physical storage in an actual location exists at the top of the scientific decision tree of safety for humanity and environment throughout the full timeframe of impacts. (0823-23 [Michetti, Susan])

Comment: It is unacceptable for the NRC to fail to address the significant decrease in regulatory oversight and the possibilities of harm to the public and the environment from contamination, specifically pertaining to factors impacting the spent fuel storage, referred to as "Waste Confidence Pool Storage" after the shut down of reactors for the next 60 years and "Dry Cask Storage License Renewal(s)" up to the next 40 years and "Long Term Indefinite Storage." Placing safety assurances upon an irrational assumption that a repository will be available at the end of 60 years of "Waste Confidence Pool Storage" is unacceptable when the overwhelming evidence points to the impossibility of safe repository. (0823-52 [Michetti, Susan])

Comment: Predictable inadvertent environmental exposure to ionizing isotopes without a safe method of disposal requires pre-emption based on the highest value, safety. The failure of the NRC to use actual scientific thinking, methodology, and practices throughout its entire oversight program, decision-making, and approval of nuclear reactor licenses and license extensions, unacceptably, has negligently allowed impacts of ionizing radiation on the complete environment to be overlooked. (0823-6 [Michetti, Susan])

Comment: Specifically, this analysis requires examination of impacts upon the full surrounding environment, its ecosystems, and its interconnecting influences to the rest of this finite planet over the complete timeline of impacts. Plants, trees, insects, wildlife, humans, and all living organisms require full consideration of impacts for the full cumulative lifetime of the isotopes which, contrary to our deepest wishes, likely will not remain contained and isolated. Other features, including water bodies, landforms, atmospheric features, and climate, require full impact identification and consideration for the complete timeline of impacts. Other variables and criteria also require rigorous and thorough scientific assessments and analyses through the complete timeline of impacts for the longest living radionuclide's ionizing wavelengths to expire. (0823-65 [Michetti, Susan])

Comment: We call for explanations of the logic used for the significance determinations in context, based on reasoning for each individual site for predicted measureable change in terms

of scope, geographic event, timing, duration, frequency, degree of irreversibility criteria. These variables are not all inclusive. (0823-82 [Michetti, Susan])

Comment: The once a nuclear power plant is shut down the NRC does not dictate how the power plant owner/operator should go about decommissioning their facility. Details about how the plant will be dismantled and the schedule is left up to the plant owner/operator. With the lack of a national repository for high-level waste the plant owner/operator must, under NUREG 2157, store the spent nuclear fuel on site. I am concerned that once a nuclear power plant is shut down, the plant owner/operator may decide that it is too expensive to build dry casks and keep spent fuel in the shut down plant's spent fuel pool until a national repository for high level waste is built. This scenario is not addressed in the NUREG 2157 and would further expose the surrounding community to prolonged periods of time where large quantities of spent nuclear fuel is in one place, relying upon active cooling, and more vulnerable to a potential terrorist aircraft attack when compared to dry casks. Allowing the plant owner/operator to make the determination of whether or not to place the spent fuel in dry casks or leave it in the spent fuel pool based upon cost/profit considerations is not fair to the surrounding community. (0826-15 [Morgal, Rick])

Comment: NRC justifiably assumes that used fuel would be removed from reactor pools within 60 years of reactor operation.⁴⁴ [footnote 44 text: Draft GEIS 1-14.] This assumption is appropriately conservative and bounding. Experience indicates that the time to remove fuel from the pool would actually be considerably less than 60 years. At the 14 reactors shut down prior to 2003, movement of fuel to dry cask storage was accomplished in 2 to 34 years. Of the 4 plants which took the longest time, over 20 years, 3 of them shut down 8 or more years before dry cask storage technology was even developed. Since dry cask storage was first deployed in 1986, the average length of time for shutdown plants to move to dry storage has been 11 years. (0827-1-17 [Ginsberg, Ellen])

Comment: The NRC's short-term and long-term timeframes reflect reasonable assumptions, and are supported by ample regulatory and technical information in the record of the environmental review and the rulemaking. For example, Section 1.8.3 of the draft GEIS clearly explains the assumptions underlying the agency's analysis, and provides the basis for those assumptions. Those assumptions are then relied upon, in conjunction with other technical information and experience, to assess the environmental impacts of continued storage at reactor sites (Section 4) and at away-from-reactor facilities (Section 5). (0827-1-18 [Ginsberg, Ellen])

Comment: NRC has assumed, for the purposes of the long-term storage scenario, that spent fuel will be moved to new casks every 100 years, and that the dry transfer station and ISFSI pads can be replaced every 100 years.⁴⁵ [footnote 45 text: Id. at 1-14] While NEI agrees that this assumption is bounding and appropriate for use in this analysis, it is important to note that this is a very conservative assumption. Experience to date demonstrates that it will not be necessary to replace the ISFSI or DTS, or to repackage spent fuel, with this frequency. (0827-1-19 [Ginsberg, Ellen])

Comment: Similarly, the assumption in section 4.1 and 4.7 of the draft GEIS that ISFSI replacement would take place on new land with old land "reclaimed" appears to overstate the associated environmental impacts.⁴⁶ [footnote 46 text: Draft GEIS at 4-6 & 4-24.] It is more likely that ISFSI owners would either repair or reconstruct the concrete pad on which the casks sit in the same location, or replace sections of the pad as needed, thus eliminating or significantly reducing the need to disturb new land. If the NRC continues to assess impacts using this

assumption, its conservatism should be recognized and the resulting small impacts should also be characterized as bounding. (0827-2-2 [Ginsberg, Ellen])

Comment: GEIS Section 1.8.3: Page 1-17, states: "It is assumed that an ISFSI of sufficient size to hold all spent fuel generated will be constructed during the licensed life for operation." Industry disagrees with this assumption. There is no reason the full ISFSI needs to be constructed (or even designed) during the licensed life of the reactor. A few plants, like Harris, won't need an ISFSI built before the license ends if there is enough room in the pool for all of the fuel. And while the vast majority of plants will have an ISFSI constructed during their licensed life, they will still retain a significant quantity of fuel in the pools for at least the first few years after shutdown. An ISFSI can (and would likely) be expanded at an appropriate time after operations cease, which may be after the license life. (0827-7-19 [Ginsberg, Ellen])

Comment: Section 1.8.3, Analysis Assumptions, pp. 1-14 to 1-17, states various assumptions used in the GEIS analysis. In general the assumptions are made in an attempt not to underestimate environmental impacts. Industry does not disagree with this approach, but believes the GEIS should recognize this fact, either at the beginning of section 1.8.3 or explicitly in each stated assumption. Sometimes, but not in every case, the assumption already explicitly explains this conservatism. The GEIS should consistently recognize the reasonably conservative or bounding nature of many of the assumptions made for analysis purposes. (0827-7-2 [Ginsberg, Ellen])

Comment: You say there are no "there are no remaining issues that require resolution" (Lxii) and yet you also say "The environmental impacts of terrorism are an area of particular controversy." That also means that it requires resolution, and therefore your first statement is incorrect. But we will see also in other comments below that this statement is patently untrue. THERE ARE REMAINING ISSUES AND THEY MUST BE RESOLVED. (0836-22 [Davis, Anonymous])

Comment: Page 1-17, Lines 14-15 "It is assumed that an ISFSI of sufficient size to hold all spent fuel generated will be constructed during the licensed life for operation." Not necessarily true. At San Onofre, they have not constructed the ISFSI completely yet, and yet their "for operation" license is no longer valid. You may have to change this to "licensed life for operation and decommissioning time (60 years)," otherwise, your assumption is clearly incorrect. Plus, why do you need to assume this? Please note you can't have it both ways, between this comment and the prior one, something has to give. (0836-36 [Davis, Anonymous])

Comment: Page 2-12, Lines 17-20. You say that you are still working on trying to determine if the design basis and systems, structures, and components important to safety, including spent fuel pools, needs to be updated. But you haven't completed that yet. You say "NRC has not yet received responses to the request for information and has not decided whether any license needs to be modified, suspended, or revoked, for purposes of analysis in this draft GEIS, the NRC assumes that the existing regulatory framework remains unchanged." That sounds like a pretty big assumption, and clearly is in violation of your other assumption and statement that "there are no remaining issues that require resolution" (Page Lxii) Gee, this seems like yet another example of an issue that requires resolution, unless it is the normal practice of the NRC to depend on assumptions that everything is fine. This is quite distressing to say the least, that a regulatory agency that has its primary mission safety, and it would simply assume that everything is fine. NO MORE ASSUMPTIONS, PLEASE! (0836-38 [Davis, Anonymous])

Comment: Page 2-17, Lines 3-5, the same comment as #21 above ["It is assumed that an ISFSI of sufficient size to hold all spent fuel generated will be constructed during the licensed life for operation." Not necessarily true. At San Onofre, they have not constructed the ISFSI completely yet, and yet their "for operation" license is no longer valid. You may have to change this to "licensed life for operation and decommissioning time (60 years)," otherwise, your assumption is clearly incorrect. Plus, why do you need to assume this? Please note you can't have it both ways, between this comment and the prior one, something has to give.] (0836-40 [Davis, Anonymous])

Comment: Page 4-.34, Section 4.9.3, as an example, "Indefinite Storage" If the ISFSI must be completely rebuilt at the end of 100 years, then THE SPENT FUEL SHOULD BE MOVED TO ANOTHER LOCATION, typically out of high-population density areas, away from water resources and to seismically inactive areas, and hopefully in a way that will not allow terrorist or wartime attacks. Therefore, IN NO CASE SHOULD ANY CO-LOCATED ISFSI CONTINUE TO OPERATE FOR MORE THAN 100 YEARS! Indeed, the canisters should be transported to a more appropriate area at that time, and this line of reasoning SHOULD BE MORE PREVALENT in the DGEIS. NO PERMANENT ISFSIs! We soundly REJECT THE NOTION presented in this section. (0836-54 [Davis, Anonymous])

Comment: With an eye toward the four specific questions the NRC requested of the public, I completely understand the need for it, the Generic Rule, but the question I have is: Has the NRC really gotten to the root issues for implementing a Generic Rule that does not undermine the Common Defense? (0838-5 [Clermont, Elaine])

Comment: No wonder NEI is attempting to convince the NRC to interpret the WCD as being so restricted in scope such that the sheer lunacy of producing more nuclear waste in the first place is ignored! NEI claims that "site-specific and generic" Environmental Impact Statements (EISs) cover all permutations of this basic question: Is what we're doing logical? However, they do not: Invariably, ALL other NRC and DOE EISs assume that the waste problem can be solved, thus relegating the dangers of continued operation, continued production of nuclear waste, and continued mining of uranium to matters which can be assessed through Probabilistic Risk Assessments (PRAs). (0856-6 [Fritz, John])

Comment: The NRC, by court order, has been required to gather public input regarding a Generic Environmental Impact Statement (GEIS) regarding the storage of nuclear waste that is grossly inadequate and leaves over 150 million Americans who live within 50 miles of a nuclear power plant at risk. The NRC has declared that it would only be a SMALL risk to the environment and communities near nuclear power plants to store nuclear waste on-site for 60 years, 160 years or even INDEFINITELY if no permanent repository is established. The analysis makes no distinctions among all of the nuclear power plants covered by the GEIS with regard to levels of seismic risk (earthquakes and tsunamis), regional population levels, proximity to transportation corridors, etc. In the GEIS Executive Summary, the stated purpose of this ruling is for the efficiencies that would be gained, minimizing expenditures and avoiding delays in licensing reviews. This apparent bias towards the industry seems to contradict the sole purpose of the NRC in protecting the public and the environment. This report only reinforces the growing mistrust of nuclear regulators who would play down the risk of storing nuclear waste wherever it may be presently, apparently bending to the will of the industry they are supposed to regulate. (0860-2 [Headrick, Gary])

Comment: Implicit in the Court's charge to the NRC is the need to forecast future conditions. NEPA itself can be seen as a requirement to predict the future. There are a wide variety of

accepted, time-honored and reliable methods for anticipating future conditions. The NRC should have used these types of futures methods to better assess the possible environmental impact of its proposed action and/or in conjunction with a more recognized method used in the past like probabilistic risk assessment (PRA) and in conjunction with a more robust generic analysis as purported to be used in the DGEIS. In the DGEIS PRA was noted in relationship to a NRC study on dry casks, in particular the Hi-Storm system (see section 4.18.2.2). That study did not necessarily use generic analysis as this technique may not be compatible with such an abstracted analysis - it relies on real data and real institutions/installations to be effective. This would be true even if the actual NPP site is obscured in the final study write-up so as to not pose a security threat or act as a blueprint for terrorists, saboteurs or otherwise increase site specific threats (NRC 2007). A perfect prediction of the future is not possible. The methods presented herein are not perfect and they are not a crystal ball. When used as part of an array of analysis techniques, the results of a triangulated analysis are more likely to be valid and reliable over those from when an unrealistic and not representative generic methodology is used. They help in taking a hard look at the issues and allow the agency to truly understand the potential environmental, social, economic and political concerns that may arise in the future. When such a generic methodology is used, its internal and external validity/reliability flaws are revealed. The listing of possible methodologies below could have been used to effectively examine future possible conditions derived from current knowledge and conditions. A discussion of some of the background for these possible techniques is useful and may show how the NRC could have used such techniques to conduct a valid and reliable NEPA analysis. (0867-1-1 [Griffin, William])

Comment: A way in which the DGEIS could have examined future alternatives would be to extrapolate from an analogous case in a manner similar to the case study method. In this method, the NRC would use real data from a real operating reactor site and then apply that data in other localities. In fact, this is what the DGEIS tries to do in its generic application. The DGEIS relied on information about the reactors and ISFSI's at Diablo Canyon, Morris, Humboldt Bay, Robinson, Surry, Calvert Cliffs, and Fort Saint Vrain (DGEIS p. 4-97-4-102). The main difference between the DGEIS and a more vigorous analogous case method is that the DGEIS uses a complete abstraction as the basis for drawing DGEIS conclusions. In an alternative to such abstracted analysis, the DGEIS could have used the analogous case method to extrapolate from operating NPP and licensed ISFSI facilities as a means of examining cask degradation and facilities degradation. The analogous case study method would have had numerous advantages over a generic analysis based on abstract and unrealistic data. First, it would leverage existing data already being collected by the site licensee and the NRC. Such an analytical framework would relate to actual conditions and would admit other problems that may not have been anticipated in an abstract construct like the DGEIS. A viable case study method also can be useful when there is not sufficient data for statistical sampling or remodeling. In this case in particular, there is very little relevant available data. By creating a robust case study method and then adapting it to other locations, the NRC could have produced a generic EIS that is less abstract and more grounded in reality. Another advantage is that analogous studies enable the development of a wide range of detailed data and investigations. This additional detail would have made it possible to develop new insights and information about this complex and difficult problem. (0867-1-10 [Griffin, William])

Comment: In this case, the NRC has developed a case study of a fictional facility, thereby combining the worst aspects of case study methods with the worst aspects of simulation. Another criticism of the analogous case study method is that it relies on data collected by a single organization and therefore may suffer from internal bias. This is the issue in the case of the NRC and its DGEIS. The agency has the political aspect of its operations, the Commission,

and the actual day-to-day operational aspect, the agency. This bifurcated structure introduces bias as the Commission tries to meet its political demands/agenda and the agency works to meet a variety of internal and external pressures. A final criticism is that it is often difficult to draw specific cause-and-effect inferences from the analogous case. A hard look at the issues does not justify a casual analysis; rather it requires a meaningful and justifiable analysis to meet NEPA, something the generic analysis fails to accomplish. (0867-1-11 [Griffin, William])

Comment: Another potential method of predicting the future implications of SNF storage is general morphological analysis (GMA). This method was developed by Fritz Zwicky and the intent of GMA is to investigate relationships in complex problems that will require judgment. The method was applied to a wide variety of fields including astrophysics, jet engine propulsion systems and legal aspects of space development. Morphological analysis was developed because many complex policy problems include non-quantifiable components that require judgment to be analyzed. This kind of complex policy problem makes quantitative methods less useful. When these methods are applied to problems requiring judgment, the result fails to show a clear, analytical link between the conclusion and the initial problem. The DGEIS demonstrates this very problem. The report amasses a wealth of facts, but there is no clear connection between the facts in the report and the conclusion drawn by the DGEIS. This gap is due to the absence of clearly articulated and analytically understood judgments. The 'judgment' problem made traditional models methods erratic and unreliable and was the impetus for the development of GMA. (0867-1-12 [Griffin, William])

Comment: To accomplish the task of analysis, GMA uses morphological boxes that are constructed by setting the parameters against each other in a matrix. Each cell of the box contains one particular value or condition from each of the parameters and thus marks out a particular state or configuration of the problem complex. This technique divides an issue into ever smaller components to try to isolate the individual effects that changes could have in the future. In this case, the NRC could have assessed the impact and various time periods of various parts of institutional control. For example, one conditional would be the loss of heavily armed guards at the storage site in say a future time frame of 30 years. Likewise this technique would allow the NRC to address the loss of monitoring in 60 years and try to understand what environmental effects would result. The robustness of this technique would have allowed the NRC staff to examine a variety of conditionals and thus provided a vehicle for the mandated hard look at those issues. (0867-1-13 [Griffin, William])

Comment: Each of these forecasts is normative in that it contains some future expectation. The DGEIS is a normative forecast of the future. It relies on assumptions about the future that oversimplify important aspects of the problem (e.g. funding, institutional control, staff). These assumptions have the same effect as value judgments on the quality of the assessment. An explanatory, or positive forecast, is one that provides a prediction about the future that does not incorporate as explicit value judgments about future conditions. Explanatory forecasts strive to be free of the values of the forecasting research team. When judgment is necessary (as it would be in the case of the DGEIS) the explanatory forecast seeks to understand and isolate its effects from the other parts of the forecast. Examples of an explanatory forecast are: • By 2030, there will be 42% fewer retail outlets to purchase guns than there are today. • By 2040, the US national debt will have grown to \$88 billion. • By 2048 funds to pay for nuclear waste site management will have declined by 56%. NEPA calls for an examination of the impacts of federal actions on the environment. To accomplish a hard look at the issues, that explanation should be free from the values and preferences of the Federal agency preparing the forecast. (0867-1-3 [Griffin, William])

Comment: *The NRC assumes that aging management, including routine maintenance activities and programs occurs between replacements. These "routine" or planned maintenance activities are distinct from the "replacement" of facilities and equipment. The NRC here assumes that there will be money, equipment, and available expertise even though each of these sites will be the responsibility of a utility which is obtaining no income from the site and may not even be in existence in the distant future. NRC also does not discuss the basis for any unspoken assumption that funding for these efforts will be adequately provided by funds that are being created today for spent fuel management when the assumed time frame is far less than the timeframes that are to be addressed in the DGEIS. None of these assumptions fall within NRC's expertise. (0867-2-12 [Griffin, William])*

Comment: *The spent fuel is moved from the spent fuel pool to dry cask storage within the short-term storage timeframe. While there may be money, equipment and expertise available to make the transfer if it were done while the plants are still operating, there is no analysis in the DGEIS to demonstrate a basis for that assumption 50 years after the plant has been shut down. None of these assumptions fall within NRC's expertise. (0867-2-13 [Griffin, William])*

Comment: *The NRC assumes that nuclear power plant decommissioning occurs within 60 years after the licensed life for operations in accordance with 10 CFR 50.82 or 52.110. The NRC also assumes that, by the end of the short-term storage timeframe, a licensee will either terminate its Part 50 or 52 license and receive a specific Part 72 ISFSI license (see 10 CFR Part 72, Subpart C) or receive Commission approval under 10 CFR 50.82(a) (3) or 52.110(c) to continue decommissioning under its Part 50 or 52 license. In either case, the NRC assumes that the NRC will conduct an appropriate site-specific NEPA analysis for either issuance of a Part 72 ISFSI license or approval to continue decommissioning in accordance with 10 CFR 50.82(a)(3) or 52.110(c). The ISFSI and DTS would be decommissioned separately. This is an appropriate assumption if the NRC continues to exist with adequate funding. The funding for the NRC is substantially derived from fees paid by operating nuclear power plants and thus the agency itself is subject to the economic whims of energy production. It may or may not be functioning and/or could be replaced as happened to the AEC. Thus, it is possible that oversight operations of this type would be given to another agency or that Congressional budget constraints would limit the funds available to fully operate the NRC or its successor to the same extent as now available. (0867-2-14 [Griffin, William])*

Comment: *Replacement of the entire ISFSI would occur over the course of each 100-year interval, starting at the beginning of the long-term storage timeframe. Construction, operation, and replacement of the DTS are assumed to occur within the timeframe, it could be near the end of its useful life by the end of that storage timeframe. To be conservative, the NRC included the impacts of replacing the DTS one time during the long-term storage timeframe. The NRC here assumes that there will be money, equipment, and available expertise. None of these assumptions fall within NRC's expertise. (0867-2-15 [Griffin, William])*

Comment: *Because an away-from-reactor ISFSI could store fuel from several different reactors, the earliest an away-from-reactor ISFSI would enter the short-term timeframe is when the first of these reactors reaches the end of its licensed life for operation. This needs to be examined for the timing of shipments and the movement of the waste. There will be substantial movement of fuel required for this to be successful. Such analysis is not generically possible, it is site specific. (0867-2-16 [Griffin, William])*

Comment: *The amount of spent fuel generated is based on the assumption that the nuclear power plant operates for 80 years (40-year initial term plus two 20-year renewed terms). A*

typical spent fuel pool of 700 metric tons of uranium (MTU) storage capacity reaches its licensed capacity limit about 30 years into the licensed life for operation of a reactor. At that point, some of the spent fuel would need to be removed from the spent fuel pool and transferred to a dry cask storage system at either an at-reactor or away-from-reactor ISFSI. This may or may not be a reasonable assumption. Burn up times for reactor fuel have changed as the technological controls for reactors have been improved. It may be that in the future, to help in recovery of costs, it will be necessary to run reactors to achieve hotter burn up fuel. This could affect the rate at which waste is produced, how fast wet storage fills to capacity and when/how SNF is moved into dry-storage casks. The results of such operational choices may impact storage, transfer and even the physical integrity of the fuel assemblies (Alvarez). (0867-2-17 [Griffin, William])

Comment: *The environmental impacts of constructing a "spent fuel pool island," which allows the spent fuel pool to be isolated from other reactor plant systems to facilitate decommissioning, are considered within the analysis of cumulative effects in Chapter 6. Because a new spent fuel pool cooling system would be smaller in size and have fewer associated impacts than existing spent fuel pool cooling systems, the environmental impacts of operating the new spent fuel pool cooling system in support of continued storage in the spent fuel pool, would be bound by the impacts of operating the existing cooling system described in Chapter 4. It is assumed that an ISFSI of sufficient size to hold all spent fuel generated during licensed life for operation will be constructed. This assumption ignores the considerable environmental impacts that would be involved in the construction of such a spent fuel pool island, the economic costs of operating and maintaining such a facility, and its vulnerability to natural disasters and malevolent acts. (0867-2-18 [Griffin, William])*

Comment: The NRC response to the need to conduct an environmental analysis of the continued production of spent fuel when no permanent repository is available and to continue to allow storage of spent fuel at reactor sites in pools or dry casks is at best inadequate. After the Court rejected NRC's 2010 attempt to address these issues, the NRC began the current process which has produced the DGEIS for comment. The DGEIS is intended to evaluate the costs of policy options, but without performing any of the detailed analysis necessary to understand the environmental impacts. Further, it abstracts the impacts through the device of a generic analysis, and assesses only the impacts on a generic basis. (0867-2-2 [Griffin, William])

Comment: It is important to recognize that the DGEIS does not contain any specific information that pertains to any real NPP. It does not describe the conditions at any operating or decommissioned NPP and it does not provide credible forecasts of the impacts that could result from the indefinite storage of SNF at a specific geographic location near or at the NPP. The DGEIS does not assess any genuine condition of the environment and it does not provide information about the environmental effects in the absence of a physical repository. (0867-2-3 [Griffin, William])

Comment: The key to the DGEIS, and the primary reason it is able to reach the conclusion that the environmental impacts of long term and indefinite storage of spent fuel at reactor sites are small, is that it relies on a number of assumptions which have the effect of eliminating the most troublesome issues from consideration. By this approach, NRC is choosing to address the issues raised by the absence of a permanent waste repository for nuclear wastes by doing normative forecasting - i.e. projecting an ideal, not a reasonably likely, future and then examining the impacts that could occur if that ideal future were reality. As already noted, this approach is inappropriate for conducting an environmental impact analysis which is intended to

assist NRC in making choices among alternative ways to deal with the problem created by the absence of a permanent waste repository. (0867-2-5 [Griffin, William])

Comment: The analysis of environmental consequences in the DGEIS does not reflect reasonably foreseeable and different future conditions. (0867-3-20 [Griffin, William])

Comment: The DGEIS does not contain a thorough and in-depth analysis of the consequences of indefinite storage of spent fuel. The DGEIS does not properly assess the impacts of indefinite storage of SNF because its analysis depends upon invalid or questionable assumptions. (0867-3-21 [Griffin, William])

Comment: The NRC is not entitled to agency deference on many these assumptions because in whole or in part, the assumptions fall outside of the agency's area of expertise. (0867-3-22 [Griffin, William])

Comment: The assessment does not properly address the risks to the environment. (0867-3-24 [Griffin, William])

Comment: The DGEIS fails to justify the use of generic analysis of many of the environmental consequences that are substantially impacted by site-specific variations. (0867-3-25 [Griffin, William])

Comment: This report examined the DGEIS and the NRC's assumptions, staff choice of methodology and the validity/reliability of the conclusions that flow from these. The use of these assumptions in the construction of the DGEIS leads the NRC to fail to address the hard look questions NEPA requires be examined. Instead it offers a generic analysis that does not provide an adequate record for NRC to make a decision on this major federal action. (0867-3-26 [Griffin, William])

Comment: First, the assumptions underlying the DGEIS conceal the real issues behind the generation, storage and movement of SNF. The NRC's assumptions in the DGEIS were used to limit the alternatives being considered and diminish the scope of the environmental consequences that needed to be evaluated. These assumptions, in conjunction with the Commission's choice to accelerate the time needed to do the analysis from the staff suggested seven years to the Commission mandated two years, resulted in an insufficient, invalid and unreliable DGEIS. (0867-3-27 [Griffin, William])

Comment: Secondly, the overall methodology used in the DGEIS avoids a valid and scientifically sound analysis of the issues. Using a normative forecasting method and thus assuming a future, rather than analyzing the facts and considering reasonably different futures, avoids the type of analysis required by NEPA. (0867-3-29 [Griffin, William])

Comment: In addition, the choice of a generic analysis does not meet the needs of NEPA because it glosses over the important site-specific conditions and factors which will markedly alter the environmental consequences and mitigation alternatives for each site. The use of unsupported assumptions led to no consideration of many of these site-specific conditions and factors. NRC has common methodological approaches like probabilistic risk assessment (PRA) that do consider different futures and make predictions about the probability of different conditions arising in the future in making consequences analyses but it fails to use a similar methodology here and thus fails to address a variety of reasonably foreseeable conditions that must be addressed in such an analysis. (0867-3-30 [Griffin, William])

Comment: Third, the analysis above offered several realistic and reasonable alternatives to the methodological choice of a generic analysis and the normative forecasting. Good methodological practice recognizes that a singular method for such an important task is often either invalid or unreliable - or degrees of both. A single method has flaws, as do all methods. What is needed is to address the issues in the best possible manner - one which seeks scientifically sound, valid and reliable results. That can better be achieved with the triangulation of methodologies - two or more wherein each covers the shortcomings of the other. NRC has not used even one of the exploratory methodologies in the DGEIS. To summarize, the choice of the generic approach, using normative forecasting and unsupported assumptions, does not meet a minimum level of research inquiry. It fails to construct a valid and reliable research endeavor that should be necessary to meet NEPA requirements. (0867-3-31 [Griffin, William])

Comment: Fourth, the choices by the NRC to avoid issues like environmental contamination from leaks in the pools/or dry storage, the real possibility of future funding shortfalls for their own operations, the realistic and foreseeable loss of institutional controls and the other issues noted above, should have been part of the analytical process but the DGEIS fails to address these very real concerns. (0867-3-32 [Griffin, William])

Comment: The nuclear industry is critically concerned about the availability of trained staff (ANS). There are reasons to believe that the industry will not be able to provide enough trained and technically sound staff if current trends continue. The continuing aging of the workforce is expected to create a severe shortage of qualified workers. The workers who are available will be needed for other, more lucrative purposes. These purposes include: • maintain the safe and reliable operation of commercial and defense nuclear plants • continue necessary research and development in education, medicine, power, and manufacturing • continue development and construction of new nuclear facilities • staff nuclear medicine needs • continue nuclear education[.] Spent nuclear fuel management will have to compete with other, more urgent and possibly more lucrative, fields for talent. Another alternative to address the impending talent shortage is that the US will be forced to hire foreign workers or outsource the spent fuel management to a foreign company entirely. This will create a different set of problems related to the safety and security of the fuel. The DGEIS is silent on this imminent problem and the implications it has for the risks and the environmental consequences of spent fuel management. (0867-3-8 [Griffin, William])

Comment: The methodology informing the Waste Confidence Rule EIS is scientifically invalid! The artificial creation of composite, generic, and non-existent nuclear sites is inherently flawed to perform qualitative analysis. (0869-3 [Homick, Nick])

Comment: YOUR CONCLUSION THAT IN ALL AREAS THE SHORT TERM, LONG TERM, AND INDEFINITE STORAGE IMPACTS ARE ALL "SMALL" IS SIMPLY 100% WRONG. (0887-5 [Chappellet, Carissa])

Comment: In addition, the DGEIS must show that it has quantified the risks and costs associated with siting a repository or failing to do so, including the risks and costs of maintaining spent fuel at reactor sites or away-from-reactor storage facilities for an indefinite period. (0897-1-15 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: In addition, the NRC conducts a generic analysis using bounding parameters that are not broad enough to cover a number of site-specific concerns. See *New York v. NRC*, 681 F.3d at 480-81 (NRC must conduct a "thorough and comprehensive" analysis using "conservative bounding parameters."). (0897-4-24 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: And, it fails to consider impacts of storage of spent fuel in pools for longer than 60 years, although such storage is reasonably foreseeable and indeed contemplated by certain NRC regulations, including the proposed rule 10 C.F.R. § 51.23 (which has no time limit on extended storage) and existing rule 10 C.F.R. § 50.82 (which allows for decommissioning beyond 60 years under certain circumstances). See *Robertson*, 490 U.S. at 350; see also *Potomac Alliance*, 682 F.2d at 1035-36 (J. Bazelon, concurring) (noting that NRC may not simply ignore reasonably foreseeable possibilities). (0897-4-25 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Second, the decommissioning regulation contemplates storage beyond 60 years in certain circumstances. 10 C.F.R. § 50.82(a)(3). In determining whether decommissioning beyond 60 years is appropriate, NRC considers several factors, including the “unavailability of waste disposal capacity.” 10 C.F.R. § 50.82(a)(3). In light of the current unavailability of a repository or disposal site, it is reasonably likely that some licensees could seek Commission approval to extend the decommissioning time period, including wet storage of spent fuel, beyond the 60 year timeframe. In order to comply with NEPA, the NRC must assess the potential impacts of wet storage beyond 60 years. (0897-6-10 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Third, the NRC’s Decommissioning GEIS contemplates pool storage for more than 60 years in the ENTOMB alternative. Decommissioning GEIS, Supplement 1, NUREG-0586 (2002). The Decommissioning GEIS presents three decommissioning alternatives: SAFSTORE, DECON, and ENTOMB. As the NRC explains: “During the short-term storage timeframe, the pools will be used to store fuel until a licensee decides to remove the spent fuel as part of implementing either the SAFSTOR or DECON decommissioning option.” DGEIS at 2-25. The ENTOMB scenario, however, contemplates storage of spent fuel in pools for up to 100 years. *Id.* at 3-25– 26. However, the NRC ignores the third option for decommissioning, the ENTOMB scenario. See Decommissioning GEIS, Supplement 1, NUREG-0586 at 3-21. (0897-6-11 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: NRC’s SFP leaks impact analysis violates NEPA because it does not consider impacts from SFP storage beyond 60 years, even though longer storage in SFPs is contemplated by the proposed regulation 10 C.F.R. § 51.23 and by 10 C.F.R. § 50.82[.] NRC assumes that spent fuel will be stored in pools for no more than 60 years after the licensed life of a reactor, and thus, only looks at SFP impacts in the 60-year short-term timeframe. DGEIS at 1-14. NRC bases its assumption on one of its decommissioning regulations which states that “[d]ecommissioning will be completed within 60 years of permanent cessation of operations.” 10 C.F.R. § 50.82(a)(3); see also DGEIS at xxix. This assumption is problematic in at least three ways. (0897-6-8 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: We are aware that an agency preparing an environmental impact statement (EIS) can proceed even when important information is missing. But it is obliged to at least specify the important information and data gaps in any EIS and provide a discussion of the available evidence of the importance of the missing data. This is not only legally required under 40 CFR 1502.22, it is a basic element of scientific integrity and a part of the meaningful assessment of uncertainties. In case the data gaps are in critical areas and are so large that meaningful uncertainty bounds cannot be put on the impacts, the NRC should make that finding in its assessment of the problem. In this case, the NRC and other agencies know the data gaps well. Moreover, the NRC itself was on a path to remedy them at least to some extent over the coming years. But the Draft GEIS fails to discuss the consequences of a failure to include that

information in its environmental impact analysis and on its conclusions. (0898-2-5 [Curran, Diane] [Makhijani, Arjun])

Comment: The Draft GEIS claims that the environmental impact of long-term or indefinite storage is small. This is an absurd statement on its face, given the known extreme hazards of radioactive wastes and the lack of any experience of storing these toxins for even a hundred years, let alone hundreds of thousands of years. (0908-2 [Mikkelsen, Sara])

Comment: On page 8-8, in the discussion of "Irreversible and Irretrievable Commitments of Resources" the Draft states "there would be no irreversible and irretrievable ... for most..... HOWEVER, IMPACTS ON LAND USE, AESTHETICS, HISTORIC AND CULTURAL RESOURCES, WASTE MANAGEMENT, AND TRANSPORTATION WOULD RESULT IN IRREVERSIBLE AND IRRETRIEVABLE COMMITMENTS THE LOSS...IN PERPETUITY....IRREVERSIBLE COMMITMENT OF CAPACITY FOR WASTE DISPOSAL" My Comment: DOES THIS MEAN ACCEPTANCE OF PERMANENTLY SACRIFICE LAND ON OUR PLANET???? (0910-12 [Carey, Corinne])

Comment: On page.iii etc., repeatedly the draft states "Impacts would be SMALL." ... in the various sections and considerations. COMPARED TO WHAT???? (0910-9 [Carey, Corinne])

Comment: The prediction of continued safe storage is probably acceptable for the ShortTerm storage (60 years). However, is it reasonable to rely on relatively short actual storage experience to predict Long-Term (100 years) or Indefinite safe storage (even with aging management programs), given the findings of indicators of potential concerns cited in the GEIS (i.e. , "chloride-induced stress corrosion cracking of austenitic stainless steel and maintenance of dry cask storage system canisters [NRC 2012b] and the "potential effects of hydride reorientation on cladding behavior [Billone et al. 2013]? (0913-6 [Bevill, Bernard])

Comment: Have indications of other potential radiation induced embrittlement issues been identified and/or studied? (0913-7 [Bevill, Bernard])

Comment: (VIII-2) The hazard posed by a nuclear fuel assembly begins at the moment when the assembly first undergoes nuclear fission, which occurs inside a reactor. That moment would be the logical starting point for any GEIS that addresses spent fuel. A less logical, but perhaps plausible, starting point would be the moment when the fuel assembly is discharged from a reactor and placed in a nearby pool. The draft GEIS uses a much later and entirely illogical starting point. The draft GEIS considers the environmental impacts of storing spent fuel during a period that begins when the reactor that discharged the fuel is no longer licensed for operation. (VIII-3) By adopting this later starting point, the draft GEIS excludes from consideration a set of significant environmental impacts that arise in earlier phases of the life of a fuel assembly. That exclusion is illogical. (0916-1-16 [Curran, Diane] [Thompson, Gordon R.]

Comment: (IX-7) In Sections VI and VII of the Thompson scoping declaration, I set forth a number of recommendations for the use of scenarios.⁸³ [footnote 83 text: Thompson, 2013b, Sections VI, VII, and X.] These recommendations could have helped the framers of the draft GEIS to avoid the self-crippling of the draft GEIS that I have described in the preceding paragraphs. The framers ignored my recommendations. Those recommendations would, in principle, have allowed the draft GEIS to bound the radiological risk of storing spent fuel. Moreover, those recommendations would have allowed the draft GEIS to compare the risk posed by different scenarios and different options for managing spent fuel. (0916-2-3 [Curran, Diane] [Thompson, Gordon R.]

Comment: Rather than analyze the risks of irradiated nuclear fuel generation, storage (on-site, in pools and dry casks; and away-from-reactor), and ultimate disposition, NRC has instead simply assumed away all the risks. Rather than analyze risks, NRC has simply assumed safety, at every turn. (0919-2-14 [Kamps, Kevin])

Comment: NRC also makes an overly optimistic assumption that technological progress will advance as time goes on, or at the very least, our society will stay at the same level of civilizational advancement as it currently is at. (0919-2-8 [Kamps, Kevin])

Comment: On Page 2-25 (lines 13-16), NRC states: "Beyond the decommissioning period, the NRC assumes that all of the spent fuel has been transferred to a dry cask storage system in an at-reactor or away-from-reactor ISFSI, as no other option currently exists." (emphasis added) This is a refreshingly frank admission, for a change, coming from NRC! But we would add, these on-site, or away-from-reactor (centralized "parking lot dumps") ISFSIs could very well themselves become de facto permanent surface storage facilities - or dumps. The on-site ISFSI at Surry, VA has been there since 1986, with no end in sight. The so-called "away-from-reactor" ISFSI (wet pool storage) at GE Morris in IL (so-called, as the Dresden nuclear power plant's three reactors are just a half-mile away!) has been there since the late 1960s, with no end in sight. The list of examples is a very long one. (0919-3-18 [Kamps, Kevin])

Comment: At Page 1-17, lines 22 to 24, NRC states: "These analyses are not intended to be, and should not be interpreted as, representative of any specific storage facility or site in the United States where spent fuel is currently stored or could be stored in the future." This passage rings oddly legalistic in sound. That's a very strange thing to say. So this entire DGEIS is essentially a fictitious, meaningless document? With no connection to reality? (0919-3-8 [Kamps, Kevin])

Comment: At Page 3-1, lines 2 and following, NRC states: "the affected environment is the environment that exists at and around the facilities that store spent nuclear fuel (spent fuel) after the end of a reactor's licensed life for operation." But of course, if the irradiated nuclear fuel spills into Lake Michigan, for example at the Big Rock Point and/or Palisades nuclear power plant sites on Michigan's Lake Michigan shoreline, then it will flow downstream; if it leaks into the air, it will blow downwind. Over vast distances. It would re-concentrate up the food chain, atop which humans sit. And the effects would persist for many generations into the future. So, NRC's definition of the potential "affected environment" needs to be expanded, significantly. (0919-4-16 [Kamps, Kevin])

Comment: Re: lines 5 and following, "Where appropriate, this chapter will discuss the environmental impacts during reactor operations to establish the baseline affected environment at the beginning of continued storage." But reactor operations is not an appropriate baseline. The pristine environment that existed before the reactor was built is the appropriate baseline, at least from a radiological perspective. To exploit the fact that the adjacent reactor has already radioactively contaminated the environment, to justify further radioactive contamination from forevermore radioactive waste storage, is not appropriate. (0919-4-17 [Kamps, Kevin])

Comment: At Page 2-27, lines 10-12, NRC states "it should be recognized that the environmental impacts of constructing and operating an away-from-reactor ISFSI would be evaluated in more details (sic) in an environmental review associated with a site-specific license application." But NRC really doesn't know what it's talking about, as it has never really done one. It's all assumptions. If PFS, LLC is the best they've got to point to, it doesn't instill much

confidence. Its licensing was highly controversial, for good reason; and in the end, it got cancelled! (0919-4-6 [Kamps, Kevin])

Comment: The enhancement of existing aging management programs for the spent fuel pool concrete structure and liner plate should not just be done under the license renewal process. This should be an ongoing process that is done prior to license renewal and continues into the short term storage timeframe whereby leaks would be detected early and repaired. (0920-2 [Foster, Ruth])

Comment: The conclusion [in the GEIS] box indicates that NRC did independent impact assessments of continued storage, considered public scoping comments and did a cost-benefit balance. How does an agency do an independent assessment of those they regulate? The NRC has a conflict of interest in this case. If the assessment was done by an outside agency such as GEO, or outside institute such as NSF, it would be an independent-impact assessment. (0920-22 [Foster, Ruth])

Comment: You say there are no "there are no remaining issues that require resolution" (Lxii) and yet you also say "The environmental impacts of terrorism are an area of particular controversy." That also means that it requires resolution, and therefore your first statement is incorrect. But we will see also in other comments below that this statement is patently untrue. THERE ARE REMAINING ISSUES AND THEY MUST BE RESOLVED. (0930-1-15 [Lutz, Ray])

Comment: Page 1-17, Lines 14-15 "It is assumed that an ISFSI of sufficient size to hold all spent fuel generated will be constructed during the licensed life for operation." Not necessarily true. At San Onofre, they have not constructed the ISFSI completely yet, and yet their "for operation" license is no longer valid. You may have to change this to "licensed life for operation and decommissioning time (60 years)," otherwise, your assumption is clearly incorrect. Plus, why do you need to assume this? Please note you can't have it both ways, between this comment and the prior one, something has to give. (0930-2-10 [Lutz, Ray])

Comment: Page 2-12, Lines 17-20. You say that you are still working on trying to determine if the design basis and systems, structures, and components important to safety, including spent fuel pools, needs to be updated. But you haven't completed that yet. You say "NRC has not yet received responses to the request for information and has not decided whether any license needs to be modified, suspended, or revoked, for purposes of analysis in this draft GEIS, the NRC assumes that the existing regulatory framework remains unchanged." That sounds like a pretty big assumption, and clearly is in violation of your other assumption and statement that "there are no remaining issues that require resolution" (Page Lxii) Gee, this seems like yet another example of an issue that requires resolution, unless it is the normal practice of the NRC to depend on assumptions that everything is fine. This is quite distressing to say the least, that a regulatory agency that has has its primary mission safety, and it would simply assume that everything is fine. NO MORE ASSUMPTIONS, PLEASE. (0930-2-12 [Lutz, Ray])

Comment: Page 2-17, Lines 3-5, the same comment as #21 above ["It is assumed that an ISFSI of sufficient size to hold all spent fuel generated will be constructed during the licensed life for operation." Not necessarily true. At San Onofre, they have not constructed the ISFSI completely yet, and yet their "for operation" license is no longer valid. You may have to change this to "licensed life for operation and decommissioning time (60 years)," otherwise, your assumption is clearly incorrect. Plus, why do you need to assume this? Please note you can't have it both ways, between this comment and the prior one, something has to give.] (0930-2-14 [Lutz, Ray])

Comment: 4-.34, Section 4.9.3, as an example, "Indefinite Storage" If the ISFSI must be completely rebuilt at the end of 100 years, then THE SPENT FUEL SHOULD BE MOVED TO ANOTHER LOCATION, typically out of high-population density areas, away from water resources and to seismically inactive areas, and hopefully in a way that will not allow terrorist or wartime attacks. Therefore, IN NO CASE SHOULD ANY CO-LOCATED ISFSI CONTINUE TO OPERATE FOR MORE THAN 100 YEARS. Indeed, the canisters should be transported to a more appropriate area at that time, and this line of reasoning SHOULD BE MORE PREVALENT in the DGEIS. NO PERMANENT ISFSIs! We soundly REJECT THE NOTION presented in this section. The affect on Aquatic resources, again, assumes NO ACCIDENTS occur. (0930-3-6 [Lutz, Ray])

Comment: It is very apparent that lawyers directed those people who were writing and compiling the document to claim that most any scenario involving radioactive waste will have a "Small" impact. When one is dealing with among the few most toxic substances known (such as some kinds of plutonium and other radionuclides) in high concentration (and sometimes near major population centers), these claims flunk the basic logic test. (0937-2 [Campbell, Bruce])

Comment: Make sure to include in the record all documents which involve analysis of potential for leaks and fires at spent fuel ponds. This should not be too much to ask seeing that these two factors needed to be included in the generic document to satisfy the D.C. Circuit concern with the earlier inadequate Waste Confidence Generic EA. Seeing that the court specifically called for it, I am appalled at what passes for a true analysis in regards to both leaks from spent fuel pools, as well as possibility of fire at spent fuel pools. The court and concerned citizens must reject this inadequate and vague document which leaves us no closer to a meaningful evaluation of the relative safety of different modes and locations of radioactive waste storage. (0937-31 [Campbell, Bruce])

Comment: Radioactive waste is radioactive waste whether or not a facility has an operating license. In fact, certain radioactive waste at facilities with an operating license and certain radwaste at facilities who no longer have an operating license can be exactly the same in terms of curies, heat, and radionuclide dispersions -- thus the distinction does not make sense except insofar as it is supposed to be vague and generic and justifying promoting future nuclear power facilities and reactors without a thorough environmental review. (0937-32 [Campbell, Bruce])

Comment: The NRC Statement rates the risks of on-site storage as almost insignificant. This is not credible at any site. (0944-5 [Pascall, Glenn] [Watland, George])

Comment: The Draft GEIS claims that the environmental impact of long-term or indefinite storage is small. This is an absurd statement on its face, given the known extreme hazards of radioactive wastes and the lack of any experience of storing these toxins for even a hundred years, let alone hundreds of thousands of years. (0951-2 [Commenters, Multiple])

Comment: Blue Ridge Environmental Defense League ("BREDL"), the Institute for Energy and Environmental Research ("IEER"), Natural Resources Defense Council ("NRDC"), Riverkeeper, and Southern Alliance for Clean Energy ("SACE") hereby submit comments on the NRC's draft report, Background and Preliminary Assumptions for an Environmental Impact Statement Long-Term Waste Confidence Update (December 2011) ("Draft Report"). The Draft Report should be withdrawn because the assumptions it proposes are inconsistent with the National Environmental Policy Act ("NEPA") and NRC regulations. In addition, by indicating that the NRC plans to prepare an EIS that discusses the environmental impacts of long-term SNF disposal without also discussing the impacts of SNF disposal in a repository and the impacts

that may occur if SNF disposal is never achieved, the NRC unlawfully segments the environmental analysis for SNF disposal. Finally, the NRC's decision to issue the Draft Report without publishing a notice in the Federal Register is inconsistent with the NRC's open government policy and long-established practice. (0954-1 [Curran, Diane] [Fettus, Geoffrey])

17. Comments Concerning GEIS Assumptions – Dry Transfer System

Comment: Under its "indefinite storage" scenario, NRC has assumed that dry cask storage -- cask pads, inner canisters, and the dry casks themselves -- will be replaced once every 100 years, forevermore into the future. NRC assumes that Dry Transfer Systems will be built (and also replaced every 100 years), since pools will have been dismantled during decommissioning, by at most 60 years after permanent reactor shutdown. But NRC has not dealt with the very real risk that the irradiated nuclear fuel will so degrade with age that such transfer operations cannot be carried out safely or smoothly. This is especially a risk with "high burn-up fuel," that has spent more time in an operating reactor core, and is thus significantly more radioactive and thermally hot. NRC has also not provided the price tag for such future transfer and replacement operations. (0002-4 [Commenters, Multiple])

Comment: I would like to know what procedures are in place to conduct dry transfer of degraded fuel assemblies from the Wholetech casks when they expire in 100 years or less. How about 200 years, 300 years? That's how long it takes cesium to become benign. What about 240,000 years? (0163-22-7 [Shaw, Gary])

Comment: [I can only imagine how the next generation and the generations after that are going to feel when the amount of nuclear waste has grown even larger and they are dealing with the inevitable problems of] the difficulties, costs, spills, and accidents that will come from moving waste from pools to dry casks and then from dry casks to other dry casks. (0163-34-5 [Azulay, Jessica])

Comment: Likewise, the Generic Environmental Impact Statement is full of predictions that we will have a yet to be invented or tested equipment like dry transfer systems and casks that can reliably last for 100 years. (0163-34-9 [Azulay, Jessica])

Comment: NRC assumes that cask pads, inner canisters, and the dry casks will be replaced once every 100 years, for hundreds of millennia. Since Spent Fuel Pools (SFP) will have been dismantled by, at most, 60 years after permanent reactor shutdown, NRC further assumes that dry transfer systems will be built and replaced every 100 years. Will degradation of irradiated nuclear fuel prevent the proper execution of such transfer operations? No one knows and the NRC appears to disregard this concern. Can anyone seriously believe that the safekeeping of radioactive waste will continue for 240 millennia or even longer? (0230-5 [Garb, James])

Comment: Dry transfer systems. I remember talking about dry transfer systems during the Prairie Island nuclear waste fight in '94, in '88, in '90, throughout that whole time, first in administrative proceedings, then in the courts, then in the legislature. We talked about it, because that was clear at the time that the waste could not remain in the casks -- that something would have to happen with the waste in the casks. It would have to be transferred. How do you do that? Well, at the time they called it a dry box, and it cost about \$100 million a copy, as I recall. (0328-7-4 [Crocker, George])

Comment: Under its "indefinite storage" scenario, the NRC has assumed that dry cask storage- cask pads, inner canisters, and the dry casks themselves-will be replaced once every

100 years, forevermore into the future. The NRC assumes that Dry Transfer Systems will be built (and also replaced every 100 years), since pools will have been dismantled during decommissioning, by at most 60 years after permanent reactor shutdown. But the NRC has not dealt with the very real risk that the irradiated nuclear fuel will so degrade with age that such transfer operations cannot be carried out safely or smoothly. This is especially a risk with "high burn-up fuel," that has spent more time in an operating reactor core, and is thus significantly more radioactive and thermally hot. The NRC has also not provided the price tag for such future transfer and replacement operations. (0336-8 [Lish, Christopher])

Comment: NRC assumes that Dry Transfer Systems will be built (and also replaced every 100 years), since pools will have been dismantled during decommissioning, by at most 60 years after permanent reactor shutdown. But NRC has not dealt with the very real risk that the irradiated nuclear fuel will so degrade with age that such transfer operations cannot be carried out safely or smoothly; This is especially a risk with "high burn-up fuel," that has spent more time in an operating reactor core, and is thus significantly more radioactive and thermally hot. NRC has also not provided the price tag for such future transfer and replacement operations (0377-5-18 [Cuthbert, Lewis])

Comment: The practical problems in storing or reprocessing waste are severe. If spent fuel stored on site cannot be transferred to a remote site, it will be necessary over time to transfer fuel from one cask to another. No one knows how to do this, especially if the casks are damaged. (0431-10 [Pascall, Glenn] [Watland, George])

Comment: An example of this problem is the way that the EIS addresses the need to replace Independent Spent Fuel Storage Installations (ISFSI), storage canisters, and casks. Without looking at specific sites where SNF is stored, the EIS fails to consider the real possibility that there may not be room on the existing sites to construct the necessary Dry Transfer Systems (DTS) and ISFSI. Without adequate space on site, it may be necessary to transport the SNF to a location where the SNF can be repackaged in the replacement canisters and casks. (0459-4 [Johnson, Abigail])

Comment: The EIS also assumes that the necessary DTS can be constructed and operated successfully, in spite of the fact that one has not been built and operated. The EIS uses a DTS design that was never licensed or constructed as a generic example of what would be constructed. NRC found that, The DTS concept has merit, but never considered a license application for such a facility. (0459-5 [Johnson, Abigail])

Comment: In fact, the Draft GEIS has not demonstrated that the effective probability of accidents and events is zero. The Draft GEIS makes the assertion regarding low probabilities of all initiating events despite describing significant uncertainties and information gaps: With respect to the safety of dry transfer systems (DTS) that would be required in the long-term and indefinite timeframes, the Draft GEIS describes that no such systems exist in the U.S. today. For the purposes of the Draft GEIS, however, the NRC references a design for a DTS developed in the 1990s. Based on this reference design, the NRC concludes that future DTSSs will be safe to support continued storage with small environmental impacts (Draft GEIS, pg. 2-19). Considering a complete lack of experience developing a DTS in the U.S., the NRC provides limited evidence to support its assumption that such a system will be safe at all sites over indefinite continued storage timeframes. This underscores our findings that codifying continued storage will be safe over the timeframes considered in the Draft GEIS is premature, and that the Draft GEIS does not provide sufficient analysis to support its conclusion. (0473-1-20 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: moreover, the DGEIS acknowledges that a dry transfer system would be required to do so, and that none currently exists in the United States (this issue is discussed in more detail below) (0473-12-10 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: No dry transfer system currently exists in the United States: The key to the NRC's long-term storage plan is the combination of ISFSIs and dry transfer system ("DTS") facilities. Currently, not every facility in the U.S. has an ISFSI. Indeed, as of November 2010, only 63 ISFSIs were licensed, at 57 sites. See NRC, Spent Fuel Storage in Pools and Dry Casks, Key Points and Questions & Answers, available at <http://www.nrc.gov/waste/spent-fuel-storage/faqs.html> (last accessed Nov. 18, 2013). More importantly, the DGEIS acknowledges that no DTS facility currently exists anywhere in the United States. DGEIS at 2-20. The Department of Energy has not asked the NRC to approve the license for a DTS facility (DGEIS at 2-21), and the NRC has thus not required licensees to construct DTS facilities.²² [footnote 22 text: See, e.g., *Northern States Power Company, Prairie Island Nuclear Generating Plant and Prairie Island Independent Spent Fuel Storage Installation, Issuance of Director's Decision under 10 C.F.R. 2.206*, 63 Fed.Reg. 8703, 8710 (Feb. 20, 1998) (rejecting petitioner's request to order licensee to build a DTS facility).] (0473-12-16 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: This is true despite NRC's acknowledgment in a 2010 Staff memorandum to the Commissioners that "[f]or most (if not all) reactor sites, the SFPs do not have sufficient capacity to hold all the spent fuel generated during 60 years of potential operation under 10 CFR Part 50, "Domestic Licensing of Production and Utilization Facilities." Memorandum, Robert Borchardt to Commissioners, COMSECY-10-0007 (June 15, 2010), ML101390413, at 2. Clearly, an alternative to spent fuel pool storage during the 60-year timeframe will be needed, and yet none is contemplated by the DGEIS. (0473-12-17 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: For both the at-reactor and away-from-reactor storage sites, the NRC assumes in the DGEIS that the construction, operation, and replacement of a DTS facility is necessary at some point to handle the transfer of fuel, and further assumes that ISFSI and DTS facilities would be replaced approximately once every 100 years. DGEIS at xxviii. The DGEIS contemplates first the construction of the ISFSI, and then at a later date, the DTS facility because it would not be needed right away (that is, it would not be constructed during short-term storage). DGEIS at 5-2, 6-8. The DGEIS contemplates that "[a] dry transfer system would be built at ISFSI sites (at-reactor or away-from reactor) in the long-term storage timeframe. A DTS would enable retrieval of spent fuel for inspection or repackaging without the need to return the spent fuel to a spent fuel pool." DGEIS at xxviii. NRC cannot rely on the hypothetical DTS option unless and until it is a reality in this country: until the technology has been proven and adopted, and until regulations requiring facilities to construct DTS facilities by a date certain have been promulgated. Otherwise, the DTS option is another effort by NRC to assume how nuclear waste storage might one day be handled to limit environmental review of present reality. The D.C. Circuit has rejected the NRC's attempts to do just that. See *New York v. NRC*, 681 F.3d 471 (D.C. Cir. 2012). In the absence of this information, the NRC cannot assume that all fuel will be removed from spent fuel pools or transferred from one dry cask to another at a certain time. Thus, the NRC must at a minimum conduct a spent fuel pool analysis, including severe accident or fire impacts, resulting from the storage of waste in pools for the long-term and indefinite time periods. (0473-12-18 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The DGEIS recognizes that each ISFSI and DTS facility must be licensed through separate licensing proceedings. DGEIS at 1-16. Yet, the DGEIS assumes that every ISFSI and DTS license application would be granted (id.), when in fact the federal government has not approved the technology itself and DOE has not asked NRC to license it. The DGEIS fails to consider options if DTS facilities never become a reality, if licenses are not granted to ISFSIs or DTS facilities at specific sites, or if these facilities are not an option at certain sites around the Nation. (0473-12-21 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Potential impacts assessed by unverified assumptions of deterioration of spent fuel pools, canisters, and casks, are as site-dependent as risks related to site-specific geology, geohydrology, and climate change with its attendant increase in severe weather events. (0553-14 [Wilshire, Howard])

Comment: Obvious problems of guesswork appear in use of existing environmental impact determinations of particular sites as "reference models for impact assessment;" for example the FEIS for the Skull Valley Utah ISFSI, which does not yet exist. The same difficulties apply to canister/cask environmental impact assessments, which are based on assumptions of reliability of a growing set of different designs, from which a "reference" model is selected which itself has no verified reliability. It is stated (p.2-12) that most dry cast storage systems fall into two main categories depending on how they are loaded. Loading is very differently handled for the two categories, posing different handling risks and different deterioration rates dependent on geographic location. Additional categories are implied by the statement that most dry casks fall into two categories. Other variants among the two categories are implied by the statements that "bare fuel casks...tend to be all metal construction" and in the canister-based system, "the canister is usually loaded while inside a transfer cask" and "transferred vertically into either a concrete or metal storage overpack or horizontally into a concrete storage module." So what "reference model is used for environmental impact assessment?" As no dry transfer systems exist in the U.S. (p. 2-19) and no design has been approved by the NRC, impact analysis is based on an arbitrarily selected reference DTS, which will be needed under the Long-Term and Indefinite storage scenarios. Performance can only be assumed and will be unverified, so no generic environmental impact assessment can be made. Reliance (p. 221) on the Transnuclear-EPRI DTS leads to an NRC conclusion "that some environmental impacts of the facility would be comparable to a DTS." (0553-15 [Wilshire, Howard])

Comment: A DTS would be built at each ISFSI location for fuel repackaging & (DTS) facilities would also be replaced every 100 years, along with casks and cask pads. Idaho National Lab report, INL/EXT-12-26218/FCRD-UFD-2012-000115 *Dry Transfer Systems for Used Nuclear Fuel*, B. Carlsen & M. Bard Raap, May 2012¹⁶ [footnote 16 text: <http://www.inl.gov/technicalpublications/Documents/5516346.pdf>] pointed out that a DTS is costly and if the Blue Ribbon's recommendation to develop one or more consolidated facilities were implemented in a timely fashion, the potential need for DTSs at ISFSIs would significantly decrease. There is no assurance that DTEs will ever be required and installed at ISFSIs--let alone replaced every 100 years.[TEXT BOX TITLED "2.3.1 At-Reactor ISFI Sites".] [TABLE 2-1 Summary of DTS Needs][Text Box and Table Submitted with Correspondence ML13354A021]. However, assuming that neither consolidated facilities nor permanent storage facilities are available, DTSs would be needed for age-related degradation of casks and unplanned events such as malicious attacks. Also a DTS would be needed if a site became available to repack assemblies in casks not suitable for transport. (0556-2-8 [Lampert, Mary])

Comment: Environmental impacts identified and specified by the Draft GEIS presume that there has been no degradation to waste fuel assemblies managed by ISFSI and DTS facilities. Because degradation will occur, however, environmental impacts must be reassessed in light of amount of waste that can reasonably be expected to experience degradation sufficient to affect DTS operations, for each degradation mode. (0608-18 [Crocker, George])

Comment: DTS-constructed during long-term time frame (160 years after operations cease): Section 2.1.4 discusses the dry transfer system (DTS) that could be constructed at or near ISFSI sites during the long-term and indefinite storage periods. According to the draft GEIS, the DTS would enable the retrieval of spent nuclear fuel for inspection or repackaging without the use of a spent fuel pool. Indeed, the concept of long-term or indefinite storage is dependent upon the ability to transfer the spent nuclear fuel, at some point in time, to new storage casks. We were therefore alarmed to read in the draft GEIS that while several DTS designs and related concepts have been put forward, there are "no dry transfer systems at US nuclear power plants sites today." Moreover, there is very little information about the "reference DTS" in the draft GEIS. Will all ISFSI sites use the same design? While there are general statements that the DTS would be licensed under 10 CFR Part 72 and would have to meet the radiological protection requirements of 10 CFR Part 20, we do not have any real licensing and operating experience with DTSs in which we can put our faith. Once again, we are asked to just trust the government. It is not clear whether dry casks will be required to be changed during the long-term or extended storage periods. We have no assurance that the casks in use can be used for 160 years or longer. As we understand from reviewing the NRC's May 2012 report, "Identification and Prioritization of the Technical Information Needs Affecting Potential Regulation of Extended Storage and Transportation of Spent Nuclear Fuel," there are a number of technical issues regarding extended dry cask storage that have yet to be resolved, such as the lack of monitoring or inspection capability for cladding, fuel cladding interactions, fuel assembly hardware and damaged fuel cans, fuel baskets, stainless steel canister, stainless steel canister, stainless steel canister and steel/cast iron and seals, polymer seals, neutron absorbers, neutron shielding and other components. Given that there seems to be no current way of internally monitoring a cask, we question whether or how a licensee can or will determine that a cask is no longer technically sound. Will the NRC make a determination, during Part 72 license renewals, that the dry casks in use are technically sound for the proposed re-licensing period? What is the expected operational life of a DTS? We have heard that the DTS could be a mobile facility, yet the DTS referenced in the draft GEIS appears to be a fixed facility. (0619-1-16 [Mahowald, Philip R.])

Comment: It is not clear which guidance document the NRC will use to evaluate DTS license applications to ensure that the requirements of NEPA are met. We remain very skeptical about the construction and operation of a facility that has never been built, but is an integral aspect of long-term and indefinite spent nuclear fuel storage. Greater detail regarding the licensing and other regulatory requirements of the DTS must be clarified and included in the final GEIS, and not just included as a reference for the reader to locate. The final GEIS should include a discussion regarding the minimum level of institutional controls that should be in place at each ISFSI and DTS during long-term and indefinite storage. There is no information regarding the skill level of workers expected to unload and re-load spent nuclear fuel that has been stored for dry casks for 100-150 years. Our Tribe is one of the closest communities in the nation to an ISFSI, and we expect assurances that environmental impacts will be thoroughly evaluated well before it is time to construct such a facility. (0619-1-17 [Mahowald, Philip R.])

Comment: It is with these questions in mind that we are reminded of the statement in the NRC's 1992 EA for the Prairie Island ISFSI: the TN-40 dry casks are designed to provide storage for spent nuclear fuel for at least 25 years. We remain very skeptical. It appears that the

technical capabilities of the dry casks in use at the Prairie Island ISFSI keep expanding and improving as time progresses and the prospect of an available repository diminishes. (0619-1-23 [Mahowald, Philip R.])

Comment: [T]he results of that research combined with results of intervening and ongoing policy, legislative, and legal activities will determine how best to carry out the acquisition, operation, and decommissioning of Dry Transfer Systems and/or the casks or ISFSI "pads" themselves. While the assumption that these are potential and envisioned steps for the period of storage that would provide continuing adequate protection of the public is understandable, much needs to be known about research results and the evolving policy and legal environment before such measures are proposed as NRC requirements. (0637-7 [Norton, Wayne])

Comment: Additionally, the draft GEIS "assumes that the licensee uses a DTS [dry transfer system] during long-term and indefinite storage timeframes to move the spent fuel to a new dry cask every 100 years." (1-14.) However, as the draft GEIS notes at 2-19, "there are no dry transfer systems (DTSS) at U.S. nuclear power plant sites today." In the same way that the Court held that it is unreasonable to assume the existence of a permanent repository for purpose of NEPA analysis on the waste confidence rule,⁹ [footnote 9 text: New York v. NRC, 681 F.3d 471 (D.C. Cir. 2012).] it is unreasonable to assume DTS exists for the purpose of analyzing impacts environmental impacts of long term storage. If nothing else, there should be analysis of impacts that does not assume the existence of DTS. (0669-11 [Walter, Joan])

Comment: Page 2-19. Discussion of Dry Transfer System[.] NRDC Comment[:] One of the fundamental linchpins of the conclusion of "small" environmental impacts in this Draft GEIS is reliance on institutional controls in perpetuity, and in particular, on the robust viability of the Dry Transfer System (DTS) discussed here. The DTS which does not, as far as NRDC is aware exist in actual form at any commercial operating reactor in this country. Further, there is not a licensed prototype in the country nor has NRC conducted any analysis to establish the ability of the DTS to isolate waste or protect public health in the event of any loss of institutional controls. NRDC has no doubt such a DTS can be constructed but we have no belief it will necessarily isolate the waste in perpetuity and to rely on such an assumption is arbitrary and capricious. (0706-3-23 [Fettus, Geoffrey])

Comment: Under section 2.1.4, pages 2-19 -2-21, the Draft GEIS addresses a DTS. The Draft GEIS should be modified to include a statement that a DTS is going to be necessary based upon the assumptions within the Draft GEIS. Not only is it going to be necessary based on these assumptions, but it will be required once interim storage or permanent disposal becomes an option. None of the casks currently used for storage are approved for transport and therefore the concept of a DTS is necessary. The Draft GEIS should also reference that one may be needed earlier if there is an incident involving a breach of the storage system. What happens in the interim when the DTS is being constructed? Is there a spent fuel pool or other containment facility? This needs to be addressed. (0783-2-17 [Harlan, Thomas])

Comment: Page 1-15, lines 16 and 17, reference is made to a dry transfer system and the construction of the same to facilitate spent fuel transfer and handling. Like the assumption of the storage facilities, there is no empirical evidence whatsoever with respect to the construction or operation of a dry transfer system (the "DTS"). The industry has no experience in building a DTS or, more importantly, transferring spent fuel or fuel assemblies from one cask to another. Will the spent fuel assemblies be intact enough to transfer in 100 years? The only experience to date does not support this supposition. The use of a DTS and the acceptability of the casks for the same must be more fully developed and cannot simply be an assumption. (0783-2-9 [Harlan, Thomas])

Comment: p. 4-76 to 4-Design Basis Events in Dry Cask Storage Systems. Comment: Potential impacts assessed by unverified assumptions of deterioration of spent fuel pools, canisters, and casks, are as site-dependent as risks related to site-specific geology, geohydrology, and climate change with its attendant increase in severe weather events. Obvious problems of guesswork appear in use of existing environmental impact determinations of particular sites as "reference models for impact assessment;" for example the FEIS for the Skull Valley Utah ISFSI, which does not yet exist. The same difficulties apply to canister/cask environmental impact assessments, which are based on assumptions of reliability of a growing set of different designs, from which a "reference" model is selected which itself has no verified reliability. It is stated (p.2-12) that most dry cast storage systems fall into two main categories depending on how they are loaded. Loading is very differently handled for the two categories, posing different handling risks and different deterioration rates dependent on geographic location. Additional categories are implied by the statement that most dry casks fall into two categories. Other variants among the two categories are implied by the statements that "bare fuel casks...tend to be all metal construction" and in the canister-based system, "the canister is usually loaded while inside a transfer cask" and "transferred vertically into either a concrete or metal storage overpack or horizontally into a concrete storage module." So what "reference model is used for environmental impact assessment?" As no dry transfer systems exist in the U.S. (p. 2-19) and no design has been approved by the NRC, impact analysis is based on an arbitrarily selected reference DTS, which will be needed under the Long-Term and Indefinite storage scenarios. Performance can only be assumed and will be unverified, so no generic environmental impact assessment can be made. Reliance (p. 2-21) on the Transnuclear-EPRI DTS leads to an NRC conclusion "that some environmental impacts of the facility would be comparable to a DTS." So, how many elements of comparability satisfy a generic assessment? (0805-14 [Wilshire, Howard])

Comment: Further, the NRC assures the public that this radioactive waste can be transferred into new casks every 100 years or less, yet no dry storage cask has ever been unloaded, and no safe, unloading procedure exists as evidenced by the 1993 Palisades situation when it was discovered that a VSC-24 cask had weld flaws. Consumers Energy "voluntary" promised to unload the irradiated fuel in the cask and put it back into the storage pool, but insurmountable technical difficulties prevented that from ever happening. Placing 400° F fuel back into 100° F pool water would result in radioactive steam hazardous to workers, and would thermally shock the fuel threatening to further degrade it. There was a short 50 hour window to cut open the welded inner cannister and unload the cask before the fuel would begin to overheat. So the cask remained fully loaded and dozens more fully loaded VSC-24 casks of questionable integrity sit on the shores of Lake Michigan. The NRC has failed to deal with the very real possibility that the irradiated fuel will so degrade with age that transfer operations cannot be accomplished safely. High burn-up fuel poses additional risk because it has spent more time in the reactor core making it significantly more radioactive and thermally hot. (0819-14 [Kline, Connie])

Comment: Experience further suggests that the installation of a DTS at each and every ISFSI location is also not likely to be necessary. If repackaging does become necessary, it is more likely that industry would consider bringing in portable systems for many locations or installing specially designed over-packs to prevent the need to open the existing canister. These activities could be accomplished with existing, proven technology and operational procedures. Portable transfer systems could be staged in central locations much like industry is currently doing with FLEX equipment as a preparedness measure for extremely severe events (earthquakes, floods, etc.) that might affect operating reactors. Furthermore, it is likely that advances in technology

over the centuries would provide for improved repackaging methods that would have even smaller impacts. (0827-2-1 [Ginsberg, Ellen])

Comment: On page xxviii, you list assumptions, and you say that the GEIS includes the assumption that "analyses in the draft GEIS are based on current technology and regulations". This statement should not be an assumption, and it is not correct. 1. The Dry Transfer Systems (DTS) are only conceptual, have never been built, and are NOT "current technology". Thus, the DGEIS is not based on current technology. 2. This statement should NOT be an assumption. Either the analyses ARE or ARE NOT based on current technology and regulations. Since the draft GEIS is your product, you should be able to state whether it is or is not based on current technology. We assert that it is not. But it is just simply wrong to assume this, that is pretty ridiculous. It would be like saying that we assume that this document has 100 pages in it. You don't need to assume if it is your own document. So this statement should be DELETED from the assumptions section, and placed in another section that makes statements of FACT. (0836-16 [Davis, Anonymous])

Comment: You rely on the existence on a Dry Transfer System (DTS) (section 2.1.4, Page 2-19) but these have never been built, are only a concept at this point, and may prove to be entirely unworkable. You can't rely on technology that does not exist as the single option! Instead, you should require either a wet-transfer system (such as a fuel pool) OR dry transfer system (that is still a figment of the designer's imagination) at any ISFSI site. Indeed, it may be easier for the ISFSI's co-located at an existing plant where a Fuel Pool already exists, to continue to utilize the fuel pool as long as practicable as a wet transfer system. The DTS envisioned cannot deal with casks and canisters that have been compromised and have significantly diverged from specifications. What happens when the fuel assemblies degrade for some reason to the point where they cannot be pulled out of the canister or cask? What if we discover the fuel assemblies have all experienced extreme embrittlement to the point that many have started to decompose? What happens if a canister starts to leak and we need to immerse it in a fuel pool to stop the leakage? From my reading, it may take 11 days or more to deal with a problem like this, with radioactivity released to the environment all the while. THIS IS UNACCEPTABLE. (0836-41 [Davis, Anonymous])

Comment: The details regarding how radiation releases will not occur by the DTS when the casks/canisters are removed from the DTS is not clear. If there is a severe problem with one of the canisters, such as a leak or accidental criticality event, then it may be necessary to immerse the cask in a fuel pool for safety until it can be stabilized. The fact that you are relying on untried and conceptual technology is yet another example of an "issue that requires resolution" that you claim does not exist. Sure, you can try to quantify releases from a conceptual DTS system, but this is yet another example of a wild-ass guess. The problem is not when the system works as it is supposed to, if it works at all, but when things go wrong. What happens if the DTS fails? is it contained in a containment building that will help to contain the release of radiation? Not addressed. (0836-42 [Davis, Anonymous])

Comment: Page 2-21 Line 20-21 "This draft GEIS considers the environmental impacts of constructing a reference DTS to provide a complete picture of the environmental impacts of continued storage." What a joke! This is only a CONCEPTUAL design of a DTS. No such thing exists. It has never been made, and the concept that you are providing a "complete picture" by analyzing a conceptual DTS as if it was a real thing, only makes us believe that you are so used to deceiving yourself that you don't even realize it when you are talking about something that does not even exist, as if it were a real thing and creates a real picture. You can't create a reference design based on a concept. (0836-43 [Davis, Anonymous])

Comment: Page 2-28, Line 4-5, you say the NRC assumes a DTS "or its equivalent" would be used to transfer fuel. What is "its equivalent" -- do you mean, as we assert, that a fuel pool should be described as THE option unless there is such a thing as a DTS that actually works? And, it may be necessary, we believe, and prudent, to maintain a (small) fuel pool as an emergency backup even if a DTS can work in some situations. (0836-45 [Davis, Anonymous])

Comment: The use of the DTS, which is all conceptual and speculative, as a key component that allows NWOs to continue to operate for 100s of years a severe defect, as these systems do not exist, and there is no track record to show that they work safely. Until these actually exist, the plan put forward MUST include a transfer system that we know will work, i.e. the wet transfer system. In other words, the fuel pools should be emptied but should not be decommissioned but remain available for an emergency. (0836-66 [Davis, Anonymous])

Comment: *A DTS will be built at each ISFSI location during long-term storage timeframe to facilitate spent fuel transfer and handling. The NRC assumes a 100-year replacement cycle for spent fuel canisters and casks. This assumption is consistent with assumptions made in the Yucca Mountain Final EIS (DOE 2008). The 100-year replacement cycle also assumes replacement of the ISFSI facility and DTS. Based on currently available information, the 100-year replacement cycle provides a reasonably conservative assumption for a storage facility that would require replacement at a future point in time. However, this assumption does not mean that dry cask storage systems and facilities need to be replaced every 100 years to maintain safe storage.* The NRC here assumes that there will be money, equipment, available expertise and an ISFSI capable of handling the waste. In addition there are no operating DTS facilities in the US and no DTS facilities of the size and complexity needed for the task that would be created by having to move 60 years of spent fuel from one group of dry casks to another group of dry casks. In addition, the DGEIS does not look at the environmental impacts that would be associated with the construction of a DTS at each reactor site or the environmental impacts that will be caused by the process of moving the wastes from the dry casks. (0867-2-10 [Griffin, William])

Comment: Additionally, the radiological risks of packaging and repackaging the materials will vary by fuel type, age, and volume. Degradation to the fuel assemblies may also adversely impact the transfer. A generic assessment may not be appropriate for these types of variability. (0867-2-20 [Griffin, William])

Comment: There is no DTS facility currently in operation in the U.S. Overseas DTS facilities are small in size and are custom designed for research reactors. The EPRI did a 2010 report (updated in 2012) that estimated the costs for operation of such systems and the early withdrawal of fuel from spent fuel pools. The report concluded there would be significant radiological doses and costs between \$3.5 and \$3.9 billion dollars. The NRC DGEIS assumes that these operations will be indefinitely feasible. (0867-2-7 [Griffin, William])

Comment: One of the underpinning assumptions of the DGEIS is that it will be possible to readily move the SNF from one storage canister system to another e.g. from a NUHOMS to a NAC type of canister. This assumption is made despite the fact that there is no system of this type currently operating in the US. There are small systems currently used for research reactors (NAC). There is no DTS currently working at any US nuclear power plant. A DTS system of the type and size envisaged by the DGEIS would require additional research and development, which would in turn require additional funding. Construction and operation of these facilities will create substantial environmental impacts, none of which are considered in the DGEIS. These facilities will need to be designed to withstand all the dangers that current reactors are

supposed to withstand, including natural events like floods and earthquakes and malevolent acts. The costs for such facilities can be substantial but the DGEIS gives that concern no consideration. The absence of the DTS raises the larger issue about how the NRC drew its conclusions about impacts. What is the basis for the NRC's conclusions about the risks and environmental impacts of its alternatives, if those conclusions are based on assumptions about the safe operation of equipment that does not exist? (0867-3-12 [Griffin, William])

Comment: According to some estimates, 10% of the inventory of SNF is damaged to one extent or another. The Blue Ribbon Commission on America's Nuclear Future received testimony about the seriousness of the damaged fuel problem. A study prepared by Bechtel SAIC (2005) concluded that for the purposes of designing a facility to handle the SNF it was necessary to assume that: a. Failed fuel quantities and types of damage arriving at the repository include: approximately 4 percent of he1 assemblies received are expected to have an average of 2.2 failed he1 rods per assembly; b. 90 percent of the failed fuel is estimated to be known and identified prior to shipment to the repository; 10 percent of the failed fuel is expected to have pinhole leaks and hairline cracks that will not be identified prior to shipment. The DGEIS mentions damaged fuel as a potential problem only twice (p. 471, p. 478). The DGEIS does not address the safety or risk implications of this damaged fuel. The Generic assessment does not include any severely damaged fuel and the long-term degradation of the damaged fuel containers is not considered. (0867-3-13 [Griffin, William])

Comment: Indeed, it should be noted in this context, that no spent fuel bundle, damaged or not, has ever been transferred from one dry cask to another. Further, while the Draft GEIS postulates a Dry Transfer System for fuel inspection, repackaging and transfer, such a facility has never been built in the United States. (0898-2-16 [Curran, Diane] [Makhijani, Arjun])

Comment: And as discussed in paragraph 4.27, the NRC even refuses to say how it would handle and repackage failed fuel. This makes the lack of discussion of the impacts of the transfer of failed spent fuel bundles even more problematic since the NRC lacks sufficient empirical basis for estimating the probabilities and consequences of the spread of radioactivity during transfers in the normal case. (0898-2-19 [Curran, Diane] [Makhijani, Arjun])

Comment: Additional details describing the projected, long-term, required aging management program using the DTS and its impact must be included in the GEIS. The program must address potential, long-term concerns that may result from long-term storage. (0913-10 [Bevill, Bernard])

Comment: While it is understood that much of the cited work that has formed the basis for the GEIS remains valid, the question must be asked as to whether the science, engineering, and operational experience (if any) has changed or is anticipated to change in the near-term that may possibly cast uncertainty on this basis. As an example, it is understood for purposes of this analysis the NRC "relies on" the facility description of a DTS (DOE 1996) that was reviewed and "the DTS concept" was found to have "merit" by the NRC (NRC 2000a), but was never licensed for operations. Also, some impact assessments contained in the GEIS were taken from the INEEL EIS (NRC 2004b), a facility that was eventually licensed by the NRC, but was never constructed, and thus no operational experience was available. It would seem that design engineering improvements or revisions would have certainly been made over time that may have revised the impact evaluation. (0913-5 [Bevill, Bernard])

Comment: Will the aging management inspections and required corrective actions that are currently performed in Spent Fuel Pools also be performed at on-site Dry Transfer Systems? (0913-8 [Bevill, Bernard])

Comment: Dry Transfer Systems Facility (DTS) Availability[:] For its "indefinite storage" scenario, the draft GEIS assumes that DTS facilities will be licensed, built, and replaced periodically on an as-needed basis (Sections 2.1.4 and 2.2.2. 1). In support of this assumption, the draft GEIS refers to the submission by the Department of Energy (DOE) to the NRC for the review of a topical safety analysis report (TSAR) on the Transnuclear-EPRI DTS design, and the NRC 's issuance of a license in 2004 to DOE for the Proposed Idaho Spent Fuel Facility. However, we are concerned that the applicability of these precedents may be limited, as neither of these proposed facilities has as yet been constructed. We also note that these facilities were conceptually less complex than the DTS envisioned in the draft GEIS. *Recommendation:* Acknowledge that these facilities have not yet been constructed and discuss how that may affect any assumptions. Provide a discussion that addresses the technical and regulatory challenges that have hindered the development of such systems in the past, as well as the potential for these challenges to be encountered in future efforts to construct and license more sophisticated facilities. Provide additional discussion of the past development and capabilities of DTS facilities. Include the following information: (i) the current status of these facilities, (ii) whether these facilities were licensed to retrieve, inspect, and repackage the fuel after prolonged storage as proposed for DTSS, (iii) whether high-burnup commercial fuel was licensed for storage, (iv) the reasons why facilities have not been constructed, and (v) whether these reasons would prevent licensing, construction and operation of similar facilities in the future. (0915-1 [Bromm, Susan E.])

Comment: Fuel Transfer/Repackaging[:] The feasibility of safe fuel transfers after long-term storage is uncertain. For example, when "new" replacement DTS facilities are built in the future, based on the degree of fuel and storage system degradation, fuel inspections may determine that it would be safer to leave some fuel in the "old" casks rather than transferring it to a "new" receiving cask. This scenario may be more likely if fuel must be transferred more than once in intervals of 100 years. Another scenario is that after an inspection, it may be determined that it would be unsafe to transfer assemblies to a new cask. These scenarios would essentially have the same consequences as not having a DTS facility available, with the additional potential for damage to the existing assembly (and subsequent releases of radionuclides) as it is being inspected. (0915-13 [Bromm, Susan E.])

Comment: *Recommendation:* Provide an additional discussion of circumstances that would affect the feasibility of repackaging in the DTS. Include fuel, cladding, and storage system degradation over long-term storage, and the likelihood of encountering such conditions. Consider the consequences of a "leave as is" scenario. Provide information on the frequency of assembly misloads based on industry data. Based on this information, provide an evaluation on how many assemblies will be impacted during long-term storage and what the radiological consequences would be during fuel storage and transfers. (0915-15 [Bromm, Susan E.])

Comment: Fuel Inspections[:] Page 2-21 of the draft GEIS states that " ...For the purposes of analysis in this draft GEIS, the NRC relies primarily on the facility description of the Transnuclear-EPRI DTS ..." However, it is EPA's understanding that the proposed Transnuclear-EPRI DTS did not have the capability of fuel inspection and remediation. Fuel inspection and remediation capabilities are critical for the assumed DTS. To support this assumption, the GEIS references pages 17 and 24 of the Carlsen (2012) report. Page 17 states that " ... The two primary DTS functions are to retrieve fuel for inspection and to transfer fuels into another package ..." Page 24 states " ...repackaging and remediation capability should be integrated into the design of future facilities." In addition, the draft GEIS provides a theoretical description of a conceptual DTS but not for an operating DTS. These conceptual descriptions do not include information on how fuel inspections will be performed or the potential impacts. Fuel

inspections would likely require cutting canisters open and repackaging the fuel in new canisters. In addition, it is our understanding that neither the license to Private Fuel Storage LLC (PFS) or to DOE for the Proposed Idaho Spent Fuel Facility included authorization to cut canisters open and inspect fuel for degradation and damages. It is also our understanding that although PFS submitted a request to the NRC to terminate its ISFSI license, DOE's facility was not licensed to handle commercial fuel that is used in commercial reactors. *Recommendation:* Provide information on how fuel inspections and remediation will be implemented at the assumed DTS facility in Section 2.1.4. Include potential radiological consequences of these operations. In addition, provide information on the potential public health and environmental impacts of the proposed fuel inspection, repackaging, and remediation at the DTS. (0915-5 [Bromm, Susan E.]

Comment: The draft GEIS relies on the fuel inspection performed during repackaging. While it may be inferred that inspections will take place within the DTS ("without the need to return the spent fuel to a pool"), this is not stated directly and the details on fuel inspections are not provided. In addition, information is not provided on the remediation actions if the fuel fails the inspection. *Recommendation:* Provide information on the fuel inspections during repackaging. Specifically, clarify whether the inspection will be performed in the pool under water or in inert atmosphere, or in air. Also provide information on remediation actions if the fuel fails the inspection. Where fuel inspections will need to be performed at a DTS either underwater or in an inert atmosphere, provide a discussion on the practicality and current regulations that would support licensing, construction, and operation of such an additional pool facility at DTSs. If fuel inspections will be performed in air, provide a discussion on potential fuel oxidation during inspections. (0915-6 [Bromm, Susan E.]

Comment: Regulation Requirements[:] The draft GEIS states that the analyses are based on current technology and regulations, and assume that a DTS will be licensed, constructed, operated, and completely replaced on a 100-year cycle. However, it is not clear which current regulations address the DTS's licensing, construction, operation, and 100-year cycle replacement. The stated capacity of the assumed DTS (to handle assembly transfers at an ISFSI licensed to store 40,000 MTU) is large, yet the draft GEIS does not discuss the practicality and feasibility of licensing, constructing, operating, and periodic replacements of a DTS at this scale. *Recommendation:* Provide information on the current regulations that address the construction, operation, and periodic replacement of DTSs with a stated capacity to serve an ISFSI storing up to 40,000 MTU and fuel inspection, remediation, and repackaging capabilities. Provide a discussion of the practicality and feasibility of constructing, operating, and periodically replacing DTSs at existing and future ISFSs. (0915-8 [Bromm, Susan E.]

Comment: Re: Page 1-14's discussion of Dry Transfer Systems (DTS), has this ever been done anywhere? At such a scale? How much will that cost at each site? NRC describes a prototype DTS that was actually abandoned before completion at Idaho National Lab. How can NRC assume all will go swimmingly with DTSs, till the end of time, when the prototype DTS, at INL, did not even go well? Given the power of fanciful assumptions, why did NRC not assume replacement pools at reactor sites? Because pools would cost more than DTSs? But NRC hasn't identified how much DTSs would cost, nor where the money would come from. What are the risks with DTSs? Although NRC has described a stuck fuel assembly during a DTS operation, that could remain stuck for two weeks, it assumes the incident would be resolved (without explaining how), with no significant impacts. NRC has largely, again, assumed safety, rather than analyzing risks. In this way, the DGEIS is meaningless, and violates NEPA, as well as the Atomic Energy Act. (0919-3-1 [Kamps, Kevin])

Comment: Steve Frishman, a consultant to the State of Nevada Agency for Nuclear Projects, has shared the story of a Yucca dump public meeting at which DOE officials presented ideas for the use of a large-scale pool for irradiated nuclear fuel storage, and transfer into disposal containers, at the Yucca site. After Mr. Frishman presented a number of concerns about pool storage during the discussion period, the DOE moderator called for a break in the meeting. When the meeting resumed, the DOE officials announced that the proposed pool, previously under discussion, was no longer under consideration. Dry transfer would not be the approach followed at Yucca. Cancelled, just like that, during a 15 minute coffee break!! I tell this story only to point out that a comprehensive DGEIS, which NRC should have carried out here, should have included a transparent examination of various options going forward. Pools? DTSs? Some combination thereof? No such comparisons have been carried out. No explanation has been given as to why DTSs were assumed, as opposed to pools. Given the large risks associated with irradiated nuclear fuel, NRC should have carried out a particularly "hard look" under NEPA at the pros and cons of various options, but has not done so. (0919-4-10 [Kamps, Kevin])

Comment: At Page 2-28, lines 20 and following, NRC states "the receiving cask lid and outer and inner canister lids are removed. Finally, the receiving cask is moved into the lower access area and mated to the transfer confinement area...", and so on. NRC makes transfer of irradiated nuclear fuel sound so smooth and simple. Reality will be different, especially considering fuel degradation with age. Irradiated nuclear fuel could simply fall apart. What can be done then? Build a sarcophagus over the DTS? What about criticality risks, if fuel debris falls to the bottom of DTS, and a later flood were to inundate the inside of the structure? What about the radiological leakage risks from such a scenario, in addition to the criticality risks? NRC has simply "assumed safety" rather than analyze such potential, and even likely (over time, given age related degradation of irradiated nuclear fuel), risks. Besides age related degradation, there is irradiated fuel that has already failed, or begun to fail, in the present day, as due to design defects, fabrication mistakes, operational damage, etc. These risks may not be off into the future - they have already begun to unfold in the present. (0919-4-11 [Kamps, Kevin])

Comment: Page 2-29, line 3: the NRC's mention of "effluent radiation monitoring" is a clear admission that there will be radiological releases from the DTSs over time. (0919-4-12 [Kamps, Kevin])

Comment: Re: Page 2-28, Section 2.2.2.1, Construction and Operation of a DTS [Dry Transfer System], the question is begged, why has NRC assumed DTSs, instead of newly constructed wet pools for transfer of irradiated nuclear fuel? For example, a GAO study published in 2009, comparing the costs of the Yucca dump, to centralized interim storage, to long-term on-site storage, did consider the potential for installing new pools (after the old ones had been dismantled during decommissioning) for the transfer of irradiated nuclear fuel from old dry casks to new ones as containers degraded with age. However, building new pools at each site would be staggeringly expensive, measured in the tens or hundreds of millions of dollars per pool. (0919-4-9 [Kamps, Kevin])

Comment: I also do not share your confidence about safe, sound, and smooth transfers between dry casks as the old ones wear out over time. In fact, as documented by Dr. Arjun Makhijani of IEER in his expert witness comments on behalf of an environmental coalition, including Beyond Nuclear, not a single cask to cask transfer of irradiated nuclear fuel has yet taken place in the U.S. (0929-2 [Kamps, Kevin])

Comment: On page xxviii, you list assumptions, and you say that the GEIS includes the assumption that "analyses in the draft GEIS are based on current technology and regulations".

This statement should not be an assumption, and it is not correct. 1. The Dry Transfer Systems (DTS) are only conceptual, have never been built, and are NOT "current technology". Thus, the DGEIS is not based on current technology. 2. This statement should NOT be an assumption. Either the analyses ARE or ARE NOT based on current technology and regulations. Since the draft GEIS is your product, you should be able to state whether it is or is not based on current technology. We assert that it is not. But it is just simply wrong to assume this, that is pretty ridiculous. It would be like saying that we assume that this document has 100 pages in it. You don't need to assume if it is your own document. So this statement should be DELETED from the assumptions section, and placed in another section that makes statements of FACT. (0930-1-9 [Lutz, Ray])

Comment: You rely on the existence on a Dry Transfer System (DTS) (section 2.1.4, Page 2-19) but these have never been built, are only a concept at this point, and may prove to be entirely unworkable. You can't rely on technology that does not exist as the single option. Instead, you should require either a wet-transfer system (such as a fuel pool) OR dry transfer system (that is still a figment of the designer's imagination) at any ISFSI site. Indeed, it may be easier for the ISFSI's co-located at an existing plant where a Fuel Pool already exists, to continue to utilize the fuel pool as long as practicable as a wet transfer system. The DTS envisioned cannot deal with casks and canisters that have been compromised and have significantly diverged from specifications. What happens when the fuel assemblies degrade for some reason to the point where they cannot be pulled out of the canister or cask? What if we discover the fuel assemblies have all experienced extreme embrittlement to the point that many have started to decompose? What happens if a canister starts to leak and we need to immerse it in a fuel pool to stop the leakage? From my reading, it may take 11 days or more to deal with a problem like this, with radioactivity released to the environment all the while. THIS IS UNACCEPTABLE. (0930-2-15 [Lutz, Ray])

Comment: The details regarding how radiation releases will not occur by the DTS when the casks/canisters are removed from the DTS is not clear. If there is a severe problem with one of the canisters, such as a leak or accidental criticality event, then it may be necessary to immerse the cask in a fuel pool for safety until it can be stabilized. The fact that you are relying on untried and conceptual technology is yet another example of an "issue that requires resolution" that you claim does not exist. Sure, you can try to quantify releases from a conceptual DTS system, but this is yet another example of a wild-ass guess. The problem is not when the system works as it is supposed to, if it works at all, but when things go wrong. What happens if the DTS fails? is it contained in a containment building that will help to contain the release of radiation? Not addressed. (0930-2-16 [Lutz, Ray])

Comment: Page 2-21 Line 20-21 "This draft GEIS considers the environmental impacts of constructing a reference DTS to provide a complete picture of the environmental impacts of continued storage." What a joke. This is only a CONCEPTUAL design of a DTS. No such thing exists. It has never been made, and the concept that you are providing a "complete picture" by analyzing a conceptual DTS as if it was a real thing, only makes us believe that you are so used to deceiving yourself that you don't even realize it when you are talking about something that does not even exist, as if it were a real thing and creates a real picture. You can't create a reference design based on a concept. (0930-2-17 [Lutz, Ray])

Comment: Page 2-28, Line 4-5, you say the NRC assumes a DTS "or its equivalent" would be used to transfer fuel. What is "its equivalent" -- do you mean, as we assert, that a fuel pool should be described as THE option unless there is such a thing as a DTS that actually works?

And, it may be necessary, we believe, and prudent, to maintain a (small) fuel pool as an emergency backup even if a DTS can work in some situations. (0930-2-19 [Lutz, Ray])

Comment: The use of the DTS, which is all conceptual and speculative, as a key component that allows NWOs to continue to operate for 100s of years a severe defect, as these systems do not exist, and there is no track record to show that they work safely. Until these actually exist, the plan put forward MUST include a transfer system that we know will work, i.e. the wet transfer system. In other words, the fuel pools should be emptied but should not be decommissioned but remain available for an emergency. (0930-3-18 [Lutz, Ray])

18. Comments Concerning GEIS Assumptions – Timeframes

Comment: The only legitimate reply to the courts should have been that NRC has no confidence that waste repositories will ever be available, let alone that NRC will even exist within these long time intervals. The DEIS, like the so called Blue Ribbon Commission on Nuclear Futures, simply puts off to a distant future any resolve to solve the problems of spent fuel. It is ludicrous to extend the definition of short term to be 60 years beyond the closure of nuclear plant operation. (0059-10 [Andrews, Richard])

Comment: Now, I only had maybe an hour and a half to review this document so I spot checked. You know, nobody's paying me to do this, nobody gave me talking points. And I hadn't seen the list of questions that they really wanted to answered. But it turns out within an hour and a half I'd spotted one of them anyway. And that's the issue of indefinite storage. And one of the things people haven't mentioned is the timeframe for indefinite storage is a million years according to the EPA, just to put that into perspective. So I obviously don't believe the document adequately addresses the environmental impacts of indefinite time storage. And, for example, Section ES.9 of the executive summary states that the indefinite timeframe is highly unlikely. This would appear to reflect a myopic and naive assumption that a repository will become available. That's in the face of mounting evidence to the contrary. We must face reality. The Yucca Mountain team consisted of the best people we have and they had unlimited resources, yet they failed. They didn't fail due to incompetent management nor did they fail for lack of resources, they failed because they were given an impossible task. (0112-20-1 [Robinson, Herb])

Comment: The document doesn't properly address the environmental impact of the indefinite timeframe because that is an impossible task. We should be using proper engineering methodology. And we better be talking engineering here, not experimental science projects. Proper engineering methodology uses proven technology to achieve a practical result. There is no proven technology to displace something for a million years. Not for 100,000 years, not even for 10,000 years. The longest lived man-made structures I know of are the pyramids. They've been around for 5,000 years and they failed at their intended purpose in prehistoric times. (0112-20-2 [Robinson, Herb])

Comment: The NRC also assumed with no factual basis that all nuclear waste would be gone from spent fuel pools by 60 years after the licensed life a nuclear power plant. (0163-1-5 [Schneiderman, Eric])

Comment: [S]o you're actually considering 200 years in the future and you're making this -- the assumption that you understand all the possible developments of climate change, of seismic activity, of terrorist threat, of the cyber issue alone, which has emerged as a major current threat, is not only just to Indian Point but a threat to the grid, which in turn affects Indian Point. (0163-12-2 [Lee, Michelle])

Comment: So when we look at the Proposed Rule here and we're talking about 60 years, or 160 years, or indefinitely, I think that the most important thing to do is to realize that we cannot look that far ahead, so that we have to come up with a solution that will enable our country to move forward. (0163-16-7 [Wolf, Peter])

Comment: The second reason, the NRC relied on a number of assumptions to write this EIS that RiverKeeper believes are completely divorced from reality. And I'll go through these very quickly. I know I don't have a lot of time. The first one is that as Ms. Dean said, all the waste will be out of the spent fuel pools 60 years after the plan is permanently shut down. I could tell you I've never heard Entergy commit to removing all the waste from the pools and there's no sign that they will do so in those 60 years. And there's also regulation with the NRC that would allow them to ask for an exemption from this requirement, so there's a way out of this. (0163-2-4 [Musegaas, Philip])

Comment: I believe that the general response here tonight has been enough to show you that we are not confident at all, so where does this confidence come from that you think you can handle nuclear radioactive waste for 240,000 years? I have a grandson who is going to be four years old this week, and the idea of 160 years, I mean that's going to be even after his lifetime. So let me see, that's his child, that's his grandchildren, his -- I can't think. (0163-24-2 [Allen, Judy])

Comment: When I contemplate 250,000 years, I just ask everyone to think a moment who could even imagine that span of time, and that's the amount of time that this, what is referred to as "Poison Fire" by Joanna Macy, who has thought about these issues a lot, has called it. And how can we conceive words like "always, certainty, leak-proof, safe, rigorously inspected, safely and reliably, and confidence." (0163-39-1 [Sack, Emily])

Comment: [T]here is a stated rush to complete this within a two year period. This is probably the largest decision this country has to make for long term throughout the nation, and to rush it, when we know that after 60 years of nuclear fission we don't know how to handle the waste, is ridiculous. And this idea that there's a possibility, there's magical thinking that there's going to be -- in 60 years there's going to be -- we're going to figure it out makes absolutely no sense. And that's what this GEIS relies upon. (0163-7-3 [Shapiro, Susan])

Comment: [T]he changing of the waist barrels every 100 years for ever just isn't realistic. (0200-3 [Individual, Anonymous])

Comment: I am going to begin my comments by quoting the executive summary at the beginning of the document: "The Court identified deficiencies in the 2010 Waste Confidence rule and supporting decision related to the NRC's environmental analysis of spent fuel pool fires and leaks, and the environmental impacts should a repository not become available." Let me repeat the last part of that sentence: "and the environmental impacts should a repository not become available." In the document, this is called the indefinite timeframe. Nowhere in the document does it mention that the indefinite time frame is one million years (according to the EPA). This document doesn't adequately address the environmental impacts of the indefinite time frame. (0208-1 [Robinson, Herb])

Comment: Section ES.9 of the executive summary states that the indefinitely timeframe is "highly unlikely." This would appear to reflect a myopic and naive assumption that a repository will become available in the face of mounting evidence to the contrary. Let's face reality. The Yucca Mountain team consisted of the best people we have and they had essentially unlimited resources. Yet, they failed. They didn't fail due to incompetent management. Nor did they fail for lack of resources. They failed because they were given an impossible task. (0208-2 [Robinson, Herb])

Comment: There is a parallel situation here. The document doesn't properly address the environmental impact of the indefinite time frame, because that is an impossible task. We should be using proper engineering methodology -- and we had better be talking engineering here -- not experimental science projects. Proper engineering methodology uses proven technology to achieve a practical result. There is no proven technology to sequester something for a million years. Not for 100,000 years. Not even for 10,000 years. The longest-lived man made structures I know of are the pyramids. They been around for very roughly 5,000 years and they failed at their intended purpose in prehistoric times. (0208-3 [Robinson, Herb])

Comment: NEPA law requires alternatives to be analyzed for a full understanding of possibilities. The DGEIS alternatives are lacking in understanding, complexity, or foresight. The 60-year time frame appears arbitrary. If you review previous decisions by the NRC, this is a doubling of an earlier 30-year recommendation (Arbitrary). I claim that the 60 year "short term" storage after license expiration is too long, that the 160 year "long term" storage is too long and that the "indefinite" storage of the materials stored in perpetuity lacks responsibility, is naive and is absolutely impossible (way beyond reasonable and foreseeable) to analyze and fails NEPA and the NRC mission. Although you do not wish to consider the "worse case scenario", other alternatives must be considered. It was disappointing to read the section on other alternatives considered but eliminated. I arbitrarily and for your consideration select 10 years post licensing expiration for the short term, 20 years post licensing for the longer term and a denial of an indefinite storage without the absolute need and accessibility of either of the following two technical solutions. 1. An approved and environmentally analyzed deep geologic repository OR 2. A reprocessing facility for nuclear materials proven to be technically adequate for recycling this highly dangerous material. Without a continued and safe final conclusion of the waste material in a safe manner, the indefinite storage is impossible and the discontinuation of the generation of the spent nuclear material should occur. There are no reasonable and foreseeable considerations for indefinite storage as described in the DGEIS. (0219-8 [Olmstead, Stan])

Comment: In their internal scoping for irradiated nuclear fuel, the NRC staff identified three scenarios: 1) evaluate storage until a repository is available mid-century, 2) evaluate storage until a repository is available at the end of the century and 3) continued storage if a repository is not available. Scenario Three is "unavailability of a national nuclear waste repository." The scenario of a repository being unavailable is the most likely of the three and the yellow arrow in slide number 13 should extend for at least 10,000 years and have 65 arrow points. (0222-13 [Zeller, Lou])

Comment: No one can predict what will happen during 100,000 years of necessary storage. Any waste MUST be neutralized as soon as it is categorized as waste. (0239-2 [Rasmussen, Kenneth])

Comment: You know, to me the answer is in the way NRC has done this GEIS. You see a lot of bounding analysis, you see looking at things like spent fuel staying open for 60 years after a plant closes when in reality the average, since we developed dry cask storage technology, is around 11 years. You know, you see us building dry transfer facilities and repackaging at all these places every 100 years. Well, not likely to be there for 100 years when you look at repository developments around the world, but even if it is we'd come up with better ways. We would bring in portable systems and different technologies, but that's okay. That what it means to be bounding. This analysis is appropriate for every site because it bounds and envelopes what is likely to happen at any site. This is where it's a good job. It is factually based. Because I've heard tonight and we've heard before, it's all assumptions, you don't know. (0244-11-6 [McCullum, Rod])

Comment: The Commission has determined that continued onsite storage of spent nuclear fuel, beyond the licensed life, for operation of a reactor is feasible. They also make the assumption that having a mined geologic repository within 60 years following the licensed life or operation of a reactor is also feasible. In the event that repository is not developed in the future when necessary, the NRC assumes that the nuclear industry will successfully develop alternative methods of storage. (0244-14-3 [Prescott, Lisa Marie])

Comment: Why does the NRC, an official regulatory agency, incorporate terminologies such as, "when necessary" in reference to permanent spent fuel disposal? (0244-14-4 [Prescott, Lisa Marie])

Comment: The NRC's draft waste confidence GEIS skirts the issue of long-time storage safety by assuming fuel and dry casks can be managed indefinitely for hundreds of years. It is not considered an impossibility, but imagine the impacts of pool leaks, especially tritium where there is a significant history of such accidents nor show concern for earthquakes, tornadoes, floods which grow stronger with climate change. (0245-14-4 [Kurz, Carol])

Comment: I read your report and I admire the effort you put forth to look at everything from tornados to terrorism, but I got hung up on time. And being an ex-teacher, I produced a visual aid here to explain what I'm concerned about. What I have here are some fishing lines, and I took the first six inches here and I measured off the time equivalent to the first -- 2,000 years from 0 A.D. up here to the present. So, if you let 2,000 years be six inches, it becomes a math problem just to fix other points along the line. The part I marked off in black here which you probably can barely see is the industrial revolution, roughly about from 1850 up to the present. And there's a little red band here at the end that you might not be able to see. That's out to the year 2100 at the end of the century. When I'm thinking about time, that's the time I'm mainly thinking about, you know, what's going to happen just by the end of this century. And scientists predict not a lot of good things. In addition to climate change, we may lose a quarter to half the world's species; we're going to lose our fisheries; our water tables are threatened. Add another half an inch if you want to extend time a little bit. We're going to run out of oil, we're going to run out of coal, and we're going to run out of natural gas. The point is, scientists right now have not a very clear idea of what the world is going to look like in just 100 years, and you're saying you know what the world is going to look like 250,000 years from now, a place where can store radioactive waste safely. To me, that's just ludicrous. To help you get a handle on the length of time that we're talking about here now, Sally is going to pull out this fishing line. And it doesn't take long until she gets just to 6 feet. And there it is, 6 feet. That represents the half-life of plutonium-239. That's out 24,000 years on this scale. Don't be too excited about that being a short distance because one half-life isn't what we need to worry about. We need to worry about several half-lives when we're storing these wastes. Now she's going out and you're going to have to move pretty quickly here. She's going out to technetium-99, which has a half-life of 210,000 years, she's going to go out 53 feet. And she's not quite there yet. Go, Sally. If she were to continue to do tin-126 she'd go out 58 feet; selenium-79, 82 feet; zirconium-93, 375 feet; neptunium-237, 500 feet; cesium-135, 575 feet; palladium-107, 1,625 feet; and iodine-129, 3,925 feet. That's three quarters of a mile. [MODERATOR CAMERON: I think we're losing Sally back there.] MR. KNEIDEL: Yes, right. Well, we'll lose more than that. How can you believe we can store waste that long with the technology we have today? That's just absolutely ridiculous. There'll be several ice ages during the length of this time. Over 500 million species have evolved and gone extinct on earth and none have left a burden like this for the species that followed. (0250-17-1 [Kneidel, Ken])

Comment: How can you believe we can store waste that long with the technology we have today? That's just absolutely ridiculous. There'll be several ice ages during the length of this time. Over 500 million species have evolved and gone extinct on earth and none have left a burden like this for the species that followed. (0250-17-2 [Kneidel, Ken])

Comment: Whether in pools or dry casks, with proper maintenance and monitoring there's no reason that used nuclear fuel cannot be stored onsite indefinitely. (0250-18-5 [Lang, Amanda])

Comment: I hear all this technical stuff. Well, you know, it's been good for 50 years. It's been good for 60 years, but it's not going to be good forever. We know that. We know it through history. (0250-26-2 [Maphet, Sheila])

Comment: One of most tenuous assumptions is 100 percent success at keeping this waste contained for the centuries, for the eons, for the million years that it needs to be contained. These assumptions have proven to be false at Chernobyl and Fukushima. (0250-5-4 [Safer, Don])

Comment: With these timelines, you know, on the short frame 60 years, mid frame 160 years, you know, you really can't see a lot of things, you know, or plan for a lot of things that are out there. And when I think back 160 years, where were we 160 years ago? I mean, you know, we were ten years before the Civil War. I mean, Abe Lincoln couldn't even see that coming in the mid-1850s. (0250-69-3 [Rundle, Steve])

Comment: I think it's also problematic to think that communities are going to take spent fuel storage indefinitely. (0250-7-4 [Corbett, Susan])

Comment: So how are we going to assume that we can contain something that has a life of 100,000, 200,000, 300,000 years? (0250-9-3 [Tomlin, Willie])

Comment: As an aside, we question the conclusion that storing used fuel essentially forever would necessarily have "small" environmental impacts in the aggregate. (0262-4 [Patterson, Karen])

Comment: We hasten to add that the NRC's short-term and long-term timeframes appear founded on reasonable assumptions and information in the record. (0262-6 [Patterson, Karen])

Comment: So first, I would just like to say, or perhaps, last, the DEIS is inadequate because it fails to articulate a method to safely store waste out west for 250,000 years. We think the future is going to be better than we are. I'd like to think so, but our pattern hasn't proven that point. Keep the faith, keep standing up, and you're right, we're going to fight you at every turn, because we have not done what we're supposed to do to make nuclear power safe. (0326-21-3 [Conn, Diane])

Comment: When I first read over your proposal tonight, or the Rule proposal, given that my long-term planning at this point is about 30 years, you lost me on short-term planning that would make my, as yet, unconceived grandchild, the father of a very old man or woman before we get into your long-term planning. (0326-43-1 [Rippner, Sharon])

Comment: A question I ask is why is there no permanent safe storage? And the answer is because that's an oxymoron. There is no permanent safe storage. This toxic waste will be a liability for millions of years, with the half-life of plutonium-239 at 250,000 years. These are time spans that really have no meaning. What are we talking about? 250,000 years? A million years?

And when we talk about infinity, I mean, do we understand what infinity is? Do we understand what a trillion dollars is? These are all words that are just thrown out there. We have no idea what we're talking about. Civilized man hasn't even been around for 250,000 years, let alone a million years. How can you possibly project that far ahead in time with any confidence at all? You can't. (0326-53-4 [McGibney, Patrick])

Comment: I wanted to say some site-specific stuff about Davis-Besse. We knew as early as a decade or 15 years ago that the new homes casks manufactured by Vectra Technologies, which are now owned by Transnuclear, which is Areva, which is the French government, and fully loaded with high-level radioactive waste at Davis-Besse were discovered to have been built below technical specifications. The aggregate used to fabricate the cask's outer concrete shells was poor quality, and the shells themselves were ground too thin. And then another Transnuclear cask located in Virginia at the Surry Nuclear Power Plant had developed six-inch-long cracks in its outer concrete shield, had loose bolts, and had a helium leak, the same cask model. So, in the NRC's Nuclear Waste Confidence Draft Generic Environmental Impact Statement, they have confidence in essentially dry cask storage forever, when we haven't gotten it right yet in this country due to massive quality assurance violations on the design and manufacture. (0327-10-3 [Kamps, Kevin])

Comment: At the outset, the GEIS needs to be refocused to separate from a Waste Confidence standpoint the continued operations of the nuclear power plant from the waste storage. The purpose of the Waste Confidence Rule is to provide a benchmark for the time that the NRC believes the spent fuel can be safely stored. Assuming that the storage is in dry casks, which the GEIS does, the identifiable time frame that has been selected by the NRC is 100 years; that is, spent fuel can be safely stored for a period of 100 years before a cask has to be replaced. This time frame does not take into account any information from the manufacturer, such as its declarations of warranty or useful life of the cask. Despite this determination, the GEIS and the Waste Confidence Rule upon which it is based uses as a starting mark the date the plant ceases operations. There is no accounting for the many casks that have been loaded and are sitting for years, indeed decades before the plant operations cease. It would be more appropriate, therefore, for the GEIS to separate operations from storage and focus solely on storage since, after all, that is the reason for the existence of it in the first place. In other words, the statement from the NRC for the confidence in storage should run from the date that the spent fuel is put into a cask, not the date that the plant that has generated that spent fuel ceases operations. (0328-2-4 [Rauterkus, Ralph])

Comment: All attestations as to the containment of large quantities of nuclear waste for 60 years, 70 years, a century, and beyond are hypothetical, based on limited collections of experiential data, and untested by reality. (0341-1-16 [Mermelstein, Richard])

Comment: The conceit advanced in the GEIS is that a protective scheme for nuclear waste can be broken down, into the following three (almost incandescently euphemistic) categories: * "Short Term" - referring to storage in spent fuel pools for the period of the next 100 years; * "Long-Term" - referring to storage in dry casks for the coming 200 years; and * "Indefinite Storage" - an indefinitely defined term, presumably to be for effectively forever. Putting the problems of hubris and absurdity aside for the moment, the entire GEIS suffers from the following fatal flaw: It does not incorporate time into its time analysis. Yes, there are lots of iterations of "aging management" plans (which, incidentally, are plans, not realities). True too, there is acknowledgement of population growth, and climate scientists' warnings of climate change bringing droughts, rising sea levels and sundry other altered climate conditions. However there is no actual analysis of the effects of time. Nor is there recognition

that long durations of time bring into play factors and events that cannot be anticipated. Reflection upon the past provides perspective. (0341-1-20 [Mermelstein, Richard])

Comment: There is nothing scientific about NRC claims that it can guarantee the safe storage of nuclear waste for a million years. This waste contains plutonium & uranium with half-lives of 24,000 years and ten billion years, respectively. You needn't have any expertise, just a little commonsense to realize how insane this is. One million years takes us to the Calabrian stage of the Pleistocene era, a period of which we know very little, hundreds of thousands of years prior to the emergence of the Neanderthal. But going forward in time, we know little if anything about events a decade from now, and we have no way to know anything about conditions ten thousand centuries from now. That the word 'confidence' is used by the NRC when talking about safeguarding radwaste for a period of time five hundred times greater than the Christian era is preposterous! There is no proven technology to displace something for a million years. Not for 100,000 years, not even for 10,000 years. The longest lived man-made structures are the pyramids. They've been around for 5,000 years and they failed at their intended purpose. (0373-10 [O'Malley, Brian])

Comment: The NRC's claim that the indefinite storage of such waste in fuel pools and dry casks provides confidence that this waste will never cause a threat has no scientific validity, particularly since neither casks nor fuel pools are designed for permanent storage. The court itself found that the NRC had no technical basis to simply assume temporary storage methods (fuel pools and dry casks) are adequate for indefinite storage. (0402-3 [Gross, Cheryl])

Comment: The time-frame of the Waste Confidence plan does not make good sense. The time-frame should start now. The environmental impact of stored nuclear waste on site or in interim sites must be considered from the start of when it is first stored. The applicability of the GEIS should not take effect as far in the future as 60 years from now. (0417-1 [Clark, Terrence])

Comment: Decisions regarding nuclear waste management have a long-term impact. Such decisions impact generations to come. The time frame that nuclear waste can impact the environment and human health was referred to by Judge Sentelle in a court document as "for time spans seemingly beyond human comprehension". The GEIS needs to consider such long term impact in the decisions pertaining to waste management. (0417-10 [Clark, Terrence])

Comment: The Sierra Club policy speaks of attainment of the fundamental safety objectives central to the federal nuclear waste isolation program. At no point does it suggest that waste storage at a retired nuclear plant site could qualify as a repository. (0431-5 [Pascall, Glenn] [Watland, George])

Comment: Another shortcoming of the EIS process is that it focuses on specific forms of environmental degradation resulting from human activity within predictable and relatively immediate time periods. It is not designed to assess systemic risk arising from a range of factors, including those that could precipitate emergency events, over indefinite time periods. (0431-7 [Pascall, Glenn] [Watland, George])

Comment: The DGEIS, like the so called Blue Ribbon Commission on Nuclear Futures, simply puts off to a distant and uncertain future any solution to the problems of spent fuel. It is ludicrous for NRC to extend the definition of short term to be 60 years, more than 100 years beyond the dawn of the nuclear age. It is even more so with cases 160 years or indefinitely beyond the closure of nuclear plant operation. (0447-2-20 [Andrews, Richard])

Comment: The extreme time frames in the NRC identified alternatives are simply unacceptable due to these major risks to human health, safety and the environment. It is even questionable that an NRC agency will even exist within these long time intervals. (0447-2-3 [Andrews, Richard])

Comment: Finally, Eureka County agrees that it is reasonable to use a scenario in the assessment that includes development of a repository sited through a consensus based process as recommended by the Blue Ribbon Commission on America's Nuclear Future. However, assuming that a geologic repository will be available by 2048 based solely on DOE's stated goal of having a repository operational by 2048 is unreasonable. This is important since then, the NRC continues to believe that 25 to 35 years is a reasonable period for repository development (e.g., candidate site selection and characterization, final site selection, licensing review, and initial construction for acceptance of waste (Draft GEIS page 2-18). This ignores a critical finding by the Blue Ribbon Commission that a problem with the previous siting effort was the reliance on arbitrary dates. No action to date indicates that it is reasonable to assume that a repository can be operational in the 25 to 35 year time frame. If anything, past experience would suggest that a much longer time frame should be considered as the short term time frame to be analyzed as one of the scenarios. (0459-7 [Johnson, Abigail])

Comment: Until NRC Completes A Legally Sufficient NEPA Analysis, Its Decisions To Allow Nuclear Reactors to Continue to Store Spent Fuel In Spent Fuel Pools At Reactor Sites and to Continue to Generate Spent Fuel for Which There is No Permanent Waste Repository Violate NEPA The initial waste confidence findings were modified over the years but, until 2010, continued to conclude that (1) a permanent waste repository would be available by a date certain and (2) the storage of spent fuel at reactors could be accomplished without undue adverse environmental impacts for 30 years after plant shutdown, provided the permanent waste repository was operational no later than 2025. However, in 2010 the Commission concluded that: there are issues beyond the Commission's control, including the political and societal challenges of siting a HLW repository, that make it premature to predict a precise date or time frame when a repository will become available. The Commission has therefore decided not to adopt a specific time frame in Finding 2 or its final rule. Instead, the Commission is expressing its reasonable assurance that a repository will be available 'when necessary.'; Waste Confidence Decision Update (75 Fed. Reg. 81037, 81042 (Dec. 23, 2010) (footnote omitted)). The finding that it was "premature to predict a precise date or time frame when a repository will become available" was undisturbed by New York v. NRC, 681 F.3d 471 (D.C. Cir. 2012). (0473-10-1 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Indeed, a number of the "assumptions" the DGEIS makes--such as requiring the replacement of dry casks every 100 years--are only "assumptions" and the NRC explains that it is not actually requiring such measures. The NRC provides no explanation for why it is not imposing -- as a mitigation measure -- the regular replacement of dry casks every 100 years. This could be because such a measure would fail to meet NRC's backfit requirements (which impose by regulation a cost- benefit analysis that is markedly different from the statutorily-required NEPA analysis). This is precisely the situation where NEPA requires assumptions to be imposed as actual mitigation measures if the agency intends to rely on them in its environmental analysis. In short, the environmental analysis required by NEPA should refer to the actual regulations that are currently in place as well as mitigation measures actually imposed by the NRC. (0473-11-2 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Instead, the DGEIS relies only on 10 C.F.R. § 50.82, the regulation requiring decommissioning of power plants within 60 years of the permanent cessation of operation of the

reactor, as the basis for its assertion that all waste will be out of pools within sixty years of the licensed life of a facility. But this regulation explicitly authorizes the Commission to extend decommissioning beyond sixty years - thus leaving spent fuel in pools - when there is no place to put the waste: Decommissioning will be completed within 60 years of permanent cessation of operations. Completion of decommissioning beyond 60 years will be approved by the Commission only when necessary to protect public health and safety. Factors that will be considered by the Commission in evaluating an alternative that provides for completion of decommissioning beyond 60 years of permanent cessation of operations include unavailability of waste disposal capacity and other site-specific factors affecting the licensee's capability to carry out decommissioning, including presence of other nuclear facilities at the site. 10 C.F.R. § 50.82(a)(3) (emphasis added). The Court explicitly required the NRC to do a full analysis spent fuel pool fires assuming that no repository or other waste disposal option is available if the probability of a fire was not zero. This same analysis applies equally to leaks. Nowhere has NRC shown that the chance of spent fuel pool fire is zero after 60 years because no spent fuel will remain in pools. In fact, the DGEIS acknowledges that an act of sabotage or terrorism on a spent fuel pool could be catastrophic. DGEIS at 4-84, 4-86, 4-89. (0473-12-11 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: As to radioactive leaks, the D.C. Circuit invalidated the 2010 findings and rule in part on grounds that, although the NRC "has addressed, or is in the process of addressing" spent fuel pool leaks, those actions were untested and that the court could not defer to the Commission's conclusion that no harm would result from leaks. NRC has even less to rely on here, as it has not even pointed to any action it is currently taking to ensure that waste is indeed moved within 60 years of a reactor's licensed life. Using the court's language, NRC has not even asserted that it is "on duty" (681 F.3d at 481) when it comes to moving waste out of pools; instead there are no "considerable enforcement and inspection efforts" underway at all to support the NRC's wishful thinking that all waste will be out of pools in time such that no analysis of spent fuel pool fires or leaks in the long-term time period is warranted here. The court required NRC to do this analysis and NRC has not done it in this DGEIS. A proper analysis here would result in adjustments to other sections of the DGEIS, for example, increased impacts on fish kill and water usage resulting from additional years of intake for cooling. (0473-12-14 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The Court recognized that finding that the probability of a given harm is nonzero does not in and of itself require an EIS, but faulted the Commission for "not undertak[ing] to examine the consequences of pool fires at all." Id. The NRC in response again fails to examine the consequences of pool fires or leaks at all for any time period other than the short-term. (0473-12-8 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: There is no basis in the DGEIS for the assumption that all waste will be moved from pools to dry cask by the end of 60 years after licensed life. See DGEIS at 1-14 (acknowledging that the precise time spent fuel is stored in pools will vary from one reactor to another, but characterizing the assumption that waste will remain in pools for the longer-term as "reasonable."). (Similarly, the NRC has also not provided a basis for its assertion that a permanent repository will be available within 60 years). The NRC did not state that it is unambiguously requiring all nuclear power plant operators to move all spent fuel, for example, or even that it intends to do so (0473-12-9 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The DGEIS states that "[t]he consideration of climate change impacts for pool storage only needs to address the short-term timeframe." DGEIS at 4-75. As discussed above, there is no basis for the NRC's assertion that all waste will be removed from pools within sixty years of the licensed life of a facility. As such, the DGEIS must analyze the potential impacts of climate change on pool storage in the long-term and indefinite timeframes. Anything less falls short of the D.C. Circuit's very clear directive. Moreover, the DGEIS houses its climate change impact within Section 4.18, entitled "Environmental Impacts of Postulated Accidents." But the NRC must examine the impacts of climate change as to ongoing waste storage in the long-term and indefinite timeframes as to everyday operations as well as in the accident scenarios the NRC considers so unlikely. The DGEIS is bereft of any discussion of the impacts of climate change on everyday operations in the waste storage context. (0473-17-2 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: In its analysis, the Commission projected that, based on international experience, 25-30 years is a reasonable estimate to site, characterize, construct, license and open a geologic repository using a consent-based process, as recommended by the President's Blue Ribbon Commission. The Commission failed to consider certain key factors in its analysis that are peculiar to the U.S. situation. These factors make the NRC's evaluation and examination of international experience less applicable to the realization of a U.S. repository, and render NRC's projected timeframe overly optimistic. (0532-6 [Kotra, Janet])

Comment: The GEIS section 1.8.3, Analysis Assumptions, assumes that spent fuel in dry cask storage systems is moved to new dry casks every 100 years during the long-term and indefinite storage periods. In other GEIS sections it is stated that the 100-year replacement cycle is a conservative estimate and that replacement may not need to occur as frequently. For instance, it is noted in Appendix B that NRC is making the 100-year replacement assumption, "even though studies and experience to date do not preclude a longer service life." NRC should acknowledge that future spent fuel storage studies are planned as a joint effort between the Department of Energy and the Electric Power Research Institute. These multi-decade studies should be described in the GEIS and a commitment made by NRC to stay involved in the studies and review the results on a real-time basis. If at any time should there be indications that spent fuel safety requires actions other than assumed in this GEIS, NRC should commit to relook at its waste confidence decisions. On the other hand, if the study results show spent fuel to be safe without 100-year repackaging, NRC should also update the assumptions in this GEIS. In any case, NRC should acknowledge the importance of collecting empirical data on spent fuel over many decades to verify the analytical assumptions in this GEIS. (0544-13 [Enriquez, Elizabeth])

Comment: The timeframes evaluated in the GEIS are confusing. This is because the discussion flip-flops between an analytical model that is forward looking only, but also includes discussion of when Dresden fuel would enter the short term continued storage phase. The only time waste confidence determinations will ever be used is during (forward looking) facility specific licensing proceedings for reactors or interim storage facilities. Safety and environmental impacts for the period of the license will be the subject of a facility specific NEPA evaluation. Waste confidence addresses the period after the licensed facility life. While the phases identified are a perfectly reasonable analytical scenario, spent fuel is currently under NRC licenses and will remain under NRC licenses until it is disposed in a geologic repository. In essence, no spent fuel will ever reach any continued storage phase. New or renewed licenses will be issued instead that ensure the fuel's safety. NWRPO suggests that the waste confidence documents be revised to address forward looking analysis only. It doesn't matter when Dresden fuel or any other spent fuel will enter the short term continued storage phase, as long as all fuel

is evaluated. Added to the confusion is the reference to the recent DOE strategy document that includes unsupported declarations of when interim storage or repository disposal capacity will be available. Since issuance of the DOE strategy, there has been no action by DOE to implement either an interim storage facility or a repository. The proposed rule and GEIS already show spent fuel to be safe for all extended storage phases and that is enough. What would be more reassuring to the public would be for the Federal government to do something that leads to spent fuel disposal, but of course, without Yucca Mountain, there is nothing to point to. (0544-14 [Enriquez, Elizabeth])

Comment: GEIS Section ES.9, pp. xxvii and xxviii. The discussion of the continued storage timeline in this section, without the confusing references to Dresden fuel and the DOE Used Fuel Strategy, makes more sense that the discussion in section 1.8.2. Consideration should be given to deleting the confusing information in section 1.8.2. (0544-20 [Enriquez, Elizabeth])

Comment: GEIS Section 1.2, p. 1-4, lines 27-29. The reference to DOE expressing its intention to provide repository capacity by 2048 should be removed. If that is the basis for NRC's conclusion that a repository will be available within 25 to 30 years, then it should not be believed. The DOE timeline is in its used fuel strategy document, but there is no basis for that timeline. In fact, DOE has taken no steps to ensure a repository will be available subsequent to its shutdown of the Yucca Mountain Project or issuance of its strategy document. The only way a repository will be available in that time frame (within 25-30 years) is if Yucca Mountain is completed. This GEIS should not cite DOE's strategy document, but instead should use Yucca Mountain as an example of how a repository can be available because current Federal law requires that the Yucca Mountain repository be licensed and operated, if possible. Why would NRC's NEPA analysis ignore what is required by Federal law while at the same time assume a scenario that is not allowed by Federal law? (0544-23 [Enriquez, Elizabeth])

Comment: GEIS Section 1.8.2, p.1-12, Figure 1-1 and associated text. Continued Storage timeframes for analytical purposes are defined in this section. An addition to the text should emphasize that the timeframes presented are just one analytical approach that ensures all spent fuel is analyzed for the entire period before geologic disposal. Other analytical approaches could have been chosen and worked just as well. Adding such emphasis in this section might help avoid confusion in later sections of the GEIS when the continued storage phases are discussed. (0544-24 [Enriquez, Elizabeth])

Comment: GEIS Section 2.2.1.1, pp. 2-22 and 2-23. This section including Figure 2-4, shows the overlap of reactor decommissioning and short-term continued storage. Both periods are 60 years after reactor operations. The analytical assumption of 60 years of short term continued storage based on the 60 year decommissioning period makes more sense that dependence on a DOE strategy document that has no basis for its timelines. (0544-29 [Enriquez, Elizabeth])

Comment: This GEIS makes an argument that it is most likely that a repository will be available for spent nuclear fuel within 60 years after an assumed 80-year licensed operating life of nuclear power plants. However, without an active repository program in the United States, this argument is weak. Further, dealing with the primary issue by stating that the disposal technology will be available when necessary, is exactly the approach that that led to the U.S. Court of Appeals for the District of Columbia Circuit in 1979 to reject the Atomic Safety and Licensing Appeal Board ruling and find it not sufficient under the National Environmental Policy Act. Additionally, the remand of NRC's 2010 waste confidence decision was largely on the basis that evidence of a repository by any particular date does not exist. The DC Circuit ruling appears to say what NRC is unwilling to say, that disposal may not be available when a

reactor's license expires (even assuming 80 years of licensed operations). So, even though NRC is having trouble admitting it, the condition noted by Judge Tamm has been met and it is time to evaluate the conditional circumstance, whether it is reasonably probable that the spent fuel can be stored safely onsite (this GEIS also considers an offsite option) for an indefinite period. (0544-5 [Enriquez, Elizabeth])

Comment: On the other hand, there is a limit to the at-reactor dry storage concept. Under its "indefinite storage" scenario, NRC has assumed that dry cask storage--cask pads, inner canisters, and the dry casks themselves--will be replaced once every 100 years, indefinitely into the future. NRC assumes that Dry Transfer Systems will be built (and also replaced every 100 years), since pools will have been dismantled during decommissioning by at most 60 years after permanent reactor shutdown. (0552-1-25 [Macks, Vic])

Comment: It is my conclusion that this DGEIS is premature and establishes an impact rating system solely related to inferred magnitude of very poorly described potential environmental impacts. It is, in the general absence or severe shortage of relevant evidence, model-driven by use of "Reference guides." None of the critical storage items-cask performance in many different environments and inadequately tested over a very short time period (14 years, one casket), the potential for catastrophic impacts on storage facilities, which can have far greater environmental consequences than any considered in the GEIS, and the human impact factor that has great potential for environmental harm, but which doesn't fit the format for this GEIS and so is ignored. The evidence base is so deficient that the indefinite time frame considerations are not credible. (0553-1 [Wilshire, Howard])

Comment: The unsupported assumptions include: • All spent fuel will be removed from spent fuel pools to dry storage by the end of the short-term storage time-frame (60 years)--Pilgrim NPS 2092. • Spent fuel canisters will be replaced approximately once every 100 years. For Pilgrim on 2192, 2292, 2392 and so on. • ISFSIs and Dry Transfer Systems (DTS) facilities will also be replaced every 100 years. (0556-2-4 [Lampert, Mary])

Comment: All spent fuel would be removed from spent fuel pools to dry storage by the end of the short-term storage time-frame (60 years). The public is not relying on NRC's crystal ball. NRC fails to provide factual support and analyses for this assumption. There is no analysis regarding the probability that a repository will be successfully sited, built, and ready and willing to accept spent fuel from every licensee by the end of the short term. There is nothing in experience or history, on which any realistic assumption must be based, that supports this unrealistic assumption. (0556-2-7 [Lampert, Mary])

Comment: Because waste fuel assembly degradation will occur during storage periods, it will not be possible to perform the functions necessary to validate the following assumptions 100% of the time: -Spent fuel canisters and casks would be replaced approximately once every 100 years; and, -Independent spent fuel storage installations (ISFSI) and dry transfer system (DTS) facilities would also be replaced approximately once every 100 years (Draft GEIS at xxviii). Unless these assumptions are completely validated, the Draft GEIS fails to provide the support necessary for the proposed revisions to 10 CFR 51.23. (0608-14 [Crocker, George])

Comment: The NRC cannot guarantee that waste Permanent disposal will be available "when necessary" or ever. There is no reasonable basis for the NRC to assume that in 60 years or 160 years there will be a storage solution to manage the massive stockpiles of radioactive waste. When nuclear energy was first developed sixty years ago the same assumption/promise was made. This promise was broken. The GEIS contemplates continued operations of nuclear plants

based on the false assumption at either in 60 or 160 years a solution for nuclear waste storage will exist There is no evidence this is true, especially since for nearly 60 years science is not one step closer to finding a nuclear waste storage solution. No other industry would be permitted continue operations creating waste when the regulatory structure originally created to protect the public does not to exist. For the past 60 years atomic scientists still have not figured out how to safely manage the tons of radioactive nuclear waste produced each year. (0611-25 [Shapiro, Susan])

Comment: Storing spent fuel above-ground indefinitely, at reactor sites or away from reactor sites, is not an acceptable alternative for disposing of spent fuel. The Nuclear Waste Policy Act (NWPA) mandates that spent fuel be stored above ground only on an interim basis while a federal repository is developed. Assuming that spent fuel will be stored above ground indefinitely is inconsistent with the NWPA. (0622-1-11 [Vale, Karen])

Comment: The DGEIS outlines impacts in three timeframes - short-term (60 years post reactor license), long term (100 years post short-term) and indefinite storage. However, it is incredibly difficult to accurately predict environmental conditions at every reactor site in the long-term timeframe and nearly impossible for the indefinite timeframe. An EIS -particularly one that is generic in nature -cannot accurately predict direct, indirect, and cumulative environmental impacts of continued spent fuel storage in these timeframes without knowing how the environment will change in particular locations or how certain ecosystems will respond to future stressors (e.g., climate change impacts, changes in community development, etc.). (0622-1-14 [Vale, Karen])

Comment: [W]e believe that the ISFSIs and casks at our sites have shown to be robust, safe, and secure. The conservatism that is built into each cask and each ISFSI is acknowledged to be more than enough to provide safety and security for long beyond the term of their initial licenses. Research done so far confirms this. We believe that these systems could be safe for a minimum of 100 years. Second, there remain additional research projects that will yield additional information to specify just what specific additional periods ISFSIs and casks can be relied upon to fulfill their safety function. (0637-6 [Norton, Wayne])

Comment: Therefore, we believe that the GEIS adequately analyzes an achievable intermediate scenario that should be viewed as an adequate surrogate for the requirements that will be developed during the next 20 -100 years. (0637-8 [Norton, Wayne])

Comment: The base assumptions upon which the draft GEIS rests not only defy logic but violate the Nuclear Waste Policy Act as well as the NRC's own regulations. The longer term storage scenarios envisaged in the draft GEIS are all but guaranteed to lead to defacto permanent storage in the biosphere. That is exactly the outcome US nuclear waste policy was developed to avoid. (0646-17 [Hanson, Courtney])

Comment: It is just plain foolish to generically say there will be minimal environmental impact: 2. regardless of the time frame. Whether it be 60 years, 160 years or (arrogantly) indefinitely. (0652-2 [Maurer, William])

Comment: The assumptions on which the draft GEIS relies are problematic. Specifically, the draft GEIS assumes that "that all spent fuel is removed from the spent fuel pool and placed in dry cask storage in an ISFSI no later than 60 years after the end of the reactor's licensed life for operation [i.e., within 120-140 years]." (1-14.) However, there are currently no rules requiring that spent fuel ever be stored in dry casks, much less within a certain time. The assumption

should, at the very least, note that NRC regulations do not specify a maximum time for storing spent fuel in pool or cask. (0669-10 [Walter, Joan])

Comment: Whether in pools or dry casks, with proper maintenance and monitoring, there is no reason that used nuclear fuel could not be stored onsite indefinitely. Many may think it is arrogant to assume we can have confidence in storing something for 100,000's of years. (0674-5 [Lang, Amanda])

Comment: We appreciate the NRC's efforts to develop bounding generic environmental analyses that address the issues raised by the D.C. Circuit Court's 2012 decision. However, we are concerned that all of the scenarios evaluated in your draft Generic Environmental Impact Statement (GEIS) involve protracted used fuel storage at reactor sites or away-from-reactor sites. One scenario even assumes indefinite at- or away-from-reactor storage accompanied by periodic (every hundred years) on-site transfer of used fuel to new dry storage canisters. Without question, indefinite storage is the wrong policy. While it is perhaps necessary to assess such a scenario in order to bound potential environmental impacts, we must point out that the scenario is entirely at odds with both the letter and spirit of the Nuclear Waste Policy Act (NWPA) and absolutely not an acceptable outcome for the citizens of the United States. (0689-3 [Boyd, David])

Comment: I do not share your confidence, expressed in your Waste Confidence Draft Generic Environmental Impact Statement (WC DGEIS, NUREG-2157), that dry cask storage of irradiated nuclear fuel is currently safe and sound, and will remain so not only for up to 80 years of reactor operations, up to 60 years beyond reactor operations during so-called 'short-term storage, up to 100 years beyond that during so-called long-term storage, and up to forevermore beyond that, during so-called indefinite storage (infinite storage?!). (0698-1 [Kamps, Kevin])

Comment: Spent fuel has such a long radioactive life where it is dangerous to people makes it impossible to guarantee the safety of all life on Planet Earth for 250,000 years. For anyone to think there is a way to store spent fuel for 250,000 years is attempting to make an assumption that will never become reality. (0701-4 [Wilson, Greg])

Comment: The Canadian Coalition for Nuclear Responsibility (CCNR) finds that it is imprudent for NRC to base its entire analysis on the assumption that a geologic repository will become available within a few decades. To provide a thorough analysis of potential environmental impacts of spent fuel storage, NRC needs to analyze the consequences of an indeterminate delay in the availability of such a geologic repository, as well as the implications of such a repository never becoming available. Anything less than that would be tantamount to basing policy decisions on wishful thinking. (0714-1-1 [Edwards, Gordon])

Comment: The NRC continues to assume that a geologic repository for the safe permanent disposal of irradiated nuclear fuel from power reactors (whether in the form of fuel assemblies or as solidified post-reprocessing waste) will become available within a few decades. There are good reasons to distrust that assumption. According to the California Energy Resources and Conservation Commission's 1977 Report on the concept of geologic disposal of nuclear waste, the USA had (up until that time) attempted on seven different occasions to locate an underground repository for the safe long-term disposal of high-level nuclear waste, and failed all seven times. (0714-1-10 [Edwards, Gordon])

Comment: The Waste Confidence Rule Should Start After Spent Fuel is Placed In Dry Storage. Throughout the scoping decision and the Draft GEIS, the timeframe being analyzed by

the NRC commences with when a particular plant ceases operation. In other words, the NRC is expressing its confidence the waste can safely be stored for a period of time after a plant ceases operation. This timeframe misses the mark. The origin of the Waste Confidence Rule stems from the failure of the Federal Government to remove spent fuel to a temporary or permanent repository after an appropriate cooling period. The Waste Management Rule was recognition that spent fuel had to be stored on site for a period of time and an expression by the Commission that such storage could be accomplished safely for a set and re-set period of time. The origin, then, of the confidence for the storage of spent fuel had nothing to do with the continued operations of the plant which generated the fuel that needed to be removed. Rather, it was an expression that it could be safely stored at the plant until such time that temporary or permanent repository could be found. (0783-1-5 [Harlan, Thomas])

Comment: Under section 1.8.2, starting on page 1-12 and continuing to 1-13, the entire section should delete any reference to the storage timeframe including operations of the plant. As noted before, the continued operation of the plant is separate and distinct from storage. (0783-2-5 [Harlan, Thomas])

Comment: On page 1-14, lines 13-18, there is an assumption regarding normal life of the storage facilities. This assumption is based upon the knowledge and experience with structure and operation of these storage facilities. This assumption does not, in any way, reference the manufacturers' information on the casks including, without limitation, any warranties or anticipated life. Rather, it is based solely upon the NRC's experience with the same. This assumption does not pass muster since the NRC does not have any experience relative to the lifetime of the structure to store the spent fuel. A full evaluation of the proposed storage facilities needs to be provided. (0783-2-7 [Harlan, Thomas])

Comment: Under section B.3.2, the Draft GEIS addresses technical feasibility of dry cask storage. Within its analysis, it includes a discussion of the "robust design of dry cask storage systems." As state above, this assumption has no support for the time frames being analyzed. (0783-3-21 [Harlan, Thomas])

Comment: It is my conclusion that this DGEIS is premature and establishes an impact rating system solely related to inferred magnitude of very poorly described potential environmental impacts. It is, in the general absence or severe shortage of relevant evidence, model-driven by use of "Reference guides." None of the critical storage items--casket performance in many different environments and inadequately tested over a very short time period (14 years, one casket), the potential for catastrophic impacts on storage facilities, which can have far greater environmental consequences than any considered in the GEIS, and the human impact factor that has great potential for environmental harm, but which doesn't fit the format for this GEIS and so is ignored. The evidence base is so deficient that the indefinite time frame considerations are not credible. (0805-1 [Wilshire, Howard])

Comment: Much of what the NRC depends upon for waste confidence is that a geological repository will be available when needed. This availability becomes a matter of timing. Timing does not stand alone. Our government, our money and all other issues that make up the nuclear fuel cycle must survive to an extent. (0818-1 [Lewis, Marvin])

Comment: Chief among my concerns is that highly radioactive, lethal commercial reactor spent fuel could remain ad infinitum at reactors never intended to be defacto disposal sites. This conflicts with NRC regulations which state that even "low-level" radioactive waste can only be safely and reliably contained for 100 years. At one time, the NRC used to oppose at-reactor

waste storage "beyond five years as a significant safety and environmental matter." This faulty DGEIS assumption is also contrary to the 1982 Nuclear Waste Policy Act (NWPA) which states that spent fuel can only be stored above ground on an interim basis while a mandated deep geological repository is being constructed. (0819-2 [Kline, Connie])

Comment: Safety assessments require thorough review of the facts surrounding expansion, contraction, and gravity upon each form of matter and upon their individual elemental forms and ionizing isotopes. This review must thoroughly identify, research, and analyze any and all weaknesses or tendencies to compromise isolation over thousands of years. (0823-76 [Michetti, Susan])

Comment: The long term timeframe introduces a major impossibility to any prerequisite of safety. This requires that we revisit and examine the irrationality or recklessness of decision-makers for the past 65 years to approve of the processes that generated the most lethal toxic substances on earth. As soon as such ionizing isotopes were measured to have extremely long term cumulated sets of half-lives that were lethally toxic, the logical reaction required to stop producing this waste until a safe solution was known. The extremely long term cumulated sets of half-lives will dangerously persist longer than almost all evidence of humanity's life on earth. It will dangerously persist longer than the records passed down from the ancients. How will we communicate that far into the future? How will we provide safety that far into the future? The extremes of this measurement in time is an indicator that prudent decision-making requires an immediate ban on man-made manufacture of such long-term persistent lethal and toxic substances. (0823-77 [Michetti, Susan])

Comment: NEI also believes that the short-term storage scenario is the most likely, and that the long-term and indefinite storage scenarios are unlikely. With respect to the indefinite storage timeframe, NEI concurs with the NRC staff's assessment in Section 1.8.3 of the draft GEIS that it would be unreasonable to assume a gross and permanent failure of the Federal government to meet its responsibility for used nuclear fuel disposal. Moreover, the draft GEIS, Appendix B, Section B.2, supports a conclusion that the "no repository" scenario is highly unlikely. In the 2010 WCD update, the NRC reached fact-based conclusions regarding the technical feasibility of a repository and the progress of other nations to site and develop disposal facilities. Those conclusions are still valid, and the record supports the NRC's determination that the time period needed to develop a repository is approximately 25 to 35 years.⁵¹ [footnote 51 text: *Id.* at B-6.] Furthermore, within the long-term timeframe there will be ample opportunity for the government to address its obligation, license a repository, and construct the facility. Therefore, the indefinite storage scenario is highly unlikely. (0827-2-4 [Ginsberg, Ellen])

Comment: The indefinite storage scenario is also remote and speculative because it is contrary to existing federal law and assumes a complete and permanent government failure to fulfill the clear need and obligation to develop a repository.⁵² [footnote 52 text: *See In Re Aiken County, et al.*, 725 F.3d 255 (D.C. Cir. 2013). In determining whether an alternative is reasonable, courts also take into account legislation that forbids the alternative. "We do not suppose Congress intended an agency to devote itself to extended discussion of the environmental impact of alternatives so remote from reality as to depend on, say, the repeal of the antitrust laws." *Kilroy v. Ruckelshaus*, 738 F.2d 1448, 1454 (9th Cir. 1984)(internal citations omitted). Although the no repository scenario is not an "alternative" to the proposed action, the same principle applies in that a scenario that is contrary to the law should not be considered "reasonably foreseeable" under NEPA.] In that regard, the "no repository" scenario arguably is a "worst-case scenario" that should not need to be considered under NEPA.⁵³ [footnote 53 text: *Robertson v. Methow Valley Citizens Council*, 490 U.S. at 359.] Nonetheless, the Court of

Appeals specifically directed the agency to assess the environmental impacts of failing to establish a permanent repository, and NEI agrees that the NRC's consideration of an indefinite storage timeframe addresses the remand on this issue. (0827-2-5 [Ginsberg, Ellen])

Comment: NRC has determined that it is feasible to have a repository "within 60 years following the licensed life for operation of a reactor."¹⁰⁵ [footnote 105 text: Proposed 10 C.F.R. § 51.23(2)(ii).] This is strongly supported by international experience. Sweden, Finland, and France all expect to have operating repositories in the first quarter of this century.¹⁰⁶ [footnote 106 text: US Nuclear Waste Technical Review Board, *Experience Gained From Programs to Manage High-level Radioactive Waste and Spent Nuclear Fuel in the United States and Other Countries*, April 2011.] The primary purpose of predicting a timeframe for repository availability is to provide a reasonable analytical timeline that ensures that all periods of continued storage are evaluated. NRC has done this. After the period of licensed operations (80 years for reactors), NRC segments the timeline for continued storage into three phases - 1) short term (between 0 and 60 years after licensed operations that have already been covered by operational NEPA analysis), 2) long-term (a period from 0 to 100 years after short-term), and 3) indefinite (a period that begins after long-term and can extend in 100-year cycles far into the future). Thus, the environmental impacts of continued storage, for any length of time, are appropriately analyzed. (0827-5-6 [Ginsberg, Ellen])

Comment: Page 1-14, Lines 5-7 "the NRC assumes that all spent fuel is removed from the spent fuel pool and placed in dry cask storage in an ISFSI no later than 60 years after the end of the reactor's licensed life for operation." -- According to testimony by SCE in the recent Nuclear Decommissioning Cost Triennial Proceeding of the California Public Utilities Commission, SCE believes they cannot terminate their license until the ISFSI is completely gone. Thus the license will still be open (although not for operation) until the ISFSI is completely decommissioned as well. There seems to be a lot of confusion here. (0836-35 [Davis, Anonymous])

Comment: Section 4.0 -- You attempt to address continued storage of spent fuel at ISFSIs with DTS, and the notion that the ISFSIs can persist for that period of time, and the contents of the canisters will be fine, even if the fuel assemblies may have completely degraded by then. WE BELIEVE YOU CANNOT ADEQUATELY ADDRESS THIS ISSUE THIS FAR IN ADVANCE. THERE MUST NOT BE A GENERAL PURPOSE "APPROVAL" OF ISFSIs "forever" using technology that does not exist (like DTSSs) and total speculation about how these structures degrade over time. I know you want to get these approved "forever" but to do so is COMPLETELY IRRESPONSIBLE! WE BELIEVE THAT AT THIS TIME, THE ISFSIs MUST NOT BE APPROVED FOR INDETERMINATE TIME PERIODS, and to even suggest it points out how far the NRC has gone astray. Thus, it is IMPRUDENT for the NRC to create a GEIS for any time exceeding the initial 60-year timeframe which was the original concept for the decommissioning period. Contrary to your assertion, there are too many unresolved items at this time, and we must work quickly to establish a permanent deep-geologic repository, which DOES HAVE safety differences in terms of fewer vulnerabilities to terrorist or wartime attack. (0836-52 [Davis, Anonymous])

Comment: Suggesting that we will be able to rely on unproven or non-existent technology for safe storage of nuclear waste for thousands of years puts the future of our entire nation at risk. (0860-3 [Headrick, Gary])

Comment: Secondly, the NRC could have written a scenario describing in detail the expected impacts on the environment at each of the time frames used in the DGEIS. The description

would have provided insight into how the NRC envisions the environmental conditions at various time periods. (0867-1-6 [Griffin, William])

Comment: Of concern in this regard is the statement by Dr. Allison Macfarlane to the Nuclear Energy Institute where she said: "In the area of subsequent license renewal, there are even greater unknowns. Due to the age of the U.S. fleet, the United States is in large measure a pioneer in this area. I must be clear that the NRC is not yet in a position to pass judgment on the viability of operation beyond 60 years" (NRC News S-13-006, February 27, 2013). There is a fundamental disjunction with a DGEIS that purports to analyze 60 and 160 year and indefinite time frames and the NRC Chairperson's admission which suggests that the agency has no expertise in predicting to those timeframes. While the NRC Chairperson's statement was about the viability of NPP, not SNF storage, the same philosophy may hold true for aspects of SNF storage as envisioned in the DGEIS. (0867-2-4 [Griffin, William])

Comment: The Proposed Rule's Determination that it is Feasible to Safely Store Spent Fuel for an Indefinite Period Violates NEPA Because it is Devoid of Valid Technical Support and Fails to Consider a Range of Factors Affecting the Long-Term Safety of Spent Fuel Storage[.] The DGEIS asserts that spent fuel can be stored safely and without significant impacts for an indefinite period of time. DGEIS at xlv-xlv, lv, 8-2 – 8-3. But the NRC's findings on this issue are almost devoid of valid technical support. Makhijani Declaration, par. 4.1 et seq. The studies cited by the NRC do not support the broad generalizations in the DGEIS. For instance, the DGEIS relies on a pilot study that was never intended to be used for regulatory purposes; and it relies on other studies that are limited to short time frames. Makhijani Declaration, pars. 4.2 – 4.5. But even the short-term studies show evidence of spent fuel degradation during storage. Makhijani Declaration, par. 4.5. As discussed in Dr. Makhijani's declaration, the DGEIS assumes that spent fuel bundles can be stored for millennia and repeatedly transferred hundreds of times from one cask to another without large releases of radioactivity. But the DGEIS contains almost no information about spent fuel characteristics that could cause adverse safety risks and environmental impacts in case of long-term or indefinite storage, both during storage and during the many transfers that must take place. Makhijani Declaration, par. 4.6. The DGEIS contains no analysis of how spent fuel characteristics may contribute to the risk of an accidental release of radioactivity during extended storage of dry casks; or how these factors may contribute to accident risks during the many transfers that would take place over an extended period of time, *i.e.*, transfers between pools and casks, transfers between storage casks, transfers between storage and transportation casks, and transfers between transportation casks and casks used for ultimate disposal of spent fuel. *Id.* (0897-4-1 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Section 1.8.6 of the draft GEIS, titled Issues Eliminated from Review in this GEIS, contains the statement:⁸¹ [footnote 81 text: NRC, 2013b, pages 1-23 and 1-24.] "The NRC is evaluating the continued storage of commercial spent fuel in this draft GEIS. Thus, certain topics are not addressed because they are not within the scope of this review. These topics include: noncommercial spent fuel (e.g., defense waste), commercial high level waste generated from reprocessing, greater-than-class-C LLW, advanced reactors (e.g., high-temperature and gas-cooled reactors), foreign spent fuel nonpower reactor spent fuel (e.g., test and research reactors), need for nuclear power reprocessing of commercial spent fuel" (IX-2) By excluding from consideration the "need for nuclear power", the draft GEIS cripples its ability to assess the environmental impacts of storing spent fuel. Nowhere in the draft GEIS is this grave deficiency corrected. The draft GEIS does not set forth any scenario for the future use of nuclear power or, more specifically, for the future creation of spent fuel. Thus, in the draft GEIS, the timeframe for creation of spent fuel spans an unknown but potentially vast range, as does

the quantity of spent fuel created in that timeframe. (IX-3) At the lower end of its range, the timeframe for creation of spent fuel will end when the last of the currently licensed reactors ceases to operate. However, since the draft GEIS sets no upper limit on the time period that it considers, the creation of spent fuel could continue ad infinitum. Thus, the upper end of the range of timeframes is undefined. (0916-2-1 [Curran, Diane] [Thompson, Gordon R.]

Comment: (IX-4) At the lower end of its range, the quantity of spent fuel that is created will be the quantity that is discharged from the currently licensed reactors. However, since the draft GEIS says nothing about the future use of nuclear power, it sets no upper limit to the quantity of spent fuel that will be created. Consider a simple, illustrative example. Suppose that nuclear power soon revives in the United States, leading to a tenfold increase in annual creation of spent fuel by the mid-21st century. Further suppose that this rate of creation continues for a few centuries. At the end of that period, the cumulative quantity of spent fuel that has been created would far exceed the quantity that is discharged from the currently licensed reactors. (IX-5) If the total quantity of spent fuel that is created were at the lower end of its range, the radiological risk posed by storing this fuel would be bounded. As the inventory of fuel aged, its radiological risk would decline, other factors being equal. Moreover, the inventory would gradually move from pools to ISFSIs, which would reduce its risk. In principle, one could assess the cumulative radiological risk of storing spent fuel, from the present until the moment when the last fuel assembly in the inventory is emplaced in a repository. (IX-6) If, however, the total quantity of spent fuel that is created is unbounded, then the radiological risk posed by storing this fuel would be similarly unbounded.⁸² [footnote 82 text: This statement holds at any given time, and cumulatively.] The draft GEIS allows for this outcome. Thus, the draft GEIS has denied itself the ability to assess the long-term radiological risk of storing spent fuel. One cannot assess a quantity that is unbounded. (0916-2-2 [Curran, Diane] [Thompson, Gordon R.]

Comment: The U.S. Court of Appeals for the District of Columbia Circuit, however, in its *New York versus NRC* ruling of June 8, 2012, seems not to have agreed with Mr. McIntyre's description of NRC's "opinion." On Page 1-13, NRC states under "long-term storage," that "one-time replacement of ISFSIs and spent fuel canisters and casks" will occur, as will "construction and operation of a DTS [dry transfer system] (including replacement)." It then goes on to state, under "indefinite storage," that "replacement of ISFSIs and spent fuel cansiters and casks every 100 years...construction and operation of an away-from-reactor ISFSI (including replacement every 100 years)...construction and operation of a DTS (including replacement every 100 years)" will also take place. NRC concludes Section 1.8.2, Timeframes Evaluated, by stating, under "indefinite storage," that "These activities are the same as those that would occur for long-term storage, but without a repository, they would occur repeatedly." At a September 11, 2013 meeting with NRC Nuclear Waste Confidence Directorate Director, Keith McConnell, he confirmed that this assumption of safe and smooth, repeated replacements would continue forever into the future. In fact, beyond the one million year hazard the U.S. EPA has acknowledged, under court-order, for high-level radioactive waste, in the context of the Yucca Mountain dump licensing proceeding. In fact, even beyond the known hazardous persistence of the various radioactive isotopes constituting high-level radioactive waste, such as Iodine-129, with a half-life of 15.7 million years, and thus a hazardous persistence of 157 to 314 million years. (0919-2-1 [Kamps, Kevin])

Comment: (Nor can nuclear power even be considered a low carbon source of electricity, much less zero carbon, or "emissions-free," electricity source, as nuclear power industry public relations campaigns like to claim. Replacing high-level radioactive waste dry cask storage systems, structures, and components, once every hundred years from now till the end of time, will require significant quantities of concrete, steel, energy, etc., and hence a large carbon

footprint. Technically speaking, assuming forever replacement of dry cask storage would mean multiplying costs, as above, as well as greenhouse gas emissions, by infinity - yielding infinite costs, and carbon emissions. These are NRC's absurd assumptions worked out, not mine!) (0919-2-3 [Kamps, Kevin])

Comment: On Page 1-16, at lines 13-14, NRC states: "The spent fuel is moved from the spent fuel pool to dry cask storage within the short-term storage timeframe." By NRC definitions, this means that high-level radioactive waste could remain in the storage pool throughout the decommissioning period, for up to 60-years post reactor shutdown. The Atomic Age has given new, Orwellian meanings to words, such as "short-term storage timeframe" referring to up to 140 years of pool storage (including during up to 80 years of reactor operations, and up to an additional 60 years post-reactor shutdown), well over half as long in terms of years into the future, as our country has been independent from the British Empire in terms of years into the past (1776 to 2013, 238 years). (0919-3-5 [Kamps, Kevin])

Comment: At line 23, NRC states: "If a repository becomes available, operations could include the transfer of spent fuel canisters to shipping casks and transportation to the repository." While the federal courts have ordered NRC to address the potential for no repository ever opening, NRC's admission here of "if, but not when" a repository ever open underscores the risk that on-site or away-from-reactor ISFSIs could well become de facto permanent, surface storage "parking lot dumps." (0919-4-8 [Kamps, Kevin])

Comment: Re: Page 4-1, at line 10, where NRC states "In the short-term storage timeframe, the NRC evaluates the impacts of continued storage of spent fuel for 60 years beyond the licensed life for operations of a reference reactor."...60 years as "short-term"? But this is 60 years of pool storage beyond the cessation of reactor operations, which themselves could have gone on not 40 years (initial operating license), not 60 years (including one 20-year license extension), but 80 years (including a second 20-year license extension). That's up to 80 + 60 = 140 years of pool storage, referred to by NRC as "short-term." The Atomic Age has certainly given Orwellian new meanings to words like "short-term," if 140 years of high-level radioactive waste storage pool risks are included in that definition! Longer-term, if 200 to 300 years of on-site storage are under consideration, it must be pointed out that this would be longer-term than our country has even had its independence from Great Britain thus far (1776 to 2014 is 238 years). But of course, NRC has - absurdly --blessed forever on-site storage as "adequately" safe! (0919-6-6 [Kamps, Kevin])

Comment: Re: Pages 4-29 to 4-34, "short-term" (60 years post reactor shutdown, after as many as 80 years of operations - at Palisades, for example, 80 years of operations would end in 2051, so 60 years of pool storage beyond that would end in 2111), "long-term" (another 100 years beyond "short-term" at Palisades, ending in 2211), and "indefinite" (aka forevermore), Nukespeak has given a whole new meaning to the word "temporary"! (0919-7-20 [Kamps, Kevin])

Comment: With about 12.5% of the plants already having spent fuel pool leaks, and the fact that they were still within their original license time frame when the leak occurred, it is not unreasonable to believe that most of the spent fuel pools will have developed leaks before end of the 60 year beyond the end of the licensed life of the reactor. Three of those leaks are at one facility here in New Jersey and two of them reached the environment: The first leak in New Jersey occurred 25 years or less after startup. With 17% of reactors that have spent fuel pools already leaking, it is not a valid assumption to say the life expectancy of a spent fuel pool would be as long as 140 years after the plant went online. (0920-24 [Foster, Ruth])

Comment: Page 1-14, Lines 5-7 "the NRC assumes that all spent fuel is removed from the spent fuel pool and placed in dry cask storage in an ISFSI no later than 60 years after the end of the reactor's licensed life for operation." -- According to testimony by SCE in the recent Nuclear Decommissioning Cost Triennial Proceeding of the California Public Utilities Commission, SCE believes they cannot terminate their license until the ISFSI is completely gone. Thus the license will still be open (although not for operation) until the ISFSI is completely decommissioned as well. There seems to be a lot of confusion here. (0930-2-9 [Lutz, Ray])

Comment: Section 4.0 -- You attempt to address continued storage of spent fuel at ISFSIs with DTS, and the notion that the ISFSIs can persist for that period of time, and the contents of the canisters will be fine, even if the fuel assemblies may have completely degraded by then. WE BELIEVE YOU CANNOT ADEQUATELY ADDRESS THIS ISSUE THIS FAR IN ADVANCE. THERE MUST NOT BE A GENERAL PURPOSE "APPROVAL" OF ISFSIs "forever" using technology that does not exist (like DTSS) and total speculation about how these structures degrade over time. I know you want to get these approved "forever" but to do so is COMPLETELY IRRESPONSIBLE. WE BELIEVE THAT AT THIS TIME, THE ISFSIs MUST NOT BE APPROVED FOR INDETERMINATE TIME PERIODS, and to even suggest it points out how far the NRC has gone astray. Thus, it is IMPRUDENT for the NRC to create a GEIS for any time exceeding the initial 60-year timeframe which was the original concept for the decommissioning period. Contrary to your assertion, there are too many unresolved items at this time, and we must work quickly to establish a permanent deep-geologic repository, which DOES HAVE safety differences in terms of fewer vulnerabilities to terrorist or wartime attack. (0930-3-4 [Lutz, Ray])

Comment: Exelon agrees with the NRC's determination that it is feasible to have a repository "within 60 years following the licensed life for operation of a reactor." This is strongly supported by international experience. Sweden, Finland, and France all expect to have operating repositories in the first quarter of this century. The primary purpose of predicting a timeframe for repository availability is to provide a reasonable analytical timeline that ensures that all periods of continued storage are evaluated. The NRC has done this. Therefore, the environmental impacts of continued storage, for any length of time, are appropriately analyzed. (0942-9 [Helker, David P.])

19. Comments Concerning GEIS Assumptions – Institutional Controls

Comment: NRC's assumption that "indefinite storage" at reactor sites can go on literally forever, without a loss of institutional control, is absurd. As the environmental coalition's expert witness, Dr. Makhijani of IEER, has pointed out, one of the oldest continuous human institutions in the world, the Catholic Church, is only 2,000 years old. Plutonium-239, for one, will remain hazardous for at least 240,000 years. (0002-3 [Commenters, Multiple])

Comment: There is simply not enough political and financial security in the long term (the real timeline for radionuclides) to support the 'Waste Confidence' rule. (0004-1 [Kelly, Dan])

Comment: I wanted to start by putting this exercise in context today. We all know the government is shutting down, and nobody really expected that, and it hopefully will be a temporary shutdown. But this radioactive waste is going to stay toxic for millions of years, and our government will not exist certainly in that timeframe to make sure that this stuff does not harm future generations. So I think we need to be humble in our relationship to future generations and stop making this radioactive waste. (0030-5-1 [Safer, Don])

Comment: And the shutdown of the government is an indication that it can't be trusted to take care of -- to have institutional controls over radioactive materials for as long as they remain dangerous. It seems incredulous to me that the -- incredible to me that the NRC is seriously talking about being able to afford and have institutional controls and re-containerize the waste indefinitely. Sixty years is a stretch; 160 years is a much longer stretch, but then into infinity pretty much. (0030-8-2 [D'Arrigo, Diane])

Comment: And I know that we have scientists lined up that will tell us that the scientific facilities are available to safely store this nuclear waste, but what we heard earlier is it's the politics. And it's the politics that always makes the mess. As we can see now, this panel might not even be able to function next week because of politics. So while I have faith in our science ability to store this radioactive material, I don't exactly have faith in the humans that are directing a lot of these administrative procedures that are supposed to make this safe, particularly as our friend from Laramie [Mr. Bern Haggerty] was telling us about the transportation difficulties and some of the other people are going to talk about some other things here tonight. (0045-8-3 [Bartlett, Bill])

Comment: So that is the Green Party position. Can we store things in an ideal political climate for long terms? Quite possibly. I'm sure the science is there. But is the human touch there? Is the finesse of our political system there? Is the political will to keep us safe there, when we already know that the shareholders of multinational corporations have the reins of our government. It's been proven. (0045-8-6 [Bartlett, Bill])

Comment: The assumption of facilities being replaced every 100 years has no historically justifiable basis. Historically, no culture or government has existed indefinitely. We cannot assume that our culture and society will continue indefinitely and that resources to maintain these facilities in a properly maintained state will continue indefinitely. Indefinite storage must include a scenario that ISFSI and DTS facilities cease to be replaced and maintained. (0093-1 [Dennis, Harold E.B.])

Comment: The probability of geologic and/or climatologic damage to a storage facility will approach certainty over time. Therefore, the indefinite storage analyses should include such scenarios as likely possibilities. One of the possible results of climate change is a run-away greenhouse effect on our climate and the extinction of human beings (and a significant number of other species). The effect of abandonment of the facilities to such species as might remain needs to be addressed in the indefinite storage analyses. (0093-2 [Dennis, Harold E.B.])

Comment: Conclusions of "SMALL" impact with regard to long term storage under sections: ES.13.1.4 Air Quality, ES.13.1.5 Climate Change, ES.13.1.6 Geology and Soils, ES.13.1.7 Surface-Water Quality and Use, ES.13.1.8 Groundwater Quality and Use, ES.13.1.9 Terrestrial Resources, ES.13.1.10 Aquatic Ecology are not justifiable and are based upon the faulty assumption that the facilities will be properly maintained and replaced at 100 year intervals. As mentioned previously, this assumption is not historically justifiable. The probability that facilities will eventually not be maintained and will be subject to degradation and disruption must be included in the indefinite analyses in order for the conclusions to be scientifically valid. (0093-5 [Dennis, Harold E.B.])

Comment: From a log scale graph on your own website last time waste confidence came up, it takes at least 3,000 years for a spent nuclear fuel rod to cool down enough for its radiological hazard to get down to the same as the ore it was made of. King David of ancient Israel reigned 3,000 years ago. So far about the longest any nation has existed as a sovereign nation, with

rule over an established territory is maybe somewhat over 2,000 years China might have lasted that long. Ancient Egypt until Mark Anthony defeated Cleopatra may have last about 2,000 years. Rome from republic to end of the Byzantine Easter Roman Empire lasted about 1,400. It is NOT acceptable to create hazardous waste that will remain hazardous longer than any sovereign nation has remained a sovereign nation and/or longer than the United States is likely to remain a sovereign nation. (0097-1 [Adams, Grace])

Comment: [T]his document is making the assumption that government will remain unchanged, that everyone will follow the rules, and that there will be no accidents for a million years. This reminds me a lot of Lily Tomlin asking for a dime on Saturday Night Live. It's a joke and it's a rather bad one. There is this little thing called entropy, or Murphy's Law for the colloquial term, and that isn't addressed by this document at all. So just how stupid is this? (0112-20-3 [Robinson, Herb])

Comment: I fortunately don't have the experience of living near a facility nor am I well-educated about nuclear plants. But I do know a bit about history. And remember history class, empires, the rise and they fall? Languages, dead languages, Latin, Greek, no one speaks them anymore. The language of the Egyptians no one knew what -- how to read it until, you know, one of Napoleon's soldiers found the Rosetta Stone. The secrets of old cultures are known to us. The new stones at Turkey, Gobekli Tepe, there's mass standing stones and they date from 1100 years ago. It's a whole culture and it's unknown to us and it's only 1100 years old. Nuclear waste is going to be around a lot longer, okay. Now, the -- going back to the proposed short-term storage, 60 years. What was life like 60 years ago? Okay. When we built things 60 years ago what were they like? What will things be like 60 years from now? Okay. How about 120 years ago? That was 1893. The technology between 1893 and today is significant. Going forward that's 2133. Those are leap years. That's talking about a big difference. So when you think about 60 years, 120 years in our country's social history 60 years we saw a lot of social and political change. 120 years, the same thing. A lot of countries, a lot of peoples no longer exist. Look at old stamp albums, there are countries that no longer are. Those years mean a lot. Our country is an empire. It might no longer be. So how safe is 60 years? Will our empire be around in 120? Well, it hasn't been around for a long time. And so I'm not really sure that I'm good with indefinite storage. I know that there's a lot that's not safe. We don't inherit the wisdom from other empires. We lose it, okay. The Egyptians didn't inherit the wisdom from their previous cultures, the Greeks didn't pass it on, the marvelous interconnection from the -- of the Roman Empire fell apart, the wonderful wonders of the Byzantine Empire fell apart with the bite of a flea. (0112-35-1 [Boyes, Pam])

Comment: The buildings it [nuclear waste] is in will decay. The warnings around it will be unintelligible, okay. (0112-35-3 [Boyes, Pam])

Comment: And after a government shutdown last week, you know, who is going to -- who is watching the stuff when everybody is furloughed? So you know, I can't, you know, have confidence that you're going to keep this together for 240,000 years despite your best efforts. (0163-15-10 [Garner-Ritter, Maureen])

Comment: Who will monitor the waste if the government defaults? I understand from what you said tonight that the plant -- if the plant operates for five years, they have another like 60 years before they consider what they do with their waste. (0163-15-8 [Garner-Ritter, Maureen])

Comment: Second, the NRC assumes that its current regulations are safely managing the waste and that...current regulations will stay in force and will make sure that the waste is safely

managed indefinitely, and that means 60 years, 160 years, and indefinitely means as long as this waste is radioactive, which is 250,000 years. And do you all think Entergy is going to be around in 250,000 years or 60 years? And do you think the NRC is going to be around? So this idea that things are just going to go on as they do now for the indefinite future is just unacceptable to us (0163-2-5 [Musegaas, Philip])

Comment: The Draft Waste Confidence Rule, in this rule the NRC makes the assumption that the storage of spent nuclear fuel poses a sufficient hazard to the environment and to humans that Regulatory controls and oversight will continue indefinitely, decades even centuries after a reactor shuts down. (0163-34-8 [Azulay, Jessica])

Comment: As I'm sure you've been reminded repeatedly, the pyramids in Giza, Egypt are only 5000 years old and we struggle to try to interpret the hieroglyphics written on stones that have survived the ages. Even if we could somehow supernaturally contain this waste in leak-proof canisters forever, what language will we use to print warning signs to future civilizations that may unwittingly uncover our spent nuclear fuel rods 10,000, 50,000 or a hundred thousand years from now? Do we just shrug our collective shoulders and exclaim, "Who cares about what happens that far in the future?" (0187-2 [Friedman, Avram])

Comment: [T]his document is making the assumption that government will remain unchanged, that everyone will follow the rules and that there will be no accidents: For a million years. This reminds me a lot of Lilly Tomlin asking for a dime on Saturday Night live. It's a joke -- and a rather bad one. There is this little thing called Entropy (or Murphy's law if you prefer the colloquial term) and that isn't addressed by this document. Just how stupid is this? (0208-4 [Robinson, Herb])

Comment: The NRC in its consideration of indefinite storage, as identified, cannot assume institutional controls would remain in place for the time frame analyzed. The NRC cannot assure that the spent fuel canisters and casks would be replaced approximately once every 100 years and also that the Independent spent fuel storage installation (ISFSI) and dry transfer system (DTS) facilities would be replaced approximately once every 100 years. The spent fuel material has an extremely long half-life (consider the dawn of civilization to the present the waste material would be hazardous much longer). (0219-6 [Olmstead, Stan])

Comment: The NRC's assumption that "indefinite storage" at reactor sites can go on literally forever, without loss of institutional control, is absurd. As has been pointed out by others, one of the oldest continuous human institutions in the world, the Catholic Church, is only 2,000 years old. Plutonium-239, for one, will remain hazardous for at least 240,000 years. (0230-4 [Garb, James])

Comment: While the NRC has confidence that long-term geologic storage will eventually be found, the public has lost confidence in the NRC to adequately address their unique and important concerns. This is especially true in light of the Draft GEIS and is based on erroneous assumptions and has the NRC confident that spent fuel will be safe onsite for an indefinite period, a period that could be literally forever. Just last month, much of our government was shut down for two weeks prompting the NRC to furlough roughly 90 percent of its employees. How can the NRC guarantee that radioactive waste here in Florida and across the country can remain safely onsite for thousands of years when the public can't even be guaranteed that the Government will be operating next year? The bottom line is this, the public's confidence has run out. We respectfully request that the NRC stop assuming that spent nuclear fuel can be safely stored forever. (0244-3-7 [Hancock, Mandy])

Comment: And then I hear, oh, 60 years, 100 years, and this is well thought out science here, oh, maybe 100, hundreds of years. Hundreds of years? Deadly radioactive for hundreds of thousands of years. Who's going to be the watchdog? This is a joke. (0244-5-3 [Klutho, Mark])

Comment: Assuming that institutional controls will work is absurd. Like this landfill that I mentioned, the Environmental Protection Agency doesn't know our pile of radioactive dirt land. It said so in its documents. It's ridiculous to think that institutional controls will work for centuries let alone a couple of decades. (0245-19-7 [Smith, Ed])

Comment: Lack of assurance exists that institutional controls will be in place 240,000 years or more in the future, the half life of plutonium is only 40,000 years, to oversee continued safe storage. (0245-29-6 [Shineflug, Marilyn])

Comment: We ask that you withdraw all statements to the effect that, because of NRC oversight programs, NRC asserts and guarantees that spent fuel can be stored safely at reactor sites indefinitely. Such a guarantee implies that the NRC will be providing constant oversight into that indefinite period of time. Yet, one month ago, the NRC could not even guarantee that its workers would be able to come to work the next day. The hubris of such an assertion, therefore, borders on colossal. (0245-3-4 [Kraft, David])

Comment: So, my question, based on the NRC's own figure, I have a bunch of them actually, does the NRC have a plan for the next 250,000 years of nuclear waste storage and disaster response? Does the NRC have a financial plan to manage nuclear waste for 250,000 years? Is the NRC prepared to consider potential disasters for the next 250,000 years? Does the NRC feel confident that factors of climate change, change into its 250,000-year plan which would include predicting water shortages, super storms, increased flooding and droughts? Has the NRC planned for the likely population explosion over the next few hundred years? Considering how fracking has been proven by the USGS to produce earthquakes in previously inactive faults, has the NRC figured a way to predict that future generations won't be fracking within a region of nuclear waste storage? Can the NRC prove that humans will be in existence in 50,000, 100,000, 200,000 years to manage this waste? (0245-43-3 [Michaud, Debra])

Comment: "The problem with nuclear," says Hubert Reeves, an astrophysicist, "is that it mortgages the future." Between the time you launch a reactor and the time you dismantle it, more than a century can go by. As a political -- more than a century, there are very few of them in history. We can't talk about political stability on the scale of a thousand years. Imagine the Egyptians had stored nuclear waste, who would manage it today? It's outrageous to think we can manage the future at such times as these. When we look at the history of mankind and all its in our peoples, it's totally outrageous. (0245-43-4 [Michaud, Debra])

Comment: I just want to give some numbers and some people did give already, and one is the 240,000 years that we're talking about when plutonium generates to the point that it doesn't pose a significant threat. And the other is how old is the homo sapiens as a species. And that's probably -- that was jacked up from 150 million to about 200 million. And it may go a little higher, but in fact this stuff is going to be around and be very dangerous longer than we've been a species on this Earth. (0245-45-1 [Aguilar, Margaret])

Comment: [I]t is a very bold assertion about the functionality of this Agency over the next 100 years and more. (0246-22-3 [Fisher, Allison])

Comment: [B]e sure that the Waste Confidence Rule and the GEIS endure changes in national policy that the Congress and the Executive may make or agree upon, or the changes in regulatory policy that this, or a future Commission may make. (0246-4-2 [Callahan, Mike])

Comment: So, basically, I see -- you know, I hear things that sound sort of reasonable, you know. If you don't think that things are ever going to change, but I know they do. I've lived long enough to see that things do not stay the same, and we don't have the control. And with our environment getting worse day by day, we have no idea what kind of weather we might have in South Carolina. (0250-26-4 [Maphet, Sheila])

Comment: As I'm sure you've heard repeatedly, the pyramids in Giza are only about 5,000 years old and we struggle to try to interpret the hieroglyphics written on stones that have survived the ages. Even if we could somehow supernaturally contain this waste in leak-proof containers forever, what language will we use to print warning signs to future civilizations that may unwittingly uncover our spent nuclear fuels 10,000, 50,000 years, or 100,000 years from now? Do we just shrug our collective shoulders and exclaim, "Who cares what happens that far in the future?" (0250-33-2 [Friedman, Avram])

Comment: The Roman Empire would have had to maintain that level of control, if they had made this type of waste. That's not going to happen. I'm sorry. Human history does not support it. (0250-5-7 [Safer, Don])

Comment: What caught my attention is our hubris that we could make nuclear waste safe for 10,000 years. We are thinking the unthinkable. (0250-52-2 [Amos, T.J.])

Comment: If you look up here, you see the lower part of the NRC logo, "Protecting people and the environment." I think that logo needs to be changed to "Protecting people and the environment for all time" because the wastes that we're talking about tonight are going to last a very, very long time. And the NRC has to accept its responsibilities for overseeing it. It is the precursor to the organization of -- how do you say? -- the high priesthood that will be looking after nuclear waste for hundreds of thousands of years. And I hope the NRC will step up to its extreme responsibility in a way that is not obvious from this document. (0250-68-3 [Robinson, David])

Comment: We ask that you withdraw all statements to the effect that because of NRC oversight programs, NRC asserts and guarantees that spent fuel can be stored at reactor sites indefinitely. Such a guarantee implies that NRC will be providing constant oversight into that indefinite period of time. One month ago, NRC could not even guarantee that its workers would be able to come to work the next day. The hubris of such an assertion, therefore, borders on colossal, if not outright psychotic. (0274-4 [Kraft, David])

Comment: Another absurd statement in the draft GEIS is that the wastes will be transferred to new storage casks every 100 years. This would require that government institutions function safely for the quarter of a million years that these wastes will remain lethal. No human institutions have been known to last even ten thousand years, let alone 250,000 years. (0287-6 [Swanson, Jane])

Comment: Section 1-14, institutional controls; we heard that alluded to briefly, earlier, that is the concept that some form of governmental control over this process could possibly exist to an indefinite period in the future. I think we heard mention of societies for 10,000 years, was Jane

Swanson, and so forth; I don't think we need to look that far. Institutional controls, the continued regulation of spent nuclear fuel will continue. This assumption avoids unreasonable speculation regarding what might happen in the future regarding Federal actions to provide for the safe storage of spent fuel. For purpose of this analysis, the NRC assumes regulatory control of radiation safety will remain at the same level as currently exists today. Let me say, we don't need to look back 10,000 years. They are making a provision for 160 years. So I did a little math and I went back 160 years, arrived in the year 1853. There was Federal regulation, or a Federal program in effect at that time. We talk about institutional policies, this was a peculiar institution, you may recognize that phrase; it was called slavery, and it was assumed to be unchanging, and in place, and going to continue. Other metaphors aside for the way we live today, it isn't. You can have a major change in the policy and the Federal government approach to regulation, like human cattle and property, for example, actually changing in our Constitution. So the idea that you can have any form of governmental institution you can be secure about for that long of period is, in our own, almost living memory, an impossibility. (0326-13-1 [Weisman, David])

Comment: My major concern is with the long-lasting nuclear waste. You can tell me anything tonight about how fine the plant is working, and how safe it is for right now; what about the thousands of years in the future? Can you look into the future and say you could guarantee that that will be safe then? (0326-29-1 [Groot, Henriette])

Comment: This is particularly true with complex systems, and it's particularly true with long timespans. The nuclear waste that's generated by these power plants, according to the EPA, I know I've heard numbers like 250,000 years, but the EPA thinks it's a million years. That's 50,000 generations of our descendants who are going to have to take care of this waste so we can boil water for 50 years. One of my deep concerns is that somewhere in those 50,000 generations they're going to learn time travel and they're going to come back and kick our ass for doing this to them. And the people who support the continued operation of these plants, I just want to know what they're response is to these 50,000 generations. What do you say to them to justify your boiling water for 50 years? (0326-34-2 [Phillips, Mark])

Comment: I have serious concerns about the long-term, and potentially, indefinite onsite storage of spent nuclear fuels, and the DGEIS did not lessen those concerns at all. I disagree with it when it determines that environmental impacts of continued onsite storage of spent fuel will be small. In almost every category that they assessed, small, in big capital letters, SMALL, not just over the short-term, up to 140 years old spent fuel, not for the next 100, but of course, indefinitely. And that small means, not detectable, so minor that they won't destabilize or noticeably alter the resources. No one has certain knowledge about the future. We can assess risks, but then we can only conjecture. We don't know what the economic, social, political, geologic, or climactic constraints will be facing future communities and states with the power plants. We don't know how much funding will be available for the personnel, for the maintenance, for the security, that continues to guarantee safety in the storage, no matter what the term, short or long. We don't know, for example, what future emergency response, or evacuation, or relocation capacity would exist, for example, in the area surrounding Diablo Canyon in the event of a catastrophe. No one knows the future water demands of communities across the United States in the future and how that will be impacted by the need for water use or continued storage of spent fuel. We don't know if the licensees will still be in business decades from now, or if funding will be sufficient for the NRC to be adequately monitoring the more and more accumulated fuel that's in storage. I will wrap-up. Yes. I believe that a fundamental flaw, then, in this DGEIS statement are these conclusions as to knowing what is going to happen, and I am deeply concerned that this overconfidence can promote government, industry, and public complacency instead of the vigilance that's needed, instead of

the allocation of resources that is needed. Yes, they are very good at making regulations, but I rarely hear about the word enforcement, and without that, we are all in great danger. (0326-39-3 [Weissglass, Theresa])

Comment: If the ancient Egyptians had built nuclear reactors instead of pyramids, we'd still be guarding their waste for 235,000 years. (0326-40-2 [Wilvert, Rosemary])

Comment: I'm also Maya Lenca. My civilization peaked about 1000 years ago. Our pyramids are still standing. There's no one manning them in terms of dry casking, which requires about, every 100 years, that you swap them out. That is the design. What is the ROI of indefinite cask replacement every 100 years? Indefinite. I understand infinity, and that usually doesn't play very well into ROI calculations. (0326-47-3 [Monge, Roberto])

Comment: Okay, and the thing which is not discussed in this is societal collapse. No civilization has lasted more than 1000 years on this planet. So for us to say that we can safeguard radioactive waste for the next 25 millennia or longer, I think is foolhardy. (0326-56-6 [Homick, Nick])

Comment: I live off Johnson. Everybody speeds down Johnson except for when? Except for when the cop is there. Otherwise they're doing whatever they want. And to think that we can monitor this for time immemorial is insane. (0326-61-2 [Henry, Anita])

Comment: We keep hearing-- now we have PG&E saying it's the government's fault, because my lobbyists made them write these rules that turned everything upside down. I feel like I live in a parallel universe. The people that are in here telling you that, still telling me, that it's safe and clean, what do, who do they think they're talking to? I mean, we've been around for decades, using simple logic, saying what are you going to do with the waste. 250,000 years. We can't read hieroglyphics in Egypt and that's only a couple thousand years ago. (0326-64-4 [Nelson, David])

Comment: Another statement in the Draft GEIS is that the waste will be transferred to new storage casks every 100 years. This would require that government institutions function safely for the quarter of the million years that these wastes will remain lethal. No human institutions have been known to last even 10,000 years, let alone 250,000 years. (0326-8-6 [Swanson, Jane])

Comment: [H]ere we are in the Commodore Ballroom, Commodore Perry, Perrysburg, War of 1812, 200 years ago there was a war raging in this neck of the woods. What's going to happen in the next 200 years, the next million years that this waste will remain dangerous. (0327-10-6 [Kamps, Kevin])

Comment: I'm an architect, and I can attest that humanity has never built anything that lasted this long no matter how many plumbers and electricians were involved. And if you give me \$500 billion, we'll have as many jobs as anybody needs, and they won't involve nuclear pollution. I think there's a dangerous presumption that's being made, and that is that we will have ongoing agency, government, corporate, or public competence. (0327-14-1 [Ellison, David])

Comment: Rolling stewardship of the radioactive mess we made should not be an option. It is a requirement. (0327-20-4 [Clemons, Victoria])

Comment: Everyone is familiar with the Seven Wonders of the Ancient World. Six no longer survive. Only the pyramids are still standing, but they have been dealing with problems from erosion, even though they have been in a mostly dry environment over their four- to five-

thousand-year existence. Now, we, as a society, are talking about constructing facilities that must last 50 times as long, a minimum of 240,000 years -- that's ten plutonium half-lives -- probably longer to contain plutonium, one of the most poisonous substances on earth. We cannot afford errors, even minor errors, if future generations are to live normal lives as we have. We must be absolutely sure that such waste containment will succeed. Here are a few questions that I have. What evidence do we have that waste-containment structures will survive for 50 times as long as the longest surviving structures, especially when they are continuously bombarded by radiation and extreme heat? How can we be sure that for the next 7,000 generations that people will, at all times, be able to maintain waste-storage casks as needed? With climate change and geological changes over this period, will there be geological changes that we cannot foresee now that will affect the integrity of waste containment or geological repositories? Nuclear waste can be reprocessed into nuclear weapons or into dirty bombs used by terrorists. How can we guarantee that these facilities will be continuously guarded for 7,000 generations? (0327-30-1 [Parker, Bob])

Comment: In the 1950s, the nuclear energy agency promoted nuclear power as too cheap to meter, meaning atomic energy was so cheap that there would be only installation costs, not usage fees. This turned out to be far from the truth. Today, we cannot accept the proclamations of safe nuclear disposal by proponents of nuclear power who have a vested interest in the construction of more nuclear plants. Already at the Hanford Reservation, radioactive waste containers are weakening after only 70 years or less. Of course, there have been fixes, but will they last 200,000 years? (0327-30-3 [Parker, Bob])

Comment: The time periods that are assumed that there will be institutional controls is quite a stretch to being ridiculous. Remember, the lifetimes of the pyramids and, I'm sorry, the Roman Empire is not very long. Underground storage is the only thing that will come anywhere near close to indefinite containment, and when you lose institutional controls you lose the ability to demand action to re-cask things. (0327-36-6 [Lamberger, Paul])

Comment: How long has the longest civilization in history lasted? The Roman Empire lasted around 2,000 years. How will nuclear waste be guarded when civilizations collapse? (0327-4-2 [Marida, Patricia])

Comment: Whether or not we wish to speak it, there will be a rolling custody of the waste and the canisters through the generations to come. They will have to deal with it in the manner of their best technology as radioactivity and time weaken the canisters and the rods must be placed in new isolation. For this to happen, we must also make every effort to ensure that civilization itself does not collapse. (0327-4-6 [Marida, Patricia])

Comment: As Dakota people, we know how the world can change in 100 years. Just last year we commemorated the 150-year anniversary of the Dakota Conflict. The Dakota ceded the first tract of land in what is now the State of Minnesota in 1805; 208 years later our land base is reduced to just 3,000 acres, and our reservation is along the flood plain of the Mississippi River. And the Federal government thinks it can make a 10,000-year promise to deal with nuclear waste. (0328-1-9 [Johnson, Ron])

Comment: So, instead of saying that we assume, we will assume that institutional controls will remain in place, what this document -- what I, as a citizen of the United States need this document to do is to lay out guidance for institutional controls for each of those storage periods. (0328-12-3 [Eide-Tollefson, Kristen])

Comment: Finally, the third issue, the GEIS assumes that there is going to be institutional control or a longevity to ensure that all of the obligations associated with the spent fuel left behind are met. The underlying assumption of institutional control is that there will be appropriate funds to insure that these activities of inspection, maintenance, repair, and replacement are taken care of. Yet, nowhere does the GEIS indicate where these funds are, or how they will be provided. This assumption that the funds will be available at some far future date without actual verification of their existence today represents potentially an intergenerational shift. Those whom receive the benefits of the low-cost electricity from nuclear power will not be obligated for the byproduct of the same. Rather, the cost will be shifted onto the next generation, two, three, or four, or as Ron says, seven, to that it is properly stored and disposed of. Sharing this burden and responsibility as a host city like Red Wing, whose residents many generations down the line will still have the obligation to maintain emergency preparedness. In the event that there is failure of institutional control, pick up the burden themselves. The assumption of institutional control,.....is simply too important to assume. (0328-2-7 [Rauterkus, Ralph])

Comment: The Draft Environmental Impact Statement simply raises more questions than it answers. What is the legal and factual basis for the NRC's assumptions that the casks will be reloaded every 100 years? Considering that the operating licenses for many plants, including the plant at Prairie Island will expire in 20 years, how do we know that the utilities will even be around in 100 years? What if the United States Government reneges on its promise and fails to rebuild the casks, rebuild the ISFSIs and to reload the casks every 100 years? (0328-3-3 [Mahowald, Philip])

Comment: But institutional controls, we have a definition of what that means provided for the record this evening from the City of Red Wing, what that means. What it means at just a very superficial level, where's the money? Considering the rate at which we are eroding the ecological foundation of this society, not just with the reactors but with central station energy, in general, in 100 years, in 50 years, in 200 years, by what right do we claim there will be a United States of America? By what right? (0328-7-1 [Crocker, George])

Comment: Institutional controls, and that's an assumption that you guys need to go forward with this. I think you need to reconsider your institutional control assumption. (0328-7-3 [Crocker, George])

Comment: I think assuming that our societal institutions will be intact and able to replace these dry casks once per century, even if it's less often than that, it's a huge assumption and I think it borders on the absurd to assume that even our current culture and society will be able to do this indefinitely into the future when, in fact, Keith McConnell, the director of the Nuclear Waste Confidence Directorate, did confirm several weeks ago that there is no cutoff point on this confidence and this assumption that the dry cask storage infrastructure will be replaced once per century forever, literally forever. So that right away is absurd. That cannot be assumed. And just to conclude this, I want to point out that some of the oldest known human institutions, things like the Catholic Church, about 2,000 years old, Buddhism perhaps 2,500 years old, perhaps some indigenous people or cultures could be looked to that extend even further back in time. But any of those examples are small by way of comparison with the radiological toxicity of the material this industry generates in order to make its profits. So I think that those assumptions have to be corrected in the final Generic Environmental Impact Statement. A strong dose of reality needs to be introduced. (0329-11-2 [Kamps, Kevin])

Comment: And the courts did order the Nuclear Regulatory Commission to look at the list of storage, well, certainly onsite in dry casks and pools, but also NRC has a whole chapter of away-from-reactor storage, and so there, too. The risks of these containers failing or lack of institutional control, abandonment of these facilities and their eventual simple corrosion and erosion with the elements and releasing their contents into the living environment, that is the risk that we face. The NRC has not analyzed it in any meaningful way in this document and needs to do so. (0329-11-3 [Kamps, Kevin])

Comment: The TVA has not been around for a hundred years and, quite frankly, there's a pretty good question about whether the Tennessee Valley Authority will look anything like it does or even exist a hundred years from now. So that assumption that this human institution, subject as it is to both economic and political frailties, is going to be here to protect the public from cask storage waste is pretty unrealistic. (0329-12-5 [Paddock, Brian])

Comment: I could see -- did we ever manage to contain, long-term, these casks that we're talking about, dry storage, or whatever? Future generations, way in the future, if we are ever even around still then, are going to come upon this and could recontaminate because they won't understand. But I don't want to get too far down that pathway. (0329-29-2 [Messer, Diane])

Comment: [Y]ou do not address the fact that no civilization and no human institution has lasted for thousands of years. And so you don't have a credible plan for mitigating the risks of environmental contamination in the event of the government's failure. Our government has been here for what, 250, 80, 75 -- I don't know -- years. I don't know how many governments have lasted for thousands of years. I think zero. I think zero is the number. So your foresight is very inadequate. (0329-32-7 [Seeley, Linda])

Comment: The NRC's assumption that "indefinite storage" at reactor sites can go on literally forever, without a loss of institutional control, is absurd. As Dr. Makhijani of the Institute for Energy and Environmental Research has pointed out, the Catholic Church-one of the oldest continuous human institutions in the world-is only 2,000 years old. Plutonium-239, for one, will remain hazardous for at least 240,000 years. (0336-7 [Lish, Christopher])

Comment: Between 11,000 and 23,000 years ago, the Bering Strait - also known as the lost continent of Berengia - formed a land bridge between Asia and North America which people crossed during the Ice Age to form some of the founding populations of Native Americans.³ [footnote 3 text: About 12,000 years ago, a major outbreak occurred on Lake Agassiz, which some experts estimate was as large as the current Black Sea. And 14,800 years ago, areas of the current Sahara desert were wet and fertile with full aquifers. Some 25,000 years ago the area now occupied by New York City was covered with ice roughly a mile high. These facts are noted to illustrate that dramatic natural events occur which dramatically transform waterways and landscapes.] (Interesting aside, Native American tribal lands are among the areas most ravaged by 20th Century uranium mining and Native American lands are identified in the GEIS as a place for large long-term nuclear waste storage! But we digress.) The half-life of Plutonium 239 (Pu-239)⁴ [footnote 4 text: Plutonium emits alpha particles that can be inhaled into the lungs. If it enters the bloodstream, plutonium moves throughout the body and into the bones, liver, or other body organs. Plutonium that reaches body organs usually stays in the body for decades and continues to expose the surrounding tissue to radiation.] is 24,100 years. So, if Upper Paleolithic cultures had come up with nuclear power, we would still be dealing with their nuclear waste. Luckily for us, they were just spearing mammoths. The point which we hope is not being too subtly made is that the NRC's assertion that it can surmise the impacts of nuclear waste tens of thousands of years - hundreds of thousands of years, or whatever the notion of

"indefinite" is - is simply ludicrous. It is so absurd that it casts serious doubt on the credibility of the GEIS in its entirety. (0341-1-21 [Mermelstein, Richard])

Comment: Less inane, but also implausible, is the assertion the NRC can predict the situation over the "Long-Term Storage" period of 200 years hence. Again, reflection upon the past provides perspective. Two hundred years ago, Napoleon Bonaparte was battling Prussia, James Madison was president, and America was fighting the War of 1812 against England. In fact in December 2013, the British burned Buffalo, New York. Two hundred years ago America still had slavery. Two hundred years ago, the population of the United States was 7.5 million. The petroleum industry did not yet exist. Sperm whale oil was still a major source of energy. There was, of course, no automobile pollution (although horse manure droppings were evidently an issue), there were no Superfund sites. Rivers were still clean enough to drink and fisheries were barely imperiled. (See, e.g., Daniels.) Thus, while it may be reasonable to believe that dry casks and independent spent fuel storage installations (ISFSs) have the technological capacity under specified conditions to contain nuclear waste for that duration, there is no reasoned basis to conclude that prevailing environmental, political, or social conditions will properly support enduring containment. (0341-1-22 [Mermelstein, Richard])

Comment: Further, today's viable and well-operated company can become tomorrow's failed corporation. This does not require a nuclear accident, just a financial disaster. (Enron.) In fact, the NRC regulatory scheme seems to have given no thought to what would or could happen if an operator goes bankrupt. This is exactly what has led to the nation's numerous (and desperately underfunded) Superfund sites. Who will be left footing the bill for all this waste?¹¹ [footnote 11 text: Answer: The American taxpayers. (See Taxpayers for Common Sense; Wald, 2008)] If the NRC really believes that nuclear operators who will no longer be pumping profits out of their old machines in 10 or 20 years will stick around to spend the following 100 or 200 years maintaining and cleaning up their defunct operations, we have a wonderful deal for you: Mars condo, ready for move-in, river view. (0341-2-11 [Mermelstein, Richard])

Comment: Plans and Laws on the Books Suffice. Over and over again the GEIS notes a potential hazard or impact and then just waves it away with the wand that the NRC/ industry has a plans or will have plan to deal with the issue. Similarly, again and again, the GEIS cites legislation or postulates that laws will be passed to deal with potential problems. But having plans and laws does not constitute evidence of either adequate protection or lack of major impact. To put it as a math equation: Plans + Laws ? SMALL impact. (0341-2-13 [Mermelstein, Richard])

Comment: At the top of the list of overoptimistic assumptions is the GEIS's repeated assertion that if there is a problem, the NRC will catch it in time. There is, of course, a vast library of documentation of past NRC failures. (See, e.g., GAO; NRC; Lochbaum; and UCS.) Allowing the possibility that the current NRC is comprised of omniscient and perfect actors, the GEIS still cannot assert that this state of affairs will continue for hundreds (or thousands) of years. Alas, as a matter of pure logic, the current NRC cannot reliably depend upon the future NRC being as fabulous as the present. The GEIS also postulates that other agencies will step in as needed, as needed. The same logical flaw applies here as well. Perhaps the most silly assertion is that Congress will step in to help as needed with just the right legislation. Do we even need to respond to that one? (0341-2-9 [Mermelstein, Richard])

Comment: There is nothing scientific about NRC claims that it can guarantee the safe storage of nuclear waste for a million years. This waste contains plutonium & uranium with half-lives of 24,000 years and ten billion years, respectively. You needn't have any expertise, just a little

commonsense to realize how insane this is. One million years takes us to the Calabrian stage of the Pleistocene era, a period of which we know very little, hundreds of thousands of years prior to the emergence of the Neanderthal. But going forward in time, we know little if anything about events a decade from now, and we have no way to know anything about conditions ten thousand centuries from now. That the word 'confidence' is used by the NRC when talking about safeguarding radwaste for a period of time five hundred times greater than the Christian era is preposterous! There is no proven technology to displace something for a million years. Not for 100,000 years, not even for 10,000 years. The longest lived man-made structures are the pyramids. They've been around for 5,000 years and they failed at their intended purpose. (0348-10 [Agnew, David] [Roscoe, Lee])

Comment: There is nothing scientific about NRC claims that it can guarantee the safe storage of nuclear waste for a million years. This waste contains plutonium & uranium with half-lives of 24,000 years and ten billion years, respectively. You needn't have any expertise, just a little commonsense to realize how insane this is. One million years takes us to the Calabrian stage of the Pleistocene era, a period of which we know very little, hundreds of thousands of years prior to the emergence of the Neanderthal. But going forward in time, we know little if anything about events a decade from now, and we have no way to know anything about conditions ten thousand centuries from now. That the word 'confidence' is used by the NRC when talking about safeguarding radwaste for a period of time five hundred times greater than the Christian era is preposterous! There is no proven technology to displace something for a million years. Not for 100,000 years, not even for 10,000 years. The longest lived man-made structures are the pyramids. They've been around for 5,000 years and they failed at their intended purpose. (0352-10 [Roscoe, Lee])

Comment: NRC's assumption that "indefinite storage" at reactor sites can go on literally forever, without a loss of institutional control, is absurd. Dr. Makhijani of IEER, has pointed out, one of the oldest continuous human institutions in the world, the Catholic Church, is only 2,000 years old. Plutonium-239, for one, will remain hazardous for at least 240,000 years. NRC "indefinite storage" scenario is delusional. It assumes dry cask storage -- cask pads, inner canisters, and the dry casks themselves --will be replaced once every 100 years, forevermore into the future. (0377-5-17 [Cuthbert, Lewis])

Comment: The long time period of spent fuel storage presents another problem, that of securing the fissionable material from misappropriation and misuse. As the fuel ages and the radioactivity decreases it becomes more attractive as a target for theft and extraction of its plutonium content. The USA is less than 240 years old so that is all the experience we have as a republic. Over the next few centuries, while the fuel remains "hot," I submit that we have no way of predicting what sorts of situations might occur. We cannot, therefore, be "confident" that the current political and economic systems will continue to provide the physical security, in perpetuity, needed to keep the fissionable materials safe. (0410-22 [Nelson, Dennis])

Comment: It is telling that the NRC uses the term "confidence" when talking about safeguarding nuclear waste. Going BACK in time, one million years takes us to the Calabrian stage of the Pleistocene era, a period of which we know very little, hundreds of thousands of years prior to the emergence of the Neanderthal. But going forward in time, we know little if anything about events a decade from now, and we have no way to know anything about conditions ten thousand centuries from now. That you dare use the word 'confidence' when talking about safeguarding radwaste for a period of time five hundred times greater than the Christian era is preposterous! (0419-2 [Agnew, David])

Comment: Rolling Stewardship is a relatively new concept. It was first introduced in the 1995 by the National Research Council, the working arm of the United States National Academies, which produces reports that shape policies. The study, "Improving the Environment", called direct attention to the concept of "Rolling Stewardship" as an important option for addressing contaminated sites that pose significant cleanup challenges. "Rolling stewardship" means planning for stewardship one generation ahead; by doing it one generation at a time with continuity of knowledge and effort. Rolling Stewardship of the radioactive mess we have made...IS NOT AN OPTION...IT IS A REQUIREMENT. (0421-6 [Clemons, Victoria])

Comment: Spent fuel rods take about 3,000 years to cool down to the same amount of radioactivity as in all the ore it took to make the fuel rods. 3,000 years is as long as from the reign of King David of ancient Israel to now and longer than any sovereign nation has lasted as a sovereign nation so far. (0439-1 [Adams, Grace])

Comment: Given NRC's flawed use of probabilities in risk assessment, the agency should also critically examine the probability of the very existence of a functional regulatory agency within the extended time frames described. (0447-2-4 [Andrews, Richard])

Comment: Enriched and used in the reactors fission process, the so-called "spent" fuel becomes more radioactive and unstable so must be removed and stored under very controlled conditions for A MILLION YEARS! BUT NO SAFE PLACE EXISTS OR HAS BEEN PLANNED TO STORE IT. How many human generations will be responsible for those controlled conditions? What geologic changes will take place on this dynamic planet in that period? Will humans even exist to safeguard the planet from it? It is not within human power to foresee cataclysmic natural events and less so volatile political events in the next 60 years, or even until 2024. (0450-2 [Bast, Nancy])

Comment: For the long term, a plan which assumes a stable society and social fabric which will continue required maintenance of on-site nuclear waste storage for many hundreds to thousands of years into the future is a stretch too far. History teaches us that governments, countries and civilizations arise, change and collapse quite frequently. There is no reason to believe the United States is exempt from this process of change and collapse. (0451-4 [Rippner, Sharon] [Rippner, Thomas])

Comment: This type of irrationality only lends strength to the argument that we cannot confidently predict that future generations will act responsibly when handling the dangerous waste we're leaving in their hands. (0454-11 [Waldstein, Joe])

Comment: The NRC's flawed environmental study is based on a number of unrealistic assumptions that must be reconsidered. The NRC assumes that current regulations and oversight, and the current corporate ownership of each reactor, will continue indefinitely after the reactors are shut down, and will be enough to ensure that the waste is stored safely for thousands of years. By relying on this assumption, NRC has improperly failed to consider what impacts would occur if so-called "institutional controls" fail. (0465-2 [Commenters, Multiple])

Comment: The GEIS assumes that "institutional controls" (i.e. NRC regulation of site owners/operators who are willing and able to meet NRC regulations) are in place as long as there is wet or dry storage on any commercial site. The recent government shutdown should give pause to the assumption that institutional controls will remain in place and effective indefinitely. Current NRC regulation is of an industry that is profitably generating power, assumes it has a future, and understands that an assurance of safety is a necessary pre-

condition for its future. Under "continued storage", alternative assumptions regarding institutional controls warrant consideration? e.g. a future in which a less well-funded NRC is regulating an industry that is no longer producing power, and an industry for which regulatory costs are no longer a manageable expense in a profitable overall operation. Does the GEIS and proposed rule consider that "institutional controls" might become weaker and less effective, even if still "on the books"? (0505-8 [Williams, Jim])

Comment: The Fukushima disaster makes clear that the problem of nuclear waste storage is ongoing. To pretend to be able to guarantee safe storage of nuclear waste for a quarter of a million years is preposterous. You know it, we all know it. (0530-1 [Proeller, John])

Comment: No human social structure has been stable on the time scale required to handle nuclear waste. The continued presence of these wastes is an ongoing threat to our health, democracy and transparency (0531-2-16 [Morgan, Sally])

Comment: The environmental impact determinations that impacts would be small in almost all scenarios are accurate and should not be surprising. Storage is a largely passive activity requiring a relatively small construction scope followed by monitoring. Assuming institutional controls to exist in perpetuity, guarantees impacts to be small. Any responsible implementer (e.g., utilities) and regulator (e.g., NRC) would make sure of that. The real issue for this analysis is whether or not a "no institutional control" scenario must be evaluated in more detail. NRC states that such a scenario is not reasonable and points to its comments on the Yucca Mountain EIS, where a no institutional control scenario was evaluated, that it has not changed its opinion on the reasonableness of such a scenario. Regardless of reasonableness, NWRPO agrees with NRC that reevaluation of such a scenario is unnecessary. However, the reference to such a scenario in GEIS section 1.8.3, Analysis Assumptions, should be expanded to explicitly acknowledge that if all maintenance and monitoring of spent fuel storage was to end, after 1,000 years or so at some locations, environmental impacts would be large. This assumes no human action to keep storage facilities maintained and safe or even action to avoid impacts. Any new analysis would yield similar results. Perhaps the no institutional control scenario is speculative and not reasonable as NRC states, but the GEIS should at least acknowledge that a repository scenario under the same no institutional control assumptions results in extremely small impacts. At a repository under Yucca Mountain standards and likely any other future standard, the environmental and safety impacts for 10,000 years and beyond, even assuming no human intervention, would be a very small radiation dose to a reasonably maximally exposed individual. Essentially there would be no human health and safety impacts from repository disposal. (0544-11 [Enriquez, Elizabeth])

Comment: The following sentences in the footnote [Footnote 2 on pages 1-14 and 1-15 of the GEIS] related to the Yucca Mountain FEIS contain inaccurate statements shown in bold [italics] below. DOE's approach to the loss of institutional controls at a dry cask storage facility was provided in its Yucca Mountain EIS (DOE 2008). In its analysis, DOE found that the loss of institutional controls resulted in catastrophic impacts for several resource areas. *These approaches to institutional controls were related to post-closure buried radioactive waste and are not relevant to the indefinite dry cask storage of licensed spent nuclear fuel considered in Waste Confidence. A dry cask spent nuclear fuel storage facility is not sited, designed, or built to avoid active maintenance like a low-level waste disposal facility.* Further, at some period beyond the closure of the disposal facility, increasing the likelihood that an inadvertent intrusion could occur. In contrast, a dry storage facility is typically a visible surface structure requiring active maintenance and security, making loss of institutional control so unlikely that it is a remote and speculative occurrence. Given that the National Environmental Policy Act does not

require consideration of remote and speculative issues, this analysis has not been included in the GEIS. In fact, the Yucca Mountain Final EIS did evaluate loss of institutional controls related to continued storage of commercial spent nuclear fuel. GEIS page 1-15, lines 6 to 15 accurately reflect what the FEIS analyzed, although the reference should be DOE 2002 (the FEIS) versus DOE 2008 (the Supplemental EIS). The words in the footnote could be modified, as follows, to be correct. DOE's approach to the loss of institutional controls at a dry cask storage facility was provided in its Yucca Mountain Final EIS (DOE 2002). In its analysis, DOE found that the loss of institutional controls resulted in catastrophic impacts for several resource areas. A dry storage facility is typically a visible surface structure requiring active maintenance and security, making loss of institutional control so unlikely that it is a remote and speculative occurrence. Given that the National Environmental Policy Act does not require consideration of remote and speculative issues, further analysis has not been included in this GEIS. Perhaps a better alternative (or in addition to) the suggestion noted above for the footnote would be to expand the discussion of the Yucca Mountain Final EIS (DOE 2002) in the bullet beginning on p. 1-15, lines 6 to 15. An addition should be added after the statement beginning on line 7, "In particular, the DOE considered a specific scenario in which spent fuel and high-level radioactive waste would remain in dry storage at commercial and DOE sites and would be under institutional controls for approximately 100 years, and beyond that time, it was assumed there would be no institutional controls." The addition should pick up the point made in the footnote and provide a slight expansion. Suggested words follow. Suggested Addition: In its analysis, DOE found that the loss of institutional controls resulted in catastrophic impacts for several resource areas. At the end of the same bullet on p. 1-15, line 15, the following addition is also suggested. Suggested Addition: Repeating the existing DOE Yucca Mountain Final EIS analysis would serve no useful purpose. NRC continues to believe that a no-institutional-control scenario is highly speculative and does not represent a reasonable assumption. Given that the National Environmental Policy Act does not require consideration of remote and speculative issues, the Yucca Mountain Final EIS no institutional-control analysis has not been replicated in this GEIS. (0544-26 [Enriquez, Elizabeth])

Comment: First, how can the NRC assume the utility in question will remain solvent or fiscally whole for a period of up to 160 years after cessation of energy production at a nuclear facility? Bankruptcy in the energy producing field is not an unknown occurrence and a protracted proceeding could take decades, involving federal intervention (SEC), litigation among insurance companies, and host of widely unpredictable variables. (0547-2 [Weisman, David])

Comment: Assumptions about long term "Institutional controls" are haphazard at best. The GEIS at (1-14) is captioned: Institutional controls would be in place. Institutional controls, i.e., the continued regulation of spent nuclear fuel, will continue. This assumption avoids unreasonable speculation regarding what might happen in the future regarding Federal actions to provide for the safe storage of spent fuel. Although government agencies and regulatory safety approaches can be expected to change over long periods of time into the future, the history of radiation protection has generally been towards ensuring increased safety as knowledge of radiation and effectiveness of safety measures has improved. For the purpose of the analyses in this draft GEIS, the NRC assumes that regulatory control of radiation safety will remain at the same level of regulatory control as currently exists today. [emphasis added] Such assumptions about the long term stability of regulatory control and institutional succession are baseless for an agenda that has a presumed time span upwards of 160 years. 160 years ago, in the United States, there was a "peculiar institution" of slavery, the enforcement of which was codified in law and justified in the Constitution. To a large segment of the U.S population for which an entire economy was dependent, this was largely viewed as not just viable, but justified and unchanging. And yet, this institution and the population which was dependent--or subject--

to it, was completely overturned in a span of time less than the current licensed life of a radioactive waste cask. (0547-4 [Weisman, David])

Comment: The unsupported assumptions include: Institutional controls will indefinitely remain in place and be at same level of regulatory control as currently exists today. (0556-2-2 [Lampert, Mary])

Comment: Institutional controls/current technology & regulations are not consistently followed today. There is no reason to believe that they will be in the future--especially into a future of 300 or more years. Examples where regulations are not consistently followed today: a. A report, "*Safety Culture is not Possible without Regulatory Compliance*" Paul Blanch, September 2013 ¹³ [footnote 13 text: <http://allthingsnuclear.org/wp-content/uploads/2013/09/20130900-blanch-regulatory-compliancereport-.pdf>] shows that the NRC has neither identified nor enforced, and licensees have not complied with NRC regulations so that the assumption that institutional controls would be in place and enforced does not hold in the future anymore than today. [Images of Text Box Submitted with Correspondence ML13354A021] b. The Union of Concerned Scientists reports that fire poses a very significant safety risk and NRC issued fire safety regulations in 1980 and an alternate set in 2004. But thirty years later, nearly half of the licensees do not comply with the regulations. The NRC is playing with fire and not enforcing its own regulations.¹⁴ [footnote 14 text: http://www.ucsusa.org/assets/documents/nuclear_power/ucs-nrc-fire-regulations-5-2-13.pdf] c. UCS's third annual review of the Nuclear Regulatory Commission's performance in policing the U.S. nuclear power industry:¹⁵ [footnote 15 text: http://www.ucsusa.org/nuclear_power/making-nuclear-power-safer/who-is-responsible/nrc-and-nuclear-powersafety-annual.html] The report takes the NRC to task for its failure to consistently enforce its own regulations, effectively leaving long-term holes in the safety net that is supposed to protect the public from the inherent hazards of nuclear power. According to the report, the NRC's lax oversight "reflects a poor safety culture," including a disconnection between the NRC's workforce and its senior management, with managers tending to downplay safety problems and react negatively when workers point them out. d. As discussed in the foregoing, there is evidence of regulators covering up problems during operations. There is basis for projecting that the same will hold true after operations have ceased. For example: "In a letter submitted Friday afternoon to internal investigators at the Nuclear Regulatory Commission, a whistleblower engineer within the agency accused regulators of deliberately covering up information relating to the vulnerability of U.S. nuclear power facilities that sit downstream from large dams and reservoirs. The letter also accuses the agency of failing to act to correct these vulnerabilities despite being aware of the risks for years." (Flood Threat to Nuclear Plants Covered Up By Regulators, NRC Whistleblower Claims, Huffington Post, Sept. 14, 2013) e. As shown in the foregoing, federal, state and NRC requirements are not followed to protect Cape Cod Bay and its aquatic resources, special status species & habitats. f. It is absurd to rely on a "crystal ball" to project assurance into the distant future. NRC cannot rely on its "crystal ball." It is one thing to make future projections based on actual past history. But there is no long history here to rely upon to make projections about future decades and centuries. No reactors have operated more than 45 years. There is no assurance that the same or equivalent regulatory bodies will exist 100, 200 300 years or more into the future. Simply by looking back to institutions and technology in 1713, 1813, and 1913 shows the absurdity of the assumption that institutional controls/current technology & regulations would be in place and be at same level of regulatory control as currently exists today. (0556-2-5 [Lampert, Mary])

Comment: The GEIS assumes institutional controls would be in place into the future, and that spent fuel canisters, casks, independent spent fuel storage installations and dry transfers

system facilities would be replaced once every 100 years. (ES, p. xxviii) The NRC believes this will be enough to ensure that the waste is stored safely hundreds and thousands of years into the future, and fails to consider what impacts would occur if these institutional controls fail. (0604-6 [Pisha, Gayla])

Comment: During our circle discussion toward the end of the December 4, 2013 Hearing in Minnetonka, NRC staff acknowledged that cost factors analyzed by the Draft GEIS were limited to administrative costs associated with the various scenarios examined by the Draft GEIS, and that the administrative cost-benefit balance between the proposed administrative action and administrative alternatives was the reason for selecting revisions to 10 CFR 51.23 as the preferred alternative. However, NRC Staff also acknowledged that nowhere in the Draft GEIS is there any accounting of the financial costs of actually performing the functions specified in the various spent fuel management scenarios. Without accounting for the costs of performing the functions required for institutional control of irradiated fuel, which are massive, any assumption of institutional control is deluded nonsense. (0608-10 [Crocker, George])

Comment: Miss-Assumption Regarding Institutional Controls Being In Place. Without the assumption that institutional controls would be in place (Draft GEIS, xxviii), the entire Draft GEIS totally unravels. Yet, the primary if not the entire justification for this assumption is contained in a footnote in Section 1.8.3, which says in significant part that several Federal agencies rely on institutional controls that, "typically include enforcement tools to address potential problems involving improper or incomplete implementation, maintenance, and breaches of institutional controls. Examples of institutional controls include permits, Federal Facility Agreements, and environmental covenants that apply continuously with present and future ownership of the subject property (under either state statute or common law (EPA 2012))." Ignoring the circular logic, that institutional controls would be in place because Federal agencies rely on institutional controls, this list of attributes is fatally incomplete in terms of identifying and defining the types of institutional control required for long-term safe and secure nuclear waste management in the scenarios presented by the Draft GEIS. For example, where is the analysis that allows us to assume that the nuclear industry will be able to maintain a work force with enough technical knowledge and expertise to perform the functions needed to manage Independent Spent Fuel Storage Installation (ISFSI) and Dry Transfer System (DTS) facilities 60 years from now, or 160 years from now, or 260 years from now? Where is the probability analysis that establishes the confidence boundaries that the required skills will be available? (0608-6 [Crocker, George])

Comment: If commercial nuclear power fails to compete economically in terms of providing electric utility services throughout the storage period, the talent pool of engineers and technicians possessing the required skills will continue diminishing and then, without extraordinary measures, disappear. What is the probability that this will happen? What is the contingency for managing ISFSI and DTS facilities if it does happen? The assumption that institutional control will be in place cannot be valid without answers to these questions, but the analysis required to answer these questions is not contained in the Draft GEIS and the need for such an analysis is not even discussed. This glaring failure pales in comparison to issues surrounding financial costs of maintaining institutional control. For any business plan to have validity, whether it's for a football stadium, operating a shopping mall, or managing nuclear waste, it must include viable financing. Pretending that institutional control can exist without accounting financially for that control, which this draft GEIS does, is grotesquely self-serving but stunningly incompetent. (0608-9 [Crocker, George])

Comment: The EIS should include past studies such as "Expert Judgement on Inadvertent Human Intrusion into the Waste Isolation Pilot Plant" Sandia Report SAND90 -- 3063, UC -- 721,

December 1991) and Expert Judgement on Markers to Deter Inadvertent Human Intrusion into the Waste Isolation Pilot Plant (SAND92 -- 1382, UC -- 721, November 1993). (0610-8 [Brechtin, Vernon])

Comment: The lethal legacy of nuclear waste is the Achilles heel of the nuclear industry. There is clearly a lack of confidence in any plan for short term, long term or indefinite nuclear waste storage, since human knowledge is limited to less than 24,000 years. (0611-23 [Shapiro, Susan])

Comment: Prof Guy McPherson of the University of Arizona states that collapse of many systems is imminent. I state that the collapse of the funding for a geological repository will depend on many of these societal structures that may not survive global warming for the next few decades per Dr. McPherson. Will the NRC analyze and explain how the NRC can expect a financial stream to build a geological repository in the face of collapse of the money system as a consequence of global warming? (0615-3 [Lewis, Marvin])

Comment: It blatantly sidesteps the fact that most of this waste will last tens of thousands of years and that recent history has demonstrated that "institutional controls" in no way guarantee that the public health and safety can be protected from its ill effects. (0620-5 [Rivera, Evelyn])

Comment: Chief among the issues to address environmental impacts of continued storage is the capacity of the owner to maintain safe and efficient operations around the clock. For pool storage, this includes maintaining electrical power at 100% reliability for the life of all facilities in the U.S. However, no owner accountability is discussed in the DGEIS. The analysis assumptions in Section 1.8.3 discusses spent fuel and high-level radioactive waste stored under institutional controls at DOE sites. Are we to assume that DOE will maintain institutional controls-i.e., ownership of all national spent fuel repositories and thereby assure continued maintenance? When is a spent fuel pool or ISFSI considered a national "repository"? (0622-1-10 [Vale, Karen])

Comment: In short, the Commission must simply be sure that the Waste Confidence rule and the GEIS endure through changes in national policy that the Congress and the Executive Branch may agree upon or the changes in safety policy that this or a future Commission may make. (0637-11 [Norton, Wayne])

Comment: Instead of fully examining the risks of spent fuel storage, the NRC incorrectly assumes that spent fuel can and will be safely stored above ground indefinitely and that government institutions will be able to adequately regulate and oversee that activity forever. It assumes a physical, social, and political world so static that spent fuel storage containers can be replaced approximately once every 100 years until the end of time. (0646-16 [Hanson, Courtney])

Comment: The United States is less than a quarter millennia old, civilization took root a bare 6,000 years ago and a scant 10,000 years ago our ancestors began to develop agriculture. Clearly the world can change drastically over time, and yet we are asked to believe the NRC and whatever follows it in time will safeguard this poison for ten times as long as mankind has lived in settled communities. We are being led to believe that under the "indefinite storage" system, the NRC or someone in the future would regularly replace the dry cask storage --cask pads, inner canisters, and the dry casks themselves every century or so in the future, through sea level fluctuation and ice ages, essentially forever, but even assuming some sense of historical memory and continuity over the eons for which there is no evidence. (0648-6 [Price, Scott])

Comment: NIC encourages NRC to include in its EIS by reference a scenario in which used fuel remains at reactor sites in perpetuity, but is under institutional controls for only about 100 years. This scenario was one of the "no action" alternatives evaluated by the Department of Energy in its Yucca Mountain Environmental Impact Statement. NIC believes that this scenario is theoretical, and not reasonably likely to actually occur. However, the analysis of the scenario was prepared by the DOE in conjunction with its EIS accompanying the Yucca Mountain License Application. Accordingly, including the scenario by reference would ensure that the pertinent information is made available to the public as part of this rulemaking. (0685-7 [Davis, Ed])

Comment: Unrecognized in the Draft GEIS is the fact that no civilization and no human institutions have lasted for hundreds of thousands of years. Any credible plan must include ways to mitigate the risks of environmental contamination in the event of failure of governments or institutions. A realistic plan must be devised to keep manmade radioactive elements isolated from the biosphere for the million years the EPA declares them to be lethal. (0686-5 [Malboeuf, Simone])

Comment: We are citing the reality of nuclear waste facilities across the nation as examples of the current loss of institutional control. These failures are also a technically sound basis for the large amount of public mistrust that exists in this country around the potential for resolving nuclear waste responsibly. (0693-2-10 [Warren, Barbara])

Comment: II. Loss of Institutional Control exists at many sites around the country and is strongly associated with a loss of public trust. (0693-2-6 [Warren, Barbara])

Comment: In the background discussion above we reviewed briefly the history of the nuclear waste problem and the failure to find a scientific or technical solution. However, we only reviewed a portion of the problem- that pertaining to spent nuclear fuel. We did not discuss the hundreds of waste sites across the country leaking and spreading radioactive contamination that impacts land, water and air as well as threatens nearby communities. There is an enormous inventory of poorly managed nuclear materials from the front end of the nuclear fuel chain to the back end. In most cases there is a federally responsible agency, often DOE, charged with site clean-up. Inadequate resources, poor management, other national priorities and lengthy delays have resulted in contamination that definitely should be described as the loss of institutional control. We find this situation completely unacceptable, given that we are dealing with just decades of experience with nuclear waste, while NRC is assuming institutional controls will be in place indefinitely. (0693-2-7 [Warren, Barbara])

Comment: It is not necessary to lose an institution in order to have the loss of institutional control. All that is necessary is for the institution or government to be ineffective at carrying out its responsibilities. Therefore, it is not credible that NRC relied on the long term maintenance of institutional control in its GEIS analysis. In fact NRC stated that loss of institutional control is "so unlikely that it is a remote and speculative occurrence." (p. 56788 FR notice proposed rule) Our government made promises about the simple problem of nuclear waste, about nuclear waste repositories, and about nuclear safety. (0693-2-8 [Warren, Barbara])

Comment: Government has failed at Hanford, at Savannah River, at West Valley and many other sites. How can so many problems be remote and speculative occurrences? These sites don't have long term multi-year cleanup funds. Each year funding must be allocated from the discretionary budget and lack of funding is frequently cited as the reason clean-ups are delayed

and spreading contamination continues. In 2013, the US government shutdown as a result of budget disagreements in Congress. (0693-2-9 [Warren, Barbara])

Comment: It is therefore reasonable under NEPA to assume that the Federal Government ultimately will accept responsibility for TVA's and other commercial SNF. (0694-2-11 [Shea, Joseph])

Comment: The NRC also has made reasonable assumptions regarding the continued availability of institutional controls over spent fuel storage. (0694-3-20 [Shea, Joseph])

Comment: It is therefore reasonable under NEPA to assume that the Federal Government ultimately will accept responsibility for Entergy's and other commercial SNF. (0697-1-28 [Bessette, Paul] [Kuyler, Raphael])

Comment: [R]egulatory requirements and the NRC's continued oversight and evolution of the requirements in response to new information or developments provide additional assurance that spent fuel will be stored and managed in a safe and secure manner. (0697-3-1 [Bessette, Paul] [Kuyler, Raphael])

Comment: No one can predict the future and no one can positively predict what humans will be doing in 10,000 years or in 100,000 years. No one can build a secure shelter for a very destructive nuclear material that will last the length of time it takes for uranium or plutonium to become safe in the environment. (0701-18 [Wilson, Greg])

Comment: *Reliance vs. Erosion of Institutional Controls as a Function of Time* —"The Draft GEIS assumes institutional controls will necessarily ensure continued public safety and security of SNF surface storage facilities, with no significant increases in environmental consequences (we address this misguided proposition later). While this may be deemed reasonable over a short term (e.g. storage during the entire extended term of licensed operation), based on the sad history of managing radioactive and other forms of hazardous waste generated by large U.S. industrial programs, such as the production of nuclear weapons and rocket fuel, this is not a reasonable assumption to apply to the full terms of more extended storage scenarios, in which various levels of degradation and loss of such controls could well occur. Based on historical experience, for any scenario in which nuclear waste (SNF) is stored on the surface longer than 20 years following expiration of the extended reactor license term – which means some spent fuel could already be 80 years old – the agency must evaluate plausible scenarios in which the responsible commercial entities go bankrupt, or otherwise assert the federal government's sole fiduciary responsibility, which the government then fails with sufficient alacrity to assume, and thus institutional controls are lost, forcing primary reliance on the engineered barriers designed into the storage systems. It is critically important for NRC to assess, and the public to know, the inherent resilience of such storage systems and how long they may reasonably be relied upon to passively protect the environment and the public without active intervention by external institutional managers. (0706-2-24 [Fettus, Geoffrey])

Comment: NRDC Comment[:] The assumptions underlying NRC's evaluation of timeframes are arbitrary and capricious and fail to meet the "hard look" requirements of NEPA. With respect to NRC's evaluation of the licensed life of the reactor and short-term storage timeframes, we direct the agency to our comments on Appendix E, Analysis of Spent Fuel Pool Leaks, found below. NRC's fourth timeframe—indefinite storage—consistent with the DC Circuit's directions, assumes a geologic repository does not become available at any point and at-reactor or away-from-reactor ISFSIs would continue to store spent nuclear fuel in dry casks indefinitely.

However, NRC goes on to presume the following activities continue uninterrupted for the next several millennia, beyond the span of human history. Specific assumptions articulated by NRC include: •Continued storage of spent fuel in ISFSIs, including routine maintenance; •Replacement of ISFSIs and spent fuel canisters and casks every 100 years and thereafter; •Construction and operation of an away-from-reactor ISFSI (including replacement every 100 years); •Construction and operation of a Dry Transfer Storage facility (DTS), including replacing the DTS every 100 years thereafter for the millennia to follow. The NRC acknowledges these activities are the same as those occurring during the "long-term storage period," but, without a repository they must occur repeatedly, forever. NRC defends these assumptions on pages 1-14 and 1-15 and note 2 on those pages. Described in detail below, NRC's assumptions are arbitrary, capricious and violate NEPA. Institutional controls will fail over the long term and the agency's arbitrary refusal to analyze the consequences of those failures at nuclear waste storage sites around the country violates NEPA's hard look requirement and renders meaningless NRC's response to the DC Circuit's clear directions. Such a perspective is not NRDC's mere assertion. The National Academy of Sciences and every federal agency that has adopted regulatory requirements related to institutional controls, *including the NRC*, expect failure and have drafted requirements with such an eventuality in mind. Further, every scientific body and federal agency that has examined institutional controls in any context (chemical or radioactive contamination) has evidence of institutional failure. As such is the case, NRC must take account of such failure in its analysis of the environmental impacts of the nuclear waste permitted to be produced under the agency's licensing decisions. And it must do so in this particular EIS. (0706-3-1 [Fettus, Geoffrey])

Comment: As a "no-action" alternative in the context of the Yucca Mountain EIS, DOE posited two scenarios for nuclear waste over a 10,000 year period. Scenario 1 assumed institutional controls last for the entirety of the 10,000 year period. Scenario 2 assumed no effective institutional control of the storage facilities after approximately the first 100 years. Such an analysis is consistent with regulatory understandings of the efficacy of institutional controls (no reliance on them after 100 years) and, as DOE itself noted, "provide[s] a basis for evaluating an upper limit of potential adverse human health impacts to the public from the continued storage of spent nuclear fuel and high-level radioactive waste." At 7-33. However, we also concur with the views of Dr. Arjun Makhijani on this precise subject.³⁷ [footnote 37 text: See Declaration of Dr. Arjun Makhijani Regarding the Scope of Proposed Waste Confidence Environmental Impact Statement, Section 8.0, pages 24-28, January 2, 2013, http://ieer.org/wp/wpcontent/uploads/2013/01/WasteConfidence_EIS_Scoping_MakhijaniDeclaration2013.pdf.] Scenario 2 is a useful starting point for NRC as an analytical tool, but only that – a starting point. Dr. Makhijani provided several examples of assumptions in Scenario 2 that are scientifically inappropriate for a Waste Confidence EIS and examples of DOE underestimating the impacts of the no-action alternative scenarios in a number of ways. *Id.* But in any event, the probabilities and consequences of the harm that should have been subjected to a "hard look" in this Draft GEIS were at least initially examined by a federal agency several years ago, no matter the weakness of the initial analysis. Here's how DOE did the work and it could have at least served as a starting point for NRC. (0706-3-10 [Fettus, Geoffrey])

Comment: DOE's Scenario 2. As noted, after 100 years, Scenario 2 assumes no effective institutional control and storage facilities are essentially abandoned (but the engineered barriers remain). DOE assumes no health risks for workers during the initial century. For the remaining 9,900 years, DOE assumes spent nuclear fuel and high-level radioactive waste storage facilities at 72 commercial and 5 DOE sites would begin to deteriorate and that radioactive materials is released to the environment, contaminating the local atmosphere, soil, surface water, and groundwater. Appendix K of the EIS provides details of facility degradation, radioactive material

environmental transport, and human radiological exposure and dose models. See discussion at 7-33. Although the size of the affected area would be impossible to predict accurately for each site, DOE believed it would involve tens to hundreds of acres at each of the 77 sites.³⁸ [footnote 38 text: For its analysis (see Appendix K, Section K.2.1), DOE collected information from each of the 77 sites where spent nuclear fuel and high-level radioactive waste was located at that time and then divided the country into five regions. Then DOE posed a single hypothetical site in each region (see Appendix K, Section K.2.1.6), and estimated the potential release rate of the radionuclide inventory from the spent nuclear fuel and high-level radioactive waste, based on forecast interactions of the environment (rainfall, freeze-thaw cycle) with the engineered barrier (concrete storage modules). See discussion in FEIS at 7-45.] (0706-3-11 [Fettus, Geoffrey])

Comment: Impacts of Scenario 2. DOE's environmental impacts analysis, while inadequate as Dr. Makhijani describes, speaks for itself and make clear why NRC should have at least endeavored to use it as a starting point for examining the environmental impacts of nuclear waste in the event of never developing a repository: During the early period (200 to 400 years after the assumed loss of institutional control), acute exposures to external radiation from the spent nuclear fuel and high-level radioactive waste material could result in prompt fatalities. In addition, after a few thousand years onsite shallow aquifers could be contaminated to such a degree that consumption of water from those aquifers could result in severe adverse health effects, including premature death. Uncertainties about these localized impacts are related primarily to the inability to predict accurately how many individuals could be affected at each of the 77 sites over the 10,000-year analysis period. See FEIS at 7-41. DOE went also noted: In addition to the 3,300 potential cancer fatalities under Scenario 2, more than 20 major waterways of the United States that currently supply domestic water to about 31 million people (for example, the Great Lakes; the Mississippi, Ohio, and Columbia Rivers; and many smaller rivers along the Eastern Seaboard) could be contaminated with radioactive material. Under this scenario, the shorelines could be contaminated with long-lived radioactive materials (for example, plutonium, uranium, and americium), resulting in exposures to individuals who came in contact with the sediments and, potentially, an increase in latent cancer fatalities. Because individuals would not be in constant contact with the sediments, these impacts represent a small fraction of the impacts estimated for the drinking water pathways listed in Table 7-7.³⁹ [footnote 39 text: *Id.* at 7-39.] It should be noted, as Dr. Makhijani points out (Makhijani Declaration at 27), when food pathways other than drinking water are considered in Scenario 2, the radiation doses and fatalities substantially increase. Dr. Makhijani went on to note: "[t]he impact of dispersed waste on vast aquifers, areas of land, and the country's most important rivers that could not be used again because of contamination is not explored in detail. The Fukushima accident that began on March 11, 2011, has shown that the economic, social, and ecological impacts of the spread of radiation contamination are far larger than a narrow view of latent cancer fatalities may indicate." NRDC concurs. (0706-3-12 [Fettus, Geoffrey])

Comment: Summing up its view of the magnitude of potential local impacts, DOE explains: For Scenario 2, localized impacts to individuals from degraded facilities at the 77 sites could be severe. DOE estimated that within a few hundred years at the several sites where early concrete failure was predicted, hypothetical individuals living close to the storage facilities would receive lethal doses of external radiation [800 millirem per hour at a distance of 10 meters (33 feet)] from the exposed dry storage containers (see Appendix K, Section K.2.4.2). To evaluate impacts from ingestion of radioactive materials, the analysis assumed that individuals would live near the degraded storage facilities and would consume contaminated groundwater and food from gardens irrigated with groundwater withdrawn from the contaminated aquifer directly below their locations. DOE estimated that within 6,000 years from now a hypothetical individual living within several hundred meters of a degraded facility could receive an internal committed

effective dose equivalent to several thousand rem per year from ingestion of plutonium-239 and -240 (see Appendix F for further information on committed dose equivalent). Using the National Council on Radiation Protection and Measurements risk factors (DIRS 101857-NCRP 1993, p. 112), ingestion of plutonium at this rate could increase the individual's lifetime risk of contracting a fatal cancer after only a few years of exposure. FEIS at 7-38-40. Dr. Makhijani questions many of the scientific assumptions in Scenario 2. He notes even "estimates of latent cancer fatalities are presented in a very skewed way. Cladding degradation once the spent fuel is put into dry storage is assumed to begin after thousands of years and 'less than 0.01 percent' of the cladding would fail in the first 10,000 years" – a proposition Dr. Makhijani and NRDC find implausible. Makhijani Declaration at 27. And as a final technical matter, Dr. Makhijani points out the Yucca Mountain EIS was completed before any physical evaluation of high burnup fuel that had been in dry storage for any length of time. *Id.* Given what we know now about the myriad of technical problems with long-term storage associated with high burnup fuel, DOE's Scenario 2 is dated and deficient, useful only as a rough starting point for the "hard look" analysis NRC must conduct for a NEPA compliant draft GEIS. But the fact that it even exists demonstrates the degree to which NRC has acted in an arbitrary and capricious fashion by positing institutional controls will last forever. (0706-3-13 [Fettus, Geoffrey])

Comment: NRC's suggested defense for why it failed to analyze the potential environmental impacts of spent nuclear fuel in the event no repository is ever sited can be concisely summarized —the loss of institutional control so unlikely that it is a remote and speculative occurrence. Draft GEIS at 1-14, 15, note 2. NRC provides no technical, regulatory, or historic support for this assertion. Rather, NRC dismisses DOE's approach in its 2002 EIS to the loss of institutional controls at a dry cask storage facility as "not relevant" and asserts DOE's approach was related to post-closure buried radioactive waste and not relevant to the indefinite dry cask storage of licensed spent nuclear fuel. This dismissal has no merit as, seen in Appendix K of DOE's analysis, DOE examined the loss of institutional controls at dry cask storage facilities. More pertinent, contrary to the finding of the National Academies, the GAO, federal agency regulations, and human history, NRC's unsupported suggestion—the loss of institutional controls over thousands of years at a dry storage facility is so unlikely it is a remote and speculative occurrence—is without merit.⁴⁰ [footnote 40 text: It should also be noted NRC has asserted active maintenance and security will continue for centuries, and has made this assertion in a timeframe where the federal government shut down for several weeks. See, *White House Puts Price on Government Shutdown*, New York Times, Annie Lowrey, November 8, 2013, <http://www.nytimes.com/2013/11/08/us/politics/white-house-puts-price-ongovernment-shutdown.html>. ("The report said that the government had not calculated the costs of actually shutting the government down and reopening it. But it described them as significant. "Disruptions at nuclear cleanup sites associated with the shutdown will cost two to three weeks of productivity," it said. The shutdown "may cause the Department of Energy to miss cleanup milestones agreed to with the states where cleanup is underway.""). During that shutdown period, much of the NRC staff stayed on duty as a result of carryover funding. However, near the end of the shutdown, much of NRC staff was furloughed. NRDC makes no suggestion government shutdowns will be more or less frequent, more or less damaging to the public health, or more or less meaningful to the proper management of nuclear waste. We merely subscribe to the observation of the National Academies—institutional controls will fail.] NRC must return to the drawing board and perform an analysis of extended storage of SNF with a failure of institutional controls. (0706-3-14 [Fettus, Geoffrey])

Comment: And finally, in bypassing performing this analysis, NRC would not have had to commence this analysis from whole cloth. DOE, in its Yucca Mountain EIS, provided NRC with at least an initial (albeit inadequate) draft to examine the environmental impacts of the failures of

institutional controls at nuclear storage sites. At bare minimum, NRC must return to the drawing board and analyze the environmental impacts of nuclear waste when a geologic repository does not become available and at-reactor or away from-reactor ISFSIs store spent nuclear fuel in dry casks indefinitely – and institutional controls then fail. (0706-3-2 [Fettus, Geoffrey])

Comment: Page 2-21. "This draft GEIS considers the environmental impacts of constructing a reference DTS to provide a complete picture of the environmental impacts of continued storage." NRDC Comment[:] This Draft GEIS does nothing of the sort and fails provide a complete picture of the environmental impacts of continued storage. See discussion (at comment #4) of failure of institutional controls and DOE's Scenario 2 as a starting point for the area NRC should have covered to being providing a complete picture of the environmental impacts of failing to secure permanent storage. (0706-3-24 [Fettus, Geoffrey])

Comment: Thus, institutional controls exist, agencies adopt policies to implement those controls, and in this Draft GEIS, NRC proposes to conduct nuclear waste management operations for the next several thousand years without any explanation of how those institutional controls might persevere. Draft GEIS at 1-14, 1-15. (0706-3-3 [Fettus, Geoffrey])

Comment: "Institutional Controls Will Fail" — National Academy of Sciences. As seen above, the efficacy and use of institutional controls is a significant and growing element of environmental policy. They have become necessities for the simple reason the polluting entity or government cannot remove the entirety of contamination from a particular site. Federal agencies have adopted regulations explicitly recognizing the difficulties of long-term reliance on institutional controls. And more to the point, there are numerous examples of how and why the institutional controls fail. Even a few examples illustrate the problems facing reliance on institutional controls and the difficulties in formulating "durable," protective remedies for long-term contaminated sites. The DOE, for example, has created the Office of Legacy Management in its Environmental Management Program. The Office of Legacy Management's mission is to manage the long term stewardship of contaminated nuclear weapons sites *after* whatever cleanup has been done has concluded.²⁴ [footnote 24 text: See DOE's Office of Legacy Management online at <http://energy.gov/lm/office-legacymanagement>.] Despite a multi-billion per year cleanup program and an Office of Legacy Management, the government appears to have lost track of significant numbers of formerly utilized sites that remain contaminated. A recent series in the Wall Street Journal by John Emshwiller documented continuing problems at a variety of sites which have receded from the institutional memory of the agencies responsible for assuring they are cleaned up.²⁵ [footnote 25 text: See, e.g., Emshwiller and Singer-Vine, "Waste-Lands: A Forgotten Legacy of Nuclear Buildup," *Wall Street Journal*, October 30, 2013.] (0706-3-4 [Fettus, Geoffrey])

Comment: Then there is waste the nation has abandoned it cannot track, but evidence of it remains with us today. From 1946 to approximately 1970, the Atomic Energy Commission approved disposing of radioactive wastes by dumping at sea. Wastes were placed in various kinds of packages, predominantly 55-gallon drums, placed on tugs or ships, taken out to ocean dumpsites, and tossed overboard. Radioactivity released from degrading canisters was subsequently found to adsorb instead onto and concentrate in bottom sediments. Bottom-dwelling organisms root through those sediments, ingesting the radionuclides and concentrating them in their bodies. They are then consumed by other marine organisms, and then by higher organisms, with radionuclides concentrating as they go up the food chain through a process called bioaccumulation. So, rather than dilution, it turned out there were radioactivity concentration phenomena at work.²⁶ [footnote 26 text: For a full treatment of this sad history, see Jacob Darwin Hamblin, *Poison in the Well: Radioactive Waste in the Oceans at the Dawn of*

the Nuclear Age, Rutgers University Press, 2008; and W. Jackson Davis, John Van Dyke, Daniel Hirsch, Mary Anne Magnier, Sherry P. Broeder, *Evaluation of Oceanic Radioactive Dumping Programs*, study presented by the nations of Nauru and Kiribati to the London Dumping Convention, LDC7/INF.2, 1982.] Further, a study done by attaching monitoring devices on barrels being dumped found roughly a third of those drums imploded before hitting the ocean floor via the differential pressure. Investigations by EPA personnel in the Alvin submersible of the Farallons Islands dumpsite and one off the East Coast, and earlier similar submersible inspections of the Santa Cruz Basin dumpsite off Santa Barbara, found that in just a few years the barrels had degraded substantially. There was significant corrosion and deformation, and radioactivity was found in the sediments nearby at levels far in excess of fallout background, having leaked from the drums.²⁷ [footnote 27 text: *Id.* And for a full recitation of this history in the context of this Draft GEIS and the proposed Waste Confidence rule, see *50 Years of Power: 500,000 Years of Radioactive Waste*, Daniel Hirsch, Committee to Bridge the Gap, Physicians for Social Responsibility-Los Angeles, Southern California Federation of Scientists 20 December 2013.] (0706-3-5 [Fettus, Geoffrey])

Comment: Failures of institutional controls in the chemical cleanup context have also been significant. In southern New Jersey, children at a daycare were exposed for significant periods of time to unacceptably high levels of mercury at a former thermometer factory.²⁸ [footnote 28 text: *See After Mercury Pollutes a Day Care Center, Everyone Points Elsewhere*, New York Times, Tina Kelly, August 19, 2006, <http://www.nytimes.com/2006/08/19/nyregion/19mercury.html?pagewanted=all>.] There are numerous lessons in this particular story, but failure to either clean up the property, or at the least to put a lien on the property and erect signs and fences around it to notify neighbors about the possible hazards, resulted in this statement: "Lisa P. Jackson, the commissioner of the environmental department, conceded in an interview this week that the agency needed better tracking of contaminated sites, clearer cleanup priorities and stronger enforcement efforts. 'This is an example when all three of those kind of collide in a bad way,' she said. 'It crystallizes some of the things we need to do differently.'"²⁹ [footnote 29 text: Another excellent press treatment of the long term and related problem of "brownfields," (which allow certain types of pollution to be left in place and capped), is the New York Times's examination of the cleanup of chromium ore in Jersey City, NJ. See *Finding the Bottom of a Polluted Field*, Anthony DePalma, February 5, 2006, <http://www.nytimes.com/2006/02/05/nyregion/05chromium.html?pagewanted=all>.] There are thousands of sites across the country where unexploded bombs, mortar rounds and other munitions, covering about 10 million acres, according to government records and experts interviewed by ABC News.³⁰ [footnote 30 text: *See Casualties of War*, Chris Francescani, ABC NEWS Law & Justice Unit, Jan. 24, 2008, <http://abcnews.go.com/TheLaw/story?id=4179408&page=1>.] Even items such as munitions from recent past are unrecognized or not properly handled. ABC News wrote "officials have undertaken an awareness and education campaign to avoid situations like that of Henry Owens, the Tennessee boy whose hand was blown off. 'People have found these things, and they think they are souvenirs, and they bring them home,' Davis said. While 'in most cases, there has to be some kind of force [to detonate a buried ordnance], we really stress what we call the three Rs: recognize, retreat and report. We do not want people picking things up and driving them to the police, or bringing them home,' Davis said."³¹ [footnote 31 text: *Id.*] (0706-3-6 [Fettus, Geoffrey])

Comment: Finally, in a thorough report addressing concerns that institutional controls may not effectively protecting human health and the environment in the context of chemical contamination, in 2005 the Government Accountability Office reviewed (1) the extent to which

institutional controls are used at sites addressed by EPA's Superfund and RCRA corrective action programs; (2) the extent to which EPA ensures that institutional controls at these sites are implemented, monitored, and enforced; and (3) EPA's challenges in implementing systems to track these controls.³² [footnote 32 text: See *Hazardous Waste Sites: Improved Effectiveness Of Controls At Sites Could Better Protect The Public*, Government Accountability Office, GAO-05-163, January 2005, <http://www.gao.gov/assets/250/245140.pdf>.] The GAO found institutional controls were used at most of the Superfund and RCRA sites where cleanup was completed and waste was left in place. Further, the GAO found that while EPA's guidance advises that four key factors be taken into account in selecting controls for a site (the objective, mechanism, timing and responsibility for the institutional control), 69 of the 108 remedy decision documents examined did not demonstrate that all of these factors were sufficiently considered to ensure that planned controls will be adequately implemented, monitored, and enforced.³³ [footnote 33 text: *Id.* at 5.] The GAO explained: Although EPA has taken a number of steps to improve the management of institutional controls in recent years, we found that controls at the Superfund sites we reviewed were often not implemented before site deletion, as EPA requires. In some cases, institutional controls were implemented after site deletion while, in other cases, controls were not implemented at all. An EPA program official believed that these deviations from EPA's guidance may have occurred because, during the sometimes lengthy period between the completion of the cleanup and site deletion, site managers may have inadvertently overlooked the need to implement the institutional controls.³⁴ [footnote 34 text: *Id.* at 6.] (0706-3-7 [Fettus, Geoffrey])

Comment: We conclude this subsection of our response to the NRC's arbitrary and capricious assertion, "[i]nstitutional controls, i.e., the continued regulation of spent nuclear fuel, *will continue*," by noting the observation of the National Academy of Sciences: "institutional controls *will fail*."³⁵ [footnote 35 text: See National Academy of Sciences/National Research Council, Board on Radioactive Waste Management, *Committee on the Remediation of Buried and Tank Waste, Long-Term Institutional Management of the U.S. Department of Energy Legacy Waste Sites*, August 2000, at page 97 (emphasis added).] (0706-3-8 [Fettus, Geoffrey])

Comment: The NRC Should Have Analyzed the Environmental Impacts of Nuclear Waste in the Event a Repository Never Opens. The DC Circuit was explicit in its directions to NRC, "[u]nder NEPA, an agency must, look at both the probabilities of potentially harmful events and the consequences if those events come to pass." *New York et al.* at 478, citing *Carolina Env'tl. Study Grp. v. U.S.*, 510 F.2d 796, 799 (D.C. Cir. 1975). In light of federal and state regulatory understanding of institutional controls, the views espoused by the National Academy of Sciences and the GAO – indeed, the entire trajectory of nearly any entity that has addressed the topic of protection of public health and the environment from significant sources of contamination left in place, NRDC finds astonishing NRC's conclusion, without a shred of support, that "[i]nstitutional controls, i.e., the continued regulation of spent nuclear fuel, *will continue*." Rather, NRC should have, at minimum, commenced work on a thorough analysis of the environmental impacts of the failure of institutional controls at reactor storage sites or IFSIs. Here, as the NRC acknowledges, (note 2 on page 1-15), a first cut at just such an analysis to at least serve as a starting point was available to them. DOE performed just such an analysis in its Final Yucca Mountain EIS, even though it is inadequate to the task for this Draft GEIS in several important ways, discussed below.³⁶ [footnote 36 text: See *Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (DOE/EIS-0250), found online in full at <http://energy.gov/nepa/downloads/eis-0250-final-environmentalimpact-statement>; and http://energy.gov/sites/prod/files/EIS-0250-FEIS-01-2002_0.pdf.] (0706-3-9 [Fettus, Geoffrey])

Comment: Page 2-28. "As described in Section 2.1.4, the NRC assumes a DTS, or its equivalent, would be used to transfer fuel as needed for inspection or repackaging. For purposes of this draft GEIS, the NRC assumes the reference DTS would be constructed, operated, and replaced once during the long-term storage timeframe, and every 100 years thereafter... As shown in Figure 2-3, receiving casks and source casks enter the preparation area and exit the DTS on rail-mounted trolleys. To begin spent fuel transfer operations, a receiving cask (i.e., the cask into which fuel will be transferred) is transported to the DTS. The receiving cask is positioned and loaded on a receiving cask transfer trolley at the DTS and rolled into the preparation area. Next, the receiving cask lid and outer and inner canister lids are removed. Finally, the receiving cask is moved into the lower access area and mated to the transfer confinement area. A source cask (i.e., the cask from which fuel will be transferred) follows a similar path as the receiving cask into the lower access area and is mated to the transfer confinement area. *No personnel are present in the lower access area for the transfer operations; all transfer operations are controlled remotely.* The lids on both the receiving cask and source cask are removed to prepare for spent fuel transfer. The fuel-assembly-handling subsystem in the transfer confinement area is used to grab and lift a spent fuel assembly from the source cask. The spent fuel assembly is lifted inside a transfer tube and then moved over an empty position in the receiving cask. The spent fuel assembly is lowered into the receiving cask and detached from the lifting device. When spent fuel transfers are complete, both casks are closed, detached from the transfer confinement area, and ultimately removed from the lower access area back to the preparation area." (emphasis added). NRDC Comment[:] Construction and operation of a DTS, while within the capacity of current technology, is a complicated business where operations are managed and performed remotely. Presuming this ability to remotely operate equipment for the thousands and tens of thousands of years flies directly in the face of the intergenerational justice concerns at the heart of the national consensus for geologic disposal. Further, and more important, such a conception of constantly increasing technological prowess runs directly contrary to history and the theory of appropriate reliance on institutional controls. See our discussion above in comment #9 on the failure of institutional controls. (0706-4-1 [Fettus, Geoffrey])

Comment: Turning to more specifics in the section, sections B.3.1.1.-2, *Technical Feasibility of Wet Storage*, and B.3.3 *Regulatory Oversight of Wet and Dry Spent Fuel Storage*, have little support in light of the Mr. Lochbaum's declaration, submitted this day and referenced above. And with respect to NRC's B.3.4., *Summary of Technical Feasibility of Continued Storage*, particularly its reliance on the proposition institutional controls can exist is perpetuity, has no evidentiary support and runs counter to the regulatory structure of every federal agency and the findings of independent observers such as the NAS. See our comment #6. (0706-4-7 [Fettus, Geoffrey])

Comment: Due to the absence of a viable repository program, the "Waste Confidence" GEIS assumes that irradiated fuel may be stored in temporary storage facilities indefinitely (or, in lay terms, possibly forever) and that "institutional controls" will remain in place to manage the waste safely for as long as that happens to be. NRC routinely justifies its institutional controls assumption by asserting that, to assume otherwise (i.e., that a similar waste management regime would not be maintained at some point in the future), amounts to wild speculation. However, not to even analyze the environmental impact of a different course of events is simply an exercise in constructing the study to support pre-determined conclusions. (0711-16 [Olson, Mary])

Comment: During the public comment period, the government was shut down due to political conflict over the nation's finances, and in addition a federal court blocked the ability of the

government to generate revenue via the Waste Fund Fee to pay for the high-level waste storage program. In the first instance, the willingness of a political faction to bring the very operation of the government to a halt over disagreements about the cost of its operations, the legitimacy of certain of those operations, and the levying of taxes to fund them is directly relevant to the reliability of institutional controls throughout the timeframes necessary to assure safe management of irradiated fuel without a repository or other permanent storage method. NRC's assumption that the repackaging and maintenance of irradiated fuel in dry storage facilities, indefinitely, forever, will not be subject to political conflicts – or will even be seen as politically relevant – one-hundred years or more in the future is wildly speculative and a manifestly unscientific assumption. (0711-18 [Olson, Mary])

Comment: [H]ow will they babysit the wastes after the fossil fuels are gone? (0711-42 [Olson, Mary])

Comment: In the absence of a safe permanent one-shot solution to the challenge of keeping nuclear waste out of the environment of living things for the indefinite future, the only responsible course of action is to adopt a policy of "Rolling Stewardship". We do know how to package nuclear waste and store it in a safe manner for decades at a time. Rolling stewardship is an intergenerational management concept. It requires monitoring and maintenance of the waste for an indefinite period of time, with responsibility being passed on from one generation to the next, including episodes of retrieval, recharacterization and repackaging of the waste. It also requires a mechanism for reinstructing the next generation, providing detailed information on the nature of the wastes and the associated hazards, and ensuring that the next generation is fully aware of the need to spend time and money on the wastes and to see that corrective action is taken on a timely basis if need be. (0714-1-21 [Edwards, Gordon])

Comment: *Rolling Stewardship gives each generation the tools to deal with the wastes. Abandonment leads to amnesia – future generations are at risk but ignorant.* (0714-1-22 [Edwards, Gordon])

Comment: CCNR [Canadian Coalition for Nuclear Responsibility] recommends that NRC elaborate a set of rules and policies related to the concept of Rolling Stewardship as applied to the intergenerational management of irradiated nuclear fuel, including detailed mechanisms for transferring responsibility for managing the wastes from one generation to the next, mechanisms for funding the long-term management of the waste including monitoring, retrieval, recharacterization and repackaging of the waste and reinstructing each successive generation. (0714-1-4 [Edwards, Gordon])

Comment: Nuclear proponents often argue that a permanent walk-away solution to the nuclear waste problem is required so as not to burden future generations. If such a solution is not available, however, then in fact future generations have already been burdened. In such a case NRC has a responsibility to address itself to the task of laying out a program of Rolling Stewardship that will make the burden manageable for future generations. The NRC also has an obligation not to add to that burden unnecessarily. (0714-2-5 [Edwards, Gordon])

Comment: Worse, history has also amply demonstrated what travesties can occur at reactors even under those watchful NRC eyes (e.g., Davis Besse; Dresden 2&3 remaining on the "close watch list" for 15 consecutive evaluation cycles; SONGS). So, the conclusion that institutional control is somehow guaranteed by the mere presence of NRC onsite resident inspectors, or whatever institutions replace them in the future, is a tautology, not proof. "Presence" does not guarantee adequate "oversight." While necessary, it by itself is insufficient. Until NRC can again

demonstrate that it is a regulatory agency (see list below), it has no business making absurd claims that HLRW can be stored safely indefinitely at nuclear stations. (0716-10 [Kraft, Dave])

Comment: As such, NRC is not an agency that can be trusted to "go beyond what's required" even today, let alone into an indefinite future of radioactive waste storage at reactor sites. It has no demonstrated interest in behaving in this manner; and it cannot even guarantee it can field a workforce on a given day, should the U.S. Government decide to shut down again in the future. This is an Agency that has accrued the following track record (a few salient examples, not an all-inclusive record)[.] (0716-19 [Kraft, Dave])

Comment: NEIS asks that you withdraw all statements to the effect that, because of NRC oversight programs, NRC asserts and guarantees that spent fuel can be stored at reactor sites indefinitely. Such a guarantee implies that NRC will be providing constant oversight into that indefinite period of time. In October of 2013, NRC could not even guarantee that its workers would be able to come to work the next day. The hubris of such an assertion that NRC oversight and institutional controls will be available ad infinitum, therefore, borders on colossal, if not outright psychotic. (0716-3 [Kraft, Dave])

Comment: NRC should withdraw all statements to the effect that, because of NRC oversight programs, NRC asserts and guarantees that spent fuel can be stored at reactor sites indefinitely. As mentioned previously, and below, the NRC cannot even guarantee its own day-to-day operation, let alone pledge "institutional control" for decades or indefinitely. This is not opinion. It is historically demonstrated FACT. Therefore, it cannot in all seriousness propose that HLRW will be afforded the everwatchful eyes of NRC onsite inspectors indefinitely. (0716-9 [Kraft, Dave])

Comment: The NRC license for nuclear power plants is 60 years, yet these plants produce radioactive waste that requires storage in a controlled environment for 100 or 1,000 times that span. This EIS says that the impact of indefinite would be "small" because storage facilities will be replaced every 100 years. That assumption is totally unreasonable for numerous economic, social, scientific and historical reasons. (0724-2 [Gamble, Dan])

Comment: What will happen if no maintenance ever occurs, or if replacement of the facilities ceases entirely? What happens when the social "reset button" is pressed, and the world as we know it is erased? Geological records show that massive changes in climate occur on the timescale in question – for example, the most recent ice age ended just ten thousand years ago, and we have absolutely no written record from human societies existing before that event. Other catastrophes: volcanoes, famines, plagues and wars all have a far shorter time line of global recurrence and resulting dramatic social changes. Unless this document considers the possibility of the storage facilities NEVER being replaced or repaired, the document is fundamentally invalid. (0724-3 [Gamble, Dan])

Comment: Right now, it looks like the waste will be stored indefinitely on-site and you are trying to create a regulatory system for it but can you even imagine that far into the future? America as you know it has only been around for a couple hundred years. Europeans have only been on this land for several hundred. Maybe you need to talk to those who have lived here continuously for over 20,000 years. Moreover, even in the very short term, there are governmental problems. The Waste Confidence meetings were postponed because of a government shut down. The very government and organization responsible for the extremely toxic radioactive waste. This hardly inspired confidence. (0734-5 [Hisasue, Carole])

Comment: NRC also assumes that the regulatory institutions will also continue to function over these time periods, and, presumably, that if the utilities cease to exist, government will take over the responsibility for the maintenance, guarding, and repackaging. But the NRC itself has only existed for less than forty years, a century less than even the first time period under consideration, 140 years. The U.S. government has existed for less than the 240 years of the second time period. And all of recorded history is two orders of magnitude shorter than the hazardous life of the plutonium-239 in the waste. Assuming institutions will be around to guard, maintain, and repackage these wastes over these time periods is exceedingly hard to defend. But NRC does not try to technically defend this proposition—it just assumes it. And it relegates to a footnote (fn. 2) its discussion of this extraordinarily consequential assumption. (0738-12 [Hirsch, Daniel])

Comment: After conceding numerous situations where long-term reliance on institutional controls is not allowed, including disposal of HLW in a geologic repository and disposal of LLRW in nearsurface sites,³⁷ [footnote 37 text: 10 CFR 20 Subpart E, rules for cleanup of contaminated sites and license termination, also bars reliance on institutional controls, unless one can show that failure of the controls would not result in doses exceeding specified limits. So even for cleanups, the impact of failure of institutional controls must be evaluated and cannot be relied upon unless that impact is within limits.] NRC proceeds to assert that indefinite surface storage of HLW is somehow different and the prospect of institutional controls being ineffective or non-existent at some point is so unlikely as to be completely speculative and thus should not be considered. (0738-13 [Hirsch, Daniel])

Comment: NRC says the casks will be visible and the consequences of not guarding, maintaining, and repackaging them indefinitely so severe, that future institutions *will* without question supply the resources, essentially forever, to so protect them. This proposition appears to turn the actual situation on its head. NRC is refusing to analyze in its draft GEIS the consequences of institutions failing. Its sole basis for doing so is its assertion that institutional controls will not fail. And its argument as to why institutional controls will not fail is because the consequences of failing are so severe. This is completely circular. Additionally, the fact that the HLW casks will be on the surface and visible increases rather than eliminates the prospect of them being broken into. Like the pyramids of Egypt, they are likely to be seen as tombs or vaults containing items of great value, worth stealing. (0738-14 [Hirsch, Daniel])

Comment: NRC also assumes that long into the future, unspecified institutions will somehow remember what is inside the HLW casks and how dangerous that material is, and therefore spend precious resources to indefinitely protect material from which they received no benefit. But such institutional memory is rather quickly lost. We still do not understand well, for example, for what purpose the *moai*, the monumental statues of Easter Island, were constructed. And what language would one write the documentation about the risks and the necessary technology needed for repackaging the casks so it can be understood far into the future? Most Americans cannot readily read even the early English of Chaucer, let alone the languages of ancient peoples. And how would those instruction manuals for repackaging the waste be preserved for future generations? And on what media? Floppy disks went the way of the dinosaurs after just a few years; operating systems become obsolete in very brief intervals; paper disintegrates, burns, or just gets lost. (0738-15 [Hirsch, Daniel])

Comment: In far shorter periods, institutional reliability appears questionable. It is not without its own irony that the NRC had to cancel several of its scheduled hearings on the Waste Confidence Rule because the U.S. government shut down. Sequesters and other budget cuts, depressions, wars, and natural catastrophes all can result in institutional obligations not being

met, even in relatively modest time frames. To count on institutional controls over centuries, millennia, or longer is difficult to defend. The recent history of waste disposal, recounted briefly in this paper, demonstrates that even in a period of just a few decades, institutions have lost track of waste disposal sites, failed to meet legally binding cleanup requirements or monitoring obligations, and otherwise have not been reliable. Long-term reliance on such institutions and institutional controls seems without basis. (0738-16 [Hirsch, Daniel])

Comment: In a 1972 article in *Science Magazine*, Alvin Weinberg, then Director of the AEC's Oak Ridge National Laboratory, famously wrote: "We nuclear people have made a Faustian bargain with society." On the one hand reactors offer an extraordinary source of energy. "But the price that we demand of society for this magical energy source is both a vigilance and a longevity of our social institutions that we are quite unaccustomed to." He went on to suggest that what might be needed was a kind of nuclear priesthood to manage these risks over the long time periods involved. He concluded by asking the fundamental question: "Is mankind prepared to exert the eternal vigilance needed to ensure proper and safe operation of its nuclear energy system?"³⁸ [footnote 38 text: Weinberg, Alvin, "Social Institutions and Nuclear Energy," *Science*, Vol. 177, No. 4043 (Jul. 7, 1972), pp. 27-34.] (0738-18 [Hirsch, Daniel])

Comment: NRC's analysis relies almost exclusively on a self-described "assumption" that institutional controls will remain in place and effective for these time periods, in order to assure that the waste is guarded 24 hours a day, seven days a week, year after year, century after century, and that someone will undertake the technically challenging task of repackage the HLW every century into eternity. It is exceedingly difficult to view this assumption as anything but arbitrary and capricious in the extreme. The NRC itself has only been in existence for forty years. Our government was not in existence 240 years ago; indeed, the United States of America did not even exist as a nation then. And with the longevity of the waste being 500,000 years or more, it is important to recall that recorded history only goes back a few thousand years. We are talking about time periods that far exceed any reasonable assumption of the longevity of institutions, let alone institutional controls. NRC arbitrarily dismisses—in a footnote—the prospect that institutional controls may not be durable and effective over these extraordinary time periods, asserting that loss of institutional controls is "so unlikely that it is a remote and speculative occurrence."⁴ [footnote 4 text: GEIS, footnote 2, pp. 1-14 – 1-15.] In this paper we review that issue and conclude the opposite, that continued and effective institutional controls over the time periods involved are so unlikely as to be a remote and speculative occurrence. In any case, the potential for such failure is real, and the environmental consequences must be examined carefully. This the NRC GEIS does not do. Among the "best evidence," the most viable datasets available, for judging the NRC claim that institutions can be relied upon to effectively manage radioactive waste over these kind of extraordinary time frames is the history of efforts by institutions to date to deal with radioactive waste. That history is examined in this study. (0738-6 [Hirsch, Daniel])

Comment: It is because of the very long hazardous life of HLW that the National Academy of Sciences (NAS) recommended, and the Court of Appeals for the District of Columbia directed, that adequate performance of HLW disposal plans be demonstrated out hundreds of thousands of years.¹¹ [footnote 11 text: National Academy of Sciences/National Research Council, *Technical Bases for Yucca Mountain Standards*, 1995; U.S. Court of Appeals for the District of Columbia, *Nuclear Energy Institute v. U.S. Environmental Protection Agency*, July 9, 2004.] EPA had adopted regulations to only require that analyses demonstrate compliance for the first 10,000 years. NAS pointed out that the wastes were hazardous for vastly longer than that; that Yucca Mountain analyses suggested peak exposures to the public from Yucca leakage occurring at several hundred thousand years; and that one should analyze for at least

one million years, the time scale for long-term geologic processes at Yucca Mountain. The Court of Appeals agreed, saying the law required the rules to be consistent with the NAS recommendations. But to have confidence that institutional controls will remain in place even for the first ten thousand years -or even the shorter periods of 140 years and 240 years--seems extraordinarily difficult to defend. (0738-7 [Hirsch, Daniel])

Comment: NRC then proceeds to indicate its confidence that irradiated nuclear fuel not just can but will be safely stored on the surface, at reactor sites or elsewhere, for three different periods: (1) 140 years from the time the reactor started operations, (2) 240 years from startup, and (3) indefinitely. NRC presumes that after a certain point, spent fuel is moved to dry casks and that there is continuity of institutional controls for these time scales for guarding, maintaining, and at regular intervals, repackaging the fuel in new casks. These are rather extraordinary assumptions. For hundreds of years the fuel gives off enough heat that they must be constantly cooled. The dry casks involve passive cooling, but this requires the cooling vents to be kept free of snow, leaves, dirt and other debris, so regular maintenance is needed. (0738-9 [Hirsch, Daniel])

Comment: Unrecognized in the Draft GEIS is the fact that no civilization and no human institutions have lasted for hundreds of thousands of years. Any credible plan must include ways to mitigate the risks of environmental contamination in the event of failure of governments or institutions. A realistic plan must be devised to keep manmade radioactive elements isolated from the biosphere for the million years that the EPA declares them to be lethal. (0757-6 [Lynch, Laura])

Comment: A principle assumption throughout the Draft GEIS is that there will be institutional control to meet the necessary obligations for long-term storage of spent fuel. At its core, this assumption concludes that the corporations and limited liability companies that generating the spent fuel will have sufficient funds to meet the requirements for long-term storage and that the regulations promulgated and enforced by the Commission will be enough to ensure safety, maintenance and good storage procedures. There is nothing in the Draft GEIS, other than this statement, to support this conclusion.⁵ [footnote 5 text: Interestingly, as is described in more detail below, the Draft GEIS focuses on oversight and regulatory control on being controlling and providing the basis for an assumption of institutional control. It does not because it presumes there is an entity to oversee and regulate. The real issue is not an entity to control, it is the availability of the funds to ensure that the activities necessary to ensure storage, transfer and transport are completed.] Unlike decommissioning funds, which are required to be set aside in order to decommission a power plant or return it to its natural habitat, there are no such funds for the handling and storage of spent fuel. Likewise, there is no assurance that an entity will even be viable in 100 years. This assumption of institutional control must be addressed – and removed. (0783-1-12 [Harlan, Thomas])

Comment: On page 1-14, lines 19-22 and carrying over to 1-15, lines 1-5, there are assumptions on institutional control. The assumption with institutional control is that the Federal Government will somehow provide safe storage of spent fuel through regulation. However, that is not what is happening in the field. The obligation to temporarily store spent fuel belongs to the generator of that fuel. Even corrected, the assumption of institutional control misses the mark. There is no reference, whatsoever, to how the generators are going to pay or provide for safe storage or whether these corporate entities are even going to exist. This assumption must be removed. On page 1-15, lines 6-15, the assumption regarding institutional control continues. Again the Draft GEIS solely focuses on Federal control. This is not the Federal Government's

obligation. Institutional control needs to be analyzed through the generators and the measures in place to ensure responsible storage and maintenance. (0783-2-8 [Harlan, Thomas])

Comment: Under section B.3.3, there is analysis of the regulatory oversight of wet and dry spent fuel storage. In this analysis, there is an assumption of institutional control through regulatory oversight and license compliance. Institutional control goes beyond oversight and must include an analysis, or at least a description, of the entities that are to be providing the structures, systems and programs for responsible storage before a permanent repository can be found. In addition, the analysis must identify where the funds will come from to properly ensure these items are completed. (0783-3-22 [Harlan, Thomas])

Comment: Interestingly enough, the Draft GEIS, consistent with current practice, assumes that the responsibility for the disposal of low-level waste lies with the generator and assumes that the industry will take care of this particular issue. Yet, for purposes of institutional control, the Draft GEIS substitutes in the Federal Government for the generator and its obligations to maintain storage until such time that the spent fuel is retrieved for either interim or permanent disposal. To be consistent, the Draft GEIS should analyze institutional control with the generator being the institution. (0783-3-6 [Harlan, Thomas])

Comment: The evidence base is so deficient that the indefinite time frame considerations are not credible. I would give pigs a better chance of flying than protocols followed indefinitely would protect the environment. (0805-16 [Wilshire, Howard])

Comment: The assumptions on which the Waste Confidence GEIS is based (listed on p. xxvi) are absurd. "Spent fuel canisters and casks would be replaced approximately once every 100 years." and "Independent spent fuel storage installation (ISFSI) and dry transfer system (DTS) facilities would also be replaced approximately once every 100 years." What this says is that the NRC believes no known design for dry storage of spent fuel can be expected to last for more than 100 years. There is no way to guarantee a future society will have resources or social organization to replace such facilities, and yet the NRC insists-by blandly making an assumption -that this capability will exist into the indefinite future. (0815-3 [Gunter, Keith] [Izant, Carol])

Comment: Prof Guy McPherson of the University of Arizona states that collapse of many systems is imminent. I state that the collapse of the funding for a geological repository will depend on many of these societal structures that may not survive global warming for the next few decades per Dr. McPherson. Will the NRC analyze and explain how the NRC can expect a financial stream to build a geological repository in the face of collapse of the money system as a consequence of global warming? (0818-4 [Lewis, Marvin])

Comment: The NRC has acknowledged that no known engineered structure (spent fuel pools, dry casks) can last the infinite length of time required to isolate these radioactive wastes from humans and the environment. As noted, the DGEIS speaks of waste management in terms of decades (spent fuel pool usage up to 60 years after reactor closure) or a century (when the waste will need to be transferred into new casks, an untested and potentially impossible procedure); however, the hazard and longevity of this waste is measured in millions or even billions of years, far longer than human civilization has existed. How can the NRC possibly assume that adequate institutional controls will exist into the future? (0819-7 [Kline, Connie])

Comment: NRC oversight has been unacceptably weak or erratic at many reactors. It will be decreased post-operation storage. We are concerned that the environmental impacts of leaks always appear to be more significant at reactors with less oversight. Safety assurances require

NRC oversight to be consistently strong with sufficient inspections and enforcement. This requires improvement. (0823-2 [Michetti, Susan])

Comment: Assuming continued institutional controls is reasonable in both the short-term and long-term timeframes. In those timeframes, the nuclear fuel storage facilities will remain under NRC license and NRC oversight. The NRC will maintain authority to compel any actions required to assure protection of public health and safety and the environment. Control of the licenses and nuclear material may not be transferred without NRC approval. The timeframes involved do not dictate a need for unreasonable, hypothetical scenarios that would involve loss of control of the facility or nuclear material, or loss of legitimate regulatory oversight.⁵⁶ [footnote 56 text: See, e.g., *Natural Res. Def. Council v. Kleppe*, 429 U.S. 1307 (1976).] (0827-2-6 [Ginsberg, Ellen])

Comment: In the "no repository" scenario, the NRC staff remains justifiably reluctant to incorporate the additional conservative assumption that there will be a loss of institutional controls at the interim storage facilities. The existing WCD record and the draft GEIS support conclusions that the no repository scenario is highly unlikely, and that the no repository scenario without institutional controls at interim facilities is even more so. That notwithstanding, NEI recommends that - to very conservatively address the remand - the NRC even more clearly acknowledge that a conservative assessment of the impacts of a no repository scenario, without reliance on institutional controls, has already been completed. The "no action alternative" in DOE's Yucca Mountain EIS provides sufficient scope and depth to fully evaluate the extremely unlikely possibility that a repository will never be developed and that institutional controls will be lost. DOE evaluated two scenarios in its "no action" alternative to Yucca Mountain: (1) spent fuel would remain at existing commercial sites under institutional controls for at least 10,000 years, and (2) spent fuel would remain at existing commercial sites in perpetuity, but under institutional controls for only about 100 years, after which time, institutional controls would be lost.⁵⁷ [footnote 57 text: DOE pointed to 10 C.F.R. Part 61 - the NRC's regulations governing disposal of low-level radioactive material - as one the sources it used when choosing the 100-year timeframe for institutional controls. Part 61 states that active institutional controls cannot be relied on for more than 100 years. Substantive safety regulations that restrict the reliance on institutional controls do not diminish the reasonableness of assuming that institutional controls will continue to exist for purpose of environmental assessments under NEPA. Regardless, assuming that institutional controls will be lost after 100 years in the waste confidence GEIS would have resulted in an overly conservative assessment.] The second of these scenarios - loss of institutional controls after 100 years - is clearly a "worst case scenario" beyond the scope of NEPA. At the time of the Yucca Mountain EIS, the NRC commented that a no repository scenario, coupled with the assumption of a loss of institutional controls, was unreasonable.⁵⁸ [footnote 58 text: Draft GEIS at 1-15.] DOE explained that neither scenario considered in its "no action alternative" was likely, but that its assumptions regarding institutional controls were meant to bound potential environmental impacts. The same reasoning applies here. The NRC could more expansively respond to the remand by referencing the DOE EIS as bounding the environmental impacts of indefinite spent fuel storage for the no repository scenario, assuming a loss of institutional controls. (0827-2-7 [Ginsberg, Ellen])

Comment: In the draft GEIS, the NRC appears to distinguish the scenario assessed in DOE's no-action alternative from the indefinite storage scenario assessed in the draft GEIS to explain the differences in assumptions regarding institutional controls.⁵⁹ [footnote 59 text: Draft GEIS at 1-14 - 1-15, n.2.] The NRC states that the approach to institutional controls in DOE's EIS was related to the post-closure burial of radioactive waste, which is not relevant to the indefinite dry cask storage considered for the purposes of Waste Confidence.⁶⁰ [footnote 60 text: *Id.*] Although

NEI concurs with the NRC's approach to institutional controls in examining the indefinite storage scenario, this distinction is unnecessary. DOE specifically stated that the no-action alternative in the Yucca Mountain EIS "assumes that all commercial spent nuclear fuel would be stored in dry configurations in independent spent fuel storage installations at existing locations."⁶¹ [footnote 61 text: Department of Energy, "Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada," Vol. I at 7-18 (Feb. 2002).] These dry storage systems are the very ones analyzed in the NRC's draft GEIS. Including a reference to the Yucca Mountain EIS would not mean that the NRC would have arrived at the same factual or policy conclusions as DOE. Instead, a reference to the DOE analysis would simply recognize that the Yucca Mountain EIS contains information available to the public, which addresses the potential environmental impacts of a worst-case scenario of government inaction, coupled with failure of institutional controls - a scenario that the NRC described as requiring "unreasonable speculation."⁶² [footnote 62 text: Draft GEIS at 1-14 - 1-15.] Although evaluation of such a worst-case scenario is not required by NEPA, such a reference would clearly and definitively demonstrate that the NRC has more than adequately satisfied NEPA's disclosure objectives. While referencing the DOE analysis, the NRC should continue to stress that the reference is not based on any conclusion that it addresses a likely or even reasonable scenario. Although we encourage the NRC to reference DOE's analysis, replicating the existing DOE Yucca Mountain Final EIS analysis would serve no useful purpose. For one thing, given that such an analysis would be addressing the very same casks over the very same time periods, it would not yield any new information. The Commission recognized the efficiencies that could be gained by referencing (but not repeating) DOE's analysis of the Yucca Mountain "no action alternative" in SRM-COMSECY-12-0016, which stated that the staff "may adopt or incorporate by reference all or part of another agency's EIS. For example, the "no action alternative" in DOE's Yucca Mountain EIS contains a foundation that the NRC should build upon."⁶³ [footnote 63 text: SRM-COMSECY-12-0016 at 1.] (0827-2-8 [Ginsberg, Ellen])

Comment: Page 1-14, Line 19+, The assumption that institutional controls will be in place for an indefinite period of time is nonsense. Our country has only been in existence for a bit over 200 years. To assume that no changes will occur for an indeterminate time into the future is an assumption we believe you cannot make. Instead, these sites must not be contemplated for that extensive period of time, and should be limited to the decommissioning time period, as we describe with respect to other issues as well. (0836-15 [Davis, Anonymous])

Comment: Thirdly, the NRC could have used scenarios to address the very real possibility of a loss of institutional control at the sites. Such a loss of control does not have to be dramatic as was the case in Japan at *Fukushima Daiichi*; rather it can represent a gradual loss of institutional command of the site and its operations as was evidenced by various DOE projects related to nuclear weapons production. The history of lost control over the byproducts of nuclear weapons production, failed oversight by DOE/NRC in their stewardship of the environment and failures in regulatory oversight by government agencies provide strong evidence that the loss of institutional control is far more common than the DGEIS would admit (See appendix A). This slide into mediocrity as a scenario could have been augmented with a more dramatic scenario like evidenced by *Fukushima Daiichi*. Such opposing scenarios, or even the use of a continuum of possibilities representing the loss of institutional control, would have better addressed real world conditions. It would have represented more accurately historical experiences with lost institutional controls by agencies like the DOE and NRC in their oversight of the fuel cycle, weapons production and more directly, the issues associated with SNF. (0867-1-7 [Griffin, William])

Comment: Closely related and fourthly, the DGEIS should have examined multi-dimensional scenarios in which institutional controls are lost after 30, 60, 100, 160 years and indefinite periods of time. These scenarios would then be looked at as to their potential impacts on the environment and over time. This combination of variables is a more robust approach to analysis that could have been chosen by the NRC staff if they had been given enough time to do their analysis. (0867-1-8 [Griffin, William])

Comment: To illustrate, as has happened in the past, high-level wastes could be exposed to the environment (e.g., Hanford, Washington). The scenarios the NRC could use should be constructed to examine specific components of institutional control in order to examine the consequences that the loss of control would have on the environment. For example a common sociological phenomenon is the attenuation of vigilance. That is, as a system is shown to be reliable and safe, the safety features are slowly removed to reduce costs. A reasonable and useful kind of scenario construction would have examined the cost of institutional control, over certain time periods and then what withdrawal of part or all of that vigilance would mean to the environment. (0867-1-9 [Griffin, William])

Comment: *Based on its knowledge of and experience with the structure and operation of the various facilities that will provide continued storage, including the normal life of those facilities, the NRC believes that spent fuel pool storage could last for about 60 years beyond the licensed life for operation of the reactor where it is stored, and that each ISFSI will last about 100 years, for a total of 160 years or less of likely continued storage if a repository becomes available.* Although it may be valid, there is little empirical data to support it. In fact a recent statement by the director of the NRC may offer insight into the questions NRC has about such timeframes (see MacFarlane statement elsewhere). Other questions arise when the details of such assumptions are questioned. For example, what about the availability of human capital and experience to address the operations of these facilities? What about the financial concerns the long term operations represent? (0867-2-8 [Griffin, William])

Comment: The NRC assumes that any loss of institutional control is unreasonable. This assumption is not valid. The NRC's assumption is also ahistorical. In the recent past, two operating NPP have been without institutional controls. April 26, 1986 the Chernobyl reactor was evacuated except for staff performing emergency cooling operations. Although firefighters responded to the accident, the site was out of control. On March 16, 2011, all of the workers of the *Fukushima Daiichi* NPP were evacuated. The NRC should prepare an assessment that assumes there is a partial or complete loss of institutional control, particularly after an extended period. This may also be true for unused facilities in remote areas, a result of decommissioning. The NRC also assumes that there will be an agency to oversee and ensure the quality and safety of the process. Additionally, the environmental consequences of a loss of institutional control cannot be assessed generically because it is inherently dependent on the NPP site, surrounding demographics and geology. (0867-2-9 [Griffin, William])

Comment: For the purposes of these comments, the EPA defines institutional controls "as non-engineered instruments, such as administrative and legal controls, that help to minimize the potential for exposure to contamination and/or protect the integrity of a response action" (EPA). The NRC does not provide a precise definition of what it considers institutional controls. Excellent insight into the range of policies that combine to form institutional controls can be found at the State of New York (<http://www.dec.ny.gov/chemical/8665.html>). The DGEIS assessment of the environmental impacts of radiological storage is insufficient because it assumes that institutional control will be maintained throughout the future. A review of the lifecycle of nuclear materials suggests that the norm may be better expressed as a partial or

complete loss of institutional control rather than a consistent level of institutional control. There have been multiple instances where institutional control of nuclear facilities has been lost. These instances have occurred throughout the nuclear fuel cycle. NRC should use analytical methods that will enable them to assess the environmental consequences of the loss of institutional control for various lengths of time. The two most prominent examples of this are the Chernobyl NPP which was evacuated in 1986 and the Fukushima NPP's which was briefly evacuated in 2011. In both cases for long and short periods of time operating nuclear facilities were completely out of control. But there are other relevant cases throughout the nuclear fuel cycle. These cases emphasize that the management of these materials has been sporadic, incomplete, and performed without sufficient institutional controls. These breakdowns have occurred worldwide and include the United States. (0867-3-1 [Griffin, William])

Comment: In fact, the DGEIS flouts both NEPA and the Court's application of NEPA in *New York*, 681 F.3d 481 (D.C. Cir. 2012) in multiple ways: In blatant violation of NEPA and the Court's decision in *New York*, the DGEIS fails to examine the probability and consequences of failure to site a repository. Instead of examining the risk of failing to site a repository, the DGEIS rationalizes the risk away, by arbitrarily assuming that spent fuel will be protected by "institutional controls" for an infinite period of time at reactor sites. This assumption is not only absurd and inconsistent with the Nuclear Waste Policy Act ("NWPA"), but it also defeats the Court's purpose of forcing NRC to reckon with the environmental consequences of its failure to site a repository. (0897-1-7 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: In *New York*, the Court concluded that the NRC's "reasonable assurance" finding that a repository will be available is insufficient to satisfy NEPA because it does not show that the "likelihood of nonavailability" is "remote and speculative." 681 F.3d at 479. Therefore the Court ordered NRC to conduct a "full analysis" of "the potential environmental effects" of storing spent fuel onsite at nuclear plants "on a permanent basis." 681 F.3d at 479. The Court stated quite clearly that the EIS must address the impacts of a "failure to secure permanent storage." *Id.* Under NEPA's rule of reason standard, the analysis of the risk of failure to secure permanent storage for spent fuel must include the following: the risk that sufficient repository capacity that meets NRC's Part 63 standards for containment will not be found; the risk that even if sufficient repository capacity is found it will not be licensed before substantial environmental harm has occurred; and the nature of the harm that could occur if interim measures to protect spent fuel from exposure to the environment fail. But the DGEIS contains no such analysis. The DGEIS completely ignores the issue of the probability that sufficient repository capacity will be available in a timely way. See Makhijani Declaration, pars. 8.1-8.24. Moreover, instead of analyzing the environmental impacts that could occur if spent fuel remains undisposed of for many decades and escapes to the environment, the NRC assumes those impacts will not happen because they will be prevented by the indefinite maintenance of "institutional controls." See DGEIS at 1-14 (stating the assumption that "[i]nstitutional controls, i.e., the continued regulation of spent nuclear fuel, will continue"). (0897-3-18 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The DGEIS' Assumption of Indefinitely Effective Institutional Controls Violates NEPA[.] Instead of complying with NEPA and the Court's decision in *New York* by examining the risk of failing to site a repository, the DGEIS rationalizes the risk away by arbitrarily assuming that spent fuel will be protected by "institutional controls" for an infinite period of time at reactor sites or away-from-reactor storage sites. This assumption is not only absurd and inconsistent with the NWPA, but it flouts the Court's requirement to reckon with the environmental consequences of its failure to site a repository. (0897-3-19 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: NRC's assumption of indefinitely effective institutional controls violates NEPA because it is inconsistent with the NWA and NRC regulations[.] NRC's determination that spent fuel can be safely stored for an indefinite amount of time above- ground is inconsistent with the NWA and NRC's own regulations. As discussed above in Section V, the NWA establishes a national policy of disposing of spent nuclear fuel in a deep geologic repository. By labeling the consideration of permanent on-site storage of spent nuclear fuel as "indefinite storage" the NRC seeks to avoid the necessary conclusion that when on-site storage becomes permanent it becomes disposal. This assumption of de facto above-ground disposal directly violates the NWA. The DGEIS' assumption of indefinite institutional controls is also inconsistent with the NRC's own regulations. For instance, the NRC's low-level waste disposal regulations assume that active controls will fail after 100 years, and intruder barriers will fail around 500 years. 10 CFR § 61.7 (b)(4) & (b)(5). To state that institutional controls are likely to fail in the NRC's regulations, and then assume throughout this DGEIS that institutional controls will last forever is inconsistent and irrational. And the NRC's assumption is inconsistent with general federal policy regarding containment of hazardous materials. When reviewing the Department of Energy's ("DOE") cleanup plans for legacy waste sites, the NRC required the DOE to assume that "contamination isolation barriers and stewardship measures at sites where wastes are left in place will eventually fail." National Research Council, Board on Radioactive Waste Management, Commission on Geosciences, Environment, and Resources. *Long-Term Institutional Management of U.S. Department of Energy Legacy Waste Sites* (Washington, DC: National Academy Press, 2000), available at <http://www.nap.edu/catalog.php?recordid=9949>. This directly contradicts the assumption of forever continuing institutional controls relied upon by the NRC in the DGEIS. Finally, as a matter of law, the NRC may not assume the effectiveness of institutional controls to prevent radiological releases to the environment during the extended period of spent fuel storage. As the Court held in *New York*, "merely pointing to [a] compliance program is in no way sufficient to support a scientific finding." 481 F.3d at 481. The question of whether institutional controls will remain in place for hundreds or thousands of years must be addressed as an element of risk. (0897-3-20 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: NRC's assumption of indefinitely effective institutional controls violates NEPA and *New York v. NRC* because it arbitrarily assumes the nonexistence of an impact instead of analyzing it[.] The NRC asserts that a loss of institutional controls is so remote and speculative that its consideration is outside the requirements of the National Environmental Policy Act ("NEPA"). *Id.* at 1-15, fn. 2. Given the many examples in history of loss of institutional controls, it is the NRC's assumption that institutions will remain intact and capable of caring effectively for spent fuel over an indefinite period of time that is more fairly characterized as remote and speculative. Makhijani Declaration, pars. 6.4, 10.3. As Dr. Makhijani discusses in Section 6 of his declaration, this assumption in the DGEIS flies in the face of facts, history and common sense. For instance, the U.S. has been in two world wars in less than 100 years. Just over a decade ago, the financial capital of the U.S. suffered a devastating attack that could have targeted a nuclear power plant. There have been a dozen government shutdowns since 1981. In the most recent shutdown, in October 2013, some waste management functions – even for "visible" facilities – almost came to a halt. For instance, the Fernald Preserve, which includes a large visible mound of radioactive waste from the Fernald uranium plant that was part of the nuclear weapons complex was closed. Had the government shutdown lasted much longer, the pump and treat operations that are a mandated part of water quality objectives, would have come to a halt. Makhijani Declaration, par. 6.7 –6.8. The NRC asserts that the purpose of its assumption of continued institutional controls is to "avoid unreasonable speculation regarding what might happen in the future regarding Federal actions to provide for the safe storage of spent fuel." DGEIS at 1-14. Admitting a lack of information satisfies the first

obligation for agencies faced with uncertainties in an EIS, but the NRC fails to complete any of the remaining three obligations under the CEQ regulation for incomplete or unavailable information. 40 C.F.R. § 1502.22(b). After admitting uncertainty, under section 1502.22(b) the agency must include within the EIS: (2) [A] statement of the relevance of the incomplete or unavailable information to evaluating reasonably foreseeable significant adverse impacts on the human environment; (3) a summary of existing credible scientific evidence which is relevant to evaluating the reasonably foreseeable significant adverse impacts on the human environment, and (4) the agency's evaluation of such impacts based upon theoretical approaches or research methods generally accepted in the scientific community.⁶ [footnote 6 text: The Supreme Court has held that Council on Environmental Quality regulations for the implementation of NEPA "impose a duty on all federal agencies." *Marsh v. Oregon Natural Res. Council*, 490 U.S. 360, 372 (1989). The NRC is a federal agency and therefore must answer this call to duty. "Reasonable forecasting and speculation is thus implicit in NEPA, and we must reject any attempt by agencies to shirk their responsibilities under NEPA by labeling any and all discussion of future environmental effects as 'crystal ball inquiry'." *Scientists' Inst. For Pub. Info. v. Atomic Energy Comm'n*, 481 F.2d 1079, 1086 (D.C. Cir. 1973).] (0897-3-21 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The draft GEIS sets forth a highly optimistic view of the future conditions that will affect stored spent fuel. It assumes that institutional controls will remain operative into the indefinite future, arguing that this assumption "avoids unreasonable speculation regarding what might happen in the future". This assumption, like other optimistic assumptions in the draft GEIS, is neither reasonable nor prudent. Moreover, assuming static conditions is speculative in the extreme, and shows a profound ignorance of human history. Given the long timeframes envisioned in the draft GEIS, the only reasonable approach is to consider a broad range of scenarios. Those scenarios would encompass substantial changes in the risk environment over time. The changes could be non-uniform across the United States. Thompson Declaration, par. VII-2. (0897-6-16 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The Impacts and Costs Related to Spent Fuel Storage and Disposal Are Significant[.] As demonstrated in the attached expert declarations by Dr. Arjun Makhijani, David Lochbaum, and Dr. Gordon Thompson, the environmental impacts of storing spent fuel are significant. Environmental impacts of indefinite storage of spent fuel may be catastrophic, as discussed in the declaration of Dr. Arjun Makhijani, Section 7. In the Yucca Mountain EIS, for instance, the DOE found that loss of institutional controls would result in the "unchecked deterioration and dissolution of the materials" in storage, with "catastrophic" effects. And the DOE conservatively underestimated those impacts. Makhijani Declaration, pars. 7.3 and 7.4. (0897-7-2 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: My second major criticism of these first findings is that they depend on the unsupported assumption that institutional controls will remain effective indefinitely. Instead of addressing the risk of accidental radioactivity releases posed by the poorly understood behavior of spent fuel in long-term storage, the NRC simply assumes that current regulations and institutional measures for managing spent fuel will remain in place indefinitely, and that any new problems that arise will be resolved, such that spent fuel storage will never pose a significant health or environmental problem. In my opinion, this assumption of active institutional control for an indefinite period of time lacks any factual, historical, or financial foundation and even common sense when it extends to very long time periods. First, it is fundamentally inconsistent with federal law and policy (including NRC's own regulations) that institutional controls should only be relied on for a period of decades, not hundreds of years. Second, it is contradicted by the experience of history that governments tend to fail or change substantially over time. To

assume that the federal government will exist for tens of millennia and each year appropriate significant sums of money to manage spent fuel at sites that produce no revenue flies in the face of current facts and U.S. history, including a dozen federal government shut downs since 1980, not to speak of the Civil War, when the United States did not have a single government, budget, or currency. In this century, the White House had received a number of petitions, some with thousands of signatures, for secession from the United States as of November 12, 2012.¹⁵ [footnote 15 text: Weiner 2012] (0898-1-5 [Curran, Diane] [Makhijani, Arjun])

Comment: The NRC may intend to use the phrase "remote and speculative" to avoid its legal obligation to analyze the impacts of the loss of institutional control. But the Draft GEIS has failed to recognize that simply throwing the phrase at the problem does not make loss of institutional control "remote and speculative" in legal or physical reality. On the contrary, it is the Draft GEIS's contention that institutional control will be maintained essentially forever to the required degree that is remote and speculative. (0898-3-10 [Curran, Diane] [Makhijani, Arjun])

Comment: Given U.S. and world history, it is not unreasonable to assume that the endurance of institutions to the degree required in paragraph 6.3 will persist for a 100 years. This is a common assumption about institutional control that is factually defensible, though even that is not without caveats (see paragraph 6.7 below). 6.5. For example, empires usually fade in a few centuries. During such periods governments and societies often suffer tremendous upheavals and internal institutional changes. The NRC's assumption of institutional control is so sweeping that it not only requires the U.S. government to endure for tens of thousands of years but that its functions and institutions remain operative and vigilant. (0898-3-11 [Curran, Diane] [Makhijani, Arjun])

Comment: Consider some elementary facts close to home. The half-life of plutonium-239 is more than 24,000 years. The U.S. government has existed for less than one percent of that time. In that period of time, the United States has suffered a Civil War during which it did not have a unified government. Indeed, it had two governments, with two budgets, two armies, two navies, and two currencies. The United States has also been in two world wars in less than 100 years. It has suffered a devastating terrorist attack just over a decade ago on September 11, 2001, that could have targeted a nuclear power plant. Even closer in time was the federal government shutdown in the first half of October 2013; there was a near-default on the U.S. sovereign debt in the same month. There have been a dozen federal government shutdowns since about 1981.⁹⁷ [footnote 97 text: As cataloged in Wikipedia at http://en.wikipedia.org/wiki/Government_shutdown_in_the_United_States.] During the October 2013 federal government shutdown, most of the NRC was shut down. Some waste management functions, even for "visible" facilities almost came to a halt. For instance, the Fernald Preserve, which includes a large visible mound of radioactive waste from the Fernald uranium plant that was part of the nuclear weapons complex was closed. Had the government shutdown lasted much longer, the pump and treat operations that are a mandated part of water quality objectives would have come to a halt.⁹⁸ [footnote 98 text: 98 Crawford 2013. Personal email communication from Lisa Crawford, Fernald Residents for Environmental Safety and Health, October 7, 2013. "Folks, the Fernald Preserve is CLOSED due to the Gov. Shut Down -- no big deal really except -- if this goes on much longer it will then begin to affect the pump and treat of the aquifer which is mandated by the OEPA & USEPA and DOE. The site is telling me that it can go about a month and then it's down to little or nothing or shut off. That could be a disaster. Since most of the site is contracted out to Stoller Co. -- those folks are still on the job, but the site is closed. Crazy if you ask me. Lc"] The NRC, without any analysis of these facts, has ruled it remote and speculative that the necessary degree of institutional controls will exist

for many half-lives of plutonium-239. In fact, the Draft GEIS puts no upper bound on the time for which such controls will exist. (0898-3-12 [Curran, Diane] [Makhijani, Arjun])

Comment: It is to be noted that there were no federal government shutdowns before 1981. There have been a dozen since then.⁹⁹ [footnote 99 text: 99 Wikipedia: http://en.wikipedia.org/wiki/Government_shutdown_in_the_United_States. Accessed on November 8, 2013.] This points to the need for a serious analysis of the reliability of federal government funding even over much shorter periods than the funding for millennia assumed in the Draft GEIS. Specifically, the short-term time frame of 60 years beyond the operating license life of "a" reactor needs to be considered, especially as it could be any reactor past, present, or future. It is also important to consider the "long-term" timeframe of 100 years beyond the "short-term." The federal government will have to continue to appropriate funds each year to compensate for its failure to fulfill its contracts with nuclear utilities to begin taking spent fuel from them starting on January 31, 1998. The discontinuities in the federal government's functioning and the uncertainties surrounding budgetary processes require specific analysis in the Draft GEIS in the context of its assumptions about institutional longevity. (0898-3-13 [Curran, Diane] [Makhijani, Arjun])

Comment: In view of the above-mentioned historical facts and current events, the attempt of the Draft GEIS to use the legalism of the phrase "remote and speculative" to avoid considering the consequences of the loss of institutional control is ridiculous, bizarre, and even surreal. Given the fact, an assumption of institutional control extending to millennia with the stringent set of controls required for spent fuel management, such as those listed in paragraph 6.3 above, is entirely remote, unreasonable, and speculative. (0898-3-14 [Curran, Diane] [Makhijani, Arjun])

Comment: Many existing authorities, including the National Research Council, have concluded that long-term waste and remediation policy should be based on the assumption that institutional controls will eventually fail. In reviewing Department of Energy cleanup plans the National Research Council stated the following: The Committee on Remediation of Buried and Tank Wastes finds that much regarding DOE's intended reliance on long-term stewardship is at this point problematic....[...]Other things being equal, contaminant reduction is preferred to contaminant isolation and imposition of stewardship measures whose risk of failure is high.[...] *The committee believes that the working assumption of DOE planners must be that many contamination isolation barriers and stewardship measures at sites where wastes are left in place will eventually fail, and that much of our current knowledge of the long-term behavior of wastes in environmental media may eventually be proven wrong. Planning and implementation at these sites must proceed in ways that are cognizant of this potential fallibility and uncertainty.*¹⁰⁰ [footnote 100 text: NAS-NRC 2000, pp. 3 and 5, original italics; bold added.] (0898-3-15 [Curran, Diane] [Makhijani, Arjun])

Comment: 6.10 Indeed, even the NRC itself put a time limit on institutional controls in its low-level waste disposal regulations at 10 CFR 61.7(b)(4) and (b)(5). These regulations effectively assume that active controls (as defined in 10 CFR 61.2) will fail after 100 years. Intruder barriers, which are passive controls, are assumed in the rule to last at most 500 years. NRC's low-level waste regulations are consistent with EPA regulations for managing and disposing of high-level waste and transuranic waste.¹⁰¹ [footnote 101 text: 40 CFR 191.14(a), 2011] The Draft GEIS has not taken account of the technical basis for these regulations. (0898-3-16 [Curran, Diane] [Makhijani, Arjun])

Comment: 6.11 It is to be noted that Department of Energy's (DOE) Yucca Mountain Final EIS "No-Action Scenario 1" examined the case of continued institutional control assumed for 10,000

years as well as an alternative "Scenario 2" in which that control was lost after 100 years.¹⁰² [footnote 102 text: DOE 2002, Vol. I, pp. 2-70 – 2-72] Similarly, EPA regulations for "Management and Disposal of Spent Nuclear Fuel, High-Level and Transuranic Radioactive Wastes" at 40 CFR 191.14 mandate that "active institutional controls" be limited to 100 years after disposal. Since dry storage can be licensed after reactor closure, the 100 years may start after expiry of the dry storage license. EPA's regulation relating to uranium mill tailings, 40 CFR 192.02, requires active management measures for 200 years and, if feasible, up to 1,000 years. But, unlike the Draft GEIS, active measures are not assumed to be feasible beyond 1,000 years. (0898-3-17 [Curran, Diane] [Makhijani, Arjun])

Comment: 6.12 The Draft GEIS notes that the EPA allows for "permanent" institutional control under some Superfund scenarios and that DOE has also assumed perpetual control of portions of the Savannah River Site.¹⁰³ [footnote 103 text: NRC 2013a, footnote 2, pp. 1-14 and 1-15] However, just because these agencies assume perpetual control does not relieve the NRC from its obligation under NEPA to examine the environmental impacts of an eventuality that is reasonably foreseeable in case a repository is not developed. For instance, the DOE has assumed perpetual control under a variety of circumstances. However, the DOE also did consider loss of institutional control in its Yucca Mountain EIS, as noted below in paragraph 6.13. Similarly, the DOE considered and evaluated the loss of institutional controls in its EIS relating to the Waste Isolation Pilot Plant (WIPP),¹⁰⁴ [footnote 104 text: DOE 1997, p. 4-33] which is cited in the Draft GEIS.¹⁰⁵ [footnote 105 text: NRC 2013a, footnote 2, pp. 1-14 and 1-15] (0898-3-18 [Curran, Diane] [Makhijani, Arjun])

Comment: The main barrier preventing theft of spent fuel in case of a loss of institutional control is external radiation from cesium-137. This radiation barrier decays with a half-life of about 30 years and is therefore less and less effective after one to two centuries. After time of that order of magnitude, the obstacles to theft of spent fuel bundles extracted from the casks would be far lower - low enough to present a real proliferation problem. Every metric ton of spent fuel (heavy metal content) contains more than enough plutonium to make a nuclear weapon. Extracting the plutonium from the spent fuel would also be greatly simplified due the loss of almost all of the radiation barrier. It is therefore essential for the GEIS to evaluate the potential for theft of spent fuel in case of a loss of institutional control and the potential impacts of the possible resultant proliferation. (0898-3-19 [Curran, Diane] [Makhijani, Arjun])

Comment: I am not arguing here that the NRC should not evaluate a case where institutional control would be maintained for a prolonged period. If the NRC wants to examine a remote and speculative case, it is free to do so. But that cannot be the basis for scientifically valid conclusions about environmental impacts. The NRC is obligated under NEPA to consider the environmental impacts in case of a loss of institutional control because, contrary to the assertion in the Draft GEIS, such an eventuality is not "remote and speculative" for the extremely long periods in question. Rather, it is reasonably foreseeable, given the facts of history, though the exact process is not and though one might wish otherwise. (0898-3-20 [Curran, Diane] [Makhijani, Arjun])

Comment: THE DRAFT GEIS FLIES IN THE FACE OF FACTS, HISTORY, AND COMMON SENSE BECAUSE IT ASSUMES INDEFINITE RELIABILITY OF INSTITUTIONAL CONTROLS (0898-3-8 [Curran, Diane] [Makhijani, Arjun])

Comment: One of the Draft GEIS's greatest defects is its assumption that institutional controls of the most active sort will persist essentially forever, which in the context of spent fuel is tens or hundreds of thousands of years: Institutional controls, i.e., the continued regulation of spent

nuclear fuel, will continue. This assumption avoids *unreasonable speculation regarding what might happen in the future regarding Federal actions* to provide for the safe storage of spent fuel. Although government agencies and regulatory safety approaches can be expected to change over long periods of time into the future, the history of radiation protection has generally been towards ensuring increased safety as knowledge of radiation and effectiveness of safety measures has improved. For the purpose of the analyses in this draft GEIS, the NRC assumes that regulatory control of radiation safety will remain at the same level of regulatory control as currently exists today.⁹⁵ [footnote 95 text: NRC 2013a, pp. 1-14 - 1-15, italics added] (0898-3-9 [Curran, Diane] [Makhijani, Arjun])

Comment: As discussed in Section 6 above, it is essential for the NRC to evaluate the environmental impacts of indefinite storage in case of a loss of institutional control. These impacts are likely to be catastrophic under a variety of circumstances. (0898-4-1 [Curran, Diane] [Makhijani, Arjun])

Comment: The NRC has cited the catastrophic impacts in case of loss of institutional control that were found in the Yucca Mountain EIS: DOE's approach to the loss of institutional controls at a dry cask storage facility was provided in its Yucca Mountain EIS (DOE 2008). In its analysis, DOE found that the loss of institutional controls resulted in catastrophic impacts for several resource areas.¹⁰⁷ [footnote 107 text: NRC 2013a, footnote 2, pp. 1-14 and 1-15] 7.3. The 2008 Yucca Mountain EIS, which is a supplement to the DOE's 2002 Yucca Mountain EIS (DOE 2002), estimates that in case of loss of institutional control there would be 1,000 "latent" cancer fatalities in the first 10,000 years and a hundred times more in the period up to a million years after that – though it considers the latter figure to be very uncertain. The impact in the longer time frame is estimated to be the result of "the unchecked deterioration and dissolution of the materials." The document describes these impacts as "catastrophic."¹⁰⁸ [footnote 108 text: DOE 2008, p. S-51. We note here that in the 2002 EIS to which DOE 2008 is a supplement, the DOE estimated latent cancer fatalities in the first 10,000 years as 3,300. (DOE 2002, Vol. II, Appendix K, p. K-28)] 7.4. While I agree with DOE 2008 that the impacts of the loss of institutional control in case of indefinite onsite storage would be catastrophic, I also note that the DOE *deliberately underestimated the impacts in this scenario*. It did so because it did not want to overstate the relative environmental benefits of deep geologic disposal at Yucca Mountain, its preferred alternative, compared to the no-action alternative. Without any implications as to the overall merits of the Yucca Mountain EIS or the DOE's license application, DOE's approach to the loss of institutional control was reasonable. If the underestimated impacts of the no action alternative are much greater than those of the preferred action, it allows a technical case to be made for the preferred action, which was, after all, the goal of that EIS. However, for the waste confidence GEIS, such an underestimation is not permissible, since the court has explicitly asked it to estimate the impacts in case a repository never becomes available. This requires as full and complete estimation of impacts as reasonably as possible. (0898-4-2 [Curran, Diane] [Makhijani, Arjun])

Comment: I provide some examples of impacts that were ignored in the Yucca Mountain EIS loss of institutional control scenario that must be included in the waste confidence GEIS. The DOE "did not attempt to quantify adverse health impacts from chemical toxicity of the waste forms (principally uranium dioxide and *borosilicate glass*) that could occur within the exposed population."¹⁰⁹ [footnote 109 text: DOE 2002, Vol. I, p. 7-35, emphasis in original] (0898-4-3 [Curran, Diane] [Makhijani, Arjun])

Comment: I provide some examples of impacts that were ignored in the Yucca Mountain EIS loss of institutional control scenario that must be included in the waste confidence GEIS.[...]The

DOE did not quantify some of the most critical ecosystem and economic impacts of the deterioration of containers in storage after institutional control is lost, but noted the following: Under Scenario 2 [no institutional control after 100 years], more than 20 major waterways of the United States (for example, the Great Lakes, the Mississippi, Ohio, and Columbia rivers, and many smaller rivers along the Eastern Seaboard) that currently supply domestic water to 30.5 million people would be contaminated with radioactive material. The shorelines of these waterways would be contaminated with long-lived radioactive materials (plutonium, uranium, americium, etc.) that would result in exposures to individuals who came into contact with the sediments, potentially increasing the number of latent cancer fatalities.¹¹⁰ [footnote 110 text: DOE 2002, Vol. II, Appendix K, p. K-29] (0898-4-4 [Curran, Diane] [Makhijani, Arjun])

Comment: I provide some examples of impacts that were ignored in the Yucca Mountain EIS loss of institutional control scenario that must be included in the waste confidence GEIS.[...] When food pathways other than drinking water are considered, the DOE estimated that the radiation doses and, hence, fatalities would triple.¹¹¹ [footnote 111 text: DOE 2002, Vol. II, Appendix K, p. K-29 and K-32] The impact of dispersed waste on vast aquifers, areas of land, and the country's most important rivers that could not be used again because of contamination was not explored in detail. The Fukushima accident that began on March 11, 2011 has shown that the economic, social, and ecological impacts of the spread of radiation contamination are far larger than indicated by a narrow view of latent cancer fatalities alone. (0898-4-5 [Curran, Diane] [Makhijani, Arjun])

Comment: I provide some examples of impacts that were ignored in the Yucca Mountain EIS loss of institutional control scenario that must be included in the waste confidence GEIS.[...] Climate change uncertainties were not evaluated in the Yucca Mountain EIS No-Action Alternative. (0898-4-7 [Curran, Diane] [Makhijani, Arjun])

Comment: In conclusion, the impacts from a failure of institutional controls are likely to be catastrophic - much more so than estimated in the Yucca Mountain EIS. Since a failure of institutional controls over millennia is reasonably foreseeable, given the facts of world and U.S. history, the NRC must realistically analyze those impacts. (0898-4-8 [Curran, Diane] [Makhijani, Arjun])

Comment: The Draft GEIS has made an unsupported assumption that institutional controls will remain effective indefinitely on the ground. An assumption that the federal government will be there to protect health and safety even thousands of years from the present is remote and speculative. On the contrary, global and U.S. history shows that it is highly remote and speculative to assume institutional control for an indefinite period. It is also fundamentally inconsistent with federal law and policy (including NRC's own regulations) to assume that institutional controls will last forever. For instance, the NRC's low-level waste regulations assume that institutional controls will last no more than 100 years and that physical barriers to intruders will last no more than 500 years. To assume that the federal government will exist for tens of millennia and each year appropriate significant sums of money to manage spent fuel at sites that produce no revenue flies in the face of current facts and U.S. history, including a dozen federal government shut downs since 1980, not to speak of the Civil War, when the United States did not have a single government, budget, or currency. (0898-5-17 [Curran, Diane] [Makhijani, Arjun])

Comment: The Draft GEIS should be redone to remedy a number of fundamental defects. Among other things, it is necessary to include a scenario that posits indefinite storage and loss of institutional control 100 years after the end of reactor operating licenses. (0898-5-26 [Curran, Diane] [Makhijani, Arjun])

Comment: The GEIS must evaluate the increasing likelihood of theft after loss of institutional control and a decay of the cesium-137 radiation barrier after 200 to 300 years. It must also evaluate the environmental and proliferation consequences of such theft. (0898-5-27 [Curran, Diane] [Makhijani, Arjun])

Comment: Unrecognized in the Draft GEIS is the fact that no civilization and no human institutions have lasted for hundreds of thousands of years. Any credible plan must include ways to mitigate the risks of environmental contamination in the event of failure of governments or institutions. A realistic plan must be devised to keep manmade radioactive elements isolated from the biosphere for the million years the EPA declares them to be lethal. (0908-5 [Mikkelsen, Sara])

Comment: (VII-4) A report from Argonne National Laboratory examines the challenge of safeguarding spent fuel during very long-term storage (VLTS), which it defines as above-ground, interim, dry storage for a period of more than 50 years.⁶⁵ [footnote text 65: Kollar et al, 2013.] That report accompanies this declaration as Exhibit #32. The challenges identified in the report arise partly from potential changes in the risk environment. Thus, the report illustrates the significance of a potentially changing risk environment for the assessment of radiological risk. The report makes the following statement:⁶⁶ [footnote text 66: Kollar et al, 2013, page 6.] "Safeguarding a VLTS facility with nuclear material for 50, 100, or 200 years will present many challenges. First of all, the integrity of the fuel or cask may deteriorate. The radioactive signature of the fuel will also change. As the fuel cools, it may become more attractive for diversion. Even though the State has the means to handle very radioactive spent fuel, cooler spent fuel will still be more attractive to divert because it is easier to handle and reprocess. Keeping data on the facility for that long may also be a challenge. If the past 50 years are any indication of the future, it is difficult to predict what the safeguards challenges and needs will be in just the next 50 years." (0916-1-14 [Curran, Diane] [Thompson, Gordon R.]

Comment: (VII-5) The draft GEIS does consider one aspect of potential change in the risk environment over coming decades. In its Section 4.18, it discusses the influence of climate change on design-basis accidents or severe accidents at spent-fuel pools or at dry cask storage facilities (i.e., ISFSIs). It acknowledges various potential outcomes of climate change, such as increased intensity and frequency of severe weather events, sea level rise, increased storm surges, shoreline retreat, and inland flooding. It assumes, however, that mitigating actions could prevent significant increase in radiological risk as a result of climate change, that NRC will continue to exist and will require the necessary mitigating actions, and that licensees will be willing and able to implement these actions. (VII-6) Section 1.8.3 of the draft GEIS, titled Analysis Assumptions, sets forth a highly optimistic view of the future conditions that will affect stored spent fuel. It assumes that institutional controls will remain operative into the indefinite future, arguing that this assumption "avoids unreasonable speculation regarding what might happen in the future regarding Federal actions to provide for the safe storage of spent fuel".⁶⁷ [footnote text 67: NRC, 2013b, page 1-14.] It further assumes that each ISFSI will be replaced on a 100-year cycle, into the indefinite future. (VII-7) For the reasons set forth in Section V of the Thompson scoping declaration, the highly optimistic assumptions used in the draft GEIS are neither reasonable nor prudent. Moreover, assuming static conditions is speculative in the extreme, and shows a profound ignorance of human history. Given the long timeframes

envisioned in the draft GEIS, the only reasonable approach is to consider a broad range of scenarios. Section VI of the Thompson scoping declaration discussed this approach. That discussion yielded three recommendations, each of which is pertinent to radiological risk, as follows:⁶⁸ [footnote text 68: Thompson, 2013b, Section VI and Section X.] "Recommendation #8: The scenarios considered in the proposed EIS should cover a range of potential outcomes regarding the role of nuclear power, including: (i) shrinkage in the number of operating reactors, with potential shutdown of all reactors by the middle of the 21st century; (ii) expansion in the number of operating reactors; and (iii) introduction of new technology." "Recommendation #9: The scenarios considered in the proposed EIS should cover future societies exhibiting a range of variation in prosperity, technological capability, and the quality of governance." "Recommendation #10: The scenarios considered in the proposed EIS should cover a range of potential future outcomes regarding the propensity for violent conflict, and should cover situations in which stored SNF or HLW would experience attacks involving States or non-State actors." (VII-8) The draft GEIS does not implement any of my Recommendations #7 through #10. Instead, the draft GEIS takes the unreasonable, imprudent, and highly speculative position that the risk environment will remain unchanged into the indefinite future. (0916-1-15 [Curran, Diane] [Thompson, Gordon R.]

Comment: But if institutional control is lost, which is almost guaranteed over a long enough period of time, the radioactivity releases will be catastrophic-on the surface of the Earth! The U.S. Department of Energy has admitted to as much, in its 2002 FEIS on the now cancelled Yucca Mountain dump proposal. Although DOE didn't delve into the catastrophic details, it observed that simply abandoning high-level radioactive wastes on-site at reactors would eventually result in the release of their radioactive contents into the environment over time, as the containers failed, with catastrophic consequences. (0919-2-11 [Kamps, Kevin])

Comment: What does DOE know that NRC does not?! Perhaps DOE's own loss of institutional control over its own inventories of highly radioactive wastes, not after 100 years, but after just years and decades, has provided it with insights that NRC has chosen to blind itself to? Dr. Makhijani points out in his expert commentary in this proceeding that during the recent October 2013 government shutdown, active pumping of groundwater, at DOE's contaminated Fernald site in Ohio, was nearly interrupted due to lack of needed funding! And this after just a few years of active pumping thus far! (0919-2-13 [Kamps, Kevin])

Comment: Whereas NRC assumes institutional control forever, on Pages 1-14 to 1-15, NRC and the commercial nuclear power industry NRC supposedly regulates has managed to lose institutional control in real time. Examples abound. Irradiated nuclear fuel has been "lost," as at Vermont Yankee, Humboldt Bay (CA), and Millstone (CT) nuclear power plants, as but a few examples. (0919-2-15 [Kamps, Kevin])

Comment: Nor has NRC taken NEPA's requisite "hard look" at its mere assumption that such institutional controls will be maintained forevermore into the future. To the contrary, NRC has simply assumed it. In Section 1.8.3, Analysis Assumptions, on Page 1-14 to 1-15, NRC states: "Institutional controls, i.e., the continued regulation of spent nuclear fuel, will continue. This assumption avoids unreasonable speculation regarding what might happen in the future regarding Federal actions to provide for the safe storage of spent fuel. Although government agencies and regulatory approaches can be expected to change over long periods of time into the future, the history of radiation protection has generally been towards ensuring increased safety as knowledge of radiation and effectiveness of safety measures has improved. For the purpose of the analyses in this draft GEIS, the NRC assumes that regulatory control of radiation safety will remain at the same level of regulatory control as currently exists today." This is a

most convenient, and overly optimistic assumption, by NRC. History provides countless counter-examples regarding what NRC is now phrasing "institutional control." (0919-2-5 [Kamps, Kevin])

Comment: These may be dramatic examples of the fragility of "institutional control." Perhaps less dramatic, but very relevant, and ironically so, was the U.S. federal government shutdown of October 2013. It threw this very NRC WC DGEIS public comment meeting schedule into chaos. A number of meetings had to be postponed to a later date, greatly complicating public participation. As was pointed out by David Kraft of NEIS at the Oak Park, IL on November 12, 2013, once that meeting was rescheduled from its original October 24th date: "NRC expects the public to accept that spent-fuel can be safely stored at reactor sites indefinitely under its supervision. One month ago, NRC could not even guarantee that it could put a workforce in the field due to the government shutdown." The postponement of public meeting dates pushed the Minnetonka, MN date back to Dec. 4th - sure enough, just in time for severe winter weather, which dampened public turnout. (0919-2-6 [Kamps, Kevin])

Comment: Re: Page 4-2, lines 18-22, "the NRC assumes that the ISFSIs are completely replaced every 100 years. This replacement activity would require separate site-specific authorization from the NRC before the start of any replacement activities. NRC authorization to relicense or replace an ISFSI and NRC authorization to construct, operate, and replace a DTS are separate licensing actions that would require an NRC review. They are considered Federal actions under NEPA and would be undertakings under the National Historic Preservation Act (NHPA)."..."NRC's assumption, that it'll be around, and these laws still in force, centuries or millennia into the future, is absurd, with so historical, or rationale, basis whatsoever. No government has ever last that long. Few human institutions of any description have even lasted millennia, let alone forever, as NRC is assuming it will do, and the nuclear industry will do. (0919-6-7 [Kamps, Kevin])

Comment: On Page 4-4, lines 27-28, NRC states "ISFSIs are designed as passive systems that require no power or regular maintenance other than routine visual inspections and checks of the cask ventilation system (e.g., for blockages of ducts)."--But what about when institutional control is lost, and those manual inspections and checks are abandoned, along with the ISFSIs themselves? For a decade, NRC has allowed Big Rock Point personnel to limit "walk by" inspections to once every two weeks. So, an incident could be under at Big Rock Point even now - such as a vent blocked by trash, debris, sand, etc., and Entergy Nuclear would not even know about it for up to two weeks - risking overheating of the irradiated nuclear fuel, its degradation, etc. (0919-6-9 [Kamps, Kevin])

Comment: NRC expects the public to accept that spent-fuel can be safely stored at reactor sites indefinitely under its supervision. One month ago, NRC could not even guarantee that it could put a workforce in the field due to the government shutdown. (0921-4 [Kamps, Kevin])

Comment: Page 1-14, Line 19+, The assumption that institutional controls will be in place for an indefinite period of time is nonsense. Our country has only been in existence for a bit over 200 years. To assume that no changes will occur for an indeterminate time into the future is an assumption we believe you cannot make. Instead, these sites must not be contemplated for that extensive period of time, and should be limited to the decommissioning time period, as we describe with respect to other issues as well. (0930-1-8 [Lutz, Ray])

Comment: The waste we speak of has thousands to hundreds of thousands of years of known activity and necessary oversight, and its impact on the environment beyond radioactive exposure is not being assessed adequately by any U.S. government agency. (0935-3 [Uhls, Agnes])

Comment: Over forevermore, indefinite storage of HLRWs on the Lake Erie shore, the dry casks will erode and release their contents. NRC assumes forevermore institutional control, including once per century complete replacement of the pads, inner canisters, and dry casks -- by using a "Dry Transfer System," DTS, as the pools will be dismantled during decommissioning. No price tag is given for this once per century complete replacement, forevermore, nor where that mysterious amount of money (infinite amount of money, by definition) would supposedly come from. NRC's assumption of forevermore institutional control comes amidst a US federal government shutdown. As Arjun Makhijani has pointed out, in just the past couple-few hundred years, North America has seen multiple wars (the Revolutionary War, the War of 1812 -- including on the Lake Erie shores, where some of the worst battles took place, including in Monroe and Port Clinton -- the Civil War). Institutional control being maintained even just 300 or less years into the future is a huge domain assumption. (0945-6 [Keegan, Michael J.])

Comment: Unrecognized in the Draft GEIS is the fact that no civilization and no human institutions have lasted for hundreds of thousands of years. Any credible plan must include ways to mitigate the risks of environmental contamination in the event of failure of governments or institutions. A realistic plan must be devised to keep manmade radioactive elements isolated from the biosphere for the million years the EPA declares them to be lethal. (0951-5 [Commenters, Multiple])

Comment: No sane person would assert that radioactive waste, with a half-life of 20,000 years, can be stored safely, given that civilization has only existed for 10,000 years, and the government of the United States has only existed for 226 years. (0998-2 [Rosanelli, Donald])

Comment: WHEN YOU DEVISE A SIGN THAT STATES "THIS SHIT WILL KILL YOU AND ALL YOU LOVE" THAT WILL LAST 250,000 YEARS IN A LANGUAGE THE FUTURE PEOPLE WILL UNDERSTAND, THEN ASK US FOR A "WASTE DUMP" PERMIT. UNTIL THEN BUGGER OFF AND STOP MAKING MORE OF THE SHIT THAT WILL KILL US AND ALL WE LOVE. (1006-1 [Killpack, Gary])

20. Comments Concerning Site and Activity Descriptions

Comment: [F]irst off I'd like to talk a little bit about the storage of nuclear fuel. The fuel pools are large robust structures, some 40-feet deep with reinforced concrete walls several feet thick and steel liners. The water offers superb cooling for radiation and the fuel pools offer 25 to 30-feet of water shielding and fuel cooling. The volume of water in these pools is so large that any evaporative process associated with loss of cooling system would provide time for operators to establish backup water supply. All used fuel pools are designed to seismic standards consistent with other important safety related structures on the plant sites. (0045-13-1 [Allen, Rick])

Comment: The dry storage containers are robust, concrete steel structures with no moving parts. Multiple barriers provide an in-depth protection. More than 100 tons of concrete and steel forms precisely engineered structures to protect 10 tons of used fuel. Over the past 30 years the nuclear industry has safely loaded more than 1700 dry storage systems. All of these systems are in service today and there has been zero release with their radioactive contents. Dry storage systems have withstood several earthquakes, hurricanes, and other natural disasters. (0045-13-2 [Allen, Rick])

Comment: Further I have seen the dry fuel storage systems used at these sites. These designs, like our AREVA Trans Nuclear dry storage system, are licensed by the US Nuclear Regulatory Commission to extremely stringent safety requirements. The storage container's one inch thick stainless steel casing and the three foot thick reinforced concrete shield buildings are serving us all well. These structures have been demonstrated to safely withstand the direct impact of high velocity missiles. The used nuclear fuel is safely stored in anticipation of its ultimate disposition. (0138-3 [Cook, Dr. Andrew G.])

Comment: I'd like to take the opportunity into say a couple of things about how we store used fuel. Immediately after discharge from the reactor, the fuel is stored in large pools filled with hundreds of gallons of water. The pools are robust concrete structures, with stainless steel liners. The water removes decay passively and provides shielding from radiation. We've never had a situation in which we needed to provide emergency makeup water to one of our pools, but we have the equipment, procedures, and training for doing so, if necessary. After years in the pool, the decay heat drops significantly and the fuel is cool enough to be loaded into dry storage. We place the assemblies in steel canisters surrounded by large concrete overpacks for shielding and protection. The dry storage systems are thick and massive, weighing hundreds of thousands of pounds. Completely passive natural circulation of the atmosphere is all that is required to cool the dry storage systems. (0250-6-4 [Nesbit, Steve])

Comment: At the same time the capacity for storing all this waste was becoming a problem. Nuclear waste is not simply "spent fuel" or "energy used up; it has served its purpose," as the present Chief Nuclear Officer at PG&E called it a couple weeks ago at the County Board of Supervisors meeting. Nuclear fission is NOT a chemical reaction like burning a log in a fireplace, where the leftover is charcoal and ashes. No, nuclear fission is taking one heavy element, Uranium, bombarding it With a particle (a neutron) which creates a little heavier form of Uranium that is so unstable that it immediately breaks into lighter, daughter elements. These new creations are things like Cesium and Strontium and Plutonium. These are not charcoal and ashes. These are not "spent" elements-they are new, completely different elements, with their own horrible, highly radioactive, extremely dangerous characteristics. The reason this process works so well to generate electricity is because when the unstable uranium atom breaks apart into its lighter, daughter elements, a piece of energy is released, free to heat up the water in the reactor. And that is why fission (this "breaking apart") is considered "clean". No smoke or charcoal or carbon dioxide is created-just heat....Well, . . . just heat and the daughter elements of things like cesium, strontium, plutonium-all of which are very radioactive and very dangerous for a long time. (0293-3 [Lewis, Sherry])

Comment: The fuel pool over here is over 40-feet deep. It's almost 120-feet long. If you walked in-- you ever been inside there? You'd want to jump in that water. I'm telling you, it's the most beautiful water you've ever seen, I swear. I'm telling you, it's the most beautiful color you've ever seen. All lined with stainless steel and everything else, you know. Yes, it sounds crazy but I'm telling you, once you're in there and you look at it, it's really refreshing looking. (0325-14-3 [Sallis, Gary])

Comment: As many of you know, our wet storage systems are comprised of heavily reinforced concrete structures that are embedded in rock and lined with stainless steel. Although both wet and dry storage systems are safe, PG&E is systematically moving the used fuel from our wet storage systems into our dry storage facilities. Our dry storage system utilizes a multi-purpose canister that is designed to store and transport used fuel. The dry storage system was initially specified for the higher seismic requirements that are appropriate for our Central Coast. We licensed, permitted, and designed our dry storage facility to hold all of the fuel that is discharged

from the plant during its 40-year licensed life. Initial construction of our dry storage facility was limited to 38 of the 138 casks that it was designed for, and that was based on the premise that the Federal government would assume their responsibilities and develop Yucca Mountain in a timely manner. With the continued delays of the development of a Federal repository, PG&E will be expanding the number of foundations that we have in our storage facility in 2014 to be able to accommodate all 138 casks, to be able to accommodate all the fuel discharged during the 40-year licensed life. This will allow us to continue to move the used nuclear fuel from our wet storage systems into our dry storage systems. To date, a full 1/3 of the fuel that's been discharged through the operation at Diablo has been moved from wet storage to dry storage. PG&E is committed to the continued safe storage of used nuclear fuel using both our wet and dry storage technologies. (0326-3-2 [Strickland, Gerald])

Comment: Nuclear waste is not simply spent fuel or energy used up. It has served its purpose, as the present chief nuclear officer at PG&E called it a couple weeks ago at the County Board of Supervisors meeting. He referred to spent fuel as energy used up. It has served its purpose. It drove me nuts. Nuclear fission is not a chemical reaction like burning a log in a fireplace, where the leftover is charcoal and ashes. No, nuclear fission is taking one heavy element, uranium, bombarding it with a particle, a neutron, which creates a little heavier form of uranium that is so unstable that it immediately breaks into lighter daughter elements. These new creations are things like cesium, and strontium, and plutonium. These are not charcoal and ashes. These are not spent elements. They are new completely different elements with their own horrible, highly-radioactive, extremely dangerous characteristics. The reason this process works so well to generate electricity is because when the unstable uranium atom breaks apart into its lighter daughter elements, a piece of energy is released, free to heat up the water in the reactor. And that is why fission, this breaking apart, is considered clean. No smoke, or charcoal, or carbon dioxide is created; just heat. Well, just heat and the daughter elements of things like cesium, strontium, plutonium, all of which are very radioactive and very dangerous for a long time. (0326-44-2 [Lewis, Sherry])

Comment: I moved to Santa Barbara seven years ago from New York City, where I lived less than 30 miles from the most dangerous nuclear power plant in the United States, Indian Point, which affects over 20 million people. Since the catastrophic events of March 11, 2011, I've become deeply concerned about the fate of nuclear energy in California, especially the fate of Diablo Canyon. There are 430 commercial nuclear power reactors in the world, in 31 countries; 70 more are now under construction. These statistics that I'm reading came from the World Nuclear Association dated November 2013. Eleven percent of the world's electricity comes from nuclear power, only 11 percent. Fifty-six countries operate a total of about 240 research reactors and a further 180 nuclear reactors power some 150 ships and submarines. Of the 104 commercial nuclear reactors in this country, 4 have been closed this year, 4 are slated to close within the next year. Closed does not mean over. The highly radioactive fuel rods left behind as so-called waste pose catastrophic dangers that we must live with for 250,000 years per rod. Keep in mind that the fuel rods are only beneficial for somewhere between one to two, I'm sorry, one to three years and then they are retired, to be cooled down in pools, where they continue to generate enormous heat and produce a by-product of radioactive water. When cool enough, they are supposed to be stored in dry casks. The number of partially used fuel rods or, as you call them, spent fuel rods continues to grow at a staggering rate. The rods are not spent. Spent means used up. This is hardly the case when the rods are removed from the reactors. We know that, and so do you. (0326-57-1 [Livingston, Rosanne])

Comment: The NRC analysis of dry cask storage of spent fuel, for decades if not centuries, is totally inadequate. The description of how the fuel canisters are hermetically sealed is not

sufficient for the reader to assess risk. The report states that "fuel is loaded into canisters, (presumably steel); the air and water are pumped out; the canister is filled with "inert gas" (what inert gas?); and the top is welded in place" to seal-in the spent fuel and isolate it from the environment. In another section, describing the long-term maintenance of casks at the facility, a comment is made that, during replacement activities, "around 10% of the casks and support pads will need to be disposed of as low-level radioactive waste." There is no explanation as to how the casks and pads can become contaminated since they are supposed to be hermetically sealed. There are two obvious possibilities: (1) there is a failure of containment in the canister with the escape of the "inert gas" and the entry of air and water into the fuel canister with subsequent corrosion. This would compromise the integrity of the containment vessel and result in leakage. Continuous exposure of the canister metal to radiation from the enclosed fuel could also weaken its physical integrity and result in metal failure, corrosion and leakage; and (2) there is neutron activation of casks, canister components and the pads themselves. In case (1) the NRC presents no history of dry cask storage to support their contention that the risk from loss-of-containment accidents is small, particularly over the super long time frames envisioned. In case (2) we are informed by the statement that "casks are placed 15 feet apart to avoid criticality events." This would seem to indicate that spent fuel in dry casks still emits neutrons at a measurable rate, which are not absorbed by the cask shielding. This presents a problem for evaluation of dose to workers since neutrons have a biological effectiveness 20 to 50 times greater than an equivalent exposure to the same quantity of gamma or x-rays. Also since dry casks are cooled by circulating ambient air through the casks, inside the concrete shield, there is a significant potential for activation of atmospheric nitrogen by neutrons to form carbon-14-carbon dioxide. (0410-25 [Nelson, Dennis])

Comment: GEIS Section 2.1.2.2, p. 2-14, lines 7-9. This section deals with multipurpose canisters. The cited lines begin with, "However, in the absence of a repository program ..." This text should be modified to recognize that there is a repository program at Yucca Mountain and NRC has received a writ of mandamus to restart the Yucca Mountain licensing process. The section should also recognize the Transportation, Aging, and Disposal canisters (TADs) that are part of the Yucca Mountain Project. TADs are designed as multipurpose storage, transportation, and disposal canisters and detailed specifications exist. Because of the Federal court ruling that NRC's suspension of Yucca Mountain licensing process was illegal and must be restarted, this GEIS cannot continue to pretend that Yucca Mountain and the NWPA do not exist. (0544-27 [Enriquez, Elizabeth])

Comment: GEIS Section 2.1.3, p. 2-18, lines 33-35. This discussion says the Federal government supports interim storage. This is another example of the GEIS pretending that Yucca Mountain and the Nuclear Waste Policy Act do not exist. In fact, current Federal law prohibits the Federal government from construction and operation of an interim storage facility. This should be recognized in this section. The analytical scenario still makes sense based on the court order and the simple fact that interim storage is a good idea, especially if repository disposal capacity is not available. This GEIS should not cover up the fact that NRC's actions to terminate the Yucca Mountain licensing process were illegal. (0544-28 [Enriquez, Elizabeth])

Comment: As noted above, WBN Units 1 and 2 share a SFP, as do Sequoyah Units 1 and 2. However, they are not listed in DGEIS Table 2-1 ("U.S. Pressurized Water Reactors with Shared Spent Fuel Pools"). ⁸² [footnote 82 text: DGEIS at 2-5.] TVA recommends that DGEIS Table 2-1 be updated to include Sequoyah with 2091 locations and WBN with 1386 locations as sites with shared SFPs. (0694-2-24 [Shea, Joseph])

Comment: Page 2-14, lines 10-12: It might be useful to clarify that the 69 ISFSIs assigns two ISFSIs to PSEG (NRC considers Salem and Hope Creek separately) and includes PFS. It may be informative to explain that there are only 62 ISFSIs in operation. The difference is the dual-license ISFSIs at Robinson, Oconee, Surry, and North Anna; the INEL spent fuel facility that was never built; and Salem/Hope Creek, which is one ISFSI. Industry data indicates that, as of mid-2013, there are 1,771 casks in service at 53 General License ISFSIs (Salem and Hope Creek are one) and 14 Specific License ISFSIs (not including PFS). (0827-7-10 [Ginsberg, Ellen])

Comment: Page 2-14, lines 27-28: It is incorrect to say the NRC approval is sought for changes to the programs cited. Each of those programs is subject to a review of the proposed changes under 50.59, 50.54, or a license condition to determine whether prior NRC review and approval is required. (0827-7-11 [Ginsberg, Ellen])

Comment: Page 2-16, line 4 and Page 2-17, line 30: When stating that fuel will be transferred to an at-reactor or away-from-reactor ISFSI during decommissioning, NRC should recognize that decommissioned reactors may have the option of keeping their fuel in wet storage until DOE picks it up for either consolidated storage or disposal. (0827-7-12 [Ginsberg, Ellen])

Comment: Page 2-16, line 7: LaCrosse should be added to this list. (0827-7-13 [Ginsberg, Ellen])

Comment: Page 2-16, line 29: 1,600 will change if changes are made per earlier comment. (0827-7-14 [Ginsberg, Ellen])

Comment: Page 2-26, line 33: "loss of confinement" is not an "effect" being managed. It is a consequence of not managing the confinement boundary material condition properly. Industry recommends that this statement be changed to "cask and canister confinement boundary material condition." (0827-7-15 [Ginsberg, Ellen])

Comment: RULE, Discussion A.6, 56780 Col. 2: The statement that the rule covers MOX fuel because it is "substantially similar" to LWR fuel should be further supported by noting that DOE considered MOX fuel in the Yucca Mountain FEIS analysis. The DOE analysis concluded that low-enriched uranium fuel and MOX were similar and environmental impact differences would be small. The GEIS should reference the Yucca Mountain FEIS in its conclusion (Yucca Mountain FEIS (DOE 2008), Appendix A, Section A.2.4.5.1.1, p. A-52). (0827-7-16 [Ginsberg, Ellen])

Comment: GEIS Section 2.1.4: NRC should clarify its position on the licensing of dry transfer and repackaging under 10 CFR Part 72 to address an apparent inconsistency between what is stated in the GEIS and other recent NRC documents. On GEIS 2-21 NRC refers to a dry transfer system and repackaging being licensed under Part 72 at Idaho National Lab (INL). Although Part 72 (72.2, Scope) does mention packaging, on August 23, the NMSS director wrote a letter to the Commissioners stating that repackaging is not within the scope of Part 72. (0827-7-22 [Ginsberg, Ellen])

Comment: GEIS Section 2.1.1: Industry has reviewed the information provided in this section and has identified a number of instances where there appears to be some discrepancy between our data and what NRC has provided in this section. These discrepancies are identified below: • Page 2-6, line 23: The low end of the range for the number of fuel rods in a BWR assembly is stated to be 91. However, an 8x8 assembly (previously referred to in the same paragraph) would have only 64 fuel rods. (0827-7-5 [Ginsberg, Ellen])

Comment: Page 2-7, Table 2-2: Industry data indicates that Haddam Neck has 1,101 fuel assemblies discharged. 82 are at Morris and 1019 in dry storage on site. (0827-7-6 [Ginsberg, Ellen])

Comment: Page 2-7, lines 11-13.: There is a statement that fuel is removed from the reactor and replaced every 12-18 months. To our knowledge, only one reactor is currently operating on a 12-month cycle. NRC's statement should be changed to 18-24 months to represent nearly all reactors. For this reason the estimate of 20 MTU discharge per year is a slightly low. The 100 operating reactors discharge about 2240 per year on average. So, 22 MTU/yr is a more accurate number to use for a per-plant average. This would take the cited total of 1600 MTU per reactor over 80 years to 1,760. (0827-7-7 [Ginsberg, Ellen])

Comment: Page 2-7, Lines 22-24: The statement regarding the 25% reduction in average MTU discharged annually (from 20 to 15) to reflect higher burnup fuel and longer cycles is not correct. There are many factors other than the length of the operating cycles between refueling that affect the amount of used fuel discharged per year. Such factors include the generating capacity of each reactor and the percentage of time the reactor operates at full capacity. These factors are resulting in more power production over a shorter period of time than historical averages per reactor and cause more used fuel to be produced per year than in past operations - offsetting any reductions in fuel used because of longer operating cycles. Industry suggests removing this 15 MTU analysis and stating that higher burnup fuel may result in longer operating cycles, but a combination of other factors will result in about the same or slightly higher annual average MTU discharged per reactor. A better analytical assumption would be to use industry projections that show on average about 22 MTU per year will be discharged per reactor in the next six years. (0827-7-8 [Ginsberg, Ellen])

Comment: Page 2-10, line 22: The 2,000 MTU per year is slightly low. 2200 MTU/yr is based on industry data, which project about 2200 MTU/yr discharged by approximately 100 reactors over the next six years. (0827-7-9 [Ginsberg, Ellen])

Comment: Page 2-28, Lines 32-34: You describe the most critical step without much effort. The hard part is closing the casks and transitioning to "detached from the transfer containment area".... how do you do that without releasing some radiation? Not clear and probably nearly impossible to implement. (0836-46 [Davis, Anonymous])

Comment: (XII-9) Holtec is a US-based vendor of dry casks used for storing spent fuel at ISFSIs. The Holtec design approach is modular. Fuel is sealed inside a multi-purpose canister (MPC) that is designed to be placed inside overpacks of various types. Holtec has developed an overpack, known as the HI-STORM 100U, that would be more robust against attack than present overpacks. A standard MPC would be placed, in a vertical- axis position, inside the 100U overpack. The 100U overpack would be sunk below ground except for its lid. Holtec has described the robustness of the 100U system as follows:¹⁴⁵ [footnote 145 text: Holtec, 2007. A current description of the 100U system was accessed on 15 December 2013 from: <http://www.holtecinternational.com/productsandservices/wasteandfuelmanagement/hi-storm/>] "Release of radioactivity from the HI-STORM 100U by any mechanical means (crashing aircraft, missile, etc.) is virtually impossible. The only access path into the cavity for a missile is vertically downward, which is guarded by an arched, concrete-fortified steel lid weighing in excess of 10 tons. The lid design, at present configured to easily thwart a crashing aircraft, can be further buttressed to withstand more severe battlefield weapons, if required in the future for homeland security considerations. The lid is engineered to be conveniently replaceable by a later model, if

the potency of threat is deemed to escalate to levels that are considered non-credible today.” (0916-3-18 [Curran, Diane] [Thompson, Gordon R.]

Comment: Re: Page 2-6, footnote 4 ,and its associated text, NRC needs to update the EIS by clarifying that Crystal River and Kewaunee have not just announced plans to permanently shutdown, but have in fact done so. In addition, so have San Onofre 2 & 3. Vermont Yankee has also announced that it will shutdown by the end of 2014. (0919-3-10 [Kamps, Kevin])

Comment: Also on Page 2-8 (lines 14-16), NRC states "Because the MOX fuel is substantially similar to existing uranium oxide light water reactor fuel and was, in fact, used in existing light water reactors in the United States, it is within the scope of this draft GEIS." (Similar text is stated at lines 24-27.) While MOX irradiated nuclear fuel certainly should be within the scope of this GEIS, given that its use is still on the table in the U.S., despite opposition to such use by countless groups, including Beyond Nuclear, it must be pointed out, and the record set straight, that MOX irradiated fuel is not like "typical" irradiated nuclear fuel. MOX irradiated nuclear fuel would be thermally hotter, as well as significantly more radioactive, in terms of its added plutonium content. MOX irradiated fuel could require more space and time in storage pools for cooling and radioactive decay, as well as enhanced safeguards against inadvertent criticality; could require upgrades to typical dry cask storage; and could require more space within a repository setting. (0919-3-13 [Kamps, Kevin])

Comment: On Page 2-27, line 5, it is unclear why NRC writes "private fuel storage facility environmental impact statement," all in lower case. Private Fuel Storage, LLC was a proper name. The phrase "Environmental Impact Statement" is also usually capitalized when used in this way. On Page 2-27, NRC writes "The proposed PFS facility was designed to store up to 40,000 MTU (44,000 tons of spent fuel) and was licensed to operate for 20 years. The NRC now allows an initial license term of 40 years with 40-year renewal terms, representing a decrease in safety regulatory oversight. (0919-4-4 [Kamps, Kevin])

Comment: Re: Page 4-3, beginning at line 1, where NRC states "The TMI.2 ISFSI is a modified NUHOMS spent fuel storage system (designated NUHOMS-12T) with 30 horizontal storage modules (DOE2012). It was licensed by the NRC in March 1999 and contains spent fuel from the damaged TMI-2 reactor (a single reactor core). Although the NUHOMS.12T storage module contents are core debris (not fuel assemblies) and the debris storage canisters could not be treated like fuel cladding, the design of the NUHOMS.12T accounts for these technical differences. Each NUHOMS.12T module provides for the horizontal dry storage of up to 12 TMI.2 stainless-steel canisters inside a dry shielded canister, which is placed inside a concrete horizontal storage module. The NUHOMS.12T modification includes venting of the dry shielded canister through high-efficiency particulate air grade filters during storage. The vent system allows for release of hydrogen gas, generated due to radiolysis, and monitoring and/or is still generating hydrogen, nearly 35 years since the meltdown! Is the venting required in order to prevent gas pressure damage, or even an explosion, in the container? Is the hydrogen gas tritiated? What radiological impact is tritium releases from TMI-2's damaged fuel storage having on Idaho residents downwind of the INL storage location? Are other radionuclides being released along with the vented hydrogen gas? Noble gases? What biologically interactive decay products do the escaping radioactive Noble gases convert into? (0919-6-8 [Kamps, Kevin])

Comment: Page 2-28, Lines 32-34: You describe the most critical step without much effort. The hard part is closing the casks and transitioning to "detached from the transfer containment area".... how do you do that without releasing some radiation? Not clear and probably nearly impossible to implement. (0930-2-20 [Lutz, Ray])

21. Comments Concerning Land Use

Comment: The public in those communities [with decommissioned reactors] have received significant financial benefits during the operation of the reactor which are no longer available. The lost economic activity in those communities should be considered in determining appropriate use for the land of the decommissioned reactor site including land that might be used for containing storage. If a community would feel burdened by containing storage under the principles of consent-based siting, that should also be considered. (0112-28-4 [Diaconeasa, Mihai])

Comment: I am writing in response to a proposed rule change to the NRC Waste Confidence Rule regarding the long term on-site storage of Spent Nuclear Fuel (SNF), as published in the Federal Register, Vol. 78, No. 178, September 13, 2013. I am writing as an individual, and not as a member or representative of any organization. The environmental impact statement for at-reactor continued storage of SNF appearing on page 56785 of the Federal Register entry identifies the land use and socioeconomic impacts of short-term, long-term, and indefinite storage as small." There is no reasonable basis for these conclusions; therefore the rule change should be rejected. (0146-1 [Buchanan, Tom])

Comment: Even if fuel is moved to dry storage in casks, there are pronounced local, regional, and state-wide economic and land use impacts that are not adequately addressed by the proposed changes, and the effects are not small. When SNF is stored at the site of a nuclear plant, the site must be secured and is not available for alternate economic development. Some nuclear plants occupy large tracts of land, and others occupy small tracts. The same is true for spent fuel pads at decommissioned reactors. The NRC offers no guidance or regulation regarding how much land is needed to store and safeguard SNF, and thus there is no means of determining how much land must be or will be committed to the maintenance of on-site SNF storage and security, rather than made available for an alternative higher economic use. Without a specific rule or regulation that defines the space needed for technical management and security of SNF it is not possible to determine generically or specifically what the land use impacts might be at more than 100 reactor sites around the country, and it is certainly not possible to determine that the land use impacts are "small." The storage of SNF at a reactor site necessarily ties up the land and decreases its availability for higher uses that might generate additional property tax revenue and employment, and it reduces the appraised and use value of surrounding land that is affected by radiological effects, security requirements, or visual impacts of the storage of SNF. The costs of managing SNF at the site of a nuclear reactor or a decommissioned reactor are generally reimbursable by the Department of Energy (DOE), but costs that are not reimbursable must be paid from another source such as a limited decommissioning trust fund or the ratepayers of a regulated utility. The DOE has not made any determination regarding a generic level of property taxes that will be reimbursable for the short-term, long-term, or indefinite storage of SNF. Without a clear determination as to how SNF storage facilities can be taxed or what level of reimbursement the DOE will allow for tax payments, it is not possible to evaluate economic value of the use of a generic site for SNF storage relative to the value of alternative uses. Without an ability to make an economic determination regarding relative tax benefits it is not possible to determine the socioeconomic impacts will be "small." (0146-3 [Buchanan, Tom])

Comment: Please consider the following passage regarding economic development from a brochure produced by Maine Yankee(<http://www.maineyankee.com/public/MaineYankee.pdf>): *"As long as the spent nuclear fuel is stored at the Bailey Point ISFSI, this valuable piece of property is unavailable for productive reuse. Among other attributes Bailey Point has a rail line*

to the site, a barge slip with deep water access, a 345 and 115 Kv switchyard, transmission lines, and municipal water and sewer." The same can be said of many other nuclear plants with ISFSI installations, and for plants that will be decommissioned in the future leaving behind just an ISFSI. While the Maine Yankee ISFSI occupies a licensed area of just 8 acres, it sits within an undeveloped 180 acre buffer zone (according to the Maine Yankee brochure). The entire 180 acre site remain undeveloped, and is not producing tax revenue equivalent to its value as developed industrial land in large part because of the presence of the ISFSI . (0146-4 [Buchanan, Tom])

Comment: Consider the case of Vermont Yankee (VY), a 148 acre site that hosts an operating nuclear station and an ISFSI. The site has access to road, river, rail, and power distribution infrastructure, and is prime industrial real estate of the highest order. Entergy Corporation, the parental owner of Vermont Yankee has announced an intention to cease operation in the fourth quarter of 2014 and to shift all the spent fuel to an ISFSI (or perhaps two separate ISFSI's). The Decommissioning Cost Analysis produced for the VY site in 2001 identified annual property taxes through SAFSTOR and SNF management of approximately \$1.47 million in 2001 dollars (this report was filed with the Vermont Public Service Board docket 7862 as exhibit PSD-Cross-12). The 2012 Decommissioning Cost Analysis produced for the VY site can be used to calculate the average annual property taxes for the site after shutdown as approximately \$7,614 to \$16,428 in 2011 dollars, based on an assumption the site will be taxed as vacant land (this report was filed with the Vermont Public Service Board docket 7862 as exhibit EN-TLG-2). The extraordinary difference in property taxes as projected by the owner/operator of the plant makes it clear that it is impossible to accurately calculate the generic or specific value of a site that hosts an ISFSI (please see the initial brief of the Windham Regional Commission (WRC) filed with the Vermont Public Service Board on August 16, 2013 in docket 7862, page 52, Section X, findings 132-141 and discussion, available at: <http://psb.vermont.gov/sites/psb/files/docket/7862relicense5/WRC%20Initial%20Brief%20Dkt%207862.pdf>). Nor has there been any determination as to the level of property tax payments the DOE will reimburse for storage of SNF, and thus it is impossible to determine the effect of property taxes for an ISFSI upon local or state municipalities that may not be able to collect the difference between the tax value allowed by DOE and the potential tax value for alternative uses. Likewise, it is not possible to determine what unreimbursed costs the ratepayers of regulated utilities will need to absorb in lieu of DOE's failure to completely reimburse all property taxes that a municipality might charge. (0146-5 [Buchanan, Tom])

Comment: Vermont Yankee occupies approximately 148 acres in the small Town of Vernon, in the state of Vermont. On October 28, 2013 the Chair of the Vernon Selectboard testified to a joint committee of the Vermont Legislature that the VY site is the primary area for industrial development in the town (in the State of Vermont a Selectboard is the governing body of a town). The loss of a viable industrial use of the land while the Station sits in SAFSTOR and following eventual decommissioning when development is limited to an ISFSI will have a significant effect on the tax base of the town, and upon the ability of the 2,200 residents to afford municipal services. The loss of the productive use of a large tract of industrial land within a small town is not a "small impact." (0146-6 [Buchanan, Tom])

Comment: In summary, the NRC does not require movement of SNF from wet to dry storage. The NRC does not regulate the amount of land needed to store and secure SNF, and it has made no meaningful effort to calculate the lost value of the land needed to store and secure SNF, or value of land that will be left fallow to buffer an ISFSI Neither the NRC nor DOE have established a standard property tax assessment for SNF or the surrounding land. Without clear regulatory guidance regarding the required size of an ISFSI and reimbursable property tax it is

simply not possible to make a generic or specific determination regarding the land use and socioeconomic impacts of the more than 100 nuclear plants in the United States. Likewise, since the NRC does not require movement of SNF from wet to dry storage it is not possible to make a generic assessment of impact of dispersed on-site storage of SNF by focusing primarily on dry storage. Absent these essential determinations the Waste Confidence Rule is built upon false premise, and should be rejected. (0146-7 [Buchanan, Tom])

Comment: As I understand it, the proposed rule seeks to replace the rule codified at 10 CFR 51.23(a) by among other things, substituting the Commission's "generic determination" that spent fuel can be safely stored "without significant environmental impact for at least 30 years beyond the licensed life...of that reactor" with a "generic environmental impact statement" that "supports the Commission's determinations that it is feasible to (i) Safely store spent nuclear fuel following the licensed life for operation of a reactor." What the proposed rule apparently fails to do is to provide any basis in fact for the conclusions in the "generic environmental impact statement." Particularly, as Table 1 (78 FR 56785) notes, the effect of at-reactor storage of radioactive waste on Environmental Impact components such as Land Use, Socioeconomics, are noted as "SMALL." (0354-3 [Oeser, Robert])

Comment: It is disingenuous on the part of the NRC to pretend that spent nuclear fuel storage is just like any other industrial enterprise with similar land and water use characteristics. Nuclear waste lasts "forever" and so will permanently alter the use possibilities of any affected site. It also bears a stigma in the public mind, largely because of its association with nuclear weapons and the proliferation problems that association represents. This perception will psychologically limit proposed future uses of any such site and will attract other equally obnoxious industrial operations. Thus the land must be considered a "sacrifice zone" from the beginning with no pretense that it will ever be reclaimed for general use. (0410-21 [Nelson, Dennis])

Comment: Additional concerns relate to aesthetics and suitability of land use given waste storage configurations that many see as inherently grotesque or problematic. This relates to the question of what if any beneficial or non-compromised land uses are currently occurring at the dozen decommissioned reactor sites that have been unconditionally released by the NRC in the past decade. To illustrate these concerns, here are two quotes from nationally-regarded experts who spoke on October 19 at a community symposium organized by the Sierra Club and other groups to inform the public on issues related to the closure of the San Onofre nuclear power plant. Marvin Resnikoff, Senior Associate, Radioactive Waste Management Associates: Edison has said spent fuel will be removed from the pool by 2034. After that, San Onofre will consist entirely of fuel casks or silos in a Stonehenge configuration. San Onofre has a blockhouse arrangement of 176 modules, including 10 for the reactor. What remains? A fuel mausoleum and the conversion of a valuable site into a wasteland. Arjun Makhijani, President, Institute for Energy and Environmental Research: The best kind of on-site storage has these kinds of characteristics: Low visual signature (low to the ground), which may include berms; the best casks, which currently may be the triple-top German model; and the best seismic science on withstanding earthquake shocks. (0431-9 [Pascall, Glenn] [Watland, George])

Comment: At best, permanent on-site storage would take these sites out of use for any purpose other than housing waste storage in above ground concrete "mausoleums." (0540-5 [Watland, George])

Comment: •In almost every area of NRC selected environmental impacts, NRC looks at the wrong impacts or those least likely to be adversely affected. (0693-3-16 [Warren, Barbara])

Comment: Land Use --the GEIS describes the land used and disturbed by construction, the types of land-- forest, field, agriculture-- and the buildings located there. Not analyzed are the potential consequences of a spent fuel pool fire and the vast area of permanent radioactive contamination that might necessitate evacuation and permanent abandonment of the land, as well as the related costs. (0693-3-17 [Warren, Barbara])

Comment: DGEIS Section 4.1 concludes that land use impacts would be SMALL because storage would only affect a small fraction of the land committed for a nuclear power plant.⁹⁵ [footnote 95 text: *Id.* at 4-4 to 4-6.] TVA agrees with this conclusion. (0694-3-3 [Shea, Joseph])

Comment: •DGEIS Section 4.1 concludes that land use impacts would be SMALL because storage would only affect a small fraction of the land committed for a nuclear power plant.⁷⁸ [footnote 78 text: *Id.* at 4-4 to 4-6.] Entergy agrees with this conclusion. (0697-2-12 [Bessette, Paul] [Kuyler, Raphael])

Comment: In summary, the generic evaluation of land use impacts in the DGEIS is sufficient for all plants, including IPEC. (0697-4-3 [Bessette, Paul] [Kuyler, Raphael])

Comment: 5) "Sites must not be located in areas where nearby facilities could ... mask or interfere with the disposal facility's environmental monitoring program." NEWGreen Legacy Services, located next to the Perry Nuclear Power Plant, received an Ohio Dept. of Health license in 2011 to "receive, acquire, possess, and transfer radioactive materials" and to decontaminate, refurbish, recycle all manner of radioactive parts and equipment, including steam generators, from commercial reactors as well as DOE facilities. (0819-21 [Kline, Connie])

Comment: GEIS Section 4.1.1: NRC has appropriately relied upon the precedent set by previously completed Environmental Assessments (EAs) to conclude that "continued operation of an at-reactor ISFSI is not anticipated to require new or additional maintenance activities that would affect current land use" (GEIS 4-4). Excerpts from the Trojan ISFSI Finding of No Significant Impact (FONSI) are provided below as an example. • *Environmental Impacts of the Proposed Action:* As discussed in the EA, no significant construction impacts are anticipated. Trojan ISFSI construction activities will affect only a small fraction of the land area of TNP. With good construction practices, the potential for fugitive dust, erosion, and noise, typical of the planned construction activities, can be controlled to insignificant levels. The only resources irretrievably committed are the steel, concrete, and other construction materials used in the ISFSI pad, storage casks, and any operating equipment. As discussed in the EA, there will be no radiological liquid or gaseous effluents during normal operation of the ISFSI. The estimated doses to both occupational workers and members of the public are below regulatory limits. As discussed in the EA, no significant radiological impacts are expected during operation of the ISFSI. The only environmental interface of the ISFSI is with the air surrounding the storage casks; the only discharge of waste to the environment is heated air from the cask's passive heat dissipation system. Climatological effects will be insignificant. • *Finding of No Significant Impact:* In summary, the TNP ISFSI is located in a small area within the confines of the TNP owner-controlled area and will require only a minor commitment of land resources. The proposed action is not expected to cause any significant release of effluents, and there will be no significant increases in individual and collective radiation doses to either the public or on-site workers. Potential offsite impacts from a postulated worst case credible accident are a small fraction of the regulatory limits of 10 CFR 72.106 and well below the U.S. Environmental Protection Agency's Protective Action Guides. Therefore, the proposed action will not significantly affect the quality of the human environment. Accordingly, pursuant to the requirements of 10 CFR 51.31 and 51.32, the Commission has determined that a finding of no

significant impact is appropriate and that an environmental impact statement need not be prepared for the issuance of a materials license for the Trojan ISFSI. (0827-7-25 [Ginsberg, Ellen])

Comment: *The NRC assumes that the land used for the ISFSI pads and DTS would be reclaimed after the facilities are demolished and, therefore, could be used again in the next 100-year replacement cycle. The NRC believes this assumption is reasonable because the characteristics of the previously disturbed land is already known and is suitable for ISFSI and DTS design and construction.* The environmental consequences of future land use cannot be assessed generically. Nor does NRC have special expertise. (0867-2-11 [Griffin, William])

Comment: At Page 3-2, lines 1 to 13, NRC states that nuclear power plants are often located in areas surrounded by "wooded or agricultural areas;" "undeveloped land (forest, wetlands, herbaceous cover, and shrub/scrub land), agricultural land, or open water;" "open water, forest, wetlands, and agricultural;" "agricultural land, open water, and forests." Left unstated is the reason for locating nuclear power plants in such undeveloped, or at least sparsely populated lands, or near open water: to create a buffer zone, so nearby, densely concentrated populations are not being exposed to "routine" radioactivity releases, and are further away if catastrophe strikes. But what about the radioactive contamination of food? Of drinking water? Of fisheries? That results from the location of U.S. nuclear power plants? (0919-4-18 [Kamps, Kevin])

Comment: Re: Page 3-3, lines 13 and following, "Some plant owners lease land for agricultural (farming) and forestry production, permit cemetery and historical site access, and designate portions of their sites for recreation, management of natural areas, and wildlife conservation." - what about the contamination of food that results? Should persons be allowed to come close to the nuclear power plants? Doesn't this increase their risk of radiogenic harm? Doesn't this increase security risks? Don't the nuclear plants irradiate wildlife? (0919-4-19 [Kamps, Kevin])

Comment: Re: Table 3-1 on Page 3-4 "Discussions of the land area requirements for dry cask storage can be significantly misleading, if context is not provided. An acre here, a half-acre there, 4/100ths of an acre there, sound like very small impacts in the grand scheme of things. Nuclear power proponents in the U.S., be they industry or government spokesmen, are wont to speak of the football stadium metaphor - all the irradiated fuel ever generated in the history of the U.S. nuclear power industry would only fill a football field to a certain height above the ground. The Canadian nuclear establishment equivalent utilizes a culturally-appropriate alternative- a hockey rink filled up so high with irradiated nuclear fuel. Of course, there's no discussion of what would happen if that much irradiated nuclear fuel were actually piled that deep in one place. It would likely catch fire, due to quickly overheating, and lead to the biggest radioactive inferno the world has ever seen. And you certainly wouldn't want to have fans in those stands - without radiation shielding, even those in the bleacher seats would be at grave risk of fatal doses, especially if the waste caught on fire. Of course, it's not the volume of the waste, or the land area of the containers needed to keep it cool and isolate it from the environment, that constitute the most significant impacts. It's the forever deadly nature of the material, and the risks should it ever escape into the environment, that much be addressed. (0919-5-1 [Kamps, Kevin])

Comment: Re: Pages 4-4 to 4-6 in the Section on Land Use--this entire Land Use section doesn't discuss radioactivity, only physical use of land. But of course, the radioactive risks are the real issue. They impair, limit, even preclude the use of the land for other purposes. (0919-6-10 [Kamps, Kevin])

22. Comments Concerning Socioeconomics

Comment: Assertions of continued tax revenue assumes the continued existence of a corporate entity owning this property and being subject to its liability. In the long term, there is no historical justification for such an assumption. The most likely scenario in the long term is that the government will end up purchasing or taking control of such properties in order to assure continued safety for the public. Long term and Indefinite storage analyses cannot assure continuation of Tax payments continuing from such properties. (0093-3 [Dennis, Harold E.B.]

Comment: The second issue, the GEIS in numerous spots references taxes, and how there will be a continued socioeconomic benefit arising from continued storage. This statement is a phantom and does not take into account the continued obligation of a whole city like Red Wing to maintain the necessary public safety services to meet the emergency preparedness to respond to a release or a threatened release. Indeed, in Section 3.2.2, the GEIS cites a number of different of examples of reductions in and taxes from operations to a storage facility alone. This precipitous drop is something similar that the city is looking at when the Prairie Island Plant ceases operations. Yet, as stated before, the city as a first responder is still going to be held responsible for ensuring that it has the necessary preparedness to respond to an incident. This area of the GEIS must be further developed and addressed. (0328-2-6 [Rauterkus, Ralph])

Comment: As previously set forth, the NRC must conduct a legally adequate evaluation of the environmental effects of "failing to secure permanent storage for spent fuel" and "to properly examine future dangers and key consequences" of spent fuel storage at reactor sites. *New York v. NRC*, 681 F.3d 471, 473 (D.C. Cir. 2012). Among these "key consequences" are socioeconomic impacts. "NEPA requires an EIS to disclose the significant health, socioeconomic and cumulative consequences of the environmental impact of a proposed action." *Baltimore Gas and Elec. Co. v. NRDC*, 462 U.S. 87, 106-07 (emphasis added). *Accord Society Hill Towers Assoc. v. Rendell*, 210 F.3d 168, 176-178 (3d Cir. 2000) (project opponents who alleged, inter alia, that "the impact of the proposed project on their neighborhood will decrease their property values" had standing); *Kelley v. Selin*, 42 F.3d 1501 (6th Cir. 1995) (residents who lived near nuclear power facility that proposed to use dry cask storage had standing to protest alleged diminution in property value); *Matter of Connecticut Yankee (Haddam)*, 54 N.R.C. 33 (Jul. 9, 2001) at *44 (affidavits alleging impact to property values by nuclear facility that had contaminated groundwater and released radioactive waste established standing because alleged injuries were within NEPA "zone of interests"); see also App'x B to Subpart A of Part 51 ("Table B-1 . . . represents the analysis of the environmental impacts associated with renewal of any operating license"); id. (requiring analysis of "socioeconomics," including license renewal impacts on housing, public services, public utilities, education, offsite land use, historic and archaeological resources, and aesthetics). Environmental impact review must also analyze the potential impacts to off- site land use. Property values are affected by amenities and disamenities, including power plants. Nuisances and amenities are important considerations in determining property values, which, in turn, are an important driver in land use. In a peer reviewed article, Glenn Blomquist demonstrated that, after adjusting for other factors (property size, demographic composition of the neighborhood, and so on), the presence of a power plant had a statistically significant impact on property values. Glenn Blomquist, *The Effect of Electric Utility Power Plant Location on Area Property Value*, Land Economics, Vol. 50, No. 1 (Feb. 1974) (ML12334A750) at 97-100. The impact to property values was most clearly detectable up to a distance of 11,500 feet from the power plant. Within this zone, increasing the distance from the power plant by 10% was associated with an increase in market value of residential properties of 0.9 percent. This level of negative impact was evaluated for sample

mean properties, meaning that it could be expected to hold for typical properties in the area. (0473-16-3 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: A study of the impact on property values in the vicinity of Three Mile Island also found evidence of a positive relationship between distance from Three Mile Island and home sales price, suggesting that the plant had a small negative impact on residential housing prices. H. Gamble and R. Downing, Effects of Nuclear Power Plants on Residential Property Values, 22 J. of Regional Sci. 457 (1982) (ML12335A686). Scholars have also studied the impact on property values of spent nuclear fuel on residential property values. Spent Nuclear Fuel and Residential Property Values: The Influence of Proximity, Visual Cues and Public Information, David E. Clark and Tim Allison, Papers Reg. Sci. 78, 403-421 (1999) (ML12341A393 (non-public)). Indeed, nearly 40 years ago the Commission determined that the alternatives analysis for the handling and storage of spent fuel had to include a cost-benefit analysis of the environmental, social, and economic costs of each alternative. 40 Fed. Reg. 42801 (Intent to Prepare Generic Environmental Impact Statement on Handling and Storage of Spent Light Water Power Reactor Fuel (Aug. 1979)). Consistent with NEPA's mandate to study the potential "effects" of a proposed action on the "human environment," 40 C.F.R. §§ 1508.8, 1508.14, the Commission has acknowledged the potential for power plant relicensing and its alternatives to impact property values. GEIS for License Renewal of Nuclear Plants, NUREG-1437, at 4-133 (June 2013) ("Property values for nearby private residences could be affected positively if plant workers were to live locally. Property values could also be affected negatively, if there were impacts associated with noise, traffic, or if there were visual impacts associated with the plant"). Although the DGEIS purports to address the land use impacts of continued storage of spent fuel in (DGEIS §§ 4.1, 5.1) it does not even mention the impact of such storage on nearby property values, whether industrial, commercial or residential. The impact of long term spent fuel storage on property values is a fundamental socioeconomic impact, a determinant of land use, which must be addressed as to both on-site and away-from-reactor storage. Property values are a key driver of land use. Because land use and tax-driven impacts are among the socioeconomic factors that an EIS must examine, the DGEIS must examine the impacts to property value caused by long-term storage of spent nuclear fuel. Absent such analysis, the DGEIS's conclusion that "the environmental impacts on land use during the long-term storage timeframe would be SMALL" (see, e.g., DGEIS at 4-6), is unsupported, arbitrary and capricious. (0473-16-4 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The Draft GEIS incorporates many of the findings of the 2001 PFS FEIS without adequate support or justification. a. The Draft GEIS states that the NRC concluded that the PFS storage facility would provide large benefits to the Skull Valley Band of Goshute Indians ("Band") and the local county -Tooele County. The Draft GEIS assumes that local and state agencies would receive tax payments from the storage licensee. Staff then conclude that local impacts on the economy would be significant and beneficial.²² [footnote 22 text: Draft GEIS at 5-9.] i. As mentioned above, the Draft GEIS fails to consider negative impacts on the local or state economy, such as the real, not merely speculative, impacts from a community losing economic development projects due to the stigma associated with nuclear waste. ii. Depending upon the owner of the property and the facility (e.g., Native American or federal), local and state property taxes, or payment in lieu of taxes may not be assessed. iii. Furthermore, the Draft GEIS states that the PFS FEIS designated proposed payments made by PFS to the Band and to Tooele County as a large benefit. The Draft GEIS fails to discuss the agreements with PFS and why the PFS FEIS found those agreements to be beneficial. In addition, there is no discussion nor supporting documentation that DOE would enter a consent agreement with a local community in the amounts purported to be paid by PFS to the Band. Nor is there any support provided that DOE would agree to similar terms with a local government for law

enforcement as that agreed to by PFS and Tooele County. b. Based on the PFS FEIS, NRC concludes that a generic facility would have a small impact on public services.²³ [footnote 23 text: Draft GEIS at 5-9.] Staff assume that all storage facilities would be sited in a "sparse population," similar to the PFS facility where only 30 individuals live on the Reservation near the facility.²⁴ [footnote 24 text: Id.] Staff fail to support its assumption beyond mere speculation. For example, staff make no effort to compare the PFS demographics to G.E. Morris or proposed storage sites. Additionally, although the Draft GEIS assumes there would be a small impact on public services, staff fail to discuss the anticipated impact by the proposed PFS storage facility in an area where the availability of law enforcement and emergency services are limited as in Skull Valley. Additionally, while the BIA ROD was vacated, BIA's denial was in part based on the limited law enforcement available at the proposed facility.²⁵ [footnote 25 text: See Skull Valley Band of Goshute Indians v. Davis, 728 F. Supp. 2d 1287 (D. Utah 2010).] c. The Draft GEIS fails to mention potential impacts on local and state infrastructure which must be assessed in a site specific analysis. (0579-13 [Smith, Amanda])

Comment: The Draft GEIS notes that during construction the impacts at the PFS facility were determined to be small to moderate and concludes that impacts due to transportation, mostly traffic, would be also be small to moderate for an away-from-reactor site.³² [footnote 32 text: Draft GEIS at 5-46 to -48.] The Draft GEIS only discusses impacts due to congestion and accidents. However, the Draft GEIS does not address transportation impacts on the infrastructure or safety related to the infrastructure. Utah State Route 196 (SR-196) is a narrow, shoulder less, undivided two lane highway. The Draft GEIS does not discuss the impacts from heavy construction vehicles and heavy haul trucks traveling on SR-196. For example, the Draft GEIS does not address accident conditions when an oversized, heavy haul truck is traveling 20 miles per hour on the narrow, undivided highway. Nor does the Draft GEIS address local impacts to maintaining the highway due to the excessive vehicular and cask. (0579-17 [Smith, Amanda])

Comment: The Draft GEIS states that the socioeconomic analysis was limited to where spent fuel storage employees and their families reside, spend their income, and use their benefits. However, nuclear waste facilities may negatively impact regional and state economics, separate and apart from Environmental Justice issues; consequently, NRC should acknowledge that such impacts will be evaluated on a site specific basis. (0579-6 [Smith, Amanda])

Comment: The Draft GEIS finds that the socioeconomic benefits for an away-from-reactor storage facility are large. The BRC recommended a transparent, consent-based siting process which would allow affected communities an opportunity to accept siting decisions.¹³ [footnote 13 text: BRC Report at 47.] In direct response to the BRC Report, the bipartisan Senate Bill 1240, "allows affected communities to decide whether, and on what terms, the affected community will host a nuclear waste facility."¹⁴ [footnote 14 text: Senate Bill 1240, Sec. 304.(1).] As a potential host community has yet to negotiate the terms of an agreement, this generic EIS cannot support a conclusion that the socioeconomic benefits at an unknown site are large. (0579-9 [Smith, Amanda])

Comment: Long term and/or permanent storage on reactor sites were not contemplated when the States first granted permission for siting of nuclear reactors, therefore this is NEW USE OF LAND without prior informed consent of the State, and as such a re-assessment of state and local taxes is necessary. When nuclear power was first sited and implemented the United States government made a promise to reactor communities that it would take care of safely disposing the nuclear waste. This commitment has not and cannot be met. Currently since there is no safe way to manage radioactive waste operators who continue producing this radioactive waste must

be charged a premium compliance tariff, set by the State in which the nuclear facility is located. The actual property values in the New York City area, within the 50 mile radius of the Indian Point reactor community are approximately 8.5 trillion dollars, not including life or business values. (See attached Exhibit F: Indian Point Property Value Study). Indian Point itself has been paying a reduced property tax rate for years. Under Price Anderson Indian Point and all other reactors in the nation are only 13 billion is insured. That is clearly not enough to cover the costs of long term/permanent on site storage both from a physical and security perspective. The NRC has not established guarantees for on-going funding to protect nuclear waste now and into the future. (0611-48 [Shapiro, Susan])

Comment: Socioeconomic Impacts --the GEIS fails to consider the socioeconomic impacts of nuclear waste storage on property values and whether businesses will be interested in locating next to nuclear waste storage. Declines in property values also affect tax revenues. (0693-3-18 [Warren, Barbara])

Comment: Demography --here the GEIS discusses populations around nuclear reactors and some of the recreational benefits provided by other resources nearby such as beaches and parks. No attempt was made to analyze the increases in population since reactors were originally licensed or how that might complicate emergency response and evacuation. (0693-3-19 [Warren, Barbara])

Comment: The Draft GEIS Does Not Evaluate the Chilling Effect on the Local Economy. The Draft GEIS, while evaluating the positive impact that continued storage will have on the local economy, does not evaluate the chilling effect of the same. As set out before, the City [Red Wing, MN] finds itself in the untenable position of continuing to be a host community for the spent fuel that has been generated by the PINGP. Based on what is currently known, as well as past experiences and statements by the Federal Government, the City believes that this hosting or better yet storage will go on indefinitely. This will have a chilling effect on the City's economy and its development. It will impact its ability to grow in the area where the spent fuel is stored, including any adjacent parcels. The chilling effect will also extend to the City's ability to attract new businesses and to otherwise present itself in a positive fashion. All of this will stymie the City's ability to naturally develop and compete with other cities to attract and maintain businesses. This chilling effect of continued storage was noted by the Blue Ribbon Commission and served, in part, as a basis for its recommendation that temporary storage be developed. The Blue Ribbon Commission recognized that cities such as the City of Red Wing were, in many ways, hostages to the spent fuel: their futures were tied to the uncertainty of continued storage. The chilling effect was also noted in this Draft EA as it relates to the Prairie Island Indian Community (the "PUC") and its use of the land adjacent to the spent fuel storage area. The City, as noted in its comments to the Draft EA attached hereto, contends that this analysis should extend to the City's land use and development. This point needs to be further developed within the scope of the Draft GEIS so that a true evaluation on the impact to the human environment is addressed. (0783-1-10 [Harlan, Thomas])

Comment: Under section ES.13 , page xxxiv, lines 15-27, the Draft GEIS concludes that the impact of continued storage would be small under the various scenarios that it is analyzing. However, the analysis does not weigh the chilling effect that continued storage will have, the drain on public safety services as first responders (like the City [Red Wing, MN]) are required to maintain the necessary readiness to respond to an incident or are any of the other factor that will have a negative impact on the development and growth of the area surrounding the ISFSI. The simple notion that the socioeconomic impact, as determined by the number of workers, the construction on any ISFSI replacement or its ongoing operations, by itself, is a measure of the

impact of continued storage would have upon cities and other areas simply falls short of any meaningful analysis. One of the fundamental NEPA mandates is to evaluate how the proposed action, in this place long-term storage, would have a *negative* impact upon the human environment in which it is based. Part of that human environment consists of the socioeconomics of the area surrounding the storage. As such, an appropriate analysis would not be limited to just the direct impact (e.g. the number of workers at the storage facility), but would be the indirect impact – especially in the unique circumstances presented by stored, but continuing, radioactive material. (0783-1-16 [Harlan, Thomas])

Comment: The City [Red Wing, MN], in all respects, is a first responder to any incident at the PINGP or the ISFSI. It is obligated, under both federal and state law, to annually provide reasonable assurance that it has the necessary facilities and infrastructure to meet and respond to any incident at either facility. The City, then, is obligated to maintain a steady state of readiness through its investment in and maintenance of the necessary equipment and personnel, as well as the necessary buildings to locate the same, in order to meet its obligations. It has and continues to do so despite the continued reduction of revenue to the City from the Company for taxes on the PINGP. The City, in turn, has been forced to shift this burden to its other taxpayers who, since 1996, have seen their property taxes increase over 188%. Thus, the City is uniquely qualified to provide comments to the Draft GEIS. (0783-1-2 [Harlan, Thomas])

Comment: The Draft GEIS Provides and Incomplete Analysis on the Impact of Taxes from Continued Storage. In evaluating the impacts of continued storage, the Draft GEIS simply concludes that tax payments will continue. While it does, in some sense, appropriately defer this analysis based on local and state taxing ordinances, regulations, and codes, it does not appropriately or discuss the impact that a reduction in taxes will have as there is a switch from plant operation to storage only. It does not evaluate what impact this will have on the host community and its ability to maintain the necessary public safety services to respond to an incident at the storage facility. That host community will still be obligated to respond to an incident but not receive the same tax revenue to do so. As noted by the NRC in the Draft EA, the financial burden on first responders such as the City of Red Wing [MN] is not going to diminish over time. Draft EA, Section 4.4, page 4-3. It is going to stay the same as long as the spent fuel is stored on site. How does this burden impact the City and other host communities? What will happen when there is the precipitous drop in revenue to them generated by the power plants? These issues related to revenue need to be further evaluated. (0783-1-9 [Harlan, Thomas])

Comment: As an overview, the Draft GEIS is flawed because it does not address a broader scope of the affected environment. Indeed, it looks solely at direct impacts (employment, transportation, and land use of the storage system itself) and does not consider a broader indirect impact on the local community that hosts spent fuel or the surrounding area. The view on the affected environment should mirror the more expensive view taken in the Draft GEIS when an examination of social justice is provided. There, there is a more detailed and specific analysis of the impact of continued storage on minority, low-income, and other vulnerable communities. The failure to have a broader view in the Draft GEIS diminishes the impact of continued storage on the other stakeholders. Accordingly, the analysis should be broadened or it will not fully evaluate the impact of the proposed action on the human environment. (0783-2-18 [Harlan, Thomas])

Comment: Under section 3.1, page 3-1 and carrying over to 3-4, the Draft GEIS addresses land use. However, as set forth above, the focus is too narrow. For example, the PINGP is located within the City's [Red Wing, MN] limits. The PINGP's spent fuel, wet or dry, is also

temporarily stored within the City's limits. It is not outside, not near, nor close to but located specifically within the City's limits. The continued storage of spent fuel will have a material impact on the development of the City in both the short-term and long-term timeframes. It will be the center of a dead zone that will have little if any commercial activity and will disproportionately use public safety services. Moreover, and more appropriately for land use, it will have a chilling effect on the ability of the City to develop the area around it because of the continued stigma associated with the radioactivity, the spent fuel assemblies, and the uncertainty of disposal and, for purposes of the Draft GEIS, storage. The concept of land use must be expanded. (0783-2-19 [Harlan, Thomas])

Comment: Under section 3.2, pages 3-4 -3-8, the Draft GEIS is woefully deficient in its analysis of the socioeconomics associated with continued storage. The Draft GEIS focuses only upon the direct impact that continued storage will have and not on the indirect impact associated with the continued storage. This includes but is not limited to the chilling effect that it will have on other land development in that area. This, in turn, will have a fall out related to employment and income, taxes, demography, and housing that this development would naturally bring. The continued storage will also disproportionately utilize public safety services because the City [Red Wing, MN] will have to maintain the necessary preparedness to respond to an incident at the storage facility. This burden is unlike any other that the City would have to maintain for a normal commercial operation within the City limits. Continued storage will not provide sufficient taxes that would otherwise offset the need for the heightened public safety services and the necessary emergency preparedness associated with the requirements of responding to an incident. All of these factors need to be addressed and weighed. (0783-2-20 [Harlan, Thomas])

Comment: Under section 3.2.2, page 3-6, lines 5-24, the Draft GEIS identifies a number of instances where there is continued tax payment for storage facilities after plant operations cease. The Draft GEIS analysis must continue to analyze what impact this reduction of tax payments has on public safety services and how that is spread throughout the community. As noted in the Draft EA, the financial burden on the host cities will not lessen – but the revenue from property taxes will decrease. What is the impact of this? Can there be a lower level of public safety services provided? In doing so, the Draft GEIS should also address the necessary emergency preparedness and the costs associated with the same. This is a direct material impact that continued storage has on hosts communities such as the City [Red Wing, MN] and it must be analyzed under the Draft GEIS. (0783-2-21 [Harlan, Thomas])

Comment: Under section 6.4.1, starting on page 6-10 and going to 6-11, the Draft GEIS analyzes land use using the aforementioned general trends and activities. Nowhere does it reference the fact that there may be no development and that continued storage will be a deterrent to development. This analysis must be amended. (0783-3-11 [Harlan, Thomas])

Comment: Under section 6.4.1.3, the Draft GEIS concludes that cumulative impact of continued storage on land use will be small. The City [Red Wing, MN] believes there is insufficient information to come to this conclusion especially when the Draft GEIS does not analyze the chilling effect of continued storage. The cumulative impact should be changed from moderate to large after the analysis described above on the negative impact of continued storage is completed. (0783-3-12 [Harlan, Thomas])

Comment: Under section 6.4.2, starting on page 6-12 going through 6-15, the Draft GEIS analyzes cumulative trends and their impact on socioeconomics. Like previous sections within the Draft GEIS, there is no reference to the negative impact of continued storage. There is no reference to the costs associated with the emergency preparedness, the shift of the burden for

the preparation of the same, the decrease in taxes, the inability to develop land around the spent storage system and the inability to adequately pay for street, sewer, water for such development, among other things. All of these factors need to be appropriately weighed and set forth in this section. (0783-3-13 [Harlan, Thomas])
