Comment: Under section 8.1, starting on page 8-2 and running to page 8-5, the Draft GEIS sets forth a number of tables that summarize the impact from continued storage both at a reactor and away from a reactor. These tables should be modified to reflect comments of the City [Red Wing, MN] and to increase the impact on land use, socioeconomic and other areas from small to moderate or large. Moreover, each of these should indicate that the impact is going to be site specific and will be dependent upon the immediate surrounding area. Again, for the City, with a location of the PINGP and the storage within the City limits, the impact on all of these will be large. (0783-3-17 [Harlan, Thomas])

Comment: Under section 8.4, starting on page 8-9 and continuing to 8-10, the productivity analysis needs to be expanded. This expanded analysis would include an evaluation of the long-term impact on productivity where there is an indefinite storage at a site. There is an indirect impact or chilling effect that continued storage will have on the natural development of the area around it. There will also be opportunity costs for the City [Red Wing, MN] (or any other entity that continues to provide first responder services) associated with the costs of continuing to maintain an emergency preparedness plan. These costs must be analyzed or at least put forth for an analysis in section 8-4.⁸ [footnote 8 text: This analysis would also find its way back into the cost benefit analysis set forth in chapter 7 of the Draft GEIS.] (0783-3-18 [Harlan, Thomas])

Comment: Under section 4.1, page 4-4 to 4-6, land use, the analysis for all time frames should be expanded to include an analysis of the chilling effect that continued storage would have on development. This would include, but not be limited to, actual land use, development of roads, sewer and gutter, as well as actual land development itself. The Draft GEIS does not, in any way, take into account the stigma associated with continued storage. (0783-3-2 [Harlan, Thomas])

Comment: Under section 4.20, starting on page 4-90 and carrying over to page 4-91, Table 4.2 should be modified to reflect the changes in the analysis set forth by the City [Red Wing, MN] in this letter. In particular, land use and socioeconomics, for all timeframes, should be modified from small or moderate to large. (0783-3-24 [Harlan, Thomas])

Comment: Under section 4.2, pages 4-6-4-8, the Draft GEIS should be modified to include a discussion on the indirect socioeconomic impacts of continued storage. This would include, but not be limited to, the inability to develop the land around the storage facility, decreased taxes, the continued requirement to maintain heightened public safety services and the other impacts associated with the same. There is nothing within the Draft GEIS that addresses the socioeconomic impact that this would have on an area. (0783-3-3 [Harlan, Thomas])

Comment: GEIS Sections 4.2 and 4.3: The worker estimates for wet storage and dry storage operations and maintenance appear reasonable, provided they include security (GEIS 4-7, lines 4-6). The logic for increasing the bottom of the range and decreasing the top of the range for dry storage versus wet is not clear. It seems the lower end of the range should be the same. (0827-7-17 [Ginsberg, Ellen])

Comment: SFP leaks, and the extensive cleanups associated with them, also may cause property devaluation. See Lochbaum Declaration, pars. 8.6, 8.9 (noting that a pipe leak at

Braidwood caused property devaluation for at least 15 property owners and the licensee either purchased the contaminated property outright or reimbursed landowners for their losses). The NRC fails to consider this impact. And, it also fails to consider the likelihood of increased impacts that will occur over time. From a socioeconomic perspective, given the typical lifespan of a corporation, an owner no longer receiving revenue from a permanently retired nuclear plant may not survive for six decades to clean up the leaks from its SFPs. Lochbaum Declaration, par. 8.10. (0897-5-14 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Re: the bottom of Page 3-4, top of Page 3-5 "NRC's socioeconomic analysis gives undue attention to the so-called "benefits" derived from "hosting" a long-term ISFSI. What about the negative economic consequences of being stuck with irradiated nuclear fuel for the long-term, perhaps forever? The radioactive stigma effect alone could prove very significant, in a negative way. As but two examples. Big Rock Point's decommissioning ended in 2006. NRC has blessed the release of that site for unrestricted reuse, despite the radioactive contamination of the environment that still lingers (something that environmental watchdogs have protested, as in this report I wrote in 2006:

<http://www.nirs.org/reactorwatch/decommissioning/bigrockbackgrounder272007.pdf>). But, because of the presence of 7 dry casks holding irradiated nuclear fuel, and an additional dry cask holding Greater-Than-Class-C so-called "low-level" radioactive waste, no development of that site can be expected anytime soon. (0919-5-4 [Kamps, Kevin])

Comment: Likewise, at an end of cycle annual meeting near the Kewaunee nuclear power plant in northern WI in June 2013, a number of concerned local residents - many of them farmers - expressed their dissatisfaction that irradiated nuclear fuel would remain on-site for the long-term future. They could not envision any alternative use of the land, while the irradiated nuclear fuel is stored there, not only due to safety and security concerns, but also because of the stigma involved. Certainly, those local residents who attended this NRC public meeting did not regard long-term ISFSI storage at Kewaunee as an economic boon for their area - quite to the contrary. (0919-5-5 [Kamps, Kevin])

Comment: Re: Page 3-5, line 1 and following "Again, NRC's flip examination of supposed economic benefits is all the more ironic, given its shallow analysis of the risks of irradiated nuclear fuel generation, storage, and disposition in this DGEIS. (0919-5-6 [Kamps, Kevin])

Comment: Re: Section 4.1.3 Indefinite Storage (page 4-6) - It's hard to understand how NRC can find SMALL impacts, when even current safety, security, health, and environmental risks due to irradiated nuclear fuel storage preclude the use of the land "hosting" the ISFSIs for any other use, as at Big Rock Point in MI. (0919-6-11 [Kamps, Kevin])

23. Comments Concerning Environmental Justice

Comment: It is inappropriate for NRC, in this GEIS, to use the Private Fuel Storage (PFS), LLC "centralized interim storage" proposal, targeted at the Skull Valley Goshutes Band of Indians in Utah, as a model for away-from-reactor storage. Although licensed by NRC for construction and operation, PFS was canceled in December 2012. NRC claims in its GEIS to observe Environmental Justice (EJ) principles, and yet PFS was a blatant violation of EJ. Nearly 500 organizations across the U.S. joined with Skull Valley Goshute traditionals urging NRC to disapprove PFS's license, due to its inherent violation of EJ. (0002-5 [Commenters, Multiple])

Comment: The EIS needs to take into consideration environmental justice questions such as who bears the burden and who reaps the benefits? Native peoples and peoples of color and those in poor communities have historically been disproportionately impacted by all the links in the nuclear chain from mining to radioactive waste dumping. Intergenerational equity should also be considered. The electricity has been used or wasted in this generation, but dozens of more generations to come must work to isolate it and protect themselves from it. (0030-21-5 [Carberry, Mike])

Comment: In my public comment, I would like to specifically focus my advocacy efforts toward the environmental justice aspect of the NRC's Waste Confidence GEIS. Under the National Environmental Policy Act (NEPA), which was established in 1969, Federal agencies must abide by Executive Order 12898. Executive Order 12898 mandates that Federal agencies must identify and address potential disproportionately high and adverse human health and environmental impacts on minority and low-income populations. Since these particular populations have been historically disregarded in the environmental decision-making process, it is imperative that these groups are granted equal opportunity to participate and have their voices and opinions heard. (0047-2 [Anonymous, Anonymous])

Comment: The primary focus of this regulatory document is to revise the initial 2010 Waste Confidence draft GEIS that was created by the NRC. Personally, I believe that the new and revised GEIS should adequately ponder local and intergenerational environmental justice. Ultimately, this would ensure that minority and low-income populations and future generations wouldn't receive the biggest burden of human health and environmental impacts due to the storage of spent nuclear fuel. According to the NRC's revised GEIS, which the intention was to address the deficiencies identified by the U.S. Court of Appeals, disproportionately high and adverse human health and environmental impacts resulting from the continued storage of spent nuclear fuel were not expected to affect minority and low-income populations. However, I would argue that these expectations could be flawed and incorrect. Although the NRC's updated GEIS projects that these certain populations won't be vulnerable to adverse human health and environmental impacts brought forth by the continued storage of spent nuclear fuel, I believe that their projections could potentially be challenged in future years. For example, the NRC truly believed that their 2010 Waste Confidence GEIS would satisfy all aspects of the NEPA obligations that they had to fulfill. Nevertheless, the NRC never suspected that their initial regulatory document would be challenged in court and identified with deficiencies. (0047-3 [Anonymous, Anonymous])

Comment: Based on the outcome of the 2010 Waste Confidence GEIS, I strongly believe that the expected projections in the revised GEIS regarding environmental justice, with respect disproportionately high and adverse human health and environmental impacts on minority and low-income populations, could also potentially be incorrect. Assuming that this is true, this could be extremely detrimental and problematic to these populations that believe they won't experience adverse impacts from the continued storage of nuclear spent fuel. (0047-4 [Anonymous, Anonymous])

Comment: I oppose locating the away-from-reactor storage of Private Fuel Storage (PFS), LLC "centralized interim storage" at the Skull Valley Goshutes Band of Indians in Utah. Although licensed by NRC for construction and operation, PFS was canceled in December 2012. Nearly 500 organizations across the U.S. joined with Skull Valley Goshute traditionals urging NRC to disapprove PFS's license, due to its inherent violation of Environmental Justice (EJ) principles. (0127-3 [Lee, Catherine])

Comment: It is inappropriate and unethical for the Nuclear regulatory Commission in this GEIS, to use the Private Fuel Storage (PFS), LLC "centralized interim storage" proposal, targeted at the Skull Valley Goshutes Band of Indians in Utah, as a model for "away-from-reactor" storage. As your agency knows, PFS was canceled in December 2012. NRC claims in its GEIS to observe Environmental Justice (EJ) principles, and yet PFS was a blatant violation of EJ. Nearly 500 organizations across the U.S. joined with Skull Valley Goshute traditionalists urging NRC to disapprove PFS's license, due to its inherent violation of EJ. (0142-1 [Solomon, Laurie])

Comment: Questions of environmental justice must be considered in the EIS. Low-income communities dominated by American Indians and people of color have historically been disproportionately impacted by nuclear energy production, from mining to radioactive waste dumping. (0143-7 [Arauz, Jorge])

Comment: So-called independent spent fuel storage installations (ISFSI) would be de facto nuclear waste dumps. The generic waste confidence rule would be based on finding one or more waste sites which would be located in economically stressed communities. Potential sites would be in the Southeast, such as Savannah River, or on Native American land, such as Yucca Mountain: This is fundamentally unjust. (0222-2 [Zeller, Lou])

Comment: And, yeah, I'd just really like to see a more -- basically a detail-oriented section in the Environmental Justice area, because aside from the very vague terminology that is provided, it goes on to say that the effects of these things -- well, they don't really specify what effects or what things are here. (0244-15-4 [Zuccarini, Ana])

Comment: And then I guess I would like to sort of, you know, make a little highlight point on here on the Environmental Justice section. It says, the ISFSIs would have minimal human health and environmental effects on minority and low-income populations. Since -- as I had asked before, you guys said that you did not have these facilities yet built and you were not able to answer my question or really address it. However, in your Draft you are already saying that it would have minimal effects on minority and low-income populations. My question is, why would you put that on here if you have no idea where you're going to locate these facilities? Is it some kind of like hint towards already you're heading in the direction of environmental inequalities? (0244-15-7 [Zuccarini, Ana])

Comment: I think a member of the audience asked a question before we got started about whether the issue of environmental justice had been considered. I think ostensibly from the perspective of where nuclear power plants are sited or whether they're sited, or the relative environmental injustice of that particular energy source that is relative to different people, I would suggest to you that it is nuclear energy that is needed more by our minority and underserved -- underprivileged communities than any other energy type. It is they who needs zero-emission energy more than anybody else. For the record, I would direct you to a wonderful guest column that was published, I think two or three months ago, by a lady named Luz Weinberg, who is the Mayor of Adventura and President of the National Association of Latin American Elected Officials, who pointed this very thing out; that it is minority communities, it is people who are -- who need clean air the most, it is people who -- also people who have health conditions who need clean air the most. It is those people who are served most by nuclear energy. Not just the nuclear energy we have today, but the prospect of more clean energy in the future. (0244-9-7 [Paul, Jerry])

Comment: So-called independent spent fuel storage installations would be de facto nuclear waste dumps. The generic Waste Confidence Rule would be based on finding one or more waste sites which would be located in economically stressed communities. Potential sites would be in the southeast, could be such as Savannah River or in the west, Native American land such as Yucca Mountain. This is fundamentally unjust. (0250-1-2 [Zeller, Lou])

Comment: I am here because I care for all the life of, for the life of all creatures on this planet. Most of my activism work has revolved around environmental racism that affects my community in Los Angeles. It is through being on the front line of environmental injustice that I have learned to be analytical of state sanctioned programs. I believe that nuclear power is not only inherently unsafe but also the entire process, including the extraction of uranium, has disproportionately affected indigenous and communities of color. (0326-51-2 [Gutierrez, Ingrid])

Comment: Within this document there are lies and misleading information. The first one I'd like to bring up is on Roman numeral Page 34 when it says that the environmental justice impact is small. Well, Fred Collins said that he was displaced from his ancestral homeland. And if I think about the people that, according to the 1805 Zebulon Pike Treaty, the Mdewakanton Dakota people that were displaced from their homeland of Prairie Island and now live with their childcare center 500 yards away from the waste storage facility on Prairie Island, I would say that the environmental justice impact is large, not small as this document states. (0326-56-2 [Homick, Nick])

Comment: And there's a lot of environmental racism going on, which nobody has mentioned, going on with the uranium because if you notice the open pits in the Navajo country, Africa, the mineral conflicts in the Congo, I mean, it just goes on and on and on and on. And even in their own statement, they mention the communities of color and low income as actually looking closer at the contamination. Why, you know -- okay, so you just can't trust them. (0327-22-4 [Muser, Mary Jo])

Comment: It is inappropriate for the NRC, in this Generic Environmental Impact Statement (GEIS), to use the Private Fuel Storage (PFS), LLC "centralized interim storage" proposal, which targets the Skull Valley Goshutes Band of Indians in Utah, as a model for away-from-reactor storage. Although licensed by the NRC for construction and operation, PFS was canceled in December 2012. The NRC claims in its GEIS to observe Environmental Justice principles, and yet PFS was a blatant violation of Environmental Justice. Nearly 500 organizations across the U.S. joined with Skull Valley Goshute traditionals urging the NRC to disapprove PFS's license, due to its inherent violation of Environmental Justice. (0336-9 [Lish, Christopher])

Comment: Curiously, the impact on Environmental Justice is noted as not being "disproportionately high [or] adverse." The support for these determinations is lacking. (0354-4 [Oeser, Robert])

Comment: Questions of environmental justice must be considered in the EIS. Low-income communities dominated by American Indians and people of color have historically been disproportionately impacted by nuclear energy production, from mining to radioactive waste dumping. (0357-6 [Daily, G. Allen])

Comment: NRC's "centralized interim storage" proposal is a despicable Environmental Injustice to any community victimized with massive lethal waste storage. NRC claims in its GEIS to observe Environmental Justice (EJ) principles, and yet this plan is a blatant violation of EJ. (0377-6-1 [Cuthbert, Lewis])

Comment: Questions of environmental justice must be considered in the EIS. Low-income communities dominated by American Indians and people of color have historically been disproportionately impacted by nuclear energy production, from mining to radioactive waste dumping. (0507-5 [Giese, Mark M.]

Comment: In addition shipping nuclear waste from the area which benefitted from the electricity to some poorer region who received no benefit from the waste as a dumping ground is a violation of Environmental Justice. (0611-31 [Shapiro, Susan])

Comment: Environmental Justice: We do not believe that the Environmental Justice impacts of long-term or indefinite storage have been fully evaluated in the draft GEIS. We fully understand that the Waste Confidence Rule is not a licensing decision and that each facility will go through a renewal licensing process. Nevertheless, the Waste Confidence Rule allows for long-term or indefinite storage by virtue of the conclusions in the draft GEIS that the environmental impacts of continued storage are SMALL (with the exception of impacts to historic and cultural resources). In the case of the Prairie Island ISFSI, which is now in the process of being relicensed for a proposed 40-year renewal term. We find it hard to believe that, given the status of the national repository (none) and the conclusions in this draft GEIS, that the storage term will be limited to just 40 years. The 40-year renewal term is an arbitrary time period, based on nothing more than the hope that a repository might be available by the end of the 40 years. The Tribe will continue to be impacted by the PINGP ISFSI long after this GEIS is final and sitting on a shelf. It will be left up to our descendants and their descendants to keep fighting for the removal of spent nuclear fuel from the Tribe's homeland. (0619-2-6 [Mahowald, Philip R.]

Comment: Quoting Beyond Nuclear's statement: "Although licensed by NRC for construction and operation, PFS was canceled in December 2012. NRC claims in its GEIS to observe Environmental Justice (EJ) principles, and yet PFS was a blatant violation of EJ. Nearly 500 organizations across the U.S. joined with Skull Valley Goshute traditionals urging NRC to disapprove PFS's license, due to its inherent violation of EJ." (0648-9 [Price, Scott])

Comment: The Environmental Justice (EJ) analysis highlights the limits of a generic EIS, and provides insufficient basis to support the findings that there would be "no disproportionately high and adverse impacts" on EJ communities (see, e.g., 8-2). The draft GEIS admits that "Demographic characteristics vary in the region around each nuclear power plant site and may be affected by the remoteness of the nuclear plant to regional population centers (NRC 2013a) . Nuclear power plants located in both rural and semi-urban areas can have varying concentrations of minority and low-income communities. (3-10 [emphasis added] .) It is therefore unreasonable for the NRC to claim that a survey of effects on a "generic" minority and low-income community provides the level of analysis that satisfies NEPA. The NRC acknowledges this in its discussion of effects on EJ communities. By way of example, in the section regarding "at-reactor continued storage" it states: "the site-specific NEPA analysis that is required prior to an NRC licensing action will include a discussion of the impacts on minority and low income populations, and will appropriately focus on the NRC decision directly related to specific licensing actions." (4-11) . Similarly, in the EJ analysis for long-term storage, which necessarily includes dry transfer systems (that don't yet exist), the draft GEIS states, "DTS license reviews would not rely on the analysis in this draft GEIS, because the site-specific NEPA analysis would consider the site-specific impacts on minority and low-income populations." (4-12.) These amount to admissions that no EJ analysis in a generic EIS is sufficient for NEPA purposes; yet they still form part of the rationale for a finding in a generic document that there would be "no disproportionately high and adverse impacts" on EJ communities (see, e.g., 8-2).

The analysis does not support the finding made, and the discrepancy should be corrected. (0669-12 [Walter, Joan])

Comment: Environmental Justice --while claiming compliance with the EJ Executive Order, which would necessitate a site-specific environmental analysis for a licensing action, NRC clearly indicates that there is no licensing action planned as part of this GEIS. (0693-3-20 [Warren, Barbara])

Comment: Questions of environmental justice must be considered in the EIS. Low-income communities dominated by American Indians and people of color have historically been disproportionately impacted by nuclear energy production, from mining to radioactive waste dumping. (0707-7 [Werner, Shahla M.])

Comment: Environmental Justice Sections: In the discussion of environmental justice impacts for at-reactor long-term storage⁹⁵ [footnote 95 text: GEIS, at Section 4.3.2, pp. 4-13.] and for indefinite at-reactor storage⁹⁶ [footnote 96 text: *Id.* at Section 4.3.3, pp. 4-14.] there is inappropriate and unnecessary reference to the possibility of moderate or large impacts to historic and cultural resources. Although the correct overall conclusion regarding environmental justice impacts is reached, i.e., small impacts in all cases, it should be recognized that for long-term or indefinite storage at decommissioned reactor sites there will be a large area of previously disturbed land that could be used for the storage facilities. A more reasonable assumption (that should be included in the historic and cultural resource sections) would be that the ISFSI can be sited to avoid significant historic and cultural resources, much like the appropriate assumption made for special status species and habitat in other sections of the GEIS. It should also be noted that the inappropriate and unnecessary references to potentially moderate/large historic and cultural resources is not included in the discussion of away-from-reactor environmental justice impacts for any phase of continued storage. (0827-4-5 [Ginsberg, Ellen])

Comment: GEIS Section 4.3: The statement that "human health and environmental effects from continued storage would be small compared to the impacts that are normally experienced during reactor operations" (GEIS 4-11) is unnecessary and could potentially be interpreted to mean that reactors have large health effects - which, experience has shown, is not the case. It is sufficient to just conclude that these impacts would be SMALL without making any comparison to reactors. (0827-7-21 [Ginsberg, Ellen])

Comment: Consider, for instance the Draft GEIS claim that a generic analysis would suffice for environmental justice issues: In the present case, however, the NRC has determined that it can provide an assessment of the environmental justice impacts during continued storage compared to environmental justice impacts of storage during reactor operations....[T]his draft GEIS and the Waste Confidence rule are not licensing actions and do not authorize the continued storage of spent fuel. The environmental analysis in this draft GEIS fulfills a small part of the NRC's NEPA obligation with respect to the licensing or relicensing of a nuclear reactor or spent fuel storage facility. Further, the site-specific NEPA analysis that is required prior to an NRC licensing action will include a discussion of the impacts on minority and low income populations, and will appropriately focus on the NRC decision directly related to specific licensing actions. As with all other resource areas, this site-specific analysis will allow the NRC to make an impact determination with respect to environmental justice for each NRC licensing action. *A generic determination of the human health and environmental effects impacts during continued storage is possible because the NRC understands how the environmental impacts change when a nuclear power plant site transitions from reactor operations to continued storage.* Based on this

knowledge, the NRC can provide an assessment of the potential human health and environmental effects during continued storage. As discussed in the following sections, the NRC has determined that the human health and environmental effects from continued storage would be small compared to the impacts that are normally experienced during reactor operations.¹³⁷ [footnote 137 text: NRC 2013a, p. 4-11, italics added] But once a determination is made that spent fuel storage impacts are small even for indefinite storage, they cannot be raised in a site-specific licensing process even if they were not considered in the waste confidence GEIS. (0898-5-7 [Curran, Diane] [Makhijani, Arjun])

Comment: The NRC's statement quoted above is an attempt to foreclose any consideration of radiation-related environmental justice site-specific issues, especially those associated with long-term or indefinite storage of spent fuel, notably in case of a failure to site a repository and indefinite on-site storage. (0898-5-9 [Curran, Diane] [Makhijani, Arjun])

Comment: On Page 2-18, NRC claims "The [PFS LLC] site would be located in the northwest corner of the reservation approximately 6 km (3.5 mi) from the Skull Valley Band's village." Having spent considerable time in the Skull Valley Band's village, as part of the resistance against the environmentally racist radioactive waste dump proposal, I find it hard to believe that the distance between the residences and targeted dumpsite was actually that great. I think the distance was shorter. Fortunately, this is now an academic point, as the dump proposal has been cancelled. NRC should really not be citing PFS, LLC in any positive way whatsoever, given the environmental injustice it represented, and its very welcome cancellation - that is, failure - despite NRC's rubberstamp of the construction and operating license. (0919-3-16 [Kamps, Kevin])

Comment: NRC continues to violate EJ, by citing PFS, LLC (even though it was cancelled a year ago) as a model, as proof positive that parking lot dumps can be licensed. (0919-3-17 [Kamps, Kevin])

Comment: Re: Page 4-9, Section 4.3, Environmental Justice, NRC states "Environmental justice refers to a Federal policy that ensures that minority, low-income, and tribal communities that have historically been excluded from environmental decision-making are given equal opportunities to participate in decision-making processes"...NRC has an odd notion what Environmental Justice means. In 2006, NRC rubberstamped, albeit by a split decision at the ASLB and NRC Commission levels, the PFS, LLC parking lot dump targeted at the Skull Valley Goshutes Indian Reservation in Utah. NRC had approved a nuclear power industry scheme to park 40,000 metric tons of irradiated nuclear fuel on the reservation homeland of a tiny, low income Native American tribe. This, despite the call by 437 environmental and environmental justice groups to "not go there." See: <http://www.nirs.org/radwaste/scullvalley/skullvalleygoshutesgroupltr772005.pdf>. NRC approving PFS, LLC anyway led me to dub the agency the "Nuclear Racism Commission," for its environmental injustice. Given PFS, LLC's inherent violation of EJ, as well as its welcome cancellation a year ago, NRC should not rely upon it as a positive example to point to, as proof that away-from-reactor storage can be licensed! (0919-6-13 [Kamps, Kevin])

Comment: NRC states on Page 4-10, that "environmental justice, as applied at the NRC, "means that the agency will make an effort under NEPA to become aware of the demographic and economic circumstances of local communities where nuclear facilities are to be sited, and take care to mitigate or avoid special impacts attributable to the special character of the community" (NRC 2002a, 2004b). How ironic then, that NRC approved the PFS, LLC license. (0919-6-14 [Kamps, Kevin])

Comment: At lines 13-14, NRC states "socioeconomic conditions affected by the continued storage of spent fuel as they relate to minority and low-income populations living near nuclear power plant sites would remain unchanged"...This is a strange logic applied by NRC. So, low income, and/or people of color communities, which already have "hosted" a nuclear power plant for 40 or 80 years, just have to deal with the radioactive waste forever, in addition, so there is no further disproportionate impact on them? This is a "nuclear sacrifice zone" attitude by NRC. It makes a "nuclear sacrifice zone" of a low income or people of color community, doomed forever to suffer radiological impacts, as by radioactive waste storage. (0919-6-15 [Kamps, Kevin])

Comment: At Page 4-10, lines 24 and following, NRC describes monitoring "releases from the spent fuel pools and at-reactor ISFSI." But any such talk, in an EJ context like this, is unacceptable. The Prairie Island Indian Community, as but one example, had suffered enough before NSP tricked their way onto the island, promoting the benefits to be gleaned from a "steam generating plant" - careful to keep the word "nuclear" out of the conversation for as long as possible. The two reactors were built against the will, and without the informed consent, of the tribe. And it's been all downhill since. There should be absolutely no discussion of radiological releases from irradiated nuclear fuel storage facilities at a place like Prairie Island. Enough is enough. NRC makes a mockery of "environmental justice" by attempting to explain how "acceptable" or "permissible" releases from radioactive waste storage at a place like Prairie Island will be "monitored" in order to assure "environmental justice" goals! (0919-6-16 [Kamps, Kevin])

Comment: Re: Page 4-11, lines 19 to 21, again, NRC is attempting to apply a "nuclear sacrifice zone" or "nuclear sacrifice community" logic here. The community is already negatively impacted by a nuclear power plant, so the relatively similar, albeit additional, impacts from radioactive waste storage are, therefore, no big deal. But another way of looking at it is, this community of color, low income community, etc. has already suffered enough from the nuclear reactors, and shouldn't be burdened again with the radioactive waste. (0919-6-17 [Kamps, Kevin])

Comment: The EIS needs to take into consideration environmental justice questions, such as who bears the burden and who reaps the benefits. Native peoples and peoples of color and those in poor communities have historically been disproportionately impacted by all links in the nuclear chain, from mining to radioactive waste dumping. (0938-7 [Sondheim, Steven])

24. Comments Concerning Air Quality

Comment: But they just go on to say that the potential for moderate impacts to air quality, terrestrial life, and transportation are based on construction-related potential fugitive dust emissions. However, there's not really like an outline of a measure of how much or which substances would be the ones that would be fugitive. (0244-15-5 [Zuccarini, Ana])

Comment: The assumption that ISFSIs would cause "some local atmospheric heating" (GEIS 4-15) based on a 1984 study (before there were any ISFSIs) appears to be without basis. Industry was unable to identify any instances in the 30 years of ISFSI operating experience since where any actual atmospheric temperature increase attributable to ISFSI operation has been documented. NRC should reconsider this statement. (0827-7-23 [Ginsberg, Ellen])

Comment: At Page 4-14, lines 28 to 29, how can NRC so confidently claim "there would be no increase in emissions during continued storage"? What if an explosion or fire occurs? That would "increase emissions"! (0919-6-18 [Kamps, Kevin])

Comment: At Page 4-15, line 12, why is it that "testing requirements may be reduced or eliminated for emergency diesel generators once the reactor is permanently shutdown."?--How smart is it to do away with EDGs when the pool is still full of waste? What if something very serious goes wrong with the primary electric grid, and it would be impossible to restore before significant boiling occurs in the pool? How will the water circulation pumps on the pool be restored before a boil down fire is sparked? (0919-6-19 [Kamps, Kevin])

Comment: NRC states at lines 18-19 that "dry cask storage systems do not have active systems (e.g., diesel generators), these activities do not involve significant releases of air pollutants."...But of course, as Dr. Gordon Thompson has warned, a malevolent act could result in a dry cask's contents going up in flames, in a Zr fire. Or, the cask could simply release radioactive gases and volatile particles over time due to nothing more dramatic than simple leakage, due to age degradation and decay under the elements. That is an impact on air quality. (0919-6-20 [Kamps, Kevin])

Comment: At Page 4-15, lines 21-22, NRC describes significant local temperature increases due to dry cask storage: "Thermal releases from the at-reactor ISFSI will cause some local atmospheric heating. Downwind from an ISFSI, ambient temperatures can increase by 2.1°C (3.8°F) at 1 km (0.6 mi) to 0.1°C (0.2°F) at 10 km (6.2 mi) from the site (NRC 1984)." Increasing the local area's temperature, out to a distance of 0.6 miles, by nearly 4 degrees F, is a significant air quality impact, just from the thermal heat of irradiated nuclear fuel alone! It is the equivalent, on a local level, of the dire global warming impacts that the UN IPCC warn about on a global level. In fact, the two should be considered together. What is the impact of raising a local area's temperature by nearly 4 degrees F just by storing irradiated nuclear fuel there, combined with another increase of temperature of several degrees F due to global warming? NRC has not carried out any such impact analysis. Such heat output from the dry casks would continue for how long? (0919-6-21 [Kamps, Kevin])

Comment: Re: Section 4.4.3, Indefinite Storage, Page 4-17 to 18 Leakage of radioactivity from one or more casks in the ISFSI would mean HUGE air impacts over time! But NRC conveniently just assumes they (who are "they"?!) will just keep replacing the casks forever! What's the price tag on THAT?! Too cheap to meter still? No! But with loss of institutional memory and control, and even societal collapse, how can NRC guarantee that will happen forevermore?! NRC can't guarantee that! (0919-6-22 [Kamps, Kevin])

Comment: The Waste Confidence Generic Environmental Impact Statement indicates that, "For the resource areas considered, this draft GEIS attempts to establish generic impact determinations that would be applicable to a wide range of existing and potential future spent fuel storage sites." The General Conformity regulation requires a Federal Agency to assess individual Federal actions (projects) through an Applicability Analysis to determine if a Conformity Determination is required. However, the General Conformity regulation provides a process, Presumed to Conform (40 CFR 93.153 Applicability), which allows a Federal Agency to address General Conformity by specific project type instead of on an individual basis. In order to make a generic determination for General Conformity and waste confidence, the presumed to conform process as described in 40 CFR 93.153 is the appropriate mechanism for making this determination. Therefore, in order to make any generic applicability statement regarding General Conformity, the "presumed to conform" process must be followed. (0920-48 [Foster, Ruth])

Comment: It is recommended that all non-road diesel construction equipment greater than 100 horsepower used on the project for more than ten days shall have engines that meet the

USEPA Tier 4 non-road emission standards, or the best available emission control technology that is technologically feasible for that application and is verified by the USEPA or the CARB as a diesel emission control strategy for reducing particulate matter emissions, except that: a. If there is no technologically feasible emission control technology verified by USEPA or CARB for specific diesel non-road construction equipment, the contractor may use the best available emission control technology verified by the Mine Safety and Health Administration or the Switzerland BUWAL program (VERT Filter List) to reduce particulate matter emissions. b. If there is no technologically feasible and appropriate emission control technology or installation of a control technology would create a safety hazard, such as impaired visibility for the operator. 4. It is recommended that all on-road diesel vehicles used to haul materials or traveling to and from the construction site shall use designated truck routes that are designed to minimize impacts on residential areas and sensitive receptors such as hospitals, schools, daycare facilities, senior citizen housing, and convalescent facilities. (0920-50 [Foster, Ruth])

Comment: Diesel exhaust contributes the highest cancer risk of all air toxics in New Jersey. State and Federal regulations require that the project complies with #1 and #2 listed below. In addition, the Department recommends that construction projects involving nonroad diesel construction equipment operating in a small geographic area over an extended period of time should implement the remaining measures to minimize the health impacts of diesel exhaust. a. All on-road vehicles and non-road construction equipment operating at, or visiting, the construction site shall comply with the three minute idling limit, pursuant to N.J.A.C. 7:27-14 and N.J.A.C. 7:27-15. b. All diesel non-road construction equipment operating at the construction site shall use ultra-low sulfur diesel fuel (<15 ppm sulfur) in accordance with the federal Nonroad Diesel Rule, 40 CFR Parts 9, 69, 80, 86, 89, 94, 1039, 1051, 1065, 1068. (0920-52 [Foster, Ruth])

Comment: Lastly, the portion of the document on Air Quality was notably insufficient since it failed to indicate how the air quality was being judged. Radionuclides often travel through the air and can be inhaled and result in cancer or worse down the road. Yet, I see no analysis of radionuclides in air (or water or on our highways for that matter) and the serious consequences on human health which some of these radioactive substances can cause. (0937-27 [Campbell, Bruce])

25. Comments Concerning Climate Change

Comment: The EIS also needs to include an investigation of the carbon effects of the fuel cycle. As we continue to try to decrease greenhouse gases in the United States, continuing to mine, mill, and process uranium is a contradiction. In fact, one of the most dangerous chemicals that depletes the ozone layer, freon, has been used in converting uranium to fuel. Construction and decommissioning nuclear power plants are also high carbon emitters. (0030-12-6 [March, Leslie])

Comment: In addition to a commitment to the safety and secure storage onsite of spent fuel, the industry is also a vital part to securing our future environmental health. Just last week the Intergovernmental Panel on Climate Change, the IPCC, released their updated executive summary on climate change and they found with 95 percent confidence that humans are behind climate change. The report also found that the surface temperature is likely to rise by 1.5, or in two cases more than 2 degrees Celsius, which is considered beyond tolerable and into the danger zone by the end of this century. (0030-18-4 [Curtin, Kenneth])

Comment: I want to talk about catastrophic climate change, because honestly we have decisions to make as a country. Are we willing to live in a world that is beset by unmitigated climate change? Are we ready to cope with the droughts, ocean acidification, collapsing crop yields, extreme weather events, species extinctions, and mass displacement of climate refugees? Clearly we are not prepared as a country or a society to deal with those sorts of challenges that will be brought by catastrophic global climate change. (0030-19-1 [Cohn, Jeremy])

Comment: To my generation action on climate change is not a heartwarming footnote to be written on our political legacy. Climate action is necessary now. The seeds of growth are being planted around the world and energy prosperity will lift billions out of poverty, but catastrophic climate change has the potential to turn that promise of prosperity into a Pyrrhic victory and to reverse the hard-won progress of those same people and our own families. (0030-19-5 [Cohn, Jeremy])

Comment: The dangerous and unpredictable effects of global warming on all aspects of the nuclear industry must also be taken into account. I've already talked about nuclear power is not a climate change solution. (0030-21-8 [Carberry, Mike])

Comment: The EIS also needs to include an investigation of the carbon effects of the fuel cycle. As we continue to try to decrease greenhouse gasses in the United States, continuing to mine, mill, and process uranium is a contradiction. In fact, one of the most dangerous chemicals that depletes the ozone layer, Freon, has been used in converting uranium to fuel. Construction and de-commissioning are also high carbon emitters. (0045-11-9 [March, Leslie])

Comment: In addition to a commitment to safely and securely storing spent fuel, the industry is also vital to the future of our environmental health. The Intergovernmental Panel on Climate Change recently released an update assessment of the state of global warming and found with 95% confidence that man is responsible. The report also found that surface temperatures are likely to exceed 1.5 degrees C and even 2 degrees C by the end of the century -2 degrees C is considered by most to be the dividing line between "tolerable" and dangerous. (0061-4 [Kirton, Kenneth])

Comment: Climate change is a reality that any safe storage plan must address. Experts agree that climate change is already causing more severe hurricanes, wind storms, tornadoes, ice storms and drought. All of these weather events increase the likelihood of both power failures and changes in water levels and well as increased scarcity of water for cooling spent fuel. Engineers can shut down the operation of a nuclear plant, but the spent fuel continues to require electricity and water to remain inactive. Climate change will make increasingly unstable sources of both. (0086-5 [Lewis, Carol])

Comment: I've dedicated all my schooling, my professional life to make sure that we can put our trust in nuclear energy. I did it because I am personally a climate change advocate. And looking at the realistic solutions towards achieving clean air, the clean-air standards that we want in the timeframe that we want, clean-energy has to be the cornerstone. (0112-12-1 [Garcia, Diego])

Comment: I think tonight you're going to hear from a group of young people that are realizing that for a realistic change in climate -- to curb a changing climate we need to embrace new technology for nuclear energy. (0112-12-4 [Garcia, Diego])

Comment: My first comment is that the draft GEIS estimates that sea level will rise less than 1 meter by the end of the century and this will not endanger any U.S. nuclear power plant. However, sea level rise will vary greatly by region. It's inaccurate to assume a blanket 1 meter rise for all plant locations and then conclude that all plants will not be in danger. 1 meter is a global average. It's been projected to be -- that it'll be much less in some areas. But it's also projected to be -- that it'll be much greater in some areas as well. Areas like the Eastern seaboard where many nuclear power plants are currently sited. Areas projected to experience the most significant sea level rise should be addressed in the GEIS using a global average to assume all plants are safe is a flawed approach. Just as an example, the projection of sea level rise for Cape Cod Bay, and this is where Entergy's Pilgrim nuclear power plant is located, ranges between 4 and 6-feet by 2100. And it's also projected that this rise will come with an increasing severity of storms, surge, and wave action on top of the higher water levels. (0112-16-1 [Vale, Karen])

Comment: My second comment is that the draft GEIS does not consider the impacts of rising temperatures on the water sources intended to cool the spent fuel pools. As an increasingly warming climate is heating the water temperatures of our oceans, lakes, and rivers, water is becoming too warm for plant's cooling systems. Cooling systems are only approved for certain incoming water temperatures and their ability to operate properly and safely has not been proven under higher temperatures. Warming water's an increasing problem. For example, just this past summer Pilgrim had to power down several times due to the water in Cape Cod Bay warming up and exceeding the 75-degree limit. Now, generally appears -- it appears that the bay is warming. And in recent years its average summer temperature has been several degrees warmer than its mean for the last century. (0112-16-2 [Vale, Karen])

Comment: If this issue [climate change impacts raising cooling water temperatures] is included in a future version of the EIS, a generic version would be unable to properly assess how individual plants would be affected. Plants have different equipment, different ages of infrastructure, different environmental conditions and changes. It's much more complicated than could be covered in a generic EIS. As with sea level rise, the NRC should consider a worst-case scenario for each facility then we might know if mitigation strategies, such as chillers, for example, would be required to sustain the temperature of wet pools during extended heat waves. (0112-16-3 [Vale, Karen])

Comment: Under NEPA, an EIS is intended to carefully investigate the environmental impacts of a potential action. One of NRC's assumptions underlying their opinion that the impacts of spent fuel storage can be considered generically, not on a site-by-site basis, is that changes in the environment around spent fuel storage facilities are sufficiently gradual and predictable to be addressed using a generic approach. This assumption clearly ignores past experience and the realities of a changing global climate. It ignores the very real possibility of severe storms and extreme circumstances. (0112-18-6 [Shaw, Sally])

Comment: Climate will be a part of the remaking of our empire. But the nuclear waste, wherever it is, is going to be burning away. (0112-35-2 [Boyce, Pam])

Comment: [O]ur nation gets 19 percent of its electricity from nuclear power. But when you look at what percentage does it get from its clean-air electricity, that number jumps up to over 60 percent. Almost two-thirds of our clean-air electricity comes from nuclear. Now, looking at everything that we know to be true in terms of climate change, looking at what the IPCC summary report that was recently released said in the upcoming meetings in Poland, climate change is a serious issue. So I personally see climate change as the largest threat that my

generation faces. And I do not understand from my personal perspective why we would try to shut down our largest source of clean-air energy and carbon-free energy. And finishing my statement I would just like to say as the Commission considers this issue and future issues, I would just encourage them to think about all we can do to strengthen our nation's commitment to all clean-air technologies, including nuclear. (0112-4-2 [Kirton, Stratton])

Comment: The NRC really needs to get to grips with the climate disruption issue. They need to be looking at what effects that's going to have on this waste especially if it ends up in the places it currently is. (0112-5-3 [Bogen, Doug])

Comment: And just to point out one of the frustrations I have with this discussion in general, one is that, as Mr. -- I believe it was Mr. Stratton [Stratton Kirton] said about clean-air electricity, it's really too bad that people from the climate front are pitting climate activists against nuclear -- or anti-nuclear activists because I think a lot of us are one in the same. I, myself, consider myself a climate activist. I believe that climate change is real and it's one of the biggest generational fights we'll have. But I also believe that even though I don't consider myself anti-nuclear, I do believe that many of the nuclear power plants are threatening us with one of the biggest lifetime threats we'll ever have. So we are not necessarily two different fronts. And I hope Mr. Stratton's point was not that you have to be pro-nuclear or pro-climate. You can be both. (0112-9-1 [Baker, Anna])

Comment: The unpredictable effects of global warming must be considered in all future licensing and waste storage decisions, including increased rising temperatures, droughts, flooding and fluctuating water levels, which increase the probability of catastrophic events involving nuclear plants and nuclear waste storage. (0143-9 [Arauz, Jorge])

Comment: Beyond the nuclear energy's commitment to safe storage of spent fuel, nuclear energy plays a crucial role in our country's future environmental health. The inter-governmental panel on climate change recently released an update assessment of the state of global warming and found with 95 percent confidence that humans are responsible. The report also found that the surface -- that surface temperatures are likely to exceed 1.5 degree Celsius and possibly even meet 2 degrees Celsius by the end of the century. Most consider 2 degrees Celsius to be the dividing line between tolerable and dangerous global warming. (0163-29-6 [Bailey, Savannah])

Comment: While nuclear energy provides about one-fifth of our country's electricity, it provides more clean-air energy than every other source of emissions free electricity combined accounting for nearly two-thirds of our clean-air energy. At a time when climate change is a paramount concern for all Americans, nuclear energy cannot be ignored, serving as one of our only forms of baseload, always on power that produces zero harmful emissions. (0163-29-7 [Bailey, Savannah])

Comment: I personally am feeling that climate change is personal. It's real. It's here. My personal pain, economic dislocation is nothing compared to what other people are suffering from climate change around the world. (0163-40-2 [Dengler, Allegra])

Comment: I am also concerned with the possible impacts of more severe weather patterns. We must take into account the effects of climate change as nuclear waste is active for hundreds to thousands of years. We cannot afford short term, short-sited strategies. The cost of being wrong is very substantial. If we don't learn from Fukushima we are doomed to repeat its tragedy. (0227-1 [Silver, Daniel])

Comment: Climate change may bring more superstorms up the coast like Sandy. (0233-4 [Dubois, Gwen L])

Comment: In the coming years, the impacts of climate change will be evident; sea level rise, stronger storms, flooding, erosion, intense storm surges, and increasingly frequent wildfires will have to be addressed with scientifically based planning. Nine U.S. nuclear reactor plants are within two miles of the ocean. Others far from the ocean already lie in regions prone to flooding. (0244-14-8 [Prescott, Lisa Marie])

Comment: You know, regardless of whether or not you believe that climate change is human-induced or if it's other factors, I think it's -- you can't deny that the seas are rising. And I think the science strongly points to the next 100 years we're going to have 2- to 5-foot increase in sea level rise. (0244-8-2 [Totoiu, Jason])

Comment: This member of the public does not share your confidence. You write as if you have access to a crystal ball providing you access to the state of our planet for a hundred plus years, when in fact with the accelerating global warming and increasingly apparent climate change, you have no idea what is to come. We are seeing an increasing detrimental super-storms wreaking unimaginable havoc, the level of which has never before occurred. (0245-11-2 [Pierman, Bette])

Comment: We need to be prepared for a super-storm and how you will handle the consequential impact on nuclear waste storage. Contrary to what you have presented, each plant's situation and environmental impact will be different, and all will be catastrophic. Climate change is real. Super-storms are occurring along with earthquakes in regions where they did not previously occur with regularity. If you do not begin to make responsible decisions regarding the protection of this planet and its humanity, then you need to remove your NRC motto, "protecting people and the environment," because your 'adequate' effort will have failed and all will be harmed as a result. (0245-11-4 [Pierman, Bette])

Comment: NRC is currently assuming what will happen in the distant future. Assumptions on the effect of climate change, for example, and some of these we can already see are wrong, for example, the GEIS says a meter rise in water level won't endanger any plant. There are in fact three plants that would be impacted by this rise in water level. (0245-15-2 [McComb, Sandy])

Comment: A healthy business climate, which was addressed earlier, is not necessarily a healthy future for mankind. Business operates generally in a current state at the expense of the public's health and the future of the planet. A lot of people think that this is hyperbole. Yet we cannot act to deal with climate change in a meaningful way. The NRC has no ability to assure me with confidence that a super-storm, a super tornado will not pass over any of the proposed future storage sites indefinitely. Can you guarantee me that 200 mile-an-hour winds will leave those fuel pools unaffected? Will you force the operators of those plants to upgrade to a level to ensure that? I don't think so, because they don't want to spend the money necessary to make an unsafe technology theoretically safe. There's a question of whether we're going to survive as a society just like Japan in the event of regional super-storms coming from increasing disturbances in the Arctic -- are big news, a real time website of observations documents what's happening there now and how it's affecting the Northern Hemisphere, especially over the Mid-Continent. We cannot be assured that a major, extreme freak storm will not pass over a nuclear power plant and drain a fuel pool of its water. (0245-25-3 [Lehman, Dale])

Comment: I'm also interested in the issue of climate change and I looked in a little bit more detail as to what they did in that section. And I saw that they had forecasted temperature range of about 5.5 degrees Celsius, and they were considering all up to that. So, I expected to see, okay, I've read the book Six Degrees and I know that when you get up to six degrees it gets pretty gripping. But I didn't see any analysis of water usage. I didn't see anything about the increasing water temperatures and how those would affect cooling. I didn't see anything about the push between climate change and water availability. Again, all of that seemed to underline the fact that I don't believe there was any scientific basis whatsoever for the risk analysis in this document. (0245-31-5 [Fox, Tracy])

Comment: We've heard about the three scenarios about the fire or things like that. But I'll just tell you, what had happened in the last couple of days, the typhoon Haiyan, 370 kilometers per hour. Climate is changing. So, that means, according to the prediction -- raised maybe half a meter high. What happens is that a lot of plants that we have here are going to completely store the fuel by the shore there and we're going to have problems. But I'm not too sure of all these climate issues after 60 years of operation here, that could become a reality. So, we are assessing the potential risk that's involved and that's the real issue. We don't see that as being analyzed. (0245-5-2 [Chen, S.Y.])

Comment: I think that the EIS does not do enough to address the issues related to the climate change and the things that may be coming along as part of, you know, as our climate is already changing, we're seeing things happening. What happens over the next 60 years, 160 years, and further into the future, I think that there's a lot of question marks there that really have not been adequately addressed. (0245-8-3 [Fox, Rick])

Comment: With the increasingly real prospect of catastrophic climate change, we are ill-advised to shrink from nuclear energy and the responsible handling of spent nuclear fuel from our energy portfolio. As with any major undertaking, there will be lessons to be learned, improvements to be made, and disagreements to be resolved. But none of these items should preclude us from pushing and pursuing anything other than an all-of-the above energy strategy. (0246-10-5 [Bennett, Nathan])

Comment: I chose to be nuclear engineer because I am a climate change advocate and I am realistic about the 21st century economy that we have, about how we are going to implement the changes that we need. And as James Hansen and the top climate change scientists have said, we need nuclear in order to make a transition before the real damage from CO2 feedback emissions happens, the irreparable damage that we will get from emissions going too high and in 2011, we know they jumped by three percent. So to conclude, I would like to thank the Commission for allowing me to speak today, to be part of the generation that is taking climate change seriously with engineering. (0246-21-4 [Garcia, Diego])

Comment: But it is hard to believe that anyone would claim that nuclear power is needed to slow global warming, which there was an article in the Associated Press in the Mercury in our town in the beginning of November. But anyway, the nuclear cycle contributes to global warming and power from nuclear plants is vulnerable to the consequences of global warming, such as more intense droughts, floods, earthquakes. (0246-23-1 [Ruppe, Lorraine])

Comment: With climate change, there are unforetold situations and circumstances that are going to be arising. And weather events are getting more and more extreme. (0246-31-2 [Sunderland, Mary Brooke])

Comment: You need to be prepared for a super storm and how you will handle the consequential impact on nuclear waste storage. Contrary to what you have presented, each plant's situation and environmental impact will be different and all will be catastrophic. Climate change is real. Super storms are occurring along with earthquakes in regions where they did not previously occur with greater regularity. (0277-10 [Pierman, Bette])

Comment: You write as if you have access to an omniscient crystal ball providing you access to the state of our planet for a 100 plus years when, in fact, with the accelerating global warming and increasingly apparent climate change, you have no idea what is to come. We are seeing increasing detrimental super storms wrecking unimaginable havoc the level of which has never before occurred. (0277-4 [Pierman, Bette])

Comment: The Commission's decision to "not [even] consider worst-case scenarios" (p. 55786) in the DGEIS is an unwarrantable omission. Important recent studies, such as by the New York Academy of Sciences and the French government's Institute of Radiological Protection have assessed and documented the almost unimaginably high human and environmental consequences and economic-damage cost in worst-scenario disasters. Under the rapidly changing climate, we must expect more Superstorm-Sandy-like events, floods, wildfires, water scarcity, lengthy power blackouts and other "abnormal" weather related events which pose threats to nuclear facilities. The assumption underlying the stated decision – that natural events and their consequences can still be "reasonably foreseen" many decades into the future – is indefensible today. A new EIS should analyze not only the potential damage effects from routine SNF storage leaks and other disturbances but also those which could befall in worst-case, catastrophic events. (0303-10 [Lamberts, Frances])

Comment: The nuclear industry has had a very good PR program that has allowed a lot of people to be totally confused and lied to. Storm surges and climate changes mean more risk for vulnerable, intensely radioactive waste sitting only 13 feet above high tide. And we don't need to choose between climate change and radioactive waste releases. That's a false choice. (0325-28-3 [Branigan, Mary Beth])

Comment: Now, I want to diverge just very briefly to talk about an issue that's personal to me, and that is climate change. I grew up on the coast. My family has seen storms, my family has seen storm surges at our house, and we understand very personally what climate change and angry sea level rises will mean. Now, I'm sure I'm speaking for a lot of people who already know this but the IEA released a World Energy Outlook, their annual World Energy Outlook report last week that found the world -- the globe was just on track to completely blow through the threshold, the ceiling that we need to keep temperatures below. And similar to that, the Intergovernmental Panel on Climate Change also found with 95 percent certainty that climate change is both manmade and that, again, we are on track to blow through that ceiling. (0325-5-4 [Kirton, Stratton])

Comment: Now, diverging a moment from the specific rulemaking here, why this is important to me is because of the issue of climate change. I grew up in a very small town on the water, and my town has seen increasing storms and increasing storm surges. Now, whether it's the IEA, or the IECC, we all know that right now, the globe is on path to reach almost 4 degrees Celsius by the end of the century, far surpassing what is said is the threshold in terms of safe rising temperatures, which is 2 degrees Celsius. (0326-16-3 [Kirton, Stratton])

Comment: I feel like we're faced with global warming. This is what we should keep our eye on; the big picture. I mean, nuclear may have an accident, there may be leak, there may be a

terrorist thing; maybe so, maybe not. We know for sure that global warming could kill a lot of people. I mean, James Lovelock, one of the leading scientists in earth science says, 4 to 5 billion people will be killed if emissions of CO2 are not curbed. I urge you to go ahead and read his book. He's got a book called, "The Vanishing Face of Gaia." By the way, he's the guy that came up with a solution to the ozone hole. He's a wonderful man, he's a U.K. scientist, and he invented something that could figure out what was causing the ozone hole. He's the same man that said global warming is going to kill a lot of people eventually. Read his book, "The Vanishing Face of Gaia." (0326-24-2 [Gloege, William])

Comment: I don't think that this document addresses the reality of global climate change, and the high probability that our society is going to be severely disrupted by it, that we're going to see great increases in, for example, the frequency of flooding and social disruption and discontinuity of business and security programs and so on. And all of this needs to be taken seriously when we consider the likely trajectory of nuclear waste management problems. (0328-11-6 [Muller, Alan])

Comment: As sea levels rise, food sources diminish because we Fukushima-ed them, there's no more food in the Pacific. And as that circulates through the globe, what happens when there's less and less food because of climate chaos and irradiation? And what happens when there's less and less space for the people to live because the sea levels are rising, and we have the chaos in society degenerating. (0328-7-2 [Crocker, George])

Comment: I just wanted to point out that to transport nuclear fuel to a safe place in south Florida, the trouble with south Florida is that due to global warming and climate change, the reactors will be underwater in probably less than 50 years. The ones at Turkey Point probably won't take as long. The entire southern part of Florida is only like eight to ten feet high. So it won't take very many years before we're looking at that whole area to be starting to go underwater. And that's seawater, which will pretty much rust out everything that comes in contact with it. So to transport, as I mentioned before, it would be the shortest possible distance from Miami or the East Coast, whether that's St. Lucie or Crystal River, to high ground, which would be in the middle of the state, to be able to store it. (0329-24-1 [Wilson, Greg])

Comment: So if I can just be specific and point to page 4-75? That's in section 4.18. And it's in addressing spent fuel pools and the climate change analysis. I think a speaker earlier, Greg Wilson in the Tampa area, had talked about some of the sea level rise concerns, among other things. And there's a line on that page in the draft GEIS that says specifically "The lowest rate above the sea level of concern for an NRC-licensed facility is currently about 4.3 meters, or 14 feet. In the event of climate change and sea level rise, the NRC requires licensees to implement corrective actions to identify and correct or mitigate conditions adverse to safety." In my comments and with our concerns is that I think this section needs further development and analysis because it's looking at the facilities themselves and we would argue first that we don't actually agree with those numbers and the sea level rise projections there. But there are infrastructures that facilities rely on: roadways, power lines, a number of things. So it's not just, for instance, Turkey Point Nuclear Plant in south Florida being able to solely operate and deal with dry casks or whatever is done with the spent fuel pool onsite for the indefinite future. Roadways are very likely to be underwater, a number of things that a facility would rely on, whether it's a nuclear plant or a hospital or something along those lines. And, therefore, that is somewhat of the nugget we were trying to get at with raising our sea level rise concerns if you have to look at the broader area, not the facility itself and where the onsite spent fuel pool storage or dry cask storage occurs. (0329-27-1 [Barczak, Sara])

Comment: [W]e have serious concerns about the impact climate change may have on the long-term storage and management of spent nuclear fuel. The effects of climate change and subsequent expected increases in storm surges and catastrophic weather events puts reactors that are along the country's coastline and even low-lying inland locations at great risk. For instance, given Florida Power and Light's Turkey Point location near Miami next to the Everglades and Biscayne Bay, storm surges are real threats that must be considered. We do not believe that the NRC and its licensees can ensure that spent nuclear fuel can safely sit at Turkey Point for even 100 years, let alone indefinitely. This is true of other reactor locations across the country, as well. The NRC must reevaluate the impact of climate change, as Section 4.18, Environmental Impact of Postulated Accidents, appears to be woefully inadequate. We do not agree with the NRC's conclusions made regarding climate change, specifically for design basis events and spent fuel pools on page 4-75 and dry casks on page 4-78 and severe accidents in spent fuel pools on page 4-81 and severe accidents with dry cask systems on page 4-83 and believes this analysis needs to be more robustly conducted. (0329-5-2 [Barczak, Sara])

Comment: We would like to make the NRC aware that, since the comment period began, a new sophisticated tool has been released, Surging Seas, a sea level rise analysis by Climate Central which can be found at sealevel.climatecentral.org. From that page, you'll start from sea level rise and storm surge to the more than 3,000 coastal towns, cities, counties, and states in the lower 48. Three states in particular, New Jersey, New York, and Florida now have expanded next generation maps and analysis available in the Surging Seas risk finder with more states to follow. (0329-5-3 [Barczak, Sara])

Comment: The unpredictable effects of global warming - from increased droughts to flooding to rising temperatures to fluctuating water levels - must be considered in all future licensing and waste storage decisions. (0357-8 [Daily, G. Allen])

Comment: The NRC makes many references to "climate change" both with respect to survivability of storage sites under expected extreme weather conditions, and the release of "greenhouse gasses" from nuclear facilities. One of the many myths about nuclear power is that it is a carbon-free energy source. Unfortunately, the construction of a nuclear plant, together with its containment structures, fuel storage pools, reactor vessels, heat exchangers, casks and storage pads and their replacement every 100 years, etc. requires prodigious amounts of steel and concrete. Steel production requires burning large amounts of coal and coke, concrete requires cement which is made by burning fossil fuels to heat limestone. Carbon dioxide is released both from the fuel combustion and the limestone decomposition. In short, the only energy source which releases more carbon dioxide into the atmosphere, during the construction phase, is hydro-power due to the massive amount of concrete used in dams. Renewable power sources such as wind, solar and biomass have a much smaller carbon footprint than fossil, nuclear or hydro. Another consideration is that thermal energy sources are only about 30% efficient in converting heat into electrical energy. The rest, 70%, of the energy produced must be discarded as waste heat which contributes to the heat load on the planet. Much of the incident radiative energy from the sun is reflected back into space because its visible wavelength remains unchanged on reflection. The waste heat from thermal sources of electricity such as nuclear and fossil fuels, on the other hand, is transmitted in the infra-red and so is mostly trapped in the atmosphere by greenhouse gasses, thus contributing to global warming. Also problematic is the fact that nuclear fuel continues to excrete waste heat into the environment even centuries after the plant has ceased to produce electricity. Fossil fuel plants cease to produce waste heat immediately upon shutdown. (0410-19 [Nelson, Dennis])

Comment: Utilize the best science as a basis for decisions. For example, incorporate the best scientific information regarding predicted climate and sea level changes and their impact on the safe management of nuclear waste storage. (0417-9 [Clark, Terrence])

Comment: The DGEIS offers only three paragraphs on climate change (4-75 -4-76). This section inexplicably only addresses the impacts of climate change on nuclear waste storage in the short term, relies on outdated climate change projections, and only addresses postulated design basis accidents instead of the potential for wholesale impacts on the storage of nuclear waste caused not only by accidents, but by increased temperatures and increased sea level rise. The DGEIS also improperly cites to the invalidated 2010 Waste Confidence Decision Update as the basis for certain scientific and technical assertions, rendering them meaningless. (0473-17-1 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The DGEIS cites out of date projections for sea level rise. The EIS says that sea levels are estimated to rise less than 1 meter by 2100. DGEIS at 4-75, citing 75 FR 81037.⁴⁸ [footnote 48 text: As a citation for this proposition, the DGEIS cites an NRC federal register notice from 2010, which in turn cites to a National Academy of Science transportation report, the IPCC 2001 report, (there have been two new IPCC reports since 2001, in 2007 and 2013) and the 2009 US Global Change report. 75 Fed. Reg. 81037, citing J.A. Church et al., Climate Change 2001: Impacts, Adaptation, and Vulnerability, Intergovernmental Panel on Climate Change, 642 (2001).] Based on this estimate, the DGEIS concludes that "none of the U.S. nuclear power plants (operational or decommissioned) will be under water or threatened by water levels by 2050. No basis for this conclusion is provided. *Id.* Indeed, the DGEIS merely repeats an uncited, unsubstantiated statement appearing in the now-vacated Waste Confidence Decision Update in support of this idea - no further information is given, including the name or location of the facility. As such, this statement cannot form the basis for any conclusions in the DGEIS regarding the impact of sea level rise on the short-term, long-term, or indefinite storage of nuclear waste. Regardless, the National Oceanic and Atmospheric Administration (NOAA) sea level rise estimates for the 2013 U.S. National Climate Assessment indicate that sea levels could rise as much as 2 meters (6.6 feet) by 2100 – double the sea level rise figures cited in the DGEIS. See Global Sea Level Rise Scenarios for the United States National Climate Assessment, NOAA, December 6, 2012 (giving a range of potential sea level rise from low (0.7 meters) to highest (2.0 meters)). The DGEIS states that "[t]he lowest grade above sea level of concern for an NRC- licensed facility is currently about 4.3 meters. DGEIS at 4-75, citing 75 FR 81037. ⁴⁹ [footnote 49 text: As discussed below, the NRC cannot cite to its own invalidated Federal Register notice in support of scientific arguments.] The basis for this conclusion, including how associated storm surge calculations were performed, precludes analysis of its accuracy. The updated 2 m sea level rise estimate should be used. NOAA suggests this "Highest Scenario should be considered in situations where there is little tolerance for risk (e.g. new infrastructure with a long anticipated life cycle such as a power plant)." *Id.* Certainly, the long-term storage of nuclear waste, especially in pools which require reliable cooling mechanisms, qualifies as a "situation where there is little tolerance for risk." The NRC does not use the NOAA estimates. As such, the DGEIS offers no reliable analysis - or adaptation measures - for the possible impact of sea level rise on nuclear waste storage. Apart from using outdated sea level rise projections, the DGEIS's conclusion that sea level rise is not a risk to nuclear waste storage due to their elevations - "[t]he lowest grade above sea level of concern for an NRC-licensed facility is currently about 4.3 meters" (DGEIS at 4-75) - is completely unsupported. The DGEIS includes no list of nuclear waste storage locations and their elevations vis-à-vis sea level, and does not even include the name or location of this one referenced facility. In support of this proposition the DGEIS cites back to the invalidated Nuclear Waste

Storage rule, which itself contains no citation for this assertion. (0473-17-3 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: DGEIS at 4-73. But the DGEIS nowhere references revisions to the design basis flood that may have occurred since facilities were initially licensed. The DGEIS should also evaluate the impacts of recent intense storms, such as Superstorm Sandy, which caused high water levels at the cooling water intakes of both the Salem Nuclear Power Plant Unit 1 and the Oyster Creek Nuclear Power Plant, forcing the shutdown of those New Jersey power reactors. See NRC Preliminary Notice of Event or Occurrence (PNO-I-12-007) issued October 31, 2012 (ML12305A460); B. Gallo, Jr., "Salem 1 nuclear reactor, shut down by Hurricane Sandy, returns to service," www.nj.com Nov. 4, 2012)(available at http://www.nj.com/salem/index.ssf/2012/11/salem_1_nuclear_reactor_shut_d_2.html), last accessed Nov. 30, 2013). Superstorm Sandy also knocked out power lines whose loss idled other power reactors, including Indian Point Unit 3. PNO-I-12-007. The NRC appears to consider storms like Superstorm Sandy design- basis events. See, e.g., 4-76 ("Summary"). If so, these northeastern plants were not able to withstand them. Other climate change impacts, such loss of cooling capacity due to increased cooling water temperatures also need to be considered. Summer heating of Long Island Sound waters put Millstone Power Station, Unit 2 offline in August 2012, and heating of Cape Cod Bay forced Pilgrim Nuclear Power Station to reduce output in July 2013. M. Wald, "Heat Shuts Down a Coastal Reactor," [NYTimes.com](http://green.blogs.nytimes.com/2012/08/13/heat-shuts-down-a-coastal-reactor/) (Aug. 13, 2012), available at <http://green.blogs.nytimes.com/2012/08/13/heat-shuts-down-a-coastal-reactor/> (last accessed Nov. 30, 2013). The increasing likelihood of climate-change-induced beyond-design basis events must be evaluated in this DGEIS , and the NRC must identify additional adaptation measures plants must take to respond to increasingly frequent, increasingly severe design conditions. (0473-17-5 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The DGEIS acknowledges that: * climate change can lead to an increased intensity and frequency of severe weather events, such as flooding and hurricanes, * in addition to impacts from sea level rise, spent fuel facilities may be affected by increased storm surges, erosion, shoreline retreat, and inland flooding, and * climate change can lead to an increase in the frequency of droughts, and that the frequency of droughts in the Southeast and West has already increased. DGEIS at 4-75. During an April 12, 2012 full committee hearing by the Senate Committee on Energy and Natural Resources that explored the Impacts of Rising Sea Levels on Domestic Infrastructure, the Committee heard testimony on the potential impacts of sea level rise on energy infrastructure. See <http://www.energy.senate.gov/public/index.cfm/2012/4/full-committee-hearing-impacts-of-rising-sea-levels-on-domestic-infrastructures-> (last visited Nov. 30, 2013). Compounding factors will further exacerbate the effect of global sea level rise due to climate change, "in some areas, especially for Louisiana, Texas, and mid- Atlantic states, sinking land will add to the total effective rise and compound problems," according to testimony from Benjamin H. Strauss, Director of the nonprofit organization Program on Sea Level Rise at Climate Central. Louisiana houses two of the nation's coastal nuclear power plants, and the Mid-Atlantic states25 power plants, and therefore nuclear waste storage facilities as well. Yet in light of that, the DGEIS offers only three paragraphs on climate change, does not mention land subsidence (though the Waste Confidence Decision Update did, 75 Fed. Reg. 81037, 81053, noting that land subsidence was already occurring in the central Gulf Coast region) and offers no adaptation measures to mitigate against the impact of these events, on the storage of nuclear waste. Nevertheless, it does acknowledge impacts, and yet offers no adaptation measures. As such, the DGEIS does not adequately assess the environmental impacts of the long-term or indefinite

storage of nuclear waste. (0473-17-6 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The unpredictable effects of global warming - from increased droughts to flooding to rising temperatures to fluctuating water levels - must be considered in all future licensing and waste storage decisions. (0507-7 [Giese, Mark M.])

Comment: By dismissing impacts to drinking water, the DGEIS is neglecting the fact that over the coming century, drinking water security will be low due to global climate change. Any prediction of environmental impacts should prioritize effects on drinking water sources. (0531-1-8 [Morgan, Sally])

Comment: By dismissing impacts to drinking water, the DGEIS is neglecting the fact that over the coming century, drinking water security will be low due to global climate change. Any prediction of environmental impacts should prioritize effects on drinking water sources. (0531-2-8 [Morgan, Sally])

Comment: The GEIS states that a one-meter water rise will not endanger any nuclear power plant, operational or decommissioned, in the U.S. This is simply false. Examples: A less than 1m water rise will completely flood Turkey Point, St. Lucie and Crystal River Nuclear power plants, just to name three near-coastal plants that would be affected by flooding. (Climate Central). 1. Surging seas interactive climate map, Climate Central, 2013. <http://sealevel.climatecentral.org/surgings seas/place/cities/FL/Miami#show=cities&per=12/25.3789/-80.3118&surge=2> or <http://sealevel.climatecentral.org/> (0552-1-19 [Macks, Vic])

Comment: GEIS on page 6-8, section 6.3.1, Table 6-1 summarizes the range of expected temperature rise by 2100 as falling between 1 degree C and 6.5 degrees C. But it fails to connect the dots between rising temperatures and the effects on water sources depended on to cool reactors and their spent fuel pools. During the summer of 2012 high temperatures interfered with the operations of several nuclear plants. (source 2 below) Over time, the warming of bodies of water used for cooling will impact the reliability of nuclear plants and potentially the safety of operations. 2. http://green.blogs.nytimes.com/2012/08/13/heat-shuts-down-a-coastal-reactor/?_r=0; As climate change makes water scarcity an ever-increasing event, the water necessary to cool spent fuel in pools becomes an unaffordable luxury. Dry casking all spent fuel is the only alternative in a world where the water necessary to sustain life is at a premium. (0552-1-20 [Macks, Vic])

Comment: Experts report that while it is too soon to say that Climate Chaos is increasing the numbers of weather events, they do report that Climate Change is causing greater severity of them. Whether hurricanes, wind storms, tornadoes, ice storms or drought, NRC has not yet upgraded its computer simulations and accident probability calculations to reflect the greater possibility that the electric power grid will go down. Loss of off-site power is a major contributor to reactor accident scenarios, many of which would also include the fuel pool and its back-logged inventories of waste. (0552-1-21 [Macks, Vic])

Comment: The assessment is not related to environmental impacts of climate change, only to increased hazards, which occur also with man-made climate change phenomena. The impacts described are related entirely activities that increase atmospheric GHGs, which are (correctly) dismissed as "Small". The section does not consider environmental impacts resulting from the effects of climate change on ISFSI facilities and their constituent dry storage casks. The integrity of dry casks is based on extremely limited data on performance of one cask in one

geographic/climate setting, and then extrapolated for a period of 100 years to all casks of whatever design, located in whatever climatic zone. This matter puts the use throughout this GEIS of "reference models" of various continued storage components on a very shaky basis, and dilutes actual potential environmental impacts with a host of assumptions rather than facts. Buttressed by a large assortment of regulations that ensure permanent protection of the integrity of constructed systems managed by humans, leads directly to an assessment of "SMALL" unspecified environmental impacts. (0553-7 [Wilshire, Howard])

Comment: Climate change is predicted to bring an increased number of severe storms and sea level rise. Sea level rise is predicted to be more extreme on the east coast and varies from location to location on the coast³ [footnote 3 text: Sea Level Rise Accelerating in U.S. Atlantic Coast, http://www.usgs.gov/newsroom/article.asp?ID=3256&from=rss_home (Released: 6/24/2012 1:00:00 PM)] . Therefore, where a reactor is located is important. For example, Pilgrim's ISFSI is located 25' above MSL and 100 yards from Cape Cod Bay. Over the short term to indefinite time frames, high storm waves on top of sea level rise will make flooding of the ISFSI far more probable than at an ISFSI located at higher elevation and not an issue at reactors located away from the coast. (0556-1-18 [Lampert, Mary])

Comment: Although the DGEIS acknowledges that climate change "may have impacts across a wide variety of resource areas including air, water, ecological, and human health," the DGEIS nevertheless states, without any explanation, that "[t]he consideration of climate change impacts for pool storage only needs to address the short term timeframe." DGEIS 4-75. Given that (a) spent nuclear fuel remains dangerously radioactive well beyond 60 years,² [footnote 2 text: The half lives of two components of spent nuclear fuel, plutonium-239 and plutonium-240, have half lives of 6,800 and 24,000 years, respectively. See, e.g., Nuclear Regulatory Commission, "Radioactive Waste: Production, Storage, Disposal," at 8, available at <http://www.nrc.gov/reading-rm/doc-collections/nuregs/brochures/br0216/r2/br0216r2.pdf>.] and (b) the prospects of a completed and operational permanent waste repository for spent nuclear fuel within 60 years are speculative, artificially limiting the analysis to the short term cannot be considered the "hard look" required by NEPA. (0558-1 [Strell, Ethan])

Comment: As set forth below, the length of time waste is stored at individual nuclear plants is not an academic issue, since the projected effects of climate change, in particular sea level rise, will only increase over time, particularly when dealing with waste whose danger and potential environmental harm is measured in many thousands of years. Sea Level Rise Projections: The only discussion in the DGEIS of the potential effect of sea level rise on the numerous spent nuclear fuel storage facilities throughout the country is the following: Rise in sea level is controlled by complex processes, and it is estimated to rise less than 1 m by 2100 (75 FR 81037). Based on this projected change, none of the U.S. nuclear power plants (operational or decommissioned) will be under water or threatened by water levels by 2050 (75 FR 81037). In addition to sea-level rise, spent fuel facilities may be affected by increased storm surges, erosion, shoreline retreat, and inland flooding. Coastal area impacts may be exacerbated by land subsidence. NRC-licensed spent fuel storage facilities are designed to be robust. DGEIS at 4-75.³ [footnote 3 text: The Proposed Rule does not address the effects of climate change on spent fuel storage. See 78 Fed. Reg. 56776, Sept. 13, 2013.] There are several problems with this "analysis." First, merely stating that sea levels are estimated to rise less than one meter by 2010 does not account for uncertainty in sea level rise projections and may underestimate risk. Second, merely accounting for a static sea level rise does not consider risks due to more frequent and severe flooding. Finally, simply stating, without further discussion or support, that NRC design standards are sufficient to protect from future climate harm, does not satisfy NEPA. The only source cited for sea level rise projections in the DGEIS is the NRC's own Federal

Register notice for its 2010 Waste Confidence Rule, which itself cites to a National Academy of Sciences transportation report, a 2001 report of the International Panel on Climate Change ("IPCC"), and the 2009 United States Global Change National Climate Assessment. See 75 FR at 81053. Aside from the fact that the 2010 Waste Confidence Update was vacated by the DC Circuit, the sources referenced are dated, and more recent projections show potentially greater sea level rise and uncertainty. For instance, the current draft of the National Climate Assessment, which is in the process of updating the 2009 report cited in the NRC's 2010 Federal Register notice, indicates that sea levels could rise as much as 6.6 feet by 2010, *double* what is considered in the DGEIS. The Draft Assessment indicates that "[i]n the context of risk-based analysis, some decision makers may wish to use a wider range of scenarios, from 8 inches to 6.6 feet by 2010."⁴ [footnote 4 text: National Climate Assessment, Chap. 2, "Our Changing Climate," p. 63, Draft for Public Comment, v. 11, Jan. 2013. The recent Working Group 1 Contribution to the Fifth Assessment Report of the IPCC, "Climate Change 2013: The Physical Science Basis," Summary for Policymakers, acknowledges that many models project such higher sea level rise, but indicates that consensus on the reliability of those models is lacking, and has low confidence for those projections. IPCC WG1 2013 Summary for Policymakers, at 24]. The report continues that "the high end of these scenarios may be useful for decision makers with a low tolerance for risk." *Id.* Certainly, nuclear waste storage epitomizes an area where there is a "low tolerance for risk." Additionally, the DGEIS discussion only looks at static flood levels due to potential sea level rise, which does not accurately disclose the risk of flooding. If the base sea level rise is higher, then flooding at many locations will occur more frequently, and those locations will be more vulnerable to more powerful and frequent storm surges. The NRC's casual and generic dismissal of potential sea level rise on every waste storage facility in the country does not properly characterize potential risk, and does not constitute a hard look under NEPA. Additionally, sea level rise is not uniform and will vary considerably among different regions. *Id.* See also New York City Panel on Climate Change, Climate Risk Information 2013, June 2013, at 17. The NRC has not explained why its generic, one-size-fits-all analysis here is appropriate. (0558-4 [Strell, Ethan])

Comment: In discharging their NEPA responsibilities, agencies are subject to a "rule of reason," and must evaluate all reasonably foreseeable significant adverse impacts. When data is incomplete or unavailable, as it is with future sea level rise projections "reasonably foreseeable" includes "impacts which have catastrophic consequences, even if their probability of occurrence is low, provided that the analysis of the impacts is supported by credible scientific evidence, is not based on pure conjecture, and is within the rule of reason." 40 CFR § 1502.22. Clearly, the consequences of underestimating potential sea level rise and storm surge could have catastrophic consequences. In the face of this incomplete or unavailable data, NEPA requires that the NRC consider greater potential sea levels based on existing credible scientific evidence. (0558-5 [Strell, Ethan])

Comment: Finally, the only assurance in the DGEIS that all storage facilities will be safe from rising seas and other effects of climate change is the statement that "NRC-licensed spent fuel storage facilities are designed to be robust." DGEIS at 4-75. (0558-7 [Strell, Ethan])

Comment: While waste storage facilities are no doubt required to be robust, simply saying so does not constitute the hard look required by NEPA. The DC Circuit similarly viewed with skepticism the Commission's self-serving assurances of robust design and administrative oversight: [T]he Commission refers to its monitoring and regulatory compliance program as a buffer against pool degradation. That argument is even less availing because it amounts to a conclusion that leaks will not occur because the NRC is 'on duty.' With full credit to the Commission's considerable enforcement and inspection efforts, merely pointing to the

compliance program is in no way sufficient to support a scientific finding that spent-fuel pools will not cause a significant environment impact during the extended storage period. This is particularly true when the period of time covered by the Commission's predictions may extend to nearly a century for some facilities. *New York v. Nuclear Regulatory Comm'n*, 681 F.3d at 481. (0558-8 [Strell, Ethan])

Comment: In sum, the DGEIS is insufficient in its consideration of how future climate change will affect the long-term storage of spent nuclear fuel. (0558-9 [Strell, Ethan])

Comment: Section 4.5 of the DGEIS evaluates the effect of continued storage on climate change. When considering greenhouse emissions (all timeframes), the NRC only considers the direct resulting CO2 footprint of continued storage. However, the DGEIS should consider the entire fuel life-cycle in its scope, including the effects of uranium mining, milling, and processing, the transport of fuel, reactor operation, decommissioning and final storage of radioactive waste. Without the entire fuel life-cycle being considered, the DGEIS is ineffective in properly examining potential environmental impacts occurring as a result of continued storage of spent fuel. (0622-1-16 [Vale, Karen])

Comment: The NRC claims to have already established criteria that provide reasonable assurance of public health and safety and due consideration of environmental impacts in the construction and operation of nuclear power plants, including facilities for continuing storage of spent fuel." However, given that the DGEIS fails to address sea level rise, proximity of installations to the coastal environment, or assess vulnerability to storm forces beyond a tornado-it does not meet the required "assurance of public health and safety" or "due consideration of environmental impacts, including facilities for continuing storage of spent fuel." (0622-4-12 [Vale, Karen])

Comment: The DGEIS estimates that sea level will rise less than 1 meter by 2100 (75 FR 81037), and this will not endanger any U.S. nuclear plant. However, sea level rise will vary greatly by region. It is inaccurate to assume a blanket 1-meter rise for all plant locations and then conclude that all plants will not be in danger. The 1 meter figure is a global average; sea level rise has been projected to be much less in some areas, but also projected to be much greater in others (like much of the eastern seaboard, where many nuclear plants are sited). Areas projected to experience the most significant sea level rise should be addressed in the DGEIS. Using a global average to assume all plants are safe is a flawed approach. For example, projections for sea level rise for Cape Cod Bay (where Entergy's Pilgrim plant is located) range between 4-6 feet by 2100. It's also projected that this rise will come with increasing severity of storms, surge and wave action on top of the higher water levels. (0622-4-3 [Vale, Karen])

Comment: The DGEIS does not consider the impacts of rising temperatures on the water sources intended to cool spent fuel pools. As an increasingly warming climate is heating the water temperature of our oceans, lakes, and rivers, water is becoming too warm for plants' cooling systems. Cooling systems are only approved for certain incoming water temperatures, and their ability to operate properly and safely has not been proven under higher temperatures. Warming water is becoming an increasing problem. For example, just this past summer, Entergy's Pilgrim plant was forced to power down several times to comply with its license when the water in Cape Cod Bay exceeded 75.. Generally, it appears that Cape Cod Bay is warming, and in recent years its average summer temperature has been several degrees warmer than its mean for the last century. (0622-4-4 [Vale, Karen])

Comment: The DGEIS also does not consider the issue of ocean acidification. This issue raises concerns about dry casks being built in close proximity to the ocean (for example, Pilgrim's dry casks will be about 100 feet from the shore of Cape Cod Bay). Dry casks are made of concrete and steel -materials already susceptible to deterioration by salt air and water. Adding even more acidic conditions raises serious concerns about carbonation-induced deterioration of the dry casks that are intended to protect the public and environment from the highly radioactive waste stored inside. If dry casks are to store nuclear waste in the long-term or indefinite time-frames, the NRC needs to consider the impact of ocean acidification, and not just salt. Again, a site-specific assessment would be needed since some regional characteristics can cause acidification to be a bigger problem in certain areas. One of these characteristics is eutrophication (when excess nitrates and phosphates enter coastal areas from lawn runoff, fertilizers, storm-water runoff, wastewater disposal, etc.). In areas experiencing eutrophication problems, such as along the Cape Cod Bay coastline, there is often die-off of algae and sea grass that produces even more CO₂. (0622-4-7 [Vale, Karen])

Comment: In general, the NRC assumes that flooding can be mitigated with pumps. In some areas this is true; however, there are some sites where flood events can occur where they were not anticipated. Over the next 60 to 150 years, this will be increasingly true at Pilgrim where sea levels will rise and storms will become more intense. As of February 28, 2013,²⁵ Entergy claims that Pilgrim is a "dry site," because it is a few feet above the previously predicted storm surge level. However, Entergy never addresses below ground installations (such as pumps and equipment that maintain proper reactor and pool cooling) that may be subject to flooding-or how flooding would be controlled during an extended storm event where the tide does not abate for several days. Entergy has not addressed the potential influences of the Atlantic Ocean on the Pilgrim site; therefore they are not likely to be prepared for a flooding event - leading to a potential disaster for the region. It is the responsibility of the DGEIS to evaluate all U.S. sites' vulnerability to a changing climate and its effects. Mitigation efforts (building barrier walls, elevation considerations, etc.) at specific locations should also be discussed in the DGEIS. (0622-4-9 [Vale, Karen])

Comment: With climate change making weather patterns ever more violent, such incidents will only make these rapidly aging plants more accident prone. (0633-5 [Kurz, Carol])

Comment: With climate change, these plants use up our water supply, increase the heat in our water supply thereby warming the planet and destroying our oceans, lakes and rivers. (0662-4 [McClintock, Francene])

Comment: The draft GEIS contains unsatisfactory analysis regarding threats posed by climate change. The draft GEIS states that "[r]ise in sea level is controlled by complex processes, and it is estimated to rise less than 1 m by 2100 (75 FR 81037). Based on this projected change, none of the U.S. nuclear power plants (operational or decommissioned) will be under water or threatened by water levels by 2050 (75 FR 81 037)." (4-75.) Confidence based on the year 2050 does not address the time-spans at issue with the waste confidence rule, which extend beyond that date. Furthermore, new information¹⁰ [footnote 10 text: Global Sea Level Rise Scenarios for the United States National Climate Assessment, December 2012 [http://cpo.noaa.gov/sites/cpo/Reports/2012/NOAA SLR r3 .pdf](http://cpo.noaa.gov/sites/cpo/Reports/2012/NOAA%20SLR%20r3.pdf). Sea-Level Rise for the Coasts of California, Oregon, and Washington: Past, Present, and Future (2012).] provides estimates of sea level rise 1 % to 2 times higher than those analyzed in draft GEIS , with some experts estimating an upper bound as high as 3 meters by the year 2300.¹¹ [footnote 11 text: Expert Assessment of Sea-level Rise by AD 2100 and AD 2300 <http://www.sciencedirect.com/science/article/pii/S0277379113004381>] (0669-13 [Walter, Joan])

Comment: The NRC did not provide any basis for its conclusion that the environmental risks due to increased intensity of thunderstorms is low for the short-term duration, despite the fact that as it states "climate models predict thunderstorms will intensify." (4-82.) Again, "short-term" could be well over half a century, or even longer for a new plant. This is an example of analysis where it would be reasonable and appropriate for the NRC to include a pledge to reevaluate as more information comes to light. (0669-15 [Walter, Joan])

Comment: •This GEIS failed to thoroughly consider the changing climate generically and made unsubstantiated assumptions about the absence of impacts. Climate change impacts for specific regions, individual plants and certain effects are just beginning to be clarified. Site-specific information can better analyze potential climate change impacts and incorporate plans for safe storage. (0693-2-14 [Warren, Barbara])

Comment: The unpredictable effects of global warming - from increased droughts to flooding to rising temperatures to fluctuating water levels - must be considered in all future licensing and waste storage decisions. (0707-9 [Werner, Shahla M.])

Comment: How many reactor sites will be under water within the next 100 years using the current (credible) prediction for sea level rise? (0711-39 [Olson, Mary])

Comment: *NRC has inadequately taken into account anticipated dramatic climate disruption and shifts weather patterns in reaching many of its conclusions.* For example, regarding the effects of leaks from spent fuel pools on surface drinking water supplies, NRC *assumes* (E-17), "...a large body of surface water is usually available, which would dilute any groundwater contaminants that flow into them." Illinois has 11 operating reactors, all sited on rivers. Climate models predict that by 2050 (certainly well within the timeframe envisioned by this DGEIS) Illinois is likely to have the climate of East Texas. In this case both the volumes and flow rates of these rivers - on which NRC depends in its assumption that dilution will occur - will be reduced significantly, and in cycles much different than today's climate provides. Unless NRC has done the volume and flow rate calculations for Illinois rivers permanently or even intermittently subjected to an East Texas climate, it has failed to provide any hard science to back up its dilution claims. Without these actual calculations, its conclusions are unfounded. (0716-12 [Kraft, Dave])

Comment: p. 4-18 to 4-20. Climate Change. This is not a resource area. "The NRC's evaluation of the effects of climate change on the intensity and frequency of natural phenomena hazards that may cause spent fuel storage accidents is provided. Comment: The assessment is not related to environmental impacts of climate change, only to increased hazards, which occur also with man-made climate change phenomena. The impacts described are related entirely activities that increase atmospheric GHGs, which are (correctly) dismissed as "Small". The section does not consider environmental impacts resulting from the effects of climate change on ISFSI facilities and their constituent dry storage casks. The integrity of dry casks is based on extremely limited data on performance of one cask in one geographic/climate setting, and then extrapolated for a period of 100 years to all casks of whatever design, located in whatever climatic zone. This matter puts the use throughout this GEIS of "reference models" of various continued storage components on a very shaky basis, and dilutes actual potential environmental impacts with a host of assumptions rather than facts. Buttressed by a large assortment of regulations that ensure permanent protection of the integrity of constructed systems managed by humans, leads directly to an assessment of "SMALL" unspecified environmental impacts. (0805-7 [Wilshire, Howard])

Comment: During the public comment period, there were a number of concerns expressed about the possibility that climate change might cause spent fuel storage sites to experience conditions beyond those considered in the GEIS. Those concerns tended to focus on the effects of sea level rise at coastal sites. It should be noted that sea level rise, while widely documented, is not occurring at a rate that would compromise the ability of those who manage spent fuel storage facilities (ISFSIs) to continue to assure their safety. Even the most extreme scenarios postulated in recent climate studies indicate sea level rise will occur at a pace of less than 10 mm/year.⁹³ [footnote 93 text: Intergovernmental Panel on Climate Change, *Climate Change 2013: The Physical Science Basis*, Working Group I Contribution to the 5th Assessment Report of the Intergovernmental Panel on Climate Change, October 2013.] At this rate, ISFSI licensees will have ample opportunity to prepare and take necessary mitigative actions (including the movement of casks to higher ground, if necessary). Such measures will be addressed, as required by NRC regulations, in license renewal applications that will be submitted every 20 to 40 years for as long as the casks are in service. (0827-4-2 [Ginsberg, Ellen])

Comment: In addition to making weather events more severe, climate change is increasing water scarcity, giving us yet another reason to move away from fuel pools as rapidly as possible: we simply cannot be sure that water of sufficient quantity will be available in the case of accident. (0864-13 [Gellert, Sally Jane])

Comment: Re: Page 4-20, Section 4.5.3, Indefinite Storage, indefinite could mean forever. So that rate of CO₂ emission X infinity = infinity, which isn't good for the climate, that much greenhouse gas emission! (0919-7-2 [Kamps, Kevin])

Comment: The impact from the spent fuel storage on climate change is indicated as small. The impact from climate change on the storage facilities should be evaluated instead. For instance, for facilities located in coastal and estuarine areas the increased rate of sea level rise coupled with the potential increase in storm frequency due to climate change will make these facilities more prone to flooding and loss of power, such as occurred from Sandy. Facilities in the inner parts of the country may experience more severe droughts which would put greater strain on local aquifers and change the ground water flow in and around these facilities. It is likely that when most or all of the current power plants and storage facilities, including those in the coastal or estuarine areas, were designed, there was never any concern for sea level rise or climate change over the life of the plant, even though it was known that both were occurring. (0920-13 [Foster, Ruth])

Comment: Lines 2 to 4 indicate they are using the License Renewal GEIS (NRC 2012) as the baseline which for the climate. That document used data from 1971 to 2000. The most significant changes in climate have occurred since 2000 and now more scientists realize that climate changes over the next hundred years will be most significant than the changes that were experienced up until 2000. Also the effect of climate on sea level changes will be greater than predictions from before 2000. Change in climate will have significant impacts on surface-water and ground water in most areas of the country. (0920-26 [Foster, Ruth])

Comment: [T]he effect of the operation on climate change is examined; but not an impact assessment of climate change on storage facility. For instance, sea level rise will have an impact on facilities near the coast or on estuaries. (0920-29 [Foster, Ruth])

Comment: The dangerous and unpredictable effects of global warming on all aspects of the nuclear industry must be taken into account. Nuclear power is not green. The chain of events that leads to the creation of nuclear fuel is very carbon intensive. The disposal and

decommissioning of nuclear reactors is a carbon cost that is not often calculated into the footprint of reactors. Nuclear power routinely emits radioactive carbon. Sea levels are rising; extreme weather events are increasing in frequency; and catastrophic damage to nuclear stations becomes even more likely. (0938-11 [Sondheim, Steven])

Comment: We have had many smaller accidents in the US due to weather. As we all know, global climate change will be bringing us much, much stronger storms, hurricanes, tornados and floods. (1001-1 [Goudeau, Terry])

26. Comments Concerning Geology and Soils

Comment: The "cure" for offsite soil and groundwater contamination is ensured by regulation and monitoring, which translates to a "SMALL" assigned impact. However, migration of contaminants in soils involve soil biota and biota all the way up the predatory scale, which can lead to distant off-site migrations. The preparers of this document need to study Hanford's remarkable history of biological pathways for spread of contaminants. The ready dismissal of leaking storage facilities is not warranted by their commonplace occurrence in nuclear power plant facilities. (0553-8 [Wilshire, Howard])

Comment: The NRC concludes in Section 4.6 of the DGEIS that the environmental impacts on geology and soils from continued storage of spent fuel would be "SMALL" (pool and ISFSI; all timeframes). However, this would depend on site-specific factors, including the soils present at each location (and general geomorphology for coastally-sited plants), the sites' vulnerability to erosion, the amount of fuel stored in pools, and the type of storage facility being planned. (0622-2-1 [Vale, Karen])

Comment: Furthermore, the NRC should not only consider the impact of storing spent fuel in ISFSI on the geology and soil, but also the impacts that varying soil types would have on the long term stability - and therefore the risk for a potential accident - of a plant's ISFSI. For example, "variable and erratic sandy soil" has been described at Entergy's Pilgrim plant in Plymouth, Massachusetts, with dense and compact material located below a depth of about 35 ft.⁷ [footnote 7 text: Department of Public Health, Environmental Toxicology Program. June 25, 2010. Memorandum: Status of Groundwater Monitoring Program at Pilgrim Nuclear Power Plant.] The impacts that sandy soil types might have on the stability of an ISFSI should be assessed by the NRC. (0622-2-3 [Vale, Karen])

Comment: p. 4-20 to 4-21. Geology and Soils. "Continued spent fuel pool operation is not anticipated to increase impacts on local geology and soils," but "spent fuel leaks could result in radiological contamination of offsite soils." **Comment:** The "cure" for offsite soil and groundwater contamination is ensured by regulation and monitoring, which translates to a "SMALL" assigned impact. However, migration of contaminants in soils involve soil biota and biota all the way up the predatory scale, which can lead to distant off-site migrations. The preparers of this document need to study Hanford's remarkable history of biological pathways for spread of contaminants. The ready dismissal of leaking storage facilities is not warranted by their commonplace occurrence in nuclear power plant facilities. (0805-8 [Wilshire, Howard])

Comment: Re: Page 4-20, Section 4.6, Geology and Soils, lines 26-28, NRC states "the NRC expects that most soil contamination from spent fuel pool leaks would remain onsite and, therefore, offsite soil contamination is unlikely to occur. Therefore, the NRC concludes that the environmental impact of spent fuel pool leaks to offsite soils (i.e., outside the power plant's

exclusion area) would be SMALL." This is preposterous. What about the leaks already documented?! NRC lists such pool leaks in Table E-4 on Page E-20. The leaks at Hatch in GA, Indian Point 1 & 2 in NY, Palo Verde in AZ, Salem 1 & 2 in NJ, San Onofre in CA, Seabrook in NH, and Watts Bar in TN, NRC admits have released radioactive liquid to the environment. Now NRC claims offsite soil contamination is not likely to occur?! As David Lochbaum of UCS points out in his expert witness commentary, the Brookhaven National Lab pool leak should have been included in Table E-4, or at least somewhere else in this DGEIS, rather than being left out. So too should have the Yankee Rowe pool leak. This growing list of pool leaks to the environment across the U.S. has included serious contamination of groundwater, and hence, soil. (0919-7-3 [Kamps, Kevin])

Comment: This section evaluates the storage impact on geology. They are not evaluating the impact of the geology on the continued storage. They are not considering any new theories, data collection, mapping of the local and regional geology around a facility and how that would impact the original estimations of the potential severity of such natural disasters such as landslides, earthquakes or sinkholes at a facility. (0920-14 [Foster, Ruth])

Comment: Lines 26 to 28 indicate that facilities are designed and built on natural or engineered strata to ensure that no safety-related facilities are on unstable material. Lines 12 to 20 indicate that the seismic hazards of the regions form the design basis for the spent fuel pools and dry cask storage systems. Lines 23 to 25 indicate that the general characteristics are discussed in this GEIS, the License Renewal GEIS and the impact statements prepared for the initial-construction and operation of the plants. This section indicates no use of more modern interpretations of the local or regional geology or a review of changes in seismic hazard ratings for the area which would be based on data obtained since the earlier plants were built. The reinterpretation of the geology of a region based on modern geologic mapping done since the 1980's to the current time is allowing hydrogeologists to better map and understand the aquifers of the various regions of the country. (0920-27 [Foster, Ruth])

Comment: By use of this GEIS's, the NRC is essentially refusing to allow any modern information on the geology and ground water interpretations at a facility when they evaluate continued storage or license extensions. (0920-32 [Foster, Ruth])

27. Comments Concerning Hydrology

Comment: We already have more than 100 reactor sites with ground water contaminated through routine operations. (0023-7 [Bridges, Martha])

Comment: The EIS must address reactor need for water and consequences related to the use of that water. Nuclear reactors use large amounts of water to cool their reactor and to keep the fuel pool stable. In California the consequences of the enormous amount of water needed in the reactors for once-through cooling were recognized. This led to concerns about dwindling water resources that resulted in statewide mandates to reduce the amount of sea water being used by all the energy plants. Water is a scarce commodity in many parts of the United States. Global warming continues to decrease the river and lake levels needed to cool reactors. (0030-21-6 [Carberry, Mike])

Comment: Then when later faced with a high-level nuclear permanent storage in the granites in western North Carolina and Raleigh area, I knew there were possibilities that this would be a major problem with ground water. Now with this issue taking place in the Northwest, we need to have some control for such a potentiality. (0079-1 [Pittillo, Dan])

Comment: In our area we face major water issues. The Draft GEIS does not address water safety issues as reactor site specific and does not include the necessary data collection needed to take a realistic look at our situation. Here are only a few examples: The Nuclear power stations, Catawba and McGuire give us 4 nuclear reactors located on drinking water reservoirs within 20 miles of downtown Charlotte. They are the largest water users on the Catawba River, a river that has been ranked the 4th most stressed river in the United States by the Union of Concerned Scientist and made the The Southern Environmental Law Center's list of the top ten most endangered places in the Southeast. Other reports are quoted: by 2040 there will not be enough water in The Catawba River to meet all of the water demands. Most individuals do not realize that more water is used to generate power for their home than is directly used in the household." The Oconee Nuclear station shut down on Oct 24 due to water issues. This plant faces serious damn issues and has had 14 high level violations since 2000. It took an NRC whistle-blower for Duke or the NRC to do anything about it! And the proposed WS LEE nuclear plant : Duke has had to build up massive ponds as a band-aid approach to resolve the serious lack of cooling water from the Broad River. The Broad is a small river that dries up in the summer so much you can just walk across the rocks. Yet Duke and the NRC think it is okay to build just 20 miles downstream of Cliffside Coal, the largest coal plant in the south, and upstream from the 3 reactors that will be at VC Summer near Jenkinsville. We want you to have the same logic as the court and keep the ban on licensing new power plants. For the sake of time for speaking...we all know the importance of water when it comes to fuel pool storage and radioactive waste. (0145-1 [Sorensen, Laura])

Comment: I am also very concerned about the amount of water that is being used to cool these nuclear reactors. We are in a period of heavy drought and they have had to shut down nuclear reactors because of too little water as well as too much water. It requires water. Guys, come on, let's be real about this. (0246-27-3 [Gerleman, Doug])

Comment: With evidence that uranium mining contaminates waterways and water tables, and with the fact that dry casks at several storage facilities around the world, including the United States, have been leaking into these water tables by trillions of tons of nuclear waste. (0326-45-3 [Baker, Crystal])

Comment: I have been reading through the GEIS book. Of course, it's 500 whatever pages. So, so far I haven't been able to find anything, in particular, dealing with the temperature of water. I think there should be a concern. I noticed at Dominion's North Anna site, they said that like the lake that they used to cool the reactors, the other day, it was at 50 degrees when it goes in and when it comes out. They said it's typically 14 degrees, but it was coming out at 76.1 degrees. So that was actually 26.1 degrees hotter and, obviously, dealing with climate change. I'm just wondering how or maybe I haven't gotten to it yet, but I haven't been able to find anything yet talking about the issues of water, in particular, cooling the reactors and as well as water usage, how, you know, how the impacts are from all the water that is used because, obviously, I guess, in the cooling process, a lot of it is turned to vapor. So the water issues -- and I haven't been able to find anything dealing with that. I realize that in parts, it was talking about, you know, in particular, with the spent fuel pools and the dangers of a drain-down or leak, but is it addressed? Maybe I haven't seen it, but what if we lose Lake North Anna and we lose the dam and we lose the water? I don't think we have water that is being piped in in the quantities that we need it if there was a diversion of the water. That is a manmade lake. So I have concerns with the water as well. I can't seem to find anything on the water issues other than the spent fuel pools themselves. So I don't know if there is something there or not. (0329-35-1 [Gray, Susan])

Comment: Off-site waste at other sites are projected to have significant adverse long-term impacts on the groundwater, which ultimately impacts other bodies of water (0377-3-2 [Cuthbert, Lewis])

Comment: The NRC apparently did not do a very exhaustive review, because the assertion that surface waters in the vicinity of nuclear power plants are usually [emphasis added] large and therefore ensures dilution to levels well below those considered safe is incorrect. The lesson that large amounts of water will not dilute contaminant streams has been demonstrated for decades. At Hanford it was shown long ago the migration of radionuclides and other toxic substances into the Columbia River were concentrated by biological uptake to concentrations far higher than river water. The ultimate fate of these contaminants is the important question, which is not addressed in this GEIS. Furthermore, climatic impacts have shown both in the US and France that reactors located on and dependent on inland rivers have been shut down due to drought limiting the supply of cooling water. Use of the word "usually" also implies conditions where the surface water supplies are not large-they would be even more vulnerable to effects of drought. In addition, the account above admits the uncertainties of rates of leakage from SNF pools, direction and rate of groundwater flow, and distance to offsite waters. We cannot predict future risks from the toxic and radioactive wastes in the environment with any confidence because we do not know all of nature's pathways. (0553-9 [Wilshire, Howard])

Comment: Despite the conclusion that the risk and/or magnitude of potential impacts would likely be small, minimized or avoided, DNR is concerned about the potential impact to natural resources in the event that a permanent repository is not approved, particularly contamination of surface and groundwater resources. Although the risk of serious contamination events may be low, the potential impact could be severe, difficult to mitigate, and of long duration. (0560-1 [Vejdani, Vivianne])

Comment: When considering groundwater quality and use, the DGEIS completely excludes the Plymouth-Carver Sole Source Aquifer (PCA) and the glacial moraine of Plymouth, Massachusetts (where Pilgrim is located). The Northeast region's PCA and glacial debris influences environmental characteristics, including water temperature, pH, salinity, soil type, and other important attributes of regional peculiarity that are likely to impact the storage of nuclear waste, as well as be vulnerable to contamination from that storage. (0622-2-12 [Vale, Karen])

Comment: It's also inaccurate for the NRC to assume "SMALL" impacts when the factors involved vary at each groundwater contamination incident. For example, the amount of contamination is never the same in each incident, soils and environmental factors differ, groundwater flows differently at each site, the chemical properties of materials potentially released can differ, etc. Site specific assessment would have to be done to determine the real potential impacts of contamination of groundwater use and quality. (0622-2-14 [Vale, Karen])

Comment: Section 4.8 also does not properly address impacts to drinking water quality. Many nuclear plants are located on drinking water aquifers, and many have negatively impacted drinking water sources. For instance, the fuel pool at Brookhaven National Labs (New York) had leaked tritium, undetected, into the drinking water aquifer for twelve years.¹⁸ [footnote 18 text: U.S. General Accounting Office. 1997. Information on the Tritium Leak and Contractor Dismissal at the Brookhaven National Laboratory] And Pilgrim's tritium leaks are occurring on the PCA, which supplies drinking water for individual residents and several southeastern Massachusetts towns. (0622-2-15 [Vale, Karen])

Comment: Section 3.6 claims that the provisions of the Clean Water Act (CWA) and issuance of "NPDES permit terms may not exceed 5 years" will regulate the discharge of pollutants into waters of the U.S. However, at Pilgrim, the NPDES permit is 17 years out-of date, and there are discharges that are not being regulated as set out in the CWA. The DGEIS does not even mention this failure or how the CWA regulations are applied throughout the country at other nuclear facilities. (0622-2-5 [Vale, Karen])

Comment: In Section 4.7, the DGEIS states that, for pool storage, most environmental impacts to surface-water resources will cease due to the end of reactor operations, and that there will be a 99% reduction in cooling-water demand. However, some water use would still occur and there doesn't appear to be adequate information available to make a "SMALL" impact determination. For example, even currently, the NPDES permit for Entergy's Pilgrim plant in Plymouth, Massachusetts is based on limited field data and outdated science. As stated above, Entergy's NPDES permit for Pilgrim expired in 1996. The NRC cannot assume "SMALL" impacts based on less water use, if the impacts are not clearly known for current full-operation water use. Even based on Pilgrim's site-specific license renewal EIS, impacts to the marine environment were considered "MODERATE" for some species and "SMALL TO MODERATE" for others. (0622-2-6 [Vale, Karen])

Comment: The DGEIS states that incidents of radioactive contamination of groundwater would have a "SMALL" impact on surface water; that the large volume of surface water available would dilute groundwater contaminants "well below limits considered safe." However, despite the ocean's capacity to dilute radiation, nuclear isotopes persist and move up the marine food chain -evident in the marine life near the Fukushima Daiichi accident; the full impacts on marine life - and human life - are still unclear.¹² [footnote 12 text: Grossman E. 2011. Radioactivity in the ocean: diluted, but far from harmless." Yale Environment 360.] (0622-2-7 [Vale, Karen])

Comment: Further, it is inaccurate for the NRC to assume "SMALL" impacts when the factors involved vary at each facility/location in the U.S. For example, the amount of contamination is never the same in each location since soils and environmental factors differ, groundwater levels and flows are different at each site, the chemical properties of materials potentially released can differ, and most importantly, the fate of those contaminants on local resources will vary greatly. A site specific assessment would have to be done to determine the real potential impacts of groundwater contamination on surface water. (0622-2-8 [Vale, Karen])

Comment: In addition, the cumulative impact assessment in the DGEIS is also legally and factually deficient because it does not include an assessment of the combined impacts of future spent fuel pool leaks and leaks of radioactive water from other plant systems that are likely to increase the levels of groundwater contamination at Indian Point, and potentially at other reactor sites around the country. In its description of Groundwater Quality and Use, the DGEIS references the numerous instances of groundwater contamination from operating reactors, stating as follows: There are 65 locations in the United States where commercial nuclear power plants are operating. Records indicate that, at some time during their operating history, 42 of these sites have had leaks or spills involving tritium concentrations in excess of the 20,000 pCi/L drinking water standard established in the Safe Drinking Water Act. Nineteen sites are currently reporting tritium concentrations, from a leak or spill, in excess of 20,000 pCi/L onsite.⁵⁵ [footnote 55 text: DGEIS, Section 3.7 at 3-19.] Remarkably, Section 6.4.8 of the DGEIS, which addresses Cumulative Impacts to Groundwater Quality and Use, fails to mention or integrate this information into its assessment, completely ignoring the obvious significance of such information to this part of the required NEPA analysis.⁵⁶ [footnote 56 text: *Id.* at 6-28, 6-29.] The failure to assess the cumulative impacts of spent fuel pool leaks and other facility leaks to

groundwater renders the DGEIS legally and factually flawed. (0710-22 [Brancato, Deborah] [Musegaas, Philip])

Comment: Further, even though the groundwater at Indian Point is not used for drinking water purposes, it is designated under state law as “GA fresh groundwaters”²⁰ [footnote 20 text: 6 N.Y.C.R.R. §§ 701.18, 701.15; See Entergy’s Detailed Responses to the New York State Department of Environmental Conservation’s Request for Information, dated May 13, 2009) at 8, *available at*, http://www.dec.ny.gov/docs/permits_ej_operations_pdf/elecbrdrdetresp.pdf.] which NYSDEC requires to be suitable “as a source of potable water supply.”²¹ [footnote 21 text: 6 N.Y.C.R.R. § 701.15; Potable water” is defined as “those fresh waters usable for drinking, culinary or food processing purposes.” 6 N.Y.C.R.R. § 700.1(a)(48).] Moreover, a NYSDEC narrative standard applicable to groundwater dictates that deleterious substances not “impair the waters for their best usages.”²² [footnote 22 text: 6 N.Y.C.R.R. § 703.2.] So, the groundwater beneath Indian Point must not be impaired for use as drinking, culinary, or food processing water, notwithstanding whether the groundwater is *actually* used for such purposes. (0710-5 [Brancato, Deborah] [Musegaas, Philip])

Comment: The NRC contemplates that these pools may remain in use for 60 years after reactor operation ceases, where they will remain vulnerable to fires and also to leakage of tritium and other radioactive materials to soil and groundwater. The Union of Concerned Scientists has documented that 100 reactors in the USA already have leaks that threaten or have already caused ground water contamination. See: http://www.ucsusa.org/nuclear_power/reactor-map/embedded-flash-map.html. While we appreciate the ground water disclosures in GEIS Section 3.7 (pages 3-16--3-20) there is no recognition in the that discussion of the long-term issues associated with locating 70,000 metric tonnes (and growing) of highly radioactive spent nuclear fuel on top of ground water for an unbounded period of time. Every site has ground water. It is a violation of the National Environmental Policy to fail to answer these basic questions both generically and at each specific site. Adopting a generic waste confidence rule could prohibit in specific licensing proceedings, the opportunity to address groundwater contamination questions due to irradiated fuel. This is even more egregious when the generic draft EIS fails to even consider them, which is the case with this one. (0711-21 [Olson, Mary])

Comment: Where is the analysis of the potential for groundwater impacts over time? (0711-35 [Olson, Mary])

Comment: Further, decisions about water intake and outflow of surface waters at nuclear plants is NOT under the jurisdiction of the NRC. It resides with the States under the NPDES permitting system. Illinois has historically experienced instances where the Illinois EPA has either curtailed reactor operations, or conversely, granted permit exemptions for thermal discharge into Illinois rivers during severe drought conditions (1988; 2005; 2006). These decisions will be made by the State, not the NRC; and as a result can impact river temperatures, chemical and biological activity, evaporation rates, recharge and other factors - many of which affect whether dilution as NRC envisions it would occur. We see no evidence in NRC’s DGEIS that this has been taken into account. (0716-13 [Kraft, Dave])

Comment: p. 4-21 to 4-24. Surface-Water Quality and Use. Consumptive use of surface water is dismissed as unimportant after license expiration and ending of plant operations, which absorb most of the surface water needs. “Surface water quality may be affected by groundwater contamination. The NRC has completed a review of its overall regulatory approach to groundwater protection (NRC 2011b). The NRC started this review in response to recent

incidents of radioactive contamination of groundwater and soils at nuclear power plants. Contaminated groundwater at some sites may discharge to nearby surface waters, resulting in indirect effects on surface-water quality. The concentrations of radionuclides in offsite surface waters would depend on the rate of release from the spent fuel pool, direction and rate of groundwater flow, the distance to nearby offsite surface waters toward which groundwater flows, the velocity or transport rates of radionuclides through the subsurface and radioactive decay rates. However, because surface waters in the vicinity of nuclear power plants are usually large to meet reactor cooling requirements, a large volume of surface water is usually available to dilute groundwater contaminants that flow into the surface waterbody. This dilution ensures that contaminants that may have been present above applicable groundwater-quality standards are diluted well below limits considered safe." Comment: The NRC apparently did not do a very exhaustive review, because the assertion that surface waters in the vicinity of nuclear power plants are usually [emphasis added] large and therefore ensures dilution to levels well below those considered safe is incorrect. The lesson that large amounts of water will not dilute contaminant streams has been demonstrated for decades. At Hanford it was shown long ago the migration of radionuclides and other toxic substances into the Columbia River were concentrated by biological uptake to concentrations far higher than river water. The ultimate fate of these contaminants is the important question, which is not addressed in this GEIS. Furthermore, climatic impacts have shown both in the US and France that reactors located on and dependent on inland rivers have been shut down due to drought limiting the supply of cooling water. Use of the word "usually" also implies conditions where the surface water supplies are not large--they would be even more vulnerable to effects of drought. In addition, the account above admits the uncertainties of rates of leakage from SNF pools, direction and rate of groundwater flow, and distance to offsite waters. We cannot predict future risks from the toxic and radioactive wastes in the environment with any confidence because we do not know all of nature's pathways. (0805-9 [Wilshire, Howard])

Comment: I will concentrate on Ohio's reactors with which I am most familiar, but these comments pertain to virtually every light water reactor in the United States. 1) "Sites should be avoided where ... known natural resources may negatively affect the ability of the disposal site to meet the performance objectives." All U.S. reactors which sit on potable or environmentally sensitive bodies of water were never intended as radioactive waste sites. Perry and Davis Besse were built on Lake Erie, part of the world's largest fresh water system, source of drinking water for millions of people. (0819-17 [Kline, Connie])

Comment: 2) "A prospective site must be well-drained and free of flooding or frequent ponding." Davis Besse was built in a marshy wetlands subject to frequent flooding, including a 1972 Lake Erie storm that broke 300 feet of dikes, submerging the entire plant site including the reactor building which, fortunately, was pre-operational. People had to be airlifted or rescued by boat; cars were unsalvageable. I have included aerial photos taken of the Davis Besse three days after the flood which show the site still submerged despite some recession of water. (0819-18 [Kline, Connie])

Comment: 3) "The disposal site should be located far enough above the water table to prevent groundwater intrusion." According to the 1983 Perry FSAR, "Observations made in the test borings at the site indicated groundwater levels usually ranging from three to five feet below the ground surface in the main plant area... In the vicinity of the Perry site, many residential users obtain their water supplies from shallow wells." Perry has an intricate drainage and sophisticated "sump pump" system due to the high groundwater table. As early as 1992, "Radiological Occurrence Report ROR-92-0023" revealed that a stream which borders Perry

and leads to Lake Erie, was radioactively contaminated due to accidental spills and leakage that went undetected for 3 years. (0819-19 [Kline, Connie])

Comment: The common concern has always been that the waste will not be removed from our reactor sites, all of which sit on or close to the banks of the Mississippi River. No river maintains a single course over hundreds of years. And any release, leak or failure to isolate wastes for any period of time, will have "disasterous" consequences. (0820-3 [Eide-Tollefson, Kristen])

Comment: To the general public the conclusion that permanently stranding waste at reactor sites across the country, on major waterbodies - has "small" environmental effects, is absurd. The conclusion of "small impacts" in the chart, is possible only because of the Analytic Assumptions (0820-9 [Eide-Tollefson, Kristen])

Comment: Leakage from some sites may reach and contaminate groundwater quicker due to unique vulnerabilities in the environment, such as very high water tables, proximity to streams and lakes, proximity to ground water, vulnerability to flooding, risks of tsunamis and high waves, and more. Such vulnerabilities that generate leaks or expand leaks will likely cause significant adverse impact upon environment and humanity; a good scientific analysis would attempt to quantify probability ranges for each type of significant impact with differing characteristics, including drinking water sources for humans and wildlife. (0823-32 [Michetti, Susan])

Comment: Scientific thinking recognizes that water molecules migrate in plumes, often in specific directions, depending on the factors of attraction and repulsion in operation at all levels of the physical world. Scientific thinking recognizes that it is merely a matter of time when migration off-site will occur. To dismiss migration off-site with insufficient consideration fails to apply measurements of plume migration of contaminated water on a timeline. Scientific analysis requires the information for each leaked isotope to be plotted into a future timeline based on all known factors that might impact that migration map. (0823-41 [Michetti, Susan])

Comment: GEIS Section 4.7.1.1: NRC has appropriately determined that "impacts on surface water consumptive use from the continued storage of spent fuel in spent fuel pools will not be detectable or be so minor that they would not be destabilizing." (GEIS 4-22). NRC's basis for this - that cooling water demand would be significantly reduced after reactor operations have ceased - is correct. As an example, data from the recently shut down Crystal River Unit 3 indicate that total raw water flow (circulating water plus service water) from the ultimate heat sink through the plant when it was operating was about 690,000 GPM. About 2,000 GPM (0.3%) of this water is used to cool spent fuel via the spent fuel pool heat exchangers. (0827-7-26 [Ginsberg, Ellen])

Comment: Clean Water Act National Pollutant Discharge Elimination System (NPDES):] Page 3-16, line 33 -Insert the following sentence after the sentence ending in "water quality-based limits." "The technology-based limits applicable to nuclear power generating plants are cited at 40 CFR Part 423." Page 3-16, line 34 -Insert the following parenthetical phrase after the "not to exceed 5 years": "(unless administratively continued)" Page 3-17, line 8 -Add the following sentence: "The intake of cooling water from waters of the US is regulated under Clean Water Act Section 316(b), and the thermal component of any effluent discharges from power generating plants may be regulated by either the applicable state water quality standard or by Clean Water Act Section 316(a)." (0915-12 [Bromm, Susan E.]

Comment: Re: NRC's statement, on Page 3-18, lines 33 and following, that "Where shallow aquifers are immediately underlain by thick, impermeable shale or massive, unjointed carbonate strata, there is likely little or no hydraulic connection with deeper, regional groundwater flow

systems."...this, of course, is entirely changed, in ways that are difficult to track, by the fracking free for all underway in many parts of the U.S. U.S. hydrogeology is being changed, in a major way, that is little understood, in many regions. NRC has not addressed the interplay between fracking and the new risks to irradiated nuclear fuel storage this represents. (0919-5-15 [Kamps, Kevin])

Comment: Re: Page 4-24, lines 21 to 25, NRC states "The NRC concludes that the potential consumptive use and surface-water quality impacts from continued ISFSI operations would be minimal. Consumptive use of surface water for ISFSI replacement and DTS construction, operation, and replacement would involve amounts of water that are a small fraction of water use during reactor operations. Therefore, the NRC concludes that the potential impacts on surface-water use and quality for the long-term storage timeframe would be SMALL." NRC seems to be attempting to justify future, and ongoing, impacts, by pointing to past impacts that are even larger in magnitude, essentially arguing that long-term and even indefinite impacts are SMALL by comparison. This is an unacceptable attempt to "normalize" radioactivity and other impacts. And the only way NRC can get away with this paper game is to assume that dry cask storage replacements will happen, and will go smoothly. Those are indefensible assumptions. Essentially, NRC is making the absurd argument that impacts - whether in the so-called "short," long, or even forever term - are essentially zero. Zero X forevermore = zero, NRC absurdly reasons. Of course, the impacts are greater than zero. And any value greater than zero X infinity = infinity, unfortunately. (0919-7-10 [Kamps, Kevin])

Comment: Re: Page 4-46's NRC's statements, re: NPDES, RCRA, and SDWA, lines 36 to 40, re: nonradiological contaminants, amount to rosy, overly optimistic assumptions. What could possibly go wrong? NRC seems to be saying. It is not a conservative, protective, precautionary approach to the risks. Casting further doubt on NRC's over optimism, the diesel spill at Braidwood, IL, eventually led to the discovery of the massive tritium spills there (which had been covered up for a decade, with the complicity of the IL EPA and NRC). Also, sodium fires and tritium spills have occurred at Fermi 1, as recently as 2008 - remarkably, 42 years post-meltdown, and 36 years post-shut down; in addition; decommissioning continues, after 41 years. (0919-7-13 [Kamps, Kevin])

Comment: At Page 4-22, lines 9-11, NRC states "consumptive water loss per 1,000 MW(e) for different cooling systems used at operating power plants ranges from 8,100 gpm for plants that use once-through cooling system to 14,000 gpm at plants with mechanical draft cooling towers (NRC 2013a)."--I'd have thought cooling towers would mean LESS consumption than once-through? Can NRC explain why this is? (0919-7-4 [Kamps, Kevin])

Comment: Re: NRC's statement on Page 4-23, starting at line 20, "As passive, air-cooled storage systems, ISFSIs do not consume water and they generate minimal liquid effluents that may be discharged to surface waterbodies during normal operation. For example, in its consideration of water-use impacts for the renewal of the Calvert Cliffs ISFSI, the NRC determined that both direct and indirect impacts would be SMALL (NRC 2012a)." (emphasis added) What about OFF normal conditions?! (0919-7-7 [Kamps, Kevin])

Comment: On Page 4-24, line 3, NRC states "During ISFSI demolition, a small amount of water could be sprayed from water trucks to minimize dust clouds."...What about the radioactivity in the dust, then entering into the runoff, flowing into the soil and groundwater and surface waters?! (0919-7-8 [Kamps, Kevin])

Comment: Similarly, at lines 16-17, NRC states "During [DTS] operations, water would be brought to the facility by tanker truck or temporary connection to public water supply for general purpose cleaning and canister decontamination." (highlight added)"Again, what about the radioactivity in the dust and runoff?!" (0919-7-9 [Kamps, Kevin])

Comment: Ground water and geology are inseparable since aquifers are geologic materials and should be examined together. Changes in geologic interpretations affect how a ground water flow system may be interpreted. In addition, research into contaminate transport combined with three dimensional computer modeling using modern geologic mapping completed since the 1980's provide a better understanding of the ground water flow at a facility than the geologic and ground water reports completed from before the facility was constructed. Based on information obtained during the ongoing tritium contaminated ground water cleanups at two of the New Jersey plants, the original geology and ground water reports for the plants, as well as early company consultant reports after the leaks were identified did not reflect actual ground water flow systems. In each case, it was stated that the clay layers would prevent the tritium from moving into the deeper aquifer, but in both cases these clays did not prevent the contamination from migrating down into a deeper aquifer. (0920-31 [Foster, Ruth])

Comment: p. 4-26-- Lines 32 to 34 indicate "Except for a few substances (e.g., diesel fuel), these hazardous spills are often localized, quickly detected, and relatively easy to remediate NRC 2002b)." Based on an extensive number of ground water cleanups which have been done in New Jersey and contrary to what is stated here, the hydrocarbon (diesel and gasoline) cleanups generally are easiest, whereas ground water cleanups of other contaminants have taken tens of years and are not yet complete. (0920-35 [Foster, Ruth])

Comment: p. 4-28 in part 4.8.1.--In lines 15 to 19, NRC concludes that the short-term storage of the spent fuel in the spent fuel pools and ISFSI's impact would be SMALL for water use and quality. Without utilizing any up-to-date data along with current geologic interpretations of the local geology and ground water evaluations, not the studies from 40 or more years earlier when the facility was being designed, it is impossible to accurately assess these impacts. For instance, for the Oyster Creek plant, between the time construction started until today the ground water use within the ten mile radius of the plant has increased from about 150,000 gallons per day to over 15 million gallons per day, not including any industrial or agricultural water pumpage. In New Jersey, ground water pumpages has changed the flow from being toward local streams and rivers to the streams and rivers recharging the aquifers and the ground water flow is toward the pumping centers. (0920-36 [Foster, Ruth])

Comment: Section 6.4.8, p. 6-30--Lines 33-35 indicate that NRC has determined that the incremental impacts on ground water from continued storage would be minor compared to trends such as climate change. The problem with these assessments is that they do not take into account the fact that the impact of each plant site on groundwater near the plant is site specific, yet they are generalizing. For plants such as Oyster Creek, the ground water pumpage from the water table to shallow semi-confined aquifer are orders of magnitude greater than at most other US nuclear power plants. When the plant shuts down to be decommissioned, and the large circulation pumps stop pumping, the local ground water to surface water flow system will change. With large pumping centers just outside the plant boundaries of Oyster Creek, the ground water flow can be away from the surface water body toward the pumping centers, not toward the surface water body as the NRC uses in scenarios. (0920-38 [Foster, Ruth])

Comment: This section stresses that for any leaks at a plant, the contaminated ground water will flow to the nearby body of surface water and any will not contaminate any offsite public wells. Without looking at the modern demographics around a plant and current ground water use, this mere conjecture, not science. Again, in New Jersey, Oyster Creek had a small population and little ground water use when the plant was built. Now the population and ground water use within 10 miles is significantly greater. At Oyster Creek and Salem the tritium has migrated downward into deeper aquifers, a scenario not taken into account in any of the discussions found in the document. (0920-47 [Foster, Ruth])

Comment: The potential for spent fuel pool leaks (and other leaks of radioactive liquids) to impact deeper aquifers, separated from the shallow unconfined aquifers by low-permeability confining layers, is overly minimized here. Recent experience at nuclear power plants in New Jersey has demonstrated that the probability that tritium contaminated water released into shallow unconfined aquifers will ultimately reach deeper confined aquifers is much greater than previously predicted. Construction activities typically associated with nuclear power plants, such as deep excavations for building foundations and other structures, and the installation of cofferdams to support dewatering operations, can significantly alter site hydrological conditions. An unintended consequence of these activities has been the creation of downward pathways through the confining layers into the deeper aquifers. Although these facts do not alter the ultimate conclusions of the GEIS with regard to impact determination, for the sake of completeness and credibility this aspect of site hydrological conditions should be discussed. (0920-6 [Foster, Ruth])

Comment: The EIS must address reactor need for water and the consequences related to that use. Nuclear reactors use large amounts of water to cool the reactor and to keep the fuel pools stable. In California, the consequences of the enormous amount of water needed in the reactors for once through cooling were recognized. This led to concerns about dwindling water resources that resulted in state-wide mandates to reduce the amount of sea water being used by all energy plants. Water is a scarce commodity in many parts of the US. Global warming continues to decrease the river and lake levels needed to cool reactors. (0938-8 [Sondheim, Steven])

Comment: The greatest danger from our current technology is contaminated groundwater. Once the harm is done, there is no recourse. And WATER is a critical daily need to support life--even more essential than electricity! (0977-1 [Maguire, Cynthia])

Comment: Leaching of any kind into our rivers, which provide our drinking water will prove to be disastrous. (0984-1 [Rossin, Linda])

Comment: We also must find ways to keep the Columbia River from contamination and clean up what contamination already exists in the Columbia River and all other rivers in the watershed of all nuclear sites! (0995-1 [Epple, Melissa])

28. Comments Concerning Ecology

Comment: The Impact Statement doesn't adequately address the real consequences and impacts on other organisms, in addition to humans. It is my understanding that you have looked at whether levels, legal release levels, which are based on the Nuclear Regulatory Commission's own -- the nuclear industry's needs. That is how they base 10 CFR 20 concentrations. That if you can make a model and a calculation that projects that doses to

people will be less than this amount, never verified, never proven, that this is okay for the entire environment and that that is dismissed. (0246-2-6 [D'Arrigo, Diane])

Comment: The upcoming 100 years throughout which the NRC claims spent fuel may merrily sit in spent fuel pools of repeatedly relicensed reactors is also a duration that, NRC jargon aside, is neither "short," nor certain. What is reasonably predictable is that these pools will leak and that the total burden of radiation being released into the environment will increase sizably. The evidence comes from an expansive library of studies and reports documenting these leaks. A few of these investigations are dutifully referenced in the GEIS "References" sections. However this GEIS suggests little tends to be learned from "Lessons Learned" reports. As these already past-their-prime spent fuel pools continue to age, they will continue to experience age-related deterioration, and leak more. This is the most plausible sequel scenario. Other radiation effluents which have been disgorged onto the reactor sites and the groundwater must also be taken into calculation. Environmental and biological systems do not abide by the artifice of separately evaluating the impacts of radiation as does the NRC. The problem - given the century of leakings which await us - is that the radiation will be chronically delivered into the environment. The combined and multiplicative effects of the continual delivery of short and long-lived radionuclides the past, present, and future bioaccumulation of long-lived radionuclides pose untenable risks to humans and other biological beings. Add to the calculus the uncertain, but very real, risk of large accidental releases, and the impacts of "Short-Term Storage" storage hardly merit the label: "SMALL." (0341-1-23 [Mermelstein, Richard])

Comment: The NRC evaluates the effect of fuel storage on aquatic organisms. Spent fuel pools continue to be cooled by external sources such as river, lake or ocean water using one-time pass through cooling systems or by recirculated pond water with atmospheric cooling towers. Aquatic organisms sometimes block the circulation and so are killed by the application of pesticides and chemicals. The organisms can also be affected by radioactive materials, such as tritium which contaminates the cooling circuit or simply by heating during transit through the reactor piping. One unintended consequence of this destruction of aquatic organisms is that many of them are essential to carbon fixation as part of the global carbon cycle. Aquatic organisms with carbonaceous skeletons are required to complete the cycle and permanently sequester carbon dioxide by precipitation to the sea floor. These organisms produce an enzyme called carbonic anhydrase, which catalyzes the conversion of dissolved carbon dioxide into carbonate anions. Dissolved carbonate in equilibrium with carbonic acid then combines with calcium cations in the water to produce calcium carbonate which is incorporated into the organism's skeleton, through biological mineralization, much like the process by which bones are formed in humans or shells in clams. When the organism dies it sinks to the sea floor where the skeleton becomes incorporated into great limestone sheets, which are eventually lifted by geological forces back to the surface to become new land masses and parts of continents. Thermal power plant cooling systems can contribute to global warming both by dumping waste heat into the environment and by killing the aquatic organisms which sequester the atmospheric carbon dioxide. Atmospheric carbon dioxide dissolves in both fresh and salt water. This solution process is reversible and depends on the temperature and pH of the water. At higher water temperatures and lower pH less carbon dioxide can remain dissolved unless it is converted to calcium carbonate and precipitated. The reversible solution of carbon dioxide in water creates a global buffering system which regulates the atmosphere concentration of carbon dioxide. The set-point for this buffering system is the equilibrium constant of the carbonic anhydrase enzyme in these aquatic organisms. (0410-18 [Nelson, Dennis])

Comment: Each reactor differs in its proximity to special species & habitats and most significantly to compliance with environmental regulations. For example, Pilgrim's NUREG-1437,

Sup 3 lists: [TABLE 2-4 OF THE PILGRIM LR (NUREG-1437 Sup 3 GOES HERE) [Table Submitted with Correspondence ML13354A021]. Of particular concern at Pilgrim is the North Atlantic right whale, one of the rarest large whales in the world with a little more than 500 individuals remaining. Most of the Bay is critical habitat for right whales. In January 2013, there was an unusual sighting of a mother-calf right whale pair within Pilgrim's 500-yard safety exclusion zone. Reactors vary not only in proximity to aquatic resources and special status species and habitats but in their compliance to applicable regulations so that a generic approach is inappropriate. For example, Entergy's non-compliance with these regulations includes: • No state CWIS permit, as required by 2006 regulations. • Discharge violations: Since at least 1995, discharging toxic corrosion inhibitors without a state or federal permit; chlorine discharge limit violations in 5 of last 12 quarters. • The joint EPA-DEP Clean Water Act "NPDES" permit expired 16 years ago; and although it has been "administratively extended" for 16 years, Entergy has violated its terms since 2000. • The Massachusetts "Section 401 certification" of the NPDES permit is outdated and invalid, given unpermitted discharges of various pollutants and other violations. • Since about 2000, no approved "marine monitoring plan" as required by NPDES permit. • Since 2000, Entergy has refused to cooperate with the required technical advisory committee, which was set up as an "integral part" of the NPDES permit. Entergy is not meeting its obligations: without compliance with this critical provision, the permit is meaningless. • Radioactive tritium is leaking into the groundwater which flows into Cape Cod Bay. • State 2006 coastal zone management "federal consistency certification" is invalid. NRC has taken no action to assure that these permits are updated with requirements followed despite its being brought forward in contentions during license renewal. The environmental impact, post-shutdown may well be entirely different at reactors in states that enforce regulations and at reactors that comply with regulations. (0556-1-20 [Lampert, Mary])

Comment: Environmental Impacts. The Draft GEIS considers only human health impacts and not environmental impacts in general. To begin with, it does not address impacts to the non-human environment. Contamination that is too low to cause disease in humans may affect plants and animals, and even small leaks may grow. In the past, the casual acceptance of leakage has undermined public trust in the NRC. (0556-3-1 [Lampert, Mary])

Comment: Staff also states that it "assumes" the site selection of an away-from-reactor storage facility would be "adjusted to minimize impacts on local resources, including ... special status species and habitats" but NRC also acknowledges "that in some cases avoiding impacts may not be possible."¹⁵ [footnote 15 text: Draft GEIS at 5-3.] If staff recognize that it is unknown whether impacts may be avoided, then staff cannot make any generic findings regarding impacts to local resources. If staff recognize that it is unknown whether impacts may be avoided, then staff cannot make any generic findings regarding impacts to local resources. (0579-11 [Smith, Amanda])

Comment: The Draft GEIS states "[i]t is likely than an away-from-reactor storage facility [like PFS] would also be located in an area away from sensitive perennial and wetland habitats to satisfy laws such as the Endangered Species Act (ESA) and the Clean Water Act (for wetlands);" but that "in some locations sensitive terrestrial features may be unavoidably affected."²⁶ [footnote 26 text: Draft GEIS at 5-26, 27.] The Draft GEIS fails to acknowledge that the intermodal storage facility for PFS was proposed to be located within two miles of the 1440-acre Timpie Springs Wildlife Management Area and the Great Salt Lake where thousands of birds migrate each year.²⁷ [footnote 27 text: See <http://publiclands.org/explore/site.php?id=1401>.] Although vacated, the U.S. Bureau of Land Management denied the PFS request for a right-of-way near the Timpie Springs Wildlife Management Area.²⁸ [footnote 28 text: U.S. Bureau of Land Management, Record of Decision Addressing Right-of-Way Applications U

76985 and U 76986 To Transport Spent Nuclear Fuel to the Reservation of the Skull Valley Band of Goshute Indians (September 7, 2006).] (0579-14 [Smith, Amanda])

Comment: Staff then mention the impacts to terrestrial resources at the PFS facility were determined to be small.²⁹ [footnote 29 text: Draft GEIS at 5-27.] Then staff concluded that the impacts at a storage site would be also small to moderate, "based primarily on the potential impacts of construction activities."³⁰ [footnote 30 text: Id.] It is mere speculation that an away-from-reactor storage facility would be located in an environment similar to the PFS facility - arid desert but with facilities near a wildlife management area and wetlands. NRC cannot support any generic conclusion for terrestrial impacts. (0579-15 [Smith, Amanda])

Comment: Section 4.9 of the DGEIS states that impacts of continued spent fuel storage in fuel pools and ISFSIs (including construction, repacking, and replacement activities) on terrestrial resources would be "SMALL". Again, it seems impossible for a generic EIS to accurately assess the impacts on terrestrial resources at every site, given that the resources (imperiled species, habitat types, etc.) vary extensively at site locations. For example, at the Pilgrim plant, there is both priority and estimated habitat for the spotted turtle (*Clemmys guttata*), which is a Massachusetts state species of special concern, and other sensitive species (although the MA Natural Heritage and Endangered Species Program will not reveal the sensitive species found or potentially found in the area). There is also an area designated as critical habitat for the northern red-bellied cooter (*Pseudemys rubriventris*) on the site. The NRC should use site-specific assessments to determine the impacts of long term storage (pools and ISFSIs) on terrestrial resources. The NRC should also fully assess the impacts of postulated accidents on site-specific terrestrial resources. (0622-3-1 [Vale, Karen])

Comment: The DGEIS (Section 4.10) states that the impacts on aquatic ecology associated with the operation of spent fuel pools would be "SMALL" due to lower withdrawal rates, lower discharge rates, and smaller thermal plumes. However, the impacts from water use of operating plants (Pilgrim for example) have not even been properly assessed, so there is no proper baseline to base this assumption on. To touch upon this point, even currently, the NPDES permit for Entergy's Pilgrim plant is based on limited field data and outdated science, and Entergy's NPDES permit expired in 1996. The NRC cannot assume "SMALL" impacts based on less water usage, if the impacts are not clearly known for current full-operation water use. (0622-3-2 [Vale, Karen])

Comment: To better understand the impacts of continued spent fuel storage (specifically in pools) on aquatic resources, the NRC should carry out site-specific assessments since aquatic resources differ greatly between reactor sites. The Pilgrim plant is located on Cape Cod Bay, which is an ecologically rich ecosystem composed of a diversity of habitats, provides a variety of estuarine and marine species and communities, including fish, shellfish, turtles, marine mammals, plants, and birds.²⁰ [footnote 20 text: Executive Office of Energy and Environmental Affairs (EOEEA). 2008. Ocean planning - draft report of the habitat work group. 75 pp.; Massachusetts Water Resources Authority (MWRA). How healthy is the marine ecosystem of the bays? Factsheet. <http://www.mwra.state.ma.us/harbor/pdf/fqa4.pdf> Accessed 10/10/2012.] Along the coast, Cape Cod Bay is lined with estuarine habitats, primarily salt marsh and tidal flats. Estuaries are among the most productive ecosystems in the world and are vital to the economy and the environment. They provide nesting and feeding areas for aquatic species of plants and animals, including fish and shellfish many of which are commercially important species. The importance of estuaries as "nurseries" for juvenile fish and shellfish has long been recognized. Estuaries are also important filters for pollutants and sediments flowing from rivers and streams in to the sea.²¹ [footnote 21 text: Beck et al. 2003. The Role of Nearshore

Ecosystems as Fish and Shellfish Nurseries. Issues in Ecology No. 11, Ecological Society of America. 12 pp.] (0622-3-3 [Vale, Karen])

Comment: Cape Cod Bay has long been recognized as a valuable and unique resource for the state of Massachusetts. In the early 1970s, the Massachusetts Oceans Sanctuaries Act recognized it as a state ocean sanctuary.²² [footnote 22 text: MA G.L. c. 132A, §§12A-16E&18 - Massachusetts Ocean Sanctuaries Act] Furthermore, in 1985, an eastern portion of the bay was designated by the Massachusetts's Secretary of Environmental Affairs as an Area of Critical Environmental Concern because of the extraordinary natural resources found in the area. A generic EIS cannot accurately determine the impacts of continued spent fuel storage on this unique and important resource. (0622-3-4 [Vale, Karen])

Comment: In Section 6.4.10 the DGEIS states, "LARGE impacts are not as likely but could occur under exceptional circumstances such as if other Federal or non-Federal actions, such as intense fishing pressure or changes in aquatic habitats from climate change, had overlapping impacts with the continued storage of waste that destabilized aquatic resources." As we have stated often in our comments, we are concerned that the NRC has a poor grip on the likely influence of climate change in all its forms on the Pilgrim facility. Warming waters, sea level rise, inundation from storms and increases in groundwater, leaking contamination into groundwater and Cape Cod Bay, unregulated discharges due to an expired NPDES permit, lack of regulatory oversight concerning wastewater and storm water discharges, ongoing impingement and entrainment of marine species, changes to ocean pH -coupled with changes in species composition over time and failure of proper consultation with NMFS and FWS -means that the impacts from long-term storage of spent fuel will have an UNACCEPTABLE LARGE impact upon the fragile aquatic resources of Cape Cod Bay. (0622-3-5 [Vale, Karen])

Comment: The DGEIS (Section 4.11) states that the NRC would be required to reinitiate consultation with the U.S. Fish and Wildlife Service (FWS) or the National Marine Fisheries Service (NMFS) if the cooling system parameters change, or if a "take" occurs for a species not included in an incidental take permit, or if a new species is listed under the ESA. However, to assume compliance with this requirement is flawed. For example, NOAA Fisheries (NMFS) concluded informal consultation with the NRC regarding the relicensing of Pilgrim with a "not likely to adversely affect" finding for all species under NMFS jurisdiction, including north Atlantic right whales (*Eubalaena glacialis*). But at that time, the federal agencies only considered Pilgrim's effects on individual, adult whales. However, in January 2012, new information emerged -a right whale mother-calf pair was seen swimming very close to Pilgrim (within the 500 yard exclusion zone). This was the first mother and calf right whale sighting in Cape Cod Bay in January in 27 years, and the only mother-calf pair ever documented occurring near Pilgrim. This new information should have required the NRC and NMFS to reinitiate ESA Section 7 consultation to reassess whether Pilgrim's operations could have negative impacts on a nursing mother and newborn calf. The reinitiation never happened. (0622-3-8 [Vale, Karen])

Comment: There are more than 80 state-and federally-listed species occurring in Plymouth County, where Pilgrim is located.²³ [footnote 23 text: Entergy Nuclear Generation Company. 2006. Appendix E. Pilgrim Nuclear Power Station, Applicant's Environmental Report, Operating License Renewal Stage. 261 pp.] Four endangered whale species (sei, right, finback, and humpback) and five endangered sea turtle species (loggerhead, leatherback, hawksbill, green, and Kemp's ridley) have the potential of occurring near Pilgrim in Cape Cod Bay. There is also critical habitat and priority habitat areas (for the north Atlantic right whale, northern red-bellied cooter, and spotted turtle) occurring near Pilgrim. The potential site-specific impacts of continued spent fuel storage should be fully assessed for these protected species and their

habitats. The impact of postulated accidents on all site-specific special status species and habitats should be assessed by the NRC (those mentioned above as well as others found in the area, such as the bald eagle, piping plover, roseate tern, Atlantic sturgeon, and all non-listed marine mammals that are protected under the Marine Mammal Protection Act). (0622-3-9 [Vale, Karen])

Comment: 3. *Significance of the Surrounding Ecology*[.] Indian Point is located in an area of high ecological significance. The plant is situated on the eastern banks of the Hudson River estuary, which is home to “an extraordinarily rich variety of fish species,” “one of the major spawning grounds for several commercially significant Atlantic species,” and “many important wildlife habitats.”¹⁵ [footnote 15 text: NOAA, Office of Coastal Zone Management, *New York State Coastal Management Program and Final Environmental Impact Statement*, available at, <http://www.dos.ny.gov/communitieswaterfronts/pdfs/NY%20CMP%20.pdf> at § II-2, 6-7.] Indian Point sits directly in front of and adjacent to designated Significant Coastal Fish and Wildlife Habitat (i.e., the “Hudson Highlands” habitat), as well as slightly upstream of Haverstraw Bay, which is also a designated Significant Coastal Fish and Wildlife Habitat (“SCFWH”).¹⁶ [footnote 16 text: See Coastal Fish and Wildlife Rating Form, Hudson Highlands (Revised Aug. 15, 2012), available at, http://www.dos.ny.gov/communitieswaterfronts/consistency/Habitats/HudsonRiver/Hudson_Highlands_FINAL.pdf (last visited Oct. 27, 2013) (hereinafter “Hudson Highlands SCFWH Rating Form”); Coastal Fish and Wildlife Rating Form, Haverstraw Bay (Revised Aug. 15, 2012), available at, http://www.dos.ny.gov/communitieswaterfronts/consistency/Habitats/HudsonRiver/Haverstraw_Bay_FINAL.pdf (last visited Oct. 27, 2013) (hereinafter “Haverstraw Bay SCFWH Rating Form”).] The Hudson Highlands SCFWH, *inter alia*, “provides highly favorable conditions for reproduction by coastal migratory fishes, especially striped bass,” is used as a migrational route for endangered shortnose and Atlantic sturgeon species, and provides an important nursery and summering area for endangered Atlantic sturgeon.¹⁷ [footnote 17 text: See *generally* Hudson Highlands SCFWH Rating Form.] The Haverstraw Bay SCFWH, *inter alia*, “regularly comprises a substantial part of the nursery area for striped bass ... American shad ... white perch ... Atlantic tomcod ... and Atlantic sturgeon,” provides habitat for numerous fish species, is a major nursery and feeding area for bay anchovy, Atlantic menhaden, and Atlantic blue crab, and provides spawning and wintering grounds for endangered shortnose and Atlantic sturgeon.¹⁸ [footnote 18 text: See *generally* Haverstraw Bay SCFWH Rating Form.] Importantly, the State of New York Department of Environmental Conservation (“NYSDEC”) has a number of regulations and standards which provide for the protection of surface waters as well as groundwaters in the State, including the Hudson River and groundwater beneath Indian Point. In particular, NYSDEC has designated the waters of the Hudson River in the vicinity of Indian Point to be suitable as aquatic habitat as well as for primary and secondary contact recreational activities, i.e., swimming, fishing, boating, etc.¹⁹ [footnote 19 text: The varying classifications of the Hudson River, all designate fishing as a “best usage.” See 6 N.Y.C.R.R. §§ 701.5, 701.6, 701.7, 701.8, 701.11, 701.13; See 6 N.Y.C.R.R. § 864.6 (classifying the portion of the Hudson River from the New York State Bronx County line to Bear Mountain Bridge as “Class SB saline surface waters”); 6 N.Y.C.R.R. § 701.11 (“The best usages of Class SB waters are primary and secondary contact recreation and fishing. These waters shall be suitable for fish, shellfish, and wildlife propagation and survival.”).] (0710-4 [Brancato, Deborah] [Musegaas, Philip])

Comment: You could examine each of the resource areas described above and find similar or greater discrepancies. In regard to “aquatic ecology,” fish in the Hudson River have been found to contain traces of strontium-90. The radioactive isotope was discovered leaking at the Indian

Point nuclear power plant; and tests on the fish found detectable amounts, as reported by the Westchester Journal News. (0762-4 [Skopic, Catherine])

Comment: The distinction made between the short term storage impact of ISFSIs and Spent Fuel Pools on Special Status Species and Habitats should be clarified. Table 1 "Environmental Impacts of At-Reactor Continued Storage of Spent Nuclear Fuel,"⁹⁴ [footnote 94 text: 8 Fed. Reg. 56779, 56785-86.] states that "ISFSI operations are not likely to adversely affect special status species and habitats," while indicating that "impacts from the spent fuel pool would be determined as part of Endangered Species Act Section 7 consultation." It is not immediately clear why short term storage in the pools would require consultation while ISFSI storage would not. NRC does explain in GEIS section 4.11.1 that the consultation in the pool case would be to consider the "parameters associated with the spent fuel cooling system," while also observing that the operation of only the spent fuel cooling system after plant shutdown would result in a "decrease in water withdrawal and discharge rates" from what had already been considered in the operating plant's Biological Opinion, and that impacts would "likely decrease." Therefore, the same statement that is made for ISFSI operations is actually also true for pool operations in that there would be no new "adverse" impacts due to short term storage. Table 1 should be revised to make the "not likely to adversely affect" statement equally applicable to pool and ISFSI storage. NRC could caveat the conclusion for pools by clarifying that the agency assumed that the continued operation of the spent fuel pool cooling system did not result in a "take" of a biological species not already covered in the operating reactor's Biological Opinion. Industry does, however, in general agree that the use of consultations would avoid and mitigate protected species impacts. (0827-4-3 [Ginsberg, Ellen])

Comment: GEIS Section 4.10: The discussion of operating plant experience with impingement and entrainment appears to contain information that is not relevant (GEIS 4-36). We recommend that this discussion address only that information which is relevant to support the statement that these impacts are "bounded" by operating plants and "minor" as concluded on page 4-38 of the GEIS (e.g. the comparison of water requirements for a spent fuel pool vs. those for an operating reactor). (0827-7-24 [Ginsberg, Ellen])

Comment: NRC's narrow framework for assessing SFP leak impacts has resulted in an "analysis" which fails to adequately consider other relevant environmental impacts as well. Particularly, NRC's consideration of the impacts posed by SFP leaks on surface water resources is severely wanting and inadequate under NEPA as well as the court's decision. NRC acknowledges that SFP leaks can discharge to offsite surface waters, but then indicates that "dilution ensures that radionuclides" would be "diluted well below EPA safe drinking-water limits." DGEIS at E-17. This limited focus on drinking water-related impacts boils down to a consideration from a public health aspect, and ignores other relevant potential environmental impacts to surface waters, namely impacts to aquatic ecology. Importantly, NRC's restricted consideration of impacts to surface waters is precisely what was deemed by the Circuit Court as insufficient. 681 F.3d at 481. Yet, the DGEIS contains no meaningful analysis of how SFP leaks may impact nearby aquatic habitats and organisms.¹³ [footnote 13 text: In fact, despite the fact that one of the purported focuses of the DGEIS is SFP leaks, the NRC's only consideration of impacts to aquatic ecology focuses on cooling water intake structure impacts, with no meaningful discussion of impacts of radioactive waste storage on such resources. See DGEIS at § 4.10, at pages 4-35-4-41.] NRC must fully analyze the extent to which SFP leaks may contaminate surface waters and the foreseeable impact of such contamination on the aquatic ecology of such waters. Such an assessment cannot be limited to NRC dose calculation methodology, but rather must focus more broadly on impacts to aquatic organisms, with regard for other Federal, State, and/or local standards and requirements. The

DGEIS must consider the length of time surface waters will be contaminated by, and thus, aquatic ecology exposed to, radiological contamination (with due consideration for the fact that SFP leaks may admittedly occur for long periods of time undetected) and the various ways in which different radionuclides have the potential to bioaccumulate in the environment, e.g. in river sediments, sub-aquatic vegetation, shellfish, and finfish. NRC must determine the extent to which aquatic organisms may be impacted over long- periods of time. An evaluation of the impacts of bioaccumulation and long-term exposure to low levels of radioactivity should be conducted by the NRC. NRC should focus attention on long- term exposure impacts to varying fish populations, as well as impacts to individuals within populations. NRC should not assume that a lack of impacts to date (at plants where SFP leaks have already contaminated surface waters) means that no future impacts will occur. See *New York v. NRC*, 681 F.3d at 481. Rather, NRC must fully evaluate the foreseeable future impacts to aquatic organisms that may occur as a result of SFP leaks. (0897-5-15 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: What risks to wildlife survival, and even genetic damage, could result from such exposures to the radioactive waste facilities, over time? (0919-5-17 [Kamps, Kevin])

Comment: At Page 3-27, re: Section 3.9.2.5, beginning at line 18, NRC states: "Other important aquatic species include cephalopods (e.g., squid and octopus), marine mammals (e.g., seals and whales), sea turtles, and reptiles. These species may be present near at-reactor storage facilities; however, because of the significantly reduced water demands for spent fuel pool cooling during continued storage, these larger organisms are more likely to avoid being impinged or entrained by the cooling system, and are therefore not discussed in Chapter 4 of this draft GEIS." But besides risks of impingement or entrainment, what about the ongoing risks from exposure to the radioactive wastes that these species will be subjected to over time, given the coastal locations of nuclear power plants and their radioactive waste storage facilities? (0919-5-18 [Kamps, Kevin])

Comment: Re: Page 4-28, line 32, NRC's statement "The significance of potential impacts on plants and animals and their habitats depends on the importance or role of the plant or animal within the ecological community that is affected."--There are no insignificant species. (Except perhaps humans. Most other species could get by just fine without us.) But we cannot get by without them, we will find out the hard way. NRC's attitude is anachronistic, belonging (never belonging) to a much earlier phase of the "industrial extinction event" humankind has unleashed on the planet. Whether from a Native American spiritual perspective (which NRC should give serious consideration to in this EIS, as an element of EJ), to a Western scientific ecosystem perspective, no species can be regarded as insignificant. Alanis Obomsawin, an Abenaki from the Odanak reserve, seventy odd miles northeast of Montreal, has put it well: "...When the last tree is cut, the last fish is caught, and the last river is polluted; when to breathe the air is sickening, you will realize, too late, that wealth is not in bank accounts and that you can't eat money." (0919-7-14 [Kamps, Kevin])

Comment: On Page 4-32, NRC has stated, beginning at line 16, that "licensees are required to adhere to the protection of eagles and migratory birds under the Federal Bald and Golden Eagle Protection Act and Migratory Bird Treaty Act. In addition, coordination with State natural resource agencies may further ensure that power plant operators take appropriate steps to avoid or mitigate impacts on State species of special concern that may not be protected under other Federal statutes."--Has NRC considered the risk of eagles or other species (osprey, birds that nest on human structures) nesting on/near dry casks, given the lure of the warmth?! Loss of institutional control - no humans around - could worsen this risk. NRC has reported that dry cask storage will increase the ambient air temperature several degrees downwind, out to a distance

of 0.6 miles. What is to prevent this warmth "island" from attracting wildlife, including endangered migratory birds, especially if their prey species are attracted to the warmth? What would be the impact of such species interacting at such close proximity to the radioactive waste storage. After all, mutagenic gamma radiation is allowed to emanate from dry casks at a rate of 10 mRem/hour at distances 6 feet away - and at a rate 20 times higher at the casks' surface. (0919-7-21 [Kamps, Kevin])

29. Comments Concerning Historic and Cultural Resources

Comment: The NRC should be careful and continue to monitor the potential LARGE impact on cultural and historical resources. It would be a horrible tragedy to lose resources that are irreplaceable and unable to regenerate independently. This is my main concern with this project, that under the bureaucratic mess, precious resources could be changed forever. (0007-2 [Anonymous, Anonymous])

Comment: 28 ES.13.1.3 Environmental Justice and ES.13.2.12 Historic and Cultural Resources: When "impacts could be SMALL, MODERATE, or LARGE", in other words, there is no GENERIC way in which these impacts can be addressed by these rules. These impacts must be addressed in each Site Specific EIS. This should be made clear in this document, so that EIS development for each site cannot simply include the Generic EIS and fail to do a Site Specific Analysis for these impacts. (0093-4 [Dennis, Harold E.B.])

Comment: Page 7-7, lines 21-23 and page 7-10 lines 8-11. "The value of reviewing continued storage in site-specific NEPA analyses is difficult to quantify; however, a site-specific analysis of the environmental impacts of continued storage would likely not reveal any new information that cannot be addressed in a generic analysis." The determinations that impacts could be SMALL, MEDIUM, or LARGE for certain impacts in certain scenarios (for example: ES.13.1.3 Environmental Justice and ES.13.2.12 Historic and Cultural Resources) shows that there is information that cannot be addressed in a generic analysis. Therefore, the above statement is false. (0093-7 [Dennis, Harold E.B.])

Comment: We, as Native people, have not granted the permission for this facility, nor the storage of this waste material. The treaties of Guadalupe Hidalgo were never ratified by the United States Government. The plant sits on land that we still own and land is ours. And we're not giving the Waste Confidence Commission permission to move forward with this project, or with, even, the EIS. (0326-2-2 [Collins, Fred])

Comment: Okay, on Roman numeral 41 it says long-term storage and indefinite storage impact could be small, moderate, or large. What? They don't know? (0326-56-3 [Homick, Nick])

Comment: The Draft Generic Environmental Impact Statement has many flaws. It seeks to analyze severe consequences and potential environmental and health impacts generically for all facilities. This makes no sense. We're not aware of another tribal nation whose entire reservation homeland could be rendered uninhabitable by a spent fuel accident. The NRC must conduct a site-specific analysis of environmental impacts. (0328-1-10 [Johnson, Ron])

Comment: The same considerations ought to apply to the ongoing - indeed, potentially indefinite - storage of spent nuclear fuel on Prairie Island. The DGEIS is insufficient because it fails to adequately consider and weigh the long-term viability of the Prairie Island Reservation as a homeland for the Tribe (and the implications for preservation of Tribal life and culture) against the risks of continued, indefinite storage of an ever-increasing amount of spent nuclear fuel. A

spent fuel accident or act of sabotage (even if unsuccessful) would have a devastating socioeconomic impact on the Tribe, and perhaps render the Tribe's reservation homeland uninhabitable. The Tribe cannot simply go out and buy new land and relocate its reservation.⁴⁷ [footnote 47 text: The Indian Reorganization Act (IRA), enacted in 1934, authorizes the Secretary of the Interior to acquire land and hold it in trust "for the purpose of providing land for Indians." 25 U.S.C. § 465; see also 25 C.F.R. Part 151.] It is a long, cumbersome and uncertain process pursuant to which the Tribe must apply to have land placed into trust by the United States for the benefit of the Tribe, and there is no guarantee that its fee-to-trust application would be approved. (0473-16-6 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The Santa Ynez Band of Chumash Indians ("Tribe" or "Chumash") hereby provides the following comments to NRC-2012-0246. (1) SANTA YNEZ BAND OF CHUMASH INDIANS; Located on the Santa Ynez Reservation in Santa Barbara County, California, the Santa Ynez Band of Chumash Indians ("Chumash" or "Tribe") was federally recognized in 1901 and remains the only federally-recognized Chumash tribe in the nation.

<http://www.loc.gov/catdir/cpsoc/biaind.pdf>. The Chumash original territory lies along the coast of California, between Malibu and Paso Robles, as well as on the Northern Channel Islands. The area was first settled about 13,000 years ago and at one time, the Chumash had a total population of about 18,000 people. The Santa Ynez Band of Chumash Indians was eventually relegated to 99-acres which lays entirely in a flood plain, 40 percent of which is within a flood zone near the unincorporated city of Santa Ynez, County of Santa Barbara, California. For many years, few tribal members lived on the Reservation since running water and electricity was not made available to Tribal residents. The establishment of indoor plumbing didn't happen on the Reservation until the 1960s. In late 1970s, the first of the Housing and Urban Development (HUD) homes were built and more tribal members were able to move on to the Reservation. Pursuant to its Articles of Organization, the day-to-day business of the Tribe is governed by an elected Business Committee. The Business Committee has an elected Chairman and selects from within the remaining Business Committee Members a Vice Chairman, Secretary and Treasurer. www.santaynezchumash.org. The Santa Ynez Indian Reservation is located 75 miles south of the Diablo Canyon Nuclear Power Plant near Avila Beach, California and 196 miles north of the San Onofre Nuclear Power Plant between Los Angeles and San Diego, California. In addition the Chumash are less than 100 miles northeast from the Santa Susana Sodium Reactor Experimental (SRE) which was a small sodium-cooled experimental reactor built by Southern California Edison and Atomics International at the Santa Susana Field Laboratory, near Moorpark in Ventura County. SRE has since been dismantled after a reactor incident and the entire Santa Susana Field Laboratory has been declared excess federal property by the General Services Administration. (2) THE NATIONAL HISTORIC PRESERVATION ACT (NHPA); The NHPA requires Federal agencies to consult with any Indian tribe that attaches religious and cultural significance to historic properties that may be affected by a federal undertaking and take those potential effects into account in their decision making. This consultation should occur at the earliest steps in general land management or project planning and may include consultation with Tribes concerning inventory methods, management prescriptions, proposed land uses, and impacts from both human and natural effects. Under the NHPA, prior to approving federal action, agencies must take into account and enter consultation concerning the effects of the action on properties eligible for inclusion in the National Register for Historic Preservation. Under the NHPA amendments of 1992, historic properties of religious and cultural importance to a Native American Tribe may be determined eligible for inclusion on the National Register of Historic Places (National Register or NRHP) and therefore subject to NHPA consultation requirements. The 1992 amendments significantly expanded the provisions

of the NHPA to ensure that Tribal interests are considered in determinations of significance and effect. (0500-1 [Cohen, Sam])

Comment: (3) EXECUTIVE ORDER 13007 "INDIAN SACRED SITES;" President Clinton's E.O. 13007 (1996) on Indian sacred sites directs Federal agencies "to the extent practicable, permitted by law, and not clearly inconsistent with essential agency functions, (1) [to] accommodate access to and ceremonial use of Indian sacred sites by Indian religious practitioners and (2) avoid adversely affecting the physical integrity of such sacred sites." A key feature of this definition is that it is Tribes and appropriate representatives of AI/AN religions who identify which sites are sacred to them, not the Federal Government. (4) EXECUTIVE ORDER 13175 "CONSULTATION AND COORDINATION WITH INDIAN TRIBAL GOVERNMENTS;" On November 5, 2009, President Obama issued a Presidential Memorandum on Tribal Coordination. That memorandum reaffirmed Executive Order 13175, "Consultation and Coordination with Indian Tribal Governments," and emphasized the importance of strengthening government-to-government relationships with Native American tribes. In response to the Presidential Memorandum, NRC staff reviewed the agency's various interactions with Native American tribes, and developed a Commission Paper (SECY-09-0180), entitled "U.S. Nuclear Regulatory Commission Interaction with Native American tribes," dated December 11, 2009. In that paper, the staff noted that the NRC's previous interactions had been limited to a small number of activities under the agency's regulatory authority. The NRC concluded that because a "case-by-case" approach had proven effective in these interactions with Native American tribes by allowing for custom-tailored approaches that met Commission and tribal needs, that no formal policy was needed at that time. (5) TRIBAL TRUST RESPONSIBILITY; The Tribal trust responsibility requires the Federal Government to maintain a fiduciary relationship towards all federally recognized Tribes. The trustee beneficiary relationship between the Federal Government and Indian Tribes has been described as resembling a "guardian-ward" relationship. The trust relationship was first recognized by the Supreme Court in its early decisions interpreting Indian treaties, and the Court's interpretation of the trust responsibility has evolved over the years. (6) UNDRIP; In December 2010, the United States announced support for the United Nations Declaration on the Rights of Indigenous Peoples (UNDRIP). In announcing this support, President Obama stated: "The aspirations it affirms--including the respect for the institutions and rich cultures of Native peoples--are one we must always seek to fulfill...[W]hat matters far more than any resolution or declaration - are actions to match those words." The UNDRIP addresses indigenous peoples' rights to maintain culture and traditions (Article 11); and religious traditions, customs, and ceremonies (Article 12); to participate in decision making in matters which would affect their rights (Article 18); and to maintain spiritual connections to traditionally owned lands (Article 25). (7) ADVISORY COUNCIL ON HISTORIC PRESERVATION (ACHP); As of June 2013 and as updated November 2013, the federal Advisory Council on Historic Preservation (ACHP) approved the UN Declaration on the Rights of Indigenous Peoples. <http://indiancountrytodaymedianetwork.com/2013/06/03/federal-agency-supports-undrip-new-era-tribalfederal-relations-149676>. ACHP will now incorporate the UN Declaration on the Rights of Indigenous Peoples in the National Historic Preservation Act (NHPA) Section 106 review process. (0500-2 [Cohen, Sam])

Comment: Resource Areas in Which Impacts May Be Small, Moderate or Large The GEIS finds that the effects on several resource areas may be small, moderate or large (in short-term, long-term or indefinite storage) depending on site-specific conditions.³ [footnote 3 text: Examples include historic and cultural resources, and environmental justice.] We assume that, in these resource areas, the general GEIS presumption that the effects will be small does not

apply, and that effects will be addressed site-by-site in licensing for short-term, long-term or indefinite storage. (0505-5 [Williams, Jim])

Comment: Reactors Vary in Proximity to Historic and Cultural Resources: Pilgrim for example is in "America's Hometown" and 37 miles from Boston and its rich cultural, historic and educational institutions. The impact on these resources would be far greater than for a reactor located in a remote rural location. (0556-1-21 [Lampert, Mary])

Comment: Staff also states that it "assumes" the site selection of an away-from-reactor storage facility would be "adjusted to minimize impacts on local resources, including historic and cultural resources...but NRC also acknowledges "that in some cases avoiding impacts may not be possible."¹⁵ [footnote 15 text: Draft GEIS at 5-3.] If staff recognize that it is unknown whether impacts may be avoided, then staff cannot make any generic findings regarding impacts to local resources. (0579-10 [Smith, Amanda])

Comment: Historic and Cultural Resources: The draft GEIS assumes replacement of the ISFSI and construction of the DTS during the long-term. Section 4.12 discusses the potential impacts on historic and cultural resources during these events. We do not believe that impacts to historic and cultural resources have been adequately evaluated in the draft Waste Confidence GEIS. As discussed in the draft GEIS, there are two possible license types for ISFSIs: a general license, which is granted by Subpart K of 10 CFR 72 (restricted to operating plants), or a site-specific license, issued under Subparts A through I of 10 CFR 72. According to NUREG-1572, Information Handbook on Independent Spent Fuel Storage Installation, the major advantages of a General License ISFSI are that no additional environmental documents are required (i.e., the applicants Environmental Report (ER) or the NRC's EA). Compliance with NEPA, for General License sites, is via the Certificate of Compliance (CoC) EA for the cask design, not the construction of the ISFSI. The draft GEIS reiterates this by stating that there is no Section 106 (of the national Historic Preservation Act) review. In other words, once a utility has a General License no additional environmental analysis seems to be required. For a Site-Specific license, like the Prairie Island ISFSI, an ER was submitted in 1991 for the original license and more recently by NSPM for the renewal. The NRC issued the original EA in 1992 and has just issued a draft EA for the renewal. Throughout much of the draft GEIS there are many statements alluding to extensive prior land disturbance during the construction of the power plant. There seems to some thought that prior construction all but removed any potential for historic or cultural resources to be present. This seems to be at odds with the statement that "for sites that had conducted field investigations, on average, the number of historic and cultural resources present were 35 per site" (page 4-4 7 of draft GEIS). (0619-1-18 [Mahowald, Philip R.])

Comment: In our own experience with the PINGP Units 1 and 2 and PINGP ISFSI license renewals, reliance on original licensing documents (for either the reactor or the ISFSI) is no guarantee that all historic and cultural resources are either documented or no longer present. That is, license applications for both the PINGP reactor and ISFSI renewals indicated that no archaeological resources were present in the vicinity of the projects. The ASLB disagreed and we subsequently learned, that in spite of extensive ground disturbing activities during the construction of the PINGP Units 1 and 2, there was still the possibility of deep prehistoric archaeological sites across most of the PINGP and that prehistoric archaeological sites could be buried under parking lots, modular buildings or other structures or features within the plant. Past construction activities is no guarantee that historic and cultural resources are no longer present. Currently, there are 68 total ISFSI licenses; of these only 14 are site-specific.⁶ [footnote 6 text: US NRC, 2013-2014 Information Digest, NUREG-1350, Volume 25, August 2013.] While some General License ISFSIs are clearly within the original footprint of power plant construction,

many are not (e.g., the Point Beach General License ISFSI, on the shore of Lake Michigan, is about .5 mile from plant, surrounded by trees and vacant fields). NUREG-1571 also states that because General License ISFSIs are restricted to plants still operating under 10 CFR 50, a utility must apply for a Site-Specific license when the plant is decommissioned. The draft GEIS states that the replacement of the at-reactor ISFSI and initial and replacement DTS would require a site specific review and compliance with the NHP A before a decision is made. Our concern is that once these General License ISFSI goes through the more rigorous site specific licensing process, it will be too late -any potential historic or cultural resources would already have been destroyed by the construction of the General License ISFSI. The final GEIS should discuss how the environmental impacts of General License ISFSI' s would be evaluated before the reactors are decommissioned. (0619-1-19 [Mahowald, Philip R.]

Comment: As we stated earlier, it is not clear how DTS facilities will be evaluated, relative to NEPA. Will DTS be evaluated using NUREG-1748 (Environmental Review Guidance for Licensing Actions Associated with NMSS Programs) or some other guidance? (0619-1-20 [Mahowald, Philip R.]

Comment: [T]he environmental impacts for historic and cultural resources would be SMALL, MODERATE, or LARGE for long-term and indefinite storage timeframes. The magnitude of adverse effect on historic properties and impact on historic and cultural resources largely depends on what resources are present, the extent of proposed land disturbance, whether the area has been previously surveyed to identify historic and cultural resources, and whether the licensee has management plans and procedures that are protective of historic and cultural resources.⁹³ [footnote 93 text: *Id.* at 4-50.] [TVA believes that the impacts would be SMALL.] (0694-3-1 [Shea, Joseph])

Comment: DGEIS Section 4.12 assumes that the environmental impacts for historic and cultural resources could be SMALL, MODERATE, or LARGE for long-term and indefinite storage timeframes. TVA agrees with NEI's comment that this impact should be SMALL for all continued storage scenarios.⁹⁷ [footnote 97 text: NEI comments.] (0694-3-5 [Shea, Joseph])

Comment: [E]nvironmental impacts for historic and cultural resources would be SMALL, MODERATE, or LARGE for long-term and indefinite storage timeframes. The magnitude of adverse effect on historic properties and impact on historic and cultural resources largely depends on what resources are present, the extent of proposed land disturbance, whether the area has been previously surveyed to identify historic and cultural resources, and whether the licensee has management plans and procedures that are protective of historic and cultural resources.⁷⁶ [footnote 76 text: *Id.* at 4-50.] [TVA believes that the impacts would be SMALL.] (0697-2-10 [Bessette, Paul] [Kuyler, Raphael])

Comment: DGEIS Section 4.12 assumes that the environmental impacts for historic and cultural resources could be SMALL, MODERATE, or LARGE for long-term and indefinite storage timeframes. Entergy agrees with NEI's comment that this impact should be SMALL for all continued storage scenarios.⁷⁹ [footnote 79 text: NEI Comments.] (0697-2-14 [Bessette, Paul] [Kuyler, Raphael])

Comment: Specifically, Entergy already has a large area of previously disturbed land at its sites that could be used for the construction of any expanded storage facilities. Entergy would also mitigate any adverse effects on historic resources. Entergy has appropriate management plans and procedures that are protective of historic and cultural resources, and these activities

would be subject to further consideration of historic and cultural impacts during future regulatory activities. (0697-2-15 [Bessette, Paul] [Kuyler, Raphael])

Comment: NEI disagrees with NRC's determination that impacts to historic and cultural resources in the long term and indefinite scenarios could be moderate or large. To the contrary, historic and cultural resources impacts can, and likely will, be avoided for all continued storage scenarios. During facility-specific licensing actions all requirements of the National Historic Preservation Act (NHPA), NEPA, and NRC regulations must be met, which provides further assurance that unavoidable impacts will be mitigated. The conclusion for all continued storage scenarios should be that cultural and historic impacts will be small. (0827-4-4 [Ginsberg, Ellen])

Comment: Historic and Cultural Resources Sections (At-Reactor Continued Storage): In the discussion of historic and cultural resources impacts for at-reactor, long-term⁹⁷ [footnote 97 text: *Id.* at Section 4.12.2, pp. 4-49 and 4-50.] and indefinite storage⁹⁸ [footnote 98 text: *Id.* at Section 4.12.3, pp. 4-50.] there is an inappropriate conclusion that moderate or large impacts to historic and cultural resources could result. It should be recognized that for long-term or indefinite storage at decommissioned reactor sites, there will be a large area of previously disturbed land that could be used for the construction of storage facilities and a DTS (if necessary). Therefore, an ISFSI or DTS can be sited to avoid significant historic and cultural resources. This assumption is similar to the assumptions made in other sections of the GEIS for special status species and habitat. (0827-4-6 [Ginsberg, Ellen])

Comment: The conclusion that ISFSIs and DTS facilities can, and likely will, be sited in a manner that avoids moderate or large impacts on cultural resources is supported by the discussion in several sections of the GEIS, including: • Section 4.12, page 4-48, lines 6-8, which states: "If adverse effects on historic properties are identified, appropriate mitigation can be developed through consultation with the State Historic Preservation Officer, tribal representatives, and other interested parties." • Section 4.12.1, page 48, lines 31-33, which states: "[I]mpacts could be mitigated if the licensee has previously identified historic and cultural resources and has management plans and protective procedures in place." • Section 4.12.2, page 4-49, lines 25 and 26, which states: "The replacement of the at-reactor ISFSI and initial and replacement DTS would require a site-specific environmental review and compliance with NHPA requirements before making a decision on the licensing action." These statements support a reasonable assumption that licensees would avoid or mitigate any large or moderate impacts on cultural and historic resources resulting from construction of storage or DTS facilities. The NRC recognizes the inherent reasonableness of this assumption on pages 4-49 and 4-50 of the GEIS, which state: Given the minimal size of the replacement ISFSI and initial and replacement DTS, and the large land areas at nuclear power plant sites, licensees should be able to locate these facilities away from historic and cultural resources. Potential adverse effects on historic properties or impacts on historic and cultural resources could also be minimized through development of agreements, license conditions, and implementation of the licensee's historic and cultural resource management plans and procedures to protect known historic and cultural resources and address inadvertent discoveries during construction of the replacement at-reactor ISFSI and initial and replacement DTS. * * * * * If replacement activities occur in previously disturbed areas (i.e., in areas that have previously experienced construction impacts) then impacts on historic and cultural resources would be SMALL. Therefore, historic properties would not be adversely affected. It is reasonable to assume that any new construction at a decommissioned nuclear power plant site would be on the large area of previously disturbed land. Thus, the NRC should conclude that the ISFSI and DTS (if there is one) can be sited to avoid significant historic and cultural resources, much like the appropriate assumption made for special status species and habitat made in other sections of the GEIS. In

sum, the conclusion for at-reactor continued storage should be that cultural and historic impacts will be small for all timeframes. (0827-4-7 [Ginsberg, Ellen])

Comment: Historic and Cultural Resources Sections (Away-From-Reactor Continued Storage): Like at-reactor continued storage, NEI believes that the impacts on cultural and historic resources for away-from reactor continued storage are properly characterized as small for all timeframes. This conclusion is supported by the discussion already provided in several sections of the GEIS, including: • Section 5.12.1 (pages 5-34 and 5-35) provides a rationale explaining why any historic and cultural resources impacts would be minimal. Lines 18 and 19, p. 5-34 discuss how any ISFSI or DTS license would require NRC NEPA review and meet NHPA requirements. Lines 26 and 27 on p. 5-34 state, "Resolution of adverse effects, if any, should be concluded prior to the closure of the Section 106 process." Lines 12-26 on p. 5-35 list ". . . several factors [that] could avoid, minimize, or mitigate impacts." • Section 5.12.2, Long-Term Storage (pages 5-36 and 5-37) makes much the same arguments for the avoidance or mitigation of impacts. Further, page 5-37 states: Given the large land area available around the ISFSI restricted area, the licensee should be able to locate the replacement facilities away from historic and cultural resources. Potential adverse effects on historic properties or impacts on historic and cultural resources could also be minimized through the development of agreements, license conditions, and implementation of the licensee's historic and cultural resource management plans and procedures to protect known historic and cultural resources and address inadvertent discoveries during construction of the replacement ISFSI and initial and replacement DTS. • Section 5.12.3, which addresses indefinite storage, merely points to the discussion regarding long-term storage. These passages reveal that the rationale for characterizing the impacts of away-from-reactor storage on historic and cultural resources as small for all timeframes is already provided in the GEIS. ISFSIs and DTS (if any are necessary) can be sited (or replaced) to avoid significant historic and cultural resources. This conclusion is analogous to the conclusions reached for special status species and habitat that are included in other sections of the GEIS. In sum, the conclusion for away-from-reactor continued storage should be that impacts on cultural and historic resources will be small for all timeframes. (0827-4-9 [Ginsberg, Ellen])

Comment: On Page 3-31, lines 10-11, NRC states "the NRC reviewed historic and cultural resource reviews that were performed for 40 license renewals." The Don't Waste MI/NIRS intervention against the 20-year license extension, from 2005 to 2007, featured a Historic and Cultural Resources proposed contention, as well as extensive public comment on the EIS component of the proceeding. Although the ASLB panel refused to grant a hearing on the merits of the contention, NRC staff was pressured to bring in additional expertise to address our allegations of significant cultural resources on-site put at risk for the license extension. NRC claimed to have reached a strict agreement with the nuclear utility to assure protection of the Native American cultural resources already identified, and those that have not yet been, located on the Palisades site. The environmental intervention and comment made a significant difference for the better in that proceeding. (0919-5-20 [Kamps, Kevin])

Comment: At Page 3-31, line 20, where NRC states "It is unlikely that historic and cultural resources are present within heavily disturbed areas," they failed to clarify that this is because the damage is already done. Any resources formerly located there have long since been destroyed. (0919-5-21 [Kamps, Kevin])

Comment: Upon review of the NRC's Draft GEIS, the HPO [New Jersey State Historic Preservation Office] broadly concurs with the report's findings regarding at-reactor and away-from-reactor ISFSIs at it relates to impacts on historic and cultural resources (historic properties)

subject to Section 106 of the Natural Historic Preservation Act. However, the HPO does not agree that an entire power block is "extremely disturbed" with no possibility for any surviving pockets of archeological sensitivity unless there is supporting documentation from the original station construction to support such an assumption within any particular area of potential effects (APE). (0920-51 [Foster, Ruth])

Comment: In the discussion of historic and cultural resources impacts for at-reactor long-term storage, Exelon believes there is an inappropriate conclusion that the possibility of moderate or large impacts to historic and cultural resources could exist. It should be recognized that for long-term or indefinite storage at decommissioned reactor sites, there will be a large area of previously disturbed land that could be used for the storage facilities and a possible Dry Transfer System (DTS). A more reasonable assumption would be that the Independent Spent Fuel Storage Installation (ISFSI) can be sited to avoid significant historic and cultural resources much like the appropriate assumption made for special status species and habitat made in other sections of the GEIS. Therefore, historic properties would not be adversely affected. It is reasonable to assume that, at a decommissioned nuclear power plant site, any new construction would be on the large area previously disturbed in an effort to avoid any undisturbed areas. The GEIS seems to reach an unreasonable conclusion regarding the possibility of large historic and cultural impacts. The rationale is already included in the discussion to conclude that impacts will likely be small. Exelon believes that the conclusion for at-reactor continued storage should be that cultural and historic impacts will be small for all phases. (0942-5 [Helker, David P.])

30. Comments Concerning Noise

Comment: Page 3-32, re: noise that is "otherwise annoying" or irritating "will live gunfire exercises, for security personnel training, continue forevermore into the future at irradiated nuclear fuel storage sites, as they do currently at nuclear power plant sites? (0919-6-1 [Kamps, Kevin])

31. Comments Concerning Aesthetics

Comment: The Draft GEIS notes that the PFS FEIS determined the aesthetic impacts to be small to moderate and similarly concludes that the impacts at an away-from-reactor ISFSI would also be small to moderate.³¹ [footnote 31 text: Draft GEIS at 5-41.] Again, whether aesthetic impacts are small or large is site dependent. For example, local researchers raised substantial concerns that light pollution from the PFS facility would destroy their research, having a substantial aesthetic impact. (0579-16 [Smith, Amanda])

32. Comments Concerning Waste Management

Comment: Waste, of any kind, is always an issue that should be considered for the health and safety of communities. Ordinances at the local level and bills at both the state and federal level exist to direct the handling of solid waste and hazardous waste, to protect the air and our waters so they are clean and nourishing. One type of hazardous waste has gotten little attention: radioactive waste, because it's relatively new. We need our elected and appointed officials to diligently seek out solutions to storing these wastes and to do so carefully and thoughtfully. (0085-1 [Davison, Heidi])

Comment: And one thing I read in the first few pages, in fact, why aren't the pages numbered here? They're all in Roman -- so on page Roman III.1.19 section, it says it's not going to consider at all anything to do with Class C radioactive waste or greater. That's the most dangerous, that's the most highly contaminated stuff. All of that stuff, all that rubble is going to go to Andrews, Texas. How are you going to get it there? It's going to go through four or five states, hundreds of towns, and this is not dangerous? So, all that rubble that you blow up and destroy, and all those pipes and valves and everything else that's radioactive is -- what about that? It's not really addressed in here. What about Class A and B low-level waste? Low-level waste is not dangerous according to the NRC for the adult male, but it is dangerous to babies and children, and the human fetus, so I'd like to see more about that. (0325-31-4 [Johnson, Roger])

Comment: I'm liking the words that the NRC are throwing around. Confidence. I feel better, don't you? This new green program. Decontamination, recycling, which is real special. Harmonize, water down. A few things stick out in my mind. One of this recycling things, it says in 2012, along bicycle baskets, tissue holders, pet food bowls that were constructed unknowingly with radioactive metals were pulled from the U.S. global markets. Isn't that nice? It was unknowing. So it's floating around, and nobody knows where the hell it's going. But, whatever, that's cool. So they're going to handle all the decontamination of large nuclear equipment, millions of pounds of metal can be reused. And it's already secured two large contracts, this new green, and has plans for future development. So there's jobs there. (0327-22-1 [Muser, Mary Jo])

Comment: ...and the proposal to recycle radioactive waste into the commercial metal stream - into our pots and pans, zippers, bedsprings, toys, and virtually everything we live with and come into contact with. (0381-12 [Fasten, Susan])

Comment: Considering that materials classified as LLRW can contain long-lived species, information should be provided on the types and concentrations of radionuclides present in cask wastes for all types of casks, storage mode, and ISFSI location factors. LLRW disposal sites across the nation have all leaked presenting, depending on the leaked constituents, environmental risks that must be analyzed. (0553-11 [Wilshire, Howard])

Comment: The DGEIS section on Low-level Radioactive Waste Management (3.14.1) treats LLRW impact generically but some reactors, such as Pilgrim, are in states that are not part of any compact. Non-compact states will have onsite LLRW generated during operations, post operations and in decommissioning activities. LLRW will present environmental concerns different from reactors having access to disposal facilities. Also all reactor types are not the same. BWR's generate approximately twice the LLRW of PWRs. (0556-1-27 [Lampert, Mary])

Comment: [T]he environmental impacts for waste management of nonradioactive waste would be SMALL to MODERATE for indefinite storage, because it is difficult to accurately estimate the amount that would be generated over an indefinite timeframe.⁹⁴ [footnote 94 text: *Id.* at 4-61.] TVA believes that the impacts would be SMALL. (0694-3-2 [Shea, Joseph])

Comment: [T]he environmental impacts for waste management of nonradioactive waste would be SMALL to MODERATE for indefinite storage, because it is difficult to accurately estimate the amount that would be generated over an indefinite timeframe.⁷⁷ [footnote 77 text: *Id.* at 4-61.] These general conclusions regarding environmental impacts apply to Entergy's plants, although Entergy believes that all impacts would be SMALL. (0697-2-11 [Bessette, Paul] [Kuyler, Raphael])

Comment: So-Called "Low-Level" Waste[:] NRC makes unrealistic, inadequate and highly speculative assumptions to dismiss potential environmental and health impacts from the so-called "low-level" radioactive generated along with and a result of the generation, storage, treatment and disposal of irradiated/spent fuel and high level radioactive waste. It can contain all the same long lasting radionuclides as irradiated fuel and high level waste, sometimes even in higher concentrations, but NRC assumes without calculations or analysis that impacts will be "SMALL" under all three scenarios--short term, long term and indefinite storage. On page xxix of the GEIS, NUREG 2157, NRC describes "low-level" radioactive waste as "a wide range of items that have become contaminated with radioactive material or have become radioactive through exposure to neutron radiation. The radioactivity in these wastes can range from just above natural background levels to much higher levels, such as seen in parts from inside the reactor vessel in a nuclear power reactor" The U.S. General Accounting Office on pages 49-52 of GAO RCED-98-40R (B-278691 , May 1998) confirmed that •"low-level" radioactive waste includes virtually everything from a nuclear reactor except the spent fuel •"low-level" radioactive waste can contain every radionuclide found in "high-level" waste •when plutonium, cesium-137, strontium-90 and similar materials are inside the fuel, they are high-level; and that when they leak out of the fuel, as happens during reactor operations, and are collected in filters and ion-exchange resins, these same materials are considered "low-level" •at a maximum Class C ("low level") waste limit of 4,600 curies, unshielded cesium-137 would yield a lethal dose to 50 percent of a hypothetically exposed population at a 1-meter distance in approximately 20 minutes... The point is that "low-level" radioactive waste is not low risk and its impact should not be considered SMALL. (0711-11 [Olson, Mary])

Comment: NRC unjustifiably concludes that the amount of "low-level" radioactive waste generated in the short and long term scenarios is less than the amount already being generated by reactor operations and decommissioning thus its impact is SMALL, not significant. NRC is irresponsibly saying that because there is already some amount of waste, additional waste can be added to it without consequence. This ignores that (1) the vast majority of the radioactivity is from the irradiated fuel in the first place and (2) there very likely could be no disposal site for it. It further ignores the failed history of "low-level" radioactive waste disposal sites in the US, most if not all of which have leaked or are leaking. There is no data provided in the GEIS to conclude that sufficient capacity will be available when needed—at least if we still live in a democracy at that time. (0711-12 [Olson, Mary])

Comment: One of the irresponsible consequences of not being able to permanently isolate so called "low-level" radioactive waste is the pressure by generators and government agencies to release the less concentrated portions from radioactive controls in essence dispersing the radioactivity into the marketplace, populace and biosphere. These consequences are potentially very significant to those exposed but are completely ignored in the GEIS. (0711-13 [Olson, Mary])

Comment: How much so-called "Low-Level" radioactive waste is generated during changing dry casks over time? If dry casks + recontainerization are used for the entire period that this waste will be a hazard, how long is that? (0711-37 [Olson, Mary])

Comment: NRC fails to adequately consider all the waste generated producing the fuel that has become this waste. We also believe that NRC has underestimated the waste that is generated in waste management and storage. NRC also assumes that all the highly radioactive spent nuclear fuel is homogeneous. (0711-8 [Olson, Mary])

Comment: Under section ES13.1.15, pages xli and xlii, lines 21-34, and 1-11, respectively, lower level waste management or disposal of the same is assumed to be available. However, as

described in more detail below, this presumption may prove to be false since currently there are very limited options for the disposal of low level waste. With the continued radioactivity in these wastes, there is a possibility that there may not be a private facility open or one that would accept certain levels of waste unless this was supported by the Federal Government. This analysis must be supplemented and described in more detail. (0783-1-17 [Harlan, Thomas])

Comment: On page 1-17, lines 16-20, there is assumption that sufficient low-level waste will be disposed of properly. This assumption is false. The industry today is facing difficulty in disposing of low-level waste and it is anticipated that low-level waste will be stored at the facility until such time that it is disposed of properly. Because of this storage alongside of spent fuel, the assumption must be removed and properly analyzed within the scope of the Draft GEIS. (0783-2-13 [Harlan, Thomas])

Comment: Under section 6.4.14, starting on page 6-45 and running to 6-50, the Draft GEIS analyzes the cumulative impacts of waste management. Its analysis must be modified to include, or at least account for, the fact that there may not be a facility available at any time in the near future to handle the waste generated by continued storage. The alternative, of course, is that even after removal of the spent fuel the low-level radioactive waste will continue to need to be stored and paid for by the generator. (0783-3-14 [Harlan, Thomas])

Comment: Under section 4.15.2.1, starting on page 4-58 and carrying over to page 4-59, the Draft GEIS discusses low-level radioactive waste that is going to be created as a result of continued storage. The underlying presumption, again, is that this low-level waste is going to be properly disposed of by the industry. This assumption, as stated before, may not be accurate. Currently, there are some facilities for the storage of low-level waste until a permanent depository can be created. However, this is not available for all generators and therefore must be stored until a facility is made available. (0783-3-5 [Harlan, Thomas])

Comment: p. 4-55 to 4-61. Waste Management. "This section describes potential environmental impacts from low-level radioactive waste (LLW), mixed waste, and nonradioactive waste management and disposal caused by the continued storage of spent fuel in spent fuel pools and at-reactor ISFSIs." Low-Level Radioactive Waste. For the Long-Term and Indefinite time frames in which casks would be replaced, disposal of cask materials that have been contaminated by contact with SNF rods will be disposed as Low-Level Radioactive Waste (LLRW). **Comment:** Considering that materials classified as LLRW can contain long-lived species, information should be provided on the types and concentrations of radionuclides present in cask wastes for all types of casks, storage mode, and ISFSI location factors. LLRW disposal sites across the nation have all leaked presenting, depending on the leaked constituents, environmental risks that must be analyzed. (0805-11 [Wilshire, Howard])

Comment: *Sufficient low-level waste (LLW) disposal capacity will be made available when needed. Historically, the demand for LLW disposal capacity has been met by private industry. NRC expects that this trend will continue in the future. For example, in response to demand for LLW disposal capacity, Waste Control Specialists, LLC, opened a LLW disposal facility in Andrews County, Texas on April 27, 2012.* This assumption may be unrealistic and fails to address the increasing costs of LLW storage. For example, as liability and costs concerns rise, it may not be a desirable business model to be in waste disposal in the future. (0867-2-19 [Griffin, William])

Comment: The DGEIS assumes that LLW storage for all of the materials will be available in a timely and cost-effective manner. The NRC produces a periodic report on the problem

(NUREG1307 Rev 15). The report indicates that some facilities do not have a LLW disposal facility available. The report must assume costs for these facilities because of the lack of low level waste storage. Additionally, the year-to-year price increase from 2010-2012 was 12%. The increase in fees is due to the changes in the fees charged by the commercial operators. Such inflationary pressures are not addressed in the DGEIS. This problem is assumed away in NUREG-1307]. These two considerations make the DGEIS assumptions that there will always be LLW storage and that its costs will be addressed in current levels of funding unrealistic. (0867-3-9 [Griffin, William])

Comment: During the Long-Term and Indefinite periods, Low Level Radioactive Waste (LLRW) will be generated on site during the repackaging of SNF, including the SNF canisters. Several references are made that waste would be processed by compaction, again including the replaced storage canisters. Temporary on-site storage of the waste is not addressed, nor is there any discussion of the waste compaction activities that will be performed, by either site personnel or contractors. The GEIS assumes "Sufficient LLW disposal capacity will be made available when needed." However, given the failures of some of the proposed compacts, and the time it takes to develop and license a new disposal site, the required LLRW capacity may not be as "available when needed" as stated and the waste would have to be stored on-site, which is less than satisfactory, and will continue to be an added burden to State and local governments. Additional details describing the on-site LLRW program must be included in the GEIS. The description must address temporary on-site LLRW storage, on-site compaction of LLRW including the SNF canisters, and the mandatory alternative actions that will be taken in the event permanent LLRW disposal facilities are not available when needed. Public and Occupational Health impact must also be reassessed in connection with an expanded description of the LLRW on-site activities[.] (0913-11 [Bevill, Bernard])

Comment: On Page 1-17, lines 16-20, NRC makes the flippant assumption that: "Sufficient low-level waste (LLW) disposal capacity will be made available when needed. Historically, the demand for LLW disposal capacity has been met by private industry. NRC expects that this trend will continue in the future. For example, in response to demand for LLW disposal capacity, Waste Control Specialists, LLC, opened a LLW disposal facility in Andrews County, Texas on April 27, 2012." NRC neglected to mention that several career Texas state environmental protection agency officials resigned their jobs, and careers, in protest over the decision to open WCS, nor that WCS now threatens the Ogallala Aquifer - essential to numerous Great Plains States for drinking and irrigation water - with radiological contamination. (0919-3-6 [Kamps, Kevin])

Comment: Re: Page 3-36, Section 3.14.4, Nonradioactive, Nonhazardous Waste, at Big Rock Point in MI, radioactive waste was simply treated as if it weren't, and was dumped in the Waters Twp., MI household trash landfill. Such "clearance level" or "below regulatory concern" exemptions permitted by NRC are unacceptable. (0919-6-2 [Kamps, Kevin])

Comment: Re: line 31, "Waste minimization techniques employed by the licensees may include source reduction and recycling of materials either onsite or offsite"...This is quite Orwellian - "recycling" hazardous wastes? Into WHAT?! What are the risks to people and the environment of doing that? What is the motivation? To save industry money on disposal costs for toxic waste? (0919-6-3 [Kamps, Kevin])

33. Comments Concerning Transportation

Comment: Trucking (or transport) of radioactive waste to the disposal site must be made in lead-lined containers, on routes which do not cross ANY populated areas or important farm/crop land. We have seen too often the horrific accidents creating hazardous waste spills from accidents to rail and truck transport in populated areas. We cannot afford to further put our land and citizens at risk. Short of this, there is no waste confidence in the disposal of nuclear fuel. (0006-2 [Van Wicklen, Betty J.]

Comment: Nuclear waste should not be transported anywhere else for "disposal", it should be stored at the reactor site where it originated. (0012-2 [Swanson, Mark])

Comment: Transporting nuclear waste to temporary waste dumps is irresponsible and dangerous. (0023-4 [Bridges, Martha])

Comment: Local conditions about our railroads and bridges, we got a hairpin curve right on the art museum a couple of blocks from midtown. And I'll tell you, I hope somebody walks those tracks before a trainload of nuclear waste goes through. (0030-14-3 [Lewis, Marvin])

Comment: The radiological impacts from spent fuel transportation conducted in compliance with the NRC Regulations are low. The NRC also concluded that regulations for transportation of radioactive material were adequate to protect public against unreasonable risk. NRC concludes that radiological impacts were incidents free and accident transportation of spent fuel from a single at-reactor storage facility to repository would be small. The same conclusion is reached with respect to a system-wide inventory. I want to list the assumptions that go into this, which I think are invalid, which I hope the Commission will address in its final report, if a Supplemental Impact Statement is compiled. The radiological doses seem to be based on an assumption that there will be only external exposures to radioactive materials, and that there will be no contaminations, say, on the outside of a shipping container. (0045-3-1 [Haggerty, Bernard])

Comment: There's also a peculiar, the Draft Environmental Impact Statement pieces together, I don't know what the technical term for this, but it pieces together a large number of transportation studies of various kinds, including two of them from 1972 and 1975, which really need to be updated. Since those dates, the Interstate Commerce Commission has been eliminated and replaced with the Service Transportation Board. And I think my basic comment here, is that the assumption of institutional controls, and the express assumption that transportation regulation is adequate is just false, and needs to be re-examined. Here's what I've learned, and this is the purpose of my visual aid, is an example of what I take to be an obvious violation of the transportation safety regulation. The safety regulations require the commercial vehicles transporting hazardous materials to use extreme caution. And when the weather is bad, basically, they're required to pull over. This is a, I don't know if you can see it from where you are, but this is a truck carrying radioactive materials. I suspect it's from Tennessee on its way to Idaho National Engineering Laboratory. On this particular day, Interstate 80 is covered in a polished ice coating. And this truck, pretty clearly, was in violation of the transportation safety regulations. If you want to hold it for a second, that's fine, or you can set it down. It's has illustrated my point. So I correspond, and I've done this several times, with the Federal Motor Carrier Safety Administration, which presumably regulates and monitors violations of transportation safety regulations. And their response in written form to the Congressman, who helped me get this response, was "the Federal Motor Carrier Safety Administration believes that the judgment about weather conditions should be left to professional truck drivers, the police, State, and local officials." In other words, the Federal

Motor Carrier Safety Administration does not monitor or enforce the transportation safety regulations that apply to shipments of radioactive materials. And I think this is in direct contradiction to the assumption stated in the Section I quoted. And so some digging needs to be done before a final Impact Statement is made. (0045-3-2 [Haggerty, Bernard])

Comment: Let me quote to you, from a description of an incident that wasn't just a weather-related violation of the transportation regulations. November of 1996, a tractor trailer overturned on an icy road in Northern Nebraska, while carrying two nuclear warheads to a decommissioning facility in Texas. And this is from an article in the Bulletin of the Atomic Scientist by Robert Alvarez. Nebraska officials criticized the Department of Energy for failing to follow protocols that required advanced notice about such shipments. They also raised concerns about their transportation of route, which required the trucks travel in an area hours away from the nearest equipment capable of salvaging the truck from the ditch. (0045-3-3 [Haggerty, Bernard])

Comment: Later, a former DOE official disclosed that the radiation monitoring equipment on the truck had been removed, by order of the Department of Energy. Apparently, in September of 1996, one of the drivers had claimed that his daughter died from a rare brain tumor, because of his exposure to radiation at work. And in response, the Department of Energy ordered the monitors removed. So two months later when the truck carrying the warheads crashed the Department of Transportation had no way of knowing whether that had been a radiation leak. To me, these are examples of the absence of effective institutional controls in the Continental Scale Transportation Project that will accompany any, either interim storage, or off-site permanent repository. (0045-3-4 [Haggerty, Bernard])

Comment: I'm opposed to the option of off-site storage, in any form, and I think that the Nuclear Regulatory Commission should not express any confidence in any plan that requires transportation off the site where radioactive materials are produced. (0045-3-5 [Haggerty, Bernard])

Comment: A national waste repository would create new and complex safety problems for our nation. If a national waste repository opened it would result in tens of thousands of shipments of high-level radioactive spent fuel and other nuclear waste across the United States, raising the spectre of weather- or transport-related accidents or terrorism in the states through which the spent fuel travels. If 10-mile emergency evacuation plans for areas surrounding all nuclear plants are required, shouldn't there be a similar requirement for areas surrounding the corridor across which the spent fuel would travel? Is this increased threat to national security worth the cost or risk to public safety? (0064-5 [Skud, Bruce])

Comment: This country should not transport nuclear waste nor should we store it in containers that do not protect us and the environment. (0076-2 [Jensen, Phyllis])

Comment: This spent fuel must never be transported via road/highway for long distances (over 50 km) and when transported via road/highway, every precaution must be taken to prevent vehicles operated by those unrelated to said movement from possibly causing an undesirable incident. Transport over distances greater than 50 km. should be discouraged, but when absolutely necessary, accomplished via rail, and measures to maintain security and the safety of the public must be implemented. This would include routing around densely populated areas and away from potable water supplies. (0080-1 [Emerson, Willis])

Comment: Even the casks approved by the NRC for on site storage are not safe enough for transport and so will not be sufficient to safely deal with environmental conditions (sea level or river rise, severe flooding, etc) that require removing casks stored on site to some more secure location. (0086-3 [Lewis, Carol])

Comment: [S]outhern indiana164 bypass around evansville just out of evansville, indiana.on my way to work one morning a small truck was rolled over on the highway. i slowed down to see if someone needed help. a head of me on a hill was the fire department, i stop to ask what was going on with the truck down the hill. in ones hand was a picture book of difference truck signs. it show the truck to be carrying radioactive waste from a mfg. plant in Tennessee. they ask if there was anything inching out of the truck. they told me they can not do anything until someone shows from up from the highway dept. and the nuclear dept. to tell them what to do with the truck. 8 hour later i drove bye to leaner they had just finish up with the truck and there be no info on the news that night. no one was to know about the waste moving there indiana. (0094-1 [Edwards, Greg])

Comment: In the remote possibility that a national repository actually opens it would result in tens of thousands of shipments of spent fuel across the nation, raising the specter of catastrophic accidents or terrorism. If nuclear plants are required to have evacuation zones, shouldn't there be a similar requirement for these spent fuel transportation corridors? At the end of the day is this new serious threat to national security really worth the environment and public safety risk? (0112-10-4 [Skud, Bruce])

Comment: Nuclear waste should not be transported and stockpiled in "interim" sites around the country, as the cost to taxpayers and risk to communities of moving this deadly cargo are too great. (0143-6 [Arauz, Jorge])

Comment: The sheer volume of nuclear waste will require thousands of shipments on our roads, rails, and waterways. Due to the risk involved in mass nuclear waste transportation, it should only be undertaken once--and when we know there is a viable solution. (0147-5 [Fallon, Gloria])

Comment: I don't want nuclear waste traveling through my city enroute to a storage facility. (0158-3 [Payne, Joanne])

Comment: Regarding storage of nuclear waste both here and across the country, I firmly believe that the risks of transportation are greater than the risk of storage onsite. Transporting highly radioactive fuel over the highway is a specter of many possible errors and accidents, collisions, mechanical breakdowns, spills, and inexperienced Hazmat personnel in areas far from any nuclear facility. (0163-20-7 [Gellert, Sally Jane])

Comment: Consider the attached article, "Burning truck hauling nuclear load flies under radar," 10/31/13 Toronto Star. (0174-13 [Thomas, Ellen] [Thomas, Ruth])

Comment: Secondly, we must not transport the waste ...anywhere...keep it where it is. (0177-3 [Craig, Anne])

Comment: As a Commissioner, I had the opportunity to participate in a 100+ mile used fuel train shipment between Duke's Brunswick and Shearon Harris plants in eastern North Carolina. The utility demonstrated extraordinary care and skill in conducting this shipment and their coordination with state and local law enforcement authorities was exceptional. (0180-4 [Merrifield, Jeffrey])

Comment: I appreciate the opportunity to offer my testimony to the Commission, regarding transportation of highly radioactive waste to "temporary" storage sites. Would not the proposed transportation of radioactive waste establish "consolidated interim storage" sites for high-level radioactive waste, initiating transport of tens of thousands of casks of lethal radioactive waste on our roads and railways for the primary benefit of the nuclear power industry, while endangering the health and safety of millions of Americans? (0189-1 [Patrie, MD, MPH, Lewis E.])

Comment: With the real potential for serious transportation mishaps and disasters on our highways and railways, I do NOT want to see any more high-level radwaste coming to (or going through) "NUCLEAR ILLINOIS: THE LAND OF LINCOLN." Illinois should NOT store an additional 9,000 tons of irradiated nuclear reactor fuel rods from our nation's closed reactors, that would come to a proposed "CENTRALIZED INTERIM STORAGE" radwaste facility here. (0196-5 [Nelson, Dennis R])

Comment: Nor should we transport this waste, endangering everyone on the route. (0226-1 [Garden, Claire])

Comment: My letter is for road safety. Although my state may not be a state within routes holding shipments of radioactive waste it is my concern because it would only be fair to the people who may find themselves without knowledge of your operations planning. Not all people have the knowledge of nuclear operations as I do and some do not even know anything regarding protest and activist activities that bring awareness to operations that cause harm to the environment. I am not here to ask you anything but to consider reviewing the options of your storing and transporting. Since you have obligations it would only be fair that you have that opportunity to continue but to transport in any unsafe or risk taking that puts people in harms way should be a discussion with state and federal officials that they assist you with funding of a route that will not be shared. In the event there is an accident that would be covered and followed through a set of regulations that you may be capable of handling and avoiding a threat to the public. (0228-1 [Wilson, Lavern])

Comment: Second thing is limit spent fuel transportation. Onsite storage also would save unnecessary transportation costs and reduce radiation exposure risk to the general population during highway road and barge transit. These risks could be significant because even undamaged transport casks do not have enough shielding to prevent gamma and X-ray radiation from escaping through the vault. (0245-29-3 [Shineflug, Marilyn])

Comment: Mass transportation of nuclear waste is insane. The sheer volume of nuclear waste will require thousands of shipments on our roads, rails, and waterways. (0245-37-2 [Bilenko, Stephanie])

Comment: Centralized or consolidated storage in temporary sites would involve significant waste handling and thousands of trips moving waste and just inherently increasing the likelihood of the various kinds of accidents. In Maryland, we are particularly concerned about environmental impacts, including water contamination in the Susquehanna River or our treasured Chesapeake Bay from the reactors at Calvert Cliffs, Peach Bottom, and the other reactors throughout the watershed. (0246-13-2 [O'Leary, David])

Comment: Again going back to the transport issue, we have concerns. Calvert Cliffs, in its location -- and this is true of other reactors around the country, but using Calvert Cliffs as an example -- transporting that waste would bring it past major metropolitan areas like Washington, D.C. and there really are no other obvious ways to move that waste around. (0246-13-3 [O'Leary, David])

Comment: And we shouldn't be having high-level nuclear waste being transported through states to go to into permanent places that are not -- have no safety or any more safety than where they are at. We need to keep everything on the site where it is right now in order to not create other accidents. (0246-16-6 [Michetti, Susan])

Comment: I keep hearing that we will be transporting our waste to a permanent site. Of course you all know that no such site has been identified. We all know that Yucca Mountain has been closed. So what is the idea of transporting masses of waste on our roads, leading through communities, having the risk of accidents? It is undoable. This is not a solution. (0246-30-1 [Fabiin, Dagmar])

Comment: And so, I have to repeat the storage in-house study in transition, although best from those that are offered. They cannot be transported because most of them are not even licensed for transport. So, everything has to be staying where they are now. And consequently, forget about transport. That is just insane. (0246-30-3 [Fabiin, Dagmar])

Comment: Now, notice that nothing is mentioned here about transporting this high burn-up fuel, just storing it. So, we are left to wonder how they are going to get the fuel to a site other than the reactor complex itself. That is not mentioned. (0246-5-2 [Leichtling, Don])

Comment: Additionally, highly protected methods of transportation, through non-populated areas must also be identified and employed. While the issues are certainly complex, it is time to move forward and resolve these problems for the long term. (0247-2 [Rogina, Raymond])

Comment: Pennsylvania's degraded roads, rails, and bridges make accidents inevitable. Extraordinary health, environmental, and financial risks on-site and along transportation routes are enormous and pose unacceptable risks in this densely populated region. (0249-11 [Dugdale, Jane])

Comment: No, it would not license such a facility, but the Generic Environmental Impact Statement would apply to a temporary storage site, if one were to be located in South Carolina at the Savannah River site, perhaps one of the leading contenders for such a site. That would mean high-level nuclear waste trucked all over the United States through Highway 77, on Highway 85, bound for the Savannah River site, and exposing people all along the way. (0250-1-6 [Zeller, Lou])

Comment: Finally, stop the secretly moving nuclear waste from here to there. Don't use our highways, rails, and waterways for such dangerous and unnecessary projects. (0250-11-5 [Kerr, Julius])

Comment: Would not the proposed transportation of radioactive waste establish consolidated interim sites for high-level radioactive waste, initiating transport of tens of thousands of casks of lethal radioactive waste on our roads and railways for the primary benefit of the nuclear power industry, while endangering the health and safety of millions of Americans? (0250-30-1 [Patrie, Lewis E.])

Comment: How can we even consider moving such waste, risking devastating consequences to people and the environment by radiation poisoning; the poisoning of our land and water cannot be reclaimed. We can't take it back. Let's not make any more mistakes about this. Let's not move any waste[.] (0250-39-5 [Richards, Kitty Katherine])

Comment: And, for some irony here, the security about transporting nuclear waste mentions crashing into high-speed concrete barriers, water immersion, 30-foot drop, severe impact, extreme heat. (0250-46-5 [Stein, Ed])

Comment: The prospect of transporting this waste across our country by rail, boats, and trucks is frightening. The American Transportation Research Institute, headquartered in Arlington, Virginia, is part of the American Trucking Association's federation and a 501(c)(3) not-for-profit research organization. They published a report May 2013, which stated for the year 2010 there were 35,000 large trucks involved in crashes in the United States. If .001 percent of the accidents are trucks transporting high-level nuclear waste, that would be 35 a year. The potential damage caused by just one truck transporting high-level nuclear waste involved in a worst case scenario accident with the container cracking and possible fire and the waste spilling and contaminating our land, our streams, innocent people and animals in the area, and those sitting in the traffic caused by the accident could be deadly and render the area uninhabitable for decades. (0250-49-4 [Gantt, Carol])

Comment: And storing it onsite in the dry cask is not safe, but it's a lot less dangerous than transporting it on our roads to go store it somewhere else. In Tennessee, they have these electronic signs over the highway that show many roadway fatalities we have had, and it's over 800 this year. So there's no reason to think it's safe to be transporting this stuff. There will be accidents inevitably. And, even without accidents, you know, the radioactive elements are getting through the containment structures that they're transporting it in. Some of these elements are created for nuclear efficiency get through steel and concrete. (0250-50-3 [Blevins, Eric])

Comment: And, if this permanent storage place does come to us from out of the ether, the problem of transporting ever increasing numbers of radio-active spent fuel cells will plague our society. (0252-5 [Golden, Leon] [Goldin, Martha])

Comment: If and when a repository is found and accepted by the community where it is located, the transport of high-level radioactive waste across this country will be on terrorist's "to do list". (0290-2 [Brown, Marty])

Comment: The NRC's plan to hide the waste problem by transporting spent fuel away from nuclear reactors to 'temporary' storage sites around the country is unsatisfactory because thousands of communities would be at risk from radioactive waste during transportation and storage, more nuclear sites would have to be safeguarded, and reactor owners could continue making waste without responsibility for managing it. The great volume of nuclear waste will require thousands of shipments on our roads, rails, and waterways. Due to the risk involved in mass nuclear waste transportation, it should be undertaken only once to a proven-safe permanent storage site. (0319-6 [Nichols, John])

Comment: Over 3,000 spent fuel shipments covering more than 1.7 million miles have been safely completed in the U.S. (0325-18-2 [Lemmon, Tom])

Comment: "If and when a repository is found, and accepted by the community where it is located, the transport of high-level radioactive waste across this country will be on a terrorist to-do list." (0326-14-2 [Brown, Marti])

Comment: The mass transportation of nuclear waste is a threat to the public. You cannot transport nuclear waste without accidents or spills. You cannot guarantee the public's safety while doing so, with this protecting people and the environment mission statement that you have. (0327-21-3 [Miskena, Jessice])

Comment: Finally, I would say that, on transportation, if you listen to the news reports every morning, you will find that there are 18-wheeler truck accidents occurring at rush hour, morning and evening, in virtually every major city since we have Interstate 75, Interstate 40, Interstate 65, and Interstate 24. And every few days, there is some kind of a collision or one of these 18-wheelers goes off a curve or goes off an on- or off-ramp. And the idea that you can transport huge volumes of nuclear waste over years without having deadly accidents and accidents for which our emergency management and hazardous waste managers are not prepared. (0329-12-11 [Paddock, Brian])

Comment: [P]utting it [nuclear waste] into geological repositories which would encourage mobile Chernobyls in transporting waste on the roads and our highways. It puts everyone at risk. Every car traveling past an entourage of waste that's being moved is endangered, not to mention if there was an accident from anything that can happen on the road or a terrorist knowing that there was a route of this waste being transported. A terrorist knowing that puts the entire country at risk, so this is just sheer madness, the issue of putting it on the highway. I resent that. I believe most everyone on the call, save for a few that are anesthetized by nuclear propaganda, would agree. (0329-15-3 [Star, Priscilla])

Comment: We're going to transport it there. Good luck with that. Those roads, he's not joking about that. And there will be protests all along the way because we need to protect our Earth. (0329-19-5 [Vandel, Niki])

Comment: And I would wholly recommend that the NRC in its sense of feeling obligated now to be more transparent takes this more to the level in the street and asking people how do they feel if there were trucks moving through their town moving radioactive waste and what will those trucks be made of and how can we feel safe when, say, we're taking our children home from school or we're going home from work or we're traveling these highways where these situations are going to occur. You know, the situation, as they say, you have blood on your hands. Is it not the same if there was an accident and the NRC had made that decision without fully canvassing whether or not these trucks should be on the road? This is just insanity. I don't think anyone would agree that it's smart. But I felt compelled to come back on and talk about that because I feel very strongly threatened, threatened by the concept that that may ever happen. The fact that that is being discussed and how to move waste from point A to point B, of course, we have to transport, right? That's what we're talking about. But that to me is insanity. You can't just take it from A to B without bringing on the worst risks known. (0329-21-2 [Star, Priscilla])

Comment: I wouldn't recommend anybody transporting nuclear waste an inch further than what they have to, such as like on the West Coast, just to move the spent fuel away from the San Andreas Fault up into the mountains, you know, just a few miles away from San Diego or wherever else they're at, to some safe underground place or sand pit or something where they could be stored away from people a little bit and away from an active possible tsunami or earthquake zone. I just wanted to throw that in there, that I just really don't want to have anybody transferring spent fuel rods, you know, 1,000 miles or 2,000 miles across the country. (0329-24-3 [Wilson, Greg])

Comment: And my final point is that one of the issues in TVA is that the transportation of radioactive waste could be considered to be done, instead of by truck, on the rivers. TVA controls the navigable waters within its area. And it has previously let highly toxic and dangerous cargos use our rivers. And that's a problem. And we think that the problem and a prohibition on river transport of radioactive waste is in order. (0329-25-5 [Paddock, Brian])

Comment: Simply stated, transport is too dangerous to become a viable solution in our analysis. On a personal note, we are continuously uncomfortable living very close to Limerick Nuclear Plant's nuclear waste, and evidence suggests that attempting to transport it would even be worse. (0329-3-4 [Cuthbert, Lewis])

Comment: It's pretty clear that the NRC nor anyone else can't guarantee safe transport of nuclear waste, and, based on the inability to provide that kind of surety, we suggest that it makes much better sense not to transport high-level radioactive waste on our nation's highways and railroads. The history of nuclear waste transport incidents and accidents would tend to refute both NRC and nuclear industry claims that transport is safe. There have been numerous incidents and accidents since the 1950s through literally last week where there have been problems. One of them occurred in Pennsylvania in 1981. (0329-3-5 [Cuthbert, Lewis])

Comment: And a number of things in the state of Pennsylvania would suggest this is a very bad idea. We have a severely deteriorating infrastructure problem in Pennsylvania that would mitigate against attempting to transport these wastes. Pennsylvania's current governor, Tom Corbett, is on record saying that the roads and bridges in Pennsylvania are crumbling, and it's also been reported that two of every five Pennsylvania bridges are structurally deficient or functionally obsolete. So the safety of transport is a very large hurdle to try to clear. (0329-3-6 [Cuthbert, Lewis])

Comment: An additional factor to consider for the NRC would be increasing extreme weather conditions and patterns and what the impact would be on transport plans. Pennsylvania, in 2011, broke all existing records for snow, ice, heat, and rain problems in terms of weather conditions. (0329-3-7 [Cuthbert, Lewis])

Comment: Final thought in terms of a separate topic is financial injustice. Our analysis suggests and our research would show and support the fact that a number of potentially negative financial impacts would occur from transportation of high-level radioactive waste. Property values have been documented to decline along nuclear waste transportation routes in several states already. Insurance does not cover radiological incidents or accidents in virtually every case, and there's a very large open question in terms of who would reimburse victims of a nuclear waste transport accident. That is not clear. And there's been an attempt in Pennsylvania and I'm going to presume in other states as well that local rights are under attack in terms of the ability to oppose nuclear waste transport through communities. (0329-3-8 [Cuthbert, Lewis])

Comment: I have also lived in Santa Fe, New Mexico and have been on the bypass and had one of the waste trucks overtake me in the middle of the night in an unsafe manner, scared the bejeezus out of me, not really comfortable with that whole process either[.] (0329-34-2 [Myers, Susan])

Comment: And I want to thank the doctor [Dr. Lewis Cuthbert]. He really brought in one side of the argument quite well. And I guess I completely -- two things. The transport thing, completely agree with that. Do not transport nuclear waste until we have a team that can provide immediate response. (0329-6-1 [Vandel, Niki])

Comment: Were there to be a repository available, the transportation of waste to it would be vulnerable to accidents and to terrorism. One only has to cite the many truck, train and ocean vessel accidents associated with the transportation of chemicals and fossil fuels to understand comparable risks. (0348-2 [Agnew, David] [Roscoe, Lee])

Comment: Were there to be a repository available, the transportation of waste to it would be vulnerable to accidents and to terrorism. One only has to cite the many truck, train and ocean vessel accidents associated with the transportation of chemicals and fossil fuels to understand comparable risks. (0352-2 [Roscoe, Lee])

Comment: Accidents can occur during transportation of waste. (0368-4 [Mattox, Judy])

Comment: Were there to be a repository available, the transportation of waste to it would be vulnerable to accidents and to terrorism. One only has to cite the many truck, train and ocean vessel accidents associated with the transportation of chemicals and fossil fuels to understand comparable risks. (0373-2 [O'Malley, Brian])

Comment: 3. Stop the extremely dangerous transport and interim storage scheme that: 4. Would drastically increase risks for a catastrophic transport disaster (0377-1-13 [Cuthbert, Lewis])

Comment: We also provided NRC with a body of evidence showing why transport of high-level radioactive waste from Limerick is even worse than on-site storage. It would present the public with even greater risks to more residents. (0377-1-4 [Cuthbert, Lewis])

Comment: ACE COMPILED A BODY OF EVIDENCE FOR THESE COMMENTS, SHOWING WHY NUCLEAR WASTE TRANSPORT IS TOO DANGEROUS! Nuclear Wastes, Some of the Most Deadly Materials on Earth, Should NOT be Transported On Our Nation's Highways and Railroads. -Transport creates extraordinary, unnecessary, and unacceptable health and financial risks for the public. -Our nation's seriously degrading roads, bridges, and train tracks add to the inherent risks from natural disasters. -Transport sets up vast numbers of inviting targets for terrorists, for which guarantee of safety is not realistic. Security will not be adequate, available, or affordable. Thousands of radioactive waste shipments in trucks and trains would be vulnerable to radioactive disasters throughout our nation due to: ACCIDENTS -There is serious cause for concern: (1) DOE acknowledges that accidents will happen; (2) Even low speed accidents can crack brittle metal tubing and unseat or damage a valve or seal, releasing radioactive particulates to the environment; (3) Fires from truck or rail accidents increase probability of devastating radioactive releases; (4) Terrorist attacks with planes, missiles, or bombs can ignite transport vehicles, causing fires that release radiation; (5) Lax security has already been documented - "Security Breach on Nuclear Waste Train." (4-30-02) Each fuel assembly contains 10 times the long-lived radioactivity released by the Hiroshima bomb. - Trucks contain 1 to 4 fuel assemblies -Trains contain up to 24 fuel assemblies - Nuclear waste casks could emit significant radiation just in transport. Thermal images of traveling nuke wastes suggest just getting stuck near a shipment is dangerous. (0377-2-1 [Cuthbert, Lewis])

Comment: FINANCIAL INJUSTICE: Property Values Decline Along Nuclear Waste Transportation Routes - Experience Shows Courts in New Mexico, Colorado, Tennessee, Washington, and Ohio already awarded property damages for reduced values; Disclosure Laws in Most States Require That Buyers Be Told If Property Is On A Transportation Route; Residents could be "stuck" with property they can't sell along a nuclear waste transportation route. This is an unacceptable and unnecessary injustice. Many PA communities would be

exposed to frequent shipments of large amounts of nuclear wastes transported to interim storage facilities, likely for far longer than 25 years (0377-2-10 [Cuthbert, Lewis])

Comment: Public Health and Safety Impact From Radioactive Waste Transportation (DOE Estimates. 50 Miles (80 kilometers) for Accident Conditions; .5 mile (800 meters) on either side of the transportation right of way for non-accident conditions; Consequences could be devastating to the economy and public health from a severe radioactive waste transport accident in an urban setting. Even a small radiation release in a rural setting would contaminate 42 square miles for over 1 year (0377-2-11 [Cuthbert, Lewis])

Comment: Insurance Does NOT Cover Radiological Incidents or Accidents: Homeowners insurance will not cover loss of real estate use or personal property caused by radiological accidents or terrorist attacks; Health insurance may not cover some illnesses related to long-term or permanent radiological damage or other long-term serious illnesses caused by a radioactive waste transport accident. Who will reimburse victims of a nuclear waste transport accident or terrorist attack? Vast numbers of people could lose everything from radioactive contamination; -Size of region impacted for public health and safety along transportation routes is 50 miles according to a DOE report; -A severe accident involving 1 radioactive waste cask, releasing a small amount of radiation would contaminate about 42 square miles for well over 1 year, with devastating economic consequences in an urban setting (DOE Report); -Economic consequences estimated at \$2 Billion (1980 NRC study); Many people could lose their homes, businesses, possessions, and health from just one radioactive waste transportation accident that turns into a radioactive fire; Neither the nuclear industry, nor state or federal governments are obligated to compensate the vast numbers of victims who could lose everything due to nuclear waste transport accidents or terrorist attacks. The Nuclear Industry Won't Pay A Dime: The nuclear industry is no longer responsible for any costs associated with nuclear waste after it leaves the site, including any costs associated with nuclear waste transportation accidents. Cash-Strapped States Can't Pay: States do not have adequate budgets to cover astronomical long-term relocation costs or for widespread radiation clean-up costs, required after a serious radioactive waste transport accident. The federal Price Anderson Act does not cover nuclear waste transportation accidents: The current Republican Congress is unlikely to provide relocation or clean-up costs; It is more likely they will deny risks. You can't see, smell, or feel radiation contamination. Many Congressmen were reluctant and very slow to help other Americans in major emergencies. Vast numbers of Sandy victims are still homeless, and the devastation from that hurricane was easy to see. (0377-2-12 [Cuthbert, Lewis])

Comment: Local Rights Are Being Steamrolled To Allow Dangerous Nuclear Waste Transport: Many jurisdictions already officially opposed nuclear waste transportation through their communities to protect the health and financial interests of their citizens, including Philadelphia, Bucks County, and Falls Township in PA (0377-2-13 [Cuthbert, Lewis])

Comment: PA State Senate Republicans are attempting to take away the rights of local municipalities to say NO to nuclear waste transport on behalf of nuclear industry interests. Local officials should have the right to say no to transporting deadly radioactive wastes through their communities to protect public safety, health, and financial interests. At stake for victims of high-level radioactive waste transport accidents or terrorist attacks - health and potential total loss of property, homes, businesses, and all possessions for generations. (0377-2-15 [Cuthbert, Lewis])

Comment: DOE Knows Accidents Will Happen; -DOE estimates at least 50 accidents could occur during shipments of the nation's radioactive wastes; -DOE's own data estimated that transporting several thousand shipments of the nation's nuclear waste off nuclear sites would

result in between: 70 to 310 accidents - over 1000 incidents - would occur during truck shipments 50 to 260 accidents - over 250 incidents - would occur by train shipments; - The American Petroleum Institute says at least 15 accidents are expected each year with thousands of truck shipments; -Facts refute deceptive NRC studies claiming nuclear waste transport is totally safe; -Independent studies show the kind of damage that can be done by transporting nuclear fuel; -Even a low speed accident could unseat a valve or damage a seal, releasing radioactive particulates to the environment; -An accident could crack brittle metal tubing around the fuel; -The more severe the accident, the more radiation would be released to the environment. Consequences of Nuclear Waste Transport Accidents or Terrorists Attacks - Size of region impacted for public health and safety along transportation routes (DOE Report); 50 Miles (80 kilometers) for Accident Conditions .5 mile (800 meters) on either side of the transportation right of way (non-accident conditions); - A severe accident involving one radioactive waste cask, releasing a small amount of radiation would: Contaminate about 42 square miles for well over a year, with devastating economic consequences in an urban setting (DOE Report); Take over a year to attempt to clean up radioactive residue (DOE Report); Economic consequences estimated at \$2 Billion (1980 NRC study); - Radiation doses from an accident or terrorist attack breaching transport containers (1 yard away) could result in devastating impacts: Lethal radiation doses from high-level radioactive waste transport (500 rem) could result when exposed for less than 3 minutes; Cancer or genetic damage risk increases after just 30 seconds (100 rem); - NRC's pamphlet says 10 years after waste is removed from reactors, an unshielded radiation dose could exceed 20,000 rems per hour; - 5,000 rems can cause incapacitation and death within a week. (0377-2-2 [Cuthbert, Lewis])

Comment: Regulations For Radioactive Transportation Accidents Are UNprotective: -8-22-13 - A burning truck carrying radioactive material was not reported until; 10-31-13. It took over two months for this dangerous incident to be disclosed to the public. -This refutes industry and NRC claims that nuclear materials transportation is absolutely secure; -In fact it suggests many nuclear transport accidents / incidents can be going unreported to NRC or the public; -It confirms major GAPS in nuclear reporting systems; -Despite the fiery emergency, NRC was not informed. There was no requirement for this major truck fire to be reported. Fires, even on nuclear materials trucks, are not required to be reported to NRC; -Many radioactive transport accidents and incidents can be going unreported; -Truck drivers are programmed, basically taught, to do everything they can to avoid the media, that the media is like terrorism. (0377-2-3 [Cuthbert, Lewis])

Comment: Deteriorating Infrastructure Makes Transport Far Too Risky: -It is not safe to transport deadly radioactive wastes on our nation's deteriorating roads and bridges. - Example: PA's Crumbling Roads and Bridges. In 2013, PA's governor admitted roads and bridges are "crumbling;" In 2011, PA bridges were among the worst in the nation (Philadelphia Inquirer), with two of every five PA bridges structurally deficient or functionally obsolete. The safety factor suggests NO radioactive wastes should be transported across PA bridges; PA leads the country in the number and percent of spans of roads and bridges deemed structurally deficient More than 1/2 of PA's major urban roads are in "poor" or mediocre condition (American Society for Civil Engineers report); - Radioactive Waste Transport in PA Unacceptable; The PA Department of Transportation does not have funding for adequate maintenance of the vast portions of badly deteriorated roads and dangerous bridges; PA is 2nd in the nation for the number of nuclear reactors, and therefore 2nd for the highest amount of high-level radioactive wastes that would be transported -In other states bridges have already collapsed and roads have already crumbled. What if radioactive waste transportation vehicles were involved? - Many states, like PA, are facing funding crises, making it unlikely all structurally deficient roads and bridges will be made safe enough to safely transport deadly radioactive wastes (0377-2-4 [Cuthbert, Lewis])

Comment: Terrorist Attacks - Deadly radioactive wastes cannot, and will not, be guarded as well along transport routes as at a nuclear plant site. The largest casks carry the equivalent of some 200 Hiroshima bombs in a long-lived radiological equivalent; Some call radioactive waste transport a potential "Mobile Chernobyl, vulnerable to terrorist attacks with planes or missiles (even from afar). Bombs ignited on transport vehicles could cause catastrophic radioactive fires, releasing massive radiation, contaminating and making uninhabitable very large areas of the transport route. Army testing proves transport casks can be penetrated with a missile; Jet plane fuel from a deliberate crash into a transport vehicle could cause a devastating fire, even with a small plane. Lax Security Documented: It is absurd for the nuclear industry to claim their wastes are self-protecting due to risk of radiation exposure. This ignores reality, including the real potential for airplane and missile attacks. Evidence confirms that "Waste Trains" are not adequately protected from terrorists, "Security Breach on Nuclear Waste Train." 4-30-02 Durham, N.C.; -Inmates Jump Wrong Train, Revealing Vulnerability. If these people intended to cause serious harm, they were in perfect position. Terrorists would not have boarded the train unarmed. -Defenders did not deny access. If those who boarded the train had been attackers carrying explosives who were willing to sacrifice their lives, there would have been a serious problem. (0377-2-5 [Cuthbert, Lewis])

Comment: Fire And Nuclear Waste Transport: Fires due to truck or rail accidents increase probability of disastrous radioactive releases.; Accidents or terrorist attacks could trigger fires during truck or train transport.; There is significant potential for a fire resulting from a transportation accident involving high-level radioactive wastes. This could have similar consequences as radiological weapons.; If a truck or train accident resulted in a fire, spent fuel rods could heat up, self-ignite and burn in an unstoppable fire. Numerous scientific experts warn that burning fire on zirconium cladding of nuclear waste can trigger an exothermic reaction. It's important to extinguish fires within 1/2 hour. Yet confusion, a lack of understanding radiation risks, and deciding who is responsible for cleanup and public health in a radioactive emergency elevate risks. Shipping containers are only designed to withstand a 1/2 hour fire at a temperature of 1475 degrees. NEI's inadequate testing was only 90 minutes at 2000 degrees. Rail fires could burn for hours, sometimes days, at temperatures considerably higher -Heat could vaporize some of the radioactive materials and sweep them up into the air - Persons downwind can inhale radioactive particles, later developing cancer or genetic defects. Burning Truck Hauling Nuclear Load Flies Under The Radar: -A burning truck hauling a nuclear load flew under the radar in Ohio 8-22-13. (Not reported until October 31, 2013) Despite the fiery emergency, there was no requirement to immediately inform NRC to independently determine if radiation was released. This incident did not turn into a disaster, but it could have. It refutes claims that nuclear materials transportation is absolutely safe. (0377-2-6 [Cuthbert, Lewis])

Comment: Extreme Weather Conditions Increase Risk Of Transport Disasters: Earthquakes, tornadoes, and hurricanes are getting far stronger and much more frequent, drastically increasing risk of transport accidents. In 2011, all PA weather records were broken for snow, ice, heat, and rain, clearly increasing risks for transportation accidents which could be disastrous if they involve nuclear waste. Since PA is 2nd in numbers of nuclear reactors, more wastes would be transported than in other states, increasing the odds of disaster. (0377-2-7 [Cuthbert, Lewis])

Comment: Earthquake Faults and Fracking: Nuclear waste on Limerick's site faces serious threats from loss of water and power from an earthquake. Limerick was built directly over an earthquake fault with 4 others within 17 miles. Transport of large volumes of this waste off-site during an earthquake could also create a catastrophic disaster. Fracking is known to trigger

earthquakes. To date, over 4200 wells have been approved for fracking in PA. PA would be transporting large volumes of waste since it has the 2nd highest number of nuclear plants. (0377-2-8 [Cuthbert, Lewis])

Comment: A truck or railway accident or terrorist attack involving transported nuclear waste could render entire cities and surrounding areas uninhabitable. Transporting radioactive materials across the nation on major interstates, highways, and railways will expose countless communities across the country to hazardous radiation. A recent DOE study estimated over 800 adults would die from cancer due to radiation emitted from the trucks in the Northwest region alone. (0377-3-1 [Cuthbert, Lewis])

Comment: Transport Is An Immoral, Unethical, Unnecessary Risk: Evidence above reveals the insanity of transporting tens of thousands of casks of lethal high-level nuclear wastes across the nation on our nation's degrading highways and railroads, potentially affecting the health, safety, and financial well-being of 100 million Americans who live within a mile or two of likely transport routes. Given the potential for a radioactive waste transport accident on our highly degraded infrastructure and the ever-growing threat of terrorism, it is insane to risk loss of health, homes, and businesses for so many people through radioactive waste transport. We urge NRC to consider inherent risks for a Mobile Chernobyl. Times 2. STOP NUCLEAR WASTE TRANSPORT TO INTERIM STORAGE SITES. (0377-3-3 [Cuthbert, Lewis])

Comment: NRC ignores dangerous, deadly, and costly transportation risks including: -Loading and Unloading; -Extraordinary health, environmental, and financial risks on-site and along the route; -Train and truck accidents are of major concern, especially for fire from fuel. (0377-6-5 [Cuthbert, Lewis])

Comment: *Criticality Risks during Transportation of Spent Fuel Pool - Revision 1.* EPRI, Palo Alto, CA: 2008. 1016635.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001016635>; This report presents a best-estimate probabilistic risk assessment (PRA) to quantify the frequency of criticality accidents during railroad transportation of spent nuclear fuel casks. The assessment is of sufficient detail to enable full scrutiny of the model logic and the basis for each quantitative parameter contributing to criticality accident scenario frequencies. The report takes into account the results of a 2007 peer review of the initial version of this probabilistic risk assessment, which was published as EPRI Technical Report 1013449 in December 2006. *Fuel Relocation Effects for Transportation Packages.* EPRI, Palo Alto, CA: 2007. 1015050.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001015050>; Spent nuclear fuel transported in large casks must remain subcritical in all credible configurations for normal operation and hypothetical accident conditions. The effects of "worst case" accident scenarios were considered in "Effects of Fuel Failure on Criticality Safety and Radiation Dose for Spent Fuel Casks" (NUREG/CR-6835, September 2003). These scenarios were postulated to provide theoretical upper limits for reactivity effects, although they were described as going "beyond credible conditions." This report shows that the effects of fuel relocation are not as significant as might otherwise be expected from the results published in NUREG/CR-6835, and are more likely to result either in small reactivity increases in some cases or in reactivity decreases in others. *Spent-fuel Transportation Applications - Normal Conditions of Transport.* EPRI, Palo Alto, CA: 2007. 1015049.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001015049>; The report describes the response of a high-burnup fuel assembly to dynamic forces that result from a one-foot drop onto a rigid surface in the most damaging orientation. This condition corresponds to a surrogate loading configuration for normal conditions of transport of spent

nuclear fuel, as prescribed in Part 71 of the Code of Federal Regulations, Title 10. (0379-10 [Kessler, John])

Comment: EPRI is pleased to provide the attached bibliography of EPRI publications that provide information and analysis related to NRC's Waste Confidence GEIS. EPRI requests that the relevant NRC Waste Confidence staff review the EPRI publications for potential use in preparing the final Waste Confidence GEIS. *Spent Fuel Transportation Applications—Assessment of Cladding Performance*. EPRI, Palo Alto, CA: 2007. 1015048; <http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001015048>; This report summarizes the results of EPRI's multi-year research effort to assess cladding performance under normal and hypothetical accident conditions of spent nuclear fuel transportation. *Assessment of Accident Risk for Transport of Spent Nuclear Fuel to Yucca Mountain Using RADTRAN 5.5*. EPRI, Palo Alto, CA: 2006. 1013450. <http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001013450>; This report evaluates the radiological impacts during postulated accidents associated with the transportation of spent nuclear fuel to the proposed Yucca Mountain repository, using the RADTRAN 5.5 computer code developed by Sandia National Laboratories. RADTRAN 5.5 can be applied to estimate the risks associated both with incident-free transportation of radioactive materials as well as with accidents that may be assumed to occur during transportation. Incident-free transportation risks for transport of spent nuclear fuel to Yucca Mountain were evaluated in EPRI report 1011821 using RADTRAN 5.5, September 2005. (0379-11 [Kessler, John])

Comment: *Summary of the NAS Report, "Going the Distance? The Safe Transport of Spent Nuclear Fuel and High-Level Radioactive Waste in the United States" and EPRI's Comments*. EPRI, Palo Alto, CA: 2006. 1010075. <http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001010075> In May 2003, The National Academy of Sciences (NAS) formed a Committee on Transportation of Radioactive Waste (NAS Committee) to examine the transportation of spent nuclear fuel (SNF) and high-level radioactive waste (HLW) in the United States. The focus of this study was on the transportation of SNF in the United States. The results of the culminated in a report that was issued in February 2006 entitled, "Going the Distance? The Safe Transport of Spent Nuclear Fuel and High-Level Radioactive Waste in the United States." EPRI was one of the principal sponsors of the study along with the U.S. Department of Energy (DOE), U.S. Nuclear Regulatory Commission (NRC), U.S. Department of Transportation (DOT), and the National Cooperative Highway Research Program. This EPRI report summarizes the principal findings and recommendations made by the NAS committee in its "Going the Distance?" report. This EPRI report concludes with some observations by EPRI on the NAS findings and recommendations. *Spent Nuclear Fuel Transportation—An Overview*. EPRI, Palo Alto, CA: 2004. 1009226. <http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001009226> Spent nuclear fuel comprises a fraction of the hazardous materials packages shipped annually in the United States. In fact, at the present time, fewer than 100 packages of spent nuclear fuel are shipped annually. At the onset of spent fuel shipments to the proposed Yucca Mountain, Nevada, repository, the U.S. Department of Energy (DOE) expected to ship 400 - 500 spent fuel transport casks per year over the life of the facility. This study summarizes work on transportation cask design and testing, regulatory requirements, jurisdictional requirements, operational procedures and experience, and transportation risk assessments. (0379-12 [Kessler, John])

Comment: EPRI is pleased to provide the attached bibliography of EPRI publications that provide information and analysis related to NRC's Waste Confidence GEIS. EPRI requests that the relevant NRC Waste Confidence staff review the EPRI publications for potential use in preparing the final Waste Confidence GEIS. Transportation of Used Fuel; *Transportation of Commercial Spent Nuclear Fuel: Regulatory Issues Resolution*. EPRI, Palo Alto, CA: 2010. 1016637.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001016637>; The U.S. industry's limited efforts at licensing transportation packages characterized as "high-capacity," or containing "high-burnup" (>45 GWd/MTU) commercial spent nuclear fuel (CSNF), or both, have not been successful considering existing spent-fuel inventories that will have to be eventually transported. A holistic framework is proposed for resolving several CSNF transportation issues. The framework considers transportation risks, spent-fuel and cask-design features, and defense-in-depth in context of present regulations as well as in context of future potential revisions of regulations that would reflect a risk-informed, technically state-of-the-art approach. Within the boundary limits of cases analyzed, the EPRI-sponsored work shows that there are no credible combinations of accident events, accident locations, and fuel misloading or reconfiguration that would result in a critical configuration during the transportation of spent nuclear fuel. The non-mechanistic criticality evaluation performed in the as-loaded or as-designed configuration can be considered the bounding case for all conditions of transportation because this hypothetical reactivity case bounds all those normal and hypothetical accident cases that can credibly exist for spent-fuel transportation packages. Criticality during hypothetical transportation accidents should be a regulatory non-issue, given that misallocation of regulatory requirements can lead to greater overall risks, specifically by increasing the number of shipments when overly restricting spent-fuel transportation payloads. (0379-9 [Kessler, John])

Comment: I attended this meeting because I was very worried about the proposal to transport radioactive waste to interim sites across the country on railroads, trucks, boats, through towns, cities, backyards, highways, fishing beds... (0381-11 [Fasten, Susan])

Comment: When a safe permanent storage area is found, transporting the waste must be done with care and security to eliminate the risk of transport accidents and incidents, contamination of the surrounding areas during transport, and inviting attack and vandalism. Not as it was done some years ago when I found myself in Connecticut on a high speed highway in a densely populated area at rush hour behind a flatbed truck carrying a huge cement cask with radioactive signs on it - no protection, no security, no escort. Not as it was done in Lexington, MA when a truck carrying radioactive material sprang a leak as it was gassing up at a service station on a busy highway - no escort, no security, no protection. Not as the Rowe nuclear plant was carelessly and rapidly dismantled and transported giving off radioactivity in all directions along the way as measured by citizens with geiger counters. Not as a Mexican truck driver transporting radioactive material last week stopped to take a nap and was hijacked - no escort, no security, no protection. The list goes on and on. (0381-8 [Fasten, Susan])

Comment: Since no one wants a high-level nuclear dump in their backyard, or the transport of high-level nuclear waste through their neighborhood, the acceptance of a "Yucca Mountain" in the backyard scenario is unlikely to happen anywhere in America. Also the very concept of away-from-reactor consolidated interim storage does not meet with the strictures of ALARA, since transporting the waste twice or more in its lifetime greatly increases the risk of accidents and exposure to bystanders. It also unnecessarily contaminates virgin land not currently radioactive. The transport of nuclear waste is also not well controlled. For example, I personally measured radiation emanating from a transport truck on Interstate-40 near Amarillo, TX of

several hundred CPM (50 times background) in just the few seconds it took to pass the truck. One can only imagine the exposure level to the driver and anyone parked next to the truck at a cafe, fueling stop, rest area or motel. The transport also exposes the fuel to the possibility of theft or traffic accidents which is clearly not a trivial risk. For the above reasons I believe that the entire Section 5 of the Generic Waste Confidence draft should be discarded as both imprudent and impractical. There may, however, be some situations where continued dry storage at the original reactor site is so dangerous that moving the spent fuel to an alternate, safer site is possibly justified, but risk versus benefit must be evaluated for each individual situation. Moving the fuel should never be merely for the convenience of the operators. (0410-24 [Nelson, Dennis])

Comment: Even transporting waste would be dangerous and vulnerable. (0450-4 [Bast, Nancy])

Comment: And even if this becomes a possibility in the near future, safe movement of the massive quantity of waste fuel already generated will still remain an extremely risky operation. (0454-9 [Waldstein, Joe])

Comment: Eureka County offers the following comments on the NRC Draft Generic EIS and draft rule on Waste Confidence. Eureka County is an affected unit of local government under Section 116 of the Nuclear Waste Policy Act. In our experience with nuclear waste planning and management as an Affected Unit of Local Government, transportation issues have been ignored or postponed. We believe that the integrity of the spent nuclear fuel (SNF), fuel rod cladding and the components of the fuel assemblies is essential to the safe transportation of SNF. As an affected unit of local government who will be primarily affected by transportation of SNF through our County, we must have assurance that the SNF can be transported safely in both normal transportation and during transportation incidents. (0459-1 [Johnson, Abigail])

Comment: This high priority information identified by the staff is essential to the determination that after long term storage, SNF can be transported safely. Unfortunately, the draft GEIS does not address this concern. It is difficult to understand how one can conclude that the waste can be stored safely for extended periods of time without addressing these critical information needs raised by the NRC staff. In our scoping comments, we also noted that it is essential that this EIS integrate the systems components of the nuclear power industry, including its nuclear wastes and components of the SNF transportation system, in order to produce a useful and meaningful analysis. By conducting a generic EIS, the EIS fails to address this concern. (0459-3 [Johnson, Abigail])

Comment: The EIS does not adequately assess the impacts associated with transportation of SNF after long term storage. The assessment of transportation impacts is limited primarily to the inconsequential transportation impacts associated with the construction of DTSs and replacement ISFSIs in a generic manner. The EIS deals with the risk, and hence impact of SNF transportation by relying on previous studies conducted and the risk of transportation of SNF. Many of these studies are dated (e.g. an AEC analysis dated 1972; an NRC FEIS dated 1977, etc.). Those studies that have been conducted recently have not considered the issues associated with possible SNF degradation such as stress corrosion cracking, embrittlement, and swelling of fuel pellets as identified as issues in the NRC staff report on information needed for long term storage assessment. (0459-6 [Johnson, Abigail])

Comment: Transporting nuclear waste across our country is asking for a disaster. (0492-2 [Maghakian, Carol])

Comment: The GEIS finds that the effects on transportation are "small to moderate." However, it reaches this conclusion only because it considers transportation only within the vicinity of reactor or interim storage sites--commuting of site workers, deliveries of supplies and replacement equipment, etc. Even within the site vicinity, the effects of overweight truck shipment and/or large-load rail shipment, often on sub-par infrastructure, are not addressed. Short-term and long-term storage presume eventual large-scale transport of SNF, possibly cross-country and affecting hundreds of corridor as well as origin and destination communities. The GEIS appears to assume that such transport is not an effect of its site-specific licensing decisions, or that cross-country transport resulting from short or long-term storage is no different than that which would occur during licensed operations--i.e. that cross-country transport is an effect of licensed operations, not of continued storage after licensed operations, even if it occurs during "continued storage". Cross-country transport is a major impact of SNF generation at 100 reactors on 75 sites. The formulation of the GEIS does not warrant ignoring this impact. The GEIS should recognize that SNF transport on this scale has not been demonstrated in the U.S., and that it results from its many site-by-site licensing decisions, except in the (undesirable) indefinite storage case. (0505-3 [Williams, Jim])

Comment: More nuclear waste means more transportation of the waste, on our highways, rails and waterways. The risk involved in nuclear waste transportation is growing exponentially as storage ponds are filling up. (0531-2-15 [Morgan, Sally])

Comment: There is no way nuclear waste can be made safe to truck around on public roads. (0539-1 [Luttinger, Lionel])

Comment: It cannot be trucked around on public roads. That is far too dangerous. We do not need deadly mobile radiation on our roads. (0539-3 [Luttinger, Lionel])

Comment: The sheer volume of nuclear waste will require thousands of shipments on our roads, rails, and waterways. Due to the risk involved in mass nuclear waste transportation, it should only be undertaken once--and when we know there is a viable solution. (0552-1-11 [Macks, Vic])

Comment: (It should be noted that the used fuel is actually much easier to transport if its temperature is above about 800 degrees Fahrenheit, because the zirconium cladding is much more ductile above that temperature. However, when the fuel is naturally that hot thermally, the damage if an accident were to occur would be much greater, because the fuel is also radioactively much "hotter" a few months after discharge than it is, say, 20 years or 50 years afterwards.) (0562-8 [Hoffman, Ace])

Comment: In discussion with our science personnel one of the big topics was transporting spent nuclear fuel to Yucca Mountain, and the mathematical certainty of train accidents irradiating large densely populated areas of the U.S. Regardless of the viability of Yucca Mountain, the material itself is much too dangerous to transport across the country. (0573-1 [Gerhart, Dan])

Comment: And transporting nuclear waste across the nation by truck and rail significantly increases Homeland security risks. (0611-32 [Shapiro, Susan])

Comment: Transportation: Chapter 6 generally discusses cumulative impacts (other past present, and reasonably foreseeable actions) and Section 6.3 .2.4 briefly discusses the transportation of spent fuel to a repository for disposal. The draft GEIS assume that this will

happen. Since no dry cask is currently licensed to transport high burn-up fuel, the final GEIS must discuss any potential licensing challenges (for high burn-up fuel) and the possibility that this particular fuel might never leave its storage location. Its not enough to assume that it will happen. (0619-2-3 [Mahowald, Philip R.]

Comment: The problem with transport to Yucca Mountain in the unlikely event that work will be restarted there and the repository will be finished is that transport of radioactive waste via truck or the nation's rail lines is inherently dangerous to the public, due to unavoidable release of radioactivity during the transportation process. (0628-2 [Perkins, V.E.]

Comment: I am a citizen concerned about transport of nuclear waste via roads or railways, putting public safety, health and first response at risk. (0636-1 [Bluestein, Bonnie])

Comment: Nor do I share your confidence about the safety and soundness of irradiated nuclear fuel transport, which would be required to go from on-site/at-reactor storage to away-from-reactor/centralized interim storage (what we prefer to call de facto permanent parking lot dumps) or final repositories. (0698-2 [Kamps, Kevin])

Comment: The probability of a transportation accident resulting in a major release of radioactive material is a major concern. (0701-3 [Wilson, Greg])

Comment: Even burying it deep in the earth or at the bottom of the sea requires getting it to its storage place -- and no one knows how to do that safely. (0719-5 [Hibbard, Angela])

Comment: No transport of the waste! (0744-6 [Bonniwell, Colleen])

Comment: Under section ES13.2.16, page lvii, lines 5-29, in that portion of the executive summary which addresses away from reactor storage sites, the analysis on transportation misses the mark. There needs to be an analysis on the risks associated with that process including but not limited to a discussion of the various canisters that are to be used for such transportation, the transfer into those casks and the risks of the transport. (0783-1-18 [Harlan, Thomas])

Comment: Under section 2.1.2.2, page 2-14, lines 1-9, the Draft GEIS should clarify, at the outset, that it has not designated any casks for transportation. Accordingly, prior to transportation, all spent fuel should be required to be transferred to transportation casks. (0783-2-15 [Harlan, Thomas])

Comment: The process of moving this fuel to a final storage solution should be treated with the same care as moving the rockets that launch items into space. This includes a military escort to secure these materials. (0786-2 [Dew, Jane])

Comment: As I mentioned in my oral comments, at least 85% of all long distance semi-truck traffic passes through Tennessee because we are the intersection of several major North-South and East-West Interstates. We have daily truck accidents and cargo spills in our cities as well as on the open road. TVA may desire to transport irradiated fuel on the Tennessee River connection between its reactors. This presents new and different issues and risks to be analyzed and avoided. No transport of irradiated fuel should occur without adequate analysis including a separate EIS and an opportunity for public comment. (0821-3 [Paddock, Brian])

Comment: GEIS Section 5: NRC's evaluation of transportation impacts is sound and well supported by referenced reports and prior environmental studies all of which have been finalized after appropriate consideration of public comment. (0827-7-27 [Ginsberg, Ellen])

Comment: GEIS Section 3.15. With respect to the transportation environment (GEIS 3-37), the GEIS provides a reasonable description of the transportation region of influence. The GEIS concludes that non-radiation impacts from transportation for all scenarios are small to moderate with moderate impacts related to traffic and characteristics at a particular site. For radiological impacts (only the away from reactor scenarios and transport to a repository in the cumulative impacts section), the GEIS defers to generic findings in 10 CFR 51.52, Table S-4; several NRC analyses subsequent to Table S-4; and analysis done for Private Fuel Storage Facility. The conclusion in all cases is that radiological impacts would be small. NRC's treatment of this topic in the GEIS is appropriate and there is no basis to reconsider the determinations documented in Table S-4. (0827-7-28 [Ginsberg, Ellen])

Comment: As for transportation, high-level radioactive waste will be regularly trucked over our nation's highways, subject to any number of catastrophic accidents daily, one of which could render a large portion of a state (or states) uninhabitable for the foreseeable future. (0834-5 [Thabit, Nick])

Comment: Section 3, in its entirety, you also do not sufficiently mention issues that need to be addressed on a case-by-case basis. For example, in Section 3.15, Transportation, you say "Local and regional transportation networks in the vicinity of nuclear power plant sites may vary considerably depending on the regional population density, location, and size of local communities, nature of economic development patterns, location of the region relative to interregional transportation corridors, and land surface features, such as mountains, rivers, and lakes." This is certainly an example of an impact where generic treatment is insufficient. (0836-50 [Davis, Anonymous])

Comment: In closing, discussing "waste confidence" is almost absurd. The waste being created (adding to the 80,000 tons of spent nuclear fuel that will remain toxic for 240,000 years or even longer) is a pending disaster. To consider moving this quantity of dangerous waste would be irresponsible even if we had someplace to put it. (0864-14 [Gellert, Sally Jane])

Comment: Regarding storage of nuclear waste both here and across the country, I firmly believe that the risks of transportation are greater than the risks of storage on site. Transporting highly radioactive fuel over the highways raises the specter of many possible errors and accidents: from collisions, to mechanical breakdowns, to spills in areas far from any nuclear facility, which of necessity would have to be handled by hazardous-material personnel who, despite being professionals, are unlikely to have experience or training in handling highly radioactive nuclear waste. In fact, even here, with Indian Point right here, when a worker at Indian Point was exposed to radiation and transferred to the local hospital emergency room, the incident required evacuation of the emergency room for a number of hours; if there had been a much bigger incident, the region would have been without a working facility for a much longer time. (0864-6 [Gellert, Sally Jane])

Comment: Generic analysis of a NPP would miss the transportation related issues associated with a real world facility. For example, if the NPP site did not have rail access, movement of the SNF to another site or even within the site may be hindered. Additionally access limitations like geographic barriers to and from the plant may limit the use of heavy haul trucks and thus increase the numbers of transportation links necessary to move the SNF from the facility, to

storage and/or to an intermodal transfer stations, that could then load the canisters onto a train, barge or other transport means. These types of site specific transportation related barriers would need to be analyzed in reality, not in the abstract. They require specific planning and articulation as to their impacts on the environment, social structures, political impacts and economic costs. Risks for such shipments rise as the number of transfers increase and as the failure to recognize such site specific realities is a critical mistake in the use of a generic analytical approach (Ballard 2002a, Ballard 2002b, Ballard 2003, Ballard 2008). (0867-3-15 [Griffin, William])

Comment: Underwater submersion could lead to inadvertent nuclear chain reactions in the fissile materials still present in the wastes; burial under sand could cause the wastes to dangerously overheat. Although written as a warning about the risks of shipping high-level radioactive waste by barge on Lake Michigan, a backgrounder I wrote a decade ago provides specific, relevant information on how an inadvertent nuclear chain reaction, or accidental criticality, could be sparked by the underwater submersion of a Palisades dry cask (whether that were to occur by a barge shipment sinking, or Palisades' dry cask storage being plunged underwater by an earthquake): "As part of its plan to transport high-level radioactive waste to Western Shoshone Indian land at Yucca Mountain, Nevada, the U.S. Department of Energy (DOE) proposes up to 453 barges carrying giant high-level radioactive waste containers onto the waters of Lake Michigan. See the second page of this fact sheet for a map of the proposed routes and a breakdown of shipment numbers by port. Accidents happen. But what if high-level radioactive waste is involved? U.S. Nuclear Regulatory Commission (NRC) design criteria for atomic waste transport containers are woefully inadequate. Rather than full-scale physical safety testing, scale model tests and computer simulations are all that is required. The underwater immersion design criteria are meant to "test" (on paper, at least) the integrity of a slightly damaged container submerged under 3 feet of water for 8 hours. An undamaged cask is "tested" (on computers, at least) for a 1 hour submersion under 656 feet of water. But if a cask were accidentally immersed under water, or sunk by terrorists, is it reasonable for NRC to assume that the cask would only be slightly damaged, or not damaged at all? Given that barge casks could weigh well over 100 tons (even up to 140 tons), how can NRC assume that they could be recovered from underwater within 1 hour, or even within 8 hours? Special cranes capable of lifting such heavy loads would have to be located, brought in, and set up. And what about the fact that Lake Michigan is deeper than 656 feet at locations not far from DOE's proposed barge shipment routes? The dangers of nuclear waste cask submersion underwater are two fold. First, radioactivity could leak from the cask into the water. Each container would hold 200 times the long lasting radioactivity released by the Hiroshima atomic bomb. Given high-level atomic waste's deadliness, leakage of even a fraction of a cask's contents could spell unprecedented catastrophe in the source of drinking water for tens of millions of people - Lake Michigan. Second, enough fissile uranium-235 and plutonium is present in high-level atomic waste that water, with its neutron moderating properties, could actually cause a nuclear chain reaction to take place within the cask. Such an inadvertent criticality event in Sept. 1999 at a nuclear fuel factory in Japan led to the deaths of two workers; many hundreds of nearby residents, including children, received radiation doses well above safety standards." (0919-1-15 [Kamps, Kevin])

Comment: Nor do I share your confidence about the safety and soundness of irradiated nuclear fuel transport, which would be required to go from on-site/at-reactor storage to away-from-reactor/centralized interim storage (what we prefer to call de facto permanent parking lot dumps). (0929-3 [Kamps, Kevin])

Comment: Section 3, in its entirety, you also do not sufficiently mention issues that need to be addressed on a case-by-case basis. For example, in Section 3.15, Transportation, you say "Local and regional transportation networks in the vicinity of nuclear power plant sites may vary considerably depending on the regional population density, location, and size of local communities, nature of economic development patterns, location of the region relative to interregional transportation corridors, and land surface features, such as mountains, rivers, and lakes." This is certainly an example of an impact where generic treatment is insufficient. (0930-3-2 [Lutz, Ray])

Comment: Furthermore, there is no safe way to transport the stuff. (0936-6 [Laney, Nan S.])

Comment: I oppose transportation of nuclear waste to temporary storage sites because it is dangerous and puts citizens at risk for radiation exposure. (0946-3 [Commenters, Multiple])

Comment: The thought of transporting these dangerous materials to distant storage sites seems short sighted and foolhardy. We now know the unthinkable can happen. (0963-2 [Jacopetti, Anna])

Comment: I am also concerned about nuclear waste that is transferred by truck and rail across country. The potential for accidents that result in radioactive waste being released into the air is frightening and needs to be curtailed. (0968-1 [Morris, Beverly])

Comment: We especially do not want to see nuclear waste transported around the country, via truck or other means, to be stored at a site location other than that of the power plant itself. Transporting and storing of these wastes poses and extreme threat to the health of communities nearby storage sites, and all those through which the waste must travel. (0970-1 [Wilde, Paul])

Comment: While we're about it, in considering the feasibility of any nuclear waste storage and disposal plan, we need to consider the dangers posed by the possible need to transport this material through the country and across state lines. Any safety plan or rules to regulate nuclear power and its waste byproducts needs ton consider safeguards for any necessary transport of this material. Not only are leaks an issue to consider, but also the possibility of this material falling into the wrong hands, such as that of terrorists. (0971-1 [Schneider, Linda])

Comment: Resistance to terror strike is a high priority. Transport to another location is an invitation to terrorists. (0988-1 [Wagner, Deborah])

Comment: NO transport of such waste should be made by rail or highway. (1000-2 [VanWicklen, Betty J.])

34. Comments Concerning Public and Occupational Health

Comment: Have we already released enough radioactivity into the biosphere that over the centuries we may stop evolution? I'd like to see that question answered. And I think every part of the nuclear fuel cycle should answer for the cumulative radioactive load on the human genome. (0030-14-6 [Lewis, Marvin])

Comment: The NRC was part of the Environmental Protection Agency protective action guides that have just -- the controversial protection action guides, which look at the consequences of large nuclear disasters at nuclear reactors, and this would include nuclear waste. And under the protective action guides, because the scenario could be so bad, because the risks to the

public could be so high, as high as one in seven cancers from the exposures from the long-term -- the intermediate and long-term allowable contamination, our regular allowable risks that the EPA has of one in a million to one in 100,000, one in 10,000, these are being jettisoned to allow for higher risks to the public because of the real potential dangers from nuclear power and nuclear waste from nuclear power. (0030-8-6 [D'Arrigo, Diane])

Comment: How many children with leukemia and other cancers which are caused by radiation will be acceptable? Are you willing to sacrifice the health of your grandchildren and their children? (0035-6 [Fulton, Doris])

Comment: As Mr. Jaczko also said, The Fukushima Daichi accident lasted nine months. The consequences of the accident, the incident itself, will go on for decades. If the National Academy of Sciences BEIR VII report is correct, and it is the best science we have on this question, there is no threshold below which exposure to ionizing radiation has no effect on the living cell. Therefore, given the half lives of all the radioactive isotopes ejected from the SPF, leaked into groundwater, and spread around the region via atmospheric deposition and ocean currents, the genetic legacy of this horrifying impact to marine and human life in Japan will go on as long as life exists in this place. It is simply unbelievable that NRC would probabilistically weight these very real consequences out of existence for the purpose of this GEIS. It is my opinion that the requirements of NEPA are not met due to this glaring omission. (0089-18 [Shaw, Sally])

Comment: Don't allow radioactive waste to hurt us. This waste can pollute the water we drink. If we drink it, we can get seriously sick. This can lead us to dying. The fish in that water could get sick or even die from breathing that water. They need clean water; not polluted water. This waste can kill the plants in the water and the ground. We can get sick and die from eating those plants too; or animals who get sick from eating those polluted plants or drinking the polluted water I mentioned. (0160-1 [Rosin, Lawrence])

Comment: I've been looking at pictures of birth defects from the kids that are being born now in Iraq from the depleted uranium that their parents are being exposed to all the time and it's radiation poisoning. And what it does is -- it's heinous, you know, I can't -- I can't describe the photographs. But it's too hideous and I'm just thinking about grandkids and stuff like that, and radiation, no matter what, is incredibly dangerous and it can't be stored safely. It's always leaking. There's always problems with it and it's going to cost -- it's going to cost lives. It's going to cost heartbreak, lives and all that kind of stuff. (0163-10-1 [Kimmich, Erl])

Comment: Europe accepts that "There is no safe lower limit" of radiation exposure. That means that low-level exposure, even close to background levels, cause the death rate to spike. We don't hear about no safe lower limit from the NRC, though you know the laws of physics are the same on both sides of the Atlantic. (0163-28-2 [Cypser, Betty])

Comment: We pay with our health and our lives. Oh, fission and leaks have caused millions of deaths. It's the cost of that cheap energy. (0163-28-6 [Cypser, Betty])

Comment: I also went over some of the summary of the EI -- what is that? GEIS and it still strikes me that it's going under the safe dose myth of radiation exposure, and I want to ask all of you that, okay, there's -- to set up the standard for a safe dose of radiation, there's this model. Okay, this model is created around reference man. That's a man. It's usually a white male in their 20's and 30's who is living based on Western diet. Raise your hand if you fall into that category? (0163-31-2 [Tonohira, Yuko])

Comment: While the Department of Energy and energy corporations have stressed a track record of decades long history of safe nuclear power, isn't there much evidence that such claims cannot be substantiated? Isn't there evidence that the entire nuclear energy cycle constantly emits low levels of radioactive nuclides which results in human exposure to these materials? (0189-3 [Patrie, MD, MPH, Lewis E.])

Comment: Have nuclear energy proponents ignored the evidence provided by many reputable scientists who believe, based on their research, that there is no threshold for radiation damage to humans, no dose which is harmless? Many scientists, including Dr. Steve Wing have discovered evidence that there isn't any safe level of radiation exposure. Also that "An important feature of alpha irradiation is that, no matter how low the total dose to the whole body, a substantial dose of radiation (approx .5 Gy) is delivered to an individual cell if it is traversed by a single alpha particle.", from Proc Natl Acad Sci USA. 1998 May 12;95(10):5730-3. Chromosomal instability in the descendants of unirradiated surviving cells after alpha-particle infiltration. Such findings exist among many reports that even very low doses of radiation can induce cellular damage that can result in increased incidences of cancer and genetic defects. Risks from incidents involving increased transportation of these very highly dangerous nuclear materials could expose populations to unacceptable dangers. (0189-4 [Patrie, MD, MPH, Lewis E.])

Comment: When it comes to nuclear waste, as stated before, its potential harmful effects on humans is very dangerous. This means that the community has every right to know about any nuclear waste that could cause problems. (0192-3 [Einhorn, Jeremy])

Comment: [T]he NRC is responsible for anything nuclear power related, and that includes and ill effects nuclear power may cause. The health effects of nuclear waste on humans can be very harmful, and fatal if exposure is high enough. (0192-5 [Einhorn, Jeremy])

Comment: And then, another point would be that there is -- they haven't addressed any human health -- there's not an actual section of public health, sort of what measures of the waste created by these. Like, what types of waste would be stored, what is the life, you know, the half-life or basically the decay time for these substances. Specifically, just because we all know that nuclear substances, they remain active and radioactive and noxious for, you know, centuries. So if the report was based on assessing, you know, the time that it would be safe to store them, how were we measuring that if it would take centuries to really, you know, really have a confidence in how long we're storing it? (0244-15-2 [Zuccarini, Ana])

Comment: And, you know, again with the word "small" in capital letters. What does that mean? In this case, when it comes to noxious substances and possible, you know, deaths of population in close proximity to these facilities, size matters, guys. The length of exposure, the amount of contact and just basically, you know, how long you're in contact with the poison, you know, even hours and it can kill you over, you know, a couple weeks or whatnot. However, we don't know if these are -- you know, we don't know the substances, we don't know the time, we don't know the times of exposures, so we can't really -- well, me, as I am reading this, I can't assess if this is small or not. (0244-15-9 [Zuccarini, Ana])

Comment: Who here is a nuclear neighbor? If you live in Illinois, you're a nuclear neighbor. If you live in the United States, you're a nuclear neighbor. It is insane to me, the previous gentleman that was up here talking about Mr. Hansen. I've seen him speak before. I have some respect for him. He doesn't live in a nuclear neighborhood, never has, doubt that he ever would, considering Dresden. He has leaks out there and water still hasn't been fixed for the people that have the leaks. The moms can't explain why their kids are leaking from their eyes, and the

parents are paying really high medical bills for dentistry to have their jaws wired shut for kids in the 4th and 5th Grade because their teeth are separating due to radiation exposure. Not to mention all the kids that keep showing up at the Mayo Clinic that have radiation overdoses and nobody knows anything about it. (0245-17-1 [Thompson, Tammy])

Comment: I'd like to start with a basic question about the fact that there has been some anecdote testimony here about the effects of living near nuclear power plants, and the people who come to represent the industry have nothing to say about the anecdotal evidence, the stories about what happens to families and children who are living near these plants and the possibility of birth defects that are almost unbelievable. So, I'm asking this question really because there was an earlier comment about this. Residents around reactor sites may not have signed up to store radioactive waste indefinitely, but they also did not sign up for 20-year extensions of operating licenses. Yet the NRC imposes that on communities without pause and without exception. So, I'm very moved by the anecdotal evidence because the anecdotal evidence from Chernobyl was cut off and the difficulties of tracing the effects of the exposure at Chernobyl were massive and eventually the strong scientific minds says, well, gee, you're just giving us anecdotal evidence, when it was all the evidence that they had. (0245-21-1 [Boudart, Jan])

Comment: I just want to clarify a few things that came up about safety concerns and the facts. Well, one of the facts that are to safety concerns is Three Mile Island. And I have a very conservative accountant who in every way is very conservative. But when it comes to Three Mile Island, he shakes his head and he hates nuclear. Why? Because his relatives are there and they're dying. That is a fact. That is not safety concern, that's fact. Please say it as it is. My next-door neighbor, who gets sick constantly, a beautiful young man and at most he's in his early 30's, he was a victim of Chernobyl. He lived in Poland. He constantly gets ill. He does not know how to solve it. That is not a safety feature. That's a fact, and that's a fact we have to look at and we have to look now. (0245-38-1 [Good, Joyce])

Comment: While the Department of Energy and energy corporations have stressed a long track record of decades of safe nuclear power, isn't there much evidence that such claims cannot be substantiated? Isn't there evidence that the entire nuclear energy cycle consistently emits low levels of radioactive nuclides which results in human exposure to these materials? Have nuclear energy proponents ignored the evidence provided by many reputable scientists who believe based on their research that there is no threshold for radiation damage to humans, no dose which is harmless? And I cite Dr. Steve Wing's study and others. Such findings exist among many reports that even very low doses of radiation can induce cellular damage that can result in increased incidences of cancer and genetic defects; risks from incidents involving increased transportation of these very highly dangerous nuclear materials could expose populations to unacceptable dangers. (0250-30-3 [Patrie, Lewis E.])

Comment: One of them is that ionizing radiation can cause cancers. We know that from Hiroshima and Nagasaki. We know that from Chernobyl and we know that from Japan, but there is whitewashing going on. There are studies coming out from the UN, and when you go to the NRC you see that what they say in their website is that we're pleased that no ill effects of radiation have occurred. They do add more time is needed. There is evidence already of thyroid cancers in children, and there's -- Chernobyl, I mean, the Japanese tragedy is not over yet. They're still actively being exposed to radiation. (0250-31-3 [Clark, Terry])

Comment: Also, I just wanted to bring up the fact that, according to the National Academy of Sciences data, a female body of people and children are more impacted by doses of radiation than other folks are. So perhaps they should have more of a say in what is being done with this stuff. (0250-50-6 [Blevins, Eric])

Comment: You must regulate nuclear waste's dumping. If it's dumped in the water, then the fish can get poisoned. It can also kill the fish. Even fish that don't get directly affected, can still get indirectly affected, if they eat enough fish affected by the nuclear waste. Also humans who eat the intoxicated fish can get sick. Also the nuclear waste can make the water dangerous to swim. We can can accidentally swallow the water. (0258-1 [Rosin, Lawrence])

Comment: Highlights from expert presentations on "high burn" and related topics: Donald Mosier, Professor of Immunology & Microbial Science at the Scripps Research Institute, asked if any dose of radiation is safe and answered, "No -Any level can be dangerous. We now know why very low doses can cause cancer. Many sites in the body are hypersensitive DNA regions highly vulnerable to cancer factors. These are areas of rapid change, which provide openings for cancerous mutation." Dr. Mosier noted that "exposure to 10,000 milli-sieverts is deadly. 1,000 brings sickness and is cancerous. The rate during the Fukushima crisis was 400 per hour. A CAT scan is 20 to 60. Amammogram is .4. A dental x-ray is .005-and requires you to wear a lead apron." He cited a 15-country study that found the risk was double the norm for nuclear industry workers, and added, "There is no reliable survey data on the health of San Onofre workers because the amount of radiation releases is not monitored at any point near the site." Dr. Mosier concluded, "The effects of exposure to cancer factors are cummulative. This is why repeated exposure matters. Why add one more insult to the mix?" (0283-4 [Pascall, Glenn] [Watland, George])

Comment: I am a 33 year local resident that lives within a 5 mile radius of the plant. The low levels of radiation are killing us! I have ad 9 miscarriages and one still born. Many good friends are not here to share their stories --- meeting untimely deaths. One died at 47 of adrenal gland cancer, one at 50 died of blood cancer, 2 died at under 50 from brain tumor. Others are still fighting cancer at ages 49, 30, 55 and 49 years old. The are just my personal friends. Coincidence?? (0292-2 [Comer, Gail])

Comment: We live just outside the 12 mile "radius" and believed that a power plant, including it's continued on-site storage of spent nuclear fuel repository would pose no threat to our families living within this community. Why, then, do we have an excessively high number of individuals living within this community that have or have had cancer? Just within our immediate neighborhood alone we have had over a dozen neighbors within the last few years with various types of cancers, most prominently breast and thyroid cancers. Have any actual studies been done on the health of people living with a certain geographic area to see if their might be a relationship to the nuclear fuel and human health? How in the world can you possibly determine the safety of an unsafe material when you haven't even verified the potential hazards to those living near it? We in this community do not consider the power plant safe, nor do we consider the continued storage of nuclear waste safe. The lives of people must be considered before the livelihood of a business! (0323-1 [Murdock, J.]

Comment: I'd like to address one thing that we might not know. In Japan, there is an ongoing triple nuclear meltdown, and they have standards for the contamination in their food. It is the lowest and strictest in the world, being 100 becquerels per kilogram. This is for food that we eat, 100 becquerels per kilogram. It's a standard of tangible waste. I'm going to finish really, really quickly. In the United States, we allow -- the FDA made the standard of 1,200 becquerels per

kilogram. Where do we think this radioactive waste, cesium-134, cesium-137, strontium-90 is allowed in our food system. This is all coming from leaking waste. I have no confidence in our waste management system at all. We need to understand that internal contamination affects the weakest in our society, the babies. We feed our children the food that is -- have you heard of tritium in the water? These are some issues that we really, really need to think about. So, go to the FDA website and you will notice when these limits were set, and it's all about the leaking radioactivity in our environment. It's showing up in our food. This is something that we need to pay attention to[.] (0325-21-2 [Iwane, Cathy])

Comment: The low-level waste problem is not really dealt with. It's whitewashed, also. If you -- the NRC website says -- adopts the linear no threshold idea that there is no such thing as a safe level of radiation. This also comes from the BEIR 7 reports of the biological effects of ionizing radiation, and the BEIR 7 report says that all radiation is potentially dangerous, and there's no such thing as a safe threshold. So, low-level doesn't mean it's safe. (0325-31-3 [Johnson, Roger])

Comment: One thing that I would like to see is radioactive monitoring. There is no real-time radioactive monitoring available to the public, so when you have a dirty day and you blow up something and a contaminant gets into the ocean and into the air, I think people who live in San Clemente or inland ought to know about it. I'd like to propose that you build real-time publicly available radioactive monitors in every town and city within 20 miles. (0325-31-5 [Johnson, Roger])

Comment: We have to look at this Waste Confidence issue from a very small level, molecular level, where it affects the area. It affects us here where we sit today. I mean, we are being bombarded by the waste that is being stored out there at Diablo and here in this room. You know, nuclear energy passes through, at a molecular level, tremendous distances. The effect that the storage of waste at the nuclear plant has on the environment and the cultural landscape of my ancestors and the occurrent families of Chumash people that live here is unacceptable. (0326-2-1 [Collins, Fred])

Comment: We believe that it is being done without the whole picture and for us, it is a highly volatile and a very harmful storage, and the continued buildup of this waste material in this very small part of our coastline is extremely dangerous. It's extremely dangerous to the future, the seven generations that are to come, so we do not give the NRC permission to re-license this plant, nor do we give the Waste Confidence Commission permission to move forward with this Generic EIS. (0326-2-3 [Collins, Fred])

Comment: Clearly, the truth about Fukushima has not been told. Nuclear efforts say there's nothing in the books on what we can do. They are making it up as they go. Helen Caldecott warns that the ace in the hole for the nuclear energy industry is the incubation period of radiation exposure. Its damage does not show up for a long time. You cannot prove that it was caused by the nuclear power plant. It's two to five years for lung cancer to show up; 15 to 17 years for solid cancers. (0326-23-2 [Malboeuf, Simone])

Comment: Okay, public and occupational health, Roman numeral 43; it says that it's small, that there is no public or occupational health. That is also a lie. (0326-56-4 [Homick, Nick])

Comment: It appears that the danger of radiation from nuclear waste depends on your clothing. With NRC's representatives and representatives from industry in suits and ties, the waste is evidently quite safe, but people in lab coats know even the tiniest exposure is dangerous. Every U.S. agency that monitors radiation says this. The National Council on

Radiation Protection says, "Every increment of radiation exposure produces an incremental increase in the risk of cancer." The National EPA says, "There is no firm basis for setting a safe level of exposure above background. Based on current scientific evidence, any exposure to radiation can be harmful or can increase the risk of cancer. No radiation exposure is completely risk-free. There is no level below which we can say an exposure poses no risk. Radiation is a carcinogen. It may also cause other adverse health effects, including genetic defects in children of exposed parents, or mental retardation in the children of mothers exposed during pregnancy." The National Academy of Sciences in Bier 7 says, "There is a relationship between exposure to ionizing radiation and the development of radiation-induced solid cancers in humans. Current evidence suggests that any exposure to radiation poses some risk; that is, there is no level below which we can say exposure poses no risk." The United States Department of Energy says, "U.S. Government regulations assume that the effects of all radiation exposures are cumulative and should be limited as much as reasonably possible." Even our own Nuclear Regulatory Commission says, "Any amount of radiation may pose some risk for causing cancer and hereditary effect, and that the risk is higher for higher radiation exposures. Any increase in dose no matter how small results in an incremental increase in risk." (0328-9-1 [LaForge, John])

Comment: [I] have seen the effects of long-term radiation, slow radiation poisoning on veterans, worked at the VA for a long time. So I have a lot of concerns about transporting waste, storing waste safely, and the long-term effects on humans. (0329-34-3 [Myers, Susan])

Comment: In concluding, one elephant in the room stands: the NRC's failure to understand the very real, well documented, science of radioactive substances which waste produces. A fingernail of plutonium could kill off, conservatively a large city. Cesium, strontium, and other radionuclides contained in waste, are some of the most toxic substances on earth, creating slow and long term illness and well as mutating genes. The NRC has a duty to protect children and grandchildren for generations to come from substances which contaminate human beings, the biosphere and the environment and which can create lasting, adverse, multi-generational changes in the genome. We believe the DWC GEIS shows that the NRC does not take that duty seriously. (0348-14 [Agnew, David] [Roscoe, Lee])

Comment: In concluding, one elephant in the room stands: the NRC's failure to understand the very real, well documented, science of radioactive substances which waste produces. A fingernail of plutonium could kill off, conservatively a large city. Cesium, strontium, and other radionuclides contained in waste, are some of the most toxic substances on earth, creating slow and long term illness and well as mutating genes. The NRC has a duty to protect children and grandchildren for generations to come from substances which contaminate human beings, the biosphere and the environment and which can create lasting, adverse, multi-generational changes in the genome. We believe the DWC GEIS shows that the NRC does not take that duty seriously. (0352-14 [Roscoe, Lee])

Comment: Spent nuclear fuel remains highly dangerous, virtually forever. It contains long-lived radioactive materials that can seriously contaminate the environment and harm public health if released. Plutonium-239 can be used to make nuclear weapons if separated from the other materials in the fuel. Plutonium-239 has a half-life of over 24,000 years. (0377-5-19 [Cuthbert, Lewis])

Comment: Tritium is a strong biological toxin because it is readily incorporated into biological tissues. It doesn't even require a chemical reaction since an organic molecule can incorporate tritium through an exchange mechanism between tritiated water and the hydrogen atoms of organic compounds by simple incubation in aqueous solution. Thus tritium can be absorbed

from the environment by both ingestion and inspiration. Once incorporated into the body, tritium is particularly dangerous because hydrogen is ubiquitous in biological tissue. Tritium decays at a high activity rate but emits a low energy electron. Low energy electrons have a high linear energy transfer to their surroundings and therefore cause maximum biological damage in a small volume of tissue. This energy deposition in a very small area of an organ results in a very high micro-dose to specific cellular and tissue components, which can lead to cancer or mutation if a cell is transformed and not cleared by the immune system. Therefore, micro-dose calculation is important for assessing the carcinogenic potential of tritium decay, in situ, and this micro-dose is much larger than what would be expected if the dose were to be distributed uniformly throughout the organ. (0410-14 [Nelson, Dennis])

Comment: Other radionuclides present in spent fuel are also selectively incorporated into certain biological tissue because they mimic some essential biological elements. For example: radioactive cesium and rubidium mimic potassium and so are concentrated in the muscles where they can cause wasting disease such as polymyocytis, or contribute to autoimmune disorders like multiple sclerosis or even heart disease. Plutonium and strontium mimic calcium and so concentrate in the bones near the bone marrow which can cause leukemia and disorders of the blood forming units. Some alpha emitters in the circulatory system damage the vascular lining causing inflammation resulting in calcified arterial plaques which can cause infarcts and heart disease. Radioactive noble gases dissolve in fatty tissues and so concentrate in tissues like the brain, breast and bone marrow, causing cancers in these organs. A variety of radionuclides mimic iron and so are transported and stored in the body by transferrin and ferritin. Radio-iodine concentrates in the thyroid, but can also be incorporated into radioactive thyroxin which can damage the thyroxin receptors in the tissues. (Dioxin is so chemically toxic precisely because it disrupts this thyroxin/receptor binding site). It is not enough to say that these atoms are simply radioactive but one must also know where in the body they are concentrated and how their decay affects the adjacent tissue and its biochemistry. These pathways are so complex that it is virtually useless to attempt to predict biological risk based on the decay properties of radioisotopes themselves outside the body. Most of the NRC risk analyses are clearly done by physicists with limited knowledge of biology or biochemistry and so lack the insight of the biological disciplines. Physicists concentrate on the external radiation component of dose, in most cases, while ignoring the subtleties of the tissue doses at the molecular level. Radiation has also been shown to have other demonstrated statistical effects besides increasing cancer rates, such as depression of the normal bodily immune response mechanisms against pathogens and a non-specific life shortening in irradiated populations. (0410-15 [Nelson, Dennis])

Comment: The NRC has used an artificially inflated number of 350 mR per year for natural background radiation (NBR). The tacit assumption here is that this "natural" level of radiation exposure results in no deleterious health effects. In the GEIS draft report the NRC constantly compares the "permissible" dose/exposure level for members of the general public (up to 500 mR/yr) to this "natural" level. They assume that if this natural level is "safe" then it must follow that exposure to man-made radiation in this same range must also be "safe." No account seems to be taken of the fact that the natural and man-made doses are additive. There is no threshold safe dose of radiation so any additional level of exposure can be expected to cause additional damage to health. Problems with this analysis also arise when one recognizes that the actual natural level of background radiation is about 81 mR/yr at sea-level with an average terrestrial radiation component (about one quarter the NRC's estimated value). Most other NRC analyses of "dose" are based on external radiation sources and the effect of penetrating radiation on biological systems. It is therefore curious that the NRC has chosen to add an internal radon dose to their estimate of NBR. This "radon" dose cannot even be generalized since it depends

on so many factors such as smoking habits, house ventilation/air exchange systems and the composition of the underlying bedrock and soils. The NRC uses this approach when it suits their purpose of inflating the background dose for comparison purposes against NRC allowed exposure limits; but they ignore internal doses when they go against their otherwise optimistic risk projections. It is also curious that they add a significant dose due to medical procedures which are clearly not "natural" at all. (0410-16 [Nelson, Dennis])

Comment: Since the earth's life forms are carbon based, carbon-14 is a particularly noxious toxicant. Carbon-14-carbon dioxide has a long half-life and is also readily incorporated into the biome by photosynthesis, where it can be assimilated into bio-molecules such as DNA which are vital to life. Carbon-14 decays by beta emission and can cause disruption and mutation of bio-molecules in three different ways: (1) the emitted beta particle can ionize and disrupt adjacent bonds in the molecule; (2) the beta decay can cause the source nucleus to recoil and be expelled from its position in the bio-molecule causing bond recombination in deleterious ways; and (3) the decaying carbon nucleus can transform itself into a different element with different chemical properties and thus compromise the chemical integrity of the bio-molecule. The NRC does not state how much carbon-14 would be produced and released into the atmosphere by the air cooling of dry casks over decades or centuries or how this would affect future generations. This is not a question of a dose distributed uniformly over the planet affecting everyone equally; but rather the effect of a widespread random distribution of discrete biological disrupters into the biosphere, (the biochemical equivalent of "land mines" or "time bombs" in the macroscopic world) each with the potential to cause random disease, mutation or premature death. During the atmospheric nuclear test era the concentration of carbon-14 in the biosphere more than doubled. This is one likely explanation for the large increase in the cancer rate during that same time frame. (0410-26 [Nelson, Dennis])

Comment: Some genetic variations, the so-called inborn errors of metabolism, also confer increased sensitivity to radiation damage on certain susceptible individuals, rendering them much more vulnerable to environmental radiation than others. This means that the same amount of radiation which might be tolerated by one person might cause harm in another. One example is hemochromatosis, a genetic defect in iron metabolism associated with a greatly increased susceptibility to radiation damage. It has also been suggested that the more common heterozygous persons with this trait may also be at increased risk. Many other genetic variations including ataxia telangiectasia also increase the radiation risk in susceptible individuals. It is well known that pregnant women and children are also more sensitive to radiation damage than are adults. In the end, the number one priority of the NRC should always be the preservation of the health of nuclear workers and the general public. The report mentions nothing in its risk assessment about susceptible genetic variants in the population or the need for increased levels of protection for pregnant women and children. This omission shows a total lack of consideration for the most vulnerable members of society, and a lack of caution in this regard could have devastating effects on the future of our nation since pregnant women and children represent our future. The NRC GEIS Draft Report is, therefore, not a true analysis of radiation health risk and is not based on the entirety of the scientific knowledge. (0410-32 [Nelson, Dennis])

Comment: Almost every facility in the nuclear complex has experienced at one time or another, during its operation, a radiological release off-site of greater or lesser magnitude. Transport of radioactive isotopes has occurred by air, ground and water. Some radionuclides have been absorbed by plant life and concentrated in the food chain and so have contaminated food and livestock. During the atmospheric nuclear bomb testing era, some pathetic countermeasures such as the iodination of table salt and the promotion of baby formula over breast feeding were attempted to mitigate the effect of iodine-131, (a short-lived environmental

and food contaminant); but the majority of contaminants were simply ignored even though they most certainly caused harm. Scores of radionuclides of varying half-lives and activities combined in hundreds of chemical compound variations are produced by nuclear fission in both bombs and reactors. Although many of these decay quickly, others persist long enough to be incorporated chemically into animal and plant tissues, through a myriad of physiological and biochemical pathways to become constituent building blocks of cells. These incorporated radioisotopes can cause mutagenic and oncogenic transformations in the host or adjacent cells. Each compound can be metabolized by a variety of anabolic and catabolic pathways with different biological outcomes. The simple-minded approach used by the NRC to estimate risk is almost entirely based on the external fluence of gamma and beta radiation, distributed uniformly over large areas, and largely ignores the multitude of specific risks due to in-situ radionuclide incorporation. (0410-4 [Nelson, Dennis])

Comment: Unlike other toxic biochemical reactions which require a certain minimum concentration of reactants (toxicants) or activation energy to proceed, nuclear processes emit particles or photons with sufficient energy to precipitate a chemical reaction from the decay of a single nucleus. Thus, there is no threshold concentration for nuclear induced chemical processes as there is with chemical toxins. In fact, some radionuclides such as polonium-210, which can be present in waste fuel, are lethally toxic even in the sub-microgram range. Analyses of the radioisotope composition of the waste from each kind of starting fuel mixture, while taking into account the degree of fuel burn-up and the stage in the cooling/aging process, is essential to fully evaluate the toxicity of all the different radioisotopes in the waste fuel in the event of an accidental release. The NRC assertion that spent fuel from mixed-oxide fueled reactors is "substantially the same" as that from uranium fueled reactors shows that they have ignored the isotope composition of the waste fuel in their risk estimations. Ideally, when dealing with intact spent fuel elements shielded by water in pools or in steel and concrete casks only the fugitive gamma and x-radiation is of health significance; but we know from experience that the fuel doesn't always remain clad and in place and that fissionable elements, fission products and activated reactor components often end up contaminating the surroundings. We also know from experience that radioactive contamination is not distributed uniformly as the NRC has assumed. (0410-5 [Nelson, Dennis])

Comment: Ionizing radiation can cause cancer. The draft ruling and plan fails to appropriately emphasize that radiation is potentially harmful to humans. The GEIS should not rely on the United Nations UNSCEAR report for effects of radiation on humans. The UNSCEAR report only utilized the probable effect of radiation released in the first week of the Fukushima meltdown. The reality is that radiation continues to be released two and a half years later. Adverse health effects, especially malignancies are most thyroid cancers especially in children. (0417-4 [Clark, Terrence])

Comment: My particular worry has not been stated in the NUREG-2157. My particular worry concerns a new discovery by a Michael Skinner of the Washington State University and written up on Page 78 of the December 2013 issue of Smithsonian Magazine. Dr. Skinner's discoveries concern the new information about epigenetics. Epigenetics has shown that negative health effects can skip generations, and then become permanent to the following generations. Deaths and damage from radiation may not show in the generation that experiences the radiation, but appear in later generations and all following generations. The present methodologies for observing and calculating damage from radiation does not show these epigenetic effects. I contacted the NRC Chairman's office, and a staffer contacted me that the NRC does not observe genetic effects, but relies on present data that does not try to include genetic effects. Will the NRC try to include genetic effects in its evaluation of the radioactivity

from spent fuel and from the entire fuel cycle in its evaluation of the nuclear fuel cycle and ,specifically, spent fuel storage? (0427-2 [Lewis, Marvin])

Comment: Here I am again with more comments upon Waste Confidence and growing less confident in the NRC to handle rad wastes as I write. I continue to study the NRC's way of calculating doses to the public and am disappointed by the methodology. The NRC accounts for any doses to the public for releases-air, water and solids- for the first year only. In many or all cases the released isotopes are considered to be part of the background and ignored after the first year. Background has risen from 60 millirems per year when I was a child to 360 millirems per year reported in many NRC publications, and 600+ per year in Protective Action Guidelines released by the Environmental Protection Administration published this year. I submit that the rate of increase and the increase of background needs to be studied and that the contribution to the background from leaving radioactive wastes on the surface be calculated for its damage to the human genome and other radiation sensitive structures. Will the NRC determine how much increase in background will issue from storing radioactive waste, particularly spent fuel, on the surface in contrast to burying in a geological repository over time? (0430-1 [Lewis, Marvin])

Comment: The essential element, Uranium, wherever taken from its entombment in the earth has created a cancer cluster (i.e. Crownpoint N.M.) and environmental degradation that will last for generations along with the climate changing production of large amounts of carbon. (0450-9 [Bast, Nancy])

Comment: The rules and regulations ignore the cumulative dose past the first year that the radiation is emitted and enters the food, water and air. When radioactive waste appeared to be handled in a fast, efficient manner, the added radiation past the first year was a matter that fell thru the cracks as a geological depository was assumed available when needed. There is now no assumption of a timely geological repository, and an admission that such a repository may need centuries. The radiation release reduces over time as a function of half life. The reverse is true for radiation stored on the surface. Will the added dosage to the public and the workers be evaluated for the added time that the HL radwaste will be stored on the surface? (0455-2 [Lewis, Marvin])

Comment: Michael Skinner, Michael Meaney and Moeshe Szyf have discovered the phenomenon called epigenetics. Epigenetics increases the damage that radiation will do to future generations. Recent discoveries about the radiation dose during the PreCambrian Explosion of Life. The radiation dose during the PreCambrian Explosion of life was roughly that which is allowed in the EPA PAGs (Environmental Protection Agency Protective Action Guidelines). During the Precambrian Explosion of Life, many new life forms came upon the scene. Evolution blossomed due to the reduction in the background dose to a level that allowed evolution to introduce many forms of life never seen before on this Earth. Are we forcing evolution back with the increase in background radiation to the point that life will stop evolving and how much will be due to the nuclear fuel cycle with the addition of high level radiative waste storage on the surface of the Earth? (0455-3 [Lewis, Marvin])

Comment: Please understand that I started a facebook page in which there are high levels of diseases in the Riverside county areas especially Temecula, Fallbrook, Murrieta, and Lake Elsinore Etc... These areas are directly 22 miles away from San Onofre power station. Hopefully a billion dollar industry would protect the citizens over profits (0478-3 [Higgins, Kevin])

Comment: Nuclear radiation is devastating to the human body and this problem need to be faced and changed right away, for the safety of every person in this nation. (0494-2 [Orlinski, Patricia])

Comment: The WCGEIS fails to address new data and studies about the harmful effects of radiation. The WCGEIS needs to be revised to address these findings in terms of a national fleet of operating reactors and spent-fuel basins. (0496-12 [Batobato, Alicia])

Comment: Failure to adequately disclose radioactive air emissions. Many LR EISs failed to publicly and accurately disclose radioactive emissions and increased dosages over time, including failure to compute emissions from multiple reactors at a single station. Nor have they computed reasonable foreseeable trends in increased emissions such as those witnessed at the Columbia Generating Station. Nor have they adequately computed the cumulative emissions to individuals over the 20-years licensing extension period. The WCGEIS needs to the total emissions and health effects from all operating nuclear reactors, combined with the emissions from all spent-fuel storage. (0496-4 [Batobato, Alicia])

Comment: The WCGEIS failed to disclose controversial or opposing technical and scientific views including other radiation and health studies that contradict NRC's conclusions. The WCGEIS needs to be revised to address these opposing views. This comment applies to a host of other controversial issues described in the WCGEIS. (0496-5 [Batobato, Alicia])

Comment: -Radiation protection standards should apply to an interim period of up to a 300 year storage period. -The HPS has a position statement on public radiation exposure, PS005-3, Ionizing Radiation Safety Standards for the General Public that supports a mSv/yr dose limit. The HPS is pleased that the NRC has not proposed a different standard for spent fuel storage nor is there a proposal to change the standard over time. -Appropriate radiological monitoring should be required for the environment surrounding the storage facility. -The regulations for spent fuel storage include adequate requirements for a Radiological Environmental Monitoring Program (REMP). No additional requirements are justified. (0534-7 [Vetter, Richard])

Comment: Radioactive waste cannot be safe, secure, clean or green. It is deadly, very long-lasting, toxic stuff that irradiates cells and damages DNA--causing cancer, birth defects, heart problems, infertility, immune deficiencies, and more. There is no safe dose of radiation, but spent or irradiated nuclear fuel is so radioactive a person near it would receive a lethal dose of radiation in just a few minutes if not seconds. (0552-1-8 [Macks, Vic])

Comment: Radiation-linked diseases in communities near reactors vary and must be looked at on a site specific basis. Additional years of exposure from onsite storage will harm an already damaged population, even if the releases are at permissible levels. Both BEIR VII and previous nuclear worker studies show that the health effects of radiation are cumulative. See Morgenstern, H. and Ritz, B. Effects of Radiation and Chemical Exposures on Cancer Mortality Among Rocketdyne Workers: A Review of Three Cohort Studies. Occupational Medicine: State of the Art Reviews, Vol. 16, No. 2, April-June 2001, pages 219-238. For example: Increases in radiation-linked disease in the communities around Pilgrim were in part attributed to operating with defective fuel; operating without the off-gas treatment system in the first years; poor management and practices culminating in the releases in June 1982 that coincided with weather conditions that held the releases over surrounding communities and parts of Cape Cod. The cancers found in the communities around the power station were studied by Dr. Sidney Cobb and Dr. Richard Clapp and their results were published in a peer reviewed journal in 1987. They included elevated rates of Myelogenous Leukemia -- a type of cancer most likely to be triggered

by exposure to radiation.⁸ [footnote 8 text: An epidemiological analysis of five towns around Pilgrim shows a 60 percent increase in leukemia rate, excluding leukemias not caused by radiation exposure. - Sidney Cobb, et al. Lancet, 1987. The rate of myelogenous leukemia (the type most likely to be triggered by exposure to radiation) among males in the 5 towns around the Pilgrim reactor was found to be 2 1/2 times greater than the statewide average. Leukemia in Five Massachusetts Coastal Towns, Sydney Cobb, et al., Abstract for the American Epidemiologic Society, March 18, 1987; and Leukemia near Massachusetts Nuclear Power Plant, letter b Clapp, R.W., Cobb, S., Chan, C.K., Walker, B., Lancet 1987, No, 2:1324-5.] This led to a case-control study carried out by the Massachusetts Department of Public Health that showed a fourfold increase in adult Leukemia between 1978 and 1983. The report stated "a dose-response relationship was observed in that the relative risk of leukemia increased as the potential for exposure to plant emissions also increased."⁹ [footnote 9 text: Adults living and working within ten miles of the Pilgrim reactor had a fourfold increased risk of contracting leukemia between the years of 1978 and 1983 when compared with people living more than 20 miles away, according to a 1990 study by the Massachusetts Department of Public Health: Southeastern Massachusetts Health Study 1978-1986, Morris, M.S., Knorr, R.S., Massachusetts Department of Health, Oct. 1990. See also Archives of Environmental Health, 1996, Vol. 51(4), p. 266.] (0556-1-29 [Lampert, Mary])

Comment: BEIR VII showed that the young, elderly, and females are more susceptible to radiation so that the demographics of these population groups on a site-specific basis must be accounted for in assessing health impacts on the public of normal and above-normal releases from spent fuel storage. The DGEIS did not do so. (0556-1-30 [Lampert, Mary])

Comment: Bio-Accumulation of Radionuclides in the Environment The history of releases into the environment varies from reactor to reactor. Its significance must be evaluated on a site-specific basis because the effects of radiation exposure are cumulative. Some types of nuclear power plant emissions stay radioactive for a long time and, because they can enter biological food chains, those materials can accumulate in the environment and adversely affect public health. Reports show that, "If radioactive emissions persist for years, decades or even centuries within the environment, then even modest reductions in annual discharges may not be sufficient to prevent an environmental build-up of those materials over time." Estimates of Environmental Accumulations of Radioactivity Resulting from Routine Operation of New England Nuclear Power Plants (1973-84), Dr. Richard W. England, Mr. Eric Mitchell, p. 4, A Report of the Nuclear Emission Research Project, Whittemore School of Business and Economics, University of New Hampshire, Durham, N.H., August 1987. It is known for example that the following radionuclides have been released from Pilgrim into neighboring communities: plutonium 239 (half life 24,400 years); neptunium 236 or 237 (half life ranging from 120,000 years to 2.1 million years); cesium 137 (half life 30.2 years); strontium 90 (half life 28.5 years); tritium (half life 12.3 years), and xenon (half life 9.17 hours). Xenon transforms after its emission into cesium 135, which persists almost indefinitely in the environment. Examples of previous releases have been reported in the Annual Radiological Environmental Monitoring Program Reports [REMP].¹⁰ [footnote 10 text: For example, in June 1982, Pilgrim blew its filters and released contaminated resin material off site into surrounding communities. The licensee's own Radiological Environmental Monitoring Program Report for 1982 showed for example: Cesium-137, 1,000,000 times higher than expected in milk tested at the indicator sampling farm 12 miles west of the reactor and no elevation at the control station, 22 miles away; Cesium-137 again 1,000,000 times higher in vegetation samples from indicator farms .7 miles and 1.5 miles from the reactor. Plutonium 239/240: Radiological Environmental Reports (REMP) 1998, Plutonium found in indicator samples; and on Duxbury Beach: REMP 1999, Plutonium found Duxbury Beach; REMP 2000, Plutonium in indicator samples from Duxbury Beach, later excused by stating contamination

must have resulted from a dirty beaker; REMP 20 Plutonium Duxbury Beach; REMP from 2003 forward stopped testing for Plutonium on Duxbury Beach.] These releases include substances that will remain active in the local environment for the foreseeable future and should be taken into account on a site specific basis when evaluating the impact of releases from continued storage of spent fuel in normal and accident scenarios. Reactors' past history of releases vary and require separate analysis. (0556-1-31 [Lampert, Mary])

Comment: Recognizing that sky-shine is a measurable phenomenon at ISFSI facilities, the radiological affects of such facilities on the environment must be analyzed and included in the Draft GEIS. (0608-17 [Crocker, George])

Comment: Since BEIR VII there has been scientific certainty that every exposure to ionizing radiation increases the risk of adverse health affects, and it is not the case that any of these events, or routine radiation releases either, for that matter, are ever really over. It's not like a train wreck or a car crash, where you can pick up the bodies, clean up the mess, grieve and be sorry and move on. Due to the half-lives of all these radiological releases, the events continue causing biological destruction and premature human death for decades and centuries into the future. Just because you don't bother to monitor radiation plumes and hot spots and dispersion patterns for their biologically active 10 half-lives, doesn't mean that the released radioactivity you enable isn't killing people. (0608-2 [Crocker, George])

Comment: --[The NRC has failed to fully examine] the impacts on public health that may occur if a geological repository cannot be sited or cannot effectively contain radioactivity. (0611-13 [Shapiro, Susan])

Comment: Studies based on CDRC and New York State Cancer Registry Data have found significantly higher levels of thyroid cancer in the areas surrounding Indian Point and other nuclear reactor. (See Geographic Variation in U.S. Thyroid Cancer Incidence and a Cluster Near Nuclear Reactors in New Jersey, New York, and Pennsylvania published in the International Journal of Health Services Volume 39, Number 4, 2009, pages 643 - 661. <http://radiation.org/reading/pubs/091116Thyroidcancer.pdf>. In addition Childhood Leukaemia near nuclear plants has been proven in peer reviewed studies to be significantly higher. See http://radiation.org/reading/pubs/ecc_948.pdf. The GEIS fails to consider the long term health impacts of continued production of nuclear waste without a solution for safe and secure storage and waste disposal. (0611-49 [Shapiro, Susan])

Comment: Fund a comprehensive, continuous independent, citizen run radiation monitoring program (reports 4 times a year are not adequate to evaluate health impacts of ongoing radioactive releases and bioaccumulation) (0611-55 [Shapiro, Susan])

Comment: Cancer is now the number one killer of children in the US, and the National Cancer Institute of Japan has sent brochures to all the children in elementary school telling them they should not fear cancer as almost everyone will die of cancer one day. How is nuclear a "safe" technology? In what world? (0617-8 [Zure, Lisa])

Comment: Consolidated storage likely would increase worker exposure at the power plant and would certainly increase worker exposures during transportation and at the consolidated storage site. (0646-5 [Hanson, Courtney])

Comment: Acceptable exposure levels should be based on standards to protect the most vulnerable members of the community. (0662-10 [McClintock, Francene])

Comment: If you choose to believe that small amounts of radiation can actually be good for you, as Ann Coulter suggested, then it's perfectly clear you have absolutely no idea what ionizing radiation is and what it can do. I, for one, don't want leukemia, therefore I'm moving to the Southern hemisphere, and I suggest you consider doing the same. (0670-6 [Anonymous, Brian])

Comment: The radiation risks from nuclear power are carefully studied. The requirements for radiation exposure to the public are so stringent that nuclear power plants release less radiation than coal plants as coal contains radioactive elements that are unfiltered before entering the atmosphere. [Max Carbon, "Nuclear Power: Villain or Victim?"] Health physicists, nuclear engineers, and regulators have made and continue to make very conservative assumptions regarding how much radiation exposure to the public is acceptable and nuclear power plants are required to operate within those limits even in the event of an accident. (0674-8 [Lang, Amanda])

Comment: Recognition that Spent Nuclear Fuel Poses Human Health and Environmental Dangers: At high levels, radiation exposure can cause death. At lower doses, radiation can have devastating health effects, including increased cancer risks and serious birth defects such as mental retardation, eye malformations, and small brain or head size. Those health effects persist for very long time spans.⁸ [footnote 8 text: See generally *Nuclear Energy Inst. v. EPA*, 373 F.3d 1251, 1258 (D.C. Cir. 2004).] Depending on the amount, the dispersion of radionuclides can render residential areas uninhabitable, make drinking water resources unpotable, and cause agricultural lands to become unsuitable for dairy and agricultural farming. The State of New York requests that any final NRC environmental impact statement squarely acknowledge, as an initial matter, the dangers posed by release of radiation into the environment. (0681-8 [Peterson, Alyse])

Comment: The ace in the hole for the nuclear industry is the incubation period of radiation exposure. It's damage does not show up for a long time. It's 2-5 yrs for lung cancers and 15-17 years for solid cancers to appear. Because radiation is invisible, undetectable, workers and the public cannot tell they have been damaged by its affects for years. The employees of NCNPP apparently think they are immune to radioactivity. The public knows we are not. It is very revealing that though PG&E says its first concern in public safety, they have not done one study on the incidence of cancer in this area since the opening of Diablo Canyon. (0686-19 [Malboeuf, Simone])

Comment: •DGEIS Section 4.17 concludes that radiological impacts from public and occupational doses would be SMALL because the doses would continue to remain below the regulatory dose limits.¹⁰⁰ [footnote 100 text: DGEIS at 4-64 to 4-67.] TVA agrees. (0694-3-7 [Shea, Joseph])

Comment: •DGEIS Section 4.17 concludes that radiological impacts from public and occupational doses would be SMALL because the doses would continue to remain below the regulatory dose limits.⁸² [footnote 82 text: DGEIS at 4-64 to 4-67.] Entergy agrees. (0697-2-16 [Bessette, Paul] [Kuyler, Raphael])

Comment: Why does NRC report radiation risk based on documents that are not supported by real-world data? What does NRC do to factor in disproportionate impact of radiation to various parts of the human life-cycle? Children? Unborn? Female? Elders? (0711-28 [Olson, Mary])

Comment: Radiation[:] There would be far less concern about waste from NRC license activities if radiation were not harmful; there is no safe dose of radiation. This is not

controversial to anyone except those for whom it is a real or potential liability, and/or loss of profit. "No safe dose" or "no threshold" is also not merely a "conservatism" in regulation of radiation, as mistakenly stated by many. The classic reviews of harm, disease and death from radiation, the National Academy of Science Biological Effects of Ionizing Radiation reports (BEIR 1--7^{vii} [footnote vii text: National Academy of Science. Biological Effects of Ionizing Radiation (BEIR 1--7).]) all affirm that there is no dose of radiation with zero risk. In addition, the European Commission on Radiation Risk^{viii} [footnote viii text: ECRR--2010 Recommendations of the European Radiation Risk Committee: <http://www.euradcom.org/2011/ecrr2010.pdf>.] documents that internal radioactivity may result in very high doses since radioactive emissions from radionuclides that get into the body deposit energy directly into surrounding tissue. Another survey of a large number of peer-reviewed published studies on the impact of radiation focused on naturally occurring radioactivity, finding that even in evolutionary timeframes, organisms are never helped by radiation exposure; always harmed (Moeller and Mousseau, 2012^x [footnote ix text: Moeller and Mousseau, 2012. The effects of natural variation in background radioactivity on humans, animals and other organisms. Biological Reviews Volume 88, Issue 1, pages 226--254, February 2013.]). (0711-6 [Olson, Mary])

Comment: Dr. Gofman (September 21, 1918 — August 15, 2007) was a Professor Emeritus at the University of California, Berkeley (Ph.D. in nuclear-physical chemistry and an M.D.) who was the first Director of the Biomedical Research Division of the Lawrence Livermore Laboratory from 1963-65 and one of nine Associate Directors at the Lab from 1963-1969. He was involved in the Manhattan Project and was a co-discoverer of Uranium-232, Plutonium-232, Uranium-233, and Plutonium-233, and of slow and fast neutron fissionability of Uranium-233. He also was a co-inventor of the uranyl acetate and columbium oxide processes for plutonium separation. He taught in the radioisotope and radiobiology fields from the 1950s at least up into the 1980s, and did research in radiochemistry, macromolecules, lipoproteins, coronary heart disease, arteriosclerosis, trace element determination, x-ray spectroscopy, chromosomes and cancer and radiation hazards. Starting in 1969 he began to challenge the AEC claim that there was a "safe threshold" of radiation below which no adverse health effects could be detected. <http://www.ratical.org/radiation/inetSeries/nwJWG.html#line41>[.] (0713-10 [Keegan, Michael J.]

Comment: How can you even contemplate moving forward when the National Academy of Sciences is only beginning to study the health impacts? That in itself is deplorable. Whatever happened to the adage "err on the side of caution"? Is there no such thought process when it comes to the NRC making decisions about nuclear safety? Your actions do not seriously take our health into consideration. (0722-5 [Headington, Maureen])

Comment: For example, looking at the area of "public and occupational health," we see that the U.S. Centers for Disease Control and Prevention reports that cancer rates are 66% above the average in the communities surrounding Indian Point. In spite of this report from the U.S. agency reporting on health issues, table 1 of these DGEIS regulations reports a "small" "Health Impact "across the board" - in all areas of Short-term, Long-term and Indefinite storage. It is clear that the DGEIS is not applicable to the specific particularities and problems of Indian Point and that this table is grossly inaccurate. (0762-3 [Skopic, Catherine])

Comment: Under section 4.20, starting on page 4-90 and carrying over to page 4-91, Table 4.2 should be modified to reflect the changes in the analysis set forth by the City [Red Wing, MN] in this letter... ..Likewise, public and occupational health should be modified from small/moderate to large for all timeframes. (0783-3-25 [Harlan, Thomas])

Comment: Repeated studies conducted a couple decades ago show that any exposure to ionizing radiation harms people by changing the structures of blood cells and by changing the complete blood count (CBC) levels at the lowest levels. Low level ionizing radiation exposure causes fatigue and other subtle function problems with impacts that decrease well-being and cognitive sharpness. Thyroid cancer, leukemia, and other illnesses may occur decades after radiation exposure. Permanent irreversible damage to genetic pools often requires waiting for the 3rd and 4th generations to present itself reproductively. An growing epidemic of thyroid cancer and leukemia is occurring in the USA. Radiation exposure is the primary known cause. I am unaware of any considerations of the actual fraction of these impacts to be attributed by NRC to known radioactive isotope exposures from Three Mile Island and other leaks inside the USA, but the timing combined with the impacts that follows afterward is an indicator that requires addressing. These illnesses represent human suffering and dysfunction from exposure to ionizing radiation. While impacts on humans may fail to register in awareness, so to speak, in terms of connecting the dots, the impacts and observed changes of any exposure level, including medical exposures, can be found in the membranes of blood cells and in the fractions within the complete blood count (CBC) in direct linear response to the ionizing exposure. With these ignored human impacts (that may be causing fibromyalgia, chronic fatigue syndrome, Gulf War Disease, non-iodine deficiency multi-nodular thyroid, thyroid cancer, leukemia, still-born births), perhaps larger impacts may be occurring sooner in plant-life, insects, and wildlife. Far-ranging impacts have been recorded with the scanty measurements available following catastrophic radioactive releases into the environment. Scientific principles require measuring releases from the source in time and space and making that data available to any researcher; anything less is unacceptable. (0823-22 [Michetti, Susan])

Comment: The Draft Generic EIS unacceptably fails to address impacts to drinking water quality. The NRC casually accepts contamination of leaking water on site. This violates scientific thinking, methods, and practices that the onsite contamination of drinking water in excess of EPA drinking water standards is somehow assumed to be acceptable because it has not migrated offsite at this point in time. This is another example of unacceptable, unscientific and irrational thinking by NRC decision-makers that is driving flawed and dangerous policy and rules without sufficient analysis regarding the complete impacts of nuclear reactor operations through the complete impacted timeline, (which is the timeframe of the complete life span of the various radioactive isotopes that encompasses their entire sets of half-lives). Scientific practices do not permit radioactive contamination leaks to continue unabated, but such unacceptable leaks are happening on-site at every reactor site in the USA. Scientific thinking, methods, and practices must include the complete timeframes upon which to build the case for safety, but this Draft Generic EIS does not do what is required in terms of protecting drinking water quality through time. The importance of protecting drinking water quality has always been critical, but even more so now that the subject of water wars is being discussed. (0823-38 [Michetti, Susan])

Comment: Of special safety concern for drinking water is the use of high burn up fuel with increased tritium load. The use varies at individual reactors. Tritium appears to be impossible to remove from groundwater, making tritium contamination very seriously significant. This represents an example of NRC's insufficient dealing with environmental exposure in a timely way for actual adverse physical reality impacts with drinking water contamination. These impacts are worsening from not being cleaned up by reactor owners. People are drinking water contaminated with tritium and experiencing adverse health effects. Harmed nearby residents are not being compensated. The NRC assures a false public safety as this occurs. An unacceptable contradiction exists between reality and the safety concept. The safety claims have become distorted. The safety assurance is untrustworthy. (0823-39 [Michetti, Susan])

Comment: Page 3.38, Section 3.16 "Public and Occupational Health" again, you deal with exposure when everything goes well, when any accident is one of those expected accidents. But not if something unexpected happens. (0836-51 [Davis, Anonymous])

Comment: Cancer is now the number one killer of children in the US, and the National Cancer Institute of Japan has sent brochures to all the children in elementary school telling them they should not fear cancer as almost everyone will die of cancer one day. How is nuclear a "safe" technology? In what world? (0844-8 [Anonymous, Anonymous])

Comment: Not safe now ask people who are poisoned in communities by the nuclear power plants that were almost hit by recent tornados in Illinois, employees who worked at Olin & employees dying from cancer now from working at nuclear facilities. (0862-3 [Thompson, Tammy])

Comment: Happy Holidays to you & yours while many US citizens are drinking contaminated radioactive water because you're doing such a good job. Happy new year to you & yours while so many in nuclear neighborhoods & mined areas for the "yellow cake" are nursing their children suffering radiation overdoses, teeth separation in children, cancers in homes at epic proportions including their pets all while losing their financial futures to pay all the medical & funeral bills. Yes, Happiest Wishes to you & hope you get yourstoo; until you stop adding insult to injury, nobody is safe or immune. (0862-9 [Thompson, Tammy])

Comment: Moreover, NRC's assessment of the impacts of SFP leaks on public health is likewise improperly narrow. That is, NRC focuses only on whether releases would "exceed permissible levels set by the NRC and the EPA." DGEIS at E-18. However, it is appropriate and necessary under NEPA to assess all *foreseeable* impacts, and not to only focus on certain narrow standards. Thus, given the court's directive to NRC to assess potential future harm to the public and "the effect of the *additional* time in [pool] storage," (*New York*, 681 F.3d at 481 (emphasis added)), NRC's DGEIS must include a comprehensive evaluation of the risks to public health posed by potential future SFP leaks and long-term exposure to such leaks, and in this regard, NRC should examine the long-term impacts from low-level exposure to SFP leaks in light of the conclusion of the Biological Effects of Ionizing Radiation VII report that every exposure to radiation, regardless of how small, and no matter what pathway, produces a corresponding increase in the likelihood of cancer.¹⁴ [footnote 14 text: National Research Council, Health Risks from Exposure to Low Levels of Ionizing Radiation: BEIR VII – Phase 2 (2006), *available at*, https://download.nap.edu/catalog.php?record_id=11340 (finding that the risk of cancer is linear with dose and that there is no level of exposure below which there is no proportional risk). (0897-5-17 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: How will these corrective actions impact certain Chapters of the GEIS, for example Public and Occupational Health? (0913-9 [Bevill, Bernard])

Comment: Not to mention the "worker doses" (and downwind resident doses) for the poor soul unlucky enough to face the replacement work. (0919-2-10 [Kamps, Kevin])

Comment: Re: Page 3-38, Section 3.16.1, Radiological Exposure, NRC states: "The Atomic Energy Act of 1954 requires the NRC to promulgate, inspect, and enforce standards that provide an adequate level of protection for public health and safety and the environment"...The highly legalistic phrase, "adequate level of protection for public health and safety and the environment," seems highly significant. Could NRC please say the phrase in plain English, and explain what it means more clearly to non-lawyers, and a lay public audience? (0919-6-5 [Kamps, Kevin])

Comment: Re: Pages 4-18 to 19, Section 4.5, Climate Change--what about radioactive C-14 releases from atomic reactor stations, irradiated fuel storage pools, etc. during decommissioning? A climate change causing greenhouse gas, plus a severe radiological hazard, all rolled into one! C-14 is a significant biological hazard. It has a very long half-life, and can integrate into the food chain and human anatomy wherever carbon does, which is just about everywhere! (0919-7-1 [Kamps, Kevin])

Comment: Re: beginning at line 10, Page 4-29, Section 4.9.1, "Spent Fuel Pools," NRC states "Operation of a spent fuel pool and its associated cooling system during short-term storage would require the withdrawal of water and discharge of effluents into a nearby waterbody."...As NAS has long affirmed that any exposure to radioactivity carries a health risk of cancer, NRC's admission that "effluents" are discharged into nearby waterbodies bodes ill for those who live downstream, and up the food chain. Where is NRC's serious analysis re: those discharges' radioactivity content, and their impact on human health? (0919-7-15 [Kamps, Kevin])

Comment: At Page 4-23, NRC states "because surface waters in the vicinity of nuclear power plants are usually large to meet reactor cooling requirements, a large volume of surface water is usually available to dilute groundwater contaminants that flow into the surface waterbody. This dilution ensures that contaminants that may have been present above applicable groundwater-quality standards are diluted well below limits considered safe." NRC is stating its unacceptable "dilution is the solution to radioactive pollution" philosophy. This is a delusion, an illusion of a solution. NRC cannot call such dumping of radioactivity into the environment "safe"! "Acceptably risky," in their opinion, perhaps, but not "safe"! NRC has carried out a cost-benefit analysis, and determined that the levels of harm to human health caused by the radioactivity releases are acceptable in their eyes, given the benefit the industry derives from the practice. For NAS has affirmed for decades that any exposure to radioactivity, no matter how small, still carries a health risk for cancer. There is no such thing as a "safe" dose. NRC cannot and should not say such a thing. NRC is intentionally misleading and deceiving the public by doing so. (0919-7-5 [Kamps, Kevin])

Comment: On Page 4-23, lines 7 to, NRC remarkably attempts to make the argument that pool leaks are really no big deal, given how much they routinely discharge with a permit anyway: "The NRC estimated an annual discharge rate for leakage from the spent fuel pool of 380 L/d (100 gpd) with contaminants at certain concentrations assumed to be present at the start of short-term storage. These concentrations were compared to annual effluent ranges for BWRs and PWRs. Even in the unlikely event that spent fuel pool leakage flowed continuously (24 hours per day, 365 days per year) undetected and unimpeded to local surface waters, the quantities of radioactive material discharged to nearby surface waters would be comparable to values associated with permitted, treated effluent discharges from operating nuclear power plants (see Table E-4). Based on the above considerations, the NRC concludes that the impact of spent fuel pool leaks on surface water would be SMALL." That is, NRC is so enamored with its own "dilution is the solution" delusion that it flippantly decides here to just double it for good measure. Now "permitted" discharges from the atomic reactor's operations, and an equal discharge rate by accidental, unintended leak from the pool, can both flow together into local surface waters, double-dosing area residents in drinking water, double-concentrating up the food chain, downstream, and down the generations. According to NAS's linear, no-threshold model for understanding the cancer risk associated with human exposure to radioactivity, that would simply double the risk that such releases cause cancer in surrounding, exposed populations. NRC's flippant acceptance of pool leakage is unacceptable. (0919-7-6 [Kamps, Kevin])

Comment: As shown in the diagram published by NRC that is featured on the cover of the pamphlet, radioactivity, once leaked from a high-level radioactive waste storage pool, can and will "cycle" back through the ecosystem and food chain (bio-concentrating there), to harm humans (with the most concentrated, and thus harmful, doses, as we sit at the top of the food chain). (0925-2 [Kamps, Kevin])

Comment: I have also attached a diagram of the human body, prepared by Russell Hoffmann, that shows where in the human body various radioactive poisons lodge, and concentrate, and do their primary damage. Given NAS's affirmation for decades, in its seven Biological Effects of Ionizing Radiation (BEIR) reports, that any exposure to ionizing radioactivity carries a health risk for cancer, and these risks accumulate over a lifetime, I cannot understand how NRC has determined that radioactivity leakage from pools will have a SMALL impact on people and the environment! (0925-3 [Kamps, Kevin])

Comment: Page 3.38, Section 3.16 "Public and Occupational Health" again, you deal with exposure when everything goes well, when any accident is one of those expected accidents. But not if something unexpected happens. (0930-3-3 [Lutz, Ray])

Comment: The National Academy of Sciences has written of the looming issues from the lack of solutions to our nuclear waste problem on this continent. The public knows full well the cancer and genetic diseases, but has no way other than citizen comment to express the experiences of hundreds of thousands whose health has been impacted, and who have died prematurely from exposure to nuclear processes and waste. (0935-4 [Uhls, Agnes])

Comment: Having just read Kristin Iverson's "Full Body Burden," I am more aware of this terrible problem. People that have been exposed even to small doses of radiation come down with cancer years later. And, the incidence of cancer is notably higher among people who live close to these sights (e.g, Rocky Flats, CO.). As you know, radioactive waste can be potent for thousands of years. (0961-1 [Frantz, Charles])

Comment: [U]ntil CEO's, and employee's, reside in the area's they have these plants, they will never understand! Some jobs are just not worth the Health of a Community, when our health care costs are over the top! Then the Healthcare Industries, have the audacity, not to cover Americans with EXISTING Healthcare issues, when many of their lingering illnesses are from plants like these. (0973-1 [Johnson, Bobie])

Comment: My father spent most of his working life as an electrical engineer and physicist developing instrumentation for the nuclear reactors on board nuclear submarines. He was accidentally exposed to high doses of radiation from test reactors at least once, and has struggled with skin cancer for years even though he has never spent much time in the sun. Right now I am nursing him after his most recent squamous cell carcinoma. It is clear to me that nuclear radiation has caused this health condition, so I am particularly sensitive to the public health risk posed by possible radiation leaks - such as those from improperly stored used rods that will continue to emit radiation for many, many years. (0975-1 [Watkins, Karen])

35. Comments Concerning Accidents and Natural Events

Comment: The NRC and the nuclear power industry have been far too comfortable with the potential extreme consequences of nuclear accidents. No technology that has such dire consequences for so many people for so long should be permitted. Fukushima is just the latest

disaster to show this, especially since it is glaringly obvious that no one knows how to abate it, nor are any solutions being proposed. NRC presumably has the knowledge and skills, but has been silent. The Earth has been lucky to this point, but the law of averages will eventually devastate us. We can survive without nuclear power, but it is far from certain we can survive with it. (0024-2 [Thomas, Bill])

Comment: While catastrophic events are not a given, they also cannot be ruled out at any given location. Consequences of such events are not satisfactory due to potential impact on health and habitability all around the world, not just locally. Decisions based on generic risk assessments are not reasonable, and this should not become the rule, with a new facility or any existing one. (0026-3 [Campbell, Mary])

Comment: I did use the search engine on the computer to look for things like Stuxnet cyberattack, Carrington event. Look, there's nothing in there. You start unloading this fuel and you have a problem with your computers or with your smart grid because of a cyber attack and you're down. Carrington Event, also known as coronal mass ejection from the sun, if it hits. Okay. It hasn't hit hard in 150 years. That means it'll never hit hard? I doubt that. I'd like to see a little more work on coronal mass ejection and how it will affect smart grids and how we're going to be in the middle of unloading when the smart grid goes down. (0030-14-1 [Lewis, Marvin])

Comment: I live 33 miles from North Anna Nuclear Power Station that was knowingly built on a fault line. Fukushima happened in 2011 and a few months later Virginia experienced its 5.8 earthquake that exceeded the reactor's design and actually knocked the plants off line. When we're talking about storage, our concrete cask moved one to four inches. Luckily, there was no release, but it does go to show that there is a problem with stability. We don't know how many more earthquakes we will have in Virginia, let alone the rest of the country, so I'll stay more specifically with Virginia. After the earthquake we experienced at least in one well at North Anna a level of tritium in a well that exceeded EPA regulations for drinking water. It's very difficult to get information pertaining to the plant. (0030-15-1 [Gray, Erica])

Comment: I just wanted to mention that in light of the earthquakes that we've seen in the past besides the Fukushima -- you know, the 7.7 the other day in Pakistan quake actually created an island. I'm sure most of you all heard that. So I really think that what we are seeing is we're seeing a down-playing in the seismic activity in dealing with storage and the risk. I mean we have some serious risk here. And so I think it's important that more of that is looked at. (0030-15-10 [Gray, Erica])

Comment: The only thing that I'll have to comment on that at the last televised meeting with Muniz and a panel that I heard and read the testimony of David Lochbaum of the Union of Concerned Scientists, and I really was amazed when I saw his written documents and testimony because, you know, it showed if our spent fuel pools, which are by the way overloaded and to the brim -- if we were to have an accident with them as filled as they are, the consequences would be just outrageously horrible. I'm not talking about, you know, this 10-mile radius that the NRC puts as an emergency evacuation zone, which by the way is ridiculous. More than hundreds of miles. (0030-15-7 [Gray, Erica])

Comment: On 9/30/13 the group PEER, a federal workers' group, sues to disclose U.S. dam risk to nuclear plants and has filed a lawsuit against the U.S. NRC for their refusal to share information with the public about U.S. dam risk. The probability of a massive dam failure destroying a U.S. nuclear plant is higher than the probability of the Fukushima tsunami and what it contributed to the nuclear disaster. The risk in place is at three dozen U.S. nuclear plants. The

NRC has been removing dam failure risk information from public view and it was caught suppressing a critical report on the dam failure risk in recent years. NRC engineering staff went public with this incident. (0030-15-9 [Gray, Erica])

Comment: I do want to make one final point, which is to the assessment of risk, you know, in this rulemaking. And one of the fatal flaws in what's been proposed, you know, in the discussion of risk that we've been having today is that the risk is evaluated in a generic environmental impact statement that is going to be used to streamline the licensing process of an unknown number of facilities that could be licensed under it. The risk that's assessed is for a single facility. And as I assume from the answers I got to my earlier question today about how the risk was calculated, whether it was based on a sum total of all of the potential causes of a spent fuel pool fire in the 60 years post-license, it seems clear that the risk that's been assessed by the NRC staff doesn't even deal with the potential consequence of the rulemaking itself, but only of licensing each individual facility. And that seems completely, you know, irresponsible if the Agency moves forward on that basis. (0030-17-8 [Judson, Tim])

Comment: Having to shut down reactors while at peak energy of all the hottest days of the summer adds to the unreliability and safety issues of storing nuclear waste in fuel pools. Water is needed in case of accidents to prevent nuclear power cores and waste pools from overheating and melting, releasing enormous amounts of radioactivity in the air. We learned that from Fukushima, that the water has gotten contaminated and then is still being released into the Pacific Ocean over two years after the initiation of the triple meltdowns. (0030-21-7 [Carberry, Mike])

Comment: The environmental consequences of dry cask fires are truly being completely ignored in these proceedings. I think that people will be replacing these things as fast as we're building them, and that is not an optimistic scenario. We are not taking into account the chances of failures in what -- in how people do things. I mean, there is -- we have almost 10,000 dry casks. They are not all going to go right. So let's look at what a really bad accident would look like. (0030-4-5 [Hoffman, Ace])

Comment: Nuclear waste held in pools above the reactors are extremely dangerous because of possible earthquakes, and many plants are built on faults. (0035-3 [Fulton, Doris])

Comment: The NRC further ducks the reality and magnitude of these catastrophic events by failing to use honest language to describe the casualties/deaths and huge societal and environmental damages. Another major flaw with the risk analysis is duration of risk. NRC does not accommodate the issue of delay in managing wastes, defined as 60 years post power operation in the short term case, stretching out to indeterminant. Does that instill any sense of "waste confidence"? NO. The longer the period of potential exposure to threats, be they natural or manmade or terror, the greater the chance that the catastrophe will happen. Time span is relevant and using only a probability per year factor is simply warping the true expression of risk. (0059-8 [Andrews, Richard])

Comment: NRC's conclusion in the GEIS that the impact of a severe accident in a spent fuel pool would be small, based as it is on a vague and hopeful probability of occurrence rather than on actual experience from Fukushima, once again devalues consequences ordinary people would find monstrously unacceptable, and erroneously and unscientifically confounds (or multiplies) probability of occurrence with consequences. (0089-11 [Shaw, Sally])

Comment: NRC is ignoring the Courts order to base their decisions on reality, and to provide evidence in an EIS. In this GEIS, NRC persists in magical thinking. THE MAGIC IS IN MULTIPLYING UNACCEPTABLE CONSEQUENCES BY VANISHINGLY SMALL AND UNREALISTIC RISK ESTIMATES. This fatal flaw in all NRC thinking puts this country at risk. It is belied by NRCs decision to recommend evacuation of Americans to 50 km away from Fukushima, due to concerns about a catastrophic spent fuel pool failure. This demonstrates NRCs inconsistency and disingenuousness in this GEIS, and the failure of theoretical numbers to inform about stochastic events. (0089-13 [Shaw, Sally])

Comment: Under NEPA, an EIS is intended to carefully investigate the environmental impacts of a potential action. One of NRCs assumptions underlying the opinion that the impacts of spent fuel storage can be considered generically, not on a site-by-site basis, is that Changes in the environment around spent fuel storage facilities are sufficiently gradual and predictable to be addressed using a generic approach. This assumption clearly ignores past experience and the realities of a changing global climate. It ignores the very real possibility of severe storms and extreme circumstances such as earthquake, malicious attack, or multiple failures of equipment at multiple reactors, as we witnessed at Fukushima. It ignores the indirect cumulative impact of Murphys law and how it played out at Fukushima (failure of on and offsite power due to natural disaster, plus failure of onsite backup power due to destruction of cooling pumps at the waterline, flooding of the diesel generators themselves, failure of the hardened vents to open causing explosion, and certainly human error compounding all of the above. (0089-14 [Shaw, Sally])

Comment: There is no such thing as a probability-weighted consequence. However, there is such a thing as an unacceptable consequence. That is what the NEPA process, if it worked, would uncover, preventing catastrophically stupid alternatives from being acted upon. The public, and the Court want to know, if X happens, Y will result. It is the NRCs responsibility to investigate and describe in detail Y, the consequences. They have shirked this responsibility yet again. The waste confidence GEIS is flawed for the same reasons as the original Waste Confidence decision. It remains faith based, grounded in probabilistic thinking, not reality or experience-based science, which we unfortunately have in abundance, due to the severe accidents at Chernobyl and Fukushima. (0089-16 [Shaw, Sally])

Comment: Because of the explosion of the #4 fuel pool at Fukushima, and the wide dispersal of fuel elements up to a mile away, the area around those reactors will never again be habitable by humans. This is an environmental consequence that really happened. It is not a probability-weighted consequence, it is a real one. The proper multiplier is ONE, not 10-14.. Because of the need to continually cool the melted fuel, water is being pumped into a leaking SFP at Fukushima #4. Because there is no engineering solution to the infiltration of ground water to the site, the #4 fuel pool is listing dangerously and we, as a global community, are not yet out of the woods. Because the site has not been isolated or contained in any way the water intentionally poured on to prevent fire and the groundwater infiltration is carrying radioactive Cesium and Strontium into the Pacific Ocean. The fish caught in that area are too radioactive to eat. In California, across the Pacific, a study of Tuna found that 100% of the fish sampled were contaminated with radioactive Cesium. These are real environmental consequences the NRC cannot magic away with wishful probabilistic thinking. What is probabilistic is the likelihood of a tsunami or earthquake. A probability is not a certainty. But unacceptable consequences of such an occurrence are a certainty. If we could prevent earthquakes or tsunamis, we would. Former NRC Chairman Gregory Jaczko recently spoke at the State House in Boston. He said, Society doesnt not accept severe accidents at Nuclear Power Plants. That is an unacceptable consequence, not matter how low the probability. (0089-17 [Shaw, Sally])

Comment: The Institute for Policy Studies reports that: "Over the past 30 years, there have been at least 66 incidents at U.S. reactors in which there was a significant loss of spent fuel water. Ten have occurred since the September 11 terrorist attacks, after which the government pledged that it would reinforce nuclear safety measures. Over several decades, significant corrosion has occurred of the barriers that prevent a nuclear chain reaction in a spent fuel pool some to the point where they can no longer be credited with preventing a nuclear chain reaction. For example, in June 2010, the NRC fined Florida Power and Light \$70,000 for failing to report that it had been exceeding its spent fuel pool criticality safety margin for five years at the Turkey Point reactor near Miami. Because of NRCs dependency on the industry self-reporting problems, it failed to find out that there was extensive deterioration of neutron absorbers in the Turkey Point pools and lengthy delays in having them replaced. There are other strains being placed on crowded spent fuel pools. Systems required to keep pools cool and clean are being overtaxed, as reactor operators generate hotter, more radioactive, and more reactive spent rods. Reactor operators have increased the level of uranium-235, a key fissionable material in nuclear fuel to allow for longer operating periods. This, in turn, can cause the cladding, the protective envelope around a spent fuel rod, to thin and become brittle. It also builds higher pressure from hydrogen and other radioactive gases within the cladding, all of which adds to the risk of failure. The cladding is less than one millimeter thick (thinner than a credit card) and is one of the most important barriers preventing the escape of radioactive materials." All of the above argue for a comprehensive NEPA review of the environmental impacts of a failure of temporary storage of spent fuel at all operating reactors, and of all new licenses or license renewals. (0089-6 [Shaw, Sally])

Comment: "ES.13.1.18 Environmental Impacts of Postulated Accidents ...Based on the assessment in Section 4.18, the environmental impacts of these postulated accidents involving continued storage of spent fuel in pools are SMALL because all important safety structures, systems, and components involved with the spent fuel storage are designed to withstand these design basis accidents without compromising the safety functions." This analysis seems to lack awareness of significant accidents which have occurred such as Chernobyl and Fukushima. The extreme environmental damage caused by accidents such as these cannot be offset by stating that they are unlikely. To state that they are not possible, as the above statement seems to be asserting is not scientifically justifiable. There is always a possibility of safety system failure which will result in a catastrophic accident that cannot be contained to the site. The low probability of such an accident cannot allow the possibility to be ignored by asserting its low probability. The fact that you are asserting SMALL impact raises a question about the method by which you are weighting the consequences of such accidents in comparison to the probability of the accident occurring. The above criticisms are likewise applicable to the section "ES.13.2 Environmental Impacts of Away-From-Reactor Spent Fuel Storage" (0093-6 [Dennis, Harold E.B.]

Comment: There is no such thing as a probability weighted consequence; however, there is such a thing as an unacceptable consequence. That is what the NEPA process, if it worked, would uncover, preventing catastrophically stupid alternatives from being acted upon. The public and The Court wants to know if X happens, Y will result. It's the NRC's responsibility to investigate and describe in detail Y, the consequences. They have shirked this responsibility again. The Waste Confidence GEIS is flawed for the same reasons as the original Waste Confidence decision. (0112-18-7 [Shaw, Sally])

Comment: But the NRC, meanwhile, needs a paradigm shift. Instead of trying to convince us over and over again that a small risk outweighs a huge consequence, maybe NRC should face the fact that sometimes consequences are so unacceptable to the people and the environment that they outweigh even the smallest theoretical risk. (0112-18-9 [Shaw, Sally])

Comment: You also look at the word, "Oh, we provide reasonable protection." Let's look at reasonable. Plausible, and unfortunately what is probably the most accurate here, inexpensive. Plants -- in looking at the problems of safety with various types of storage, the NRC takes consequences on the one hand and it multiplies them by probability on the other. And if you look at the probability you see numbers like 10 to the minus 7, 10 to the minus 8, 10 to the minus 15, which basically guarantees that no matter how large the potential consequences are -- and a study done for the Mass attorney general said the potential consequences of a spent fuel fire at Pilgrim is \$488 billion. And this was in dollars a few years ago. And 24,000 latent cancers. Does anyone believe that that is generic? (0112-2-4 [Lampert, Jim])

Comment: The study [NRC-2013-0136] assumes there is no risk to cask, but it doesn't show that. What we need is a comparison of casks storage under various conditions to spent fuel pool various conditions, and then you might come out with something. That's what we expect. We don't expect no science to masquerade as science. (0112-3-6 [Lampert, Mary])

Comment: But we should all recognize that our plants, especially at Seabrook, they only have four hours of battery power. That, again, is an absurd situation in the age of extended batteries. And we do not trust the current systems to really protect us in the case of a power outage. And that's really what we're dealing with here whether it's due to an earthquake or due to a storm, it's the power going out that we have to be concerned about. (0112-5-5 [Bogen, Doug])

Comment: And my wish is that the people who make these rules spend time with the individuals who are impacted by the small risk. I see it over and over again in the 544-page document, small risk. I am sure that they said the same thing about Fukushima. (0112-7-2 [Sachs, Leslie Sullivan])

Comment: And what if an earthquake, terrorist attack or aging infrastructure expose the rods now stored at our nuclear facilities? (0129-2 [Cunningham, William and Barbara])

Comment: Risks, both natural (hurricanes, flooding, earthquakes, etc.) and man-made (intentional and unintentional), are obvious facts of life. We must also be prepared for the unexpected, the unimaginable. Prudence calls for policies that minimize our exposure. The NRC is in a position to determine how best to limit the radioactive waste in this region, and carefully control its disposition. Please do so. (0131-2 [Felder, H.M.])

Comment: What happens to dry casks of waste when there is an earthquake? After Fukushima and the earthquake in Virginia on August 23rd 2011, people are becoming nervous. Their homes may become unusable and off limits. There is little earthquake insurance for home owners in either the areas of Indian Point in New York or North Anna Power Station in Virginia. Seismographs at North Anna were removed at North Anna in 1990! Why? Do you know if Indian Point which is on two earthquake fault lines, has any seismograph reporting equipment? (0137-2 [Cypser, Betty])

Comment: The Draft EIS recognizes that spent fuel pools are susceptible to fires and that a fire would have severe consequences comparable to those of a severe nuclear reactor accident. However, the Draft EIS is critically flawed because it attempts to analyze those consequences generically for all nuclear facilities based on the modeled consequences of severe accidents at two nuclear power plants located in rural or less populated areas. Accident consequence factors specific to Indian Point, such as surrounding population, building density, critical infrastructure, and proximity to significant surface drinking water supplies have not been taken into consideration in assessing the consequences of a fire or other spent fuel pool accident. (0163-1-3 [Schneiderman, Eric])

Comment: [A]ccident reports I was looking at weren't accidents at all. They were simply incidents. Incidents of human error, human commission or omission, with unintended results. Now, if you look at the same thing with the nuclear accidents that occurred with Three Mile Island and Chernobyl, a large part of each disaster is attributable to human error. (0163-16-2 [Wolf, Peter])

Comment: There's a denial of the risk of a spent fuel pool and there are all kinds of studies, and I would cite the Union of Concerned Scientists for the work that they have done in that regard. There is no long-term plan to require, encourage, force the company to put those spent fuel pools -- high-level irradiated fuel assemblies is a more accurate word. Spent means they're kind of used up. These aren't. They're worse than when they went into the pool. And the NRC was created 40 years ago, and this is the best they can offer us. All of these exemptions, all of these oversights, all of these cracks in the wall of the model, so what would the real thing be like? (0163-21-3 [Elie, Marilyn])

Comment: Regarding Indian Point nuclear reactor site (Docket ID NRC-2012-0246) (located in Buchanan, New York) and its nuclear waste storage plan: Does the plan realistically take into account Hudson River increasing water levels expected over this century due to global warming and in particular during storm or hurricane events and during an earthquake event, happening at the same time or separately? Does it realistically take into account activities related to terrorism (including theft), assault with bombs or war? Does the plan realistically take into account presently proposed United Water desalination of water plant (Haverstraw Water Supply Project) several miles downstream and across the Hudson River? Or future desalination water plants that takes water from the Hudson River and place it into the water supply that is consumed by people? One concern is excess radiation release from the nuclear plant enters the water system. This excess radiation release can be from stored nuclear waste as well as other sources from the nuclear plant. (0195-1 [Tompkins, Robert])

Comment: Regarding Indian Point nuclear reactor site (Docket ID NRC-2012-0246) (located in Buchanan, New York) and its nuclear waste storage plan: Does the plan realistically take into account Hudson River increasing water levels expected over this century due to global warming and in particular during storm or hurricane events and during an earthquake event, happening at the same time or separately? Does it realistically take into account activities related to terrorism (including theft), assault with bombs or war? Does the plan realistically take into account presently proposed United Water desalination of water plant (Haverstraw Water Supply Project) several miles downstream and across the Hudson River? Or future desalination water plants that takes water from the Hudson River and place it into the water supply that is consumed by people? One concern is excess radiation release from the nuclear plant enters the water system. This excess radiation release can be from stored nuclear waste as well as other sources from the nuclear plant. (0206-1 [Tompkins, Robert])

Comment: Of course, this estimate is high. When one engineers a solution properly, one doesn't just come up with a single predicted outcome, one comes up with a range of predicted outcomes: This is basic error analysis. The goal is to design a system such that the entire range of predicted outcomes is acceptable. In this case, the high end of the predicted range of outcomes is clearly unacceptable. I don't have the time to look through the entire document for other inaccuracies (I am not getting paid to produce this commentary), but it doesn't bode well that there is a glaring deficiency in the first place I chose to spot check. (0208-6 [Robinson, Herb])

Comment: The DGEIS only analyzed reasonably-foreseeable events, such as design-basis and severe accident, and did not include worst-case scenarios. However, as the development of

nuclear technology, the safety standards of nuclear power plants have been upgraded. As we can see from the IAEA Specific Safety Requirements [1], Design Extension Conditions have been required to be considered. Therefore, it is necessary to include certain ensemble of worst-case scenarios. (0210-3 [Individual, Anonymous])

Comment: Historian Doris Walker, in the book "Dana Point Harbor/ Capistrano Bay" published by To-The-Point Press in Dana Point, reports on page 54 that an earthquake on December 12, 1812 caused the largest tidal wave ever reported on the Pacific coast -- the water rising 35 to 50 feet above sea level, washing away many shoreline encampments. This report by the Spanish friars from about 200 years ago (much less than 10,000) tells me that the spent fuel pool should be designed for at least a 50-foot tsunami. Of course the response will be that the friars were of doubtful reliability. On the other hand, modern attempts to predict tsunamis have been proven unreliable, not just doubtful. Remember that when the famous ship Titanic sank, all of the engineers testified at the official inquest that the ship went down in one piece, while other survivors reported that ship broke in half. The remains of the ship later demonstrated that the ship had broken on the surface. This should demonstrate to all of us that engineers and scientists resist accepting anything that they believe is not possible, even when that belief is based on incomplete knowledge. Let us not fall into that trap again. (0214-2 [Deshotels, Bob])

Comment: I would be completely confident in the design of the spent fuel storage at all sites subject to tsunami or storm surge hazards if the following actions would be taken: 1. Given the relatively undeveloped state of tsunami prediction technology (due to lack of information, not intelligence), non-expert reports should be included as credible possibilities for beyond-design-basis analysis of tsunami or storm surge damage. Specifically, the written reports of the friars after the 1812 earthquake that struck San Juan Capistrano should be included in the beyond-design-basis analysis of the storage pools and any back-up systems. Although there does not seem to be any obvious geology that could cause a tsunami as large as the 35 to 50-foot tsunami reported in 1812, I would like to mention that about half of the recent earthquakes in the Los Angeles area have been from faults that were previously unknown. Given the fact that the friars definitely saw something, we should consider it at least credible that there is a fault that has the potential for sudden vertical motion, or some other scenario that could cause a tsunami larger than the design basis for San Onofre. (0231-1 [Deshotels, Bob])

Comment: Computational fluid dynamics modeling can determine accurately whether any such unsafe condition could result from a beyond-design-basis tsunami by looking at a number of hypothetical cases with different height and direction. If unsafe conditions are possible according to the analysis, then mitigating structural features, standby systems, or offsite recovery plans could be developed to react to such unexpected, but credible situations. (0231-3 [Deshotels, Bob])

Comment: Natural disasters including hurricanes, tornados, flooding and earthquakes are clearly more common and present safety threats to the communities and industries that surround the plants. Davis Besse was within millimeters of a failure event due to internal corrosion of the reactor lid. The American nuclear community has experienced traumatic events (such as three mile island). (0240-2 [Remein, Warren])

Comment: We don't want to see that happen here, but it can. The reason being is that there are new shows coming out on the Science and History channels that talk about things like tsunamis and asteroid airburst. The most recent asteroid airburst -- the most recent asteroid airburst was in Russia about three months ago, that damaged the Russian town up in Siberia. There was a airburst back in 1908, I believe it is -- yeah, June 30th, 1908, an event that release

somewhere around 10 to 15 megatons of TNT. It was 1000 times greater than the atomic bomb dropped on Hiroshima. It's taken them up until just a few years ago to figure out exactly what caused the damage up there. Some thought it was a volcano, but the studies on tree rings have shown that it is a -- it was either an asteroid or comet that blew up somewhere around 10 miles high or so. They have found nuclear type of material in the tree rings showing that it was something that fell from the sky. If we have an asteroid burst or an asteroid hit somewhere in -- near any nuclear reactor it would devastate it. The event that happened in Russia damaged the entire town. It was caught on dashboard cameras. And it was quite interesting to watch because there was a four-story school there, it blew all the glass into the school and blew all the window frames out on the ground, and it was about 100 window frames that dropped out all at one time. But every single building in the entire town was damaged. (0244-13-2 [Wilson, Greg])

Comment: Another show that's came on is -- talks about the Hawaiian Islands and the volcanoes out there. And the scientists, with a reporter, went climbing down into the lava flow tubes that is in the shield volcano -- and this is on the big island -- that's still around. And they were just walking around and looking at things and realized that the rock that's made from the volcano is pumice, has a lot of air bubbles in it and it's very soft rock. And the scientists went over and picked up a rock and he flipped it over and there was rust on the backside, so there's a lot of iron in that rock and it causes the island to basically fall apart faster than normal erosion or any kind of thing like that. And they were wondering why a lot of the Hawaii Islands are elongated, they're not round, and they started looking from satellite pictures and they were able to see how the islands are basically peeling off like an onion with big chunks of rocks, some of them 10 miles long, that kick out tsunamis. One of them actually flooded the LA basin. (0244-13-3 [Wilson, Greg])

Comment: So these are massive earthquakes that can happen from volcanic islands. And the nuclear plant that's down in San Diego is directly in line of one of these tsunamis, because even though it's on a cliff it could still get hit by a tsunami and wipe it out. So basically the spent fuel rods that are stored along these power plants that are along the ocean coastlines are at a really high risk of having a tsunami. And this brings me to the island of -- in the Canary Island it's the island of, let's see, Viga -- wait a minute, Cumbre Vieja, in the Canary Islands, which belongs to Spain. The island is also an elongated island, it sits on a fault line that has fissures on it, which means there's several volcanoes on this island. Back in, I think it was about '49 or 1959, a 10-mile piece of the island slid over some 15 yards. So that piece of rock is loose and it's about 10 miles long. They say that if it falls into the ocean and drops the 2000 feet to the bottom of the Atlantic Ocean it will kick up a tsunami 600 feet tall moving at 600 miles an hour, and it will affect most of the Atlantic basin. Spain, France, and the British Isles will be hit within three hours. There's a place in Southwestern England that has 800 tons of plutonium -- excuse me -- 800,000 tons of plutonium stored there. That will be hit by a very tall tsunami. The East Coast of the United States will be hit in about five hours, and the movie that I was watching it said that -- and the movie's name is, Tsunami Apocalypse. It's on the Science and History channels. And it says that 26 nuclear power plants will be wiped out. So we'll have a whole bunch of Fukushimas going on at one time. The bridges and highways and roads around that area -- up and down the entire East Coast will be wiped out, so it will be very hard for anybody to get to these nuclear power plants. Turkey Point and Hutchinson Island, they'll be gone. There isn't anything that we have, if the spent fuel rods are blown out into the Everglades, that would be able to go out there and pick them up. We don't have air boats or swamp buggies or anything that big that could actually go out there and get it. I grew up in Miami and I've seen quite a number of very large swamp buggies. They're not going to be able to pick up big, heavy, spent fuel rods. It's just that the ground will support that much weight. And it will be scattered all over the place and it will be very hard to find until, you know, you come upon one and it will be too late. So basically all the

spent fuel rods in all them power plants up and down the East Coast and the West Coast need to be moved out of the range, up to high ground, away from where a tsunami could hit it. It would be like up in the Appalachian Mountains or up in the Rocky Mountains, a ways away from the power plants so that they're protected. And to build another power plant or two down at Turkey Point, that's just insane. To be honest with you, I don't see why they would want to do that. (0244-13-4 [Wilson, Greg])

Comment: And on the way over I realized I forgot to add in Yellowstone. I don't know if you all know about that, but there's a super volcano growing underneath Yellowstone National Park, and it's making moves like it's going to explode again. It explodes around every 600,000 years and it's been 660,000 years since the last time it blew up, so it's due any time. And a super volcano, like the last time Yellowstone blew up, it was a major impact upon the entire planet. I saw a movie the other night that was talking about Yellowstone, and the ash cloud will go from central Canada all the way down to Mexico and it will cover -- from side to side it will be from the Blue Ridge Parkway in the Appalachian Mountains over to the Continental Divide on the west side will be covered in hot ash, burning stones. Now, airplanes can't fly through volcanic ash. It burns up the jet engines and they come crashing down. That's already happened, or came close to happening on several occasions. So when there was the volcano in Iceland that happened just a few years ago all the jet travel in Europe was shut down days at a time, if y'all remember that. So anybody living in and around Yellowstone for several hundred miles, when that thing goes off they will probably be dead. (0244-13-5 [Wilson, Greg])

Comment: Underestimating the risk puts taxpayers, as some of the folks said, to significant risk due to the liability factor. Just because we haven't had one doesn't mean one can't happen. There's tons of unknown unknowns out there, and one accident will cap the liability of \$21 billion -- I believe it is. And with Congress not being able to allocate funding to Sandy, how are we going to expect them to fund a nuclear disaster? (0245-19-12 [Smith, Ed])

Comment: In the meantime, we are exposed to the possibility of a nuclear accident. Nobody here in this room can say with assurance that there will not be an accident. We have the evidence of Fukushima. I listened to the proponents. They downplay the effects of Fukushima. They downplay the accidents that can happen. And we're supposed to bear that kind of a risk. (0245-22-3 [Headington, Vince])

Comment: I just got some things that are echoed in the executive summary tonight categorizing everything as small risk, small risk, small risk. And I've done quite a bit of technical writing in my life and I was a little bit concerned as to how is that risk laid out and how are they analyzing it? And I didn't really find any metrics they gave me to my confidence. I didn't see that they had looked beyond just stating, hmm, infinitesimal possibility of this happening, therefore, we should dismiss it. To me, when we're looking at risk, we need to look at what's the probability that it's going to occur, how severe will it be if it occurs, and how likely is it that we can detect it early and put a stop to it? But I didn't see any of that kind of analysis done at all. And that's the kind of analysis that should underlie engineering. And it was painfully absent. (0245-31-4 [Fox, Tracy])

Comment: It ignores numerous catastrophic risks to everyone in and far beyond their heavily populated region. The Alliance for a Clean Environment, ACE, has studied these risks for over a decade and found volumes of evidence for these risks published at www.acereport.org. The Waste Confidence Statement is simply sweeping these risks under the carpet. Unless you give the draft statement a vote of no confidence, the NRC is recklessly endangering our communities and the risks described should make the NRC liable for regulatory mismanagement. (0246-17-2 [Dugdale, Jane])

Comment: After the nuclear disaster in Fukushima Japan, one of the arguments made that such a disaster couldn't happen here is that we were very unlikely to have a tsunami at most nuclear reactors in the USA. Statements like we won't have a tsunami in Illinois were being made by those defending the nuclear energy industry. Then the Mississippi River flooded and the Fort Calhoun Nuclear Facility was overwhelmed by water. It remains shut down to this day. Concerns of the failure of a dam upstream would break and finish off the facility were real and we were all lucky it didn't happen. The NRC did a study on the possibility of dam failures impacting nuclear facilities and it took an NRC whistleblower to reveal that the NRC covered up information that showed the vulnerability of nuclear facilities across the country to dam failures. The NRC's own reliability and risk engineer claimed, as reported in the Huffington Post article, that NRC officials falsely invoked security concerns in redacting large portions of the report detailing the Agency's preliminary investigation into the potential for dangerous and damaging flooding at U.S. nuclear power facilities due to upstream dam failure. Then joined by another NRC engineer, they suggested that the real motive for redacting certain information was to prevent the public from learning the full extent of these vulnerabilities and to obscure just how much the NRC has known about the problem and for how long. (0246-25-3 [Snyder, Gail])

Comment: It ignores numerous catastrophic risks to everyone in and far beyond our heavily populated region. The Alliance for a Clean Environment (ACE), has studied these risks for over a decade and found volumes of evidence for these risks. Ignoring these risks belies the NRC claim to have "confidence" about its nuclear waste. (0249-2 [Dugdale, Jane])

Comment: The intolerable and deadly effects of nuclear energy shown by Fukushima and the accident that happened there proves that nuclear energy is not safe, is not clean, and it's not reliable. Just because a major accident hasn't happened yet in the United States doesn't mean it won't[.] (0250-39-3 [Richards, Kitty Katherine])

Comment: I do follow history a little bit. I make an allusion to the Third Reich in this. And I very nearly lost my nerve to speak, but after hearing previous speakers, I realized that, although we are all breathing the same air in this room, we are living in two very different worlds. The allusion is to an institutionalized and unquestioning mindset. It is not a personal insult to anyone here. Let me mention a few names from history: HMS Titanic; the Halifax Harbor explosion; the airship Hindenburg; the Texas City dock explosion; two world wars; Three Mile Island; Bhopal, India; Chernobyl; Challenger and Discovery explosions; and Fukushima. All of these tragic events represent human failures interacting with the advanced technologies of their time. In hindsight, most were avoidable but for misplaced confidence in the technology, human error, and bad luck. (0250-46-1 [Stein, Ed])

Comment: As I read the draft EIS statement, I am afraid that the Nuclear Regulatory Commission with its judgments about so many of these activities and possible resource areas having a small risk; the word "small" is used throughout this document. It is used because of their determination with the probability that the occurrence of any single accident taking place is small. (0250-68-1 [Robinson, David])

Comment: But, you know, spread from coastlines to mountains, you have a variety of natural things from hurricanes, tsunamis, et cetera, that can be taken into account for and can be engineered for. And we have heard, you know, about all of the great engineering that goes into these things. But what worries me is what you can't see coming over the horizon. (0250-69-2 [Rundle, Steve])

Comment: I have not witnessed anywhere in your documents your consideration for the prospect of a super storm wiping out nuclear power plant(s) in this country and the ramifications of such an occurrence. Instead, we are told that all steps that you and your staff have taken are "adequate" -- adequate for what and for whom? (0277-6 [Pierman, Bette])

Comment: Keeping radioactive waste in an area prone to earthquakes and in a tsunami zone is a disaster waiting to happen. (0282-4 [Haber, Jim])

Comment: California's nuclear waste is sited on an eroding coastline, in tsunami zones, and is exposed to a highly humid and corrosive coastal environment. NRC's NUREG/CR-7030 states "atmospheric corrosion of sea salt can lead to stress corrosion cracking within 32 and 128 weeks in austenitic (corrosion resistant) steel canisters". (0284-6 [Borchmann, Patricia])

Comment: A radiological disaster impacts the nations, and world's security, economy, and food supply. California is the eighth (8th) ranking economy in the world, virtually tied with Italy and Russian Federation, larger than Canada, Australia, and Spain.

More than 40 percent of containerized imports enter the country through California ports. A radiological release from San Onofre would destroy public infrastructure, and disable Ports of Long Beach, Los Angeles, and possibly San Diego, causing irreversible economic damage at a local, regional, statewide, national, global scale.

California produces nearly ~ of US grown fruits, nuts, vegetables. Californias remained the number one state in case farm receipts in 2011, with \$43.5 billion in revenue representing 11.6 percent of US total. US customers regularly purchase several crops produced solely in California.

San Onofre is located adjacent to the primary vehicle transportation artery between Los Angeles and San Diego (1-5), and one of the largest military installations (and targets) on West Coast (Camp Pendleton). (0284-8 [Borchmann, Patricia])

Comment: In determining the risks of a spent fuel pool accident, the NRC is relying on a 1994 study of plants east of the Rocky Mountains. And then, in an unsupported leap of faith, it claims that the risks and consequences of an accident are the same for the west coast plants. (I have attached to my written comments a copy of the paragraph and footnote in the draft GEIS with this information. - footnote included below) 5. The seismic risk analysis performed in NUREG-1738 was based on site-specific seismic hazard estimates for nuclear power plants in the central and eastern United States found in NUREG-1488, "Revised Livermore Seismic Hazard Estimates for 69 Nuclear Power Plant Sites East of the Rocky Mountains" (NRC 1994). As such, nuclear power plants in the western United States, such as Diablo Canyon, San Onofre, and Columbia, were not specifically considered in this study. Nothing in NUREG-1738, or the NRC's reliance on it here, undermines the NRC's determination that the impacts of a severe accident in a spent fuel pool will be comparable to severe reactor accidents for all facilities. (0287-5 [Swanson, Jane])

Comment: The short-term storage methods currently in use are too vulnerable to accidents and terrorism. (0288-1 [Wickham, Wendelyn])

Comment: It is not safe to have nuclear power on an earthquake fault on a coast vulnerable to sunamis (sic). These are only a few of the many safety issues. Over the lifetime (250,000 years) of the fuel the likelihood of an accident is very very probable. The results of an accident are

more horrific than I can imagine. Accidents have and will happen. I care too much about the earth. Nuclear energy is obsolete. (0289-2 [Curren, Elizabeth])

Comment: San Luis Obispo was named the "happiest place on earth," so long as you don't consider the fact that Diablo Canyon Power Plant is sitting just over the hills, with pools full of spent fuel rods, which were never supposed to be stored on site. Every one who lives in SLO county is gambling that the big earthquake, that is overdue, is not going to take place while we are still residing in this county. We all try to pretend that it isn't going to happen. The fact is, that if the quake does happen, there will be a disaster similar to that of Fukushima, and San Luis County will instantly become one of the most nightmarish places on earth. (0298-2 [Terra, Ben])

Comment: One cannot but be struck by the Commission's stated opinion, based on the DGEIS, that any and all potential impacts of long-term HL and SNF storage, whether on-site at the reactors or elsewhere, are "small." They are seemingly written off as being so minor that they will "not noticeably alter any attribute of the resource." How "minor" to the Commission are the findings from studies of wildlife and flora in Chernobyl and Fukushima, published in dozens of refereed, respectable scientific journals? Those of similar studies which document widespread malformations in insect populations around nuclear plants in several countries in Europe? Those of highly increased thyroid abnormalities in children around Fukushima? Those increased cancers among children living near nuclear plants, in northern Germany? How "small" is the damage if land is made uninhabitable for hundreds of years, of people losing home and livelihood by the thousands, through major nuclear accidents? (0303-11 [Lamberts, Frances])

Comment: [I urge that] to-be-expected worst scenario nuclear accidents be included in new EIS analyses. (0303-14 [Lamberts, Frances])

Comment: The Waste Confidence rule prevents radioactive waste issues from even being considered, based on the presumed low probability of an accident, which is proven false by Fukushima, Chernobyl, Three Mile Island, and less severe releases of radiation and accidents at other nuclear plants. (0319-4 [Nichols, John])

Comment: Of particular interest to our chapter were the environmental impacts of postulated accidents and of potential acts of sabotage or terrorism to spent fuel pools and dry casks, ranging from short-term to indefinite storage, all of which were found by the NRC to have small impact, small being defined as effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attributes of the resource. These findings are in agreement with findings of the United States Nuclear Waste Technical Review Board in their evaluation of the technical basis for extended dry storage and transportation of used nuclear fuel in December 2010, which noted that reinforced concrete structures for dry storage systems can be designed with a life over 100 years and longer. And the American Physical Society in their consolidated interim storage of commercial spent nuclear fuel in February 2007, which concludes that there are no technical barriers to the safe and secure interim storage of spent fuel as long as adequate resources and attention are devoted to maintaining storage facilities. This is mirrored, as well, by the stance of Senator Feinstein's office communicated in person during a student delegation last July with Matthew Nelson and Mr. Platz. Give me any corrections afterwards, but where Matt stated, "The remaining hurdles to managing waste are political rather than technical. Senator Feinstein's office has been deeply informed and involved in the management of used nuclear fuel through the process of drafting the Nuclear Waste Administration Act." (0325-17-2 [Pearson, Jeremy])

Comment: Risks are under-estimated, consequences are very large, though. The consequences are huge. We don't even know how bad these consequences are. We'd have to all move out of the area. The probability is real, real low but not zero, so that will happen somewhere. Over thousands of years, it's going to happen. Accidents happen, this is what Gregory Jaczko said, the former NRC Chair, I guess he is. He said all the nuclear reactors in the United States should be shut down. This was the former Chair of the NRC. (0325-19-2 [Lutz, Ray])

Comment: The fuel pools at Fukushima, there is one that's just about to go down that they're desperately trying to save. Part of what this talk is about is fuel pools, that they're safe in seismic conditions. Bullshit. Okay? This is what this whole document is talking about. That's in there. They are not hardened. The roof of the fuel pool, a plane can go right through it, and then splash the water out, it would be a disaster. Seismic concerns. We don't know how big the earthquake is going to be. We just don't. We've only been around for so long. They keep going up, what's possible. Mexico just had a 7.5. This is only designed for 7.0. It can happen, way over. Just because NRC says a plant shows -- is supposed to be designed to withstand a maximum quake doesn't mean it's designed that way. It doesn't mean it would withstand it. Just because it says it -- this is what this says. And, you know, the problem with this is they're putting this out, we're supposed to be confident, and that means that all of these plants will have permanent nuclear waste dumps next to them that we can't stop, because it's already there. SONGS already has it. (0325-19-5 [Lutz, Ray])

Comment: It's about the fact that that could be a source of not one disaster, but a series of disasters. And people don't seem to be as aware of it as in -- and if you're here just for this and it's a part of your Federal job, I can understand that, but it looks a little different when you live nearby. (0325-24-3 [Kernahan, Gary])

Comment: This is a time of increasingly severe storms, sea rise, and increasing frequency of major earthquakes on the Ring of Fire. Catastrophic events at nuclear power stations have happened much more frequently than the NRC and the nuclear industry have assumed would ever happen. We had Three Mile Island, we had Chernobyl, we had Fukushima, we've had Rocketdyne, and there are many, many more. (0325-28-2 [Branigan, Mary Beth])

Comment: The Draft EIS evaluates environmental topics and issues if all goes according to plan. It would be virtually pointless if unexpected stochastic events take place. And we live in a day and age now where, unfortunately, the norm is no longer what one needs to expect. I've been living in fear, as my neighbors have, since 2001 of San Onofre in general. I'm even more horrified knowing that the spent nuclear fuel is going to be standing there for even seven years, let alone the 60, 160, and indeterminate time that is being considered in this generic document. (0325-34-2 [Waller, Viviane])

Comment: I'm concerned about tsunami damage to the pool that contains the fuel, and for two reasons. One is that the tsunami that struck Fukushima showed that we don't have the technology, even with the brilliant minds working on the problem, to really do a good estimate of tsunami magnitude. The second concern I have is that back in 1812, the earthquake that knocked down the mission at San Luis Obispo was accompanied by a tsunami that was estimated and recorded by the friars there to be 35 to 50 feet high above sea level, depending what Indian village you were at the time. And this makes me worry that modern scientists, knowing that these friars were not ISO 9000 certified, and knowing that they're not calibrated against other tsunamis, might discount and say that their reporting was not believable. On the other hand, scientists have a poor record of not believing things unless there's a good

explanation for what happened. I would like the NRC and other people to give some credibility, maybe not 100 percent to the friars, and consider an earthquake that might happen not 200 years ago, and a tsunami that might occur on the basis of maybe a 1,000 year interval, in other words, a one in thousand chance of occurring while the fuel is in the cooling pool. (0325-6-1 [Deshotels, Bob])

Comment: At the heart of this analysis lies the use of probabilistic risk assessments. Yet, such assessment suffers fundamentally from the fact that the results don't reflect the remotest real-life occurrences. The reason it appears to be, that classical probability risk assessments cannot accurately predict nuclear catastrophe because of the low base rate for events in the past, and that such events usually have a multitude of causes and/or causes based on human error, or contributables, which are not calculable in mathematical equations. Examples: Three-Mile Island occurred after 500 reactor years, while the prediction was once in 3 million. Chernobyl, after 300 reactor years; the prediction was once in 10 million. And the prediction for Fukushima would have been off the scale all together. For three reactor meltdowns and pool problems all at once, the series of unpredicted events, combined with unforeseen human errors: the beyond design basis quake, the drop in the coal slime, insufficient sea walls, emergency generators in the basement, and battery backup power for just eight hours. (0326-15-4 [Schumann, Klaus])

Comment: In determining the risks of a spent fuel pool accident, the NRC is relying on a 1994 study of plants east of the Rocky Mountains. And then, in a totally unsupported, unscientific leap of faith, the NRC concludes that the assumptions they have about the plants east of the Rockies will apply to the coastal plants on California's coast. I've attached to my written statements, a direct quote from the DEIS to show where this assumption is made. (0326-8-5 [Swanson, Jane])

Comment: You say it's safe to store it onsite anywhere. It's actually insulting to the intelligence of anyone who's concerned about the dangers of nuclear power to make that kind of assertion. Of course, your calculations do not take into account the core meltdowns that have already happened all around the world. I guess those are statistically inadmissible to your Draft GEIS. (0326-9-4 [Seeley, Linda])

Comment: The probability of accidents are not low, as you say in your DGEIS, which Connie so greatly put it, has no substance, and it's been designed that way. It is inaccurate to say that the probability of accidents are low and dismiss it like this, because the consequences of the accidents are not low. Look at Three Mile Island, look at Chernobyl, look at Fukushima. "One nuclear accident can wipe out half the globe," to quote Yablokov and Nesterenko's book on the catastrophe of Chernobyl. That's one nuclear accident such as the ongoing disaster of Fukushima Daiichi with all of its spent nuclear fuel rods that are a million times more radioactive than when we put them in the core. This can wipe out the globe. This is not science fiction, this is the reality that we are dealing with, and this is the insane risk that we are taking when we allow the reactors to operate and produce radioactive waste. (0327-21-4 [Miskena, Jessice])

Comment: Remember the tornado that started the whole Wizard of Oz story? One major tornado hit, a simple tornado hit to a nuclear reactor could cause a major disaster. And like disasters at Chernobyl and Fukushima, what will we do with the waste then? Throw it somewhere over the rainbow? (0327-35-2 [Poprasky, Nancy])

Comment: And when it [nuclear power] is not safe, it is catastrophically unsafe. Let us ask the people in Chernobyl, Russia who may not be able to return to their homes for 20,000 years, the people of Fukushima, Japan, Three Mile Island, and how close were the residents in northern

Ohio to a catastrophic disaster in 2002 when a corrosive hole was found in a Davis-Besse nuclear plant reactor. The list could go on and on. (0327-42-3 [Faris, Kelly])

Comment: Low probability is not a substitute for protection. As we all have learned from the disastrous spread of radioactive materials from reactor disasters at Windscale in England in 1957, Three Mile Island, Pennsylvania and Church Rock, New Mexico both in 1979, Russia's Chernobyl in 1986, and its 1993 waste explosion in Tomsok, and the unending radiation geyser catastrophe in Fukushima today. (0328-9-5 [LaForge, John])

Comment: And to follow on another earlier commenter, I think he was right in saying that these vulnerable storage facilities along the coastline, for example, need to be moved to higher ground, to more stable geology. And, in fact, that's been part and parcel of hardened onsite storage from the very start, a recognition that some of these nuclear power plant sites are entirely inappropriate and unsuitable for long-term storage. Prairie Island, Minnesota is another key example of that, a flood plain in the Mississippi River immediately adjacent to a Native American reservation. The reactors never should have been built there in the first place against the will and consent of the Tribe. And, of course, the storage for high-level waste should not be there either. (0329-11-6 [Kamps, Kevin])

Comment: We have other problems that are not really adequately addressed in anything that's going to talk about waste confidence, one of which is the aboveground wet storage at places like Browns Ferry where the reactors are the Fukushima-style reactors and have these wet storage pools at higher, much higher than design density stored up in the air and were only recently, by the grace of God, saved from a direct hit by a tornado which did, in fact, cause a station blackout for several days as the high-tension system went down. (0329-12-6 [Paddock, Brian])

Comment: They're [the nuclear industry] not covering the cost of accidents or anything like that. These are barely being discussed here or in any other way, the problem of making the waste. We're only discussing, well, what to do now that we've got it. We're part of an organization, the NRC and the public, that can determine that this whole idea is bad, and that's what we need to do. How much are we putting into these waste confidence hearings? A hundred thousand dollars, if that, to go around the country and have a couple of meetings? There could be a trillion dollar accident based on what we decide here, so we're not even spending a million of what it might cost if we fail to come to the correct decision here. So I think we need to consider that. (0329-16-4 [Hoffman, Ace])

Comment: North Anna was built on a fault line. We had a fairly large earthquake in -- it's an active fault line -- in 2011, we had a large earthquake. It damaged the plant. And it moved the dry cask storage containers that were onsite. We were told that couldn't happen. So I have to say that, frankly, we don't trust industry as far as we can throw them. And we are extremely dubious about the level of government oversight on this. (0329-30-1 [Price, Scott])

Comment: The trouble with the east coast of Florida is there is an island in the Canary Islands that has a volcano on it called Cumbre Vieja, I believe is how it's spelled in the Isle of La Palma that has, the western side of the island is starting to slide off, a ten-mile long piece of land of volcanic rock. And I was watching a science show talking about the Hawaiian islands and why some are round and some are elongated. Apparently, as the magma comes up, it has iron in it which rusts out, which allows the island to basically rust out and fall apart, like an onion being peeled apart. The Isle of La Palma could have that ten-mile long piece of island fall off and create a tsunami, which they claim that will be about a thousand feet tall moving at a thousand

miles an hour. This will affect the entire Atlantic Basin, so everything from the bottom part of the western side of Africa to all the way up to England and including South America and North America will be hit by a monster tsunami. As it relates to the U.S. East Coast, we would be hit in about 5 hours by a tsunami about 600 feet tall moving at about 600 miles an hour. In Florida, there is no place to bury the nuclear waste or even secure it that it would withstand the force of that magnitude by a monster wave. (0329-8-1 [Wilson, Greg])

Comment: But to leave the spent fuel rods down in South Florida would be insane because, if it does ever get hit by a tsunami from La Palma or even an asteroid strike out in the Atlantic Ocean and the fuel rods get basically shot out across the Everglades, there is no way to go pick them up. Nobody has any type of equipment that could actually reclaim those fuel rods, and you'd have a massive environmental disaster on your hands. (0329-8-3 [Wilson, Greg])

Comment: When the Deep Horizon sank during the BP Oil spill, it caused earthquakes as far away as in the New Madrid fault line zone up around Memphis, Tennessee. So we cannot predict what's going to happen in the Gulf Coast either, and to leave any waste close to the coastline, basically any coastline in the country, is not doable. Short-term to long-term storage units should be set up to where all the waste is moved away from the coastline to the closest safe location, such as on the West Coast where the San Onofre and the El Diablo sites, nuclear power plants, they should be moved up away from the San Andreas fault line and into elevated hills or mountains in the area, which would probably be over a thousand feet in elevation from the Pacific Ocean. (0329-8-5 [Wilson, Greg])

Comment: The tsunamis that are kicked up by the Hawaiian earthquakes or tsunamis where the islands are falling apart as seen from space. One of them actually did flood the LA Basin, and I haven't seen any further studies on that so I don't know how bad it flooded it, but it was a pretty big tsunami that hit. So that being said, even though transportation is very dangerous, to leave the spent fuel in areas where it could be basically destroyed or, you know, scattered about by things that we really don't know that much about at this time. (0329-8-6 [Wilson, Greg])

Comment: There was an air blast asteroid that exploded over Russia that was caught on dashboard cams, and they say that one was about the size of two school buses or so. It wasn't very big, but it blew out every window in the entire city and there was over a thousand people injured from flying glass. If you ever seen it on the dashboard cam videos from that explosion, it was quite amazing to see the amount of damage that happened, and that was a small one. In the early 1900s, there was the Tunguska event that it took them about 30 years to figure out that something had happened up there. And it was in Siberia, and it knocked down almost 900 miles, square miles of trees. So it was a major event, larger than the Hiroshima blast from World War II. And we should really take a look at what we're doing with the spent fuel as to what could actually happen. It should be moved away from earthquake and fault line zones. (0329-8-7 [Wilson, Greg])

Comment: In the U.S., there are nuclear plants and nuclear waste sites such as Indian Point which sit in densely and highly populated areas. The majority of climate scientists around the globe have warned that climate change is occurring and that it brings risks of warming and extreme weather. Regardless of whether the "cause" is anthropogenic activity or not, events in recent decades such as hurricanes Katrina, Irene and Sandy, the prolonged droughts and forest fires that have plagued the Southwestern U.S., powerful tornadoes, earthquake activity, flooding, and numerous severe wind and snow storms, which have severely stressed the nation's infrastructure. Many of these events have caused prolonged and wide-scale electric outages due to downed power lines, substation flooding and transformer explosions. Difficulties

in power recovery have resulted in areas challenged by downed trees, flooding, damaged bridges, impaired rail lines and obstructed roads. Deteriorated infrastructure conditions add other challenges. Nuclear power stations and spent fuel pools need electricity for safe operation. Indeed the root cause of the Fukushima disaster was loss of electric power. (0341-1-11 [Mermelstein, Richard])

Comment: An honorable and honest GEIS would make these points clear. And it would not bury the reality that very serious - potentially catastrophic - consequences could ensue if current NRC calculations are wrong. Whether significant amounts of radioactivity will be released into the environment is not a question of if, but of when, and where and with what impact? The Sept 11 and Fukushima disasters put such questions into stark relief. Further they show why it is critical to understand the impact the GEIS will have at the global level. (0341-1-5 [Mermelstein, Richard])

Comment: It must also be pointed out that the NRC does not even apply its own absurdly reductive probabilistic risk formulation correctly. Firstly, by determining every serious event with negative consequences to be "unlikely," the GEIS unceremoniously excises a key factor out of the formula upon application. Secondly, despite using the word "consequences," the analysis wholly ignores the likely consequences of a severe accident such as a major spent fuel pool fire at Indian Point which could render the New York Metropolitan area uninhabitable for centuries. (0341-2-3 [Mermelstein, Richard])

Comment: We urge GEIS analysis be reformulated to consider all risks and include rare yet credible events including: internal and external hazards, during all modes of plant operation, evaluated in a riskinformed manner. This approach should include consideration of so-called "cliff-edge" events - those for which a small incremental increase in severity can yield a disproportionate increase in consequences. This argument was made in ASME Technical Report which resulted from a task force set up at the direction of the president of the American Society of Mechanical Engineers (ASME). The ASME task force was co-chaired by the former Chairman of your agency, Dr. Nils Diaz, and the former Senior Vice President and Chief Technology Officer at Westinghouse Electric Company, Regis A. Matzie. The report observes:

- * The Fukushima accident "has indicated that the events now needing to be protected against include large fires and explosions, extreme natural phenomena, station blackouts of indefinite duration, and combinations of internal failures that can cause the loss of normal and backup core cooling..." (ASME Technical Report, p. 39)
- * Fukushima shows the risks of not preparing "for the possibility that the safety-related electrical distribution system, and many of the plant safety systems, could be rendered inoperable by a single event. Also, the possibility of losing all AC power for an extended period of time, and the resulting depletion of the plant batteries (i.e., all DC power) was not considered in preparations for accident management....They also had to deal with spent fuel pool cooling and potential damage to the spent fuel pools." (ASME Technical Report, pp. 50-51; see also NRC Special Inspection Report, 2003)
- * "Many recent examples exist of the occurrence of highly improbable events with unforeseen loss of control, where human actions and decisions have contributed to, or ultimately led to, unacceptable consequences. Recent examples include the Deepwater Horizon fire, explosion, and oil leak in the Gulf of Mexico; inundation of New Orleans following Hurricane Katrina; crashes of the Space Shuttle Columbia and Concorde aircraft; and collapse of the World Trade Center buildings after terrorist actions on September 11, 2001. It is presently not possible to predict the occurrence of such events; furthermore, attempts to predict such events even if information is available will encounter significant uncertainty. The capability to predict and control an event becomes increasingly more difficult as the frequency of occurrence of the event decreases." (ASME Technical Report, p. 40)
- * "The probability of any action is represented and weighted or

adjusted by situational multipliers representing stress, environment, and time pressures. It is practically impossible to describe the nuances, permutations, and possibilities behind individual and collective human decisionmaking, so the human-technological system must be treated as an integral system." (ASME Technical Report, p. 40) America has had numerous nuclear power plant safety and security lapses. America has also endured a sobering series of terrorist and criminal events (9/11, Boston Marathon, etc.) and extreme weather events since commencement of the current century. So far we have dogged the bullet of a concurrent nuclear emergency, grid failure, and extreme weather and/or security crisis. But at what point do the odds change for that bullet to connect? (0341-2-6 [Mermelstein, Richard])

Comment: The level of denial that things can go wrong in the GEIS borders on the level of delusion. Sept 11th, Katrina, BP, now Fukushima. How many more examples do we need of the way events can aggressively overwhelm human-engineered systems? How many failures of "fail safe" structures must destroy the lives of thousands? Somebody at the NRC, pick up a newspaper. Read it. Please.[10] (0341-2-8 [Mermelstein, Richard])

Comment: With climate change, the likelihood of extreme weather events is increasing along with the potential for catastrophic results affecting any waste storage facility, especially those near the coast. We are concerned that seismic risks have been underestimated just as the NRC has historically underestimated flooding and seismic risks. (0348-6 [Agnew, David] [Roscoe, Lee])

Comment: With climate change, the likelihood of extreme weather events is increasing along with the potential for catastrophic results affecting any waste storage facility, especially those near the coast. We are concerned that seismic risks also have been underestimated. (0352-8 [Roscoe, Lee])

Comment: 2. The decision to allow DCNPP to be built next or near 13 active earthquake faults has proven to be reckless, especially in light of the recently discovered Shoreline fault and the events at Fukushima! (0358-4 [Schumann, Klaus])

Comment: With climate change, the likelihood of extreme weather events is increasing along with the potential for catastrophic results affecting any waste storage facility, especially those near the coast. We are concerned that seismic risks have been underestimated just as the NRC has historically underestimated flooding and seismic risks. (0373-6 [O'Malley, Brian])

Comment: I point out in the TMI#2 and in the Fukushima accident, the plants were allowed to run because they met 'regulation'. In the Fukushima accident conditions exceeded design. In the TMI#2 accident a technician (Hartman) described how adding hydrogen allowed the reactor to run despite leakage that should have caused a stop. The NRC believes that meeting regulation will provide adequate safety to the public. Fukushima and TMI#2 accidents provide examples of meeting regulation and causing disaster. Is the NRC sticking to its belief that meeting regulation is sufficient provision of safety to the public? (0376-3 [Lewis, Marvin])

Comment: LIMERICK'S PACKED FUEL POOLS ARE VULNERABLE TO EARTHQUAKES: Limerick's fuel pools are stories high over the reactors, similar to Fukushima's. There is no protective containment such as exists around the reactors; Shaking from earthquakes can cause cracking in cement of fuel pools leading to leaks. Power and cooling water sources can be disrupted by damage in the miles of underground pipes due to an earthquake. Eventually consequences from an earthquake can lead to radiation leaks and meltdowns (0377-4-6 [Cuthbert, Lewis])

Comment: Health and Economic Impacts Of A Fuel Pool Accident or Terrorist Attack Could Be Astronomical (0377-4-9 [Cuthbert, Lewis])

Comment: EARTHQUAKE THREATS TO CASKS. The earthquake in Virginia proved heavy cement casks, each weighing many tons, can be jarred and even moved. Casks at a nuclear plant 12 miles from the epicenter of the August 23, 2011 earthquake in VA were moved by the earthquake. There is an earthquake fault directly under the Limerick site with two others within 2 miles. Two other earthquake faults are very close to Limerick. One 9 miles away is active. The other is 17 miles away. After a natural disaster like an earthquake, there is no proof that this deadly waste will be able to be removed safely, especially after corrosion has taken place. None have ever been removed after a long period of time. What could happen if damaged or overheating fuel rods in casks cannot be removed because of jarring from an earthquake? No one knows. It's like playing Russian Roulette. (0377-5-1 [Cuthbert, Lewis])

Comment: There no long-term solution for atomic waste. The NRC's "confidence" that this waste will never cause a threat to public health and safety based on the low probability of an accident is ... misguided to say the least. This is not, say, an oil refinery blowing up with only local effect; deadly radioactivity spreads worldwide. Ignoring alleged "low" probability threats which would affect millions is way too chancy and appears to be manslaughter or even criminally negligent homicide PLUS suicidal with people who self-harm being institutionalized. (0401-1 [Hoffman, David])

Comment: Any cask storage should be protected from corrosion, natural disasters, and attack. (0404-4 [Smith, Roger])

Comment: It [the GEIS] doesn't even mention the fact that the Fukushima plant was sited in an earthquake and predicted tsunami zone, due to bad management decisions, and that such an "accident" was eventually inevitable. It cites the earthquake at the North Anna facility in Virginia as proof that dry casks can survive an earthquake; but fails to mention that the siting of this reactor failed to even predict such an earthquake in the first place. (0410-28 [Nelson, Dennis])

Comment: This type of hubris on the part of the NRC officials shows that their analyses are not comprehensive and cannot be expected to represent the truth, much less to protect the public from such disasters in the future. The NRC draft report does not discuss the important issue of the lack of insurance for radiation damages in the event of a widespread release nor does it explain who will pay to make people whole again afterwards. (0410-29 [Nelson, Dennis])

Comment: The NRC classifies the risk of catastrophic accidents as "small" not because it believes that widespread radiological contamination is not a catastrophic event; but because it assumes the likelihood of such an event to be vanishingly small. Unfortunately, history shows us that this assumption is flat-out wrong. History shows that catastrophic nuclear accidents with widespread contamination, (with various combinations of land use sacrifice and large population relocations), have occurred about every 20 to 30 years. Examples include the reactor accidents at Fukushima and Chernobyl and the radiological waste accident at Kyshtym/Mayak/Techa River. Other intentional releases and contaminations, some with widespread dislocations, have occurred at Bikini, Mururoa, Eniwetok, Hanford, Nevada, Semipalatinsk, Lop Nor, Novaya Zemlya, Maralinga, Christmas Island, North Africa, etc. Serious accidents with major releases of radioactive materials off-site have occurred approximately once every decade. Some examples include: Windscale, Fermi and Three Mile Island in addition to the above incidents. Accidents at a military reactor in Idaho and a research reactor in Yugoslavia, as well as several lethal and non-lethal criticality accidents like the one at Tokaimura, which usually affect only workers,

happen with about the same frequency. Near misses include numerous "excursions," an electrical fire at a Browns Ferry plant and a near perforation of the reactor vessel at a Davis-Bessie plant. All these demonstrate the extreme risks and perils of the nuclear enterprise. There is no reasonable expectation that in the future we will be any more clever or lucky than we were in the past. (0410-6 [Nelson, Dennis])

Comment: The GEIS needs to add more consideration of the environmental impact of water on waste management. A persistent source of water is needed for cooling spent fuel rods. Please address the impact of droughts and floods on nuclear waste management. The catastrophe in Fukushima demonstrated the continual need for huge amounts of water needed for cooling year after year. The GEIS needs to address the environmental and health risks of floods, earthquakes tsunamis and droughts. (0417-11 [Clark, Terrence])

Comment: As a concerned citizen who lives only about 25 miles from San Onofre Nuclear Power Plant, I want the NRC to know that storing nuclear waste on-site for many more years is totally unacceptable to me, my family and my neighbors. We also happen to live in a very geologically active area, perhaps over due, for a large earthquake. Earthquakes and nuclear fuel do not mix well as can be demonstrated by the disaster of Fukushima. There are over 8 million residents in the potential disaster area which would need to be first evacuated, then housed and fed, and would we/they ever be allowed to return? (0425-1 [Individual, Anonymous])

Comment: The GEIS framework may not be adequate or appropriate for nuclear risk assessment. EIS analyses focus upon impacts of proposed human activity on the environment. Yet hazards related to nuclear plant operations and to spent fuel storage can be profoundly affected by the reverse; i.e., impacts of the environment upon a facility. The earthquake, tsunami, and subsequent nuclear emergency at Fukushima demonstrate this sequence, with negative interaction between the environment and the facility that continues. This example applies most clearly to reactors in active earthquake zones but all reactors are sited near water, and earthquakes can strike at widely varied points in the U.S. including the national record 8.5 magnitude quake at New Madrid, Missouri in 1835. (0431-6 [Pascall, Glenn] [Watland, George])

Comment: Approximately 75% of the nuclear waste is currently being stored in pools which are vulnerable to natural disasters, terrorist attack or human error. (0433-3 [Stone, Gene])

Comment: Suspended pools, fields of casks, all unacceptable. My closest reactor is on a fault that had a 5.8 quake a couple of years ago and over a hundred aftershocks. That quake caused considerable damage over 100 miles away. Luckily the reactor and casks remained intact, luckily. I do not appreciate such a potential hazard depending on luck, I find it reprehensible that the NRC allows this hazard to remain and is even considering permitting an additional reactor, and I am sitting here stroking a rabbit's foot depending on luck to keep me safe. That is what regulatory agencies like the NRC are for. I urge you to do your job and not gamble with the well being of Americans. Statistics and probabilities are not the surety we desire. (0436-3 [Patrick, Kay])

Comment: The other inane argument the NRC document makes is that there is a low probability that a serious accident will occur. Really? What world are these people living in? A climate gone wild with enormous and destructive storms, tsunamis and hurricanes that have wiped out entire cities, earthquakes that have shattered major areas of the world - and the NRC thinks that "accidents" are rare? (0443-2 [Sabo, Betty])

Comment: The NRC flawed methodology of determining risk is founded a formula of multiplying consequences times probability. NRC cannot with certainty define either of these

multipliers, and consequently risk is not properly assessed. In many scenarios of accidents or intentional radiological or chemical releases from spent nuclear fuel, the consequences can be defined with more certainty than the probabilities of occurrence. NRC chooses to assign exceedingly low probability of occurrence to events that have very high consequences. They go on to assert low or very low risk without also assigning a relative probability of accuracy to the product, risk. While the NRC acknowledges that environmental and health and impact consequences may be very high, they state that the probabilities of accident or attack events are very low, and then simultaneously discredit their own methods when a few pages or paragraphs later state they event probability is not quantifiable. Using clear logic one must then conclude that the risk assessment is flawed and risk is also not quantifiable or is subject to extreme uncertainty. I argue that with such circumstances of either unquantifiable impacts and consequences or unquantifiable probability that risk has to solely relate to the consequences alone as best they can be determined, not relying on unquantifiable probability multipliers. Instead the NRC bluntly asserts very low risk in text and tables throughout the DGEIS to numerous accident events, and notably for the next topic, events of terrorist attacks. Legitimate catastrophe theory and logic reveals this methodology flaw, no matter how entrenched these methods may be at NRC. NRC must correct its methods of risk assessment and more importantly revise appropriate responses, particularly to events with high consequence. (0447-1-10 [Andrews, Richard])

Comment: Another major flaw with the risk analysis is the handling of duration of risk, the opportunity time interval for an event to occur. Specifically NRC does not accommodate the issue of delays in managing wastes, defined as 60 years post power operation in the short term case, stretching out to indeterminate. Does that instill any sense of "waste confidence"? NO. The longer the period of potential exposure to threats, be they natural or manmade or terror, the greater the likelihood that the catastrophe will happen over the extended interval. Time span is relevant and using only a probability per year factor is simply warping the true expression of risk. Furthermore, given the continued population growth of our country, nuclear power plants and ISFSIs that were once somewhat remote are being and will continue to be encroached upon by urbanization, particularly over the long periods in the three EIS cases of continued on-site storage of SNF (60 years, 160 years, indefinite periods). (0447-1-12 [Andrews, Richard])

Comment: The NRC in the Waste Confidence DGEIS further ducks or obscures the reality and magnitude of these catastrophic events by failing to use plain honest language to describe the casualties/deaths and the huge essentially perpetual societal, financial, and environmental damages. Those failings must either be corrected or the DGEIS scrapped as inadequate. (0447-1-23 [Andrews, Richard])

Comment: The DGEIS simply fails to address reality of the dangers of SNF, in fact throughout the document the NRC continually denies and misrepresents by understating the dangers of inherent catastrophic consequences from any of many potential causes for system failures, failing to even legitimately or completely describe the consequences. (0447-1-4 [Andrews, Richard])

Comment: flawed methodology used by NRC to calculate and describe risk for high consequence events (0447-1-5 [Andrews, Richard])

Comment: Since our collective will to avert disaster is weak, (note the incomprehensible collective failure to address climate change in a meaningful manner) probabilities abound for disasters untold, which neither we nor our immediate descendants will be able to imagine. (0454-7 [Waldstein, Joe])

Comment: Large-Scale, Long-Term Power Outages Could Lead to Multiple Concurrent Reactor Meltdowns and Spent Fuel Pool Fires. An extreme solar storm (geomagnetic disturbance) could cause over 300 extra high voltage (“EHV”) transformers¹¹ [footnote 11 text: The NRC has explained that “[l]arge transformers are very expensive to replace and few spares are available. Manufacturing lead times for new equipment range from 12 months to more than 2 years.” See NRC, “Long-Term Cooling and Unattended Water Makeup of Spent Fuel Pools: Proposed Rules,” Docket No. PRM–50–96, NRC–2011–0069, Federal Register, Vol. 77, No. 243, December 18, 2012, p. 74794.] to fail, “leading to probable power system collapse[s] in the Northeast, Mid-Atlantic, and Pacific Northwest,” which could last months or longer, “affecting a population in excess of 130 million.”¹² [footnote 12 text: *Id.*, pp. 74788-74798.] Such a solar storm—with an intensity similar to that of the 1859 Carrington event¹³ [footnote 13 text: The Carrington event in 1859 is the largest solar storm ever recorded.]—could occur as frequently as once in 153 years to once in 500 years ($2.0 \times 10.3/\text{yr}$ to $6.5 \times 10.3/\text{yr}$), according to the NRC, and initiate “a series of events potentially leading to core damage at multiple nuclear sites.”¹⁴ [footnote 14 text: NRC, “Long-Term Cooling and Unattended Water Makeup of Spent Fuel Pools: Proposed Rules,” p. 74790.] (This is an international nuclear safety issue, not only pertinent to the U.S.) (On March 14, 2011, Thomas Popik, submitted a petition for rulemaking, PRM50-96,¹⁵ [footnote 15 text: Thomas Popik, PRM-50-96, March 14, 2011 (ADAMS Accession No. ML110750145).] on behalf of the Foundation for Resilient Societies, requesting regulations to help prevent SFP severe accidents—like zirconium¹⁶ [footnote 16 text: For consistency, this report will use the term “zirconium” to refer to all the various types of zirconium alloys that comprise fuel cladding. Zircaloy, ZIRLO, and M5 are particular types of zirconium alloy fuel cladding. In a SFP accident, the oxidation behavior of the different fuel cladding materials, with various zirconium alloys, would be similar because of their shared zirconium content.] fires in racks of densely-packed spent fuel assemblies—in the event of prolonged outages of “North American commercial electric power grids...caused by extreme space weather, such as coronal mass ejections and associated geomagnetic disturbances.”¹⁷ [footnote 17 text: NRC, “Long-Term Cooling and Unattended Water Makeup of Spent Fuel Pools: Proposed Rules,” p. 74788.] In 2012, the NRC decided to consider the issues raised in PRM-50-96 in its rulemaking process.)¹⁸ [footnote 18 text: *Id.*, pp. 74788-74798.] Additionally, either devices designed specifically to disrupt (or destroy) electronic equipment or the detonation of a nuclear device high above the earth’s atmosphere could also produce an electromagnetic pulse with a magnitude that could cause large-scale, long-term power outages.¹⁹ [footnote 19 text: Metatech Corporation, “Electromagnetic Pulse: Effects on the U.S. Power Grid,” Executive Summary, January 2010. A June 2010 North American Electric Reliability Corporation (“NERC”) and U.S. Department of Energy (“DOE”) report states that such power outages could also be caused by pandemics, “coordinated cyber, physical, and blended attacks”²⁰ [footnote 20 text: NERC, DOE, “The High-Impact, Low-Frequency (HILF) Event Risk Effort,” June 2010, pp. 3, 8.] and that “[d]eliberate attacks (including acts of war, terrorism, and coordinated criminal activity) pose especially unique scenarios due to their inherent unpredictability and significant national security implications.”²¹ [footnote 21 text: *Id.*] (**0463-1-1** [Leyse, Mark])

Comment: In a SBO boil-off accident, if enough water boiled off, the water level would drop in the pool, uncovering the fuel assemblies; and if temperatures in the SFP were to increase to approximately 657°C (1214°F), the Boral plates of the fuel assembly storage racks would melt.⁶³ [footnote 63 text: Zachary I. Franiewski et al., Pennsylvania State University, “Spent Fuel Pool Analysis of a BWR-4 Fuel Bundle Under Loss of Coolant Conditions Using TRACE,” NucE431W S2013, May 2013, pp. 1-2.] (Boraflex would melt at even lower temperatures and not be effective once heated above approximately 300°C (572°F).⁶⁴ [footnote 64 text: EPRI, “Severe Accident Management Guidance Technical Basis Report,” Volume 2: “The Physics of Accident Progression,” 1025295, Appendix EE, p. EE-9.]) Boral and Boraflex are neutron-absorber

materials that are placed in high-density storage racks to help prevent criticality accidents. (Fission—the splitting of atoms in the nuclear fuel—occurs in a criticality accident.) If Boral were to melt in *BWR* high-density storage racks, neutrons would diffuse throughout the SFP; in scenarios in which water was injected back into the boiled-off SFP, fission could possibly commence. (BWR SFPs do not use borated water.⁶⁵ [footnote 65 text: NRC, “Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I Boiling Water Reactor: Draft Report,” p. 30.] If fission were to occur, local fuel and fuel-cladding temperatures would rapidly increase. Fission would also “cause an increase in decay products, which [would] have a delayed effect on temperature increase[s].”⁶⁶ [footnote 66 text: Zachary I. Franiewski et al., Pennsylvania State University, “Spent Fuel Pool Analysis of a BWR-4 Fuel Bundle Under Loss of Coolant Conditions Using TRACE,” NucE431W S2013, pp. 1-2.] (A June 2013 NRC document states that “if an [inadvertent criticality event] were severe enough to produce significant heat, the fuel will be harder to cool.”⁶⁷ [footnote 67 text: NRC, “Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I Boiling Water Reactor: Draft Report,” p. 29.] Rapid increases in the fuel and fuel-cladding temperatures could lead to a SFP fire. And radiation releases, caused by a criticality accident in a SFP, would impede (or possibly prevent for significant time periods) efforts to mitigate either a partial SFP LOCA or SBO boil-off accident, making it more probable that such accident scenarios would lead to SFP fires. (Criticality accidents are discussed in more detail in Section D.) (0463-1-12 [Leyse, Mark])

Comment: As the NRC observes, large-scale, long-term power outages, which lasted months or longer, could initiate “a series of events potentially leading to core damage at multiple nuclear sites.”⁶⁸ [footnote 68 text: NRC, “Long-Term Cooling and Unattended Water Makeup of Spent Fuel Pools: Proposed Rules,” p. 74790.] Radiological releases resulting from core damage would contaminate the NPP site and impede efforts to mitigate the accident, especially if radioactive debris were propelled throughout the site by hydrogen explosions, as occurred in the Fukushima Daiichi accident.⁶⁹ [footnote 69 text: Institute of Nuclear Power Operations (“INPO”), “Special Report on the Nuclear Accident at the Fukushima Dai-ichi Nuclear Power Station,” INPO 11-005, November 2011, pp. 9, 12, 21, 24, 25, 32, 37, 79, 85, 86, 96.] After the Fukushima Dai-ichi site was contaminated, workers had to wear additional protective clothing and limit the time they spent, working to mitigate the accident.⁷⁰ [footnote 70 text: Id., p. 9.] Efforts to mitigate a SFP accident would also be impeded (or possibly entirely prevented for significant time periods) by the radiologically-contaminated environment. Hence, if large-scale, long-term power outages lead to core damage, it would be more probable that such outages would also lead to at least one SFP boil-off accident and fire. (0463-1-13 [Leyse, Mark])

Comment: Regarding nuclear electromagnetic pulse (“EMP”) attacks, a May 21, 2013 Wall Street Journal op-ed, “How North Korea Could Cripple the U.S.: A Single Nuke Exploded above America Could Cause a National Blackout for Months,” states: The Congressional Electromagnetic Pulse Commission, the Congressional Strategic Posture Commission and several other U.S. government studies have established that detonating a nuclear weapon high above any part of the U.S. mainland would generate a catastrophic electromagnetic pulse. An EMP attack would collapse the electric grid and other infrastructure that depends on it—communications, transportation, banking and finance, food and water—necessary to sustain modern civilization and the lives of 300 million Americans. EMP effects can be made more powerful and more catastrophic by using an Enhanced Radiation Warhead. This is a low-yield nuclear weapon designed not to create a devastating explosion, but to emit large amounts of radiation, including the gamma rays that generate the EMP effect that fries electronics.²² [footnote 22 text: R. James Woolsey, Peter Vincent Pry, “How North Korea Could Cripple the U.S.: A single nuke exploded above America could cause a national blackout for months,” Wall

Street Journal, May 21, 2013.] And discussing the North American power grid's vulnerabilities to large-scale, long-term power outages, the executive summary for "Electromagnetic Pulse: Effects on the U.S. Power Grid," a series of reports Metatech prepared for the Oak Ridge National Laboratory ("ORNL"), states: The nation's power grid is vulnerable to the effects of an electromagnetic pulse (EMP), a sudden burst of electromagnetic radiation resulting from a natural or man-made event. EMP events occur with little or no warning and can have catastrophic effects, including causing outages to major portions of the U.S. power grid possibly lasting for months or longer. ... The cost of damage from the most extreme solar event has been estimated at \$1 to \$2 trillion with a recovery time of four to ten years,²³ [footnote 23 text: National Academy of Sciences, "Severe Space Weather Events—Understanding Societal and Economic Impacts: A Workshop Report," 2008.] while the average yearly cost of installing equipment to mitigate an EMP event is estimated at less than 20 cents per year for the average residential customer.²⁴ [footnote 24 text: Metatech Corporation, "Electromagnetic Pulse: Effects on the U.S. Power Grid," Executive Summary, January 2010.] (0463-1-2 [Leyse, Mark])

Comment: Neutron-Absorber Materials and How the Potential for Criticality Accidents in SFPs Has Increased. Neutron-absorber materials are needed in the SFP storage racks that have densely packed fuel assemblies—high-density storage racks. Neutron-absorber materials are needed *to help prevent criticality accidents*; in fact, "new rack designs rely heavily on permanently installed neutron absorbers to maintain criticality requirements."¹⁰⁴ [footnote 104 text: NRC, "On Site Spent Fuel Criticality Analyses NRR Action Plan," May 21, 2010, (ADAMS Accession No. ML101520463), p. 1.] High-density storage racks also rely on the particular arrangements of discharged and fresh fuel assemblies that help to control reactivity in the SFP. In the SFP, fuel assemblies might be arranged within checkerboard configurations. One of the reasons that criticality accidents could occur in SFP high-density storage racks is that the center-to-center distance between the spent fuel assemblies (the pitch) in such racks is close to that of fuel assemblies in the reactor core. For example, some BWR reactor cores have a fuel assembly pitch of 6.0 inches (in)¹⁰⁵ [footnote 105 text: OECD Nuclear Energy Agency (NEA), "Boiling Water Reactor Turbine Trip (TT) Benchmark," Volume I, "Final Specifications," NEA/NSC/DOC(2001)1, February 2001, p. 9.] and some BWR SFPs have a spent fuel assembly pitch of 6.28 in.¹⁰⁶ [footnote 106 text: K. C. Wagner, R. O. Gauntt, Sandia National Laboratories, "Mitigation of Spent Fuel Pool Loss-of-Coolant Inventory Accidents And Extension of Reference Plant Analyses to Other Spent Fuel Pools," November 2006, (ADAMS Accession No. ML120970086), p. 57.] Furthermore, some PWR reactor cores have a fuel assembly pitch of 8.587 in¹⁰⁷ [footnote 107 text: NRC, "Pressurized Water Reactor, B&W Technology, Crosstraining Course Manual," Chapter 2.1, "Core and Vessel Construction," Rev 10/2007, (ADAMS Accession No. ML11221A103), p. 2.1-14.] and some PWR SFPs have a spent fuel assembly pitch of 9.0 in.¹⁰⁸ [footnote 108 text: NRC, "Regulatory Analysis for the Resolution of Generic Issue 82, 'Beyond Design Basis Accidents in Spent Fuel Pools'," NUREG-1353, April 1989, (ADAMS Accession No. ML082330232), p. 4-6.] (0463-1-23 [Leyse, Mark])

Comment: A May 2010 NRC document states that "the dimensions of the SFPs cannot be changed so licensees are putting more fuel assemblies into the same volume." The May 2010 NRC document provides an example: "One plant went through several steps to go from a SFP originally licensed for a capacity of 600 fuel assemblies to its current licensed capacity of 3300."¹⁰⁹ [footnote 109 text: NRC, "On Site Spent Fuel Criticality Analyses NRR Action Plan," pp. 1, 2.] The May 2010 NRC document observes that over the years "fuel assemblies have become more reactive," and states: Increased U235 enrichment is an example [of increased reactivity]. But there are other more subtle changes; e.g., increased fuel pellet diameter; increased fuel pellet density; the BWR transition from fuel assemblies with 49 fuel rods to those with 91 fuel rods; increased use of fixed and integral burnable absorbers; and, changes to core

operating parameters due to power uprates resulting in more reactive fuel assemblies to be stored in the SFP.¹¹⁰ [footnote 110 text: Id., p. 3.] Regarding historical limitations of critical experiments that did not include actinide and fission product nuclides that are important to determining reactivity in a SFP environment, the May 2010 NRC document states: [H]istorically the critical experiments used in the benchmarking do not include Actinide and Fission Product nuclides that are important to determining reactivity in a SFP environment. Rather than address the issue in the validation, SFP [license amendment requests] were silent on the issue. This is inconsistent with NRC guidance on performing these validations as described in NUREG/CR-6698¹¹¹ [footnote 111 text: NRC, “Guide for Validation of Nuclear Criticality Safety Calculational Methodology,” NUREG/CR-6698, January 2001, (ADAMS Accession No. ML050250061).] [published in January 2001]. Historically there were no publicly available experiments with Actinide and Fission Product nuclides. With the issuance of NUREG/CR6979¹¹² [footnote 112 text: NRC, “Evaluation of the French Haut Taux de Combustion (HTC) Critical Experiment Data,” NUREG/CR-6979, September 2008, (ADAMS Accession No. ML082880452).] [in September 2008], experiments with Actinides are available for benchmarking. However, *there are still limited experiments that contain Fission Products* that can be used in the validation¹¹³ [footnote 113 text: NRC, “On Site Spent Fuel Criticality Analyses NRR Action Plan,” p. 5.] [emphasis added]. And regarding the fact that thinner fuel cladding usually results in a higher reactivity for spent fuel rods, the May 2010 NRC document states: As a fuel assembly is depleted in an operating reactor, it undergoes physical changes. Some of those changes have the potential to affect the SFP criticality analysis. For example, fuel rods experience irradiated rod growth. As the rods get longer, the cladding gets thinner. Thinner cladding usually results in a higher reactivity. As the amount of burnup credited in the analysis increases the more of an effect this could have on the criticality analysis.¹¹⁴ [footnote 114 text: Id.] (0463-1-24 [Leyse, Mark])

Comment: The May 2010 NRC document concludes that industry trends over the years “have resulted in reduced conservatism/margins to criticality, thus reducing or eliminating the ability to use engineering judgment when determining that there is reasonable assurance an inadvertent SFP criticality cannot occur. Additionally, uncertainties associated with SFP criticality analyses, due to lack of benchmark data for example, also decrease margins to criticality.”¹¹⁵ [footnote 115 text: Id., p. 3.] III.D.1.a. Information about Newer BWR Fuel Assemblies: Regarding axial variations in BWR fuel assemblies of the loading of the U235 enrichment and gadolinium integrated burnable absorber material, an October 2000 Oak Ridge National Laboratory (“ORNL”) report states: [N]ewer BWR fuel designs typically employ larger arrays (e.g., 9 x 9 and 10 x 10) of smaller fuel rods with higher enrichments, increased gadolinium loading through higher concentrations and more gadolinium-bearing rods, and greater axial variation in enrichment and gadolinium loading. ... The axial variations in enrichment and gadolinium loading naturally necessitate separate calculations for unique axial segments and are important to the criticality calculations.¹¹⁶ [footnote 116 text: J. C. Wagner, M. D. DeHart, and B. L. Broadhead, Oak Ridge National Laboratory (“ORNL”), “Investigation of Burnup Credit Modeling Issues Associated with BWR Fuel,” ORNL/TM1999/193, October 2000, pp. 62-63.]. There are also axial variations in the number of fuel rods in BWR fuel assemblies.¹¹⁷ [footnote 117 text: NRC, “On Site Spent Fuel Criticality Analyses NRR Action Plan,” p. 1.] And regarding the effect of integrated burnable absorbers on the reactivity behavior of BWR fuel as a function of burnup, the October 2000 ORNL report states: [F]or BWR fuels (with integrated burnable absorbers) the reactivity increases as fuel burnup proceeds, reaches a maximum at a burnup where the absorber (gadolinium) is nearly depleted, and then decreases monotonically with burnup in a nearly linear fashion. The initial period of burnup (i.e., before the gadolinium is depleted and the reactivity peaks) adds an additional complication to BWR depletion that is not present in the depletion of PWR fuels (without integrated burnable absorbers).¹¹⁸ [footnote 118 text: J. C. Wagner, M. D. DeHart, and B. L. Broadhead, Oak Ridge National Laboratory (“ORNL”),

“Investigation of Burnup Credit Modeling Issues Associated with BWR Fuel,” ORNL/TM-1999/193, p. 13.]. (The October 2000 ORNL report states that “[f]or PWR fuels (without integrated burnable absorbers), the reactivity decreases monotonically with burnup in a nearly linear fashion.”¹¹⁹ [footnote 119 text: Id.]) (0463-1-25 [Leyse, Mark])

Comment: Neutron-Absorber Materials Could Melt in a Station Blackout Boil-Off Accident. In a SBO boil-off accident, if enough water boiled off, the water level would drop in the pool and uncover the fuel assemblies. If fuel assemblies were uncovered, temperatures in the SFP could increase enough to cause neutron-absorber materials placed in high-density storage racks to melt. Boraflex and Boral are neutron-absorber materials. Boraflex vitrifies and melts at approximately 300°C (572°F) and 500°C (932°F), respectively; Boraflex would be ineffective once heated above approximately 300°C (572°F).¹²⁰ [footnote 120 text: EPRI, “Severe Accident Management Guidance Technical Basis Report,” Volume 2: “The Physics of Accident Progression,” 1025295, Appendix EE, p. EE-9.] And Boral melts at approximately 657°C (1214°F).¹²¹ [footnote 121 text: Zachary I. Franiewski et al., Pennsylvania State University, “Spent Fuel Pool Analysis of a BWR-4 Fuel Bundle Under Loss of Coolant Conditions Using TRACE,” p. 1.] Regarding the melting of Boral in a SFP accident, EPRI SFP accident guidance states: With the aluminum cladding and the aluminum in the mixture, the BORAL would melt at temperatures of 1200°F (660°C). With this low melting temperature, the conservative evaluations for the intact response of those SFP configurations using this absorber are recommended to not use temperatures higher than 1100°F (593°C). If conditions are detected that would lead to conditions where the estimated fuel assembly/bundle temperature exceeds this value, the SFP should be assumed to have a degraded configuration *including the possible melting and downward relocation of the BORAL absorber plates to the bottom of the SFP*. Specifically, the reactivity of the SFP should be considered to be uncertain and somewhat increased from the nominal pool value¹²² [footnote 122 text: EPRI, “Severe Accident Management Guidance Technical Basis Report,” Volume 2: “The Physics of Accident Progression,” Appendix EE, pp. EE-8-EE-9.] [emphasis added]. (0463-1-26 [Leyse, Mark])

Comment: EPRI SFP accident guidance also notes that “[t]ypically the fuel assemblies/bundles are supported within stainless steel racks that form a square matrix” but that “[s]ome racks are also fabricated from aluminum.”¹²³ [footnote 123 text: Id., Appendix EE, p. EE-9.] And EPRI states that Boraflex could “begin to relocate due to softening or melting” above approximately 300°C (572°F).¹²⁴ [footnote 124 text: Id.] (It is noteworthy that in a SNL experiment simulating a complete SFP LOCA in which BWR fuel assemblies were heated in air, “[p]ost-mortem examination of the integral test assemblies revealed gross distortion of the pool rack and channel box, rubblization of the tubing bundle and accumulation of debris on the bottom tie plate that resulted in flow blockage. Flow blockage was also evident from molten aluminum (*originating from Boral plates built into the pool rack*) that *collected on and below the bottom tie plates*”¹²⁵ [footnote 125 text: E. R. Lindgren, Sandia National Laboratory, “Characterization of Thermal-Hydraulic and Ignition Phenomena in Prototypic, Full-Length Boiling Water Reactor Spent Fuel Pool Assemblies After a Postulated Complete Loss-of-Coolant Accident,” NUREG/CR-7143, March 2013 (ADAMS Accession No. ML13072A056), p. xx.] [emphasis added].) And regarding what the SFP water levels would be when Boraflex and Boral began to lose their integrity, EPRI SFP accident guidance states: If the water level [in the SFP] were to decrease to approximately 0.85 (Boraflex) or 0.75 (Boral) of the fuel height, the fuel assembly/bundle outlet temperature would approach a level where the integrity of the neutron absorber shims would be in question and the geometric configuration of the structures in the SFP could begin to change.¹²⁶ [footnote 126 text: EPRI, “Severe Accident Management Guidance Technical Basis Report,” Volume 2: “The Physics of Accident Progression,” 1025295, Appendix EE, p. EE-17.] (0463-1-27 [Leyse, Mark])

Comment: A 2001 NRC report, NUREG-1738, states that “[i]f the stored assemblies are separated by neutron absorber plates (e.g., Boral or Boraflex), loss of these plates could result in a potential for criticality for BWR pools.”¹²⁷ [footnote 127 text: NRC, “Technical Study of Spent Fuel Pool Accident Risk at Decommissioning Nuclear Power Plants,” NUREG-1738, February 2001 (ADAMS Accession No. ML010430066), p. 3-26.] (BWR SFPs do not use borated water.¹²⁸ [footnote 128 text: NRC, “Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I Boiling Water Reactor: Draft Report,” p. 30.] One of the reasons that criticality accidents could occur in BWR SFP high-density storage racks is that the center-to-center distance between the spent fuel assemblies (the pitch) in such racks is close to that of fuel assemblies in the reactor core.) (0463-1-28 [Leyse, Mark])

Comment: EPRI SFP accident guidance does not specify the extent that the neutron-absorber materials would relocate downward immediately after they began to melt in a SFP boiloff accident; however, it is not likely that neutron-absorber materials located below the water surface would be adversely affected by any downward relocation of melted materials. Hence, the neutron-absorber materials located below the water surface would remain intact and continue to prevent criticality accidents. But if the water level continued to drop, additional neutron-absorber materials, located at lower elevations, would melt. In this scenario, the SFP would be vulnerable to criticality accidents if water were injected back into the SFP to raise the water level and cover the fuel assemblies, again. Regarding injecting water into a SFP with a reduced water level, EPRI SFP accident guidance recommends considering whether or not “the water level has been sufficiently low [such] that *the location of the absorber material* could have been jeopardized”¹²⁹ [footnote 129 text: EPRI, “Severe Accident Management Guidance Technical Basis Report,” Volume 2: “The Physics of Accident Progression,” 1025295, Appendix EE, p. EE-12.] [emphasis added]. EPRI also recommends injecting borated water into the SFP if it is available.¹³⁰ [footnote 130 text: Id., Appendix EE, p. EE-13.] (0463-1-29 [Leyse, Mark])

Comment: The NRC has pointed out that a 2012 NERC report, “Effects of Geomagnetic Disturbances on the Bulk Power System,”²⁵ [footnote 25 text: NERC, “2012 Special Reliability Assessment Impact Report: Effects of Geomagnetic Disturbances on the Bulk Power System,” February 2012.] disagrees with conclusions of the Metatech report, stating that “[b]ased on an assumed frequency of a once-in-100-year geomagnetic event, the NERC report indicates that potential damage to EHV transformers of recent design is of a low probability, and thus challenges the assertions of the Metatech report that 300 large EHV transformers would be at risk of failure.”²⁶ [footnote 26 text: NRC, “Long-Term Cooling and Unattended Water Makeup of Spent Fuel Pools: Proposed Rules,” p. 74795.] The 2012 NERC report states that “[t]he most likely consequence of a strong GMD [geomagnetic disturbances] and the accompanying GIC [geomagnetic induced currents] is the increase of reactive power consumption and the loss of voltage stability,” “which could lead to...power system collapse.”²⁷ [footnote 27 text: NERC, “2012 Special Reliability Assessment Impact Report: Effects of Geomagnetic Disturbances on the Bulk Power System,” pp. iii, iv.] The NERC report concludes that if the power system were to collapse from a loss of voltage stability that it could be restored in a time period of “hours to days.”²⁸ [footnote 28 text: Id., p. iv.] However, Lawrence J. Zanetti, a physicist in the Space Department of the Johns Hopkins University Applied Physics Laboratory, disagrees with conclusions of the 2012. NERC report, stating that “[i]n this NERC report, the strong denial of the likelihood of a large number of multiple transformer failures is misleading and purveys a false sense of grid security.”²⁹ [footnote 29 text: Zanetti, L. J., “Review of North American Electric Reliability Corporation (NERC) Interim Report: Effects of Geomagnetic Disturbances on the Bulk Power System—February 2012,” Space Weather, Vol. 11, doi:10.1002/swe.20060, 2013, p. 335.] (0463-1-3 [Leyse, Mark])

Comment: Discussing the progression of a partial BWR SFP LOCA, a 2013 PSU report observes that after the Boral in high-density storage racks melted, neutrons would diffuse throughout the SFP, and possibly cause fission to commence.¹³¹ [footnote 131 text: Zachary I. Franiewski et al., Pennsylvania State University, “Spent Fuel Pool Analysis of a BWR-4 Fuel Bundle Under Loss of Coolant Conditions Using TRACE,” NucE431W S2013, May 2013, p. 1.] (Although not explicitly stated, the 2013 PSU report must be referring to scenarios in which water would be injected back into the drained SFP.) If fission were to occur, local fuel and fuel-cladding temperatures would rapidly increase. Fission would also “cause an increase in decay products, which [would] have a delayed effect on temperature increase[s].”¹³² [footnote 132 text: Id., pp. 1-2.] (A June 2013 NRC document states that “if an [inadvertent criticality event] were severe enough to produce significant heat, the fuel will be harder to cool.”¹³³ [footnote 133 text: NRC, “Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I Boiling Water Reactor: Draft Report,” p. 29.]) And radiation releases, caused by a criticality accident in a SFP, would impede (or possibly prevent for significant time periods) efforts to mitigate a SBO boil-off accident (or a partial SFP LOCA), making it more probable that such accident scenarios would lead to SFP fires. (SFPs would also be vulnerable to criticality accidents after Boraflex vitrified in high-density storage racks and became ineffective.) EPRI SFP accident guidance states that “BWR analyses have indicated that spraying water into fresh, uncovered fuel bundles could result in a critical configuration. This could possibly also be the case for spent fuel where there has been sufficient decay of fission products that act as poisons.”¹³⁴ [footnote 134 text: EPRI, “Severe Accident Management Guidance Technical Basis Report,” Volume 2: “The Physics of Accident Progression,” 1025295, Appendix EE, p. EE-12.] (0463-1-30 [Leyse, Mark])

Comment: *Perhaps* it would be valid to speculate that if there were one or more criticality accidents, severe enough to produce significant heat, a SFP fire would not always commence on a fuel assembly that was part of the group most recently discharged from the reactor core—the group producing the highest amount of decay heat in the pool. (0463-1-31 [Leyse, Mark])

Comment: (It is noteworthy that a June 2013 NRC report on how earthquakes could affect BWR Mark I SFPs provides the results of a number of MELCOR computer safety model simulations of SFP LOCAs in which there was a *moderate leakage rate*.¹³⁵ [footnote 135 text: A moderate leakage rate is “[a] state with leakage from the bottom of the SFP, corresponding to through-wall concrete cracking at the bottom of the walls and tearing of the liner that propagates to an extent such that water leakage is controlled by the size of the cracks in the concrete.” See NRC, “Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I Boiling Water Reactor: Draft Report,” p. 61.] In some simulations, SFP temperatures reached the point at which neutron-absorber materials would melt; spray cooling was employed,¹³⁶ [footnote 136 text: NRC, “Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I Boiling Water Reactor: Draft Report,” pp. 211-213.] however, the MELCOR simulations did not even consider the possibility of criticality accidents.¹³⁷ [footnote 137 text: Id., p. 20.]) (0463-1-32 [Leyse, Mark])

Comment: The Potential for Criticality Accidents When Water is Sprayed onto Fuel Assemblies in Certain Spent Fuel Pools. Optimum-moderation conditions occur in water films and low-density water; optimum-moderation conditions could increase the potential for criticality accidents in a SBO boil-off accident if the pitch of PWR fuel assemblies were in a range between approximately 25 centimeters (“cm”) (9.84 in) and 50 cm (19.68 in).¹³⁸ [footnote 138 text: G Caplin et al., “Criticality Accident in Case of a Spent Fuel Pool Dry-Out,” Institut de Radioprotection et de Sûreté Nucléaire (“IRSN”), 2011, Information Sheet.] It would seem that the range of vulnerable pitches would be similar for BWR fuel assemblies; however, criticality

analyses should be conducted on a case by case basis to make such a determination. Criticality analyses need to consider how optimum moderator conditions would affect BWR fuel assemblies with or without channel boxes. Plant specific criticality analyses should also be conducted for PWR fuel assemblies. According to an April 1989 NRC report, NUREG-1353, BWR and PWR medium-density storage racks have fuel-assembly pitches of 22.86 cm (9.0 in) and 33.02 cm (13.0 in), respectively. And NUREG-1353 states that BWR and PWR low-density storage racks both have fuel-assembly pitches in a range from 50.8 cm (20.0 in) to 76.2 cm (30.0 in).¹³⁹ [footnote 139 text: NRC, “Regulatory Analysis for the Resolution of Generic Issue 82, ‘Beyond Design Basis Accidents in Spent Fuel Pools’,” NUREG-1353, April 1989, (ADAMS Accession No. ML082330232), p. 4.6.] It is clear that NUREG-1353 provides values of typical fuel-assembly pitches; plant-specific values of fuel-assembly pitches would be likely to vary. In the US, there are not many (if any) SFPs that have fuel assemblies stored in low-density racks. Any plans to re-rack fuel assemblies stored in high-density racks to either medium-density or low-density racks, need to consider requiring that neutron-absorber materials be placed into the new storage racks; criticality analyses should be conducted on a case by case basis to determine if neutron-absorber materials would be needed. (It is noteworthy that “[a] PWR SFP would typically end up with high density and “moderate density” racks. ... PWRs have a need to store fresh fuel assemblies in the SFP. To accommodate that need PWRs typically installed “moderate density” storage racks with smaller flux traps than the original and usually more neutron absorber than the high-density storage racks. With a fully intact neutron absorber, burnup requirements for the high-density storage racks can be fairly low and fresh fuel up to 5.00 w/o U235 could easily be accommodated in the moderate density storage racks.¹⁴⁰ [footnote 140 text: NRC, “On Site Spent Fuel Criticality Analyses NRR Action Plan,” May 21, 2010, (ADAMS Accession No: ML101520463), pp. 1-2.]) (0463-1-33 [Leyse, Mark])

Comment: Optimum-moderation conditions in water films and low-density water do not increase the potential for criticality accidents in PWR SBO boil-off accidents if the pitch of the fuel assemblies is less than approximately 25 cm (9.84 in). It would seem that the dividing pitch-value of approximately 25 cm would also be true for BWR fuel assemblies; however, criticality analyses should be conducted on a case by case basis to make such a determination. In an operating reactor core, a decrease of water density decreases the reactivity of the core,¹⁴¹ [footnote 141 text: G Caplin et al., “Criticality Accident in Case of a Spent Fuel Pool Dry-Out,” IRSN, 2011, Information Sheet.] because the pitch of the fuel assemblies is less than approximately 25 cm; in BWR cores, the fuel assembly pitch is approximately 6.0 inches. In fact, in the upper regions of BWR cores, steam voids, which decrease water density, reduce the core reactivity. An inherent safety feature of BWRs is that “a transient power increase will produce more steam voids, reducing reactivity, which reduces power and thus limits the excursion.”¹⁴² [footnote 142 text: NRC, “BWR/4 Technology Manual (R-104B),” NRC Technical Training Center, Rev 0100, (ADAMS Accession No: ML022830867), p. 1.3-1.] (0463-1-34 [Leyse, Mark])

Comment: A June 2013 NRC report on how earthquakes could affect BWR Mark I SFPs recommends cooling fuel assemblies with a “spray flow” in partial SFP LOCA scenarios in which there would be “no natural circulation of air through the racks.”¹⁴³ [footnote 143 text: NRC, “Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I Boiling Water Reactor: Draft Report,” Appendix D, p. D-12.] It is pertinent that in the Fukushima Dai-ichi accident “pumper trucks employing high booms spray[ed] water from a distance into the spent fuel pools.” There was no other means available to the operators; hence, the Near-Term Task Force that the NRC established in response to the Fukushima Dai-ichi accident recommended that the NRC “[o]rder licensees to have an installed seismically qualified means to spray water into the spent fuel pools, including an easily accessible connection to

supply the water (e.g., using a portable pump or pumper truck) at grade outside the building.”¹⁴⁴ [footnote 144 text: Charles Miller et al., NRC, “Recommendations for Enhancing Reactor Safety in the 21st Century: The Near-Term Task Force Review of Insights from the Fukushima Dai-ichi Accident,” SECY-11-0093, July 12, 2011, (ADAMS Accession No. ML111861807), pp. 45, 46.] In the event of a partial SFP LOCA, it would be important to cool the fuel assemblies if a means were available. However, spraying water onto exposed fuel assemblies (especially unused fresh-fuel assemblies—more reactive than spent fuel), stored in racks that had a fuel-assembly pitch in a range between approximately 25 cm and 50 cm and did not have neutron-absorber materials, or whose neutron-absorber materials had previously melted, could cause a criticality accident. (In some partial SFP LOCA and boil-off scenarios, neutron-absorber materials would begin melting when the water level dropped 15 or 25 percent (depending on the materials) below the top of the fuel assemblies.) Historically, neutron-absorber materials were not typically placed in either low-density open racks or medium-density racks with flux traps in order to help prevent criticality accidents.¹⁴⁵ [footnote 145 text: NRC, “Technical Study of Spent Fuel Pool Accident Risk at Decommissioning Nuclear Power Plants,” NUREG-1738, p. 3-25.] (PWR SFPs are required to use water that is borated with at least 2000 parts per million (“ppm”) of boron; BWR SFPs do not use borated water.¹⁴⁶ [footnote 146 text: NRC, “Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I Boiling Water Reactor: Draft Report,” p. 30.]) (0463-1-35 [Leyse, Mark])

Comment: If large-scale power outages were to last months or longer, multiple nuclear power plants (“NPP”) would lose their supply of offsite alternating current (“ac”) power, which is necessary for daily operation and preventing severe accidents. Multiple loss-of-offsite power (“LOOP”) events—especially in the event of prolonged electrical grid failures—could lead to a number of station-blackouts (“SBO”); a SBO is a complete loss of both grid-supplied and backup onsite ac power. The Fukushima Dai-ichi accident was a SBO accident that caused three reactor core meltdowns. Many of the safety systems that are required for cooling the reactor core and SFP in a SBO—removing decay heat: the heat generated by the radioactive decay of the nuclear fuel’s fission products—need ac power to operate. In a LOOP event, a NPP’s emergency diesel generators (“EDG”) are intended to “supply power [promptly and] continuously to the equipment needed to maintain the plant in a safe condition” for an extended time period, “with refueling every 7 days.”³⁰ [footnote 30 text: NRC, “Application and Testing of Safety-Related Diesel Generators in Nuclear Power Plants,” Regulatory Guide 1.9, March 2007, Revision 4, p. 2.] The NRC has stated that, in a LOOP event, EDGs should be able to maintain a NPP in a safe condition for a mission time of “typically around 30 days.”³¹ [footnote 31 text: NRC Inspection Manual, “Emergency Diesel Generator Technical Specification Surveillance Requirements Regarding Endurance and Margin Testing,” May 2008, (ADAMS Accession No. ML080420064), p. 3.] Most U.S. NPPs are required to have an a 7-day capacity of fuel oil for EDGs onsite; many NPPs have additional fuel oil onsite and arrangements to receive prompt deliveries of fuel oil.³² [footnote 32 text: NRC, “Long-Term Cooling and Unattended Water Makeup of Spent Fuel Pools: Proposed Rules,” p. 74796.] However, there could be problems with transporting and maintaining a fuel supply, amidst varying degrees of social disruption, in the event of large-scale, long-term power outages. There could be cases in which EDGs would not be able to either operate promptly or continuously for months (or longer), causing a SBO. A 2011 report, “Fukushima Fallout,” states “that there have been recurrent prolonged malfunctions of [EDGs] at nuclear power plants in the U.S” and that “[i]n the past eight years there have been at least 69 reports of EDG inoperability at 33 nuclear power plants. A total of 48 reactors were affected, including 19 failures lasting over two weeks and 6 that lasted longer than a month.”³³ [footnote 33 text: The Staff of Congressman Edward J. Markey, “Fukushima Fallout: Regulatory Loopholes at U.S. Nuclear Plants,” May 12, 2011, pp. 9, 25.] (EDG endurance and margin tests are typically performed every 18 to 24 months; a 24-hour test period is intended to ensure that

an EDG would be able to meet its 30-day mission time. The NRC allows some NPP personnel, including Indian Point's, to perform the test for *an 8-hour test period*.³⁴ [footnote 34 text: NRC Inspection Manual, "Emergency Diesel Generator Technical Specification Surveillance Requirements Regarding Endurance and Margin Testing," pp. 1, 3.] (0463-1-4 [Leyse, Mark])

Comment: It has been documented that solar storms have damaged NPPs. For example, in March 1989, a geomagnetic storm caused a generator step-up ("GSU") transformer to fail at the Salem Nuclear Plant.³⁹ [footnote 39 text: John Kappenman, "Geomagnetic Storms and Their Impacts on the U.S. Power Grid," Metatech Report Meta-R-319, January 2010, p. 2-29.] And, in April 1994, a "moderate intensity" geomagnetic storm caused a GSU transformer at Zion Nuclear plant to fail: "[t]he failure was so severe that the transformer tank, containing thousands of gallons of oil, ruptured and started a major fire in the yard at the plant, which eventually involved control circuits and other sensitive systems."⁴⁰ [footnote 40 text: *Id.*, p. 2-33.] It has also been documented that high-altitude electromagnetic pulses produced by nuclear detonations *caused diesel generators to fail* in 1962, when the USSR detonated a few nuclear weapons at high altitudes—above an altitude of approximately 30 kilometers—in an experimental program.⁴¹ [footnote 41 text: Edward Savage et al., "The Early-Time (E1) High-Altitude Electromagnetic Pulse (HEMP) and Its Impact on the U.S. Power Grid," Metatech Report Meta-R-320, January 2010, pp. i, 2-1, 3-4.] (The NRC maintains that solar storms would not adversely affect EDGs, because they are normally not operating and that "any [geomagnetically-induced currents] that enter the plant's electrical system during EDG operation should not result in excessive overheating of the generator windings."⁴² [footnote 42 text: NRC, "Long-Term Cooling and Unattended Water Makeup of Spent Fuel Pools: Proposed Rules," p. 74796.] The NRC does not require NPP owners to be prepared for large-scale, long-term power outages, and notes that "in the event of a widespread electrical transmission system blackout for an extended duration (beyond 7 days and up to several months), it may not be possible to transport...necessary offsite resources to the affected NPPs in a timely manner. Thus, government assistance (local, state, or Federal) may be necessary to maintain the capability to safely shutdown nuclear plants and cool spent fuel pools in the affected areas. Prior planning is needed to efficiently and effectively use government resources to ensure protection of public health and safety."⁴³ [footnote 43 text: *Id.*, p. 74797.] In other words, in the event of prolonged electrical grid failures, neither the NRC nor any other government agency has a strategy for implementing measures that would effectively prevent multiple concurrent reactor core meltdowns and SFP fires, which would cause catastrophic releases of radiation. It is worrisome that the frequency of extreme solar storms, causing the large-scale, long-term power outages that could lead to at least one SFP fire, is estimated to be *as high as once in 100 years* ($1.0 \times 10^{-2}/\text{yr}$).⁴⁴ [footnote 44 text: John Kappenman, "Geomagnetic Storms and Their Impacts on the U.S. Power Grid," Meta-R-319, pp. 3-14, 3-22, 3-26, 3-27.] The U.S. is particularly vulnerable to SFP fires, because its SFPs are densely-packed with spent fuel assemblies. (Low-density storage would help prevent SFP fires.) For example, in August 2013, Indian Point Unit 3's SFP—located less than 25 miles north of New York City—contained 1199 fuel assemblies, approximately 89 percent of storage capacity.⁴⁵ [footnote 45 text: NRC, "Summary of August 26, 2013, Meeting with Entergy Nuclear Operations, Inc. and Netco on Indian Point Unit 2 Spent Fuel Pool Management," September 24, 2013, (ADAMS Accession No. ML13256A086), p. 1.] (0463-1-6 [Leyse, Mark])

Comment: A 2011 Institut de Radioprotection et de Sûreté Nucléaire ("IRSN") information sheet on preventing SFP criticality accidents, in the event that PWR fuel assemblies would be uncovered by the pool's water, discusses results of an investigation of the potential affects of low-density optimum-moderator water conditions. The CRISTAL computer code was used to simulate scenarios in which a SFP did not have neutron-absorber materials in its storage racks;

the SFP contained 625 undamaged uranium-oxide PWR 17x17 assemblies in a height of 1.5-meters water.¹⁴⁷ [footnote 147 text: G Caplin et al., “Criticality Accident in Case of a Spent Fuel Pool Dry-Out,” IRSN, 2011, Information Sheet.] The CRISTAL computer code simulated how different low-density optimum-moderator water conditions would affect the effective neutron multiplication factor (*keff*)¹⁴⁸ [footnote 148 text: The effective neutron multiplication factor (*keff*) is the estimated ratio of neutron production to neutron absorption and leakage.] of fuel assemblies that had different pitches in a range between approximately 25 cm and 50 cm. The 2011 IRSN information sheet states that “injecting borated water to cool the [uncovered] assemblies [is] preferable when possible.” The use of borated water would help prevent a criticality accident, because boron absorbs neutrons; however, the 2011 IRSN information sheet states that water borated with 2000 ppm of boron reduces yet does not completely eliminate the risk of criticality.¹⁴⁹ [footnote 149 text: G Caplin et al., “Criticality Accident in Case of a Spent Fuel Pool Dry-Out,” IRSN, 2011, Information Sheet.] (It is pertinent that “BWR SFPs do not use borated water so the fact that the SFP may be refilled with unborated water is not a deviation from the norm.”¹⁵⁰ [footnote 150 text: NRC, “Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I Boiling Water Reactor: Draft Report,” p. 30.] (0463-2-1 [Leyse, Mark])

Comment: The NRC’s 2010 “On Site Spent Fuel Criticality Analyses NRR Action Plan,” states that “virtually every permanently installed neutron absorber, for which a history can be established, has exhibited some degradation. Some have lost a significant portion of their neutron absorbing capability;” and states that “[t]he ability of licensees to control the material condition of any permanently installed neutron absorber that is credited for maintaining sub-criticality *is essential for the prevention of an inadvertent criticality event*” [emphasis added].¹⁷⁷ [footnote 177 text: NRC, “On Site Spent Fuel Criticality Analyses NRR Action Plan,” May 21, 2010, (ADAMS Accession No. ML101520463), pp. 1, 6.] And NRC information notice 2009-26 states that “[t]he degradation mechanisms and *deformation rates* of any of the neutron-absorbing materials in the SFP are not well understood” [emphasis added].¹⁷⁸ [footnote 178 text: NRC, “Information Notice 2009-26: Degradation of Neutron-Absorbing Materials in the Spent Fuel Pool,” p. 4.] (The degradation of neutron-absorber materials is especially worrisome for BWR SFPs, because they do not use borated water.¹⁷⁹ [footnote 179 text: NRC, “Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I Boiling Water Reactor: Draft Report,” p. 30.] It is possible that the degradation of neutron-absorber materials would increase the potential for a criticality accident occurring in the event a SFP boil-off accident. If overheated, it is probable that previously-degraded neutron-absorber materials would lose their effectiveness more quickly than non-degraded neutron-absorber materials. (0463-2-10 [Leyse, Mark])

Comment: Experiments measuring the densities of water discharged from sprinklers and fire hoses have found that the maximum water density (0.004 g/cm³) is well below the *optimum-moderation* densities of water (0.05 to 0.1 g/cm³) that could cause fuel assemblies to have a criticality accident. However, “it has been observed¹⁵¹ [footnote 151 text: The source of this information is provided in the report: D. A. McCaughey and G. H. Biding, “Film Effects of Fire Sprinklers on Low-Enriched-Uranium Storage Systems,” Transactions of the American Nuclear Society, Vol. 56, p. 329 (1988).] that a quantity of mist moderation judged to be safe might still be unacceptable due to water film formation on the fuel material. The film thickness is due to the viscosity of water.”¹⁵² [footnote 152 text: E. D. Clayton, Pacific Northwest Laboratory, “Anomalies of Criticality: Revision 6,” PNNL19176, February 2010, pp. 76-77.] (In a SBO boil-off scenario with heated uncovered fuel assemblies, there would be water film formation on fuel-cladding surfaces after the cladding was cooled by the sprayed water. EPRI SFP accident guidance states that “effective cooling could be initiated because the spray droplets wet the high

temperature cladding surface and cause the formation of a sputtering water film that slowly drains over the high temperature cladding and quenches it.”¹⁵³ [footnote 153 text: EPRI, “Severe Accident Management Guidance Technical Basis Report,” Volume 2: “The Physics of Accident Progression,” 1025295, Appendix EE, p. EE-11.] Simulations with a computer safety model—KENO V.a—demonstrated that super-criticality could occur if water films formed on fresh fuel assemblies in dry storage racks, “display[ing] this effect for fuel assemblies containing 256 rods, composed of UO₂ at 4.1 wt.% enrichment, in a 16 x 16 array. The assemblies were in 19 x 34 storage array.”¹⁵⁴ [footnote 154 text: E. D. Clayton, “Anomalies of Criticality: Revision 6,” PNNL-19176, pp. 77, 80.] (See Figure 3.) [See Figure 3. Film Effects of Water Sprinklers on Storage Array of 4.1%-enriched UO₂ Rods in NRC Adams Database ML13351A310]. In storage racks that had a fuel-assembly pitch in a range between approximately 25 cm and 50 cm and did not have neutron-absorber materials, or whose neutron-absorber materials had previously melted, the upper end of exposed spent fuel rods also could be susceptible to criticality if sprayed with water. In the case of PWR rods, “[t]he majority of [spent] PWR fuel assemblies have...significantly under-burned fuel at the ends (with burnup of 50 to 60% of the assembly average);” and the “under-burned [end] regions are dominant in terms of reactivity.”¹⁵⁵ [footnote 155 text: J. C. Wagner, M. D. DeHart, Oak Ridge National Laboratory, “Review of Axial Burnup Distribution Considerations for Burnup Credit Calculations, ORNL/TM-1999/246, March 2000, pp. 2, 5.] The 2011 IRSN information sheet states that there could be a risk of criticality in PWR rods with a burnup of 10 GWd/t *in their upper ends*¹⁵⁶ [footnote 156 text: G Caplin et al., “Criticality Accident in Case of a Spent Fuel Pool Dry-Out,” IRSN, 2011, Information Sheet.] (their average burnup would be greater). (0463-2-2 [Leyse, Mark])

Comment: III.D.4. The Potential for Criticality Accidents When Water Boils in Certain Spent Fuel Pools: If a SFP had a SBO boil-off accident, optimum-moderation conditions—caused by water films—could occur at locations where the boiling water’s bubbly surface directly contacted fresh fuel assemblies.¹⁵⁷ [footnote 157 text: This is pertinent to racks (without neutron-absorber materials) that had fresh fuel assemblies stored with a pitch in a range between approximately 25 cm and 50 cm.] The temperature at the surface of the fuel rods would be approximately 100°C; hence, water films in the bubbly surface would be in direct contact with the cladding. 100°C is below the temperature at which a boundary layer of vapor would form between water and a metal surface (the Leidenfrost phenomenon). Furthermore, the 2011 IRSN information sheet states that there could be a risk of criticality in a SFP boil-off accident from the water mist generated by boiling water;¹⁵⁸ [footnote 158 text: G Caplin et al., “Criticality Accident in Case of a Spent Fuel Pool Dry-Out,” IRSN, 2011, Information Sheet.] the mist just above the boiling surface would be *extra-dense* water mist (with a density of approximately 0.05 g/cm³) prone to optimum-moderation conditions. Hence, after fuel assemblies were uncovered, BWR SFPs would be susceptible to criticality accidents in *boiling water*—provided the fuel assemblies had a pitch in a range between approximately 25 cm and 50 cm and their storage racks did not have neutron-absorber materials. As stated, the 2011 IRSN information sheet states that water borated with 2000 ppm of boron reduces yet does not completely eliminate the risk of criticality;¹⁵⁹ [footnote 159 text: Id.] therefore, if PWR fuel assemblies were uncovered in boiling water, they would be also susceptible to criticality accidents.¹⁶⁰ [footnote 160 text: Provided the fuel assemblies had a pitch in a range between approximately 25 cm and 50 cm and their storage racks did not have neutron-absorber materials.] Therefore, any plans to re-rack fuel assemblies stored in high-density racks to either medium-density or low-density racks, need to consider requiring that neutron-absorber materials be placed into the new storage racks; criticality analyses should be conducted on a case by case basis to determine if neutron-absorber materials would be needed. (In the US, there are not many (if any) SFPs that have fuel assemblies stored in low-density racks.) (0463-2-3 [Leyse, Mark])

Comment: 10 C.F.R. § 50.68 requires that safety analyses be conducted for scenarios in which SFP “spent fuel storage racks loaded with fuel of the maximum fuel assembly reactivity” would be flooded with unborated (and with borated water) water. 10 C.F.R. § 50.68 also needs to require that safety analyses be conducted for SFP-accident scenarios in which fuel assemblies that had a pitch in a range between approximately 25 cm and 50 cm and were stored in racks that did not have neutron-absorber materials, or whose neutron-absorber materials had previously melted, would be exposed to either low-density, optimum-moderation firefighting foam or water mist, or water films. (0463-2-5 [Leyse, Mark])

Comment: Perhaps the NRC would argue that in SFP-accident scenarios, it would not be a safety risk if such fuel assemblies¹⁶³ [footnote 163 text: Fuel assemblies that had a pitch in a range between approximately 25 cm and 50 cm and were stored in racks that did not have neutron-absorber materials, or whose neutron-absorber materials had previously melted.] were exposed to either low-density, optimum-moderation firefighting foam or water mist, or water films. A 2001 NRC report, NUREG-1738, states: The phenomenon of a peak in reactivity because of low-density (optimum) moderation (firefighting foam) *is not of concern* in spent fuel pools since the presence of relatively weak absorber materials, such as stainless steel plates or angle brackets, is sufficient to preclude neutronic coupling between assemblies. Therefore, personnel actions to refill a drained spent fuel pool containing *undeformed* fuel assemblies would not create the potential for a criticality¹⁶⁴ [footnote 164 text: NRC, “Technical Study of Spent Fuel Pool Accident Risk at Decommissioning Nuclear Power Plants,” NUREG-1738, Appendix 3, p. A3-2.] [emphasis added].; In their assessment that the presence of *relatively weak absorber materials*, such as stainless steel plates or angle brackets, would be sufficient to preclude neutronic coupling between assemblies, it is possible that the authors of NUREG-1738 were only considering spent fuel assemblies, overlooking the fact that fresh fuel assemblies—which are much more reactive—are also stored in SFPs. (In March 2011, the Fukushima Dai-ichi Unit 4 SFP was storing 204 fresh fuel assemblies (and 1331 spent assemblies).¹⁶⁵ [footnote 165 text: Juan J. Carbajo, Oak Ridge National Laboratory, “MELCOR Model of the Spent Fuel Pool of Fukushima Dai-ichi Unit 4,” 2012, p. 1.]) It is pertinent that fresh fuel storage racks, *in a dry environment*, also have stainless steel material—a relatively weak absorber material. The authors of NUREG-1738 might have also overlooked the fact that the upper ends of spent fuel rods (perhaps PWR rods more than BWR rods) are significantly under-burned—“with burnup of 50 to 60% of the assembly average”—making those locations “dominant in terms of reactivity.”¹⁶⁶ [footnote 166 text: J. C. Wagner, M. D. DeHart, Oak Ridge National Laboratory, “Review of Axial Burnup Distribution Considerations for Burnup Credit Calculations, ORNL/TM-1999/246, March 2000, pp. 2, 5.] The authors of NUREG-1738 might have *non-conservatively* assumed that spent fuel assemblies have a uniform axial burnup distribution. Additionally, the authors of NUREG-1738 did not consider that “[s]ome [spent fuel] racks are also fabricated from aluminum,”¹⁶⁷ [footnote 167 text: EPRI, “Severe Accident Management Guidance Technical Basis Report,” Volume 2: “The Physics of Accident Progression,” 1025295, Appendix EE, p. EE-9.] which like zirconium is quite transparent to neutrons. (0463-2-6 [Leyse, Mark])

Comment: The results of the CRISTAL computer code simulations discussed in the 2011 IRSN information sheet on preventing SFP criticality accidents, in the event that PWR fuel assemblies¹⁶⁸ [footnote 168 text: The PWR fuel assemblies could be either fresh fuel assemblies or assemblies with a burnup of 10 GWd/t in their upper ends; in both cases, the fuel assemblies would be stored in racks without neutron-absorber materials with a pitch in a range between approximately 25 cm and 50 cm.] would be uncovered by the pool’s water, indicate that criticality accidents, caused by optimum-moderation low-density water or water films, could occur in SFPs.¹⁶⁹ [footnote 169 text: G Caplin et al., “Criticality Accident in Case of a Spent Fuel Pool Dry-Out,” IRSN, 2011, Information Sheet.] This means that optimum-moderation

conditions could cause criticality accidents in either low-density open racks, without neutron-absorber materials, or medium-density racks with non-borated flux traps—provided the stored fuel assemblies had a pitch in a range between approximately 25 cm and 50 cm. (0463-2-7 [Leyse, Mark])

Comment: III.D.5. Boraflex and Boral Degradation in Spent Fuel Racks: In a September 2013 NRC, Japan Lessons Learned Project (“JLLP”) meeting, Rodney McCullum of the Nuclear Energy Institute (“NEI”) stated: “We understand in the industry we can no longer rely on Boraflex. We’re not relying on it anymore.”¹⁷⁰ [footnote 170 text: NRC, “Japan Lessons Learned Project Directorate Public Meeting,” September 18, 2013, Transcript of Proceedings, (ADAMS Accession No: ML13277A215), p. 214.] As stated above, Boraflex is a neutron absorber, intended to help prevent criticality accidents, that is located in spent fuel racks. Boraflex degrades; nonetheless, it is still used in a number of SFPs, including Indian Point Unit 2’s.¹⁷¹ [footnote 171 text: NRC, “Summary of August 26, 2013, Meeting with Entergy Nuclear Operations, Inc. and Netco on Indian Point Unit 2 Spent Fuel Pool Management,” September 24, 2013, (ADAMS Accession No. ML13256A086), p. 1.] In May 2002, the high-density storage racks in Region 1-2 of the Indian Point Unit 2 SFP were “assumed to have sustained a 50 percent loss of Boraflex,” due to degradation.¹⁷² [footnote 172 text: NRC, Letter Dated May 29, 2002 to Michael R. Kansler, Entergy, “Indian Point Nuclear Generating Unit 2: Amendment Regarding Credit for Soluble Boron and Burnup in Spent Fuel Pit,” Enclosure 2, “Safety Evaluation Regarding Indian Point Unit 2,” (ADAMS Accession No: ML021230367), p. 3.] And, a NRC document, dated September 24, 2013, states that “[t]he existing Unit 2 SFP criticality analysis of record, which takes credit for Boraflex inserts as neutron absorbers, was submitted by letter dated September 20, 2001.”¹⁷³ [footnote 173 text: NRC, “Summary of August 26, 2013, Meeting with Entergy Nuclear Operations, Inc. and Netco on Indian Point Unit 2 Spent Fuel Pool Management,” p. 1.] Hence, even though there has doubtless been further degradation of Boraflex over the last dozen years, the Boraflex in a region of Indian Point Unit 2’s SFP is still assumed to have sustained a 50 percent loss. (Indian Point Unit 2 is a PWR; its SFP is required to use water that is borated with at least 2000 ppm of boron.) (0463-2-8 [Leyse, Mark])

Comment: Regarding Boraflex degradation and eroded subcriticality margins, a September 2012 NRC document states: Among neutron absorbing materials used in spent fuel pools, Boraflex degraded most severely. Boraflex is a neutron absorber material comprised of silicone polymer and boron carbide powder. When gamma-irradiated by spent nuclear fuel, Boraflex is prone to degradation and dissolution in the aqueous environment of the spent fuel pool. Consequently, *the subcriticality margins that existed when Boraflex was first installed have eroded*¹⁷⁴ [footnote 174 text: NRC, “Boraflex, RACKLIFE, and BADGER: Description and Uncertainties,” September 2012, (ADAMS Accession No: ML12216A307), p. ii.] [emphasis added]. As stated above, Boral is also a neutron absorber that is located in spent fuel racks; and like Boraflex, Boral degrades. Regarding Boral degradation, NRC Information Notice 2009-26 states: Blisters and bulges of Boral cladding are material deformations that change the dimensions of the material. These blisters and bulges can be either water filled or gas filled (from the reaction of the SFP water and aluminum from the Boral), which may not be accounted for in the criticality analysis.¹⁷⁵ [footnote 175 text: NRC, “Information Notice 2009-26: Degradation of Neutron-Absorbing Materials in the Spent Fuel Pool,” October 28, 2009, (ADAMS Accession No: ML092440545), p. 4.] And providing an example of the progression of Boral degradation, NRC Information Notice 2009-26 states: [T]he licensee at Beaver Valley stated that licensee inspections in 2007 of the Boral neutron absorber material coupons identified numerous blisters of the aluminum cladding, while only a few small blisters were identified in 2002. ...blisters can displace water from the flux traps between storage cells and challenge dimensional assumptions used in the criticality analysis.¹⁷⁶ [footnote 176 text: Id., p. 2.] (0463-2-9 [Leyse, Mark])

Comment: EIS analyses focus upon impacts of proposed human activity on the environment. Yet hazards related to nuclear plant operations and to spent fuel storage can be profoundly affected by the reverse; i.e., impacts of the environment upon a facility. (0464-2 [Nelson, Pam])

Comment: The NRC's flawed environmental study is based on a number of unrealistic assumptions that must be reconsidered. Instead of a strict risk/consequence approach, the NRC relies on a "probabilistic risk analysis" which allows it to underestimate the consequences of an intentional attack, based on its belief that the risk is extremely low. (0465-4 [Commenters, Multiple])

Comment: THE DRAFT GEIS DOES NOT PROPERLY EVALUATE THE CUMULATIVE RISKS OF POTENTIAL LOW PROBABILITY BUT HIGH-CONSEQUENCE EVENTS AND THEREFORE DOES NOT SUPPORT ITS CONCLUSIONS THAT ASSOCIATED ENVIRONMENTAL IMPACTS ARE "SMALL" ACROSS ALL TIMEFRAMES CONSIDERED. Even if the framework applied in the GEIS were valid, and the conclusion that environmental benefits do not differ across Alternatives were supported, the approach used in the GEIS to describe the cumulative risks of low probability / high consequence events is flawed. (0473-1-15 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: 1. The Draft GEIS provides very limited quantitative information on the probabilities or consequences of severe accidents or events associated with continued storage. Both pieces of information are required to support the NRC's conclusion that risk is "low" and therefore impacts are "small." The Draft GEIS states that severe accidents, such as spent fuel pool fires, would generate significant and destabilizing impacts (Draft GEIS, pg. 4-68). In weighing these environmental consequences, the NRC multiplies the expected impacts by the probability of occurrence of an initiating event (e.g., seismic events, loss of offsite power, cask drops, aircraft crashes, or tornado missiles). The Draft GEIS describes multiple types of accidents that may occur over the short-term, long-term, and indefinite time frames, but only includes a quantitative assessment of the risk of spent fuel pool fires from seismic events.² [footnote 2 text: 2 The NRC concludes that the probability-weighted impacts from a spent fuel pool fire are small because the probability of an initiating event is extremely remote (Draft GEIS, pg. F-1). The NRC relies on two key pieces of information to support this conclusion. First, to determine the probability of an event, the NRC references the expected frequency of the most likely initiating events (i.e., seismic events or cask drops). The probability of these events occurring in a given year is based on information from previous NRC studies and varies between 5.8×10^{-7} (one chance in 1.7 million) to 2.4×10^{-6} (one chance in 417,000). Second, the NRC estimates the total economic cost per spent fuel pool accident of approximately \$57 billion (Draft GEIS, pg. F-4).]; For all other types of accidents and events (cask drops, earthquakes, floods, high winds, terrorist attacks, etc.), the NRC simply asserts that existing design criteria and safety requirements ensure environmental consequences would be small because licensees must demonstrate that either probabilities or consequences of events are sufficiently low. This Draft GEIS repeatedly points to the NRC's existing safety programs as evidence of low probabilities of accidents despite the following statement in the Court decision with respect to the 2010 Waste Confidence Decision: "With full credit to the Commission's considerable enforcement and inspection efforts, merely pointing to the compliance program is in no way sufficient to support a scientific finding that spent-fuel pools will not cause a significant environment impact during the extended storage period. This is particularly true when the period of time covered by the Commission's predictions may extend to nearly a century for some facilities." (New York v. NRC, 681 F.3d 471 (D.C. Cir. 2012), pg. 17). (0473-1-16 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The evaluation of impacts of accidents and events associated with spent fuel storage should consider both the probability and consequences of events, as described by the D.C. Circuit Court: "As should be clear by this point in our opinion, an agency conducting an EA generally must examine both the probability of a given harm occurring and the consequences of that harm if it does occur. Only if the harm in question is so "remote and speculative" as to reduce the effective probability of its occurrence to zero may the agency dispense with the consequences portion of the analysis." (New York v. NRC, 681 F.3d 471 (D.C. Cir. 2012), pg. 18-19). (0473-1-17 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: In fact, the Draft GEIS has not demonstrated that the effective probability of accidents and events is zero. The Draft GEIS makes the assertion regarding low probabilities of all initiating events despite describing significant uncertainties and information gaps: With respect to sabotage or terrorist attacks, despite acknowledging that the probabilities are "numerically indeterminable," the Draft GEIS nevertheless asserts they are "very low" (Draft GEIS, pg. 4-86). (0473-1-18 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: In fact, the Draft GEIS has not demonstrated that the effective probability of accidents and events is zero. The Draft GEIS makes the assertion regarding low probabilities of all initiating events despite describing significant uncertainties and information gaps: Following the March 2011 earthquake and tsunami incident at the Fukushima Dai-ichi nuclear power plant in Japan, the NRC requested that all U.S. nuclear power plants identify and address vulnerabilities and adequacies of monitoring and maintenance procedures, as well as re-evaluate the flooding and seismic hazards of the plants. The Draft GEIS states that it has not yet received these responses and so has not decided whether any existing licenses need to be modified, suspended, or revoked (Draft GEIS, pg. 2-11). Here, the Draft GEIS acknowledges that such vulnerabilities are site-specific, and that the NRC requires more information from licensees to better understand them. NRC's conclusion that they can rely on a GEIS approach and conclude that probabilities are low enough to result in "small" impacts is not consistent with this acknowledgement. (0473-1-19 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Despite insufficient information to demonstrate the probability of these events is effectively zero, the NRC dispenses with the need to evaluate consequences of certain types of accidents and events (the only impact estimates presented are for spent fuel fires, as described above). The Draft GEIS acknowledgement of insufficient information regarding the probabilities of particular high-consequence events should have led to the conclusion that codifying that environmental impacts of continued storage are small based on a generic assessment is premature and erroneous. Without information on both the probabilities and consequences of all postulated accidents and severe events, it is unclear how the NRC has the information to generically conclude that the product of the two is "small" across all sites and timeframes. (0473-1-21 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The Draft GEIS does not properly evaluate the cumulative risks of potential low probability but high-consequence events and therefore does not support its conclusions that associated environmental impacts are "small" across all timeframes considered. (0473-1-5 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: As discussed above, not only does this characterization violate NEPA and CEQ regulations, it is also in direct conflict with the D.C. Circuit's holding that "[o]nly if the harm in

question is so 'remote and speculative' as to reduce the effective probability of its occurrence to zero may the agency dispense with the consequences portion of the [NEPA] analysis." New York v. NRC, 681 F.3d 471, 482. (D.C. Cir. 2012). Commissioner Magwood has observed that "there were several interveners or NGO groups that had the comment that the [license renewal] GEIS is deficient because it doesn't take into account these future unplanned releases, and I struggle with this because I don't know how you go about estimating that." Transcript of Proceedings, Briefing On Proposed Rule To Revise The Environmental Review For Renewal Of Nuclear Power Plant Operating Licenses (Part 51) (Jan. 1, 2011), ML120180209 at 69. (0473-10-10 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: NRC's cumulative impacts assessment for severe accidents in Section 6.4.17 of the DGEIS is wholly insufficient. The DGEIS completely ignores the fact that if a severe accident were to occur at a reactor site, it could affect not only a spent fuel pool, but also one or more reactors at the site - and one or more spent fuel pools at the site. The multi-facility accident at Fukushima demonstrated that such events are not speculative. Moreover, the radiation that was released during the Fukushima does not reflect the upper limit of severe accident scenarios. See Official Exhibit - NYS000420-00-BD01 - Pre-filed Rebuttal Testimony of Dr. Francois J. Lemay, Ph.D. in support of Contention NYS-12C at 11-16 (June 29, 2012) (ML12340A678). (0473-10-11 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: There is no attempt to quantify this in the DGEIS, or perform a site-wide SAMA-type analysis. In fact, some of the assumptions in the DGEIS regarding what will happen at a site following an accident involving the spent fuel pool assume that the rest of the plant is intact. However, if the initiating cause of the accident is an earthquake or other natural disaster, it is likely that the entire plant, not just the spent fuel pool, will be damaged, as occurred at Fukushima. This synergistic destruction is ignored in the DGEIS's optimistic assessment of the consequences of a severe accident. (0473-10-12 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: In the license renewal context, recent severe accident mitigation alternatives analyses have focused on a severe accident occurring at a single reactor. In a similar manner the DGEIS and its Appendix F focus on a severe accident occurring at a single spent fuel pool. This approach ignores the real world reality that several sites have two reactors along with two adjacent spent fuel pools and that some sites have three reactors and three adjacent spent fuel pools. In July 2011, following the multi-unit accident at Fukushima, the NRC Commissioners convened a meeting to discuss site-wide probabilistic risk assessments. (0473-10-13 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Although the DGEIS does not mention any ongoing NRC efforts to prepare a comprehensive, site-wide level 3 PRA analysis (including a consequence analysis) of severe accident risk, publicly-available documents show that such an effort is underway, but appears to be at a preliminary stage. It is not clear when this will be completed or for which sites this will be completed. See, e.g., SECY-13-0118 - Recent Accomplishments and Near-Term Anticipated Accomplishments - 2013 at p. 11 (ML13273A122). It is for one plant only, and will not be completed by NRC for several years. The DGEIS should at least mention this effort, explain how and if it relates to the cumulative impact analysis, and examine whether it should be prioritized. For sites such as Indian Point where the potential severe accident consequences are enormous, a site-wide level 3 PRA that considers the risk of a severe accident for the whole site (reactors, spent fuel pools, and dry casks included) must be performed to evaluate the true cumulative impacts under NEPA. See Expert Review of Analytic Assumptions and Methods Applied in the NRC's September 2013 Draft Waste Confidence GEIS prepared by Robert E.

Unsworth and Maura Flight of Industrial Economics, Incorporated, Ex. E ("IE Report") (discussing probabilities that are calculated for one year at one reactor and not multiplied by the number of reactors and the number of years).¹⁸ [footnote 18 text: The IE Report is discussed in more detail below.] (0473-10-14 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Instead of performing a site-wide level 3 PRA to assess the severe accident risks at a plant site, the DGEIS essentially concludes that the probability-weighted risk of a severe reactor accident is small and the probability-weighted risk of a spent fuel pool fire is small, so the cumulative impacts of a severe accident, even when allowing continued on-site fuel storage in pools, is small. The DGEIS and the Spent Fuel Pool Consequence Study approach that looks only at a severe accident to one spent fuel pool at a multi-facility nuclear power station segments the analysis from the site wide risk and avoids examining cumulative impacts. Such a narrow inquiry violates NEPA. (0473-10-15 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: As counsel for the State of Connecticut represented to the Commissioners in January of 2012 at a public meeting regarding the License Renewal GEIS, Connecticut would shoulder the environmental consequences of displacements from residents fleeing an accident at Indian Point. *Id.* at 17-24. Those impacts have not been analyzed in the DGEIS, though they are indirect impacts from the long-term storage of high level nuclear waste on-site at Indian Point and thus required to be addressed under NEPA. (0473-10-17 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: NRC's Characterization of the Probability-Weighted Impacts of Severe Accidents As "Small" Is Inadequate Under NEPA: In evaluating the potential impacts of severe accidents, the DGEIS acknowledges that "[t]he consequences of a severe (or beyond-design-basis) accident, if one occurs, could be significant and destabilizing," but then goes on to characterize them as "small." See, e.g., DGEIS at 4-68- 69. NRC is only able to reach the conclusion that severe accident impacts are small by accounting for "the low probability of these events." *Id.* Former NRC Chairman Jaczko expressed his concern about this approach during a public meeting on the impacts of an accident in the license renewal context: CHAIRMAN JACZKO: So, you know, I can appreciate that so, you know, it's kind of the catch-all with all the things dealing with severe accidents is that it becomes small because you don't think it's going to happen. I can't say the more I hear of this that I'm comfortable with that. The more I hear it I think I don't think that's the right approach. I mean, I think the practical reality is that we should be honest about what the consequences are and, you know, again it is -- we are dealing in the environmental space, so our ability here is not regulatory requirements that we're putting in place, but I think it would be much more straight forward if we were actually communicating severe accidents in the actual way in terms of what their consequences were, which would bring in then, more naturally, I think this discussion about what are the environmental impacts of an evacuation. So, it's probably one of the most confusing things I think about the EIS and the - it's not restricted, of course, to this GEIS or to how we do it. I mean, the good part about it is we do it consistently in all our EISs. So in that vein, and I want just to highlight, I know that severe accidents are generally site-specific. To what extent, I mean, when we look at the site- specific analysis, to what extent is the site-specific analysis, the severe accident analysis, is that most of what is really in the site-specific or there are other things that get addressed? ANDREW IMBODEN: Well, in the site-specific reviews, the staff -- well, the applicants bring us in and the staff assesses the severe accident mitigation alternatives, how the severe accidents would be mitigated and then are the costs beneficial or not? And all of that is discussed in the site-specific reviews, because it is, you know, very dependent on which site and how you mitigate those.

CHAIRMAN JACZKO: And, again, we're dealing with this in NEPA space and we're not in -- this is not a licensing review piece. To what extent, you know, we ultimately have no authority then. I mean, we're not -- these mitigating measures are not things that we have authority to implement, maybe in some cases we put license conditions on, I don't know. But in general there are things that come about as part of the analysis. Do we keep track then of what they do for mitigation measures or anything that comes out of the same analysis? I mean, do we track that in any way? Does it become a commitment or does it get any kind of tracking? MELANIE GALLOWAY: No, no we don't. ANDREW IMBODEN: And to explain that a little bit further is sometimes, and we're seeing this in Columbia's environmental review, the applicant goes through this process, identifies something and does it by the time we finish our review. CHAIRMAN JACZKO: [affirmative] ANDREW IMBODEN: So there's that. CHAIRMAN JACZKO: But it's not -- I mean it's not captured other than maybe being referenced in the EIS. ANDREW IMBODEN: Well, and if there is anything that then needs to be done - CHAIRMAN JACZKO: Yeah. (0473-10-8 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: ANDREW IMBODEN: The staff would have a process for, you know, making sure it goes through the backfit as appropriate and those kinds of things. *Id.* at 81-82. CEQ regulations require the opposite of the NRC's approach, providing that impacts "include[] *impacts which have catastrophic consequences, even if their probability of occurrence is low*, provided that the analysis of the impacts is supported by credible scientific evidence, is not based on pure conjecture, and is within the rule of reason." 40 C.F.R. § 1502.22(b)(4)(emphasis added). Under NEPA, an agency cannot dispense with impacts based on probability alone. (0473-10-9 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The Draft GEIS does not properly evaluate the cumulative risks of potential low probability but high-consequence events and therefore does not support its conclusions that associated environmental impacts are "small" across all timeframes considered. (0473-12-2 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The IE Report also demonstrates that even if the generic approach were acceptable, the DGEIS fails to properly evaluate the consequences and probabilities, and thus the risks, of indefinite spent fuel storage at reactor sites because it ignores the cumulative risks associated with the proposed action. By using the DGEIS to support a rule that excludes consideration of any environmental impacts associated with spent fuel storage at reactor sites on an individual basis, the DGEIS provides a generic approval of such storage but it fails to conduct a generic analysis of the consequences of that approval. To do that the DGEIS would have to look at the cumulative risks of allowing these conditions to exist at over 100 reactors for the indefinite future. Instead the DGEIS provides a single year's risk for a single hypothetical reactor. NEPA does not allow the use of such a distorting methodology to assess environmental consequences. This problem is made even worse by the failure of the DGEIS to use well-accepted methodologies to properly discount impacts to estimate a present value. Both EPA and the OMB have developed such methodologies but the DGEIS relies on neither. (0473-12-5 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: In addition, the DGEIS includes a few short sections briefly discussing potential severe accidents at spent fuel pools including spent fuel leaks, spent fuel pool fires, and sabotage or terrorist acts. DGEIS at Sections 4.18, 5.18, and 6.4.17. However, the only type of accident that is analyzed in detail is a spent fuel pool fire. (0473-13-7 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The ISR report explains that one of the lessons learned from the Fukushima accident is that mitigation measures that stop the progression of a severe accident may have clear benefits in the short term, but may create longer term hazards from liquid releases to the environment. ISR Report at 18-19. At Fukushima, the emergency workers pumped water into the damaged reactors. This water became contaminated on contact with the damaged fuel elements and leaked out into the basement of the reactors. This additional volume of highly radioactive water continues to add to the complexity and severity of the Fukushima accident. A recognition of this issue, much less any discussion of it, is utterly lacking from the DGEIS. There have been many reports regarding continuing radiological aqueous releases at the Fukushima site - more than two and a half years after the start of the severe accidents that damaged four of the Dai-ichi nuclear facilities. According to news articles, the receptacles holding radiation contaminated fluids at the Fukushima site have leaked and have released radiological material to the environment. See, e.g., Martin Fackler, *Damaged Nuclear Plant in Japan Leaks Toxic Water*, New York Times (April 6, 2013); Mari Iwata, *Japan Nuclear Plant Finds New Leaks*, Wall Street Journal (April 7, 2013); Hiroko Tabuchi, *Nuclear Plant in Japan Has Leak in Other Tank*, New York Times (April 9, 2013); Hiroko Tabuchi, *Fukushima Nuclear Plant Is Still Unstable, Japanese Official Says*, New York Times (April 10, 2013); *Fukushima Plant Has 300-Ton Water Leak*, Associated Press, New York Times (Web Edition) (August 20, 2013) ("The operator of Japan's tsunami-crippled nuclear power plant said Tuesday that about 300 tons (300,000 liters, 80,000 gallons) of highly radioactive water have leaked from one of the hundreds of storage tanks there -- its worst leak yet from such a vessel."); Martin Fackler & Hiroko Tabuchi, *Memo From Japan With a Plant's Tainted Water Still Flowing, No End to Environmental Fears*, New York Times (October 24, 2013); *Latest Leak at Japan's Fukushima Plant Contaminates Six Workers*, Mari Saito, Reuters (October 9, 2013); Mari Iwata & Toko Sekiguchi, *Japan Unveils Strategy to Deal With Fukushima Daiichi Water Leaks Projects to Cost Around \$475 Million Include a Wall of Ice, Second Processing Plant to Filter Radioactive Particles*, Wall Street Journal (Sept. 3, 2013). On August 1, 2013, NRC made the transcript of a December 2012 Advisory Committee on Reactor Safeguards ("ACRS") subcommittee meeting publicly available. July 30, 2013 Memorandum to ACRS Members regarding Certified Minutes of the ACRS Reliability and PRA Subcommittee Meeting on Level 3 PRA on December 4, 2012 (ML13211A477) ("ACRS Transcript"). At that meeting Alan Kuritzky from NRC's Office of Research, Division of Risk Analysis, explained Aqueous transport and dispersion of radioactive materials, this is something very big given the Fukushima event, but something we simply are not going to address in our study, but the Agency as a whole is looking into it. ACRS Transcript at 43:17-21. (0473-14-1 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: In fact, the MACCS2 code, used by the NRC to examine severe accidents, does not even take aqueous releases into consideration. A presentation by the Director of NRC's Research Office from NRC's March 2013 Regulatory Information Conference makes clear that the MACCS2 computer code used to examine severe accidents lacks the ability to analyze the impacts to water resources and the environment resulting from aqueous radiological releases accompanying such an accident. International Session - Post-Fukushima Research, Brian Sheron, Director, NRC Office of Nuclear Regulatory Research (March 13, 2013).²⁶ [footnote 6 text: 26 The document is available at <https://ric.nrc-gateway.gov/m/Docs/Abstracts/sheronb-rev1-hv-w15.pdf>.] In slide 7 of that presentation (reproduced below), NRC notes (1) aqueous releases occurred during the Fukushima accident, and (2) current models do not address aqueous release pathways. The term "current models," as used in the slide, would include computer codes such as MACCS2. Aqueous releases following a severe accident would be of particular concern at Indian Point, which sits on the Hudson River. Aqueous releases have the potential to contaminate the Hudson River's waters, riverbanks, riverbed and sediment, adjacent

freshwater tidal wetlands, and fish and other aquatic organisms, and impacts to the environment and human health could exceed the impacts flowing from the aqueous releases into the Pacific Ocean at Fukushima. (0473-14-2 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The DGEIS offers absolutely no analysis of the impact of a spent fuel pool fire, accident, or leak on non-human biota. As discussed above, the low probability of an accident or fire does not absolve the NRC of performing the analysis of potential impacts, as the D.C. Circuit made clear. Quantifiable impacts to biota occur after releases of radioactivity from power plants. For example, after the meltdown at Fukushima, the New York Times reported that:

- Initially, scientists found that the abundance of birds, butterflies and cicadas had decreased significantly as the level of radiation increased. Bumblebees, dragonflies and grasshoppers were not affected by the release of radioactive materials, however. Surprisingly, spiders actually increased in abundance with the rise in radiation. *Fukushima v. Chernobyl: How Have Animals Fared?*, NYTimes GreenBlog, July 13, 2012, available at http://green.blogs.nytimes.com/2012/07/12/fukushima-vs-chernobyl-how-have-animals-fared/?_r=0 (last visited Nov. 15, 2013).
- Dr. Mousseau (a biologist at the University of South Carolina at Columbia) speculates that perhaps the insect prey that spiders normally feed on are weaker and easier to catch in the radioactive zones, and that spiders are possibly not particularly sensitive to the immediate contaminants. He predicts that over the long term, the [population of] spiders, bees, dragonflies and grasshoppers will eventually begin to drop off. *Id.*
- In Fukushima, animals have only cycled through a few generations at most since the disaster, so any mutations have probably not begun to manifest themselves. For short-lived species like insects, however, mutations could soon start to appear. *Id.*
- Scientists found that contaminated areas of Chernobyl and Fukushima are unlikely to be hospitable habitats for years to come. In Chernobyl, for example, the amount of americium-241, a highly radiotoxic isotope if ingested, is actually increasing as its parent nuclide, plutonium, decays. Radioactive materials like cesium are brought back to the surface soil each year by plant growth and pollination. *Id.*
- Scientists conclude that "artificial radionuclides from the Fukushima Nuclear Power Plant caused physiological and genetic damage to [pale grass blue butterflies.]" CNN, "Mutant butterflies a result of Fukushima nuclear disaster, researchers say" (Aug. 14, 2012), available at <http://news.blogs.cnn.com/2012/08/14/mutant-butterflies-a-result-of-fukushima-nuclear-disaster-researchers-say/> (last accessed Nov. 18, 2013), citing Hiyama, et al., The biological impacts of the Fukushima nuclear accident on the pale grass blue butterfly, SCIENTIFIC REPORTS (Aug. 9, 2012), available at <http://www.nature.com/srep/2012/120809/srep00570/full/srep00570.html> (last accessed Nov. 18, 2013). Moreover, sensitivity to irradiation varies between species (CNN, *supra*), warranting a species-by-species examination of the impacts of a spent fuel pool accident or fire. Similarly, past studies by Fukushima Prefecture found that as time passed, radioactivity levels declined at a faster pace for fish and shellfish in deeper parts off the coast than those on the seabed closer to the coast, indicating that analyses must be done both near and farther from each plant to capture full impacts. Asahi Shimbun, "With radiation fears rekindled, researchers seek truth off Fukushima coast," available at <http://ajw.asahi.com/article/0311disaster/fukushima/AJ201308120096> (last accessed Nov. 18, 2013).

(0473-16-1 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: NRC's analyses of the adequacy of a current design to protect against natural phenomena hazards are based upon the original design basis. Climate change renders invalid analyses that rely only on historical conditions as a proxy for the future. In addition, the original design for plants in the Northeast, particularly Indian Point, were based on seismic analyses that are outdated. Recent analyses conducted by the United States Geological Survey show a

greater probability of a severe earthquake in the Northeast in general, and at Indian Point in particular, and a greater likelihood of more severe damage from such an earthquake, than was assumed when Indian Point was sited and when its seismic design was determined. Statement in Support of New York State Contentions and in Response to the April 30, 2007 License Renewal Application Submitted by Entergy for Indian Point Units 2 and 3 by Lynn. R. Sykes, Ph.D. Higgins Professor Emeritus, Earth & Environmental Sciences Lamont-Doherty Earth Observatory of Columbia University, Palisades NY 10964 (Nov. 29, 2007) and Declaration Of Leonardo Seeber, senior research scientist at the Lamont-Doherty Earth Observatory of Columbia University (Nov. 29, 2007) both filed as exhibits to New York State Notice Of Intention To Participate And Petition To Intervene in Entergy Nuclear Indian Point 2, LLC, Entergy Nuclear Indian Point 3, LLC and Entergy Nuclear Operations, Inc., Docket Nos. 50-247-LR and 50-286-LR (Nov. 30, 2007), ML073400205. If meteorological and climate conditions relevant to the design basis have changed over the intervening years, which is likely given observations in, for example, current trends in rainfall intensity, such changes have not been considered. As vulnerabilities from natural hazards change over time, a determination on the adequacy of systems to protect against such hazards should include up to date information available at the time of the DGEIS is written, not no longer relevant historical information. In this same vein, when the DGEIS states that General Design Criterion 2 (of Appendix A, "General Design Criteria for Nuclear Power Plants," to 10 C.F.R. Part 50) requires the design bases for structures, systems, and component reflect appropriate consideration of the most severe natural phenomena historically reported for the site and surrounding area (DGEIS at 4-71), the phrase "historically reported" should be interpreted as information available up until publication of the DGEIS in September 2013. DGEIS states that All safety-significant structures, systems, and components are required to be protected against the design basis flood by siting them above the highest flood water-surface elevation or providing adequate flooding protection. The NRC requires that this protection be achieved by using a dry site concept, external barriers, or incorporated barriers (NRC 1976). The dry site concept involves constructing the nuclear power plant above the design basis flood water surface elevation using either the natural terrain or engineered fill. External barriers are engineered solutions that can include levees, seawalls or floodwalls, bulkheads, revetments, or breakwaters. Incorporated barriers are also engineered solutions that involve specially designed walls or penetration closures. (0473-17-4 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The Draft GEIS does not evaluate the cumulative risk associated with the potential for multiple types of accidents and severe events over time. Furthermore, the Draft GEIS inappropriately evaluates probabilities and consequences on a per-year and per-accident or event type basis, separately concluding that the environmental impacts of each accident or event type are small in a given year. In a given year, however, the expected value of accidents/events would include the cumulative risk of all potential types of events (floods, earthquakes, terrorist attacks, cask drops, etc.). The Draft GEIS does not attempt to sum consequences across risk categories to determine the cumulative risk of multiple types of accidents and events (i.e., the combined probability and consequences of all potential disasters) in a given year. The Draft GEIS also does not include any acknowledgement that risks are cumulative over time. Even in the case that the environmental impact of severe events in a given year is small, the Draft GEIS considers continued storage over long timeframes (160 years and indefinitely). In short, over longer time frames the cumulative probability of a high consequence event is greater than over shorter timeframes, and such calculations could have been easily performed. (0473-2-1 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: *The Draft GEIS excludes any consideration of the effects of people's perceptions of risk associated with continued storage. Despite historical or statistical data describing risk, risk perceptions drive people's behavior and can generate real economic impacts.* In addition to not being supported by available information, a sole focus on statistical risk of high-consequence events, without consideration of people's perception of risk, is inconsistent with well-accepted risk-perception literature. Factors unrelated to historical or statistical data affect perceptions of risk. Many of these factors are relevant to the management of nuclear waste, including: voluntariness of exposure, dread associated with the hazard, the extent to which the risk can be controlled, the potential for catastrophe, and the level of uncertainty associated with the hazard.⁷ [footnote 7 text: Jenkin, Clinton M. July 2006. "Risk Perception and Terrorism: Applying the Psychometric Paradigm." *Homeland Security Affairs*. Vol II, No. 2.] For high-consequence events, the perception of risk, whether or not data demonstrate the risk is actually present, may generate real impacts. One example is the adverse effect of hazardous waste sites on neighboring property values, despite data demonstrating safety. Because perceptions of risk drive behavior and the public's priorities, and result in real impacts and consequences, these perceptions need to be taken into account in order to appropriately reduce impacts and consequences.⁸ [footnote 8 text: Ibid.] In light of this, the NRC's persistent assurance throughout the Draft GEIS that the probabilities of initiating events are very low is unlikely to reduce public perceptions of risk. In only addressing historical and statistical data describing probabilities of events, the NRC ignores that these data are not indicative of the public's level of concern with respect to management of spent fuel. Despite repeated assurances of low probabilities of severe accidents and events, the public remains significantly concerned as evidenced through the scoping process on the Draft GEIS. Importantly, it is the public's perception of risk that generates some types of environmental consequences (e.g., property values or participation in recreational activities in areas surrounding plants). In addition to reducing property values, in the case that people choose not to recreate within the area of a continued storage site, local economies may suffer from the reduced tourist spending. It is therefore important for NRC to recognize and assess the impacts of these risk perceptions. As opposed to repeated assurances of low probabilities, a more effective analysis would focus on the site-specific consequences of events, and the best approaches to avoid or mitigate events within the context of a given site. In line with this approach, in response to September 11, the Department of Homeland Security has treated high consequence events differently, effectively doing everything they can to avoid such events. The NRC asserts in the Draft GEIS that it applies a "defense-in- depth philosophy" to identify all safety features, measures, and plans to protect human and environmental health and safety (Draft GEIS, pg 4-68). It follows that this philosophy should include capitalizing on every opportunity to obtain site-specific information on vulnerabilities and risks, and design appropriate management and mitigation strategies accordingly. The decision to rely on a generic evaluation of environmental impacts and codify that no site-specific evaluation of continued storage is required is counter to the NRC's own stated philosophy. (0473-3-1 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Finally, the limited information provided in the Draft GEIS does not support the finding that environmental consequences of continued storage, particularly as relates to postulated accidents and severe events, are "small" across all sites. (0473-4-2 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: It is extremely unsafe to leave nuclear waste so near so many earthquake faults. It is in a highly populated county with no evacuation routes EXCEPT the 5 which is already overcrowded. There is potential for so much damage to so many not to mention the economic ramifications. (0485-1 [Karas, Catherine])

Comment: Rather than insist on a robust waste management system intentionally designed to handle conceivable accidents whether through equipment failure, natural disasters, operator error or any other cause that could release radioactive materials to the environment, the NRC's draft document ultimately relies on the low probability of an accident to justify its position that reactor licensing and relicensing may resume. Low probability is not a substitute for protection, as the world already has learned from Fukushima to Chernobyl to Bhopal and Love Canal. (0491-5 [Commenters, Multiple])

Comment: Most people who live within a 50 mile radius of SONGS want the spent fuel stored there removed to assure safety in the case of a large Earthquake and the possible resulting Tsunami - while the odds of such events occurring are low they are possible. (0495-1 [Grigg, Richard])

Comment: On reviewing the Draft of "Waste Confidence Generic Environmental Impact Statement" the NRC states (Draft NUREG-2157 - page xxx dated September 2013) : "The NRC's concept of risk combines the probability of an accident with the consequences of that accident. In other words, the NRC examines the following questions: . What can Go Wrong? . How likely is it? . What would be the consequences?" They conclude that the risk for Short Term, Long Term and Indefinite Storage the risk of problems or of injury is SMALL see Draft NUREG-2157 Pages xlv, xlv dated September 2013. I believe this position is very close to the position the Japanese Regulators took prior to the disaster at Fukushima. The problem that is not addressed in the NRC approach is that the extremely large amount of damage and the extreme cost of the sort of disaster that a loss of spent fuel cooling water could cause by contaminating a large area is staggering (it is estimated that the existing spent fuel at SONGS contains 50 times the Cesium 137 that was released during the 1986 Chernobyl disaster which resulted in the initial evacuation of 350,000 people and at this time the land and homes in a 19 mile radius have been forcibly abandoned with entry limited to Monitoring and Research Personnel who stay only a short time). Most will agree with the NRC that the chances of a monster earthquake which causes a widespread disaster may in fact be quite low, however, the potential extent of damage is so great that it over rides the conclusion that the risk is small because the chance of such an event occurring is small - reason demands that every step possible be taken to eliminate the chance of such a disaster be taken immediately (0495-4 [Grigg, Richard])

Comment: Inadequate Consideration of Impacts or Mitigation of a Station Blackout: One of the most devastating events facing any nuclear plant is that of a station blackout. DLR's EISs have virtually ignored such an event and consequently have failed to evaluate the impacts on the public or mitigation measures for preventing such an event. The WCGEIS needs to be revised to address these risks and impacts posed by such events in terms of a national fleet of operating reactors and spent-fuel basins. (0496-10 [Batobato, Alicia])

Comment: 1. This constitutes a national program and requires a programmatic EIS. 2. Purpose and Need. 3. xxviii Risk Assessment (<http://www.nrc.gov/aboutnrc/regulatory/riskinformed.html/>) doesn't exist therefore cant understand it. 4. Admitte on page Xiii that env impacts of spent fuel are "large" should be "LARGE." 5. Flooding, Earthquakes Page 4-73 risk is small- no evidence. Solar flares never considered. 6. Page xii states "the environmental impacts of these postulated accidents involving continued storage of spent fuel in pools are SMALL" Incorrect, the risk is small not consequences. 7. No consideration of beyond design accidents 8. Page 4-68/69 says that impact could be low if prob is low- incorrect. The risk is low but the consequences are large. 9. New Alternative: Shut reactors down until a permanent method of disposal is found.

10. Cumulative risk from all spent fuel sites in the nation. They only looked at risk from spent fuel fire at one site! I can absolutely, unequivocally prove that the risk of an accident is not small. I took half a day off from my consulting practice to review the Waste Confidence EIS. In just half a day, I can see this analysis is profoundly flawed. The flaws start on Chapter 1 (Statement of Purpose and Need [SPN]) and continue into all the other sections that I briefly reviewed. For instance, NRC couldn't even define its "purpose" and "need" correctly - and in fact confused both terms).¹ [endnote 1 text: 1 Eccleston, Environmental Impact Statements: A Comprehensive Guide to Project and Strategic Planning, "Schmidt's Model for Defining the Scope of Alternatives." pp92-93 Eccleston, The EIS Book, Chapter 3, "Defining the Statement of Purpose and Need," 2013.] Since the SPN forms the basis for the range of alternatives this may mean that the scope of alternatives is also flawed. (0496-14 [Batobato, Alicia])

Comment: But I see much more interesting problems. For example: 1. The EIS actually states (admits) that the impacts of a severe accident would be "large" and "significant and destabilizing." [This is a logical and correct statement] 2. It then argues that impact determinations are made with consideration of the low probability of an accident. The environmental impact determination is based on the risk (product of the probability and the consequences of an accident). [This is incorrect. The risk determination is based on probability. The consequences are as they admitted above "large"] 3. It then incorrectly concludes that a high-consequence low-probability accident (severe accident), could result in a "small impact determination, if the risk is sufficiently low." This conclusion is completely bogus. They have mixed up the engineering concept of "risk" with NEPA's concept of "impacts." They started off admitting that the "impacts" of a large accident are "large" and "significant and destabilizing." Then they introduce "risk" to argue that these same impacts are actually "SMALL." They have mixed up the concept. The "risk" of an accident could indeed be "SMALL." But that does not mean that the "impact" posed on the public is "SMALL." The actual impact of a severe accident would in fact be "LARGE"! In other words: $R = I \times P$; The impacts are large and will always remain large. It is the risk that they argue (incorrectly) is small. But as the equation shows, it is the risk of an accident that they argue is small not the impacts. I did a word count. The NEPA Regulations provide direction and mention the concepts of "impact", "effect", and consequences, 77 times, 55 times, and 5 times, respectively. Not once do the regulations state that "risk" can be substituted for evaluating impacts or reaching a significance determination of an impact (e.g., effect or consequence). NRC is on mighty shaky ground in its attempt to show the public that there is nothing to worry about. This is a huge error and very misleading to political leaders, decision-makers, stakeholders, and the public. Moreover the entire analysis has neglected other vital considerations such "similar actions," "cumulative impacts," "cumulative risk"....I could go on and on. These other factors could significantly increase both the impacts and risk of an accident. Finally, they have reached these implausible conclusions without a technical justification or basis. To me, this looks, walks, and quacks like an "arbitrary and capricious" conclusion. In fact, I have a published mathematical technique that can absolutely prove, unequivocally prove, that the risk of an accident is not small. I can irrefutably prove that the risk is "LARGE;" If this is anything like the LR EISs (I suspect it's much worse given how fast they slapped this thing together) it is flawed to high heaven. You should be able to rip this thing to smithereens! I only wish I had more time to examine this in real detail. (0496-15 [Batobato, Alicia])

Comment: 1. Risk of Severe Accidents: NRC has routinely concluded that the risk of a "severe accident" at a nuclear power is "small." Likewise the Waste Confidence Generic Environmental Impact Statement (WCGEIS) concluded that the risk of a "severe accident" involving a spent fuel is "small." This conclusion is bogus and indefensible. The probability of a severe accident involving spent fuel is much larger than NRC is attempting to portray to the public. The

probability of a severe nuclear reactor accident triggering a severe accident involving spent fuel only increases the risk of a tragic accident. The analysis presented in the WCGEIS needs to be redone to openly assess and disclose the true probability and consequences of a severe accident. Based on this re-analysis, the risk needs to be reassigned as "moderate" or "large". 2. Failure to Compute the Complete Risk of an Accident: Neither the WCGEIS nor NRC's LR EISs have evaluated the total risk that the public faces from accidents involving the nation's fleet of operating reactors. Nor has the WCGEIS evaluated the total risk from all spent-fuel stored around the nation. The WCGEIS must be revised to assess the total national risk posed by a severe accident from the entire fleet of operating nuclear reactors and spent fuel storage. The WCGEIS must also be revised to assess the total risk posed by a severe accident from all nuclear reactors combined with the risk posed by a severe accident involving the spent-fuel for all nuclear power plants. (0496-2 [Batobato, Alicia])

Comment: 3. The Impacts of Severe Accidents are not Investigated: The NEPA regulations are clear: The "impacts" or "consequences" must be evaluated NOT the risk of an accident. The LR EISs utterly fail to perform even a rudimentary assessment of the consequences of a severe accident. The environmental and health consequences of a severe accident need to be evaluated and disclosed to the public. Conflicting scientific opinions by other experts must also be addressed. This LR EIS re-analysis needs to be combined with the impact assessment of the spent-fuel basins provided in the WCGEIS to evaluate the combined effect posed by the nation's fleet of operating reactors. (0496-3 [Batobato, Alicia])

Comment: Impacts of Natural Disasters: The potential risk and effects posed by potential disasters such as posed by floods, dam failures, solar storms, and tsunamis' have not been adequately evaluated in the WCGEIS. New scientific data clearly shows that the risk posed by some of these events is much greater than NRC has acknowledged. For instance, the risk of a dam failure and flooding resulting in a severe accident to the nuclear reactor and/or spent fuel basin has not been adequately addressed. The WCGEIS needs to be revised to address the risks and impacts posed by such events in terms of a national fleet of operating reactors and spent-fuel basins. (0496-8 [Batobato, Alicia])

Comment: Did you know that an extreme solar storm hit Earth in the late 1890's? Did you know that this storm sent large electrical sparks shooting out of the telegraph line machines that existed at the time? http://youtu.be/_6th-VLxKrk Did you know that a huge solar super storm is powerful enough to fry all electric circuits, fry all transformers, and burn/short circuit all electric power grids WORLDWIDE? Did you know that this super solar storm (the Carrington Effect) has been extensively studied, researched and talked about in scientific circles? The scientists are even predicting another one will hit Earth soon, with potentially catastrophic results. "The National Academy of Sciences and several other federal government studies suggest that this extreme solar activity and emissions may result in complete blackouts for years in some areas of the nation. Moreover, there may also be disruption of power supply for years, or even decades, as geomagnetic currents attracted by the storm could debilitate the transformers. supply for years, or even decades, as geomagnetic currents attracted by the storm could debilitate the transformers. <http://youtu.be/GjgDhbKY8vs?t=4m>; Our research team talked with an engineer that is an expert with EMP pulses, such as those that can and will be generated by the sun, via the Carrington Effect. He said there is no way to protect electrical circuits from EMP generated damage or destruction unless they are inside a Faraday Cage, even if they are DISCONNECTED and turned OFF. Watch the PBS NOVA program, called Secrets Of The Sun, which talks in great detail about the Carrington Effect, but leaves out the nuclear power plant link to it. So what did we just learn? Solar scientists, NOAA, NASA, and other researchers all agree that a Carrington Effect is not only possible, but that it is coming. The only question is

when the next huge solar storm will hit Earth. The next question is; will we be ready for it? So what do the pro nuclear apologists say in response to this. First of all, they claim this Carrington Effect does not exist, and will never happen, much like the climate change deniers are all hired by huge corporations to come up with a pro pollution conclusion. Others will claim that this never happened, and it was just ordinary lightning that caused sparks to come out of the telegraph wires. Some naysayers will even claim that they know that an EMP pulse is not possible and cannot exist. The EMP pulse is a well known, well researched and known effect. Read more about it in the following article, by clicking on this link. EMP; lectromagnetic Pulse Effect And High Altitude Nuclear Bombs; via A Green Road Blog; <http://agreenroad.blogspot.com/2012/04/emp-electromagnetic-pulse-effect-and.html>; Next, the pro-nuclear power advocates may say that they will just disconnect a nuke plant from power grids during a Carrington Effect. Unless the whole nuclear plant is inside a Faraday Cage (which not one is) disconnecting it from the grid will make absolutely no difference. But let's assume for a second, just for argument's sake, that the nuclear plant is safe, and the power grid goes down for a lengthy period. (0498-1 [AGreen Road Project, Anonymous])

Comment: A government remote viewing program contained in the CIA reports the same thing is going to happen. The team of remote viewers confirm that the sun will in the very near future produce a HUGE solar storm that will reach Earth and knock out all electricity, plus fry all communications methods. See related articles links below to see the video by a remote viewer. (0498-10 [AGreen Road Project, Anonymous])

Comment: SOLUTIONS FOR THE CARRINGTON EFFECT; Dr Christopher Busby and RSRRW President Roland Von Malmberg discuss this issue in the video below and propose some solutions. They discuss and predict 4,000 Chernobyl disasters will happen worldwide, if nothing is done to prepare for the Carrington Effect. <http://youtu.be/P3L1atAcXwU> The book Busby recommends everyone read is titled: "Defending the Environment: Civil Society Strategies to Enforce International Environmental Law". By Linda A. Malone, Scott Pasternack. 2004, New York. Let's say that somehow you still believe that a solar storm cannot cause a major nuclear disaster. Ok, what are the odds of a major nuclear disaster happening in the USA, even without the Carrington Effect, or a nuclear war? Bottom line, the odds are astronomically high, that a major Fukushima like mega accident will happen in the USA in the foreseeable future. What Is The Statistical Probability Of A Major Nuclear Accident Like Fukushima In The USA? via @AGreenRoad <http://agreenroad.blogspot.com/2013/09/what-is-statistical-probability-of.html> (0498-11 [AGreen Road Project, Anonymous])

Comment: There is only one small problem. This super mega nuclear disaster of 800 nuclear plants and spent fuel pools melting down will go on for tens of thousands of years, with no end. Unless they are willing to live underground PERMANENTLY and forever, they better make some changes happen above ground. No life can survive above ground if all of these plants and spent fuel pools melt down. (0498-13 [AGreen Road Project, Anonymous])

Comment: Bottom line, having the power turn off for a year is a bummer and a lot of people will die. But having the power off for a year and having 400 nuclear power plants and their 400 associated spent fuel pools melt down, melt through and then blow up, just like Fukushima did recently, that is a MUCH BIGGER bummer and a terminal one for humanity. This sad horror story is entirely preventable. Humanity can live through a super solar storm, but only if we all get ready. Do you need some encouragement and passion to be part of the solution, instead of the problem? Listen to a song, and maybe that will help. FRYING DUTCHMAN "humanERROR" <http://www.youtube.com/watch?v=Q5p283KZGa8&feature=youtu.be> This young performer deserves to be on Oprah, all of the news channels and every talk show and

become a #1 hit song worldwide. SAVE THE CHILDREN! If not you, then who? If not now, then when? Who will save the children after the Carrington Effect melts down 400 to 1,000 nuclear power plants, 400 - 1,000 spent fuel pools and they all self destruct, start burning and releasing their HUGE Pandora's Box of horrors on humanity? Will it turn out that for lack of you, it will be too little, too late, with warnings ignored, and predictors silenced? This song should be on NPR, PBS, and all public access cable channels. Get involved. Make a difference. Do what you can. Write a letter to the editor. Pass on the Youtube song. Start a blog and post the link to this article. Copy the article and pass it around at work. Those who serve to cover up the crimes that these criminals are committing are JUST AS GUILTY, as accessories after the fact. HIDING A MURDER ABOUT TO HAPPEN IS NOT ANY DIFFERENT THAN MURDER ITSELF. (0498-17 [AGreen Road Project, Anonymous])

Comment: Most people will agree that having the power go out all across the globe for months, a year, or even longer is a HUGE problem. That power loss will cause a lot of suffering, loss of life and maybe even collapse entire civilizations. But the human race can live through this, if it were not for nuclear power plants. There is something that is even worse than non power for a year. What could be worse than mass starvation, no power, no gasoline pumps and no water pumps working? What we are pointing at is the Fukushima Effect. When the power went out there, we all know what happened there, within 8 hours. MULTIPLE Fukushima nuclear plants melted down, and blew up, along with their spent fuel pools, because they lost their power source FOR 8 HOURS. The pro nuclear apologists promised everyone that this would NEVER happen. source FOR 8 HOURS. The pro nuclear apologists promised everyone that this would NEVER happen. What will happen to all of these 400 global nuclear power plants and their 400 spent fuel pools, if planet Earth loses power for MONTHS or YEARS GLOBALLY, as these scientists and solar researchers are predicting? Remember, this is going to happen, for sure. It is not subject to debate. It is only a question of when it happens, not if. How do we keep all 400-1000 nuclear power plants, spent fuel pools, research facilities, university nuclear research plants, military plants and secret facilities around the world and their associated spent fuel pools globally from melting down and blowing up, after the power has been out for potentially weeks and/or months? The backup power systems of batteries and generators only last for a couple of days at most, if they are not burned out immediately by the EMP pulse. The "experts" all said that the Titanic could NEVER sink. The experts also said that the tsunami that hit Fukushima could NEVER happen. The experts said a multiple melt down and melt through of nuclear power plants could NEVER happen. The experts in the nuclear industry are claiming that a Carrington Effect can NEVER happen. They are not getting ready for it. Do you trust them, after all of the broken promises of free power, safe energy source, and an easy solution for the nuclear wastes? These same nuclear 'experts' knew 20 years ago that a tsunami was coming, but they ignored the warnings. These supposed nuclear experts had plenty of time to get ready for both a tsunami and an earthquake, but they depended on luck more than preparation. It would have cost 100 million bucks to get ready and modify the plant to protect against the tsunami. The experts did nothing. except attack the messengers and 'outsiders' who tried to warn them. The nuclear industry is doing NOTHING to get ready for this Carrington Effect, at least so far. (0498-18 [AGreen Road Project, Anonymous])

Comment: The next climax of solar storms is going to happen, possibly as soon as late in the year 2013, according to various sources. Here is a really neat video and close ups of the sun doing what it does <http://www.youtube.com/watch?v=t0Ehe77wrV0&feature=related> The Solar SuperStorm of 1859 It can happen again, and it will happen again..... guaranteed. NOAA, NASA and all solar scientists, plus PBS experts featured in the video above, all agree on this point. Just like gigantic tsunamis, earthquakes and fires happening at regular though infrequent intervals in human history, a Super Solar Storm will happen again.

http://science.nasa.gov/science-news/science-at-nasa/2009/29may_noaaprediction/ We had better get ready, because the perfect super solar storm is coming soon, just like the tsunamis that have hit various areas of the world recently.. Tsunamis are part of what happens normally every couple of hundred to several thousand years. They are natural. Look what happened to Japan, because they did not get ready for something that was in their historical documents, and in warning monuments placed all along the coast. Super solar storms are natural too. They happen every 50 to 200 years. We may very well experience a Super Solar Storm very soon. Are we ready for this? (0498-19 [AGreen Road Project, Anonymous])

Comment: What happens to a nuclear power plant without ANY POWER supply? As we know, Fukushima melted down within 8 hours of no power. If the generator control circuits are fried, if the computer systems inside the nuclear plant are fried, then the same thing happens and the nuclear plant melts down, along with the spent fuel pools. For those who don't know what happened at Fukushima, here is a short video explaining this mega disaster. Fukushima 5 Minute Summary Of Events 2011 to 2012; via A Green Road <http://agreenroad.blogspot.com/2012/06/fukushima-5-minute-summary-of-events.html>; If the EMP pulse from the sun (or a nuclear weapon) fries the large transformers that connect the nuclear power plant to the grid, that also means the end of human civilization. If the EMP pulse fries the electronics that controls the valves, pumps, meters, etc, that still means a nuclear plant will melt down. ALL of these things have to be protected from an EMP pulse. These circuits, transformers, computers and controls can be protected, but someone has to get these things ready for what is coming. Of course, this all costs a lot of money. The nuclear industry definitely does not want to spend money on this, despite risking an extinction level event. The US military has been doing EMP pulse protection preparation for many years now. They have 'hardened' much of their communications, vehicles and infrastructure to prevent them from being 'fried' in case of a huge solar storm, or an EMP pulse from a nuclear weapon explosion, which is another way this can happen. What if this EMP PULSE/Solar Storm lasts for eight hours or longer? Again, we know that without any doubts or arguments, Fukushima melted down within 8 hours of NOT HAVING ANY POWER.. None of the spent fuel pools will last much longer than that. None of the spent fuel pools can be passively cooled. The spent fuel pools all take electricity and powerful pumps to keep them cool. Fuku again proved this fact by actual example. Without power, the spent fuel pools will boil off the water inside of them, melt down and catch on fire or explode, releasing all of their radioactive contents. This also happened at Fukushima, to multiple spent fuel pools, but is being covered up by TEPCO, the regulators and the Japanese government. (0498-2 [AGreen Road Project, Anonymous])

Comment: We might not be as ready as people were back in the 1890's when the last Solar Super Storm hit Earth, to live without any power at all. Back then, human and animal power accounted for about 95-99% of all power needed for a task. Nowadays, less than 1% of all power needs are generated by animals or humans in the USA. Back then all that existed were a few telegraph wires. When the storm hit, sparks flew out of the telegraph clickers, and started a few fires, but that is about all. Electricity and technology as we know it today did not exist back then. (0498-5 [AGreen Road Project, Anonymous])

Comment: Imagine 10,000 times as much radioactive elements (or more) as Fukushima mega nuclear disaster going into the air, globally, and then NEVER STOPPING, due to radiation releases from uncontrolled melting blobs of corium fissioning into the air forever and possibly causing 400-800 China Syndromes all at the same time. Once these coriums get started, they never stop, and these fires never go out. There is no way to 'extinguish an out of control raging 2,500 - 5,000 degree Fahrenheit nuclear fireball, which is called corium. Corium melts through concrete, steel and soil like a hot knife through butter. What is the Nuclear Regulatory

Commission (NRC) doing to protect the public? What is the EPA doing to protect the public? What is the IAEA doing to protect the public? What are any of the other regulatory, safety, or nuclear marketing and sales organizations doing to protect the public from this Super Solar Storm? NOTHING. As a matter of fact, they are covering up what is happening and protecting the people who are responsible for the potential life extinction event above. (0498-8 [AGreen Road Project, Anonymous])

Comment: In the GEIS, the "probability weighted" impacts of severe accidents (i.e. "design basis" accidents, exceeding parameters to which facilities are designed and built) and "postulated accidents" (hazards from natural phenomena) are estimated to be small, since severe potential consequence is offset by very low calculated probability. Particularly when the potential consequence is severe, NRC's equal weighting of probability and consequence simply does not "calculate" for those most directly affected. For them, the potential consequence of a spent fuel fire or potential sabotage cannot be offset by an analyst's calculation of its very low probability. Thus, the same stakeholders make the same criticisms and suggestions over and over; NRC listens politely; and the critics never feel "heard" by NRC. Perhaps the recently-released NRC white paper on a risk management regulatory framework² [footnote 2 text: Which entertains questions regarding the acceptable level of risk, how risk should be measured and monitored, how to treat uncertainties, and the application of "defense-in-depth"] can suggest ways in which NRC can adjust its heavy reliance on technical risk to the exclusion of other perspectives and other dimensions. (0505-4 [Williams, Jim])

Comment: Storing spent fuel rods on location at nuclear power plants is unsafe from acts of nature and acts of mankind. Dry cask storage is not 100% safe either. The magnitude of the risk is so great that even a slight chance of something going wrong should not be taken. (0512-1 [Bibb, William])

Comment: IED could easily penetrate. Tornadoes, ice storms, flooding, solar flares, meteorites, or even a suicide aircraft could penetrate. (0512-5 [Bibb, William])

Comment: Robert Alvarez, formerly of the DOE, has said the spent fuel from Reactor 4 at Fukushima alone, if its building were to fail and it fell to the ground, could "end civilization" as we know it. In the U.S. reactors have been granted extensions to operate far beyond their useful lives, and beyond design capacity. Our air and aquifers are being contaminated; billions of gallons of water containing dangerous tritium are allowed to enter waterways and our coastal areas. The U.S. has tens of thousands of tons of spent nuclear fuel sitting in waste storage ponds and spent fuel pools. This is a disaster in the making. It has the makings of an event of Biblical proportions. The potential consequences of the failure of one of these pools is unthinkable, and could destroy the Northern Hemisphere, if not the entire world. We truly should learned more, and applied the lessons from Fukushima Daichi. An international response to the crisis is desperately needed. (0515-4 [Stennes, Nancy])

Comment: The Draft tells us that impact of a severe accident would be small. Based on what empirical evidence? Other nuclear powered nations seem to have information - and caution - very differently from the NRC. (0541-4 [Justesen, Evelyn])

Comment: - The Waste Confidence Rule should require that safety margins for spent fuel storage pools and dry cask storage mitigate risks associated with the widest reasonable range of accidents, natural disasters, and security threats. - The safety margins for natural disasters should explicitly consider earthquake seismic threats to storage facilities. - The GEIS does not

appear to explicitly consider seismic risks in the analysis assumptions of potential impacts (Sec 1.8.3) (0548-2 [Gibson, Bruce])

Comment: The NRC has approved on-site storage casks that are not approved for transportation of spent nuclear fuel (SNF). In the event that sea-level or river-level rise threatens the cask site, the fuel would have to be re-casked immediately into approved-for-transportation casks. This would result in an unnecessary radiation exposure to workers, as well as added costs and delays. It is not clear how this transfer would be accomplished since fuel pools will be decommissioned with the reactors. Any additional handling of irradiated fuel increases the odds of an accident and release of radioactivity. (0552-1-18 [Macks, Vic])

Comment: The NRC's Office of Nuclear Security and Incidence Response uses a predictive tool to aid emergency responders during nuclear accidents which indicates that the radiological release from a pool fire following an earthquake could dwarf that of a reactor meltdown. It also indicates that the consequence of the breach of a dry cask is thousands of times less severe. (U.S. Nuclear Regulatory Commission, Office of Nuclear Security and Incidence Response, RASCAL 3.0.05 Workbook, NUREG-1889, September 2007). (Curran). Curran, Diane." Mothers for Peace Attorney Diane Curran urges public participation in Sept. 18 NRC meeting", San Luis Obispo Mothers for Peace, <http://mothersforpeace.org/data/mothers-for-peace-attorney-diane-curran-urges-public-participation-in-sept.-18-nrc-meeting> (0552-2-19 [Macks, Vic])

Comment: Consider, for example, that a storage facility location makes it vulnerable to a catastrophic event of uncommon occurrence. How many facilities located in such places would it take to make a low-probability event be categorized as having a greater than SMALL impact? For example, the NRC recognizes six US reactor sites to have "high" vulnerability to severe flooding by upstream dam failure, and an additional nine reactors have "medium" vulnerability. This information was obtained from a memo entitled "Identification of Generic External Flooding Issue Due to Potential Dam Failures" prepared by the Chief of the Probabilistic Risk Assessment Operational Support Branch of the NRC. The memo further states that "Since dam failures were excluded from consideration of most [safety reviews], its risk contribution has not been addressed to date," and "There is an increase in the estimated frequency of potential dam failure of an order of magnitude" from previous assessments. It is evident from the testimony of Fukushima that one such event would have enormously greater environment impact than all the generic factors considered in the GEIS put together. The left hand of NRC needs to know what the right hand is doing. This particular issue must be evaluated in this GEIS. (0553-12 [Wilshire, Howard])

Comment: Furthermore, this section fails to include an important cause of accidents or exacerbation of accidents: the human factor: There is a very large literature on the contributions of human errors to accidents that have significant impacts on the environment. That history is ignored in this GEIS, but it needs to be factored in for all time frames considered. Human errors are not a given, but their frequency and persistence throughout our grand nuclear experiment have a certain generic flavor. The opportunity for mistakes with environmental consequences is enhanced by the large, and getting larger, number of dry cask designs, which require broadened knowledge for activities designed to ensure cask integrity, including inspection, monitoring, and replacement repeated at intervals greater than typical life-times of the inspectors-that is, the "activity" may be the same or similar forever, but those implementing the actions have by comparison a very rapid turnover. The historical record shows clearly that the majority of significant accidents are due to, or exacerbated by human errors, so calling on the "protections" of design, construction, and regulations is irrelevant. The opportunity for human error, especially considering the time that continued storage at a reactor is rationalized as

generically safe (up to 140 years), warrants assessment. In effect, most of the environmental impact assessments are best case scenarios. (0553-13 [Wilshire, Howard])

Comment: The draft assessed environmental impacts using a faulty and outdated Probabilistic Risk Assessment (PRA). NRC multiplied consequences by an unjustified low probability so that no matter how large the consequences, they are trivialized by NRC's choice of a "generic," infinitesimally small, probability of occurrence. (0556-1-12 [Lampert, Mary])

Comment: NRC relied on consequence studies that used an unreliable and outdated consequence code - MACCS or MACCS2. David Chanin, who wrote the FORTRAN for the code while at Sandia said, "It is my firm belief that the MACCS2 cost model is so seriously flawed that even with reevaluation and modification of all its input parameters, its cost results should not be used unless for replicating prior studies." (0556-1-13 [Lampert, Mary])

Comment: Reactors vary in susceptibility to flooding. For example, the Prairie Island reactors are located on an island in the Mississippi River and the Three Mile Island reactors are located in an island on the Susquehanna River. The Columbia Washington Reactor is located close to the Columbia River, and Indian Point is located close to the eastern shore of the Hudson River. Reactors also vary in whether NRC has covered up a reactor's susceptibility to flooding. The Huffington Post² [footnote 2 text: Flood Threat to Nuclear Plants Covered Up By Regulators, NRC Whistleblower Claims, Huffington Post, Sept., 14, 2013] reported in September that: In a letter submitted Friday afternoon to internal investigators at the Nuclear Regulatory Commission, a whistleblower engineer within the agency accused regulators of deliberately covering up information relating to the vulnerability of U.S. nuclear power facilities that sit downstream from large dams and reservoirs. The letter also accuses the agency of failing to act to correct these vulnerabilities despite being aware of the risks for years. (0556-1-17 [Lampert, Mary])

Comment: In addition to failing to evaluate impacts on a site specific basis and relying on unsupported and absurd assumptions, the DGEIS used an outdated and faulty PRA to reach its conclusions, which defy common sense. NRC evaluated environmental impacts using probabilistic risk assessment, multiplying the probability of an accident with the consequences of the accident. Because NRC used an outdated and unsupported low probability and minimized consequences, the environmental impacts were assessed as small over the three time frames, with the exception of historic and cultural resources, for which it could not determine the impact over the long and indefinite storage time frames. For example, NRC determined that "The consequences for severe (or beyond-design-basis) accident, if one occurs, could be significant and destabilizing. The impact determinations of these accidents, however, are made with consideration of the low probability of events... a high- consequence low-probability event, like a severe accident, could still result in a small impact determination, if the risk is sufficiently low." (DGEIS, 4-68) NRC's evaluation of environmental impacts -- consequences -- relied on "cherry-picked" studies that used pre-Fukushima probabilities and assumptions, and antiquated consequence codes: MACCS and MACCS2. It is as if NRC started with the answer and worked backwards to get the predetermined result. (0556-2-11 [Lampert, Mary])

Comment: Qualitative factors are ignored in the DGEIS analysis and as a consequence they do not account for unknowns such as human error, meteorology, future sea level rise, manufacturing defects, corrosion rates, etc. Chairman Macfarlane explained in the Notation Vote that, "These uncertainties are best done qualitatively (and) [t]he uncertainties in attempting to quantify an accident frequency should be offset by defense-in-depth. Being a geologist, I have an acute appreciation for the challenge of predicting the Earth's behavior. Since the earth

is constantly changing and our recorded knowledge represents one millionth of the Earth's history, there is much we do not know. In light of this, we must be wise in balancing confidence in our engineering prowess with the humble recognition that natural systems have repeatedly demonstrated the ability to confound us. The staff (SECY-12-107) also points out the large uncertainties involved in estimating the economic consequences given a large release of radioactive material using the existing economic consequences framework. An increase in either the event frequency or economic consequences of a severe accident at a nuclear power facility could easily push a filtered vent (in the Notation Vote context) into cost beneficial space." (0556-2-13 [Lampert, Mary])

Comment: If NRC treated uncertainties qualitatively, it "could easily push" the environmental impacts from small or moderate to large. Kamiar Jamali's *Use of Risk Measures in Design and Licensing Future Reactors*,¹⁹ [footnote 19 text: Kamiar Jamali, *Use of Risk Measures in Design and Licensing Future Reactors*, Reliability Engineering and System Safety 95 (2010) 935-943. Jamali is DOE Project Manager for Code Manual for MACCS2.] explained further that "PRA" uncertainties are so large and so unknowable that it is a huge mistake to use a single number coming from them for any decision regarding adequate protection. "Examples of these uncertainties include probabilistic quantification of single and common-cause hardware or software failures, occurrence of certain physical phenomena, human errors of omission and commission, magnitudes of source terms, radionuclide release and transport, atmospheric dispersion, biological effects of radiation, dose calculations, and many others." (Jamali, Pg., 935) (Emphasis added) Probability analysis has other pitfalls. PRAs do not consider human error. More important, PRAs project into the future and assume (based on very little real experience) that there is a likelihood that an accident scenario will occur in hundreds, if not thousands, of years is vanishingly small. But no reactors have operated more than 45 years, and there have been at least six severe accidents.²⁰ [footnote 20 text: Including the 1961 fatal accident at SL-1] The uncertainty inherent in predicting the future must be respected by making certain that appropriate and up-to-date assumptions are used in the analysis. NRC did not do this. (0556-2-14 [Lampert, Mary])

Comment: In the event of a severe accident at Pilgrim's location, there will be enormous aqueous radioactive releases and damage. The NRC's approved consequence analysis code (MACCS/MACCS2) ignores aqueous releases. Fukushima shows their huge impact on environmental resources. (0556-2-16 [Lampert, Mary])

Comment: NRC assumes that an accident will last only a day (that is also the usual industry practice) and in any event not more than 4 days (MACCS2 code's maximum limit). Fukushima showed accidents can extend for weeks and months, greatly increasing environmental impact. (0556-2-17 [Lampert, Mary])

Comment: The MACCS2 code that referenced documents used to model economic consequences of a severe accident is, at best severely limited in what it can do and what it cannot. Even in those areas where the MACCS2 code has some applicability, the code is manipulated to intentionally minimize potential consequences, to ignore real health costs, and to assign a too low cost to the value of a human life, compared to other agencies such as EPA. It uses essentially useless evacuation time estimates; the user chooses the input parameters into the model and chooses to average the code's inputs by a mean instead of using the 95th percentile. David Chanin, who wrote the MACCS/MACCS2 code's FORTRAN and SAND96-0957, finds the economic cost model "seriously flawed": "I have spent much time thinking of a way to--jigger the inputs so that the cost model of MACCS2 could be used in a sensible way. As the person who coded it into MACCS and then refined it for MACCS2, and also the person who

wrote SAND96-0957, I think what you are attempting is impossible. The economic cost model in MACCS2 was included (at request of sponsors) only for historical reasons to allow comparison of its cost estimates to those of previous studies. It is my firm belief that the MACCS2 cost model is so seriously flawed that even with reevaluation and modification of all its input parameters, its cost results should not be used unless for replicating prior studies. When I was involved with the MACCS2 project (from 1991-1996, and also later in 2000-2001) the NRC had no interest in implementing the cost model of SAND96-0957 into MACCS2. I could have done it without a lot of work, but they weren't interested."²¹ [footnote 21 text: EHD, Pilgrim 50-293-LR, Intervenor Exhibits, PWA00004, August 23, 2006] (PWA00004, August 23, 2006) (0556-2-21 [Lampert, Mary])

Comment: Mr. Chanin also explained²² [footnote 22 text: Ibid, PWA00004, "The Development of MACCS2: Lessons Learned," [written for:] *EFCOG Safety Analysis Annual Workshop Proceedings*, Santa Fe, NM, April 29–May 5, 2005]] that the MACCS2 code was not held to the QA requirements of NQA-a (American Society of Mechanical Engineering, QA Program Requirements for Nuclear Facilities, 1994). Rather it was developed using following the less rigorous QA guidelines of ANSI/ANS 10.4. [American Nuclear Standards Institute and American Nuclear Society, *Guidelines for the Verification and Validation of Scientific and Engineering Codes for the Nuclear Industry*, ANSI/ANS 10.4, La Grange Park, IL (1987)]. What this means is that all steps of the code development have not been documented and tested, and hand calculations have not verified the code's implementation of major transport and exposure pathways for a subset of the radionuclide library. (*Ibid.*) Mr. Chanin says further that, "If errors are later found in authorization basis calculations, an Unreviewed Safety Question (USQ) could be raised, and continued operation of the facility would then require a demonstration that the facility's safety basis was adequate." (Emphasis added.) Further, Mr. Chanin explains the importance of this point in his concluding remarks in *The Development of MACCS2, Lessons Learned*, prepared for the Energy Facilities Contractor Operating Group Safety Analysis Working Group, Annual Workshop, April 29–May 5, 2005, Santa Fe, NM. [T]he QA distinctions between an NQA-1 "licensing code" and a "research code" like MACCS2 have been emphasized in light of the fact that MACCS2 calculations are being used to support the Severe Accident Mitigation Alternatives (SAMA) analyses required for the license renewal of commercial nuclear power plants. It seems to me that the code's QA shortcomings and the lack of input justifications are again being ignored. The analysis described above applies to use of the code in studies referenced for support by the DGEIS and in turn the Waste Confidence decision. (0556-2-22 [Lampert, Mary])

Comment: Pilgrim's situation is instructive, in that its location on the coast of the Atlantic Ocean, unprotected from storm and wave action, creates unique environmental exposures relative to an inland plant. We need look no further than the Fukushima Nuclear Plant disaster to see how destructive wave action and salt water can affect a nuclear plant's systems. When we take into account the world's rising sea levels, and the inevitability of a destructive 100-year storm, the dangers of nuclear storage for Pilgrim become even more apparent. (0607-3 [Messinger, Michael])

Comment: The NRC is inappropriately applying the same weighting of probability and risk ratios that one would apply to a standard industrial mishap to an accident involving the release of radio-nucleotides into the environment. In fact, the NRC is unable to calculate the likelihood of all the variables and contingencies that attend major nuclear accidents, most significantly operator error. The NRC's theoretical probabilistic risk assessment is fraught with ambiguity and uncertainty, and does not rise to the level of accuracy needed to justify the claim of insignificant risk. The GEIS cannot assess or quantify the billions of small events that contribute to nuclear

accidents in the real world. We note that the probabilistic risk assessment used in the GEIS is the same approach used by Japan's Nuclear and Industrial Safety Agency in assessing the safety of Fukushima Daiichi and served as the basis of approval of a ten-year extension of the plant's operating license a month before it was destroyed by an earthquake and tsunami. The GEIS fails to note that nuclear accidents happen with greater frequency than the NRC's probabilistic risk assessment model predicts.⁴ [footnote 4 text: 4 Bulletin of the Atomic Scientists, "Beyond our Imagination: Fukushima and the problem of assessing risk," April 20, 2011.] The Bulletin of the Atomic Scientists cites the actual frequency of severe accidents in contrast to misleading claims about reactor accident frequency based on PRA, the poor record of PRA in modeling unexpected failure modes and common-cause failures, and the finding by MIT researchers that the PRA model fails to include indirect, non-linear and feedback relationships in chain-of-event risk assessments. It concludes: "The multiple problems with the probabilistic risk assessment method suggest that any conclusions about overall accident probabilities derived from its use are far from dependable...[Probabilistic risk assessments] create overconfidence among those designing and operating reactors." We agree that the complete reliance of the GEIS on probabilistic risk assessment to determine the actual risk and impact of accidents at nuclear power plants is misplaced. (0614-10 [Christie, Andrew])

Comment: The GEIS omits meaningful description of risk. In virtually every instance, the GEIS underplays or omits the actual consequences of a nuclear accident or an attack on a facility resulting in the release of radioactive material into the environment. The GEIS primarily contents itself with a single adjective -- "small" or "large," or "significant" and "destabilizing" -- offered as an analysis of environmental impacts. Had such an analysis been performed for Fukushima Daiichi, pre-tsunami, the potential impact of multiple reactor core meltdowns would have been classified as "small" because the possibility was remote. Potential effects would have been termed "large" or "significant and destabilizing" but such details of the possible evacuation of Tokyo and the destruction of Japan's economy would have been omitted. (0614-5 [Christie, Andrew])

Comment: The NRC's method of determining risk is deficient. The NRC's method of determining risk of accident or attack, in every instance, results in a determination that a high-consequence/low-probability scenario equates to a "small" environmental effect: The NRC finds that even though the environmental consequences of a successful attack on a spent fuel pool during continued storage are large, the very low probability of a successful attack ensures that the environmental risk is SMALL. Similarly, for operational ISFSIs during continued storage, the NRC finds that the environmental risk is SMALL. (0614-9 [Christie, Andrew])

Comment: In reality, PRAs utterly fail to assess the dangers of ongoing operations with no end in sight. 100-year floods and earthquakes become inevitable instead of rare if you wait long enough -- and that seems to be exactly what the nuclear industry wants: For us all to wait until there is a disaster, only to claim they never saw it coming. (0616-7 [Hoffman, Ace])

Comment: There isn't any city or town in Southern California which is a suitable site for a nuclear waste dump, and certainly not ours. San Onofre is situated in an earthquake and tsunami zone in the middle of two large metropolitan areas. (0618-3 [Johnson, Roger])

Comment: Severe accidents: Section 4.18 of the draft GEIS discusses the environmental impacts of postulated accidents (design basis or severe) and concludes that, although the consequences would be significant and destabilizing, the risk is SMALL because the likelihood of these events occurring is remote. There is no discussion of the potential economic consequences of postulated accidents. This should be included in the final GEIS. It is not

enough to state that the likelihood is remote and end the discussion. These consequences must be fully evaluated in the draft GEIS. As the final Waste Confidence GEIS will no doubt be held up by some as 'proof' that long-term or indefinite storage is without environmental impact, the final GEIS must include some discussion or evaluation of the socioeconomic impacts to communities from severe or design-basis accidents. As one of the closest communities to an ISFSI, our Tribe has a lot at stake. Our lands are held in Trust by the United States government for the benefit of all current and future tribal members. Our main source of revenue -Treasure Island Resort and Casino -is located on this land, just one mile from the PINGP ISFSI. The economic consequences to our Tribe from an accident would be great: the Tribe could no longer provide needed benefits and services to our tribal members, tribal members could no longer reside on tribal lands (due to contamination), and our traditions and culture would be irreparably harmed. This is not an impact or consequence that can be addressed generically. (0619-2-1 [Mahowald, Philip R.])

Comment: Lastly, the impacts of postulated accidents on surface water quality and use should be fully assessed in Section 4.18 of the DGIS. (0622-2-10 [Vale, Karen])

Comment: Lastly, the impacts of postulated accidents on groundwater quality and use should be fully assessed in Section 4.18 of the DGIS. (0622-2-17 [Vale, Karen])

Comment: Lastly, the NRC should also fully assess the impacts of postulated accidents on site-specific aquatic resources. (0622-3-7 [Vale, Karen])

Comment: Section 4.18 discusses the environmental impacts of postulated accidents involving the continued storage of spent fuel. However, the NRC primarily discusses the impacts that natural phenomena and external events would have on the safety systems associated with pools and ISFSIs. Instead, the DGEIS should fully assess the impacts that postulated accidents would have on the affected environment (e.g., aquatic resources, special status species, terrestrial resources, etc.). (0622-4-1 [Vale, Karen])

Comment: We disagree with the statement on page 1-5, where the NRC states, "Changes in the environment around spent fuel storage facilities are sufficiently gradual and predictable to be addressed using a generic approach." While climate change is predicted, its impacts are not considered to be exact and orderly, nor are these changes expected to be "gradual." Storms such as "Superstorm Sandy" in October 2012 and the recent cyclone in the Philippines are but two examples of unexpected, unpredicted, and rapid changes with extraordinary significance. The environmental consequences of super storms, storm surges, and excessive wave action on dry casks are not acknowledged nor are they addressed in the DGEIS (the issues are only briefly mentioned as they relate to pool storage). (0622-4-10 [Vale, Karen])

Comment: Section 4.18 of the DGEIS also concludes that the environmental impacts of postulated accidents involving continued storage of spent fuel in pools and ISFSIs would be "SMALL" because all important safety structures, systems, and components involved with the spent fuel storage are designed to withstand these design basis accidents without compromising the safety functions. However, the NRC should assess environmental impacts associated with postulated accidents where safety structures and systems do not work properly -as has happened in real world situations. (0622-4-2 [Vale, Karen])

Comment: The DGEIS also does not consider the issue of marine debris. More debris comes ashore during and after periods of inclement weather (e.g., storms and heavy seas).²⁴ [footnote 24 text: Ribic CA, Sheavly SB, Rugg DJ, and Erdmann ES. 2010. Trends and drivers of marine

debris on the Atlantic coast of the United States 1997-2007. Marine Pollution Bulletin. 60: 1231-1242] Therefore, when storms occur and their intensity increases due to climate change, the coast could increasingly be subject to problems associated with marine debris. The NRC should assess impacts of marine debris clogging intake structures needed to provide cooling water for spent fuel pools as well as clogging ISFSI cooling vents. There are regional differences in quantity, composition and trends of marine debris, therefore the NRC should carry out site-specific assessments of this potential problem. (0622-4-6 [Vale, Karen])

Comment: Out of sight does not mean out of mind for most of us who are aware of where this deadly waste is being kept until an earthquake or some other natural or man made event damages the storage facility, as it 100% will. (0625-4 [Mandrell, Rebecca])

Comment: Further, the current storage periods are grossly out of touch with known and established hazards and potential loss of life and habitat following any breach of containment or cooling. (0629-2 [Individual, Anonymous])

Comment: In addition, plants are close to population centers--over 1/3 of the U.S. population now lives within 50 miles of a nuclear power plant. Many plants are in flood plains, or in earthquake, hurricane, or tornado zones. (0633-4 [Kurz, Carol])

Comment: The Fukushima disaster in Japan, Chernobyl in the Soviet Union and Three Mile Island in the USA have demonstrated very clearly that a technologically elite country with a strong government, like the USA can still have a disaster with stored radioactive waste (spent fuel) that literally may be so costly as to make the countries future uncertain, and ruin the health of literally millions of people. (0634-7 [Cato, Michael])

Comment: Probabilistic Risk Assessments are empty words and math when they fail utterly to assess the dangers of ongoing operations with no end in sight. The 100-year flood or earthquake WILL happen. (0640-5 [Geary, B.])

Comment: I have to write to you again after listening to the NPR interview of a former anti-nuclear activist who now believes the only way to counter global warming is to increase nuclear power and to "make it safer". He overlooks that it has not been made safer in the half century it has existed and that saying it will "be safer" does not make it so. He forgets that in over 50 years, the nuclear industry has found no solution to the problems of nuclear waste and the countless contaminating accidents and errors and catastrophes that have already occurred.. (0641-1 [Fasten, Susan])

Comment: Please act in the most responsible way possible and choose the surest and quickest path for PREVENTING any chance of a future problem by putting the waste in the most secure and advanced form of storage far away from oceans, people and seismic zones. History has proven that it is not safe to accept any level of risk, because now matter how conservatively we estimate tolerances and requirements, nature always exceeds our wildest estimates. (0659-2 [Stanick, Kim])

Comment: If there was just one lesson to be learned from the ongoing nuclear disaster in Japan it is that our best science and engineering is no match for the unpredictable forces of nature. (0660-4 [Headrick, Gary])

Comment: Nuke plants are grid dependent for cooling. When the grid goes down, there is only one week of diesel on site to provide back-up to cool the plants. The diesel generators have

been known to fail. More Chernobyls and Fukushima's are a certainty if we do not shut these plants down while we have some control and foresight. (0662-5 [McClintock, Francene])

Comment: California is not safe ground, we have not had a earth quake of powerful magnitude in the San Clemente area. Even worse if there is an earthquake in this area, we could have another Japan incident which is radiating the ocean and our fish and moving to all coasts i that meet the pacific ocean (0664-2 [BojeLebs, Nannette])

Comment: ESPECIALLY WITH EARTHQUAKES! JAPAN, NOW HAVING ABOUT A 5.0 per day, after Fukushima (and probably before). We are long overdue and a Cascadia Sub-duction event could trigger a San Andreas Fault event. (0668-3 [Gordon, Mark] [Gordon, Michelle])

Comment: The NRC 's analysis of a design basis event in dry cask storage fails to consider at least one foreseeable event , and provides no rationale as to why the two accidents that it does consider are representative. It examines only two scenarios involving a DTS : rods getting stuck and a loss of the air filtration system while a cask is open. (4-77 to 4-78 .) It calls these "representative" of types of events that could impact the environment, but it provides no basis or reason for this. (4-77.) The draft GEIS also states that the accident with highest consequences is a canister being dropped during cask loading when an earthquake happens. (4-82.) Consequently, it would be reasonable to expect analysis of the effects of an earthquake occurring while a cask is open; but it does not appear that the NRC considered this. (0669-14 [Walter, Joan])

Comment: The four reactor sites located in New York have different characteristics from one another. NRC also must carefully examine the environmental impacts that would occur as a result of an accident with the waste storage facilities at Indian Point. The Indian Point reactors and waste storage pools and casks are located in Westchester County -- 24 miles from the northern border of the City of New York. In 1956, the federal government authorized the construction of a nuclear power reactor at the Indian Point site before there were siting criteria for such facilities - and before there was a federal policy to allow the accumulation of spent nuclear waste at such facilities. During the construction of the second and third reactor at Indian Point, the federal government told New Yorkers that the spent nuclear fuel generated at the Indian Point facilities would be quickly removed from the site and transported to facilities located elsewhere where the waste would be reprocessed. Indian Point Unit 2 Final EIS ML072390276 at 257 (Sept. 1972); Indian Point Unit 3 Final EIS, ML072390284 at 412 (Feb. 1975). The Indian Point site has the highest surrounding population of any licensed reactor site in the United States. NRC previously found that more than 15 million people lived within 50 miles of Indian Point as of 1990.⁹ [footnote 9 text: NUREG-1437 Generic Environmental Impact Statement for License Renewal (1996) at Table 2.1 & § 2.2 (pages 2-2 - 2-8).] That population will grow in coming years. According to the Environmental Report prepared by Entergy and submitted as part of its application to renew the operating licenses for Indian Point Unit 2 and Unit 3, by 2035 19.2 million people will live within 50 miles of the Indian Point site and its inventory of spent nuclear fuel.¹⁰ [footnote 10 text:Environmental Report for License Renewal of Indian Point Unit 2 and Unit 3 (2007) at 2-35 ("The total population (including transient populations) within a 50-mile radius of the site is projected to be 19,228,712 in 2035.").] As confirmed by NRC's own data, no reactor site in the country comes close to the population profile of Indian Point [Table included in original correspondence...See ML13360A111 for table] Top Ten U.S. Nuclear Power Plant Sites in Terms of Surrounding Population Based on NRC NUREG-1437 (1996) Table 2-1, Nuclear Power Plant Baseline Information. Moreover, each day tens of thousands people commute or travel into the 50 mile radius around the plant site. According to Entergy, "An estimated 41 million people visit the New York Metropolitan area each year, or approximately 112,329 people

per day."¹¹ [footnote 11 text:Entergy Environmental Report for License Renewal of Indian Point Unit 2 and Unit 3 at 2-62./rulemaking1cem.resource@nrc.gov.] Indian Point is in close proximity to the New York City metropolitan area, the financial center of the country, critical transportation links, and unique scientific, medical, educational, and historical resources. Indian Point's spent fuel pools, dry storage casks and reactors are 6 miles from reservoirs that are part of the New York City Watershed - which provides drinking water for 8 million city residents. It is also near drinking water resources for other New York and Connecticut communities. (0681-10 [Peterson, Alyse])

Comment: Given these unique and specific characteristics, the State requests that NRC conduct an open, credible, and transparent site specific severe accident mitigation (SAMA) alternatives analysis for the continued storage of spent nuclear fuel in the pools and in the casks at the Indian Point site - similar to the SAMA analysis that NRC conducted for each reactor at the Indian Point site. 10 C.F.R. § 51.53(c)(3)(ii)(L). (0681-11 [Peterson, Alyse])

Comment: In terms of risk analysis, I am troubled by the epistemic uncertainties that fundamentally undermine any claim to adequately model and regulate systems as complex and hazardous as nuclear power plants, used fuel storage pools, interim storage sites, waste transportation infrastructures, and permanent waste repositories. (0684-2 [Kinsella, William])

Comment: The Draft GEIS claims that impact of a severe accident would be small. Such a conclusion cannot be supported by logic or experience. A severe accident would release deadly radioactivity into the environment. Every release of manmade radioactive matter into the environment to date has had serious and long-lasting impacts on humans and other living things within the area affected. (0686-3 [Malboeuf, Simone])

Comment: It's my understanding based on the former Chief of the Nuclear Regulatory Commission that all 104 of our nuclear plants have safety issues as well. Many sit beneath dams or near earthquake faults. Many on the East Coast are old and now endangered by climate change tremendous hurricanes as Hurricane Sandy demonstrated. (0690-2 [Eisman, Val])

Comment: The Near Term Task Force said, "NRC Inspection and licensing programs give less attention to beyond design basis requirements and little attention to industry voluntary initiatives since there are no requirements to inspect against. As a result the NRC gives much more attention to design-basis events than to severe accidents." (p. 19) The Task Force called for correction of the patchwork regulatory approach that consists of some requirements as well as voluntary industry initiatives. Spent fuel pools were identified as being in this regulatory patchwork with some safety related equipment and some equipment not identified as safety related. The potential for catastrophic harm from spent fuel falls into the severe accident scenarios that NRC has not given sufficient attention to. The Waste Confidence GEIS should have provided an opportunity to address the patchwork and to address severe accidents associated with fuel pools. Instead the NRC deferred this entire issue to the future, making the assumption that the entire regulatory structure remains the same. (p. 2-12 GEIS) NRC has requested additional information from licensees regarding spent fuel pools but has not yet received this information. (0693-2-16 [Warren, Barbara])

Comment: •According to the NRC, there is no potential for accidents, for release of radioactivity, for leaks that impact air or water quality, for adverse impacts because they are all under some sort of regulatory control. This view is factually and scientifically unsupportable. Under such a belief system, a grain silo would pose a more significant environmental impact than a highly radioactive spent fuel storage facility. As we have experienced in many different

situations, regulatory control is not fool proof - airplanes and trains crash, industrial facilities explode, catch fire and release poisonous gases, food is contaminated and recalled, etc, etc. (0693-3-12 [Warren, Barbara])

Comment: •The environmental analyses are repeatedly constrained to NORMAL operations. In other words, adverse impacts from errors, spills, accidents, fires, loss of water in fuel pools have not been analyzed, because they are not NORMAL. Severe accidents have largely been dealt with by NRC under voluntary industry initiatives, and as a result have few regulatory requirements. This issue was highlighted by the Fukushima Near Term Task Force as part of the "regulatory patchwork" problem. Unfortunately severe accidents are a major concern associated with the storage of spent fuel. (0693-4-4 [Warren, Barbara])

Comment: •For risk-based determinations, NRC uses the probability of occurrence as well as the potential consequences, to find such occurrences unlikely. The experience of Richard Feynman, Nobel Prize winner, in analyzing the Challenger Disaster, that killed all astronauts aboard, is illustrative. NASA assumed that a severe accident would occur very infrequently--almost never--when the actual probability was once in 200 flights. US banks used probabilistic risk assessment to evaluate the risks of their portfolios only to find after the 2008 economic crash they caused, that their analyses served to ensure failure rather than providing a measure of safety. (0693-4-5 [Warren, Barbara])

Comment: Moreover, the significant robust protection from external events has been demonstrated by real world events, including the August 23, 2011 Mineral, Virginia earthquake near the North Anna nuclear power plant and the March 11, 2011 earthquake and subsequent tsunami that damaged the Fukushima Dai-ichi nuclear power plant. Neither event resulted in significant damage to or the release of radionuclides from the dry cask storage containers. (0694-3-9 [Shea, Joseph])

Comment: Moreover, the significant robust protection from external events has been demonstrated by real world events, including the August 23, 2011 Mineral, Virginia earthquake near the North Anna nuclear power plant and the March 11, 2011 earthquake and subsequent tsunami that damaged the Fukushima Dai-ichi nuclear power plant. Neither event resulted in significant damage to or the release of radionuclides from the dry cask storage containers. With respect to the earthquake near North Anna, Entergy's ISFSIs, including the IPEC ISFSI, similarly use NRC-approved casks and comply fully with the requirements of 10 C.F.R. Part 72. (0697-2-18 [Bessette, Paul] [Kuyler, Raphael])

Comment: The theory that Spent Nuclear Fuel should be stored at the existing Nuclear Power Plants is a very dangerous theory. The information below is why I know that storing Spent Fuel at Nuclear Power Plants is a very reckless activity. Nuclear Power Plants were built in locations that are ideal for nuclear production of electricity. Recent discoveries of previously unknown fault lines and our improved understanding of Tectonic Plate Activity has changed the safety factor for storing spent fuel at Nuclear Power Plants. Each Nuclear Power Plant must have a separate topographical survey and access to a safe transportation corridor to the closest safe location for spent fuel to be stored in a safe accessible manor. (0701-1 [Wilson, Greg])

Comment: No one can safely predict what changes the California Coastline will experience over the next 250,000 years. The west coast could be hit by an Hawaiian tsunami. The movie "Hawaiian Tsunami" exposes the fact that the Hawaiian Islands crumble apart due to iron mixed in with the lava erupting out of the volcano. The iron rusts causing the volcano dome to fall apart creating massive tsunamis. At least one tsunami has flooded the Los Angeles Basin in California.

Large tsunamis from several different fault lines have hit the West Coast without warning and a Fukushima type of event or meltdown could happen to any spent fuel stored along the Pacific Coast. (0701-11 [Wilson, Greg])

Comment: The active volcano named Cumbre Vieja is on the Isle de La Palma in the Canary Islands west of Africa in the Atlantic Ocean. During a previous eruption of Cumbre Vieja 10 miles of the western flank of the island slid several yards to the west. A large portion of the island is ready to slide into the Atlantic Ocean. The assumption can be made that Cumbre Vieja also has iron mixed in the lave that comprises the lave rock on the island. When the large part of the island falls into the Atlantic Ocean a large 1,000 foot tall massive tsunami moving at 1,000 miles per hour will hammer all of the surrounding continents in the Atlantic. Western Europe, The British Isles, the Irish Sea, Ireland and West Africa will be hit in three hours with devastating results. All nuclear power plants and spent fuel must be moved off the Atlantic Ocean including the facilities Europe and the British Isles and the Irish Sea. The East Coast of the United States, The Caribbean Islands, Puerto Rico, Cuba, and South America will be hit in five hours by a 600 foot tall tsunami traveling at 600 miles per hour. Millions of Americans will die and 26 Nuclear Power Plants will be destroyed. The spent fuel containers at every Atlantic nuclear power plant will be destroyed and the spent fuel will be washed away and scattered across the land. All of the spent fuel must be moved away from the Atlantic Ocean and to a Long Term Storage on high ground. The Long Term Storage must be at the closest possible site for the Nuclear Power Plant that it supports. If two Nuclear Power Plants are close to each other a common Long Term Storage site could be used. The Long Term Storage sites must be built on a raised ground at least 1,000 feet in elevation. This same strategy could increase the safety during hurricanes with their 20 foot plus tall storm surge wave and the 12 foot high surf zone. Hurricanes are getting bigger and stronger due to global warming and they are having a greater impact on northern coastlines. (0701-12 [Wilson, Greg])

Comment: All spent fuel and associated waste must be moved away from all coast lines world wide. Russia has lost two unmanned nuclear power lighthouses into the Arctic Ocean. The land under the lighthouses was washed away by storms. Predicting earthquakes, volcanoes, landslides, asteroids, comets, methane gas bubbles will always cause tsunamis that will destroy coastlines. Long Term Storage at a nuclear power plant of spent fuel and/or nuclear waste should never be an option. I have zero confidence in storing any spent fuel on any coastline in the world. The oceans must be respected as the source of all life on Mother Earth. (0701-15 [Wilson, Greg])

Comment: No one can predict when or even if the Yellowstone Volcano will erupt but the warning time is very short and there will not be any time to develop a plan to deal with total destruction in the middle of the country. All of the Nuclear Power Plants in that region must be shut down and moth balled as fast as possible. All nuclear material must be transported out of the predicted ash cloud area. Internal combustion engines have a very hard time running with volcanic ash in the air. The back up diesel for the nuclear power plants will not run very well as the air filters will clog up. The workers that survive the eruption working at the power plants must be evacuated to a safe part of the country. The ash cloud could last for decades and it may be centuries before the region is repopulated. The eruption of the Yellowstone Super Volcano will be a planet wide near extinction event. Add in the radioactive nuclear debris to the volcano event and it will be a complete worldwide extinction event. (0701-16 [Wilson, Greg])

Comment: An asteroid the size of Tunguska exploding over a nuclear power plant would destroy the reactor core and all of the spent fuel storage containers. All Long Term Storage Containers must be stored underground to protect them from asteroid air blasts. A direct hit on

any spent fuel storage by an asteroid will be a major radiation release event. Many more Nuclear Power Plants are located over unknown fault lines and which may not be revealed for centuries. (0701-17 [Wilson, Greg])

Comment: The prediction by the geologists in this movie is 99% that Southern California will have a major San Andreas earthquake in the next 30 years. The movie did not mention what will happen to the San Onofre Nuclear Power Plant or the spent fuel. A safe long term storage site that is near San Onofre should be found. Due east within ten miles of the nuclear plant would be a better location than keeping the spent nuclear fuel on the coast line and on the fault line. Everyone must see this movie before a decision is made about what to do with the spent fuel rods and how they are stored. This is not the only movie that explains Plate Tectonics, and/or volcanoes that will destroy Nuclear Power Plants. (0701-8 [Wilson, Greg])

Comment: Probabilistic Risk Assessments and Environmental Impact Statements: Both of these tools must assume that events such as earthquakes and 100-year floods will happen at some time during the lifetime of a nuclear facility, because these events do happen sooner or later. (With climate change and fracking, they are happening more often.) If we continue to operate nuclear power plants, there will eventually be another disaster. (0705-4 [Spring, Janet])

Comment: If high burnup fuel rods (or other spent fuel rods) were involved in a criticality accident as the water boiled away in the pool, any degraded thermal conductivity of such fuel rods would play a *significant* role in increasing local fuel and fuel-cladding temperatures, because the heat flux would be high. (0706-5-25 [Fettus, Geoffrey])

Comment: In reality, PRAs utterly fail to assess the dangers of ongoing operations with no end in sight. 100-year floods and earthquakes become inevitable instead of rare if you wait long enough -- and that seems to be exactly what the nuclear industry wants: For us all to wait until there is a disaster, only to claim they never saw it coming. (0709-7 [Wythe Elnagar, Romi])

Comment: NRC Fails to Address, Communicate or Mitigate Real Hazards[:] NRC staff uses the GEIS to merely dismiss risks associated with the clear--and--present--dangers associated with the waste that has resulted from the licenses it has granted as "insignificant" or not "cost effective" to mitigate. NRC has a long-term historical pattern of protecting its licensees rather than the public. In addition, the notion of "The Public" misses impacts to real people that occur on a daily basis. NRC must stop the policy of protecting its licensees from the outcomes of nuclear failures. In addition to "risk" there is the matter of "significance." It is time that the significance of the impact of nuclear events be understood from the perspective of our communities. After the impacts and consequences of a potential event (like a fuel pool fire) are assessed, they should be disclosed, in full, without a risk or probability "factor" or modifier. Once a clear statement of the potential impacts and consequences (it may be a range) is done--and communicated, then it would be appropriate to communicate the probability / risk factors including the assumptions used, choices made, how the analysis was generated, how it would be applied. All of this should be fully disclosed in lay-person's terms so that a baby's mother can understand it. She may still not agree to accept the plan, but elected and appointed decision-makers have a right to know what, exactly, they are "signing-off" on if they choose to accept NRC staff's mortal calculations and assurances. If the terms "risk," "acceptance" and "significant" are defined solely by the NRC staff and its licensees, the so-called "protection" NRC offers will not be for the planet we live on; it will be pure fiction. (0711-23 [Olson, Mary])

Comment: How does a larger fraction of transuranics impact hazard (calculated for cancer and cancer death) from a major reactor, fuel pool, transport or storage accident? (0711-31 [Olson, Mary])

Comment: How high would a "reference" artificial surface for waste storage have to be to be above a typical storm surge at that sea level given existing US reactor sites? (0711-40 [Olson, Mary])

Comment: It is sad to think that NRC staff might be subject to the popularized junk science that holds that large distribution of radioactivity including the Chernobyl and Fukushima Daiichi nuclear disasters can be dismissed as low to no impact. While there is a range of discussion as to how many cancers over time will be attributable to these mass contaminations of our environment even the low end of official analysis projects thousands of cancer deaths from each. Anyone who justifies thousands of deaths resulting from a licensed industrial activity as a "low" or SMALL impact needs to reread our comment on "impact" and "significance" and the Principles section, and take a course in ethics. Further, the legal projections of health consequences completely and deliberately ignore impacts other than cancer in humans and ignore all impacts to other species and biosystems or in rare cases claim to assess impacts on a reference mammal or fish or bird. Nonetheless, these estimates of effects on humans from Chernobyl and Fukushima have been criticized by world class experts,^x [footnote x text: Letter to Secretary General of the United Nations, November 2013: <http://www.nirs.org/fukushima/expert-ltrbankimoon-09-2013.pdf>.] some of whom have documented why the impacts of large-scale environmental contamination are much higher. See for instance the 2006 TORCH Report.^{xi} [footnote xi text: The TORCH report was published by Dr Ian Fairlie and Dr David Sumner on the 20th anniversary of what was then the worst nuclear power reactor accident in history. A summary that makes the relevant points (and link to download the full report is posted here: <http://www.chernobylreport.org/?p=summary>.] The findings include for Chernobyl: about 30,000 to 60,000 excess cancer deaths are predicted, 7 to 15 times greater than IAEA/WHO's published estimate of 4,000; predictions of excess cancer deaths strongly depend on the risk factor used; predicted excess cases of thyroid cancer range between 18,000 and 66,000 depending on the risk projection model; other solid cancers with long latency periods are beginning to appear 20 years after the accident; Belarus, Ukraine and Russia were heavily contaminated, but more than half of Chernobyl's fallout was deposited outside these countries; fallout from Chernobyl contaminated about 40% of Europe's surface area; collective dose is estimated to be about 600,000 person Sv, more than 10 times greater than official estimates; about 2/3rds of Chernobyl's collective dose was distributed to populations outside Belarus, Ukraine and Russia, especially to western Europe; Caesium-137 released from Chernobyl is estimated to be about a third higher than official estimates[.] All of these findings are relevant to the assumptions underpinning the finding of SMALL impact in GEIS/NUREG 2157. It is also worth noting that even the low estimates of cancer deaths from Chernobyl likely exceed, by a large factor the dose--risk tables published by NRC in 1990.^{xii} [footnote xii text: See NRC, 1990 Expanded Policy Statement on Below Regulatory Concern(risk table).] None of these reports factor disproportionate level of harm to females; particularly in the 0--5 age group (BEIR VII data shows 10 times more cancer developing in girls exposed 0--5 than in boys at the dose), but the data also shows a 50% greater impact (cancer) over the entire lifespan.^{xiii} [footnote xiii text: See Olson, Mary "Atomic Radiation is more Harmful to Women, posted with other materials: <http://www.nirs.org/radiation/radhealth/radhealthhome.htm> and "Healthy from the Start" campaign at Institute for Energy and Environmental Research: <http://ieer.org/projects/healthy-from-the-start/>.] (0711-7 [Olson, Mary])

Comment: A second example of NRC failing to take into account both reality and a reasonable measure of anticipatory thinking is the near catastrophe at the Port Calhoun (nee "Fort" Calhoun) reactor in Nebraska in 2012. It stands as a perfect example of NRC failure "to analyze the cumulative impacts that may result from past, present, and reasonably foreseeable future radiological leaks from non-SFP systems, structures, and components." Photographic evidence shows that while in 2012 the spent fuel casks at the reactor stood above the catastrophic flood level, NRC has no means to assure that this would be the case in future catastrophic flooding; or that Cooper NPP or Oconee NPP dry casks would be above flood level after a catastrophic upstream dam failure. Should this occur the lower cooling vents of the casks could potentially become submerged or clogged with debris that staff would not be able to intervene to clear. Should the vents become plugged or submerged, convection air cooling would cease in the casks. This could result in the fuel overheating and possibly becoming damaged; or, possibly could result in a cask rupture if severe enough. In this case, intermingling of radionuclides from a NON-SFP source would occur. NRC has provided no analysis of this possibility; nor has it taken into account at all the effects of NON-SFP sources of contamination. (0716-15 [Kraft, Dave])

Comment: In a Nov. 14, 2013 webinar meeting scheduled by NRC itself to "inform" the public on the virtues of ISFSIs and dry casks, we asked the NRC "experts" several questions: Q: *If those vents [on the dry casks] are blocked, how long can the canister go before experiencing overheating and fuel damage?* NRC staff replied that, well, they did not know, but that site staff would surely be able to intervene before any consequential overheating occurred. We submitted a follow up question: Q: *That does not answer the question about blockage. In an emergency on the order of Fukushima, there was no guarantee that personnel could have intervened effectively if those vents got blocked. If Port Calhoun went under any more water the same situation would have existed. So the question stands -- HOW long before the canister overheats, and fuel damage occurs? If you have not done that calculation, you're doing the same "assuming" that the Courts said is not acceptable in the waste confidence docket.* We received no response to this question, neither during the session or afterwards. This demonstrates that 1.) NRC itself has not done sufficient homework to answer fundamental questions about cask and fuel integrity, and perhaps does not have the answers itself, yet claims that both will operate flawlessly for indefinite periods; and 2.) NRC displays no vitally necessary creative imagination into likely future emergency scenarios over the next, say, 10,000 years, in express violation of what the 2012 Court ruling mandated they should do. It has not done sufficient future analyses into these matters. REQUEST TO NRC: We request that NRC provide written answers to the above two questions asked (not merely responses predicated on baseless opinions or assertions), demonstrating the model used, the calculated temperatures derived, and predictions about fuel and cask failure times over the entire line of currently licensed storage casks; within 75 days of the submittal of these comments. (0716-16 [Kraft, Dave])

Comment: As NRC seeks to fulfill its mandate under the National Environmental Policy Act and examine the site-specific environmental impacts associated with authorizing the operation of Indian Point facilities in the future, it should in a proactive way address the issue of how it deals with severe nuclear events – be they releases from reactors or spent fuel pools – that lead to significant environmental impacts including, as in the case of Japan, land contamination and displacement, perhaps permanently, of people from their homes and their livelihoods and their communities. (0718-1-10 [Sipos, John])

Comment: Need for Site-Specific and Site-Wide Severe Accident Review for the Indian Point Facilities[.] Recent events should compel NRC to conduct a site specific analysis of spent fuel pool risks. Such events include: the U.S. government has withdrawn its application to create a

spent nuclear fuel repository at Yucca Mountain; events in Japan and Virginia demonstrated that external events (such as earthquakes or flooding) can pose severe risks to spent nuclear fuel residing at nuclear plants; the Tennessee Valley Authority, a federal agency that operates commercial nuclear reactors, has announced plans to consider an alternative strategy to shift spent nuclear fuel from spent fuel pools to dry cask storage; and recently-released NRC and Sandia National Laboratories documents confirm the State's concern and that alternatives are readily available. These developments indicate that spent nuclear fuel will continue to be housed indefinitely in densely-packed spent fuel pools at individual nuclear reactor sites, that such storage entails substantial, yet differing, site-specific risks due to the potential for seismic activity and other external events, and also, that alternatives exist to mitigate these site-specific impacts. Based on the experience it has gained in the Indian Point license renewal proceeding, the State of New York has concerns over the scope and adequacy of the required site-specific analyses of severe accidents at nuclear power plants, known as severe accident mitigation alternatives analyses, or "SAMA" analyses. NRC conducts SAMA analyses pursuant to NEPA and as a result of the Third Circuit's ruling in *Limerick Ecology Action, Inc. v. Nuclear Regulatory Commission*, 869 F.2d 719 (3d Cir. 1989). The SAMA analyses submitted with license renewal applications examine only severe accidents resulting in releases from the reactor core; they do not consider the site-specific impacts of spent fuel pool accidents. Because NRC Staff and reactor owners do not consider the environmental impacts of spent fuel pool accidents as part of their NEPA analysis when reviewing an application to renew an operating license, they do not consider alternatives to current spent fuel pool storage configurations. Moreover, NRC Staff and the industry steadfastly oppose any State or citizen request under NEPA to review the environmental impacts of spent fuel pool accidents or alternatives to current spent fuel pool practices. It does not appear that NRC Staff's NEPA-based SAMA analyses take severe accidents resulting in a radiological release from the spent fuel pools into consideration at all. This is a significant gap in Staff's NEPA analyses. To close that gap, the State requests that NRC perform a site-specific analysis of severe accidents to include both reactor core and spent fuel pool releases as well as the means and alternatives to mitigate the impacts of such accidents. The State also wishes to bring to the NRC's attention a separate concern over the conduct of site-specific severe accident mitigation alternatives analyses. Separate and apart from the concern over dense storage of spent nuclear fuel in spent fuel pools, the State is also concerned that site-specific SAMA alternatives have relied on inputs developed for Surry, a relatively rural reactor site, that are not appropriate for reactors whose emergency planning zones include more suburban or urban areas. The site-specific analysis of potential severe accidents must rely on site-specific data from the region around the specific reactor in question, and not replicate the data from the Surry site or a "sample problem" for a computer code. (0718-1-11 [Sipos, John])

Comment: To comply with NEPA, NRC's should expand its analysis to include the impact of severe spent fuel pool accidents on drinking water resources within NRC's designated 50-mile Emergency Planning Zone around the Indian Point facilities. (0718-1-2 [Sipos, John])

Comment: NRC uses a computer code, known as MACCS2, to assist its analysis of severe accidents. The economic cost model of the MACCS2 code is intended to estimate the direct offsite costs from a severe nuclear accident. If other indirect costs were included such as medical expenses, adverse health effects, permanent income loss, costs of disposal of contaminated wastes, and economic impact of losing a resource— including the loss of drinking water and replacement for reservoirs during interdiction, the total economic cost would increase. See, e.g., Transcript of Evidentiary Hearing, Indian Point License Renewal Proceeding ("Tr.") 2278:7-8 (Bixler) (MACCS2 code "does not consider the migration through the ground water."); Tr. 2284:6-10 (Bixler) (MACCS2 code "does not account any economic value to the loss of the

water. I think what would probably happen in reality is that people would buy bottled water in that area, and consume that. . . . [but it] is not factored in."); Tr. 2285:5-8 (Ghosh) ("[A]re we accounting for the economic impact of losing some resource? I just want to comment on that. Certainly, MACCS does not do that."); Tr. 1975:9-20 (J. McDade/Bixler) (While an input parameter called per capita cost of long-term relocation (POPCST) does address unemployment for 20 weeks under Sample Problem A, it does not address permanent salary loss.). (0718-1-3 [Sipos, John])

Comment: In the wake of the Fukushima disaster, NRC is considering conducting site-specific reviews of the risks involved with spent fuel pools as part of a Level 3 Probabilistic Risk Assessment ("PRA"). In the policy position paper on options for PRA activities, NRC wrote, "To be complete, estimation of total site accident risk should also include an assessment of the risk from accidents involving other site radiological sources, to include spent nuclear fuel."¹²⁵ [footnote 125 text: Nuclear Regulatory Commission, *Options for Proceeding with Future Level 3 Probabilistic Risk Assessment Activities*, SECY-11-0089, at 6, ML11090A042 (July 7, 2011).] The scope of the proposed PRA is depicted in the diagram below.¹²⁶ [footnote 126 text: Figure taken from slides prepared by NRC Staff: Nuclear Regulatory Commission Office of Nuclear Regulatory Research, *Severe Accidents and Options for Proceeding with Level 3 PRA Activities*, ML11209B927 (July 28, 2011).] [figure inserted] In a July 28, 2011 public meeting on PRA activities, Commissioner Apostolakis observed: ["It seems to me that a major change in the way that we think about things . . . after Fukushima, is that we really have to talk about the site risk. We should start talking about site years rather than reactor years. So that is probably a major change."] ¹²⁷ [footnote 127 text: *Id.* at 83. Also in that meeting, Stuart Lewis, Program Manager for Risk and Safety Management, Electric Power Research Institute, Inc., said, "[W]e have started to do some investigations that lead us to believe there is more that ought to be done in the area of understanding spent fuel pool risk . . . " *Id.* at 26.] During the same meeting, NRC Chairman Jaczko stated: ["I think that there's no question that the state of the art has improved significantly over the last two decades and that there are new issues that perhaps should be examined through the completion of Level 3 PRAs. As the staff notes in their paper, those include issues raised by the Fukushima accident, specifically the challenges posed by multi-unit events in the risks of radiological releases from spent fuel pools."] ¹²⁸ [footnote 128 text: Nuclear Regulatory Commission, *Briefing on Severe Accidents and Options for Proceeding with Level 3 Probabilistic Risk Assessment Activities*, Transcript of Proceedings, at 3, ML112140574 (July 28, 2011).] The State supports a comprehensive and realistic analysis of the risks posed by spent fuel pools and requests that such a review be brought into the site-specific NEPA review. (0718-2-12 [Sipos, John])

Comment: The recent earthquakes in Japan and Virginia present significant new information that affirm the importance of site-specific evaluation of spent fuel pool risks. (0718-2-4 [Sipos, John])

Comment: Nor does the DGEIS effectively identify, discuss, and evaluate other available mitigation measures to reduce or minimize the impacts of a severe spent fuel pool accident. For example, although the DGEIS relies upon NUREG/BR-0184's calculation of the consequences of pool fire accidents, including protective measures such as the use of a spray system, post-Fukushima US-NRC Order EA-12-049 does not mandate the installation of fixed spray systems in spent fuel pools. Similarly, the DGEIS does not examine the alternative of reducing the volume of spent nuclear fuel (and hence the potential accident source term) in spent fuel pools, although this information is available in other documents (US-NRC 2013a). (0718-3-10 [Sipos, John])

Comment: Quantitative Health Objective[.] The following quantitative health objectives are used in determining achievement of the two safety goals set forth in the policy document discussed above in Section 2.2 (US-NRC 2001, p. A4C-2): •*"The risk to an average individual in the vicinity of a nuclear power plant of prompt fatalities that might result from reactor accidents should not exceed one-tenth of 1 percent (0.1 percent) of the sum of prompt fatality risks resulting from other accidents to which members of the U.S. population are generally exposed."* •*"The risk to the population in the area near a nuclear power plant of cancer fatalities that might result from nuclear power plant operation should not exceed one-tenth of 1 percent (0.1 percent) of the sum of cancer fatality risks resulting from all other causes."* These objectives have been translated into two numerical objectives as follows: •*"The individual risk of a prompt fatality from all 'other accidents to which members of the U.S. population are generally exposed,' such as fatal automobile accidents, is about 5×10^{-4} per year. One-tenth of one percent of this figure implies that the individual risk of prompt fatality from a reactor accident should be less than 5×10^{-7} per reactor year."* •*"The sum of cancer fatality risks resulting from all other causes for an individual is taken to be the cancer fatality rate in the U.S. which is about 1 in 500 or 2×10^{-3} per year. One tenth of 1 percent of this implies that the risk of cancer to the population in the area near a nuclear power plant because of its operation should be limited to 2×10^{-6} per reactor year."* The numerical objectives above are compared to the early fatality risk to an average individual within 1.6 km (1 mi) and the latent cancer fatality risk to an average individual within 16 km (10 mi) of the plant. When NRC established these criteria, it developed them to be applicable to all sites since individual prompt fatality risks are the same regardless of the population density surrounding a reactor. Although the policy statement mentions societal risks, the numerical objectives do not. The risk to society should be comprised of, at minimum, the latent health effects (i.e., the radiological impact to the population) and economic costs. One possible quantitative objective for the radiological component of societal risk may be obtained by multiplying the objective for latent fatalities (2×10^{-6} latent fatalities per reactor year) by the nominal risk of latent fatalities (assumed to be 5% per person-Sv based on guidance from the International Commission on Radiological Protection (ICRP 2007)). This results in a numerical objective for collective dose of 4×10^{-5} person-Sv per reactor year, or 4×10^{-3} person-rem per reactor year. If the DGEIS had adopted societal risk criteria, the analysis would have been dependent on the population density around the site, making it impossible to develop a generic approach that applies at all sites. (0718-3-14 [Sipos, John])

Comment: After reporting the results of NUREG-1738, NUREG/BR-0184, and NUREG-1353, the DGEIS attempts to benchmark the radiation dose consequences and the economic cost of a spent fuel pool accident against values for severe reactor accidents. Based on these results, the US-NRC concludes (US-NRC 2013, p. F-10): *"This analysis shows that the probability-weighted consequences for a spent fuel pool fire, as analyzed in NUREG-1738, are comparable to the probability-weighted consequences for severe power reactor accidents analyzed in the 1996 and 2013 License Renewal GEIS (NRC 1996, 2013)."* Based on this conclusion, it is reasonable to expect that US-NRC would implement similar requirements for severe reactor accidents and spent fuel pool accidents. This would include the conduct and documentation of a Severe Accident Mitigation Alternatives (SAMA) analysis that is based on a site-specific cost-benefit comparison of the costs of implementing mitigation alternatives with the benefits achieved by those mitigation alternatives. Furthermore, risk assessments and SAMA analyses for reactor and spent fuel pool accidents at the same site should not be conducted independently; an integrated, site-wide analysis is the way to quantitatively assess the risks posed by all operations conducted on a single site. In conclusion, although US-NRC reports the similarities between spent fuel pool fires and reactor accidents, the DGEIS does not actually use this information. The DGEIS does not contain societal dose acceptance criteria or a SAMA analysis

considering the costs and benefits of mitigation alternatives given the cost of a spent fuel pool fire. (0718-3-16 [Sipos, John])

Comment: Severe Accident Mitigation Alternatives Analyses and Spent Fuel Pools[.] The destruction of the Fukushima facilities demonstrates that severe accidents can occur and can have significant, real world consequences.¹⁷⁰ [footnote 170 text: NRC Chairman Gregory Jaczko, *Looking to the Future*, S-12-002 (Feb. 9. 2012).] The State calls on NRC to revise its approach to severe accident mitigation alternatives (or SAMA) analyses. Under 10 C.F.R. § 51.53(c)(3)(ii)(L), NRC must conduct a site-specific review of alternatives to mitigate a severe accident at a reactor that seeks to renew its operating license. NRC promulgated this regulation in 1996 in response to the court ruling in *Limerick Ecology Action, Inc. v. Nuclear Regulatory Commission*, 869 F.2d 719 (3d Cir. 1989). However, while NRC purports to examine alternatives to mitigate severe accidents that occur in the *reactor*, applicants and NRC do not review alternatives to mitigate severe accidents that occur in the *spent fuel pool* that is adjacent to the reactor but outside of the containment shell. In fact, the SAMA analyses only take into account releases from the reactor core. Releases from spent fuel pools that would occur during a severe accident are not taken into consideration at all in the SAMA analyses. Thus, the communities and states that host power reactors do not receive a comprehensive review of all severe accidents at a licensed facility or the available means to mitigate the environmental effects of such severe accidents. It is important that radionuclide releases from spent fuel pools be considered as part of the SAMA analyses because the offsite cost risks of these releases can be higher than those from the reactor core.¹⁷¹ [footnote 171 text: Gordon R. Thompson, Risk-Related Impacts from Continued Operation of the Indian Point Nuclear Power Plants, at 28 (Nov. 28, 2007).] Today's reality is that large quantities of spent fuel are being stored at nuclear reactor sites. Indeed, under the dense storage regime in place today at Indian Point and other reactors, the spent fuel pool holds considerably more fuel assemblies than the reactor core. The NEPA review of severe accident mitigation alternatives should not exclude releases from these spent fuel pools or alternatives that could mitigate severe spent fuel pool accidents or releases. NRC Commissioners should revise current NRC NEPA policy and ensure that during this proceeding or during a license proceeding, a comprehensive and objective review of severe accidents takes place for the entirety of each facility that NRC licenses. Similarly, for sites that have more than one reactor and spent fuel pool, the SAMA review should not be limited to a severe accident at a single reactor or a single pool, but should examine the consequences of, and mitigation alternatives for, a severe accident that affects more than one reactor or pool at a NRC licensed site. (0718-3-2 [Sipos, John])

Comment: In addition, the SAMA analyses must reflect the true, site-specific costs of an accident involving a spent fuel pool or resulting in a release from a spent fuel pool. As discussed in the accompanying report from ISR, in the context of SAMA analyses for severe nuclear reactor accidents, applicants have not been using site-specific data to calculate the economic costs. Instead, licensees have been relying on data from "Sample Problem A" to calculate the economic costs associated with a severe nuclear reactor accident in their SAMA analyses. Sample Problem A was one of fourteen sample problems provided with the MACCS2 code as an example for users to check whether the MACCS2 software was installed and operating properly. Sample Problem A is an example set of inputs that were developed for the Surry reactor site located in rural Virginia and was not meant to serve as default input values in the MACCS2 program.¹⁷² [footnote 172 text: The "Sample Problem A" values were derived from the Surry facility and discussed in NUREG-1150, *Severe Accident Risks: An Assessment for Five U.S. Nuclear Power Plants* (Dec. 1990).] Yet NRC Staff, Entergy, and other applicants rely on Surry's Sample Problem A in conducting SAMA analyses for other reactor sites, such as Indian Point, that differ markedly from Surry and its environs. Each of the approximately 65 sites that

host the 104 operating nuclear power reactors has a different profile and "context."¹⁷³ [footnote 173 text: "Context is the geographic, biophysical, and social context in which the effects will occur. In the case of license renewal, the context is the environment surrounding the facility." *Draft GEIS for License Renewal* at 1-5.] NRC cannot credibly maintain that all U.S. reactor sites are the same or that an accident at one site will have the same consequences as an accident at another site. Stated differently, the 50-mile emergency planning zone around the two operating Indian Point reactors in New York is materially different from the 50-mile emergency planning zone around the single Fort Calhoun reactor in Nebraska. The two Indian Point plants and single Calhoun plant are different with respect to: electrical output; spent fuel pool inventory; surrounding population; topography; prevailing wind; precipitation and snowfall; seismic hazards; tornado hazards; surrounding agricultural resources; and surrounding public drinking water/reservoirs—to name just a few material differences. (0718-3-3 [Sipos, John])

Comment: By using Sample Problem A inputs instead of inputs derived from site-specific data, applicants are failing to conduct the required site-specific SAMA analyses for nuclear reactor accidents in violation of NEPA, CEQ regulations, and NRC regulations. This error should not be carried into ongoing or future SAMA analyses of the reactor accidents, risks from a spent fuel pool accident, or radiological releases from a spent fuel pool. Any such SAMA analyses must rely on site-specific data from the plant at issue and its surrounding community and environment, not from Surry and its inputs in Sample Problem A. Use of accurate, site-specific cost is especially important in light of a recent inter-agency dispute among federal agencies over which agency is responsible for ensuring the clean-up and decontamination of contaminated property and the funding source of such decontamination. A November 2010 article entitled *Agencies Struggle To Craft Offsite Cleanup Plan For Nuclear Power Accidents*, reported: "[E]PA, the Nuclear Regulatory Commission (NRC) and the Federal Emergency Management Agency (FEMA) are struggling to determine which agency—and with what money and legal authority—would oversee cleanup in the event of a large-scale accident at a nuclear power plant that disperses radiation off the reactor site and into the surrounding area. The effort, which the agencies have not acknowledged publicly, was sparked when NRC recently informed the other agencies that it does not plan to take the lead in overseeing such a cleanup and that money in an industry-funded insurance account for nuclear accidents would likely not be available [T]he NRC officials also indicated during the meetings that the industry-funded account established under the Price Anderson Act—which Congress passed in 1957 in an effort to limit the industry's liability—would likely not be available to pay for such a cleanup."]¹⁷⁴ [footnote 174 text: Douglas P. Guarino, *Agencies Struggle To Craft Offsite Cleanup Plan For Nuclear Power Accidents*, Inside EPA (Nov. 10, 2010).] Moreover, meaningful site-specific severe accident mitigation alternatives analyses should be conducted each time a facility seeks to extend its operating license. This is so because the population in the emergency planning zones, characteristics of the surrounding community, set of potential mitigation alternatives, and economic cost values may all experience significant change over the course of a 20-year operating license. (0718-3-4 [Sipos, John])

Comment: Since hydrological and geological properties vary from site to site, as does the proximity of sites to bodies of water and the configuration of the reactor(s) and spent fuel pool(s), the consequences of contaminated water leaking into ground water and surface water should be assessed on a site-specific basis. (0718-4-10 [Sipos, John])

Comment: NUREG-1150, however, contains a gaping hole—the source of the decontamination cost parameters in NUREG-1150, and thus the source of the decontamination cost parameters used in Sample Problem A, simply does not exist. Neither NUREG-1150 itself nor its companion, NUREG/CR-4551, explain how the Sample Problem A costs were obtained.

NUREG/CR-4551 cites NUREG/CR-3673, as a reference for the Sample Problem A decontamination cost values, but NUREG/CR-3673 states only that: *"The cost estimates used in this study for various levels of decontamination effort in an area are taken from a detailed review of decontamination effectiveness and costs performed at Sandia National Laboratories (SNL) [Os84]."* "Os84" is listed as "Ostmeyer, R.M., and G.E. Runkle, An Assessment of Decontamination Costs and Effectiveness for Accident Radiological Releases, Albuquerque, N.M.: Sandia National Laboratories, *to be published*," in NUREG/CR3673's references section. NUREG/CR-3673 at p. 8-8 (emphasis added). The Os84 document does not exist, at least in any available form. Os84 appears to have never been published, nor peer-reviewed. Even if Os84 did still exist, the author of NUREG/CR-3673 (which cites to Os84) made it clear that these were tentative results: *"Little data exist which are directly applicable to the small particle sizes (0.1-10 μ m) and soluble materials which are anticipated in releases from the LWR accidents. The cost and effectiveness estimates for decontamination contain large uncertainties, and results of future experimentation with decontamination techniques should be used to update models for decontamination."* (NUREG/CR-3673 at p. 4-15) No one knows the origin of the NUREG-1150 decontamination cost values, other than a cryptic description that they were based upon "national average statistics." NUREG/CR3673 at p. 4-17. Public comments on a draft of NUREG-1150 state "Decontamination costs used in the calculations may be based on decontamination of test sites in deserts instead of agricultural, residential, and commercial property." NUREG-1150 at D-32. The comments received on a draft of NUREG-1150 suggest that its authors expected that site-specific estimates of decontamination costs would be developed. NUREG-1150 states: *"[PUBLIC] COMMENT: The models used in calculating the cost of a severe accident lack many factors that should be taken into account. Many of the assumptions are questionable and unfounded. The models have not been benchmarked. Some interpretations and conclusions that were made in draft NUREG-1150 are questionable. The cost estimates need to be more thoroughly documented to understand and evaluate the calculations. [NRC] RESPONSE: The present version of NUREG-1150 provides a limited set of risk-reduction calculations, principally related to the potential benefits of accident management strategies in reducing core damage frequency. It does not assess the cost of these or other improvements. Such analyses are more properly considered in the context of specific regulatory action. * * * [PUBLIC] COMMENT: Decontamination costs used in the calculations may be based on decontamination of test sites in deserts instead of agricultural, residential, and commercial property. [NRC] RESPONSE: The draft NUREG-1150 cost/benefit analyses reflected the conventional NRC methods for assessing costs and benefits. Because cost/benefit analyses are more properly considered in the context of specific regulatory activities, they are not provided in this version of NUREG-1150."* These comments support the notion that reliance on Sample Problem A instead of developing site-specific inputs is unreasonable. (0718-4-17 [Sipos, John])

Comment: The DGEIS should contain a discussion of how aqueous releases can occur during a severe accident, and the potential consequences of aqueous releases during a severe accident, given the unfolding experience at Fukushima. The MACCS2 code does not model "aqueous release pathways." NRC Regulatory Information Conference (RIC) International Session - Post-Fukushima Research, NRC Office of Nuclear Regulatory Research (March 13, 2013) slide 7; see also Certified Minutes of the ACRS Reliability and PRA Subcommittee Meeting on Level 3 PRA on December 4, 2012 (ML13211A477). The DGEIS should acknowledge this limitation of the code, and discuss options for determining and mitigating the effects of aqueous releases. (0718-4-9 [Sipos, John])

Comment: Revise the MACCS2 consequence assessment to be conservative and bounding or make it site-specific and compatible with the current practices for severe accident mitigation alternative analyses for reactors. (0718-5-10 [Sipos, John])

Comment: Include a re-assessment of the time and cost of decontamination for severe accidents, which are higher for areas with higher population densities. (0718-5-11 [Sipos, John])

Comment: Develop a quantitative health risk acceptance criteria compatible with the Commission's Policy Statement regarding societal risk (in addition to the criteria for individual risk). (0718-5-3 [Sipos, John])

Comment: Analyze alternatives to mitigate the potential severe accident impacts. This should be done in a site-wide manner that integrates all hazards and corresponding risks that exist on the site (i.e., all reactor units and spent fuel pools are assessed in a single risk assessment). The DGEIS should either employ conservative bounding or direct site-specific review for certain plants like Indian Point (0718-5-4 [Sipos, John])

Comment: Include an assessment of the environmental consequences and cost of liquid releases during a spent fuel pool accident, with specific reference to and discussion of the unfolding events at Fukushima. (0718-5-9 [Sipos, John])

Comment: Instead the short-term programs currently followed have proved to be inadequate to guarantee public safety in case of earthquake, tornado, tsunami, hurricane etc. -- events which have become devastatingly common in this warming world. In cases of potential accidents caused by equipment failure or human error the NRC provides no safeguard beyond "low probability." This is absolutely not a substitute for actual protection! Those of us who are paying attention have not forgotten Fukushima, Chernobyl, Bhopal, or Love Canal. Why -- when there are rapidly developing clean alternatives to nuclear power generation -- would we end the moratorium on new power plants? (0719-3 [Hibbard, Angela])

Comment: An NRC technical expert, working on NUREG-1738, averred that a cask drop in a Mark I spent fuel pool would not be significantly slowed by passage through water and that a drop from as little as four feet from the bottom would result in complete cask penetration. That would be an approximately 11 foot/diameter hole with potentially several tons of spent fuel crushed and punched through to ground level. (0723-9 [Shadis, Raymond])

Comment: If there was just one lesson to be learned from the ongoing nuclear catastrophe in Japan it is that our best science and engineering is no match for the unpredictable forces of nature. (0757-10 [Lynch, Laura])

Comment: •California's nuclear waste sits in the world's earthquake "ring of fire", the same as Fukushima, the most active and dangerous earthquake zone in the world. California's nuclear waste is surrounded by known active earthquake faults and the USGS says no one has ever predicted a major earthquake. •Most of California's nuclear waste sits along an eroding coastline, in tsunami zones, and is exposed to a highly humid and corrosive coastal environment. NRC's NUREG/CR-7030 states atmospheric corrosion of sea salt can lead to stress corrosion cracking within 32 and 128 weeks in austenitic [corrosion resistant] stainless steel canisters. (0764-4 [Gilmore, Donna])

Comment: •A radiological disaster impacts the nation's and world's security, economy and food supply. California is the eight ranking economy in the world, virtually tied with Italy and the

Russian Federation, and larger than Canada, Australia and Spain. •More than 40 percent of containerized imports enter the country through California ports, and nearly 30 percent of the country's exports depart through them. •California produces nearly half of the U.S. grown fruits, nuts and vegetables. California remained the number one state in cash farm receipts in 2011, with its \$43.5 billion in revenue representing 11.6 percent of the U.S. total. U. S. consumers regularly purchase several crops produced solely in California. •San Onofre is located adjacent to the primary vehicle transportation artery between Los Angeles and San Diego (I-5), and one of the largest military installations (and potential target) on the West Coast (Camp Pendleton). (0764-6 [Gilmore, Donna])

Comment: If there was just one lesson to be learned from the ongoing nuclear disaster in Japan it is that our best science and engineering is no match for the unpredictable forces of nature. (0774-4 [Revilla, Oscar])

Comment: Do not assume that nuclear power plants in the Central and Eastern USA will not be exposed to major earthquakes. The New Madrid Earthquake was a very large historical earthquake that affected part of this region. Also, there is evidence that hydraulic fracturing and/or underground disposal of wastewater are triggering or causing earthquakes, so earthquakes may occur where they have not historically happened. (0788-3 [Sattler, Alfred])

Comment: Each spent fuel pool can contain up to six times the mass of nuclear fuel as is stored in the reactor core itself. Spent fuel is much dirtier--much more radioactive--than new fuel. Any event that causes a single spent fuel pool to lose its integrity could result the release of a large portion that highly radioactive spent fuel into the environment, as airborne radioactive contamination similar to what was seen in Fukushima. With six times the fuel of an operating reactor core, it would release twice the contamination compared to the 3 Fukushima cores which became meltdowns. But because it is dirty spent fuel, it would be much worse. We simply cannot allow such a development. And most certainly, we cannot allow such a development to be kept secret. But if recent history is any indication, we cannot expect to be informed. (0801-3 [Magyar, Michael])

Comment: p. 4-67 to 4-83. Environmental Impacts of Postulated Accidents. p. 4-68. The consequences of a severe (or beyond-design-basis) accident, if one occurs, could be significant and destabilizing. The impact determinations for these accidents, however, are made with consideration of the low probability of these events. The environmental impact determination with respect to severe accidents, therefore, is based on the risk, which the NRC defines as the product of the probability and the consequences of an accident. This means that a high-consequence low-probability event, like a severe accident, could still result in a small impact determination, if the risk is sufficiently low. **Comment:** Consider, for example, that a storage facility location makes it vulnerable to a catastrophic event of uncommon occurrence. How many facilities located in such places would it take to make a low-probability event be categorized as having a greater than SMALL impact? For example, the NRC recognizes six US reactor sites to have "high" vulnerability to severe flooding by upstream dam failure, and an additional nine reactors have "medium" vulnerability. This information was obtained from a memo entitled "Identification of Generic External Flooding Issue Due to Potential Dam Failures" prepared by the Chief of the Probabilistic Risk Assessment Operational Support Branch of the NRC. The memo further states that "Since dam failures were excluded from consideration of most [safety reviews], its risk contribution has not been addressed to date," and "There is an increase in the estimated frequency of potential dam failure of an order of magnitude" from previous assessments. It is evident from the testimony of Fukushima that one such event would have enormously greater environment impact than all the generic factors considered in the

GEIS put together. The left hand of NRC needs to know what the right hand is doing. This particular issue must be evaluated in this GEIS. (0805-12 [Wilshire, Howard])

Comment: Furthermore, this section fails to include an important cause of accidents or exacerbation of accidents: the human factor: There is a very large literature on the contributions of human errors to accidents that have significant impacts on the environment. That history is ignored in this GEIS, but it needs to be factored in for all time frames considered. Human errors are not a given, but their frequency and persistence throughout our grand nuclear experiment have a certain generic flavor. The opportunity for mistakes with environmental consequences is enhanced by the large, and getting larger, number of dry cask designs, which require broadened knowledge for activities designed to ensure cask integrity, including inspection, monitoring, and replacement repeated at intervals greater than typical life-times of the inspectors--that is, the "activity" may be the same or similar forever, but those implementing the actions have by comparison a very rapid turnover. The historical record shows clearly that the majority of significant accidents are due to, or exacerbated by human errors, so calling on the "protections" of design, construction, and regulations is irrelevant. The opportunity for human error, especially considering the time that continued storage at a reactor is rationalized as generically safe (up to 140 years), warrants assessment. In effect, most of the environmental impact assessments are best case scenarios. (0805-13 [Wilshire, Howard])

Comment: Human error or equipment failure in moving loaded dry casks, weighing more than 100 tons, could have catastrophic consequences. Dropping an empty or loaded cask inside the fuel pool building could severely damage critical safety equipment and the entire integrity of the pool. A near-miss occurred in 1995 at Prairie Island in Minnesota when a loaded, 120 ton TN-40 cask became stuck and dangled precariously for 16 hours over the spent fuel pool containing tons of irradiated fuel stored for over 22 years. Should we just rely on NRC's wishin', hopin', and sheer luck that everything will be okay? In some GE BWRs, the fuel storage pools are several stories up in the reactor building, making cask movement even more dangerous and potentially disastrous. (0819-13 [Kline, Connie])

Comment: 4) "Sites and areas where tectonic processes -such as faulting, folding, seismic activity or volcanic activity -and surface geological processes such as mass wasting, erosion, slumping, landsliding, or weather -occur ... must be avoided." The Perry area is subject to earthquakes like the 1986 one that registered 5.0 on the Richter Scale, the epicenter of which was less than 10 miles from the plant. According to the Perry FSAR, there is a known "offshore fault intersecting the cooling water tunnels." According to 1979 Plain Dealer newspaper articles, a huge chasm -"30 feet wide and 20 feet deep in the bedrock running through about two-thirds of the Perry site's huge excavation " was discovered during construction, deemed glacial in nature, and "filled with concrete." After the 1986 earthquake, a fault line running from Lake Erie near the plant south to Akron, Ohio was confirmed, and there have been numerous smaller earthquakes in the area since. The Perry site which sits on a high bluff is also subject to severe erosion which caused an entire park just west of the plant to fall into Lake Erie and has forced multi-million dollar erosion control to protect safety structures such as the emergency service water pumphouse. The Ohio EPA has said that the Perry site would be deemed unsuitable for any type of solid waste facility. At a 10/1/92 NRC informational meeting held in Lake County, the NRC admitted that due to its proximity to Lake Erie, high groundwater table, erosion, and other factors, the Perry site could not meet the bare minimum NRC criteria for radioactive waste disposal per 10CFR61. They were unable to reconcile how Perry can continue to operate and generate tons of radioactive waste on such an environmentally unsuitable site. (0819-20 [Kline, Connie])

Comment: The NRC's security regulations insufficiently ensure that spent fuel pools are protected from electric blackouts. If the electric grid has a blackout to a nuclear power plant that lasts more than the 4 or 8 hours for which the backup generator provides, that electrical blackout becomes a vulnerability for that location. Spent fuel pools require constant cooling. (0823-26 [Michetti, Susan])

Comment: Astrophysicists have warned US Congress that extreme sun spot activity can direct a CMT into the earth's atmosphere with the potential to knock out a significant part of the world's interconnected electric grid in a domino effect. The US grid is interconnected with much of Canada and parts of Mexico. In the recent past, various locations in the USA were hit by super tornados or hurricanes often with surge waves. Some areas were totally leveled. Some areas were without electricity for more than a month. Other areas were flooded. Yet, the backup steam generators are stored in the basement where irrationally flood potential is maximized, returning back to NRC's approval with insufficient safety assessment and overview. The lessons of Fukushima have not been adapted to vulnerabilities. (0823-28 [Michetti, Susan])

Comment: Such lengthy lack of electricity likely will occur at a nuclear plant in the future. Potentially catastrophic, this lengthy lack of electric grid access could seriously impact safety at a nuclear power plant and its spent fuel pool which requires constant cooling. The impact is not if, but when. Without access to sufficient, constant electricity, the security regulations to protect us from this predictable catastrophic problem are missing. It is unacceptable, given the extreme dangerousness of burning ionizing spent fuel pools or a reactor core with the potential for a chain reaction, to not mandate sufficient backup electricity solutions to provide the full potential timeframe when access to grid electricity may be unavailable. Safety claims without sufficient backup energy are invalid. This was the vulnerability at Fukushima. One-quarter of the US's 103 nuclear plants are of the same General Electric design. All nuclear power plants have that vulnerability, which makes it insane to continue to incorrectly assume that sufficient electric grid energy will always be available. (0823-29 [Michetti, Susan])

Comment: A sufficiently scientific overview and assessment requires placing this safety vulnerability at the top of the decision tree, where licensing plant operation must first go through the appropriate gate-keeping, that first requires that the problem be solved, in order to guarantee sufficient backup or reliable alternative energy solution that can keep working for at least a month or for the entire timeline of any potential electrical shortage, whichever is longer. The very operation of any nuclear plant and the creation of its storage pools should depend upon its ability to be able to continue necessary operations for safety indefinitely. (0823-30 [Michetti, Susan])

Comment: This recommendation is not directed towards the process of decommissioning. The recommendation is directly related to the general confidence of the surrounding community towards onsite storage of spent nuclear fuel addressed in NUREG-2157. Although the NRC believes both the spent fuel pools and dry cask storage are equally safe means of storing spent nuclear fuel, Fukushima has shown that spent fuel pools are nowhere near as robust in surviving an earthquake-tsunami event when compared to dry cask storage. (0826-20 [Morgal, Rick])

Comment: The NRC's use of probability-weighted consequences to determine overall risk in environmental impact reviews has been upheld by the Courts. In *Carolina Environmental Study Group v. United States*, the Court found that the Commission's general consideration of the probabilities and severity of a Class 9 accident did not amount "to a failure to provide the required detailed statement of its environmental impact."⁷¹ [footnote 71 text: 510 F.2d 796, 799]

(D.C. Cir. 1975).] There, the Court ruled that it was "entirely proper, and necessary" for the agency to consider both the probabilities and consequences of Class 9 accidents when assessing the environmental impacts of those accidents.⁷² [footnote 72 text: *Id.*] It reasoned that "[t]here is a point at which the probability of an occurrence may be so low as to render it almost totally unworthy of consideration. Recognition of the minimal probability of such an event is not equitable with nonrecognition of its consequences."⁷³ [footnote 73 text: *Id.*] It follows that very low probability of an occurrence can lead to a finding of no significant impact, notwithstanding the population distribution and density, and the hypothetical consequences at any particular site. (0827-2-12 [Ginsberg, Ellen])

Comment: NRC has appropriately cited NUREG-1864, its 2007 probabilistic risk assessment (PRA), in support of statements made about the low risk associated with dry cask storage. These statements could be further strengthened by also citing an independent PRA study conducted by EPRI (EPRI Document 1009691, dated Nov 2004), which also supports the conclusion that the risks are low. Industry agrees with NRC that the low risks calculated by these studies were confirmed during the Mineral, Virginia and Fukushima earthquakes, neither of which resulted in significant damage to dry cask storage systems or release of radionuclides. (0827-4-1 [Ginsberg, Ellen])

Comment: We find this attempt to avoid oversight by the public as a serious concern, given the obvious lack of oversight and poor choices by the industry, exemplified by the failures of the San Onofre Nuclear Generating Station (SONGS), and the disaster at Fukushima, which used similar "Probability Risk Assessment" approaches to conclude that a tsunami of that size would be extremely improbable, and therefore inconsequential. PRA is a broken approach. (0836-10 [Davis, Anonymous])

Comment: We disagree that you can make safety determinations using Probability Risk Assessment (PRA). First, you take a really small number, which is a wild guess as to the probability that some event will occur. Then you take another number, which is a wild guess as to the total consequences of an accident. You multiply these together, making the uncertainty wild-guess-squared, or actually indeterminate. Then, you multiply this by a constant cost of \$2000 or maybe \$4000 per mREM of release, and compare that with an ever-changing and inflated cost for providing safety measures. At the end of all this, you predictably discover that the risk is small, and any changes to improve safety cost too much. (0836-17 [Davis, Anonymous])

Comment: You also ignore the fact that the RISKS increase with every additional NWO that exists and the extended period of time they are envisioned to be in operation. Thus, you need to multiply the indeterminate risk by the number of years and by the number of NWOs in operation. You also have no means to increase the cost per mREM as it is a fixed number, but the utilities charge as much as they can to fulfill regulatory requirement, sometimes exceeding the NRC (and any reasonable estimate) by as much as 10x. (0836-18 [Davis, Anonymous])

Comment: There is never much of any consequence that needs to be analyzed if everything goes well. The problem is when things don't go well. You analyze spent fuel fires based on limited concept of type of accidents that might occur. "Design basis accidents" are used as a way to limit the cost for dealing with accidents, because only a limited number of scenarios need be considered. In this document, you consider only two possible scenarios, when in fact there are an unlimited number of scenarios, some of which we could not think of because we don't understand everything. For example, at SONGS, the steam generator tubes were analyzed for only one type of rattling motion. Motion along the other plane was considered inconsequential.

In actuality, the steam generators were rattling themselves apart at the seams. So what is the likelihood that you have it wrong? Probably 100%. (0836-19 [Davis, Anonymous])

Comment: Section 3.0 "Affected Environment" considers only the effects when everything goes well, not when the accidents happen, and THEY WILL HAPPEN! This is the lesson, more than anything else, we must accept from Fukushima, and the nuclear industry in general. No matter how unlikely the accident, they STILL WILL OCCUR, and you SHOULD consider this in the affected environmental analysis. THE ENTIRETY OF THIS SECTION MUST BE CHANGED to address the consequences of accidents, not operation without any problem. No one is concerned about non-accident operation of an ISFSI!!!! If there is no accident, there is by definition, no problem. But when there is an accident, then there is, and this is why your treatment of the effects on the environment are ALL INSUFFICIENT! (0836-47 [Davis, Anonymous])

Comment: Section 3.14 "Waste management" only concerns EXPECTED waste when everything is going well. What happens when something happens that is out of expectation? Not addressed. (0836-49 [Davis, Anonymous])

Comment: Page 4-77, Line 30+, you consider two design basis accidents in the hypothetical DTS. You did not consider unusual and unexpected events, like partial meltdown inside a canister due to failure of cladding around high-burnup fuel pellets, a problem that has been described as a concern. At this point, we assert that there are simply TOO MANY UNKNOWNs and "unresolved issues" for this DGEIS to apply to any period longer than the normal decommissioning period. As more information is learned, if a DTS is actually ever designed and constructed, if we get statistics about how well the fuel lasts inside canisters, etc. etc. then it may be possible, IN ABOUT ANOTHER 50 YEARS to speculate about the subsequent 100. Until then, your optimism is far too apparent, and again a sign that the NRC has gone so far astray that it does not even realize that it is lost. (0836-55 [Davis, Anonymous])

Comment: Page 4-78, you consider a "loss of containment event" but constrain it to filters that are inoperable. Why not assume the entire DTS fails and radiation is emitted? Then what? There is no containment around the DTS, in the design you have conceptualized. Ridiculous. STANDARDS FOR DRY/WET TRANSFER MUST BE IMPROVED! (0836-56 [Davis, Anonymous])

Comment: The affect on Aquatic resources, again, assumes NO ACCIDENTS occur. (0836-71 [Davis, Anonymous])

Comment: The NRC has yet to recognize the risks related to solar flares, their incapacitating impact on the nation's electrical infrastructure, and the resulting impact on the ability to cool nuclear power plant spent fuel pools. Nuclear power plants and their electrical systems have not been made impervious to the effects of such electrical storms. A large solar flare has the potential to incapacitate the nation's electrical distribution infrastructure for years and/or render all electrical components at plants inoperable. In either scenario, the lack of a constant source of power to the spent fuel pool cooling systems will inevitably result in radiological fires at all spent fuel pools across the US. (0840-5 [Taylor, Tom])

Comment: So, the NRC's new Waste Confidence Generic Environmental Impact Statement acknowledges prolonged above-ground storage and a multitude of issues including ground water contamination from spent fuel pools, severe accident consequences, and terrorism. The NRC considers "reasonably foreseeable" events including a severe accident that may result in evacuating millions of people, vacating thousands of square miles, rendering expansive areas of

land unsuitable for agriculture, and costing billions of dollars not including replacement power costs. With evacuation, the NRC emphasizes that radiological doses to the public should be low. The NRC declares that the impact of indefinitely continued spent fuel storage is "SMALL" with a probability-weighted determination that almost sounds reasonable until you consider multi-year operation of multiple plants which makes a severe accident likely. (0851-1 [Thatcher, Tami])

Comment: In the 40 years since SONGS has been operating, the number of people living within 50 miles of the plant has grown exponentially representing one of the most populous areas in the state. This includes 65,000 residents now living in San Clemente within 10 miles of San Onofre. Since 9-11 Americans are acutely aware of the ongoing threat of a terrorist attack on a facility like this, and all southern Californian's know that a major earthquake in our region is long overdue. The disaster at Fukushima is yet another reminder of our vulnerability to earthquakes, tsunamis, and circumstances beyond human control. (0855-2 [Holloway, Patricia])

Comment: In reality, PRAs utterly fail to assess the dangers of ongoing operations with no end in sight. 100-year floods and earthquakes become inevitable instead of rare if you wait long enough -- and that seems to be exactly what the nuclear industry wants: For us all to wait until there is a disaster, only to claim they never saw it coming. (0856-7 [Fritz, John])

Comment: If there was just one lesson to be learned from the ongoing nuclear disaster in Japan it is that our best science and engineering is no match for the unpredictable forces of nature. (0860-4 [Headrick, Gary])

Comment: After Frankenstorm Sandy, I am especially concerned that the NRC has not updated its computer simulations and accident-probability calculations to reflect greater likelihood of the electric power grid going down. As it was, despite the "evacuation routes" being completely closed, Indian Point continued to operate as the water rose (remember: the power was out-there was no need for it to keep generating electricity!). Many of us called to check on the situation as the storm progressed; we were transferred from office to office without our questions being answered; nobody really seemed to know what was happening. We turned to the experts for answers; they had none. Loss of off-site power is a major contributor to accident scenarios at nuclear reactors. Many potential scenarios would also include damage to the fuel pool and its back-logged waste inventories. (0864-12 [Gellert, Sally Jane])

Comment: An additional issue is the potential problem of decontamination and cleanup in the event of an incident at any one of these individual spent fuel storage facilities. What are the guarantees from the NRC for the costs and expertise needed to address such remediation events if in fact the NRC does not recognize these in their vision of the future? An example of an unfunded mandate now being imposed on states from mismanaged nuclear wastes is that states all over the United States are forced to devote staff, time, political and social attention to the problems created by the contamination of DOE site. For example, the need for Nevada to maintain a Bureau of Federal Facilities devoted solely to the problems of overseeing DOE facilities (<http://ndep.nv.gov/boff/index.htm>). The record is clear - agencies like the DOE and NRC have in the past left such issues off of analysis when in fact those have very real environmental consequences. (0867-3-11 [Griffin, William])

Comment: A vital ingredient for the continued management of the spent fuel is the skilled and trained staff able to perform the work. The potential failure to train and identify high quality staff will have a variety of effects not discussed in the DGEIS. The NRC and the nuclear industry have paid close attention to human factors engineering as it relates to plant operations because

of its effect on accident and other risks. There has been relatively less work on human factors risks associated with the dry cask storage of spent nuclear fuel. If the quality of human capital declines, the risks associated with continually transferring and packaging the spent nuclear fuel will increase. The DGEIS does not comment on this problem. (0867-3-7 [Griffin, William])

Comment: I cannot believe that what was the case then is now considered unimportant, that is that it is all right to have containers of radioactive material left on site where it is vulnerable to weather, fire, or terrorism, or earthquake. (0882-2 [Wright, Margaret Z.])

Comment: A fundamental problem with the draft GEIS is its method of assessing risk. The DGEIS defines radiological risk as the numerical product of the probability and the consequences of an event, and further argues that a high-consequence, low-probability event, such as a severe accident, could be determined to have a small environmental impact if the risk is sufficiently low. In the context of the DGEIS, that definition of radiological risk, and the associated determination of environmental impact, are fundamentally flawed from at least four overlapping perspectives: • First, numerical estimates of consequences and probability are typically incomplete and highly uncertain. • Second, significant aspects of consequences and probability are not susceptible to numerical estimation. • Third, larger consequences can be qualitatively different than smaller consequences. • Fourth, devotees of this definition of risk typically argue, as does the DGEIS, that equal levels of “risk”, as they define it, should be equally acceptable to citizens. That argument may be given a scientific gloss, but is actually a statement laden with subjective values and interests. An informed citizen could reject the argument on reasonable grounds. (0897-6-13 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Thompson Declaration, Section IV. The qualitative difference between large and small consequences is not a well-known factor in the United States, but is recognized in Europe. For example, analysts at the French government’s Institut de Radioprotection et de Surete Nucleaire (“IRSN”) have found a qualitative difference between larger and smaller radiological consequences. The IRSN analysts estimated the costs (i.e., economic damage) that would arise from an accidental, atmospheric release of radioactive material from the Dampierre nuclear generating station in France. They considered two types of release – a “controlled” (smaller) and a “massive” (larger) release. A paper summarizing their findings was presented at the 2012 Eurosafe conference. Thompson Declaration, par. IV-11. The IRSN analysts concluded that the costs arising from a massive release would differ “profoundly” from the costs arising from a controlled release, in terms of both qualitative and quantitative factors. Indeed, they described the massive release as “an unmanageable European catastrophe.” Their paper concluded with the statement: “Safety decisions may also be informed by this picture, in particular if it is realized that the most severe cases actually carry huge stakes for the nation and therefore that their lower probability may not balance their catastrophic potential.” (0897-6-14 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: As Dr. Thompson observes, the full array of consequences of a large, atmospheric release of radioactive material from a nuclear facility in the United States is difficult to predict. The nature and scale of those consequences would vary according to the characteristics of the release and other factors. It is clear, however, that there are unresolved socio-political tensions in this country. Thus, the consequences of a large release could include substantial political stress. It is unlikely that aggrieved citizens would be comforted if they learned that NRC had determined, at a prior time, that the release was a low-risk event. Thompson Declaration, par. IV-16. The DGEIS relies on probabilistic risk assessment (“PRA”)-type studies for its estimation of radiological risk. Studies of this type can provide useful information about radiological risk, for certain purposes. However, these studies cannot provide a credible estimate of the probability

of a radiological event such as a pool fire. Thompson Declaration, pars. X-31–X-39. (0897-6-15 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The Draft GEIS should comprehensively analyze all aspects of accidents involving dry cask storage and inter-cask fuel transfers based on sound scientific information. When the information is incomplete or has significant uncertainties, these should be stated. If there are methodological studies that provide a guide to how calculations should be done, the guidance should be used to develop estimates. In some cases, the data gaps are so large, that a realistic calculation of uncertainties can be operationally meaningless in the sense of its usefulness for choosing among alternative courses of action. The Draft GEIS should have assessed data gaps in this manner. Instead of such a procedure, the Draft GEIS has improperly used a pilot study (hereafter Pilot Study) intended to demonstrate a method to declare that public health impacts due to an accident during spent fuel storage transfer would be SMALL⁴⁵ [footnote 45 text: 45 NRC 2013a, pp. 4-82 and 4-83] for the purpose of the waste confidence regulation, when the study explicitly states that it should not be used for regulatory purposes: The methodology developed in this study can be used as a guide for performing other similar PRAs [probabilistic risk assessments]. Moreover, the results of this study can be used in conjunction with the methodology selected to determine the need for other PRAs, improvements in data gathering and analysis, and additional engineering design analysis. It should be noted that the focus of this pilot study *was solely on the methodology* and its limited (i.e., case-specific) application. Thus, *no inferences or conclusions should be drawn with regard to the study's regulatory implications*.⁴⁶ [footnote 46 text: NRC Pilot 2007, p. v, italics added] (0898-1-13 [Curran, Diane] [Makhijani, Arjun])

Comment: There are a number of reasons that the Pilot Study should not be used in a generic, regulatory context, especially in a situation where the impacts of indefinitely long periods of storage and repeated transfers are being assessed, as is the case in the Draft GEIS. First, it was a pilot study done to develop methodology; it was not designed for general use. For instance, the study considered high burnup Boiling Water Reactor (BWR) spent fuel.⁴⁷ [footnote 47 text: NRC Pilot 2007, p. 1-2] Most U.S. reactors are pressurized water reactors (PWR). The space between the fuel pellet and the fuel rod decreases with burnup. However, the gap between the fuel pellet and the fuel rod is reduced much more in a PWR than a BWR.⁴⁸ [footnote 48 text: NRC Pilot 2007, Table D-2, p. D-8] As the Nuclear Waste Transportation Review Board (NWTRB) has pointed out, “[h]igh-burnup fuels tend to swell and close the pellet-cladding gap, which increases the cladding stresses and can lead to creep and stress corrosion cracking of cladding in extended storage.”⁴⁹ [footnote 49 text: NWTRB 2010, p. 11] This shows that the difference in the fuel pellet cladding gap between PWRs and BWRs is of material importance for high burnup fuel; it needs to be taken into account in the analysis of impacts of spent fuel storage and transport. (0898-1-14 [Curran, Diane] [Makhijani, Arjun])

Comment: The Pilot Study listed a number of uncertainties but did not consider them in its quantitative analysis: The changes that occur in the properties of the fuel and the cladding while in-reactor may introduce *large errors* into the determination of the release factors, because of the uncertainty of the database....*No attempt has been made to quantify the degree of the uncertainties* or to determine if they are significant to the risk.⁵⁰ [footnote 50 text: NRC Pilot 2007, p. D-19, italics added] By implication, the estimate of health impact cited in the Draft GEIS has not considered a substantial number of uncertainties. (0898-1-15 [Curran, Diane] [Makhijani, Arjun])

Comment: The NRC's first proposed findings are that spent fuel can be safely stored for an indefinite time period (10 CFR 51.23(a)(2)) and that it can be stored indefinitely without

significant adverse environmental impacts (Table B-1).¹² [footnote 12 text: NRC 2013b, p. 56804-56805] These findings have scant technical support; the available analysis generally points in the opposite direction. The Draft GEIS fails to provide a detailed quantitative analysis of the impacts to public health and the environment that would occur in the event of an accidental release of radiation during spent fuel storage or transfer. Given the high level of radioactivity in spent fuel, the high burnup of much of the spent fuel, and the very long half-lives of certain radioactive materials (including plutonium-239 and long-lived fission products with half-lives that range from 30 years to millions of years), these impacts could be substantial. (0898-1-2 [Curran, Diane] [Makhijani, Arjun])

Comment: The Draft GEIS has considered only criticality accidents in spent fuel pools.⁹² [footnote 92 text: NRC 2013a, pp. 4-69 - 4-70] However criticality is an issue for dry cask storage and transport, notably for high burnup fuel as noted in NUREG/CR-6835. Irradiation of nuclear fuel to high-burnup values increases the potential for fuel failure during normal and accident conditions involving transport and storage. The objective of this work is to investigate the consequences of potential fuel failure on criticality safety and external dose rates for spent nuclear fuel (SNF) storage and transport casks, with emphasis on high-burnup SNF. Analyses were performed to assess the impact of several damaged/failed fuel scenarios on the effective neutron multiplication factor (k_{eff}) and external dose rates. The damage or failure was assumed to occur during use in storage or transport, particularly in an accident. Although several of the scenarios go beyond credible conditions, they represent a theoretical limit on the effects of severe accident conditions. Further, the results provide a basis for decision making with regard to failure potential and a foundation to direct future investigations in this area.⁹³ [footnote 93 text: NUREG/CR-6835 (2003), p. iii] (0898-3-5 [Curran, Diane] [Makhijani, Arjun])

Comment: As the abstract quoted above in paragraph 5.1 notes, the study explored the theoretical limit of criticality risks for high burnup fuel. The fuel was assumed to have been in storage for 20 years. The Draft GEIS could have used these calculations to provide bounding calculations on doses to the public and to workers in the event of an accident approaching the limits described. But it did not consider criticality risks associated with dry storage at all. (0898-3-6 [Curran, Diane] [Makhijani, Arjun])

Comment: The Draft GEIS fails to provide a detailed quantitative analysis of the impacts to public health and the environment that would occur in the event of an accidental release of radiation during spent fuel storage or transfer. Given the high level of radioactivity in spent fuel, the very long half-lives of certain radioactive materials (including plutonium-239 and long-lived fission products with half-lives that range from 30 years to millions of years), and the high burnup of much of the spent fuel, these impacts could be substantial. (0898-5-14 [Curran, Diane] [Makhijani, Arjun])

Comment: Having initially testified before the A.E.C. in 1969 of my experiencing numerous earthquakes (6.0+ in 1966) in Avila Beach, I was quickly, superficially & continuously ignored. Ignoring the NRC's own regulations on seismic issues & without initially shutting down the Devil until the seismic studies are completed, only further demonstrates the committees collusion & corruption. Is that your legacy? (0905-2 [Schmidt, Otto])

Comment: The Draft GEIS claims that impact of a severe accident would be small. Such a conclusion cannot be supported by logic or experience. A severe accident would release deadly radioactivity into the environment. Every release of manmade radioactive matter into the environment to date has had serious and long-lasting impacts on humans and other living things within the area affected. (0908-3 [Mikkelsen, Sara])

Comment: On page xxx, the box states "NRC's concept of risk probability consequences HOW LIKELY IS IT ...etc". Surely the facts of Hiroshima/Nagasaki, Three Mile Island [where setting a manageable fire was considered], Chernobyl [and its continuous wind-caused unexpected hotspots], and Fukushima ongoing uncontrolled hazards etc..... sadly show the Industry/NRC/etc. disrespect for human, environmental and planetary welfare. (0910-7 [Carey, Corinne])

Comment: Design Basis Events in Dry Cask Storage Systems[:] The draft GEIS assumes that during repackaging, hundreds of thousands of assemblies will have to be transferred one-by-one across all DTS facilities. The draft GEIS also uses a "stuck assembly" accident as bounding for the accident scenario analyses. However, a "stuck assembly" accident does not include rupture of the cladding and release of radioactive material, while a cask/assembly drop scenario would be likely to include a release. It is not clear why the "stuck assembly" accident is used for bounding the accident scenario analyses when the consequences of a cask/assembly drop would be more severe than those of a "stuck assembly" accident. The draft GEIS also states that since the postulated fuel assembly or cask drop is among the design basis accidents analyzed by licensees, the environmental consequences associated with these accidents during continued storage would be small. It is our understanding, however, that existing facilities are not currently licensed for extended fuel storage, and they are not licensed to perform fuel inspections and repackaging involving multiple assembly transfers. The number of projected assembly transfers during ISFSI/DTS operations is not provided in the draft GEIS, although we expect the number of such transfers will likely be significant. With a large number of transfers, even low frequency events may have a non-negligible, non-speculative 1likelihood of occurring during the lifetime of all of the assumed DTS facilities. The draft GEIS does not provide information provided on the number, frequency and consequences of assembly drops anticipated during ISFSI/DTS operations for all three timeframes. *Recommendation:* Provide the following information in the final GEIS in Section 4.18.1.2: (i) total number and annual frequency of assembly drops across the industry, (ii) projected frequency of assembly drops during transfers of assemblies in the course of loading, repackaging, inspection, and other pertinent ISFSI/DTS operations for all three timeframes, (iii) whether cask/assembly drops could occur at least once in the lifetime of any of the assumed DTS facilities, and (iv) projected consequences of these cask/assembly drops during transfer operations. Assume high burnup fuel and degraded cladding for all three scenarios, and provide information on why the consequences of "stuck assembly" accidents are considered more severe than consequences of the cask/assembly drops during transfer operations. (0915-7 [Bromm, Susan E.]

Comment: Natural Phenomena Hazard Events[:] The draft GEIS does not discuss the potential for an increased likelihood of the occurrence of natural phenomena hazard events, such as seismic events, given extended storage time frames. We also note that because the fuel, cladding and assembly hardware are not designed for storage beyond 100 years after irradiation, the potential degradation of the hardware may exacerbate the impact of natural phenomena hazard events. *Recommendation:* Provide information on the potential for an increased likelihood of the occurrence of natural phenomena hazard events over extended time frames, as well as the potential degradation of the hardware and how that may exacerbate the impacts of natural phenomena hazard events. (0915-9 [Bromm, Susan E.]

Comment: (V-21) These five core-melt incidents provide a data set that is comparatively sparse and therefore does not provide a statistical basis for a high-confidence estimate of CDF. Nevertheless, this data set does provide a reality check for PRA estimates of CDF. From this data set - five core-melt incidents over a worldwide experience base of about 15,500 RY - one observes a CDF of 3.2×10^{-4} per RY (1 event per 3,100 RY). This value can be regarded as a

"simple" estimate of CDF. (V-22) A PRA analyst employed by NRC, Raymond Gallucci, has written a paper that develops CDF estimates based on direct experience.³⁷ [footnote text 37: Gallucci, 2012.] Gallucci's paper accompanies this declaration as Exhibit #21. The paper considers both reactor core-melt and ASP experience, leading to a "simple" CDF estimate of 6.0×10^{-4} per RY (1 event per 1,700 RY). The paper does not adopt that estimate. Instead, it makes some analytic assumptions, and ultimately concludes that CDF, worldwide and in the USA, is in the range 0.7×10^{-4} to 4.0×10^{-4} per RY (between 1 event per 14,300 RY and 1 event per 2,500 RY). I question the assumptions underlying this downward adjustment of the "simple" CDF estimate. However, Gallucci's analysis deserves careful consideration in view of his professional expertise. On another note, Gallucci ends his paper by expressing his personal willingness to tolerate a CDF of the level that he has identified. On that matter, his opinion has no more weight than the opinion of any citizen. (V-23) As shown in the preceding paragraphs, direct experience suggests a CDF as high as 6.0×10^{-4} per RY. The lowest value in the range suggested by Gallucci is 0.7×10^{-4} per RY. It is instructive to compare these numbers with the CDF estimates shown in Figures V-1 and V-2. The only CDF estimates in those figures that approach direct-experience levels are the upper-bound (95th percentile) levels of earthquake-caused CDF using Livermore seismic estimates. Thus, direct experience indicates that NUREG-1150 substantially under-estimated CDF. This finding does not mean that NUREG-1150 was a bad study. On the contrary, as stated above, NUREG-1150 was the high point of PRA practice. My finding simply confirms that PRA cannot account for all of the factors that determine the probability component of radiological risk. (0916-1-10 [Curran, Diane] [Thompson, Gordon R.]

Comment: (V-27) A paper by Sornette et al reveals the limitations of PRA findings by comparing them with lessons from direct experience.³⁸ [footnote text 38: Sornette et al, 2013.] That paper accompanies this declaration as Exhibit #22. The paper considers monetized losses from nuclear-facility incidents, using two sources of information. One source is a reactor PRA. The other source is a compilation of data on actual incidents at nuclear facilities. Figure V-5 of this declaration reproduces a figure from Sornette et al. That figure shows that the PRA substantially under-estimates the probability of a monetized loss. The under-estimation grows as losses become larger. In other words, the PRA findings show a thin-tail probability distribution, whereas the empirical data show a fat-tail distribution. (0916-1-11 [Curran, Diane] [Thompson, Gordon R.]

Comment: (V-30) At this point in Section V, I have shown that reactor PRAs typically yield estimates of probability (i.e., the probability of accident outcomes) that are substantially lower than is implied by direct experience and insurers' judgment. This finding carries over to PRAs for non-reactor facilities, because it arises from limitations in the art of PRA itself. Those limitations are significant for the draft GEIS, because the draft GEIS relies upon PRA findings for estimation of radiological risk. (0916-1-12 [Curran, Diane] [Thompson, Gordon R.]

Comment: (VIII-9) At this point, I have established that pool storage of spent fuel, as considered in the draft GEIS, could occur, and probably will occur, at locations near operational reactors. It follows that the draft GEIS should have carefully considered the potential linkage of pool risk and reactor risk. (VIII-10) PRA practice has neglected linkage of risk among multiple reactors at a site. That neglect is summarized in Karl Fleming's paper, discussed above. The paper says:⁷² [footnote text 72: Fleming, 2011.] "Our current state of knowledge about the risks from accidents is derived from PRAs. For the most part PRAs on multi-unit sites have been performed on individual reactors separately. In fact, some multi-unit sites have performed a PRA only for one of the sited reactors, arguing that symmetry considerations justify a single reactor PRA. In order to meet expectations for PRA quality, as defined in the various PRA standards, such PRAs must address certain multi-unit dependencies in the modeling of risks

that involve damage to a single reactor. The capability to use equipment from one reactor to back up failures on another is typically considered, however the probability that resources are consumed by concurrent reactor accidents is almost always ignored." (VIII-11) In a 2013 journal article, Schroer and Modarres proffer an event classification schema for applying PRA to multiple reactors at a site.⁷³ [footnote text 73: Schroer and Modarres, 2013.] That article accompanies this declaration as Exhibit #34. At the time of publication, co-author Suzanne Schroer was a member of the NRC staff. The article says:⁷⁴ [footnote text 74: Schroer and Modarres, 2013, page 49.] "Currently, multi-unit nuclear power plant PRAs consider the risk from each unit separately and do not consider combination events between the units. To gain an accurate view of the site's risk profile, the CDF for the site rather than the unit must be considered. This paper has presented a classification system that utilizes existing single-unit PRAs and combines them into a multi-unit PRA. Six main commonality classes that can cause multiple units to be dependent have been presented: initiating events, shared connections, identical components, proximity dependencies, human dependencies, and organizational dependencies. A seventh class, independent events, was only marginally discussed because it does not address dependencies between the units." (VIII-12) From the two preceding paragraphs and the documents cited therein, one sees that linkage of risk among multiple reactors at a site has been long neglected, but is beginning to receive some attention from NRC and licensees. Linkage of pool risk and reactor risk at a site has been similarly neglected, but has not been properly addressed by NRC or licensees. (0916-1-17 [Curran, Diane] [Thompson, Gordon R.]

Comment: (VIII-13) Although NRC has not properly addressed the linkage of pool risk and reactor risk, NRC has taken a small, initial step in that direction. This step was taken in a pool-fire study that NRC published in 2013. As discussed in paragraph I-11, above, NRC published a draft version of the pool-fire study in June 2013.⁷⁵ [footnote text 75: Barto et al, 2013a.] The study was republished in final form in October 2013, with no substantial change.⁷⁶ [footnote text 76: The October 2013 version is: Barto et al, 2013b. It was published as an enclosure under the SECY memo: Satorius, 2013a. That memo stated: "None of the comments or responses [i.e., on the draft version of the study] has necessitated making substantial changes to the report." (See: Satorius, 2013a, page 3.)] The October 2013 version, with its cover memo, accompanies this declaration as Exhibit #35. Hereafter, I refer to it as "NRC's consequence study". I assume that the technical parts of the June 2013 and October 2013 version are identical. Thus, the Thompson draft consequence declaration applies equally to both. (VIII-14) NRC's consequence study took a small step toward addressing the linkage of pool risk and reactor risk in the sense that it identified aspects of that linkage. It did not proceed to analyze those aspects. The identification occurred under the rubric, Multi-Unit Considerations, via the following statement:⁷⁷ [footnote text 77: Barto et al, 2013b, Section 2.2, pp 28-29.] "Observations Regarding a Concurrent Reactor Event: There are four broad interplays that can be defined between the SFP [spent fuel pool] and the reactor: 1. an initiating event that directly affects both the reactor and the SFP 2. a reactor accident that prevents accessibility to the SFP for a prolonged period of time (e.g., due to high radiation fields), leading to a SFP accident 3. a reactor accident that includes ex-containment energetic events (e.g., a hydrogen combustion event) or other ex-containment interplays (e.g., steaming through the drywell head that affects refuel floor combustible gas mixtures) and creates a hazard to the SFP (e.g., by causing debris to fall in to the pool) or otherwise changes the SFP event progression 4. an SFP accident that prevents accessibility to key reactor systems and components for a prolonged period of time or which creates a hazard for equipment used to cool the reactor (e.g., the flooding of low elevations of the reactor building due to a leak in the pool or excessive condensation from continuous boiling of SFP water), leading to a reactor accident[.] For each of these interplays, large seismic events and severe weather SBO [station blackout] events are logically the most relevant initiators, as

they are the type of initiators that are most likely to initiate an accident at the reactor and SFP, while simultaneously hampering further accessibility to key areas, key systems and components, and key resources. To the extent practicable, this study has attempted to qualitatively account for some of these effects. For example, when the reactor and SFP are hydraulically connected (during refueling), the decay heat and water volumes from both sources are considered. The study also explores these effects on mitigation (Section 8), and addresses some aspects of the uncertainty associated with this treatment (Section 9). However, explicitly modeling multiunit effects was not a focus of this study, because of the existing limitations with the available computational tools. An ongoing project described in SECY-11-0089 will attempt to more rigorously address these effects in the framework of a multiunit Level 3 PRA for Vogtle Electric Generating Plant Units 1 and 2." (0916-1-18 [Curran, Diane] [Thompson, Gordon R.]

Comment: (VIII-15) The four "interplays" described in this statement are far from the final word about linkage of pool risk and reactor risk, but they would provide a useful starting point for technical analysis on that linkage. These interplays could occur in situations where pool storage of spent fuel, as considered in the draft GEIS, occurs at a location near an operational reactor. Thus, the draft GEIS should have carefully considered the implications of these interplays for the environmental impacts of storing spent fuel in pools. Unfortunately, the draft GEIS failed to consider those implications. (VIII-16) The second half of the statement quoted in paragraph VIII-14 shows clearly that NRC's consequence study does not provide credible technical analysis of the pool-reactor interplays that it identifies. Instead, it says that another project "will attempt" to address these interplays at some future date. Until that work is done properly, NRC will not be able to complete an adequate GEIS on the environmental impacts of storing spent fuel. (0916-1-19 [Curran, Diane] [Thompson, Gordon R.]

Comment: (IV-4) NRC has articulated several, inconsistent definitions of risk. The definition in the NRC Glossary is, on its face, similar to my definition. Other NRC definitions, discussed below, deviate from the NRC Glossary to the point where they become fundamentally flawed. The NRC Glossary defines risk as:¹⁸ [footnote 18 text: NRC website, <http://www.nrc.gov/reading-rm/basic-ref/glossary/risk.html>, accessed on 21 October 2013.] "The combined answer to three questions that consider (1) what can go wrong, (2) how likely it is, and (3) what its consequences might be. These three questions allow the NRC to understand likely outcomes, sensitivities, areas of importance, system interactions, and areas of uncertainty, which can be used to identify risk-significant scenarios." (IV-5) In the draft GEIS, the concept of risk is first introduced using a definition close to, but not identical with, the definition in NRC's Glossary. The Executive Summary of the draft GEIS says:¹⁹ [footnote 19 text: NRC, 2013b, page xxx.] "NRC's concept of risk combines the probability of an accident with the consequences of that accident. In other words, the NRC examines the following questions: What can go wrong? How likely is it? What would be the consequences?" (IV-6) Later in the draft GEIS, the definition of risk deviates further from NRC's Glossary and becomes fundamentally flawed. In Section 4 of the draft GEIS, this later definition is embedded in an instructive paragraph. The paragraph is:²⁰ [footnote 20 text: NRC, 2013b, pages 4-68 and 4-69 (emphasis added).] "The consequences of a severe (or beyond-design-basis) accident, if one occurs, could be significant and destabilizing. The impact determinations for these accidents, however, are made with consideration of the low probability of these events. The environmental impact determination with respect to severe accidents, therefore, is based on the risk, which the NRC defines as the product of the probability and the consequences of an accident. This means that a high-consequence low-probability event, like a severe accident, could still result in a small impact determination, if the risk is sufficiently low." (IV-7) Through this deviation, NRC has ended up with a particular, limited definition of risk, as the arithmetic product of a numerical indicator of harmful consequences and a numerical indicator of the probability that those

consequences will occur.²¹ [footnote text 21: Often, the arithmetic product is calculated for each of a range of scenarios, and these products are summed across the scenarios to yield an overall "risk".] I refer to that definition hereafter as the "arithmetic" definition of risk. The arithmetic definition is flawed from several perspectives, as discussed below. It is, however, used extensively in the nuclear industry. (IV-8) The above-quoted paragraph from the draft GEIS suggests a powerful motive for use of the arithmetic definition of risk. Consider the following situation. The consequences of a potential event could be severe; indeed, they could be "significant and destabilizing", to use the words of the draft GEIS. Yet, if the event has, allegedly, a sufficiently low probability, then its "risk", arithmetically defined, would be very low. A devotee of the arithmetic definition could then argue that no action is required to mitigate the risk. In that way, the cost of mitigating actions would be avoided. (0916-1-2 [Curran, Diane] [Thompson, Gordon R.]

Comment: (VIII-18) Figure VIII-2 illustrates how intimately a spent-fuel pool can be associated with the reactor it serves. Moreover - as discussed in paragraph VIII-6, above - at 17 sites in the United States, any fuel in a pool is intimately associated with two adjacent reactors. In other instances, the association between a pool and a different, nearby reactor may not be quite so intimate. Nevertheless, physical proximity, sharing of buildings, and/or sharing of support systems could establish a strong linkage of pool risk and reactor risk. One concern is that a release of radioactive material from a reactor could create a radiation field that precludes personnel access needed to keep a nearby spent-fuel pool in a safe state. Lack of that access could lead to a pool fire. (0916-1-20 [Curran, Diane] [Thompson, Gordon R.]

Comment: In the context of radiological risk in the commercial nuclear sector, the arithmetic definition of risk is flawed from at least four overlapping perspectives: First, numerical estimates of consequences and probability are typically incomplete and highly uncertain. Second, significant aspects of consequences and probability are not susceptible to numerical estimation. Third, larger consequences can be qualitatively different than smaller consequences. Fourth, devotees of the arithmetic definition typically argue that equal levels of "risk", as they define it, should be equally acceptable to citizens. Their argument may be given a scientific gloss, but is actually a statement laden with subjective values and interests. An informed citizen could reject their argument on reasonable grounds. (0916-1-3 [Curran, Diane] [Thompson, Gordon R.]

Comment: (IV-11) The third perspective is that larger consequences can be qualitatively different than smaller consequences. There is ample evidence to support this proposition. For example, analysts at the French government's Institut de Radioprotection et de Surete Nucleaire (IRSN) have found a qualitative difference between larger and smaller radiological consequences. The IRSN analysts estimated the costs (i.e., economic damage) that would arise from an accidental, atmospheric release of radioactive material from the Dampierre nuclear generating station in France. They considered two types of release - a "controlled" (smaller) and a "massive" (larger) release. A paper summarizing their findings was presented at the 2012 Eurosafe conference.²² [footnote text 22: Pascucci-Cahen and Patrick, 2012.] That paper accompanies this declaration as Exhibit #11. (IV-12) The IRSN analysts concluded that the costs arising from a massive release would differ "profoundly" from the costs arising from a controlled release, in terms of both qualitative and quantitative factors. Indeed, they described the massive release as "an unmanageable European catastrophe". Their paper concluded with the statement: ²³ [footnote text 23: Pascucci-Cahen and Patrick, 2012.] "Safety decisions may also be informed by this picture, in particular if it is realized that the most severe cases actually carry huge stakes for the nation and therefore that their lower probability may not balance their catastrophic potential." (IV-13) To illustrate the potential for qualitative difference between larger

and smaller consequences, consider the IRSN description of a massive release as "an unmanageable European catastrophe". Underlying that description is the potential for major sociopolitical impacts that would, in Europe, have substantial trans-boundary dimensions. The European Union might not survive the political stress arising from this event. (0916-1-4 [Curran, Diane] [Thompson, Gordon R.]

Comment: (IV-16) The full array of consequences of a large, atmospheric release of radioactive material from a nuclear facility in the United States is difficult to predict. The nature and scale of those consequences would vary according to the characteristics of the release and other factors. It is clear, however, that there are unresolved socio-political tensions in this country. Thus, the consequences of a large release could include substantial political stress. It is unlikely that aggrieved citizens would be comforted if they learned that NRC had determined, at a prior time, that the release was a low-risk event. (0916-1-5 [Curran, Diane] [Thompson, Gordon R.]

Comment: (IV-17) As mentioned above, the arithmetic definition of risk is used extensively in the nuclear industry, despite its flaws. It is also used in other contexts. One manifestation of this definition is the "probability-threshold position" on risk. Supporters of that position argue that levels of risk below some numerical threshold can be ignored. That position means, in effect, that risks below the threshold are assigned a value of zero. The threshold might be, for example, an average probability of human fatality of 1×10^{-6} per annum. The probability-threshold position has been critiqued in a paper by the philosopher Kristin Shrader-Frechette.²⁶ [footnote text 26: Shrader-Frechette, 1985.] That paper accompanies this declaration as Exhibit #14. Shrader-Frechette found that arguments for the probability-threshold position are fundamentally flawed. (0916-1-6 [Curran, Diane] [Thompson, Gordon R.]

Comment: (IV-18) Devotees of the arithmetic definition of risk often claim that their position is "scientific" and "rational". It is neither. The arithmetic definition is laden with subjective values and interests, and is prone to abuse. It is given a scientific gloss because it is expressed in numbers. However, the neatness of its numerical expression is achieved by ignoring significant factors that are not susceptible to numerical assessment. Ignoring such factors is the antithesis of a scientific approach. Moreover, the arithmetic definition pre-empts important ethical considerations, such as the tolerability of large consequences. Accordingly, the Thompson scoping declaration offered the following recommendation, which I continue to endorse:²⁷ [footnote text 27: Thompson, 2013b, Sections IX and X.] "Recommendation #21: In considering radiological risk, the proposed EIS [i.e., the draft GEIS] should repudiate the arithmetic definition of risk." (0916-1-7 [Curran, Diane] [Thompson, Gordon R.]

Comment: (V-8) The first reactor PRA was the NRC's Reactor Safety Study (RSS).²⁹ [footnote text 29: NRC, 1975.] NRC set up a group of experts, chaired by the physicist Harold Lewis, to review the RSS. Their report accompanies this declaration as Exhibit #15. In their report, the review group succinctly described the challenge of developing a credible PRA as follows:³⁰ [footnote text 30: Lewis et al, 1978, page 6.] "RSS was faced with the problem of estimating the probability of occurrence of an extremely rare event - core melt - in a system of great complexity, a nuclear power reactor. Since the event has never occurred in a commercial reactor, there are no direct experimental data on which to base an estimate. The only datum that exists is the observation that there have been no core melts [as of 1978] in several hundred reactor-years of light water power reactor operation, and this fact provides at best an upper bound on the probability to be estimated. Therefore, it is necessary to resort to a theoretical calculation of the probability. But since the system is so complex, a complete and precise theoretical calculation is impossibly difficult. It is consequently necessary to invoke simplified

models, estimates, engineering opinion, and in the last resort, subjective judgments." (V-9) The preparation of a "complete and precise theoretical calculation" of core damage frequency remains "impossibly difficult" today, just as it was when Lewis and his colleagues wrote in 1978. This difficulty is intrinsic to the complexity of a reactor and the large number of potential failure modes. The difficulty is compounded when PRA analysts move from estimation of CDF (Level 1) to estimation of radioactive release (Level 2) and to estimation of offsite consequences (Level 3). At Level 2 there are many phenomenological uncertainties and variabilities. At Level 3 there is great variation in a variety of factors, such as atmospheric characteristics, and basic difficulties in characterizing indirect consequences. Thus, the radiological risk posed by a reactor is much more uncertain than other technological risks that are readily susceptible to actuarial analysis (e.g., automobile accidents). (V-10) The complexity of a reactor is not the only reason why PRA findings are uncertain. Another reason is that a PRA examines an idealized system. The idealized system is properly designed, properly built, properly operated, and composed of independent components that typically fail randomly. PRA analysts have recognized that component failures may not always be independent. In response, they have developed analytic techniques to account for "common mode" failures that are attributable to influences (e.g., an earthquake, or a maintenance error) that can simultaneously affect more than one component. Although these techniques are useful, they leave some significant threats unaddressed. (V-11) Three exemplary threats show how the idealized system examined in a PRA can be an incomplete representation of reality. First, a PRA cannot account for gross errors in design, construction, or operation. Second, it cannot account for malevolent acts. Third, it cannot account for deficiencies in institutional culture and practice. Each threat is significant. All three threats can lead to common mode failures. PRA's inability to account for malevolent acts is notable because a malevolent human intellect can identify weak points in a system, and can exploit destructive forces that are latent in the system. (0916-1-8 [Curran, Diane] [Thompson, Gordon R.]

Comment: (V-13) A commission, chaired by John Kemeny, was established by US President Carter to investigate the TMI accident. The commission's report accompanies this declaration as Exhibit #16. The commission concluded that systemic deficiencies in human behavior and organization were the dominant causes of the accident. To illustrate, their report included the statement:³¹ [footnote text 31: Kemeny et al, 1979, page 8.] "We are convinced that if the only problems were equipment problems, this Presidential Commission would never have been created. The equipment was sufficiently good that, except for human failures, the major accident at Three Mile Island would have been a minor incident. But, wherever we looked, we found problems with the human beings who operate the plant, with the management that runs the key organization, and with the agency that is charged with assuring the safety of nuclear power plants." (V-14) Two Harvard University physicists, one of whom had previously worked in a reactor physics group in the USSR, published a paper in 1992 that examined the Chernobyl accident. Their paper accompanies this declaration as Exhibit #17. The abstract of their paper stated:³² [footnote text 32: Shlyakhter and Wilson, 1992.] "The Chernobyl accident was the inevitable outcome of a combination of bad design, bad management and bad communication practices in the Soviet nuclear industry. We review the causes of the accident, its impact on Soviet society, and its effects on the health of the population in the surrounding areas. It appears that the secrecy that was endemic in the USSR has had profound negative effects on both technological safety and public health." (V-15) The National Diet (i.e., parliament) of Japan established an independent commission to investigate the Fukushima accident. The executive summary of their report accompanies this declaration as Exhibit #18. The commission's principal conclusion was:³³ [footnote text 33: Diet, 2012, page 16.] "The TEPCO Fukushima Nuclear Power Plant accident was the result of collusion between the government, the regulators and TEPCO, and the lack of governance by said parties. They effectively betrayed

the nation's right to be safe from nuclear accidents. Therefore, we conclude that the accident was clearly "manmade". We believe that the root causes were the organizational and regulatory systems that supported faulty rationales for decisions and actions, rather than issues related to the competency of any specific individual." (V-16) The combined experience of these three incidents strongly suggests that a non-quantifiable factor, which cannot be accounted for in a PRA, will be a major or dominant risk factor underlying the next core melt at a commercial nuclear reactor. Thus, reliance on PRA to estimate the probability of the next core melt would be neither reasonable nor prudent. (0916-1-9 [Curran, Diane] [Thompson, Gordon R.]

Comment: The flawed nature of the arithmetic definition of risk is clearly evident in the draft GEIS, NRC's consequence study, and the NRC staff's Tier 3 analysis. Each of those documents uses frequency-weighted consequences, as discussed in paragraph X-40, above, as a measure of environmental impact. In that manner, disastrous consequences of a potential pool fire, such as the long-term displacement of 4.1 million people, are made to appear small by multiplying the consequences by a supposedly low frequency. (0916-3-1 [Curran, Diane] [Thompson, Gordon R.]

Comment: The draft GEIS relies on PRA-type studies for its estimation of radiological risk. Studies of this type can provide useful information about radiological risk, for certain purposes. However, these studies cannot provide a credible estimate of the probability of a radiological event such as a pool fire. The relationship between a PRA finding and reality can be represented as follows: Actual probability of event = (PRA finding)x(Reality factor #1) + (Reality factor #2) Where the variables in this equation are as follows: "Actual probability of event" refers to the real-world numerical probability of an outcome such as: fuel damage; release of a specified amount of radioactive material; contamination of a specified area of land above a specified dose threshold; or accrual of a specified collective dose to people offsite. "PRA finding" refers to a PRA estimate of the probability of the outcome in question – this could be a mean, median, or other representation of a probability distribution. "Reality factor #1" is a number, typically greater than 1, that represents influences that are within the paradigm of PRA but are not properly accounted for in contemporary PRAs – these influences include: complexity; inadequate data; and deficiencies in institutional culture and practice. "Reality factor #2" is a number that represents influences outside the paradigm of PRA – these influences include: gross errors in design, construction, or operation; and malevolent acts. And the following observations apply: Experience suggests that Reality factor #1 for severe accidents may have a value that exceeds 1 by several orders of magnitude (i.e., factors of 10). Reality factor #2 has two numerical components: (i) a retrospective component that can be determined empirically based on the occurrence of events; and (ii) a prospective component that will remain unknown for the foreseeable future. Both Reality factors may vary significantly in response to variations in the future risk environment. This version of the equation is applicable when the values of "PRA finding" and "Actual probability of event" are both less than 1. At higher values, the term "probability" would be replaced by the term "frequency". (0916-3-19 [Curran, Diane] [Thompson, Gordon R.]

Comment: Also, NRC focuses on each facility in isolation. That focus is evident in NRC's discussion of frequency in terms of occurrence per reactor-year or per pool-year. For some, limited, technical purposes, this single-facility focus is appropriate. It is, however, inappropriate when considering the risk experienced by a citizen. The United States currently has 100 operational, commercial reactors, roughly the same number of spent- fuel pools, and various other nuclear facilities.¹³⁴ [footnote 134 text: An operational reactor is a reactor that is normally in operation except when shut down for refueling, maintenance, or repair.]A citizen is exposed to the radiological risk associated with a number of facilities. This point is illustrated by NRC's finding, as discussed in paragraph X-42, above, that a pool fire at the Peach Bottom site could

lead to the long-term displacement of 4.1 million people. About 800,000 of those people would have resided within 50 miles of the site, while about 1.2 million would have resided between 50 and 100 miles from the site, and about 2.1 million would have resided between 100 and 500 miles from the site.¹³⁵ [footnote 135 text: Barto et al, 2013b, Table 36 (page 169).] Clearly, this event would have long-range consequences, extending far beyond the vicinity of the afflicted site. A citizen at a given location could be vulnerable to impacts of this nature originating at any of a number of sites.¹³⁶ [footnote 136 text: The flexRISK project in Austria developed a computer-model capability to assess the radiological risk, at any location in Europe, that arises from operation of all nuclear facilities across Europe. That capability could be applied to the United States. An overview of the flexRISK project was accessed on 14 December 2013 from: <http://flexrisk.boku.ac.at/en/index.html>] (0916-3-2 [Curran, Diane] [Thompson, Gordon R.]

Comment: The draft GEIS considers the risk of a pool fire in terms of the probability of its occurrence at a particular pool within a 1-year timeframe. That approach to risk assessment does not account for the potential magnitude and scope of the consequences of a pool fire. Instead, the radiological risk of a pool fire should be considered in terms of the cumulative frequency of its occurrence, over a period of a century, at any location within the United States. (0916-3-23 [Curran, Diane] [Thompson, Gordon R.]

Comment: (X-55) Thus, in considering the probability of a pool fire, an appropriate indicator would be the frequency of the event occurring anywhere in the United States during a specified time period. Given the existence of operational reactors in Canada and Mexico, the geographic perimeter might logically be extended to North America. For the purposes of this declaration, however, I set that option aside because it would be legally and politically difficult to implement. (X-56) What would be the appropriate time period for a determination of frequency? Given that a pool fire could be a national disaster of historic dimensions, a reasonable time period would be a century. If that time period were employed in the context of the United States as a geographic unit, then the frequency of a pool fire would be expressed in terms of the number of occurrences per century, where the occurrence could be at any location within the United States. This concept of frequency would be compatible with the particular characteristics of pool-fire risk. Hereafter, I refer to this concept as “cumulative frequency”. Note, as discussed previously, that this indicator could have a value greater than 1. (X-57) There are now 100 operational reactors in the United States. As discussed in Section IX, above, the draft GEIS allows for the continuation of this situation indefinitely. Thus, for the purpose of illustrating pool-fire risk, it is reasonable to consider a scenario in which 100 reactors are operational throughout a period of 100 years. In this scenario, each reactor has a risk linkage with one nearby pool other than its own pool, and vice versa. Each of these nearby pools is assumed to fall under the ambit of the draft GEIS because the reactor that it served is no longer licensed for operation. I assume that each nearby pool is equipped with high-density racks, and that the risk posed by each reactor-pool linkage is uniform across the fleet and constant over time. This “status quo” scenario is entirely compatible with the draft GEIS. (X-58) For this illustrative scenario, the cumulative frequency of a pool fire can be determined by simple extrapolation of current estimates of pool-fire frequency, which are expressed on a per-pool-year basis. Consider first the frequency estimate of 2.4×10^{-6} per pool-year that is set forth in the draft GEIS in the context of an accident-induced pool fire, as discussed in paragraph X-31, above. In that case, the cumulative frequency would be $100 \times 100 \times 2.4 \times 10^{-6} = 0.024$ events per century. Now, consider the revised frequency estimate of 3.2×10^{-5} per pool-year that is set forth in paragraph X-33. This revised estimate accounts for linkage of pool risk and reactor risk, still in the context of an accident-induced pool fire. In this case, the cumulative frequency would be $100 \times 100 \times 3.2 \times 10^{-5} = 0.32$ events per century. (0916-3-4 [Curran, Diane] [Thompson, Gordon R.]

Comment: Section 4.18, pgs. 4-71 to 4-76--This section discusses the impact of earthquakes, floods, high winds from tornadoes and hurricanes, and climate change on the facilities, with the summary on page 4-76. According to the summary the environmental risk from accidents related to these hazards is small since all important safety features and components related to the spent fuel are designed to withstand the "design basis" for each of these accidents. A review of the design basis for tornadoes indicates a reduction in the design wind speed from the original design basis. For the earthquake hazard, as a result of the March 2011 earthquake and tsunami at the Fukushima Dai-ichi nuclear power plant, NRC requested all US nuclear power plants to (1) conduct walkdowns of their facilities including spent fuel pools and address plant-specific vulnerabilities and verify the adequacies of monitoring and maintenance procedures and (2) reevaluate the seismic hazards against present day NRC requirements and guidance. Page 4-75 indicates the lowest-grade above sea level for an NRC-licensed facility is currently about 14 feet. Hurricane Sandy had storm surges in the area of Oyster Creek up to at least 7 feet above mean sea level with very little rainfall for the storm. If Sandy produced a normal amount of rainfall for a hurricane-tropical storm, the flooding on the bay in and around Oyster Creek would have been substantially greater. (0920-37 [Foster, Ruth])

Comment: We disagree that you can make safety determinations using Probability Risk Assessment (PRA). First, you take a really small number, which is a wild guess as to the probability that some event will occur. Then you take another number, which is a wild guess as to the total consequences of an accident. You multiply these together, making the uncertainty wild-guess-squared, or actually indeterminate. Then, you multiply this by a constant cost of \$2000 or maybe \$4000 per mREM of release, and compare that with an ever-changing and inflated cost for providing safety measures. At the end of all this, you predictably discover that the risk is small, and any changes to improve safety cost too much. (0930-1-10 [Lutz, Ray])

Comment: You also ignore the fact that the RISKS increase with every additional NWO that exists and the extended period of time they are envisioned to be in operation. Thus, you need to multiply the indeterminate risk by the number of years and by the number of NWOs in operation. You also have no means to increase the cost per mREM as it is a fixed number, but the utilities charge as much as they can to fulfill regulatory requirement, sometimes exceeding the NRC (and any reasonable estimate) by as much as 10x. (0930-1-11 [Lutz, Ray])

Comment: There is never much of any consequence that needs to be analyzed if everything goes well. The problem is when things don't go well. You analyze spent fuel fires based on limited concept of type of accidents that might occur. "Design basis accidents" are used as a way to limit the cost for dealing with accidents, because only a limited number of scenarios need be considered. In this document, you consider only two possible scenarios, when in fact there are an unlimited number of scenarios, some of which we could not think of because we don't understand everything. For example, at SONGS, the steam generator tubes were analyzed for only one type of rattling motion. Motion along the other plane was considered inconsequential. In actuality, the steam generators were rattling themselves apart at the seams. So what is the likelihood that you have it wrong? Probably 100%. (0930-1-12 [Lutz, Ray])

Comment: We find this attempt to avoid oversight by the public as a serious concern, given the obvious lack of oversight and poor choices by the industry, exemplified by the failures of the San Onofre Nuclear Generating Station (SONGS), and the disaster at Fukushima, which used similar "Probability Risk Assessment" approaches to conclude that a tsunami of that size would be extremely improbable, and therefore inconsequential. PRA is a broken approach. (0930-1-3 [Lutz, Ray])

Comment: Section 3.0 "Affected Environment" considers only the effects when everything goes well, not when the accidents happen, and THEY WILL HAPPEN. This is the lesson, more than anything else, we must accept from Fukushima, and the nuclear industry in general. No matter how unlikely the accident, they STILL WILL OCCUR, and you SHOULD consider this in the affected environmental analysis. THE ENTIRETY OF THIS SECTION MUST BE CHANGED to address the consequences of accidents, not operation without any problem. No one is concerned about non-accident operation of an ISFSI If there is no accident, there is by definition, no problem. But when there is an accident, then there is, and this is why your treatment of the effects on the environment are ALL INSUFFICIENT. (0930-2-21 [Lutz, Ray])

Comment: Section 3.14 "Waste management" only concerns EXPECTED waste when everything is going well. What happens when something happens that is out of expectation? Not addressed. (0930-3-1 [Lutz, Ray])

Comment: Page 4-77, Line 30+, you consider two design basis accidents in the hypothetical DTS. You did not consider unusual and unexpected events, like partial meltdown inside a canister due to failure of cladding around high-burnup fuel pellets, a problem that has been described as a concern. At this point, we assert that there are simply TOO MANY UNKNOWNs and "unresolved issues" for this DGEIS to apply to any period longer than the normal decommissioning period. As more information is learned, if a DTS is actually ever designed and constructed, if we get statistics about how well the fuel lasts inside canisters, etc. etc. then it may be possible, IN ABOUT ANOTHER 50 YEARS to speculate about the subsequent 100. Until then, your optimism is far too apparent, and again a sign that the NRC has gone so far astray that it does not even realize that it is lost. (0930-3-7 [Lutz, Ray])

Comment: Page 4-78, you consider a "loss of containment event" but constrain it to filters that are inoperable. Why not assume the entire DTS fails and radiation is emitted? Then what? There is no containment around the DTS, in the design you have conceptualized. Ridiculous. STANDARDS FOR DRY/WET TRANSFER MUST BE IMPROVED. (0930-3-8 [Lutz, Ray])

Comment: The risks known and unknown of widespread accidental contamination to large population centers in and of themselves have never been disclosed and are instead minimized by a long program of secrecy. (0935-6 [Uhls, Agnes])

Comment: Having to shut down reactors while in the peak energy need of the hottest days of summer adds to the unreliability and safety issues of storing nuclear waste in fuel pools. Water is needed in case of accident to prevent nuclear power cores and waste pools from overheating and melting, releasing enormous amounts of radioactivity into the air. We learned from Fukushima that that water has gotten contaminated and is still releasing into the Pacific Ocean over 2 years after the initiation of the triple meltdowns. (0938-9 [Sondheim, Steven])

Comment: For spent fuel storage risk, Exelon recommends that the NRC use existing information to the extent possible, and bolster it with new analyses only as necessary. Exelon does not consider it necessary to utilize "worst case" assumptions and believes that the NRC should focus on explaining how data on past events informs the NRC on the likelihood and impacts of future events. For example, the NRC has appropriately cited NUREG-1864, "A Pilot Probabilistic Risk Assessment of a Dry Cask Storage System at a Nuclear Power Plant," dated March 2007 in support of statements made about the low risk associated with dry cask storage. These statements could be further strengthened by also citing an independent Probabilistic Risk Assessment (PRA) study conducted by the Electric Power Research Institute (EPRI) (i.e., EPRI Document 1009691, "Probabilistic Risk Assessment (PRA) of Bolted Storage Casks: Updated

Quantification and Analysis Report," dated Nov 2004), which also supports the conclusion that the risks are low. EPRI confirmed low risk for bolted storage systems. Exelon, along with the industry, agrees with the NRC that the low risks calculated by these studies were evident during the Mineral, Virginia and Fukushima earthquakes, neither of which resulted in significant damage to dry cask storage systems or release of radionuclides. (0942-4 [Helker, David P.]

Comment: The aerial photos attached from 1972 flooding beg the question what if HLW was on site / what will be the contingency. To elevate them against flood, is to tee them up for tourists. (0945-4 [Keegan, Michael J.]

Comment: The Draft GEIS claims that impact of a severe accident would be small. Such a conclusion cannot be supported by logic or experience. A severe accident would release deadly radioactivity into the environment. Every release of manmade radioactive matter into the environment to date has had serious and long-lasting impacts on humans and other living things within the area affected. (0951-3 [Commenters, Multiple])

Comment: Increasingly extreme weather as well as earthquakes and volcanic activity in new areas makes minimizing the "low probability of an accident" an insult to anyone, anywhere, who has suffered any of the results of these natural accidents, many of which have been powerful enough already to change the shape of seashores and the earth's tilt on its axis. This sounds like the pap released by the Oil industry who would also like us to believe that further "accidents" and spills won't happen with drilling or fracturing! If we trust this viewpoint, we are living in a fools' paradise. (1000-1 [VanWicklen, Betty J.]

36. Comments Concerning Security and Terrorism

Comment: Now, we're not allowed to talk about -- or we don't want to talk about terrorism, we can't get into detail about what size of airplanes can crash into a dry cask safely, but that is not what they are designed to do. They are just designed to keep the little rods held safely and to let somebody walk by them because they shield the radiation, the gamma rays, and so on. But we're talking about delaying this -- the permanent repository. But, meanwhile, this is when the worst fuel is -- when the fuel is the absolute most dangerous because of all the fission products that are inside. (0030-4-3 [Hoffman, Ace])

Comment: Let me focus the rest of my comments on one of the key elements that I wanted to deal with in the generic EIS, and that is the issue of terrorist attacks. I find that the statement totally understates the risk of terrorist and sabotage. The mechanism that NRC uses to define risk is, let's multiply what the consequences are times the probability of occurrence. They do admit the consequences are significant in their statements. They also say that they would be destabilizing. Well, I think those are kind of internally jargon or code words for significant yes, permanent, yes, if an accident happens. Destabilizing, that just totally understates the reality of how many deaths would occur if a single spent fuel fire, or Zirconium clad fire, or other dispersal from an attack or some other event, be it natural or manmade occurs. The tables that are presented in the appendices that describe these just totally understate those impacts. The probabilities are totally understated. We know that terrorist attacks happen in our world. They happen anywhere, anytime and anyplace that a terrorist wished to make them happen. If we look at 9/11 as an example, the situation could have been enormous in its impacts. In fact, 9/11 was small. We don't want to admit that but it was small. The potential of those same multi-tiered attacks at three locations simultaneously could have wiped out all of New York City and much of New England, if they had merely decided to put one of those planes and attack the spent fuel

pools at Indian Point. They didn't do that. They chose politically, targets that were chosen for other reasons, to just prove that they could attack the government, they could attack the airline industry, and they could attack a financial symbol. (0045-6-9 [Andrews, Richard])

Comment: I will focus my comments at this time on the dangers of terrorist attacks or inside sabotage which have been summarily dismissed as improbable by the NRC. The EIS states that it has only reluctantly considered a terrorist attack threat because of the 9th Circuit court decision. This points to the arrogance or possible ignorance seemingly rampant at NRC to seek to deny the realities of our world. There is no nuclear installation in the world that is truly secure from terrorists, and particularly not nuclear power plants. Had those who attacked multiple targets on the same day of September 11, 2001 chosen to hit multiple nuclear plants, the losses of life would have measured in the hundreds of thousands, the environmental destruction would have affected thousands of square miles, the land that would be uninhabitable would be even larger due to permanent radioactive contamination. Terrorists could have hit the spent fuel pools without any possibility of prevention, then or now. They simply chose to make their statement elsewhere. (0059-5 [Andrews, Richard])

Comment: The NRC assigns truly understated probabilities to terrorist attacks, simply denying the truth. They apparently do this so they can argue that the risks are low using their flawed formula that risk is the product of consequences times probability. I believe this to be a deceitful representation of risk, and not applicable to high consequence risk. NRC admits casually perhaps callously that a terror attack could be "significant and destabilizing". Is destabilizing a euphemism for immediate deaths and lingering slow deaths of huge numbers of people? Is "significant" NRC code speak for destroying the agricultural lands and businesses within areas encompassing hundreds or thousands of square miles. The NRC argues that nuclear power plants are ((generally) not located near major population centers this is a flat out lie. Just take a look at the map for these locations, nearly all are very close to major metropolitan areas. Had the 9/11 terror attacks chosen to fly into Indian Point, or Millstone or any of the many reactors around Chicago, the death count would be extremely high, likely in the hundreds of thousands, far greater than acknowledged by NRC in its flimsy and undocumented risk analysis in the GEIS. (0059-7 [Andrews, Richard])

Comment: NEPA and the Appeals Court require NRC to study the environmental consequences, not the environmental risk. NRCs logic regarding the environmental impact of a terrorist attack on a spent fuel pool having anything to do with probability of occurrence entirely ignores the need to evaluate what the consequences would be should such an attack occur. Thus NRC fails to satisfy the intent of NEPA. The GEIS states: The NRC finds that even though the environmental consequences of a successful attack on a spent fuel pool beyond the licensed life for operation of a reactor are large, the very low probability of a successful attack ensures that the environmental risk is SMALL. AND in regard to spent fuel pool fires; As a result, the NRC finds that the 1996 and 2013 License Renewal GEIS conclusion that the probability-weighted consequences of atmospheric releases, fallout onto open bodies of water, releases to groundwater, and societal and economic impacts of spent fuel pool fires are SMALL is applicable for a spent fuel pool fire during the continued storage timeframe. (0089-15 [Shaw, Sally])

Comment: Another thing about airplane strikes. When any government declares a no fly zone for a particular area, like around a nuclear power plant, this decree assumes that a plane is in working order. If for any reason after takeoff, the plane becomes inoperable what then? The fact is, that a plane crashes every several days somewhere around the world. Currently, there around fifty cask storage sites in the United States. Either on, or close to a nuclear plant. From a

terrorist point of view, that's fifty targets. From a security point of view, that's fifty places to guard. All that need be done is to place all of the casks in one area, and guard it carefully. (0100-18 [Behling, Steve])

Comment: As of this year, 2013, Nuclear Regulatory Commission is going to upgrade the weapons the security guards use to protect the spent fuel storage sites at power plants. A new rule to be published in the Federal Register changes a 2011 regulation giving security guards high caliber fully automatic weapons. Even though the private security at the sites are already armed. Initial cost would be around forty million dollars No one stated what a long term maintenance cost would be. The NRC hopes this action will stop terror attacks towards nuclear plants. Of the 65 operating power reactor sites, 53 store spent fuel in casks on site. (0100-29 [Behling, Steve])

Comment: You want us to believe another, expletive deleted, probabilistic risk assessment, PRA, which assures that a high-level rad waste pool can't be drained by an aircraft -- I'm sorry, it assures us that a high-level rad waste pool can't be drained by an aircraft carrying C4. I live near a, bleep, Mark 1 reactor that's on a flight path for a major airport. There's no airspace restrictions. Even a partial drain down is likely to result in an inextinguishable, filthy, bleep, uranium fire. The only thing between a 747 and the spent fuel pool is a thin sheet metal roof. It's not safe now and I have no confidence that it will remain safe until it has thoroughly decayed about a half a million years. Sorry, but for me there's no reason for me to believe your PRAs. (0112-11-5 [Agnew, David])

Comment: And then I asked them what are you going to do about a terrorist attack? Well, we have a barbed wire fence and three guards. And so the next question was what are you going to do if a plane filled with fuel leaves Logan Airport and goes right directly into nuclear power plant, what would you do? And you know what the response was, "Listen, lady, things like that don't happen so just don't worry about it. It's not an issue. Don't spend your time thinking about that." So all of us -- I want to tell you that planes do not go into any buildings. Planes don't do those things. We know better. The nuclear power plant was so sure, don't worry about it, don't worry about it. (0112-29-2 [Roman, Margo])

Comment: The spent fuels are attractive targets for terrorists. We love that in Vermont. Fly right over and go to Indian Point on the way. (0112-7-5 [Sachs, Leslie Sullivan])

Comment: Why isn't the storage of nuclear waste, military and commercial, as secret as the Manhattan Project? Isn't it a matter of national security that we put all this deadly waste in a few inland caverns as soon as possible and do so without informing our enemies and without any public debate? (0190-1 [Phelan, Steven] [Phelan, Walter])

Comment: Furthermore, all storage sites are potential targets for terrorists who want to launch or detonate a nitrogen explosive, effectively creating a dirty bomb. The subsequent air and water pollution could cripple Florida's tourist industry and freeze snowbirds in their tracks. Removing the waste will not spare an operating reactor from terrorist attack, but it would reduce the problem of recovery and the extent of the damage. Every power plant will be safer from its own accident if the waste is carried to a secret national depository, more or less immediately. There it can be retrieved whenever Bill Gates and his foundation have figured out a way to make more energy out of it and reduce its toxicity. The more sites for waste, the more danger. Why not make one broader rule to say that the military will take control of the commercial waste and find a few safe inland caves and salt mines, like their own site near Carlsbad, NM, in the interest of national security. (0190-5 [Phelan, Steven] [Phelan, Walter])

Comment: [A] terroristic attack on a nuclear storage site would be disastrous to the United States. (0205-10 [Lyons, Laura])

Comment: Storage casks and pools are not only expensive to build, but they are expensive to maintain as well due to the necessity to constantly guard them from terrorism. (0205-11 [Lyons, Laura])

Comment: These pools can also present a target for terrorism or danger in the event of a natural disaster (Kintisch, 2011). (0205-8 [Lyons, Laura])

Comment: Protect fuel pools: Irradiated fuel must be kept in pools for several years before it can be stored in a dry facility. The pools must be protected to withstand an attack by air, land, or water from a force at least equal in size and coordination to the 9/11 attacks. The security improvements must be approved by a panel of experts independent of the nuclear industry and the Nuclear Regulatory Commission. (0222-17 [Zeller, Lou])

Comment: There is no safe or effective way to neutralize radioactive waste, it lasts for tens of thousands of years, polluting our essential resources and land for untold generations, and the toxic waste which is often mismanaged, is a NATIONAL SECURITY THREAT--as any terrorist (foreign or domestic) can use that material to make dirty bombs which would be devastating. SAY NO, to nuclear. (0241-1 [Nixon, Kerry])

Comment: In 300 years, our land will be littered with high-level waste that is no longer theft-proof, as the shorter-lived isotopes disappear, leaving purer and purer plutonium waste. This is a nightmare for those of us who are concerned with the growing nuclear weapons proliferation risk we leave to the world that we don't even know who will be left to govern. (0246-11-3 [Dubois, Gwen L])

Comment: It is also a lot harder to get at, as someone else pointed out. By the time the fuel starts to be not so dangerous to get near, it becomes a proliferation threat. So, at all times, it is not a good idea to have anything to do with this stuff. (0246-29-11 [Hoffman, Ace])

Comment: I hope that you don't mind me straying a bit, but my problem with the radioactive fuel and what have you is that this GEIS, draft Generic Environmental Impact Statement, doesn't go into reality. There is a reality out there. It may not be in a GEIS but there is a reality. For instance reality raises its ugly head, like there is a man who operates -- who is an operator at a nuclear power plant. He headed south when he was caught trying to hijack and perhaps even kill another citizen. His coconspirator, another coworker, is also up for charges. In other words, what I am saying on that issue is that we look at these people and these people are often very, very good people working nuclear power plants, but we forget that there are people who do bad things. (0246-6-1 [Lewis, Marvin])

Comment: And nuclear radioactive waste is a lovely target for terrorists who can use it to make a so-called dirty bomb, just with conventional explosives and to disperse radioactive waste and make an area a real problem. And that is something we forget. We forget completely about that. And it is pretty much close to what has happened already and we forget all about that. In fact, if you don't believe it has almost happened already, please go to the people in Boston and ask them if it has almost happened already with terrorists. (0246-6-2 [Lewis, Marvin])

Comment: These aboveground spent pools are not guarded well, and many South Carolina residents are gravely concerned about attacks from terrorists, like a bomb, a plane, or anything that could easily set these aboveground pools on fire. (0250-20-5 [Cooper, Elaine])

Comment: With respect to potential acts of sabotage or terrorism, many analyses of highly improbable sabotage or accident occurrences have shown that such events are most unlikely to result in dry used fuel system containment boundary breaches because of their rugged designs. For terrorist-induced, beyond design-basis events, only those involving high energy density devices or a specific type of military weapon have any real opportunity of compromising dry used fuel system integrity. The probability of system breach is still vanishingly small, since reasonable proximity to the package and time consuming precise placement of such weapons must be achieved for perfect impact condition which is commonly called zero obliquity. Substantial testing and analyses show that radioactive material release from such an attack would be extremely limited. Used fuel that might be released would be of such a small quantity and it would be very localized to around the system. The fraction of contents that would be released would be trivial. What this means is that any resulting exposures would be far below, and I say far below the unregulated doses to the public received from dozens of non-nuclear industries year after year, decade after decade. (0250-27-3 [Pennington, Charlie])

Comment: Spent fuel pools are targets for terrorists, and moving the waste to interim storage would create hundreds of new waste sites, the mobile waste sites, plus trucks and trains and boats, whatever; ships, and not to mention new targets. (0250-29-3 [Rivard, Betsey])

Comment: The last 20 years we have been using depleted uranium, artillery, and tank rounds in a part of the world where we are despised. Let's take a 10 to 20-foot piece of steel pipe of a matching diameter or caliber. Let's improvise a breach in it. Let's put one of those depleted uranium rounds in there with a charge. Let's have an improvised firing mechanism, and you have created an improvised recoilless rifle. And it can penetrate any steel and concrete building or shipping cask because that is what those rounds were made to do. So there is the security. (0250-46-6 [Stein, Ed])

Comment: Opponents of nuclear energy paint a picture of piles of glowing waste sitting out in the open poisoning our air-or implying that they are easy terrorist targets. All this hyperbolic hot air just obscures the fact that there has never been a single incident where spent fuel storage has been compromised by any outside individual or group. It has been safely stored for decades and I believe the NRC and the owners of nuclear plants can and will keep it that way. (0275-3 [Wolf, Tom])

Comment: I am deeply concerned about the possibility of someone deciding it would be interesting to see what would happen if an airplane was flown into a nuclear facility. I don't believe it is a matter of IF... But more a matter of WHEN and even more importantly is WHERE does this tragic event occur. According to a report by Robert Alvarez entitled "Reducing the hazards of high-level radioactive waste in Southern California" published by Friends of the Earth ...If an airplane was successful in starting a spent fuel pool fire in one of the two cooling pools at San Onofre that burned only 30% of the pool's current contents ... The radioactive release from this event would be comparable to 10 Chernobyl accidents. The Generic Environmental Impact Study estimates the largest number of Early fatalities to be 191 people for a spent fuel accident. Latent Fatalities are estimated to be 20,000 to 27,000 people. These data points have been taken from an NRC document NUREG-1738 published in January 2001. Before September 11th, 2001, I might add. Clearly there is a huge difference of opinion as to what could happen based upon the probability of the event occurring. I believe the NRC is very aware of the

possibility of a catastrophic event occurring from a spent fuel pool fire. But they are unwilling to entertain the fact that this possibility is anything but extremely remote. I don't understand how they can arrive at that conclusion based upon the fact that the Draft Generic Environmental Impact Statement contains the following passage: "The NRC has determined that the probability of a successful terrorist attack on a spent fuel pool, although numerically indeterminate, is low." There is no basis to include the last two words in the Draft Environmental Impact Statement. The two words "is low" should be omitted from the Generic Environmental Impact Statement and the NRC needs to stop using probability risk analysis when addressing the issue of terrorism in the Generic Environmental Impact Statement. Just in case my logic went too fast for some of the audience, let me restate that if something is truly "numerically indeterminate" it is not possible to attach a number to. So if the probability of a successful terrorist attack is truly "numerically indeterminate" then no numeric probability can be assigned to the event. Without a numeric probability for the occurrence of a potentially catastrophic event, it is not appropriate to apply probability risk analysis to determine the risk and potential impact of a terrorist attack on a spent fuel pool. This is mathematically hocus-pocus that is endangering the public's safety. By allowing the NRC to choose an arbitrarily low probability of a terrorist event makes the risk of even a catastrophic event seem tolerable. Hence the loss of 191 Early Fatalities and 20,000 to 26,000 Latent Fatalities. The problem here is that you are not only playing with people's safety and possible loss of life, which is a horrific disgrace to mankind ... The potential severity of 10 Chernobyls will impact the entire Northern Hemisphere ... It is reasonable to assume that a piece of land, five times the size of New Jersey, will be turned into uninhabitable wasteland and if such an event happens in Southern California... The event will very severely impact the entire world economy. One last thing is for sure, if someone does figure out how to fly a large aircraft into a spent fuel pool and start a spent fuel pool fire, the damage it will do to the nuclear industry will be on par with the damage done to the surrounding environment. If you value your jobs you need to tackle the terrorist issue head on[.] (0279-1 [Morgal, Richard])

Comment: Please accept this comment on NUREG 2157, the Waste Confidence Generic Environmental Impact Statement, as follows. On page 4-85 of NUREG 2157 there is a reference to physical protection criteria as defined in 10 CFR 73.1 Purpose and Scope for the 'Physical Protection of Plants and Materials.' I would point out that 10 CFR 73.1 omits airborne attacks, which would likely be the method of choice for any attacks in this century. The land-or-waterborne attacks that are defined in 10 CFR 73.1 for the scope or protection are the preferred methods of the 20th century. Please update the scope of the defined threats to include airborne attacks by drone, commandeered airliner, model airplane, helicopter, light aircraft (as kamikaze) and/or model helicopter. Unless you make just such a change to 10 CFR 73.1, NUREG 2157 is totally irrelevant to its intended purpose. (0316-1 [Donnelly, Dennis])

Comment: I'm deeply concerned about the possibility of someone deciding it would be interesting to see what would happen if a large airplane were flown into a nuclear facility. I don't believe it is a matter of if, but more a matter of when. But even more importantly is where does this tragic event occur? San Onofre is my biggest concern. (0325-22-1 [Morgal, Richard])

Comment: I don't understand how they can arrive at this conclusion based on the fact that the Draft Environmental Impact Statement contains the following passage. "The NRC has determined that the probability of a successful terrorist attack on a spent fuel pool, although numerically indeterminate, the probability is low." Is low? If it's numerically indeterminate, how can it be low? There's no basis to include the last two words of this passage in the Draft Environmental Impact report. The two words "is low" should be omitted from the Generic Environmental Impact Statement, and the NRC needs to stop using probability risk analysis when addressing the issue of terrorism in the Generic Environmental Impact Statement. I think

that it's a game that's being played, and we're all being subjected to a much larger risk, that when it happens and we see it on television like the 9/11 towers that came down, everybody in this room that's saying it's safe, it's not a problem, don't worry about it, is suddenly going to go whoa, wow, this is dangerous stuff. But until then, we're just going to have to wait. (0325-22-3 [Morgal, Richard])

Comment: Why don't you put the dry cask storage inside the domes instead of blowing them up? Why don't you put them inside the domes, leave the -- so when it gets hit with a missile, we know that the whole place is not protected against high explosives. We know bunker buster bombs go through 20 feet of reinforced steel. This place is not safe. It was never designed to be safe from terrorist attack. And there's a million ways terrorists could attack this plant. So, that is not dealt with in this report either. (0325-31-6 [Johnson, Roger])

Comment: We had a seminar last month where we had our own experts come in. One of them told us that a shaped charge missile or weapon can go through three feet of steel. A dry cask is three feet of concrete and maybe two inches of steel. These are vulnerable. A 747 is a very large airplane. If you put one next to a dry cask, it will dwarf it. The turbine shafts on those four jets are going to go right through those dry casks. (0325-7-4 [Hoffman, Ace])

Comment: On Roman numeral page 44 it says that the impact of terrorism would be small. This is a lie. If that pool was drained at Diablo Canyon we would have a Fukushima type incident here. (0326-56-5 [Homick, Nick])

Comment: [Y]ou can look at TVA's records at the NRC, security is very bad at these sites. We have, of course we're a nuclear area in Tennessee and we've had cases where little old ladies in tennis shoes literally have cut their way through fences and gotten into high-security areas because the security has been so bad at ORNL. Well, this is also true at TVA. TVA has tried contract security, and it's tried staff-based security, and neither one has worked consistently. Every 18 or 24 months they find that their security system is broken, and people are using drugs, people are letting their friends in to look around, and so on. So the idea that you can keep aboveground storage secure has not proven out, in fact, here in the Tennessee Valley. (0329-12-10 [Paddock, Brian])

Comment: Saying that there is a risk of a terrorist attack, although the consequences would be high that the probability is so low that the consequence or the environmental consequence or whatever you call it would be small, risk is small, well, that's crazy. That's absurd. We have already had two planes that went into the twin towers. And that was only like what, 2001, 12 years ago. And apparently they thought that they were going to or, they were planning on going to Indian Point, but they thought it would be too well protected against them. So that in itself, this is insane. (0329-32-6 [Seeley, Linda])

Comment: The U.S. government, intelligence and security experts have identified nuclear power plants to be terrorist targets. (0341-1-17 [Mermelstein, Richard])

Comment: Even putting everything noted above aside, there is one astonishing omission that renders the entire GEIS fatally flawed: The GEIS completely fails to look at cyber.¹³ [footnote 13 text: In fact, we found only one mention of the word "cyber" in the entire GEIS.] The GEIS it ignores cybersafety issues, cybersecurity issues, complications that can result from interactions between computer networks. This area is scopic and critical. Were space and copyright law not at issue, we would insert the complete contents of the book America the Vulnerable by Joel Brenner, former head of counterintelligence for the director of National Intelligence here.

Somebody at the NRC should read it, with special attention to the chapter "Dancing in the Dark" about vulnerabilities to nuclear power installations and the grid in general.¹⁴ [footnote 14 text: Incidentally, aside from being informative, the book is a terrific read. (Brenner)] The NRC also needs to review the government findings on the Davis-Besse boric acid corrosion fiasco with attention to the fact that the same nuclear operator was implicated in setting off the East Coast and Canada blackout of 2003, and recall that Davis-Besse turned out to also be infected with the malicious virus known as the Slammer worm. Connect some dots and add in a storm like Sandy. (0341-2-15 [Mermelstein, Richard])

Comment: At Pilgrim, nearly 3300 bundles of irradiated fuel are stored in an attic pool designed for 880. The NRC's probabilistic risk assessment (PRA) assures us that a high level radwaste pool can't be drained by an aircraft carrying C4. The PNPS in Plymouth is a Mark 1 reactor that's on a flight path for a major airport - and there are no airspace restrictions. Even a partial drain down is likely to result in an inextinguishable uranium and plutonium fire. The only thing between a 747 and the SFP is a thin sheet metal roof. It's not safe now, and claiming that it will remain safe until 2092 is only wishful thinking. (0348-8 [Agnew, David] [Roscoe, Lee])

Comment: At Pilgrim, nearly 3300 bundles of irradiated fuel are stored in an attic pool designed for 880. The NRC's probabilistic risk assessment (PRA) assures us that a high level radwaste pool can't be drained by an aircraft carrying C4. The PNPS in Plymouth is a Mark 1 reactor that's on a flight path for a major airport - and there are no airspace restrictions. Even a partial drain down is likely to result in an inextinguishable uranium and plutonium fire. The only thing between a 747 and the SFP is a thin sheet metal roof. It's not safe now, and claiming that it will remain safe until 2092 is only wishful thinking. (0352-7 [Roscoe, Lee])

Comment: National security - Prolonged dry cask storage at the plant sites provides the additional concern that the casks are situated in conspicuous view to terrorist planners. The June 2, 2006, ruling of the U.S. Court of Appeals for the Ninth Circuit in *San Luis Obispo Mothers v. NRC*, 449 F.3d 1016 (9th Cir., 2006), lends substantial credence to the proposition that onsite dry cask storage might lead to or increase the risk of a terrorist attack because (1) the presence of the casks would increase the probability of a terrorist attack on the plant, and (2) the casks themselves would be a primary target for a terrorist attack. (0355-6 [Skov, Jeff])

Comment: At Pilgrim, nearly 3300 bundles of irradiated fuel are stored in an attic pool designed for 880. The NRC's probabilistic risk assessment (PRA) assures us that a high level radwaste pool can't be drained by an aircraft carrying C4. The PNPS in Plymouth is a Mark 1 reactor that's on a flight path for a major airport - and there are no airspace restrictions. Even a partial drain down is likely to result in an inextinguishable uranium and plutonium fire. The only thing between a 747 and the SFP is a thin sheet metal roof. It's not safe now, and claiming that it will remain safe until 2092 is only wishful thinking. (0373-8 [O'Malley, Brian])

Comment: The environmental impact statement should assess the radiological risk arising from a range of conventional accidents or attacks, including those conducted by terrorists. (0377-5-12 [Cuthbert, Lewis])

Comment: Other reasons aside, it is not a good idea to concentrate such a large amount of waste in one place especially if it is stored above ground. This makes it a target for aerial and surface terrorism and creates the potential for a huge accident with widespread contamination of the air, land and water. (0410-23 [Nelson, Dennis])

Comment: Security and safety are closely intertwined and both need to be addressed in the GEIS. For example, the threat of sabotage of a commercial nuclear power site from terrorists, or others with ill intent, are real risks. The environmental impact of such sabotage needs to be considered in the GEIS. Various scenarios need to be considered such as explosion, flood, drought, fire. (0417-3 [Clark, Terrence])

Comment: Terrorism is a risk for environmental and adverse health effects. This is minimized and not thoroughly considered in the draft EIS. 5.) Security never is 100% (0417-7 [Clark, Terrence])

Comment: You want us to believe another EXPLETIVE probabilistic risk assessment (PRA) which assures us that a high level radwaste pool can't be drained by an aircraft carrying C4. I live near a EXPLETIVE Mark 1 reactor that's on a flight path for a major airport - and there are no airspace restrictions. Even a partial drain down is likely to result in an inextinguishable filthy EXPLETIVE uranium and plutonium fire. The only thing between a 747 and the SFP is a thin sheet metal roof. It's not safe now, and I have no confidence that it will remain safe until it has thoroughly decayed (about half-million years). Sorry, but there is no reason for me to believe your PRAs. (0419-5 [Agnew, David])

Comment: The nation's rad-waste sites are sitting ducks for backpacking terrorists, and irradiating people at airports will do nothing to stop such an attack. Those who keep our nation's population under this sword of Damocles deserve jail time. (0441-1 [Baker, Helen])

Comment: What about terrorism as a threat? Before 911 the thought that people could bring down huge buildings by flying planes into them was unthinkable - or should I say of "low probability"? What about Fukushima, Chernobyl, Bhopal and Love Canal? If we have learned anything from these past "low probability" incidents is that the unlikely happens far too often and is deathly devastating. (0443-3 [Sabo, Betty])

Comment: Terrorist actions are simply not readily definable by probabilities, being random in nature, and unpredictable, particularly identifying emotional instability of potential actors. Statistical probability values of historical occurrences are not valid predictors for terrorist action, unlike probabilities of such things as home fires, football injuries, or auto accidents. There are very limited measurable factors that may help define probability are such things as terrorism: stimulations to hate and revenge from foreign interventions and wars and repression, and possibly opportunity analysis of means, time and place windows when terror actions will have the greatest impact on the intended target, or the resulting social and economic impacts. But overall, predictability of terrorism is nearly impossible. (0447-1-11 [Andrews, Richard])

Comment: The EIS states that it has only reluctantly considered a terrorist attack threat because of the 9th Circuit court decision. This points to the arrogance or possible ignorance seemingly rampant at NRC to seek to deny the realities of our world where terrorist methods have heavily replaced conventional wars. There is no nuclear installation in the world that is truly secure from terrorists, and particularly not nuclear power plants, and spent fuel or radiological waste facilities. Had those who attacked multiple targets on the same day of September 11, 2001 chosen to hit spent fuel facilities at multiple nuclear plants with the same aircrafts, the losses of life would have measured in the hundreds of thousands, perhaps millions, the environmental destruction would have affected many thousands of square miles, the lands, lakes, and oceans that would be uninhabitable or otherwise unusable would be even larger due to permanent radioactive contamination, and enormous part of our nation's economic industrial of huge cities and agricultural lands could have been destroyed. Terrorists could have

hit the spent fuel pools without any possibility of prevention, then or now. The tools of such possible attacks were readily available then, and remain so now. The 9/11 terrorists simply chose to make their statement elsewhere. Gordon R. Thompson provides a much more comprehensive analysis and elucidation of these threats than the NRC acknowledges (Gordon R. Thompson, comments on NRCs Draft Consequences Study, Aug 2013). You should heed his advise and comments. (0447-1-13 [Andrews, Richard])

Comment: The NRC assigns truly understated probabilities to terrorist attacks, simply denying the truth. In numerous tables and text in the DGEIS, the risks are stated as LOW. They apparently do this so they can argue that the risks are low using their flawed formula that risk is the product of consequences times probability. I believe this to be a deceitful representation of risk, and not applicable to high consequence risk. NRC admits in the DGEIS casually perhaps callously that a terror attack could be "significant and destabilizing". Is "destabilizing" a euphemism for immediate deaths and lingering slow deaths of huge numbers of people? Is "significant" NRC code speak for destroying the agricultural lands and businesses and making uninhabitable areas encompassing hundreds or thousands of square miles from a single terrorist attack or spent fuel accident. The NRC argues that nuclear power plants are ((generally) not located near major population centersthis is a flat out lie or gross misrepresentation. Just take a look at the map for these nuclear power plant locations, nearly all are very close to major metropolitan areas. Waste Confidence is not provided by the flawed and misleading arguments of the NRC in the DGEIS. (0447-1-15 [Andrews, Richard])

Comment: Had the 9/11 terrorist attackers chosen to fly aircraft into Indian Point, or Millstone or any of the many reactors near major cities such as around Chicago, Atlanta, Miami, Baltimore, or many other major cities, the near term fatalities and lifetime excess cancer death counts would be extremely high, likely in the hundreds of thousands for any single event, far greater than acknowledged by NRC in its undocumented risk and consequence analysis presented in the DGEIS. Others have postulated and reviewed consequences of various modes of terrorist attacks on spent nuclear fuel facilities, including large and small aircraft, artillery with bunker penetrating shaped charges, truck delivery of explosives, and other scenarios. I will not review those in this paper, but encourage the NRC to heed these documents (see various papers of Gordon Thompson, Robert Alvarez et al, prior risk assessment NUREG documents, e.g. Sailor et al 1987 NUREG-4982 and Collins and Hubbard 2001 NUREG-1738, and the National Research Council report on spent fuel). (0447-1-22 [Andrews, Richard])

Comment: flawed assignment of low probability of potential terrorist attacks or inside sabotage on facilities handling and storing spent nuclear fuel, and (3) flawed and understating misrepresentation of the catastrophic consequences of terrorist attacks and accidents involving pool storage of spent nuclear fuel (0447-1-6 [Andrews, Richard])

Comment: Further, the analysis dismissed the possibility of "an identifiable threat to nuclear activities" such as terrorism: Increased storage of aged spent fuel at either reactor or away-from-reactor sites has little relative safeguards significance. This conclusion is based upon the staff's consideration of: (1) the absence of any information confirming an identifiable threat to nuclear activities, (2) the physical characteristics and conditions of storage (which include specific security provisions) of aged spent fuel, and (3) the magnitude of the estimated consequences of certain postulated sabotage events. Id. at ES-7. Id. at ES-7 (emphasis added); NUREG-0575 has never been updated or supplemented.¹² [footnote 12 text: 12 In *Marsh v. Oregon Natural Resources Council*, 490 U.S. 360, 372 (1989) the Court held that NEPA "impose[s] a duty on all federal agencies to prepare supplements to either draft or final EISs if there "are significant new circumstances or information relevant to environmental concerns and

bearing on the proposed action or its impacts;" citing CEQ Regulations. The new and significant information since NUREG-0575 includes, no date for a permanent waste repository, compelling evidence that terrorism is a credible threat to spent fuel stored at nuclear reactors, the accident at Fukushima, the recognition of the greater possibility of more devastating earthquakes for sites in the upper Midwest and the Northeast, the use of high burnup fuel with its special problems for fuel rod integrity and residual heat, to mention only a few.] (0473-7-3 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Independent Studies of the Hazards of Spent Fuel Pool Storage: In 2003, Congress directed the National Academy of Sciences ("NAS") to conduct a study of spent nuclear fuel storage at commercial reactor sites, including the "safety and security advantages, if any, of dry cask storage versus wet pool storage at reactor sites." Conference Report to Accompany H.R. 2754, Making Appropriations For Energy And Water Development For The Fiscal Year Ending September 30, 2004, And For Other Purposes, Title IV, 108th Congress 1st Session, H.R. 108-357. NAS produced the report in 2006 in both a public and a non-public version. Only the public version is referenced here. Safety And Security Of Commercial Spent Nuclear Fuel Storage (Public Report), Committee on the Safety and Security of Commercial Spent Nuclear Fuel Storage Board on Radioactive Waste Management Division on Earth and Life Studies National Research Council Of The National Academies (2006) ("NAS Study"). The NAS Study concluded that The probability of terrorist attacks on spent fuel storage cannot be assessed quantitatively or comparatively. Spent fuel storage facilities cannot be dismissed as targets for such attacks because it is not possible to predict the behavior and motivations of terrorists, and because of the attractiveness of spent fuel as a terrorist target given the well known public dread of radiation. *** The committee finds that, under some conditions, a terrorist attack that partially or completely drained a spent fuel pool could lead to a propagating zirconium cladding fire and the release of large quantities of radioactive materials to the environment. *** It appears to be feasible to reduce the likelihood of a zirconium cladding fire following a loss-of-pool-coolant event using readily implemented measures. The following measures appear to have particular merit: Reconfiguring the spent fuel in the pools (i.e., redistribution of high decay-heat assemblies so that they are surrounded by low decay-heat assemblies) to more evenly distribute decay-heat loads and enhance radiative heat transfer; limiting the frequency of offloads of full reactor cores into spent fuel pools, requiring longer shutdowns of the reactor before any fuel is offloaded, and providing enhanced security when such offloads must be made; and development of a redundant and diverse response system to mitigate loss-of-pool-coolant events that would be capable of operation even if the pool or overlying building were severely damaged. *** The potential vulnerabilities of spent fuel pools to terrorist attacks are plant-design specific. Therefore, specific vulnerabilities can be understood only by examining the characteristics of spent fuel storage at each plant. The previous NRC analyses and independent analyses of the safety of spent fuel stored at reactor sites, particularly the safety of such storage in spent fuel pools, is directly relevant to the task NRC should be undertaking here. (0473-8-6 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Finally, the NRC states the chances of a successful Terrorist Attack are low and the risk is small, however, a study done by the National Academy Of Science after 9/11 that has been de-classified suggests that spent fuel should be stored dry at a non reactor site specifically because of the possibility of Terrorist Attack. At first review, the NRC' s position that a successful terrorist attack is unlikely and unthinkable and creates small risk. Unfortunately, the whole 9/11 attack was unlikely and unthinkable also - it succeeded partly for that reason but also because the attackers were willing to spend an exceptional amount of resources and time to get it done and they did not have a problem with suicide or killing in general - these factors have not been properly factored into the NRC evaluation of the Terrorism issue. (0495-6 [Grigg, Richard])

Comment: Terrorist Attacks: Terrorist could attack "soft targets" such as the utility lines or generators that supply electricity to plants. This could lead to a severe nuclear power plant accident and/or a severe accident involving the spent-fuel basins. The WCGEIS needs to be revised to address these risks and impacts posed by such events in terms of a national fleet of operating reactors and spent-fuel basins. (0496-9 [Batobato, Alicia])

Comment: [R]epositories of nuclear waste must be secured against human mischief and environmental upheaval by every means at our disposal. Long-term storage of nuclear waste from medical sources and munitions must also be addressed with similar levels of vigilance. (0522-3 [Rogers, William])

Comment: The increase in nuclear materials due to operation of more nuclear power plants would undermine all efforts to increase nuclear security and prevent proliferation. (0531-2-17 [Morgan, Sally])

Comment: The US Dpt Of Homeland Security labeled nuclear power plants potential terrorist targets. (0541-5 [Justesen, Evelyn])

Comment: Since spent nuclear fuel contains large quantities of fissile material that can be used to make nuclear weapons, it also must be safeguarded to prevent theft. (0552-1-4 [Macks, Vic])

Comment: Some reactors are more likely targets than others due to their symbolic value as a target and proximity to large population centers. Pilgrim is located in America's Hometown, a symbolic target, and a successful strike would impact a large population --Boston, Providence and beyond. Likewise, Indian Point is proximate to dense population clusters, notably New York City, and very close to West Point. What serious terrorist would chose to attack Wolf Creek in Kansas over Indian Point or Pilgrim? BWR's are more susceptible to attack than PWR's due to the location of the pool outside primary containment, in the upper level of the reactor with a thin roof overhead. A small plane could easily penetrate the roof and cause a spent fuel pool fire⁶. [footnote 6 text: Environmental Impacts of Storing Spent Nuclear Fuel and High-Level Wastefrom Commercial Nuclear Reactors: A Critique of NRC's Waste Confidence Decision and Environmental Impact Determination, Gordon R. Thompson, February 6, 2009, Ch. 7 and Tables 7-2 thru 8-2.] (0556-1-25 [Lampert, Mary])

Comment: Spent fuel is building up at every reactor site in the country, stored in high-density pools that are vulnerable to attack and pose a risk of catastrophic fire. The NRC contemplates that these pools may remain in use for 60 years after operation ceases, where they will remain vulnerable to fires and attacks. Our government assumes that terrorists are not going away, either foreign or homegrown. According to the NRC, the risk of attacks need not be addressed in the GEIS because NRC security regulations ensure that reactor spent fuel pools are protected. This is not true. Reactors are not protected from an air attack. No reactor licensee in the U.S. has lowered risk by eliminating the use of high-density storage racks from fuel pools, or even lowered the density of fuel stored in pools. Thus, a serious environmental threat remains. Likewise casks are poorly defended and vulnerable to attack by airplane, vehicle bomb, perforation by shaped charge with or without incendiary device, or removal of overpack lid⁷. [footnote 7 text: Ibid at Table 7-8] (0556-1-26 [Lampert, Mary])

Comment: BWR Mark I and II reactors' spent fuel pools are located outside primary containment, elevated at the top of the reactor building with a thin and vulnerable roof overhead. They are vulnerable to an air attack even from a small aircraft, more so than a separate spent

fuel pool that is partially submerged into the ground. The vulnerability of these high-density, closed frame spent fuel pools to acts of malice is the single biggest issue that is missing from the draft GEIS. They are vulnerable to attack and pose a risk of catastrophic fire. The NRC says that these pools may remain in use for 60 years after the license expires, where they will remain vulnerable to fires. According to the NRC, the risk of attacks need not be addressed in the GEIS because NRC security regulations ensure that reactor spent fuel pools are protected. They are not. Reactors are vulnerable to air attack and readily available sophisticated weapons. No reactor licensee in the U.S. has eliminated the use of high-density storage racks from fuel pools, or even lowered the density of fuel stored in pools. Thus, a serious environmental threat remains and varies from site to site. But, although one cannot remove the threat of a malicious attack, NRC can require the fuel to be moved to dry casks and greatly reduce the environmental threat of a catastrophic fire. NRC's proposed rule fails to do so. (0556-1-32 [Lampert, Mary])

Comment: No consideration of attack: The Study ignores the potential for an attack on a pool or adjacent reactor to initiate a pool fire. NAS Study after 09/11 showed that a terrorist attack on spent fuel pools was a credible event. Yet, the probability of an attack with a substantial likelihood of success is at least equal to the probability of the severe earthquake that the Study does consider. Table IV-1²⁸ [footnote 28 text: Declaration by Dr. Gordon R. Thompson: Comments on the US NRC's *Draft Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a US Mark I Boiling Water Reactor*, August 1, 2013] [Table Submitted with Correspondence ML13354A021] Table IV-2²⁹ [footnote 29 text: Ibid] [Table Submitted with Correspondence ML13354A021] Table IV-3³⁰ [footnote 30 text: Ibid] [Table Submitted with Correspondence ML13354A021] (0556-4-3 [Lampert, Mary])

Comment: Re: NEPA; Addressing possible "accidents and acts of sabotage during continued storage of spent nuclear fuel," the NRC considered risks and "potential consequences" in the DGEIS. However, "[a]s with all NEPA analyses, the DGEIS analyzed reasonably-foreseeable events and did not consider worst-case scenarios." (78 FR 56783, Section III, A17). "Given that NEPA does not require consideration of [assumed to be] remote and speculative [occurrences and] issues, this [such] analysis has not been included in the DGEIS," with respect to the continuation of regulatory "institutional controls" during "continued storage" of spent nuclear fuel after the end of the licensed life for operations of a nuclear reactor. (78 FR 56788, Section III, B10). These points get to the "heart of the matter" of misguided risk calculations and naive assumptions embedded throughout the DGEIS; the present interpretation of NEPA obligations forms the Achilles heel of the current nuclear regulatory regime. (0603-22 [Schonberger, David])

Comment: The consequences of an intentional attack are underestimated by the probabilistic risk analysis done by the NRC. (0604-8 [Pisha, Gayla])

Comment: High levels of confidence is typical among human males with strong technical backgrounds. Yet, many aspects of the existing storage of this nation's spent nuclear fuel have been overlooked in existing studies. One of them is the effects of terrorist attacks, or an exchange of nuclear weapons in a future war. As the spent fuel is presently stored there are plenty of opportunities for wide scale dispersal of enormous quantities of radioactive elements into the atmosphere. Countries, such as Germany, have found far better ways of storing it's nuclear waste and the EIS needs to consider such options. (0610-5 [Brechtin, Vernon])

Comment: Regarding NEI's specific responses to comments made during the hearings, I take particular exception to NEI's first "correction," their description of the 1998 Aberdeen proving ground dry cask test as "not a conclusive indicator" of dry cask resiliency. America cannot afford even ONE catastrophic dry cask accident, so even ONE failure -- and that test was indeed a

failure -- is a show-stopper. A hole was successfully punched in the dry cask, using far less powerful weaponry than might be available to modern-day terrorists -- who might even be using our own weapons against us, such as A-10 Warthog anti-tank airplanes (perhaps by turning an American pilot into a terrorist while rising in the ranks of our own military), or by using a tank stolen from a local military training facility or even a National Guard station (it happened in San Diego in the 1990s). It is also possible that terrorists will acquire some other nation's high-powered weapons on the black market. The Sandia National Laboratory test NEI refers to was similarly insufficient: A "typical" anti-tank weapon is not necessarily a shaped-charge weapon, it is probably nothing more than a Rocket-Propelled Grenade or RPG, and certainly does not "typically" explode once inside a tank or dry cask (it never gets inside but can disable a tank tread, for instance). Such a weapon "typically" is not even made of so-called "depleted" uranium. Are they talking about pea-shooters or real weapons that real terrorists might use? Are they talking Molotov Cocktails or MOABs (Mother Of All Bombs, a thermobaric weapon deployed with great horror by the U.S. Military during the early stages of the Afghan war)? To say the Sandia test used a "device" (unnamed) "30 times more powerful than a typical anti-tank weapon" is evading the issue, and has no real meaning. What if a terrorist gets hold of a nuclear weapon and discharges it near the dry casks? It can happen. Regarding the "large commercial aircraft traveling low to the ground at 350 MPH" this description clearly belies that it was not tested to be able to survive a jumbo-jet intentionally flown into the facility at 500 MPH or more, and wouldn't stand a chance against a mildly-well-trained suicidal pilot flipping the big bird over on its back, pulling back on the control stick, and diving at 700 MPH or even faster directly into the facility from above. It is a "1-G" maneuver, for that matter --the passengers would barely even notice if it's done right!! And an F-16? The "Fighting Falcon" is a beautiful LITTLE jet that barely cracks the speed of sound at sea level. 21 tons maximum takeoff weight, and that drops pretty quickly as it burns fuel. Maximum speed at sea level: Mach 1.2. For the test described by NEI, I believe the F-16 body was on a pulled rail system, well below its maximum speed, and was NOT loaded with fuel (or bombs) during the test. A Boeing 747, on the other hand, weighs in at about 420 tons, so at least 20 times the inertia of an F-16 -- and nearly half that weight is fuel. Cruises at Mach 0.84. The four turbine shafts for the engines weigh, together, about as much as an F-16. (0616-8 [Hoffman, Ace])

Comment: The dismissal of terrorist attacks shows that this is not a serious report. Everyone who has read the Sandia reports knows that a truck bomb (or missile, or high explosives, etc.) outside the perimeter could have disastrous effects on fuel pools. Nuclear power plants were never designed to be fortified against such attacks, and any report which ignores this is a report not to be taken seriously. (0618-14 [Johnson, Roger])

Comment: It is an extremely inviting target for terrorists. The waste is stored in an extremely vulnerable location with free public access on all sides: it is a few hundred feet from a public beach and a few hundred feet from an important Interstate Highway. (0618-4 [Johnson, Roger])

Comment: Terrorism: Section 4.19 of the draft GEIS discusses the potential environmental impacts from acts of terrorism and sabotage at the fuel storage facilities. The document discusses the two US Court of Appeals decisions regarding the consideration of environmental impacts from terrorist attacks in NEPA analyses. The Ninth Circuit held that the NRC needed to consider these environmental impacts in its NEPA reviews. The Third Circuit upheld the NRC's position that acts of terrorism are too far removed or remote to be included in the agency's reviews. The draft GEIS further states that because some continued storage will occur within the Ninth District, "this draft GEIS discusses the environmental impacts of successful terrorist attack to comply with San Luis Obispo Mothers for Peace v. NRC." According to the draft GEIS, "the environmental impact for a successful terrorist attack, if one occurs, could be significant

and destabilizing" (page 4-84). To the Tribe, with its tribal members homes just 600 yards from the Prairie Island ISFSI, this statement is the one of the most significant in the draft GEIS. The draft GEIS later discusses various generic events that could occur during the three time periods- theft of materials, physical attacks, etc and all were found to have a low probability of occurring and therefore the environmental risk would be SMALL. This conclusion, that that the environmental risk is SMALL, should not be the end of the NRC's analysis. In the absence of a national repository or interim storage site, the NRC will eventually relicense every existing ISFSI. Current general license ISFS is will switch to a site-specific license once the reactors are decommissioned. The NRC must include an analysis of the potential environmental impacts of terrorism in all of its NEPA reviews for ISFSI licenses. This is especially important given the dry storage time periods we are discussing in the draft GEIS. Since we have no idea whether the draft GEIS will ever be updated once its final, the NRC must include an analysis of terrorist acts on every site specific ISFSI renewal. It shouldn't be up to host communities or others to expend their own resources to force the NRC to include this review in NEPA documents via litigation. Every day our society is confronted by the reality that there are people willing to give their lives to harm our nation to make political or religious statements. The terrorism analysis in the draft GEIS referenced events that occurred in recent time (i.e., September 11, 2001 attacks); we have no idea what might happen in the future, especially during the timeframes discussed in the draft GEIS (i.e., 160 years or beyond). (0619-2-2 [Mahowald, Philip R.]

Comment: Second, long term dry cask storage on site appears to be expensive and is probably not impervious to terrorist attack. Nevertheless, the presence of spent fuel rods in open to the air cooling ponds is also clearly unacceptable. One aircraft crash into such a pool, such as the crash of aircraft into the World Trade Center on 9/11-01, would create a disaster of dreadful proportions for the surrounding area. (0628-3 [Perkins, V.E.]

Comment: Discussions of terrorist attack scenarios are a waste of time if they are restricted to convenient testing options. Get real! (0640-7 [Geary, B.]

Comment: The draft GEIS assumes spent fuel pools will remain full, and therefore at risk of fire, for 60 years after reactors are decommissioned and greatly downplays fire risk based on a flawed risk assessment. The draft GEIS completely fails to take into consideration risk of fire as a result of an attack on high-density spent fuel pools. (0646-20 [Hanson, Courtney])

Comment: The Draft GEIS assumes that the impact of terrorism would be small. However, according to the National Institute of Health, an attack on a nuclear reactor could result in a "massive release of radioactive material". In the aftermath of 11 September, David Kyd, spokesman for the International Atomic Energy Agency, confirmed this view, stating: "[Reactors] are built to withstand impacts, but not that of a wide bodied passenger jet full of fuel. . . . These are vulnerable targets, and the consequences of a direct hit could be catastrophic." (0686-4 [Malboeuf, Simone])

Comment: The full article [Alvarez, R. et.al., Science and Global Security, 11:1-51, 2003] discusses some of NRC's rationale for failing to act on the risks of spent fuel pools: "No established method exists for quantitatively estimating the likelihood of a sabotage event at a nuclear facility." Given that NRC is the sole government agency authorized to deal with nuclear facilities officially, it would be incumbent upon NRC to establish this method. The draft GEIS provided an opportunity for NRC to advance an appropriate method. (0693-2-4 [Warren, Barbara])

Comment: Waste storage is vulnerable to terrorist attacks. Consider the incident in Aberdeen where a hold was punched in a dry cask. Terrorists now have access to much more powerful

weapons, such as nuclear weapons and powerful airplanes. How many such incidents does NEI consider acceptable? I suggest zero. (0705-5 [Spring, Janet])

Comment: Pages 4-84 to 4-91 Potential acts of sabotage or terrorism. NRDC Comment[:] NRC has failed to consider the environmental impacts of terrorism related to storage and transportation at both a generic and site-specific level." Notably, NRC planned to do so, at least generically, in its 2011 Report for the Long Term Storage EIS. See LTR at 13. Given the long timeframe covered by the Draft GEIS, provisions should be made for periodic updating of the terrorism and sabotage analyses to address: (1) advances in the technology of terrorism and counter-terrorism; (2) changes in population density near storage facilities and shipment routes; and (3) changes in understanding and definition of the design basis events and design basis threats. (0706-4-4 [Fettus, Geoffrey])

Comment: Regarding NEI's specific responses to comments made during the hearings, I take particular exception to NEI's first "correction," their description of the 1998 Aberdeen proving ground dry cask test as "not a conclusive indicator" of dry cask resiliency. America cannot afford even ONE catastrophic dry cask accident, so even ONE failure -- and that test was indeed a failure -- is a show-stopper. A hole was successfully punched in the dry cask, using far less powerful weaponry than might be available to modern-day terrorists -- who might even be using our own weapons against us, such as A-10 Warthog anti-tank airplanes (perhaps by turning an American pilot into a terrorist while rising in the ranks of our own military), or by using a tank stolen from a local military training facility or even a National Guard station (it happened in San Diego in the 1990s). It is also possible that terrorists will acquire some other nation's high-powered weapons on the black market. The Sandia National Laboratory test NEI refers to was similarly insufficient: A "typical" anti-tank weapon is not necessarily a shaped-charge weapon, it is probably nothing more than a Rocket-Propelled Grenade or RPG, and certainly does not "typically" explode once inside a tank or dry cask (it never gets inside but can disable a tank tread, for instance). Such a weapon "typically" is not even made of so-called "depleted" uranium. Are they talking about pea-shooters or real weapons that real terrorists might use? Are they talking Molotov Cocktails or MOABs (Mother Of All Bombs, a thermobaric weapon deployed with great horror by the U.S. Military during the early stages of the Afghan war)? To say the Sandia test used a "device" (unnamed) "30 times more powerful than a typical anti-tank weapon" is evading the issue and has no real meaning. What if a terrorist gets hold of a nuclear weapon and discharges it near the dry casks? It can happen. Regarding the "large commercial aircraft traveling low to the ground at 350 MPH" this description clearly belies that it was not tested to be able to survive a jumbo-jet intentionally flown into the facility at 500 MPH or more, and wouldn't stand a chance against a mildly-well-trained suicidal pilot flipping the big bird over on its back, pulling back on the control stick, and diving at 700 MPH or even faster directly into the facility from above. It is a "1-G" maneuver, for that matter -- the passengers would barely even notice if it's done right!! And an F-16? The "Fighting Falcon" is a beautiful LITTLE jet that barely cracks the speed of sound at sea level. 21 tons maximum takeoff weight, and that drops pretty quickly as it burns fuel. Maximum speed at sea level: Mach 1.2. For the test described by NEI, I believe the F-16 body was on a pulled rail system, well below its maximum speed, and was NOT loaded with fuel (or bombs) during the test. A Boeing 747, on the other hand, weighs in at about 420 tons, so at least 20 times the inertia of an F-16 -- and nearly half that weight is fuel. Cruises at Mach 0.84. The four turbine shafts for the engines weigh, together, about as much as an F-16. (0709-8 [Wythe Elnagar, Romi])

Comment: Malicious acts directed against the spent fuel bay could trigger such releases as well. These potential threats are exacerbated by the fact that the spent fuel bay is typically not located within the containment system, and is not reinforced against potential terrorist attacks. (0714-2-2 [Edwards, Gordon])

Comment: As summarized in the NRC's *A Short History of Nuclear Regulation 1946-2009*, NUREG/BR-0175, Revision 2 (Oct. 2010) ML102980443, the September 11 airplane attacks revealed a weakness at U.S. commercial nuclear power plants, namely that the commercial U.S. nuclear facilities were not designed to withstand aircraft crashes and that the densely packed spent fuel pools were located outside of the concrete containment shell were potentially vulnerable to sabotage. [image inserted] NUREG/BR-0175, Rev. 2, at 86; see also *id.* at 87 (discussing spent fuel pools, which are located outside of the containment shell). Consistent with its statutory responsibilities, the NRC has analyzed sabotage events in previous documents. For example, the 1996 GEIS for License Renewal Applications discussed the effects of sabotage – albeit in a pre-9/11 world. NUREG-1437, Vol. 1, at 5-18 (1996); see, e.g., NUREG-0179, *Final Environmental Statement on the Transportation of Radioactive Materials by Air and Other Modes*, (Dec. 1977) (discussing potential sabotage impacts). In 1981, NRC published NUREG/CR-1345, *Nuclear Power Plant Design Concepts for Sabotage Protection*, Vols. 1 & 2 (Jan. 1981). The Waste Confidence DGEIS contains a few brief generic phrases about the environmental impacts that could result from sabotage or terrorism. DGEIS § 4-19 (4-84 -- 4-89). The document contains conclusory statements to the effect that "the environmental impact for a successful terrorist attack, if one occurs, could be significant and destabilizing." DGEIS, at 4-84; 4-86 (consequences of sabotage could be "severe"). These statements and the remainder of § 4-19 provide no real descriptive analysis of the impacts beyond noting that the "damages could exceed \$ 70 billion" and lead to "192 early fatalities." It is not clear how these passing observations would apply to the Indian Point facilities and the New York City metropolitan area. The document implies that the Severe Accident Mitigation Alternatives analysis prepared for *reactor* accidents "provide a means for mitigating the potential consequences of a terrorist attacks," but that conclusory statement is inconsistent with New York's experience with the SAMA process in the ongoing license renewal proceeding for Indian Point – and is plainly inapplicable to spent fuel pools. Equally important, § 4-19 does not identify, discuss, and evaluate alternatives and mitigation measures. Given these omissions, the DGEIS's discussion of the environmental impacts of sabotage events does not comply with NEPA. Moreover, in its current form, the DGEIS fails to account for cumulative impacts, segments review, and does not address site-specific issues relevant to Indian Point and the New York City metropolitan area. (0718-3-5 [Sipos, John])

Comment: Fuel pools are filled beyond their designs. We have become a terrorist target. (0722-2 [Headington, Maureen])

Comment: Shock waves affecting elevated spent fuel pools need not be limited to natural seismic shock. The Murrough/ Oklahoma City Federal Building was destroyed by ground shock waves from a truck bearing low-grade explosives and parked more than 75 feet away. At Vermont Yankee, just a few years ago, an ice truck entered the security zone with no search or security challenge. It is clear that NRC has chosen to look the other way on all of these challenges to spent fuel security to the detriment of its credibility and the public's risk of health, safety and security. (0723-10 [Shadis, Raymond])

Comment: The fuel inside, if attacked by terrorists, could release large amounts of radioactivity, and so NRC requires constant guarding of the material by plant security forces. Over the centuries, as the radiation levels diminish from decay of the intermediate-lived

radionuclides such as cesium-137 and strontium-90, it will at some point become much easier and thus more attractive as weapons-usable material for theft, i.e., to obtain the plutonium inside that could be used for atomic bombs.³⁶ [footnote 36 text: It has long been accepted that that reactor-grade plutonium can be used to make nuclear explosives. It has somewhat larger percentages of the higher-numbered plutonium isotopes than plutonium produced specially for weapons states, but can produce a large nuclear yield. The primary difference is in the reliability of predicting what that yield will be; i.e., it could be 1 kiloton or 10, whereas with weapons-grade plutonium one has high confidence that the yield would be, say, 5.3 kilotons. But even that issue can be overcome by designs that employ faster insertion of reactivity. Cite sources.] Thus, need for security to protect the spent fuel will not diminish over time and arguably increases. (0738-10 [Hirsch, Daniel])

Comment: The Draft GEIS assumes that the impact of terrorism would be small. However, according to the National Institute of Health, an attack on a nuclear reactor could result in a "massive release of radioactive material." (0757-5 [Lynch, Laura])

Comment: Had the 9/11 terrorists attacked Indian Harbor, there's no telling where we'd be today. We got lucky. While I trust the Government in general, what would happen if 200 heavily armed suicidal terrorists decided to attack Indian Harbor in the middle of the night? No smart bombs will dislodge them without catastrophic consequences. (0766-2 [Poole, Jesse])

Comment: The Waste Confidence Draft EIS fails to adequately address a serious threat to nuclear spent fuel pools from terrorists as well as mentally unstable single white male war gamers without significant relationships who are likely to displace anger or who are likely to be delusional. Suspected al-Qaeda member, Sharif Mobley, accused of murder in Yemen, worked at 5 US nuclear plants, per The Sierra Club's John Muir Chapter's *Nuclear Energy: A Bad Bargain for Wisconsin* (2013). Based on the fact that the top financial priority in the US government budget in 2013 is military and war, excluding war debt, combined with too many changing and unstable socio-economic factors, rationally it is very difficult to conclude that terrorism, malicious destruction, and delusional confusion of reality for war games might go away without addressing the root of pent up anger and instability. Hopefully, the NRC receives rapidly evolving accurate intelligence information that warns of special vulnerabilities upon which the NRC can rapidly mobilize sufficient extra resources to protect safety. (0823-25 [Michetti, Susan])

Comment: Acts of maliciousness or terrorism are always possible in terms of both the external electric grid feeding to operations and storage as well as from internal operations. Sharif Mobley, suspected al-Qaeda member, worked at 5 US nuclear plants. (0823-27 [Michetti, Susan])

Comment: The NRC has also addressed common misconceptions and clarified that used nuclear fuel is well-protected from potential natural events and terrorist attacks - all made possible by a combination of strategic design and construction, multiple safety systems, ongoing surveillance and inspection, and state-of-the-art security measures. (0825-5 [Palomarez, Javier])

Comment: The Draft NUREG-2157 Section F.2.2 then equates the probability weighted consequences of a spent fuel pool to the probability weighted consequences of a severe nuclear reactor accident. Thus, a numeric probability is indirectly placed onto a numerically indeterminable probability. I would argue that the probability of a successful terrorist attack on a nuclear reactor is also numerically indeterminable. Yet with a broad-brush statement that a severe nuclear reactor accident and a spent fuel pool accident have equal probability weighted consequences, the error associated with applying a probability weighted consequence to a

successful terrorist attack on a nuclear reactor is now being applied to determine the weighted consequence of a successful terrorist attack on spent fuel pool. The probability of a successful terrorist attack on a spent fuel pool is numerically indeterminable and probability weighted consequences should not be applied to spent fuel pool fires or severe nuclear reactor accident. (0826-10 [Morgal, Rick])

Comment: It is telling that in several documents, including 10 C.F.R. § 73.1., the NRC and the nuclear power plant operator, by charter, are NOT responsible to defend our nuclear power plant spent fuel pools from large aircraft attacks. Thus, it is known that the spent fuel pools are unprotected from an aircraft attack similar to what occurred to the World Trade Center on September 11th 2001. Yet the risk "is very low" in the minds of the owners of the plants and their regulators. (0826-11 [Morgal, Rick])

Comment: A known weakness in our nation's nuclear reactor's spent fuel pools has been categorically ignored by the NRC and plant operators due to the economic costs associated with adding infrastructure that could make the success of a terrorist attack with a commercial aircraft less likely. The fact that spent fuel pools in all new nuclear power plant designs are required to be able to survive an impact from large commercial aircraft is an indication that the NRC knows our nation's legacy spent fuel pools are vulnerable to aircraft attack, yet there is no incentive to fortify our infrastructure because of economic reasons. Eight million people being affected and half of California's economy should be worth protecting from the likes of what happened on September 11, 2001. But adding the cost of protecting all the spent fuel pools in the US to the cost of nuclear power would impact the cost per kilowatt of nuclear generated electrical power. (0826-12 [Morgal, Rick])

Comment: This situation brings to mind the popular quote: "Never underestimate the power of a few committed people to change the world. Indeed it is the only thing that ever has." We all understand the above quote but in the context of an event probability being determined as "numerically indeterminate" the NRC needs to realize that it would take a relatively small group of committed people to charter a Mexican cargo plane filled with fuel and heavy machinery to fly less than 20 minutes in US airspace before crashing down into one of the San Onofre spent fuel pools. The down wind impacts of such an event would be devastating to our nation, the nuclear industry and the world. It is paramount that the NRC keep in mind that TSA improvements in commercial aircraft security due to the September 11, 2001 tragedy are not effective in stopping international plane attacks. Dirty bombs are hard to manufacture due to the difficulty in obtaining the nuclear material. But a well placed surplus cargo plane on a San Onofre Nuclear Generating Station's spent fuel pool would be the largest dirty bomb possible with the perpetrators having no need to obtain, prepare or handle any nuclear material. This very real terrorist threat should not be allowed to exist longer that is required for the fuel within the spent fuel pool to cool sufficiently to be placed in dry casks. (0826-14 [Morgal, Rick])

Comment: This situation is especially true in light of the severe consequences of a successful terrorist aircraft attack on a spent fuel pool and the numerically indeterminable probability of such an event occurring. National security issues are based upon the fact that dry cask storage systems take time to fabricate and after a first successful terrorist aircraft attack on a spent fuel pool it will take years to build and transfer all the fuel stored in spent fuel pools into dry casks. During those years of cask building, our country will be placed on red alert for potential terrorist aircraft attacks on the remaining spent fuel pools on the nation's reactor sites. (0826-19 [Morgal, Rick])

Comment: When hearing this I feel as though the NRC is in the same state of mind that the FAA was in just before September 2001 or the SEC was in before the financial crisis of 2007. Even if the TSA has been successful in preventing another event similar to the September 11th 2001 event, technology is continually making their job harder. The NRC's Draft Waste Confidence Generic Environmental Impact Statement is proposing spent nuclear waste storage system that will remain in place for 60+ years. Just in the last two years 3-D printing technology has become mainstream and now people can print a plastic gun able to pass undetected through the TSA X-ray screening systems. Now domestic US commercial aircraft have raised the risk of being hi-jacked for terrorist purposes. It's difficult to project what technology will enable people to easily do 60 years from now but it is quite possible the risk of an aircraft being acquired for terrorist purposes will increase over time and possibly quite significantly. (0826-28 [Morgal, Rick])

Comment: Section F.2.2 of the Draft NUREG-2157 describes using a Probability-Weighted Consequence to estimate the number of fatalities associated with a spent fuel pool fire. This mathematical approach to quantifying risk basically counterbalances a catastrophic event with a small probability that the event would occur. By using this type of analysis the NRC creates an illusion that few fatalities will ever transpire due to the perceived unlikelihood of a spent fuel pool fire occurring. The error in using the Probability-Weighted Consequence approach to predict fatalities associated with a Spent Fuel Fire is based upon attempting to estimate the probability of a successful terrorist attack on a spent fuel pool. In that light, Paragraph 4.19.1 of Draft NUREG-2157 states: "The NRC has determined that the probability of a successful terrorist attack on a spent fuel pool, although numerically indeterminable, is very low." The Draft NUREG-2157 Section F.2.2 then goes on to justify how the NRC determines the probability of a spent fuel fire is low based upon structural features of spent fuel pools, security measures and emergency procedures in place at the plant that would thwart a terrorist attack. (0826-9 [Morgal, Rick])

Comment: The NRC has postulated that the environmental risk of a terrorist attack on a dry spent fuel storage facility is small because the probability of such an event is miniscule.⁷⁷ [footnote 77 text: Draft GEIS Sections 4.19 and 5.19.] While that is certainly true, further assurance that the risk is small involves the consideration of the potential population exposure that might result from a highly improbable, but successful terrorist attack on a dry spent fuel storage system. During the presentations and discussions provided by industry to the Blue Ribbon Commission on America's Nuclear Future (BRC) on the safety of dry spent fuel storage, an evaluation was provided to validate the comparatively small population doses that might result from a highly improbable, successful attack on a dry storage system by terrorists. This evaluation confirmed that dry used fuel storage and transportation are among the safest of all industrial activities. As explained by the National Academy of Sciences, tens of thousands of tons of used fuel have been stored and shipped around the world in many thousands of storage and transportation packages, even traveling tens of millions of miles, without a radiation-induced injury or fatality.⁷⁸ [footnote 78 text: National Academy of Sciences (NAS), National Research Council, 2005. "Safety and security of commercial used nuclear fuel storage: Public Report," Washington, DC: National Academies Press; National Academy of Sciences (NAS), National Research Council, 2006. "Going the distance? The safe transport of used nuclear fuel and high-level radioactive waste in the United States," Washington, DC, National Academies Press.] Used fuel and radioactive material packaging have a unique characteristic among all other hazardous material packaging: the need for gamma-ray shielding. Gamma-shielding materials are dense and strong and must remain attached, even following accident conditions. This shielding provides enhanced robustness with larger structural safety margins than other packages. (0827-3-1 [Ginsberg, Ellen])

Comment: The robustness of dry cask storage systems also addresses the concern that fuel becomes less selfprotecting over time. This concern is expressed in both the proposed rule and draft GEIS, where the NRC discusses its intent to evaluate whether additional security requirements are warranted in the future.⁷⁹ [footnote 79 text: 78 Fed. Reg. 56776, 56795; GEIS Section 4.19.] This discussion overstates the potential additional security risk that might accrue over time as the fuel becomes less radioactive. Industry believes that current practices would sufficiently protect even less radioactive fuel, making additional security requirements in the future unnecessary. While it is true that, as the fuel ages over time, it will become less radioactive and, hence, less self-protecting; a more significant factor is that the physical design of the individual storage systems will continue to provide a protective barrier and offer a robust security protection system relative to any terrorist attack. The concrete over-packs are in the range of 150 tons and the welded spent fuel canisters have individual weights in the range of 25 to 50 tons. Because of the physical size, special lifting and transport systems are needed to remove a full containment package. Successful individual system attacks or diversion of a specific fuel mass from storage systems would be problematic due to the bulk of the systems, layers of packaging, and fuel handling at the ISFSI even in the unlikely event that the containment boundary could be breached. (0827-3-2 [Ginsberg, Ellen])

Comment: Extensive safety analyses and testing have been performed to conclude that casks in a licensed configuration will not release radioactive material under any credible accident conditions, and these analyses and testing have been accepted by the NRC in the package licensing process. Assumptions regarding cask "material failure," imposed by the application of conservative regulatory codes and standards, help to make a "no release" design possible. An example of conservatism in materials is stainless steel, a predominant material of choice for containment boundaries, which has about 2 orders of magnitude more energy absorption capability before failure than required by design codes. Many analyses of aircraft impacts, aviation fuel fires, aircraft attacks with explosives, and other highly improbable sabotage or accident occurrences rely on impact, thermal, or overpressure events to theorize damage. These analyses have shown that such events are very unlikely to result in dry storage or transport system containment breaches because of the robust design of the systems. This was summarized in the NAC presentation to the BRC of September 23, 2010.⁸⁰ [footnote 80 text: "Storage and Transportation of Used Fuel: Does Storage/Transportation System Hardening Enhance Safety and Security," Sept. 23, 2010.] (0827-3-3 [Ginsberg, Ellen])

Comment: Despite this rugged design, the possibility of terrorists acquiring and using very sophisticated military weaponry to destroy used fuel storage or transport systems is often raised as a scenario that could result in grave population dose consequences. The probability, however, of successful deployment of such weapons must still be viewed as vanishingly small, since reasonable proximity to the storage systems and time-consuming, precise placement or delivery of such weapons must be accomplished. Over the last three decades, substantial testing and analyses have been performed to bound releases from used fuel casks following a perfect assault. Robert Luna⁸¹ [footnote 81 text: Luna, R.E., Yoshimura, H.R., Vigil, M.G., Philbin, J.S. Lange, F., Pretzsch, G., Koch, W. Cheng, Y.S., 2001. Perspectives on used fuel cask sabotage. Proceedings of the Waste Management '01 Symposium, Feb. 25 - Mar. 1, 2001, Tucson, Arizona.] provides an excellent summary of this testing and offers an analysis of the likely respirable fission product release fractions from the used fuel system that are supported by testing. Luna has continued to research the release characteristics of used fuel storage and transport package sabotage events using military weaponry, and this research^{82, 83} [footnote 82 text: Luna, R.E., 2006. Release fractions from multi-element used fuel casks resulting from HEDD attack. Proceedings of the Waste Management '06 Symposium, Feb. 26 - Mar. 2, 2006, Tucson, Arizona.] [footnote 83 text: Luna, R.E., Yoshimura, R.H., Sorenson, K.B., 2007,

Parametric study of the release of used fuel aerosol resulting from HEDD attack. Proceedings of the 15th International Symposium on the Packaging and Transportation of Radioactive Materials, PATRAM, 2007. Oct. 21-26, 2007, Miami, Florida.] (0827-3-4 [Ginsberg, Ellen])

Comment: The research reported by Luna shows that: 1) there is a large momentum transfer from the weapon penetrator to the used fuel towards the interior of the canister or cask; 2) used fuel, with its multiple layers of radically different densities, is a good medium for stopping high energy projectiles; and 3) the separated, individual used fuel storage cells made of steel in the basket of the canister or cask system tend to limit used fuel dispersion to the environment from all but the outer row of basket cells. When compared to an event like the accident at Chernobyl, a release from a storage or transport system would result in small quantities of used fuel ejected into the proximate environment and none injected into the high atmosphere. Therefore, using the Luna research on release fractions for a terrorist attack on a used fuel storage or transportation system, in combination with the Accident Dose Assessment and Projection Technique from Radionuclide Analysis at Chernobyl (ADAPTRAC) modeling described by Pennington to calculate maximum population exposures,^{84, 85} [footnote 84 text: Pennington, C.W., 2010. A demonstration of the comparative radiological safety of commercial nuclear power generation in the USA. Int. J. Nuclear Governance, Economy and Ecology, Vol. 3, No. 1, pp.59-103.] [footnote 85 text: Pennington, C.W., 2010. Radiological safety of used fuel storage and transport. Proceedings of the 16th International Symposium on the Packaging and Transportation of Radioactive Materials, PATRAM, 2010. October 4 -8, 2010, London, UK.] a bounding CEDE for a credible terrorist sabotage attack on a used fuel storage or transportation system can be calculated. This assessment is described by Pennington and is summarized below.⁸⁶ [footnote 86 text: Pennington, C.W., 2010. A demonstration of the comparative radiological safety of commercial nuclear power generation in the USA. Int. J. Nuclear Governance, Economy and Ecology, Vol. 3, No. 1, pp.59-103.] A high-capacity used fuel storage or transport system contains less than 0.06% of the radionuclides in the Chernobyl reactor core. ADAPTRAC modeling uses the reference⁸⁷ [footnote 87 text: United Nations Scientific Committee on the Effects of Atomic Radiation (UNSCEAR), 2000. Report of the United Nations Scientific Committee on the Effects of Atomic Radiation to the General Assembly, Annex J: Exposures and effects of the Chernobyl accident. Vienna, Austria: United Nations Publications.] 50-year, post-accident dose distribution for the long-lived radionuclides released from the event, the half-lives of the radionuclides with significant dose participation, the total involved population, and the full application of all the longlived radionuclide release, dispersal, and exposure pathway conditions that existed at Chernobyl. All the highly conservative Chernobyl conditions involving ejection into the upper atmosphere, a 40 day release period, wide dispersion, and the affected populations are retained in the ADAPTRAC model. For example, the first two plumes from the Chernobyl release continued for more than 36 hours, covering an area within a 5 km radius having a population density of almost 640 people/ km² . However, for the 45° dispersion arc of these first two plumes, the effective population density within that 5 km distance and 45° arc was more the 5,000 people/ km² . This population density is about two orders of magnitude higher than the population density surrounding U.S. nuclear dry storage facilities. The plume duration, combined with the very high population density within the early dispersion arcs, makes the Chernobyl dispersion characteristics very conservative for application of ADAPTRAC to [an] attack on a used fuel storage or transport system in the U.S. (0827-3-5 [Ginsberg, Ellen])

Comment: [Continued from Comment 827-3-5] The radionuclide release fractions applied in ADAPTRAC that result from [an] attack on a used fuel system are taken from Luna,^{88, 89} [footnote 88 text: Luna, R.E., 2006. Release fractions from multi-element used fuel casks resulting from HEDD attack. Proceedings of the Waste Management '06 Symposium, February

26 - March 2, 2006, Tucson, Arizona.] [footnote 89 text: Luna, R.E., Yoshimura, R.H., Sorenson, K.B., 2007. Parametric study of the release of used fuel aerosol resulting from HEDD attack. Proceedings of the 15th International Symposium on the Packaging and Transportation of Radioactive Materials, PATRAM, 2007. October 21 - 26, 2007, Miami, Florida.] but are increased by a factor of 6 due to the assumption of using a very modern, used fuel storage or transportation system with a 100 psig pressurized canister for the used fuel, based on discussions with Mr. Luna regarding likely outcomes for such pressurized systems. The used fuel released and ejected from the system, mostly located in close proximity to the breached cask, would be in the range of several kilograms (kg), with longer-lived fission product radioactivity, including cesium-137 (¹³⁷Cs), likely less than 10,000 curies (Ci) and in the range of 1,000 - 4,000 (Ci). Because there are low population densities around U.S. at-reactor dry used fuel storage facilities, the involved population would be much, much less than 500,000 people. For such a credible but low probability sabotage event, the population receiving significantly elevated doses would likely be site workers, and the peak 50-year total effective dose equivalent (TEDE) would be well under 1 cSv. Members of the public living around the dry storage facility that might receive a 50-year TEDE in the range of 1 -3 mSv would number far less than 100,000. These doses and affected populations are well below those resulting from non-nuclear industries every year. (0827-3-6 [Ginsberg, Ellen])

Comment: Perhaps the largest danger presented by the establishment of some 69 NWO sites in 34 states (Page 2-14 line 10) is that these become potential terrorist or wartime targets. An attack with a conventional missile will not just take out an area much larger than the NWO itself. The dry cask storage systems, and certainly the fuel pools, are NOT hardened against such attacks, and it is doubtful that there is any ultimate hardening approach short of a deep geologic repository. The fact that the NWO installations DIFFER substantially from a deep geologic repository in this regard must also mean that there must be some serious risk that is now included. YOU NEED TO DESCRIBE THIS RISK AND DIFFERENTIATE THIS OPTION WITH THE PERMANENT GEOLOGIC REPOSITORY OPTION. (0836-20 [Davis, Anonymous])

Comment: We disagree that you can conclude that the IMPACTS of Accidents or Sabotage or Terrorism are all SMALL. I know you want this to be the case, but it is not, and if you continue to assert this, I don't know how you can sleep at night. The reason the deep geologic repositories are proposed is to avoid these dangers. THIS MUST BE SPELLED OUT. (0836-23 [Davis, Anonymous])

Comment: Page 2-16, Lines 17-18. You say that the NRC issued orders to ISFSI licensees etc. based on 9/11 attacks, and that the details are withheld from the public. But can you reveal how these orders were reviewed by other parties to ensure that they are adequate? If there was no review, this does not help us be confident that you are doing your job, given the fact that rarely do you push safety over profits. WHO REVIEWED THIS? (0836-39 [Davis, Anonymous])

Comment: Page 4-84 "The environmental impact for a successful terrorist attack, if one occurs, could be significant and destabilizing." We agree with this statement, it is probably one of the few things you have said that were admitting the truth in this document. However, then you go on to say that because the probability is so low, we don't have to worry about a thing. If we used this method for dealing with risk that you use, then we would not have any defense department at all. They do not determine whether to create a defense only if the probability says that it might happen using PRA, and you must not use it to allow permanent ISFSIs. (0836-58 [Davis, Anonymous])

Comment: Page 4-85, Line 15-16, "The NRC has determined that the probability of a successful terrorist attack on a spent fuel pool, although numerically indeterminable, is very low." That's probably what they said about the attack on the World Trade Center by 19 hijackers. Very low probability. And even lower probability that the towers would completely fall to the ground. But it happened anyway. So we object to the notion that you know that the probability is so low that we can disregard this risk. First you say you have no clue as to the probability, and yet you say it is low and therefore inconsequential. THIS IS THE MOST SIGNIFICANT THREAT POSED BY SITING 69 NWOs AROUND THE COUNTRY, resulting in 69 targets for conventional missiles that will result in a massive radioactive release, just like a "dirty bomb". I DON'T THINK THE PENTAGON WILL LIKE THIS IDEA, or at least I hope they still have some people there who still realize real risk when they see it. (0836-59 [Davis, Anonymous])

Comment: Page 4-85 Lines 24-30. Changing procedures and adding training, improving security through access authorization, etc. are of no consequence when considering the possibility of a missile launched from North Korea, or a shoulder-launched missile directed at a fuel pool from well outside the secure perimeter of the power plant.. It is very distressing to learn how easily the NRC disregards these serious national security concerns. (0836-60 [Davis, Anonymous])

Comment: Page 4-88 Lines 19-23. Adding new rules will not defend against serious wartime attacks. Our country was attacked in WWII and it can happen again. We do not want 69 NWOs around that will be targets, esp. if these are in densely populated areas, which most are. (0836-61 [Davis, Anonymous])

Comment: Page 4-88 Lines 24-26, another ridiculous statement: "The NRC has determined that the measures described above, coupled with the robust nature of dry cask storage systems, make the probability of a successful terrorist attack, although numerically indeterminable, very low." Really? How do you figure that out. First, we do NOT know the likelihood of a war or terrorist attack over a 100 year period. So please, stop it with the jokes, will you? This only makes the NRC look pretty naive, to be sure. The trouble with your calculations is that a terrorist attack in 100 years is probably a certainty. A world war, probably also will happen. If it is a conventional war, then these NWOs will be targets. We can't let that happen. Period. (0836-62 [Davis, Anonymous])

Comment: In Section 4.19.1, paragraph 1, the NRC takes credit during potential attacks on spent fuel pools for the presence of emergency procedures and "Severe Accident Mitigation Alternatives guidelines" in mitigating the potential consequences of terrorist attacks (see page 4-85, lines 20-23). While operating reactors have these procedures and guidelines and can apply them to an attack against the spent fuel pool, reactors that are permanently shutdown often scale back their EP programs and are granted exemptions to NRC requirements. Therefore, it is not clear that this GEIS statement applies to all power reactor spent fuel pools. Additionally, for the sole wet pool ISFSI licensed under Part 72, these types of procedures and guidelines would not be required by Part 72. Accordingly, the NRC should clarify in the final EIS whether these conclusions are applicable to all spent fuel pools. And if not, what are the impacts of this information. (0841-7 [Corrino, G])

Comment: In Section 4.19.2, paragraph 3, the NRC states that the potential for theft and diversion of spent fuel from an ISFSI is not credible based upon three reasons (see page 4-87, lines 26-32). However, this is limited in the DGEIS to "light water reactor spent fuel" stored in an ISFSI. But, not all ISFSIs store light water reactor spent fuel. Consequently, to be complete, the

NRC should characterize in the final EIS whether the potential for theft and diversion is not credible for both light water reactor spent fuel and non-light water reactor spent fuel. If such scenarios become credible during the long term storage or indefinite storage time periods, then the NRC should also evaluate revising Table 4-2's entry for Sabotage or Terrorism to reflect potential for increased impacts. (0841-8 [Corrino, G])

Comment: In Section 4.19.2, paragraphs 6 and 7, the NRC speaks of additional security requirements being necessary as the spent fuel ages and its radiation level (i.e., the amount of self-protection) drops (see page 4-88, lines 19 - 26). However, the NRC has not addressed in Section 4.19.2 any increased security risks due to the operation of a Dry Transfer System (DTS) at the ISFSI. In Section 2.1.4 of the DGEIS, the NRC assumes the presence of a DTS to transfer fuel from one cask to another, when the cask lifetime is up in 100 years. At that point, self-protection would be greatly diminished; and potentially may not be relied upon. Secondly, a DTS may be needed much sooner to transfer spent fuel from an existing storage cask, that is not certified for transportation purposes, to a dual purpose storage and transportation cask. Thirdly, the NRC has not characterized the security hazards from a DTS due to theft and diversion in Section 4.19. Consequently, the NRC should characterize the theft and diversion risk from the use of a DTS in Section 4.19 over the range of potential times of use. Also, as noted in the above comment. This issue may affect the conclusion in parts of Table 4-2. Conforming changes may also be necessary in Section 5.19; and elsewhere. (0841-9 [Corrino, G])

Comment: Not safe & you can't make it safe no matter how many planes your fly into your cement casks; remember 9/11. (0862-2 [Thompson, Tammy])

Comment: Although I think that, as a society, we place too much emphasis on terrorism in the "post-9-11 world", it is nevertheless true that spent fuel pools are more attractive to terrorists than hardened on-site dry-cask storage; that simply adds to the advantage of changing our current system that is inherently less risky. (0864-11 [Gellert, Sally Jane])

Comment: The potential for a terrorist attack against the wet storage pools, dry storage and/or transportation between the reactor and such facilities is another example of a set of issues not appropriate for generic analysis. Terrorism is a potential issue for such shipments, no matter the probability of an attack. Low-probability, high-consequence attacks could happen and the characteristics of an attack will depend on the physical constraints of the facility, the geography of the transportation routes and such variables as the training and expertise of the local first responder community to address any radiological issue that arises. A radiological emergency could range from the inconsequential to a significant radiological release and first responders will need training, expertise and equipment to address such contingencies. The consequences of an attack are not similar to a run-of-the-mill accident and would vary depending on wind patterns, the presence of fire, the size/location of the breach to the cask and many other variables. Pre-existing methodologies and computer programs exist for analysis of these variables but they require site specific knowledge and inputs on the unique characteristics of the local conditions to offer useful data when the analyses are run (Ballard 1997, Halstead and Ballard 1997a). (0867-3-16 [Griffin, William])

Comment: The draft GEIS significantly under-estimates the probability of an attack-induced pool fire. That probability cannot be determined quantitatively. In light of human history, observation of the contemporary world, and consideration of possible societal trends, a prudent decision maker would conclude that a successful attack on a reactor or spent-fuel-storage facility in the United States over the coming decades is as likely to occur as are major national

challenges that are planned for, such as severe natural disasters or engagement in wars. Thompson Declaration, pars. VI-10, X-35. (0897-6-17 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Dr. Thompson also testified that the cumulative frequency of successful attacks on ISFSIs could be substantial and that the consequences of a successful attack could be severe. Thompson Declaration, Section XI. (0897-7-3 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The Draft GEIS assumes that the impact of terrorism would be small. However, according to the National Institute of Health, an attack on a nuclear reactor could result in a "massive release of radioactive material". In the aftermath of 11 September, David Kyd, spokesman for the International Atomic Energy Agency, confirmed this view, stating: "[Reactors] are built to withstand impacts, but not that of a wide bodied passenger jet full of fuel. ...These are vulnerable targets, and the consequences of a direct hit could be catastrophic." (0908-4 [Mikkelsen, Sara])

Comment: The draft GEIS assumes that spent fuel will be stored initially in pools and subsequently in dry casks. The potential for a pool fire has been mentioned above. There is also a potential for a "cask fire". Such an event could occur if a malevolent actor gains access to a dry cask containing spent fuel and attacks the cask in a manner that produces a self-propagating reaction between air and zircaloy fuel cladding. (0916-1-1 [Curran, Diane] [Thompson, Gordon R.])

Comment: (VI-10) The documents listed in paragraphs VI-7 and VI-8, the numerous citations within those documents, and the tables and figures identified in paragraph VI-9, provide a thoroughly documented basis for the following conclusions: 1. A reactor, spent-fuel-storage facility, or other nuclear facility in the United States could be attacked by a State or by a non-State actor. 2. A non-State actor could acquire the capability to execute an attack that releases to the environment a large amount of radioactive material from a reactor core or from stored spent fuel. 3. Storage of spent fuel at high density in a pool adjacent to an operating reactor is advantageous to an attacker, because this arrangement would help the attacker to obtain a large, radioactive release from the reactor and the pool. 4. The amount of radioactive material that would be released by an attack could exceed the amount that would be released by an accident. 5. NRC requires licensees to implement only a "light" defense of a nuclear facility, namely a defense that is designed to resist attacks within the lower end of the spectrum of severity of potential attacks. 6. NRC does not require any defense against attack from the air, although a non-State actor could execute such an attack. 7. Licensees routinely lobby NRC to reduce the scale of threat against which licensees are required to mount a defense. 8. Measures deployed by licensees to mitigate the effects of potential accidents would be ineffective in many scenarios of potential attack. 9. The probability of a successful attack cannot be estimated by statistical methods or by analytic arts such as probabilistic risk assessment. 10. In light of human history, observation of the contemporary world, and consideration of possible societal trends, a prudent decision maker would conclude that a successful attack on a reactor or spent-fuel-storage facility in the United States over the coming decades is as likely to occur as are major national challenges that are planned for, such as severe natural disasters or engagement in wars. 11. Options are available to reduce radiological risk arising from potential attacks. 12. The attack-related risk of storing spent fuel could be dramatically reduced by reequipping spent-fuel pools with low-density, open-frame racks, and by otherwise storing spent fuel in protected dry casks. 13. Requiring licensees to implement options that substantially reduce the attack-related risk at nuclear facilities would enhance protective deterrence as a national strategy, with substantial benefits. (0916-1-13 [Curran, Diane] [Thompson, Gordon R.])

Comment: (X-35) As discussed in paragraph VI-11, above, the draft GEIS asserts that the probability of an attack-induced pool fire is “very low”. In Section VI, however, I present evidence to the contrary. In my judgment, a prudent decision maker would conclude from this evidence that a successful attack on a reactor or spent-fuel-storage facility in the United States over the coming decades is as likely to occur as are major national challenges that are planned for, such as severe natural disasters or engagement in wars. (X-36) Here, I expand slightly upon the discussion in Section VI, while being careful to not disclose information that would assist a potential attacker. First, consider a potential situation in which a malevolent actor creates a cascading sequence of incidents that includes a radioactive release from a reactor. Given such a situation, the radiation field created by the reactor release, and other influences, could preclude mitigating actions needed to keep nearby pools in a safe state. (X-37) In paragraphs VIII-19 through VIII-22, above, I draw from analysis by Morris et al to discuss a potential situation in which a large aircraft strikes a reactor. That event could be a malevolent act. I show that the aircraft impact could be part of a cascading sequence of incidents that includes a pool fire. Since the attacks of 11 September 2001 in New York and Washington, acquisition of a large aircraft by a malevolent actor has become more difficult. Also, precise aiming of a large aircraft at low altitude is difficult. However, a malevolent actor has other options. That actor might, for example, employ a comparatively small aircraft equipped with explosive devices. (X-38) Now, consider a situation in which a malevolent actor has direct access to a pool. NUREG-0575 postulated such a situation, as discussed in paragraphs VI-2 through VI-6, above. The malevolent acts postulated in NUREG-0575 are summarized in Table VI-1. In the Mode 4 case, adversaries are assumed to temporarily take command of a spent-fuel pool while deploying an explosive device that could breach the floor of the pool. In that situation, as a slight adjustment of the Mode 4 case, the adversaries could use the explosive device to breach a wall of the pool, causing rapid drainage of water. The adversaries could ensure that some residual water is present. The exposed portion of the fuel would begin to heat up. Without prompt implementation of mitigating actions, a pool fire could follow. The adversaries could, in various ways, hinder or preclude mitigating actions. (0916-2-18 [Curran, Diane] [Thompson, Gordon R.]

Comment: (X-39) NRC proffers two, mutually inconsistent narratives about the threat of an attack on a spent-fuel pool. In one narrative, the pools are safe and secure, and no further action is needed to reduce the risk of a pool fire. In the other narrative, information about the potential for a pool fire must remain secret, because that information could be useful to an adversary.¹²⁰ [footnote 120 text: NRC’s consequence study mentions “security assessments” that were completed in 2006-2008, and further states that the results of these studies are not publicly available because they contain “sensitive information that could be useful to an adversary”. (See: Barto et al, 2013b, page 14.)] Both narratives cannot be true. Apparently, NRC recognizes that the pools are vulnerable to attack, but believes that hiding that vulnerability under a veil of secrecy will eliminate the potential for attack. That belief is imprudent. Non-State adversaries of the United States have repeatedly demonstrated a level of technical knowledge such that they could readily understand the mechanisms underlying a pool fire, without recourse to NRC’s secret studies. Thus, NRC’s secrecy does not provide protection. Instead, it denies US citizens a full accounting of the risk of a pool fire. (0916-2-19 [Curran, Diane] [Thompson, Gordon R.]

Comment: (X-3) In paragraph VI-2, above, I note that NRC explicitly considered the impacts of malevolent acts in its 1979 GEIS on Handling and Storage of Spent Light Water Power Reactor Fuel, which was designated NUREG-0575.⁸⁴ [footnote 84 text: NRC, 1979.] Potential malevolent acts were described in Appendix J of that document. NUREG-0575 is not cited in Sections 4.18 and 4.19 and Appendix F of the draft GEIS. That omission is significant because the malevolent

acts postulated in Appendix J of NUREG-0575 could, with slight adjustment, readily initiate a pool fire. I discuss that matter below. (0916-2-4 [Curran, Diane] [Thompson, Gordon R.]

Comment: (XI-9) The first step in assessing potential consequences of an attack-induced cask fire is to determine the inventory of radioactive material that is in the cask and available for release. Here, I focus on the radio-isotope Cs-137. I consider, as an illustrative example, a cask holding 32 PWR fuel assemblies. With reasonable assumptions, one can readily calculate that the cask contains 67 PBq (i.e., 1.8 MCi) of Cs-137.¹⁴¹ [footnote 141 text: Assumptions in the calculation are: (i) there are 32 PWR spent fuel assemblies in the cask; (ii) each fuel assembly has a mass of 0.45 Mg HM; (iii) the fuel has a burnup of 50 GWt-days per Mg HM; (iv) the fuel is aged 10 years after discharge from a reactor; and (v) 1 GWt-day of fission energy yields 1.17×10^{14} Bq of Cs-137.] (XI-10) A successful attack on an ISFSI, in which attackers expended an effort roughly the same as the effort needed to successfully attack a spent-fuel pool and cause a pool fire, could cause a cask fire in one or perhaps two casks. For illustration, let us assume that two casks would experience a fire and the fractional release of Cs-137 to the atmosphere would be 50%. In that case, the total atmospheric release from two typical casks holding 32 PWR fuel assemblies per cask would contain 67 PBq of Cs-137. That would be a substantial release, with a magnitude between the Fukushima release (36 PBq) and the Chernobyl release (85 PBq), as shown in Table V-1. (XI-11) Section X, above, discusses the consequences of atmospheric releases of various amounts of Cs-137. For example, as discussed in paragraph X-42, release of 330 PBq of Cs-137 could lead to severe consequences including long-term displacement of 4.1 million people. Also, as discussed in paragraphs X-46 through X-48, release of 100 PBq of Cs-137 could create economic damage of about \$1 trillion in the “base” case and \$8 trillion in the “high” case. In addition, there would be severe consequences of a social and political nature. (XI-12) Thus, it is clear that a release of 67 PBq of Cs-137 during a cask-fire incident could lead to severe consequences. Yet, a pool fire could lead to a much larger release, with correspondingly greater consequences. For example, as noted in paragraph X-42, each of the two pools at the Peach Bottom site now contains about 2,180 PBq of Cs-137. The fractional release of Cs-137 during a pool fire could be substantial, potentially exceeding 50%. At Peach Bottom, where two pools are in close proximity, an attack on one pool could ultimately lead to fires in both pools. Thus, a pool-fire release exceeding 2,000 PBq of Cs-137 is entirely credible. (0916-3-11 [Curran, Diane] [Thompson, Gordon R.]

Comment: (XI-13) The effort needed to successfully attack an ISFSI and produce an atmospheric release of 67 PBq of Cs-137 could be roughly the same as the effort needed to successfully attack a spent-fuel pool and produce a pool fire. However, the pool-fire release could be much larger than 67 PBq of Cs-137. As discussed above, at Peach Bottom a pool-fire release could exceed 2,000 PBq of Cs-137. Informed attackers would be aware of this discrepancy in potential outcomes. Accordingly, they would tend to target a pool rather than an ISFSI, other factors being equal. If the ISFSI were provided with enhanced protection, the comparative attractiveness of the ISFSI as a target would be even lower. Section XII, below, discusses some options for providing ISFSIs with enhanced protection. (0916-3-12 [Curran, Diane] [Thompson, Gordon R.]

Comment: (XI-14) At present, pools and ISFSIs coexist in the United States. Thus, given the comparative attractiveness of pools and ISFSIs as targets, a successful attack on a pool is currently more likely than a successful attack on an ISFSI. However, the draft GEIS contemplates a future in which there would be ISFSIs and no pools. That situation could continue into the indefinite future. Diminution of radioactive decay heat in spent fuel over time would be irrelevant to the creation of a cask fire. The risk environment could become more adverse over time. For example, security measures at ISFSIs could degrade over time. Also, an

increased propensity for violent conflict could find expression through attacks on ISFSIs. Thus, the frequency of successful attacks on ISFSIs could be much greater in the future than it is today. (XI-15) The findings set forth in Section XI, up to this point, support three conclusions about the environmental impact of attacks on ISFSIs. Here, I use the creation of one or more cask fires as an indicator of the success of an attack on an ISFSI. (XI-16) The first conclusion is as follows. As discussed in paragraph VI-11, above, the draft GEIS asserts that the environmental impact of attacks on ISFSIs is SMALL. However, the cumulative frequency of successful attacks on ISFSIs could be substantial. Also, the consequences of a successful attack could be severe. Therefore, the environmental impact of attacks on ISFSIs is not SMALL. Instead, it is LARGE. Thus, the draft GEIS substantially under-estimates the environmental impact of attacks on ISFSIs. Also, the draft GEIS ignores the possibility that the risk environment will become more adverse in the future. In addition, the draft GEIS uses a flawed definition of risk – the arithmetic definition. Moreover, application of the arithmetic definition is additionally flawed in this instance because the indicators that are multiplied together are nebulous. (XI-17) The second conclusion is as follows. While pools and ISFSIs coexist, as is true today, the cumulative frequency of successful attacks on pools is likely to exceed the cumulative frequency of successful attacks on ISFSIs. However, the draft GEIS contemplates a future in which there would be ISFSIs and no pools. In that case, the cumulative frequency of successful attacks on ISFSIs could be comparable to the currently-applicable cumulative frequency of successful attacks on pools, if there were no change in the risk environment. Whether or not pools coexist with ISFSIs in the future, the risk environment could become more adverse, leading to an increase in the cumulative frequency of successful attacks on ISFSIs. (0916-3-13 [Curran, Diane] [Thompson, Gordon R.]

Comment: The draft GEIS significantly under-estimates the probability of an attack-induced pool fire. That probability cannot be determined quantitatively. My qualitative assessment is provided in Conclusion #3, above. (0916-3-21 [Curran, Diane] [Thompson, Gordon R.]

Comment: (X-61) The draft GEIS further asserts that the environmental impact of attack-induced pool fires is SMALL.¹³⁸ [footnote 138 text: NRC, 2013b, Table 4-2 (page 4-91).] However, from the discussions in Section VI and paragraphs X-35 through X-39, above, it is clear that the cumulative frequency of attack-induced pool fires could be substantial. Also, NRC's consequence study shows that the consequences of a pool fire could be severe, with outcomes such as the long-term displacement of 4.1 million people. IRSN's analysis shows that outcomes could include economic damage measured in trillions of dollars. Therefore, the environmental impact of attack-induced pool fires is not SMALL. Instead, it is LARGE. Thus, the draft GEIS substantially under-estimates the environmental impact of attack-induced pool fires. Also, the draft GEIS ignores the possibility that the risk environment will become more adverse in the future. In addition, the draft GEIS uses a flawed definition of risk – the arithmetic definition. Moreover, application of the arithmetic definition is additionally flawed in this instance because the indicators that are multiplied together are nebulous. (0916-3-6 [Curran, Diane] [Thompson, Gordon R.]

Comment: (XI-1) The draft GEIS assumes that spent fuel will be stored initially in pools and subsequently in dry casks. A group of dry casks will constitute an ISFSI. During cask storage there is a potential for a "cask fire". That event could occur if a malevolent actor gains access to a dry cask containing spent fuel and attacks the cask in a manner that produces a self-propagating reaction between air and zircaloy fuel cladding, leading to a substantial atmospheric release of radio-isotopes including Cs-137. An accident could conceivably cause a cask fire at a storage facility, but I do not consider that possibility here. The draft GEIS does not consider the occurrence of a cask fire caused by either accident or attack. (0916-3-7 [Curran, Diane] [Thompson, Gordon R.]

Comment: (XI-2) In the Thompson scoping declaration, I outlined the potential for an attack-induced cask fire.¹³⁹ [footnote 139 text: Thompson, 2013b, paragraphs VII-15 through VII-16 and VIII-14 through VIII-18.] I first discussed a potential precursor to a cask fire – a reasonably foreseeable attack that would penetrate a cask, damage fuel inside the cask, and cause a release of radioactive material to the atmosphere. The feasibility of such an attack has been demonstrated in tests whose findings have been openly published. In my judgment, an attacker could, with a few additional steps, readily initiate a cask fire. NRC has not conceded that an attacker could take these additional steps and initiate a cask fire. (XI-3) The difference between my position and that of NRC could be resolved by commissioning an independent “Red Team” of persons who have relevant experience in practice and research. That team could conduct tests at a national laboratory or military base, to determine how readily a cask fire could be initiated. The tests could involve the use of tracer materials, thereby contributing to estimation of the radioactive release that could result from a cask fire. The general findings of the tests should be published, but some details of the tests may not be appropriate for publication. Until such tests are done, NRC will not be able to complete an adequate GEIS on the environmental impacts of storing spent fuel. (0916-3-8 [Curran, Diane] [Thompson, Gordon R.]

Comment: (XI-5) The effort needed to successfully attack an ISFSI and produce a cask fire could be roughly the same as the effort needed to successfully attack a spent-fuel pool and produce a pool fire. Let us examine the implications of that finding during a future period when pools and ISFSIs coexist. As discussed in paragraph VI-10 and elsewhere in this declaration, there is persuasive evidence that an attack-induced pool fire is as likely to occur as are major national challenges that are planned for, such as severe natural disasters or engagement in wars. An identical statement could be made about a cask fire, if two provisos were satisfied. The first proviso is that attackers would be able to achieve roughly the same outcomes by attacking a pool or an ISFSI. If that proviso were not satisfied, and the attack on the ISFSI would achieve a lower outcome, the attackers would have a reduced incentive to attack the ISFSI. The second proviso is that the casks sit on concrete pads in the open air without additional protection, which is current practice. If that proviso were not satisfied, and additional protection was provided, the attackers would have to expend greater effort to achieve the same outcome, which would reduce their incentive to attack. (XI-6) These provisos show how probability and impacts are interrelated. If the expected outcome of an attack on an ISFSI would be smaller than the outcome of an attack on a pool, other factors being equal, then a malevolent actor would be less likely to attack the ISFSI. The probability of the attack would decrease even further if the casks in the ISFSI were provided with additional protection against attack. Thus, either decreasing the expected outcome of an attack, or increasing the effort required to achieve a given outcome, would decrease the probability of attack. In the context of national security, that effect is encompassed within the concept of protective deterrence. Implementation of that concept could benefit the nation. Accordingly, the Thompson scoping declaration made the following recommendation:¹⁴⁰ [footnote 140 text: Thompson, 2013b, Section IX and Section X.] “Recommendation #22: In assessing the overall impacts of storing SNF or HLW, the proposed EIS [i.e., the draft GEIS] should consider the implications of alternative storage options for a national strategy of protective deterrence.” (0916-3-9 [Curran, Diane] [Thompson, Gordon R.]

Comment: NRC has not analyzed the security risks of such nuclear weapons usable substances as Pu-239 becoming ever more available, over time, in on-site or away-from-reactor dry cask storage - another showstopper shortcoming of this DGEIS, NRC's woefully inadequate treatment of nuclear weapons (as well as dirty bomb) proliferation risks. (0919-2-7 [Kamps, Kevin])

Comment: At lines 12-14 on Page 2-16, NRC states: "Following the terrorist attacks on September 11, 2001, the NRC issued Orders to ISFSI licensees to require certain compensatory measures. For example, on May 23, 2002, the NRC issued an Order to GEH Morris wet storage ISFSI (NRC 2002b)." But in August or September 2002, while traveling through Morris, IL, I saw with my own eyes that the GE Morris ISFSI was "wide open" to a potential attack. Although anti-car bomb concrete "Jersey" barriers had indeed been installed, they had been parted open, wide enough to allow a vehicle to drive through. And although a law enforcement squad car was parked there, its door was wide open, revealing that the car was in fact unoccupied. I witnessed this obvious security breach while just happening to pass by, which does not instill confidence in the security status of the GE Morris ISFSI. (0919-3-15 [Kamps, Kevin])

Comment: At Page 2-26, NRC admits, re: "Activities at At-Reactor ISFSIs," that there is but "limited physical and continuous electronic surveillance." Thus, ISFSI security leaves a lot to be desired! This is certainly the case at the Big Rock Point ISFSI in northwestern MI, the Palisades ISFSIs in southwestern MI, and many other sites! But security is not the only risk being neglected. So is safety. Even such basic safeguards as radiation monitors, temperature monitors, and pressure monitors are not required on ISFSIs, remarkably. At a site like Big Rock Point, MI, this is all the more alarming. NRC has permitted once every two week walk by inspections. This means a problem could be underway for two weeks, and Entergy Nuclear could well not even know about it! (0919-3-19 [Kamps, Kevin])

Comment: At line 18, NRC states "Groundwater wells could be installed for potable water use or aboveground storage tanks could be erected for potable water and water for fires and the batch plant." Re: fires at an ISFSI, would fire fighting water help or hurt, in terms of a zirconium fire, once initiated, as in a dry cask, a risk that Dr. Gordon Thompson, expert witness on behalf of dozens of environmental groups, has identified in this proceeding. (0919-4-7 [Kamps, Kevin])

Comment: At Page 3-5, line 30 and following, NRC states "At GEH Morris, an away-from-reactor spent fuel pool storage facility; fewer than 20 full-time employees monitor and maintain the spent fuel at the site (NRC 2004)." Fewer than 20 people, manage 772 tons of irradiated nuclear fuel at GE Morris? What about the security and safety risks of 772 tons of irradiated fuel, stored in an age-degraded facility upwind of Chicago? What if a 9/11-scale attack were launched at GE Morris, involving 19 attackers as took part in the 9/11 attacks? How many of those 20 GE Morris are actually on shift at any given time? How many of those 20 are security guards? As I described above, driving past GE Morris in September 2002, I found GE Morris's truck bomb barrier wide open, and its security squad car not only open, but unmanned. The sight did not instill confidence. (0919-5-9 [Kamps, Kevin])

Comment: On Page 4-31, NRC states "Normal operation of an ISFSI does not require water for cooling and the facility would produce minimal gaseous or liquid effluents."--But, if the ISFSI is attacked, as Dr. Gordon Thompson has commented, or involved in an accident, or simply leaks over time, then disastrous levels of hazardous radioactive gases and liquids could escape out into the environment. (0919-7-19 [Kamps, Kevin])

Comment: Protect fuel pools: Irradiated fuel must be kept in pools for several years before it can be stored in a dry facility. The pools must be protected to withstand an attack by air, land, or water from a force at least equal in size and coordination to the 9/11 attacks. The security improvements must be approved by a panel of experts independent of the nuclear industry and the Nuclear Regulatory Commission. (0927-8 [Kamps, Kevin])

Comment: Perhaps the largest danger presented by the establishment of some 69 NWO sites in 34 states (Page 2-14 line 10) is that these become potential terrorist or wartime targets. An attack with a conventional missile will not just take out an area much larger than the NWO itself. The dry cask storage systems, and certainly the fuel pools, are NOT hardened against such attacks, and it is doubtful that there is any ultimate hardening approach short of a deep geologic repository. The fact that the NWO installations DIFFER substantially from a deep geologic repository in this regard must also mean that there must be some serious risk that is now included. YOU NEED TO DESCRIBE THIS RISK AND DIFFERENTIATE THIS OPTION WITH THE PERMANENT GEOLOGIC REPOSITORY OPTION. (0930-1-13 [Lutz, Ray])

Comment: We disagree that you can conclude that the IMPACTS of Accidents or Sabotage or Terrorism are all SMALL. I know you want this to be the case, but it is not, and if you continue to assert this, I don't know how you can sleep at night. The reason the deep geologic repositories are proposed is to avoid these dangers. THIS MUST BE SPELLED OUT. (0930-1-16 [Lutz, Ray])

Comment: Page 2-16, Lines 17-18. You say that the NRC issued orders to ISFSI licensees etc. based on 6 9/11 attacks, and that the details are withheld from the public. But can you reveal how these orders were reviewed by other parties to ensure that they are adequate? If there was no review, this does not help us be confident that you are doing your job, given the fact that rarely do you push safety over profits. WHO REVIEWED THIS? (0930-2-13 [Lutz, Ray])

Comment: Page 4-84 "The environmental impact for a successful terrorist attack, if one occurs, could be significant and destabilizing." We agree with this statement, it is probably one of the few things you have said that were admitting the truth in this document. However, then you go on to say that because the probability is so low, we don't have to worry about a thing. If we used this method for dealing with risk that you use, then we would not have any defense department at all. They do not determine whether to create a defense only if the probability says that it might happen using PRA, and you must not use it to allow permanent ISFSIs. (0930-3-10 [Lutz, Ray])

Comment: Page 4-85, Line 15-16, "The NRC has determined that the probability of a successful terrorist attack on a spent fuel pool, although numerically indeterminable, is very low." That's probably what they said about the attack on the World Trade Center by 19 hijackers. Very low probability. And even lower probability that the towers would completely fall to the ground. But it happened anyway. So we object to the notion that you know that the probability is so low that we can disregard this risk. First you say you have no clue as to the probability, and yet you say it is low and therefore inconsequential. THIS IS THE MOST SIGNIFICANT THREAT POSED BY SITING 69 NWOs AROUND THE COUNTRY, resulting in 69 targets for conventional missiles that will result in a massive radioactive release, just like a "dirty bomb". I DON'T THINK THE PENTAGON WILL LIKE THIS IDEA, or at least I hope they still have some people there who still realize real risk when they see it. (0930-3-11 [Lutz, Ray])

Comment: Page 4-85 Lines 24-30. Changing procedures and adding training, improving security through access authorization, etc. are of no consequence when considering the possibility of a missile launched from North Korea, or a shoulder-launched missile directed at a fuel pool from well outside the secure perimeter of the power plant.. It is very distressing to learn how easily the NRC disregards these serious national security concerns. (0930-3-12 [Lutz, Ray])

Comment: Page 4-88 Lines 19-23. Adding new rules will not defend against serious wartime attacks. Our country was attacked in WWII and it can happen again. We do not want 69 NWOs around that will be targets, esp. if these are in densely populated areas, which most are. (0930-3-13 [Lutz, Ray])

Comment: Page 4-88 Lines 24-26, another ridiculous statement: "The NRC has determined that the measures described above, coupled with the robust nature of dry cask storage systems, make the probability of a successful terrorist attack, although numerically indeterminable, very low." Really? How do you figure that out. First, we do NOT know the likelihood of a war or terrorist attack over a 100 year period. So please, stop it with the jokes, will you? This only makes the NRC look pretty naive, to be sure. The trouble with your calculations is that a terrorist attack in 100 years is probably a certainty. A world war, probably also will happen. If it is a conventional war, then these NWOs will be targets. We can't let that happen. Period. (0930-3-14 [Lutz, Ray])

Comment: The document sidesteps the key issue... These NWOs are not as safe as a deep geologic repository due to the obvious risk of terrorist or wartime attack. THIS ISSUE CANNOT BE LEFT OUT. And if you are honest, you will decide that there is no way we can continue to license new plants and extend the licenses of old plants, particularly those with Mark-I containments, which have fuel pools above grade and much easier to attack and cause a problem than one that is built at ground level. (0930-3-20 [Lutz, Ray])

Comment: Along with this recognition came one with the Pentagon study saying PNPS was in the top ten highest at risk for terrorist attack. Its vulnerability is UN questioned first, because of its location in the flight path of one of the country's busiest airports-----the site of the take off of the 2001 terrorist air attack on NYC Trade Towers. The roof of the plant is where the spent fuel pool is located, filled to its maximum and outside the containment walls. It is especially vulnerable to attack because the protection is merely a thin tin rook likened to a tin roof as found at a Home Depot. The fact that it is within 50 miles of large, economically important cities with millions and millions of residents, adds to its consideration as a target. (0933-7 [Anonymous, Janet])

Comment: The Draft GEIS assumes that the impact of terrorism would be small. However, according to the National Institute of Health, an attack on a nuclear reactor could result in a "massive release of radioactive material". In the aftermath of 11 September, David Kyd, spokesman for the International Atomic Energy Agency, confirmed this view, stating: "[Reactors] are built to withstand impacts, but not that of a wide bodied passenger jet full of fuel. . . . These are vulnerable targets, and the consequences of a direct hit could be catastrophic." (0951-4 [Commenters, Multiple])

Comment: I think the on site storage is a very significant terrorist target with major impacts if attacked. On site storage needs to be fully examined and a much safer storage facility constructed that will not endanger our communities near nuclear plants. (0982-1 [Sieling, Jerry and Jean])

Comment: In addition to all conceivable and not-yet-conceived-of accidents, intentional sabotage must also be taken into account. Intentional damage intended to spread radiation is a potential terrorist agenda and may as likely or more likely than accident. Dispersed storage presents a multiplicity of potential targets. (1007-2 [Diamond, Jim])

Comment: All waste should be managed with an eye to security against both accident and intention. (1007-5 [Diamond, Jim])

37. Comments Concerning the Feasibility of Geologic Disposal

Comment: In my opinion, disposal of nuclear/radioactive waste cannot be made safely unless it is buried in lead-lined containers, deep underground in an area far from ANY location where it could possibly effect people or wildlife, and not on national or state park or wilderness lands[.] (0006-1 [Van Wicklen, Betty J.])

Comment: This should have been anticipated and solved prior to the development of any nuclear reactors - the NRC knew the half-life of the fuel rods, and their dimensions. They also knew the projected life of the rods and the projected life of the reactors. Who is asleep at the switch? (0006-3 [Van Wicklen, Betty J.])

Comment: Extension of continued storage in these facilities should be minimized, not extended further, as proposed. Permanent waste storage will continue to be put off if there is an ever lengthening of the allowable plant storage period. Safe waste disposal must be available and allotted before a plant is licensed to operate, not after some period of operation. (0026-1 [Campbell, Mary])

Comment: My comment: For the present, leave the waste where it is in dry cask storage. Do not transport over roads and highways, ships or trains. Be still with it! Next, gather leading scientists, ngo representatives, statesmen/women to discuss over a long period of time if there is and what would be a 'permanent' storage solution. (0028-1 [Craig, Anne])

Comment: It is high time to rethink nuclear waste storage. Keep the waste on site in dry cask storage. Organize a long term and serious study to see if there is a 'long term' storage solution and stop making the waste! (0029-1 [Craig, Tom])

Comment: in its analysis, the Commission projects that, based on international experience, 25 to 30 years is a reasonable estimate using a consent-based process as recommended by the President's Blue Ribbon Commission. I believe the NRC fails -- excuse me --25 to 30 years is a reasonable estimate to site, characterize, construct, license, and open a geologic repository using a consent-based process, as recommended by that Blue Ribbon Commission. I believe the NRC fails to consider key factors in its analysis, factors that are peculiar to the United States. These factors may render NRC's projected timeframe overly optimistic. (0030-1-2 [Kotra, Janet])

Comment: [W]hile I agree that today there exists a much stronger technical basis for confidence in geologic disposal, the current rulemaking fails to take into account whether there exists sufficient social and political bases for continued confidence that such disposal will be realized in the United States and what these inadequacies portend or imply for the rulemaking. (0030-1-3 [Kotra, Janet])

Comment: [I]f a community in the United States is to step forward and to consent to host a repository, or even, for that matter, a centralized interim storage facility, such a community must trust in the integrity of political and regulatory systems with which it is to consent. Members of such a community are effectively entering into a contract on behalf of the safety of their citizens, and especially, in the case of a repository, the safety of their future generations. The Nuclear Waste Policy Act that led to selecting Yucca Mountain is such a statutory framework enacted by

Congress which set forth a process for developing not one but two repositories. This process was to be implemented by the executive branch and licensed and overseen by an independent Nuclear Regulatory Commission. Any prospective host community today will have to confront the sober reality that the U.S. Government failed to implement its own nuclear waste law. Absent an executive branch willing to carry out a nuclear waste law enacted by Congress, and overseen by a safety regulator perceived as truly independent by that host community, how could any community have confidence going forward that this or any other nuclear waste law will in fact be honored or implemented? And I have to say that in reading this proposed rule no attempt has been made in this proposal to address the impact of this breakdown in the U.S. public's ability to rely on its government and on NRC itself to comply with the nation's own nuclear waste laws, especially in light of the recent ruling of the U.S. Court of Appeals, District of Columbia Circuit. (0030-1-5 [Kotra, Janet])

Comment: [A]fter all that has happened since 1999, should NRC still have confidence in waste disposal? Since 1984, the Commission has expressed, and later affirmed, its confidence that deep geologic disposal is feasible. Nothing has emerged to lessen NRC's confidence in the technical feasibility of repository disposal. That much is not in dispute. As this rulemaking notes, much more scientific and engineering experience and evidence has emerged to reinforce the Commission's initial findings. And I have to add that a lot of the confidence has been contributed to, quite ably, by NRC scientists and engineers and their colleagues at the Center for Nuclear Waste Regulatory Analysis in San Antonio. Also among the reasons for greater confidence are the findings and recommendations of the Blue Ribbon Commission for America's Nuclear Future, which endorsed disposal in deep geologic repositories when selected using a consent-based process. (0030-1-6 [Kotra, Janet])

Comment: I think it's worth noting that more than 35 years ago the 2nd Circuit Court of Appeals in *NRDC v. NRC* confirmed that halting reactor licensing until definitive findings on repository safety are reached, it is simply not required by the Atomic Energy Act. (0030-16-4 [Bonanno, Jerry])

Comment: The history of how we arrived at this point is well summarized in the documents that we're here to comment on and going back to the passage of the Nuclear Waste Policy Act, which initially mandated that the Department of Energy site or come up with recommendations for siting two repositories in this country for the permanent disposal of nuclear waste. And over a few years it became clear that that was too hot of a political potato for the nation to manage and the law was revised to require the siting of one repository and cap the amount of waste that could be stored in that repository until a second one could be sited. And then a few years later when it became more clear that that was going to be such a heavy political lift, you know, the requirement for DOE recommending a second repository site was stripped entirely. And so we were left with one proposed site, Yucca Mountain, capped at a capacity of 70,000 metric tons of nuclear waste. And that's been the process where we've been stuck until it became clear that the Department of Energy needed to withdraw its application for a license because the facility was too controversial, would not have the political support necessary, and there were massive technical problems with the site. So we arrive at 2010 and the Federal court case that's filed that ultimately went out and forced the NRC to withdraw the Waste Confidence rule as it was revised after the demise of Yucca Mountain. We're, you know, 60 years into the nuclear experiment and we've not been able to site a single repository in this country to store nuclear waste. (0030-17-5 [Judson, Tim])

Comment: And with respect to, you know, the statutory limit on the capacity of even the first repository at this point of 70,000 tons, according to the generic environmental impact statement

that amount of waste is already being stored at reactors across the country. So we've already filled the first repository before it's even been built. And so now going forward with the licenses the NRC has already issued, based on the estimate in the GEIS that we generate 2,000 metric tons of spent fuel every year in this country going forward, we've essentially already filled the second repository if its to be built to the same capacity. So all the licenses that would be issued going forward would be essentially for what we must presume at this point would be a third repository, and the Nuclear Waste Policy Act has never even contemplated building a third repository, even though we know if we generate that waste we're going to need to do something with it. (0030-17-6 [Judson, Tim])

Comment: Since 1982 the Government has amassed a nuclear waste fund of \$30 billion for money collected from customers of nuclear electricity. It is time to use that money for its purpose, the review of the Yucca Mountain repository license application, which would certainly address a lot of the concerns raised here today. The country has already spent upwards of \$10 billion in Yucca Mountain and the American people deserve to see the results of the independent objective safety review performed by the NRC. As President Obama himself pointed out at the beginning of his first term of office, regulatory decisions should be based on sound science, not politics. We heard a little bit about the physical limitation on the repository. In fact, Yucca Mountain has a statutory ceiling of 70,000 metric tons, but that is not a physical ceiling. In fact, I think there's been some work done showing that it could easily accommodate 140,000 metric tons. (0030-23-10 [Blee, David])

Comment: While long-term storage of used fuel is safe and feasible, it is not an appropriate permanent solution. Ultimately, the United States must dispose of used fuel or its recycling byproducts. Fortunately there is an international scientific consensus that geological disposal of used fuel is feasible and safe. The United States is fortunate to have a variety of sites suitable for underground end placement of used fuel in a manner that will isolate it from the environment while its radioactivity decays away. Countries such as Finland, Sweden, and France are making good progress towards geological disposal. (0030-23-8 [Blee, David])

Comment: I've listened to everything today and I think that "confidence" is a word that's been bandied around a lot, but I for one have really no confidence in the ability of our Government to maintain radioactive waste in a safe way. And all the experience that I've had in my long life has shown me that this is actually true. Not only have we not been able to contain nuclear waste from bomb testing, we've not been able to contain the waste from reactors. (0030-24-1 [Nelson, Dennis])

Comment: I want to start by talking about money. I think that what we are all looking for is a cheap solution to a very complicated problem. I would like to recommend, for example, that we wrap our nuclear waste in gold or iridium, iridium because a metallurgist suggested it would be good, and gold because I think that obviously would be good because of its secure properties, it's strong, it's -- instead, we are using lead and steel and cement. (0030-4-1 [Hoffman, Ace])

Comment: And maybe they don't understand what is going on here, which would suggest that you haven't done your job of reaching out to the public, so that they understand what's going on here in this meeting today, because right now that fuel is 100 times or 1,000 times more dangerous than it is going to be when you finally decide to put it someplace safe. And I think right now is the time to make sure that it's someplace safe, and there is no place that is going to take it. (0030-4-7 [Hoffman, Ace])

Comment: The fact that we have been making it for 60 years or more, and we have no place to put it and no prospect, and that you are talking about going 100 years into the future before we actually have some place to put this material, and whether that is even going to be, those are all geologic bets, whether whatever we decide, whatever deep ground deposit we put these materials into, in terms of geologic time, thousands of years, tens of thousands of years, there is no real certainty that you are not going to have some geologic shift, and the material that we thought was safely removed from the environment will then become exposed in some unexpected manner. (0030-5-5 [Safer, Don])

Comment: We do think that the international consensus on geologic disposal will someday reach our government and it will build a repository. (0030-6-10 [McCullum, Rod])

Comment: Thirdly, you cannot say that nuclear waste can be safely stored. Plutonium will be dangerous for 240,000 years. Who will be around during this time range to guarantee its safety? What monstrous situation are we leaving for future generations? I have a grandson. I tell him that when he makes a mess he should clean it up. Are we telling future generations that they must clean up our messes? What is the cost? How many lives? (0035-5 [Fulton, Doris])

Comment: Take action to protect our communities from nuclear waste! (0039-1 [Littlejohn, Nick])

Comment: Our Federal Government does not know how to keep the doors open and the lights on. We are lacking in confidence in the larger picture as well, about the Federal Government or any agency of the Federal Government, to be able to sustainably and competently manage these issues. (0045-1-5 [English, Becky])

Comment: I want to make one thing perfectly clear. I am not confident that the NRC will be able to site a permanent repository within 25 to 30 years. (0045-11-3 [March, Leslie])

Comment: While long-term storage of used fuel is safe and feasible for extended periods it is not a permanent solution. Ultimately, the United States must dispose of used fuel for its recycling byproducts. Fortunately, there is an international scientific consensus that geological disposal of used fuel is feasible and safe. I visited the Onkalo spent fuel repository, the world's first deep geological repository located in Finland, and have high confidence in the multiple release barriers at minimal impacts to humans and the environment. (0045-15-1 [Sandos, Theann])

Comment: Simply stated, the NRC is correct, in concluded that it is feasible to have a mined geologic repository available within 60 years after the licensed operating life of a nuclear power plant. There are no technical barriers to achieving this result, nor are there any financial barriers given the current and growing balance in the nuclear waste fund. (0045-2-2 [Green, Michael])

Comment: The NRC is correct in concluding that it is feasible to have a mined geological repository available within 60 years after the licensed operating life of a nuclear power plant. There are no technical obstacles to achieving this, nor are there any financial obstacles, given that the Nuclear Waste Fund now has a balance of more than \$26 Billion Dollars. (0045-5-1 [Cannon, Tom])

Comment: There is a strong international scientific consensus that geological disposal is the best solution to permanently isolate spent nuclear fuel from the public and the environment. Studies by the National Academy of Science, and the International Atomic Energy Agency have confirmed this conclusion. In fact, the International Atomic Energy Agency concluded in 2003

that the geological disposal is the generally accepted solution in practically all countries faced with the issue. Sweden and Finland are developing geological disposal facilities and are expecting to begin disposal of their spent fuel by the early 2020s. France is making significant progress. They have selected and characterized the geological region and are now working to identify a specific site. Belgium, China, and the United Kingdom, plan to start geological disposal by 2050 or earlier. (0045-5-2 [Cannon, Tom])

Comment: We have the technology to develop a geological repository for spent nuclear fuel, and we have the money to do so. The only thing blocking the United States from building a geological repository is political decision-making. (0045-5-5 [Cannon, Tom])

Comment: [W]hen I look at internationally what's going on, because all countries that have nuclear power are confronting this issue of storage, transportation, handling, terrorist attacks and ultimately the permanent, safe, long-term disposal of nuclear waste, and what I find deficient in the current EIS is the lack of real sort of summary review documentation identifying this real progress that's going on in other countries. In a few years they'll probably be opening repositories in several European countries. In ten years there will be several different types of repository concepts that are going forward in terms of licensing. That kind of progress really should be reflected in this whole idea of 60 years being a short term, really. In six years we're probably looking at high confidence that there will be these kind of successful, licensed, under-regulatory-review repositories. And I think that theme should be more closely represented in the EIS. (0045-7-1 [Apted, Michael])

Comment: Currently I serve as a technical expert for the regulatory authorities in both Finland and Sweden. Construction license applications for geologic repositories have been issued, they're under current review. I think, Finland, the current schedule is a decision, yes or no, by sometime late in 2014, in Sweden, the schedule now is sometime in 2015. So these decisions on showing that there can be a successful and robustly safe closure of the nuclear fuel cycle are coming soon, not 60 years but in a few years. And I think that perspective, again, should be built in and brought into this EIS. Now in addition to Sweden and Finland, France, Switzerland they're a few years behind. Somewhere in about the next five to ten years they'll also be bringing new and different repository concepts to their regulatory authorities. Again, looking to show and demonstrate a safe closure of the fuel cycle. I think, again, some sort of appreciation of looking outside the borders of the United States. A few weeks ago in Canada, for example, they're looking at regulatory licensing, public commentary review of these deep disposal of intermediate and low level waste at the Bruce site in Canada. This kind of progress really needs to be brought forward into this idea of confidence. (0045-7-2 [Apted, Michael])

Comment: Other nations, Canada, as I mentioned, U.K., Japan, Russia, China, all are also heavily invested in progress and developing new ideas, new concepts for safe, long term -- and by long term I mean out to a million years -- safe, permanent disposal of this highly radioactive material. And so again, this kind of progress, the NRC has bilateral agreements with many of the regulatory agencies around the world. It would be useful if they used those bilateral connections to bring in that kind of information to be reflected in this EIS report. (0045-7-3 [Apted, Michael])

Comment: [M]y view is that really there is high confidence as of today that there will be demonstrated safe, long-term, permanent geologic disposal of spent nuclear fuel, high level waste that's arising from the nuclear industry and nuclear weapons programs. This kind of information really ought to be reflected more in the report as it stands today. (0045-7-4 [Apted, Michael])

Comment: Tonight we're talking about waste confidence. And in my home, if, for instance, we have plastic bottles, and if we had to recycle those, we recycle plastic bottles when we get them. It's fantastic. But this isn't exactly plastic. (0045-8-2 [Bartlett, Bill])

Comment: If the NRC and the Nuclear Power industry could not burry spent nuclear fuel at Yucca Mountain during the last 56 years. How long might it take to find a place to burry it if it is not safe under Yucca Mt. for any period of time according to Sn Harry Reid? (0050-1 [Waterman, Charles])

Comment: For my entire life, the government has been promising the benefits of nuclear technology, but all we really have to show is a legacy of broken and false promises, laying all the problems on our children. When I grew up in Kansas in the 1950s the AEC was planning for nuclear waste disposal in Kansas salt mines. That never happened. Nor has anything since. (0059-15 [Andrews, Richard])

Comment: Since 1998 the US has been delinquent in supplying a location for final disposal of nuclear spent fuel that the federal government promised when nuclear reactors were being built in the late 1960's. There is currently no place being prepared to take the US nuclear spent fuel. When President Obama shut down Yucca Mountain after nearly 30 years of preparing the site to be a final geologic deposit for all of our nuclear waste for the entire country, America became a deadly accident waiting to happen at 104 reactors. But SONGS sits with everyday a potential to destroy as in Fukushima the land from Oceanside to Laguna Beach, shut down forever. The nuclear reactors built in the 1960's were never built to store the waste on site. No state is willing to accept the nuclear waste. The NRC is now wrongly requiring that the waste is safest being stored on site. These old plants were not designed for that. What other plan is possible? (0063-10 [Magda, Marni])

Comment: The United States has searched for a way to dispose of spent fuel for over five decades. At this point, there are no specific nuclear waste storage proposals that would solve this problem in the foreseeable future. Even if a seemingly suitable storage scheme for high-level radioactive waste were conceived, it could take decades to plan and implement. The closing of the Yucca Mountain facility in Nevada in 2010 demonstrated that planned facilities may never open, even after billions have been spent on development. Simply put, the safe disposal of nuclear plant waste is a problem that may never be solved. (0064-3 [Skud, Bruce])

Comment: Putting aside the formidable technical challenges of locating a proper geologic site, governors and legislatures vigorously oppose siting a national waste repository in their states. The reason for their relentless opposition is that their constituents, including the business community, however open to nuclear power they might be, do not want a national nuclear waste repository in their own backyard under any circumstance. (0064-4 [Skud, Bruce])

Comment: Where might that secure location be? The US has yet to find any permanent site for storage of spent fuel rods. (0086-4 [Lewis, Carol])

Comment: The U.S. has searched for a way to dispose of spent fuel for five decades. It has become an intractable problem. The closing of the Yucca Mountain facility demonstrated that planned facilities may never open even after billions of dollars has been spent. Putting aside the formidable challenges of locating a geological site, governors and legislatures vigorously oppose the siting of a national repository in their states. The reason for their opposition is that their constituents, including the business community, are adamant that they do not want a repository in their own backyard under any circumstance. Let's be realistic, the fact that there is

federal jurisdiction over the siting of a national repository means nothing. There's no question a national repository would create new and horrible safety problems. (0112-10-3 [Skud, Bruce])

Comment: The fact that that has been going on for 50-plus years, 60 years and it can't come to fruition gives us no confidence that any type facility could ever be built by our government. And so anything that needs to look at needs to take that into consideration. It might be possible for private enterprises to build such a facility, but they're not going to do it on, you know, without some financial support. Based on past performance that I can't see how anybody would have any confidence at all that such a facility could be built by our government. (0112-17-3 [Stamm, Steve])

Comment: [N]obody is more interested in seeing used nuclear fuel leave the reactor sites that it's currently stored at than I am. The reason for this is the last 15 years of my career I have been working for the Nuclear Energy Institute. I currently work as director of used fuel programs there towards this very goal, towards moving used fuel to safe geological disposal. I continue to work towards it because I know we'll get there. I know because in Sweden and in Finland they're within a decade of safely disposing of their used nuclear fuel in geological repositories already under development. I know France is not far behind. And I can't imagine that our country would ever come in too far behind France in anything. (0112-25-1 [McCullum, Rod])

Comment: I'm going to concentrate on the timeline for geological repository since this is what I study. There are a variety of policy implications on this repository's construction, but it is evident that a timeline, though complicated, is actually achievable. My recent lecture on the history of nuclear waste there at MIT was met with some challenges because of its title. I called it the search for Tartarus, i.e., it could be called the search for hell. Some may recognize that nuclear waste repository may be a very difficult place to site. But I recognized it as a place that is absolutely findable if you have Godly intentions. (0112-26-1 [Brinton, Samuel])

Comment: In 1957 the National Academies of Science established that a geological repository was the preferred system for the permanent storage of nuclear waste. Now, I wasn't around in 1957 nor was I around in 1970 when we tried to site the very first geological repository. I was raised on farms in Kansas and I am proud to say that the very first repository was tried to be sited in my home state there in Lions, Kansas. This did not work out well. There were technical challenges. And I've studied how horribly the government mangled its issues trying to site a repository in Lions, Kansas. And I can see a lot of shaking heads. I recognize that challenge. We didn't do it right. But we can do it right in the future. (0112-26-2 [Brinton, Samuel])

Comment: In 1982 the National Nuclear Waste Policy Act began the site characterizations of a variety of geological formations. And during 1987, the year I was born, a political maneuvering destroyed that process. Geological repositories exist. In 1979 when my mother was evacuated from the school next to Three-Mile Island the Congress also authorized the Waste Isolation Pilot Project. We have to recognize that these geological repositories exist and that they are also being constructed. This is applicable because the permanent solution is feasible. Let students like myself have the time to study these challenges. And with enough political action it will be able to move forward. (0112-26-3 [Brinton, Samuel])

Comment: Long-term storage is available and students like myself are ready to take the technical capabilities of geological repositories as the next challenge. (0112-26-4 [Brinton, Samuel])

Comment: And one of the other things about the repository, it's a nice word for putting this poison that's going to murder gazillions of people, they call it no nukes. We call it the dump if they were going to put all this stuff in the Great Lakes that would have affected the water of 42 billion people, ho-hum. (0112-30-5 [Parks, Sheila])

Comment: I've been involved in this issue really not by choice approximately 30 years now. I was a kid when I started. And there was a plan to site a high-level nuclear waste dump here in the northeast, the Eastern repository. And looking over some of the documents tonight I realized some of the terminology hasn't changed at all. That's interesting. So it's eating up a huge part of my life. There are things I would rather been doing and still today there are things I would rather be doing. (0112-31-1 [Johanson, Birgit])

Comment: I also want to say that I was moved and I appreciated Gregory Jaczko, the former Chairman of the NRC said pretty much what amounts to a death bed conversion although he didn't die, but he saw other people dying. And he came out and said that these plants are inherently unsafe. And I am sure that he would say that much that we know about long-term storage is their solutions are unsafe. And we can't go forward pretending that we have solutions in order to just let the clock run out for these companies. (0112-34-6 [Chichester, Ben])

Comment: [W]e've [Seacoast Anti-Pollution League] been raising these issues of what to do with the waste all that time for four decades now and still no solution. This is really a bizarre situation. It feels like we're watching endless reruns of a bad movie. This past procrastination is finally catching up with the NRC and with the nuclear industry and we really need a serious investigation of these issues. (0112-5-1 [Bogen, Doug])

Comment: The waste storage issue which we are here to discuss tonight is the result of years of gridlock in Washington, DC and the federal government's failure to follow through on its promise to create a national repository for used nuclear fuel. Although we would like to see a resolution to the fuel storage issue, it likely won't be over for quite some time, nor will it affect whether the U.S. Nuclear Regulatory Commission approves license renewal for Indian Point. (0119-3 [Mooney, William])

Comment: I guess better-late-than-never, but what a sad commentary on the responsibility that the NRC feels for its mission. Obviously nuclear waste has been one of the defining problems with nuclear energy technology since its beginning, but in my opinion the attitude that "we'll just deal with that later" seems to have been the approach for decades. (0126-1 [Houston, Ann E.])

Comment: Even IF successfully removed, WHERE WILL THEY PUT THE REACTIVE MATERIALS? THERE IS NO PLACE ON EARTH SAFE AND SECURE (and NO NO NO don't DON'T send them into space!!!) (0133-2 [Sunflower, Susan])

Comment: The truth is that there is no real plan to isolate high level radioactive materials effectively for the amount of time really necessary to protect public health and safety. (0136-10 [Shaw, Gary])

Comment: When NRC says it has a viable waste management plan with public health and safety as the preeminent concern, we must look at that in the light of NRC's record. When NRC talks about "lessons learned" what they are in fact saying is "glad that unexpected bad day didn't happen here." (0136-7 [Shaw, Gary])

Comment: As a physicist and engineer, I know the used nuclear fuel can be safely stored. I know that because the US Federal Government is today storing highly radioactive nuclear fuel material in the US' own Waste Isolation Pilot Project in New Mexico. This project, known as WIPP, has been licensed by the US Government. It is used by the US Department of Energy for the long term underground storage of transuranic actinides thousands of feet underground in a "salt dome" formation. Safe underground geological disposal is being done today, by the US Government. (0138-5 [Cook, Dr. Andrew G.]

Comment: By why do I say the used fuel will be safely stored with confidence? Let's consider a long term geological storage site. Here is what must happen for anything to get into our environment. First water must penetrate thousands of feet into the rock in a location where water has not been present for millions of years. Assuming water can even get there, through the rock, the water has to dissolve the inch thick stainless steel canisters that contain the nuclear fuel, then if the water has to dissolve the zirconium metal cladding around the fuel, and finally that water has to dissolve the fuel itself, which is a hard ceramic, just like this coffee cup I am holding. Water does not dissolve ceramics. However, if all of that occurs the water now may contain a small fraction of the radioactive materials. Let's consider what must happen next. Somehow the water has to get back out of the ceramic, past the zirconium, past the stainless steel canister and now the greatest challenge of all, penetrate the rock and get back thousands of feet, up against gravity to the surface. What happens when water carries something and starts to migrate? Those things in it precipitate out of solution. You can see that natural phenomena here on my handkerchief. I spilled some coffee. You can see that the coffee precipitated out in a ring on my handkerchief, while the water continued outwards. How far did the coffee get - two inches. The same will happen to the fission products. They will precipitate out of solution and form crystals, just as happened at Oklo within feet of the point of origin. They will never make it the thousands of feet UP through solid rock to the surface aquifers. Of course we may want to recover that fuel. Why? Because it represents the OPEC oil equivalent of energy for the US in terms of the energy it still contains. It could be used by our grandchildren and great grandchildren and their children down on the line as one of our great energy resource legacies. (0138-7 [Cook, Dr. Andrew G.]

Comment: Nuclear waste is still a problem without a solution, even after 20 years and billions of dollars spent to locate a viable site. Waste confidence is anything but a solution to inspire confidence since allowing nuclear plants to continue to produce waste with no scientifically proven solution for safely disposing of it exists. (0139-1 [Hodik, Barbara J.]

Comment: It is important that the NRC admit that there is no safe, permanent repository, and that 70,000 tons of accumulated nuclear waste may be permanently stored at reactor sites. (0143-1 [Arauz, Jorge])

Comment: In the US: According to the Government Accountability Office The amount of spent fuel stored on-site at commercial nuclear reactors will increase by 2,000 metric tons per year, doubling to about 140,000 metric tons -- before it can be moved off-site, because storage or disposal facilities may take decades to develop. In examining centralized storage or permanent disposal options, GAO found that new facilities may take from 15 to 40 years before they are ready to begin accepting spent fuel. Once an off-site facility is available, it will take several more decades to ship spent fuel to that facility. (0145-3 [Sorensen, Laura])

Comment: Federal law has only authorized the siting of one nuclear waste repository. As of 2010, nuclear power plants had already generated 70,000 tons of spent fuel, enough to fill that repository. That means a second repository would have to be built to hold all the waste nuclear

reactors are continuing to generate, but there is no plan or Act of Congress on the table for where to do it. (0147-3 [Fallon, Gloria])

Comment: As you are aware, the president appointed a commission to examine nuclear waste management issues. The report suggested finding two or three alternative sites using a consent-based process. It is MEA's [Multicultural Education Alliance's] understanding that legislation is pending in the Senate to begin the process of selecting alternative sites. We believe we have the technology to develop a geologic repository for spent nuclear fuel, and we have the money to do so. The only thing blocking the United States from building a geologic repository is political decision-making. (0150-2 [Rivera, Wendy])

Comment: I do feel that there needs to be progress on locating a Federal Depository to help ease some of the concerns that some of the American citizens may have regarding the long term storage of spent fuel. (0153-3 [Capurso, Thomas])

Comment: I understand that storage of spent nuclear waste is a major environmental problem as well as security problem. I urge you to not look at our country's desert areas as "wastelands" and thus garbage dumps for nuclear waste. The deserts are very fragile ecosystems which need to be cared for, not trashed. (0161-1 [Rose, Melene])

Comment: We need to find a way to stop polluting with this waste. Yucca Mountain isn't the answer, there are fault lines running under and an organic farm nearby. Please do all you can to work on these problems. Thank you for taking comments. (0162-2 [Ramsey, Betty])

Comment: Currently, there are no available offsite locations to store high-level nuclear waste from those facilities or even an ongoing process to identify such a site. (0163-1-6 [Schneiderman, Eric])

Comment: As for disposal of spent fuel, the President's own Blue Ribbon Commission recognized that a geologic repository is still the best method of disposal. Sweden and Finland are both already developing geological disposal facilities, which frankly should be an embarrassment to the country that pioneered commercial use of nuclear energy and built such large undertakings as the Hoover Dam. (0163-11-4 [Gutherman, Brian])

Comment: Someone asked me a while ago, when you post -- and they asked me to ask you, when you put a warning sign on these long-term casks, what language is it going to be in? Because do you think the people that find these casks in 500 years will be speaking English? (0163-13-3 [Jaffee, Ellen])

Comment: There's no viable option for long-term storage. People have talked about that over and over. (0163-21-2 [Elie, Marilyn])

Comment: Not only that. I want to express right now the fact that it's not only wrong to pass this off to somebody else, it's also very anti-Democratic. Nevada didn't want it and who does? Who wants to become the national high-level radiated dump for the entire country? Are there citizens in this country besides those who can't say no, besides those who are poor, besides those who are Native American, besides those who are people of color that would say that? And where is our responsibility, our moral responsibility to take care of our own mess? (0163-21-4 [Elie, Marilyn])

Comment: And the problem is what about long-term storage? What happens to this stuff when however many, 1200 generations -- well, how about even the fourth generation, let alone the

1200, okay. If we choose not to deal with that seriously by putting it off, which is what this GEIS does, it puts the problem off. If we continue to deny, we compound the problem and we become morally sick. And it is a great regret and a matter of great sadness for me that our country is in the midst of doing that. (0163-23-2 [Fullerton, Dan])

Comment: We're here today because the production of nuclear waste and the absence of adequate plans on how to store it safely for 250,000 years threatens the health and the lives of everyone's grandchildren. (0163-28-1 [Cypser, Betty])

Comment: I was born in 1979 and that's the year the NRC started writing the first version of its Waste Confidence Rule, so for my entire lifetime this rule has been used by the NRC to dodge hard questions about the legacy of the dangerous radioactive waste building up at our reactors...I'm now 34 and tens of thousands more tons of nuclear waste have been generated since 1979, but in all this time, we've not come any closer to a solution. In fact, with the cancellation of the Yucca Mountain project, we may be farther away than ever, and we have more radioactive waste problem than ever. I have to tell you, no offense to the people in the room who have been fighting this issue for a long time, but it makes me pretty mad that previous generations decided it was fine to create piles of deadly toxic waste without a plan. (0163-34-2 [Azulay, Jessica])

Comment: And it comes down to what's real and what's imaginary. What's imaginary is gridlock in Washington. Gridlock in Washington is something that we create as humans, as citizens and it means nothing. (0163-35-1 [Shaw, Jeanne])

Comment: You can't go burying this stuff anywhere in the world and expect to get away with it. Just because they're doing it in Finland doesn't mean we can do it here. It doesn't even mean they can do it there. They just are. Hello. It's the world. The earth is not static. The earth moves constantly, and I mean constantly. Everything in the world is going to what we now think of as hell or heaven and that's real. And that's not theological, so what are you going to do with nuclear waste? It's not anything you can do with. (0163-35-5 [Shaw, Jeanne])

Comment: There's a lot -- there's been a lot of focus on the issue of repository availability in these public meetings and there's understandably a lot of frustration regarding the politically motivated delays in siting and constructing a geologic repository in the United States. It's worth noting that the NRC's role in a Federal repository program is distinct from the agency's consideration of repository availability when it licensed commercial nuclear power reactors. Focusing on the NRC's role in the Federal repository program, it's important to understand that the NRC is not responsible for siting, constructing, or operating a geologic repository for used nuclear fuel. Under the current legal framework, that responsibility falls squarely with the Department of Energy. Instead as the D.C. Circuit recently reiterated, the law requires that the NRC review DOE's application, make a decision about whether the proposed repository can be constructed and operated safely. (0163-38-1 [Bonanno, Jerry])

Comment: Setting aside decisions regarding the licensing of specific repositories, the relevant question in this proceeding is what, if anything, is the NRC obligated to conclude with respect to repository safety when licensing commercial power reactors. For the past 35 years, the Commission has characterized the necessary finding as reasonable assurance that methods of safe permanent disposal can be available when necessary. This reasonable assurance finding does not equate to a definitive finding on the safety of a specific repository. In a 1978 decision called NRDC versus NRC, Second Circuit Court of Appeals clarified that halting reactor licensing until definitive findings on repository safety are reached is not required by the Atomic

Energy Act. In that decision the court recognized that Congress enacted a framework that calls for development of a repository and parallel with the development of commercial nuclear power in the United States. It's equally clear that uncertainty caused by the political and social resistance to the development of a repository might justify examination of extremely unlikely scenarios such as in a repository scenario in order to satisfy NEPA. But it's not the NRC's role to resolve such uncertainty or cure such resistance. In fact, the same decision -- in the same decision, the Second Circuit concluded that resolution of such political and social resistance to the development of a geologic repository must come from a legislative branch of government, not the NRC. The primacy of a legislative branch in setting national nuclear energy policy was also stressed by the U.S. Supreme Court in its 1978 decision *Vermont Yankee versus NRDC*. So absent a clear scientific or technical barrier to achieving safe geologic disposal or continued storage or a drastic change in the Federal Used Fuel Policy completely abdicating the government's responsibility to dispose of used fuel in position of a broad open ended moratorium on licensing commercial power reactors by the NRC would raise serious separation of powers issues. (0163-38-2 [Bonanno, Jerry])

Comment: "The waste storage issue which we are here to discuss tonight is the result of years of gridlock in Washington, D.C. and the Federal Government's failure to follow through on its promise to create a national repository for used nuclear fuel. Although we would like to see a resolution to the fuel storage issue, it likely won't be over for quite some time nor will it affect whether the U.S. Nuclear Regulatory Commission approves the license renewal for Indian Point." (0163-4-3 [Thomas, Richard])

Comment: And it's kind of like we're having this long meeting to determine "Gee, is it safe to drink the arsenic," you know. You know, is it safe to jump off a ten-story building? Well, we're at story number five. Everything is cool, right, why worry? It's safe, you know, it's that kind of thinking. So I'm just going to touch on a few points to emphasize a few points that other speakers have made so well. (0163-41-1 [Kidney, Barbara A.])

Comment: The denial process, you know, Daniel Fullerton, I think, touched on that. By trade I am a psychologist, so I think I'm somewhat, you know, equipped to deal with the issue of denial and dysfunctionality, as in, "Well, sure, I drink five quarts of vodka today, but I'm not an alcoholic. Come on, you know." (0163-41-2 [Kidney, Barbara A.])

Comment: I don't -- I don't think anybody has figured that out, and the one thing that I think I can maybe add to this conversation is, two people spoke about the program in Finland. And there is a wonderful movie whose name I can't remember now, but I'm going to -- Here to Eternity, right. Sorry, Into Eternity, and it is about the program in Finland Onkalo. It is a -- I'm going to send that to this email and I really hope that everybody involved in anything at the NRC watches it, because what is really impressive about it is that on the one hand, if you could think of the ideal way of doing this, Finland of course is relatively remote and certainly not extremely densely populated, and they have picked a site that is as much in the middle of nowhere as you could possibly imagine. I believe the geology is such that the rock base is very firm. They are going incredibly far down. This is all shown beautifully in the film, and yet despite all of that, the risks and the problem of beginning to deal with what is going to happen in 1,000 years, 2,000, there are lots of very interesting problems, and they would be more interesting if they weren't endangering the entire planet. One of the people asked the -- I think it was Darcy, what language are the signs going to say? Well, they are dealing with that. They're even dealing with the question of should there be signs. What would it mean to people if they say, you know, don't go, this is very dangerous. Some people might react and think oh, there's something there that I -- anyway, so Onkalo, the Into Eternity film shows both sort of what the best-case scenario of

best minds trying to deal with the storage and despite all that, the fact that it is far from inadequate -- far from adequate. (0163-47-2 [Segal, Elizabeth])

Comment: We need to stop the farce that we can find safe geological storage for nuclear waste for 250,000 years. (0163-48-3 [Meyer, Bill])

Comment: How can we trust NRC when we see all of these flaws in their assumptions? The point I would like to make here is that the system for long-term mined geological storage has failed. We see that through Yucca Mountain, through the salt caverns in Kansas[.] (0163-48-7 [Meyer, Bill])

Comment: The first one is that when necessary there will be permanent waste disposal. That is absolutely impossible as I have stated already. We're just burning dollars rather than moving forward in anything meaningful. Yucca Mountain, salt mines in Kansas, many different things have been proven unsatisfactory and un-geologically safe. (0163-7-6 [Shapiro, Susan])

Comment: The Federal Government has spent the last three decades trying to decide where to put the more than 70,000 tons of spent fuel from our nation's power plants. The Waste Confidence Rule, although a good first step in the right direction, is not the solution the Federal Government promised us. Further, it has no bearing on the continued operation or license renewal of the U.S. nuclear power plants, including Indian Point. (0163-8-1 [Milone, Deb])

Comment: With regards to nuclear waste management in our country, it is suffice to say that we need a long term plan for nuclear waste storage. However, I want to point out that should the NRC's determination fall in favor of long-term storage facility, I have confidence in the industry's ability ensure that the waste is managed in a safe and efficient manner and that the human is considered in this process. (0176-2 [Stringfellow, Paris])

Comment: The safe and long term storage of nuclear waste is an intractable challenge. I don't envy the work you have in front of you. (0177-1 [Craig, Anne])

Comment: As for disposal of spent fuel, the president's own Blue Ribbon Commission recognized that a geologic repository is still the best method of disposal. Sweden and Finland are both already developing geologic disposal facilities which, frankly, should be an embarrassment to this country that was once a leader in this area but has since relinquished that position because of political dysfunction. Geologic disposal remains a well understood, technically viable option for the United States to pursue for disposal of spent nuclear fuel. We just need politicians with the courage to move forward, and a regulator that will follow the law in this area. (0181-3 [Waters, Christine])

Comment: As for disposal of spent fuel, the president's own Blue Ribbon Commission recognized that a geologic repository is still the best method of disposal. Sweden and Finland are both already developing geologic disposal facilities which, frankly, should be an embarrassment to this country that was once a leader in this area but has since relinquished that position because of political dysfunction. Geologic disposal remains a well understood, technically viable option for the United States to pursue for disposal of spent nuclear fuel. We just need politicians with the courage to move forward, and a regulator that will follow the law in this area. (0183-3 [Green, Carlyn])

Comment: Members of the Nuclear Regulatory Commission, let me begin by stating that there is no confidence in the prospect that there is or will ever be an adequate solution to the

permanent storage of high-level nuclear waste. No public confidence, no judicial confidence, no regulatory confidence, no industrial confidence. Every thoughtful, sane and intelligent person within this room and outside this room knows through common sense that it is impossible to guarantee the containment of anything for hundreds of thousands of years, much less corrosive, hot and deadly spent nuclear fuel rods containing plutonium 239. Plutonium 239 has a half-life of 24,110 years and is among the deadliest, most carcinogenic substances known to humankind. (0187-1 [Friedman, Avram])

Comment: As we consider the EIS proposal, remember there is nothing to as likely become as permanent as a temporary solution. Is there any likelihood that with political realities a permanent longterm solution can be achieved? (0189-7 [Patrie, MD, MPH, Lewis E.])

Comment: The policy forced the cancellation of the GESMO hearings. Carter created a moratorium on nuclear plant orders that lasted almost four decades. His legacy created the impasse the nation still finds itself in: rewriting its Waste Confidence Rule in light of Sen. Harry Reid's personal agenda. It is the Rule that is the obvious target of activist groups who use nuclear power as their pet issue. The parallel? In 2008, a new President found himself indebted to Sen. Harry Reid. All Reid asked President Obama to do was to let him defund Yucca Mountain. Then Reid barely won re-election in Nevada and became Majority Leader. Sen. Reid stopped the NRC review of the Yucca Mountain Safety Analysis Report. Five years later we are in EIS hearings about a well-established process, the storage of used nuclear reactor fuel. This simple issue has succeeded in creating more delay and confusion on the way to finalizing NRC's Waste Confidence Rule. (0191-2 [Rossin, A. David])

Comment: I understand in these 30+ years, a number of these nuclear plants have accumulated in excess, spent fuel rods. While safety may have improved in these last 15 years concerning the engineering of the plants themselves, no engineer has offered a real world, long term, answer to the waste. (0204-2 [Stein, Tami])

Comment: The new rule also asserts that a mined geologic repository will be available within the next 60 years for long-term nuclear waste storage. Although Yucca Mountain in Nevada is ideal for long-term storage and stands as one of the safest places in the country to store nuclear wastes ("Nuclear waste can't," 2013), the Obama administration shut down plans for the location in 2010 after spending about \$10 billion on the project. Without the Yucca repository, which has been targeted as the planned location for a national repository for decades, the United States does not have another potential location. Furthermore, there has been a long debate over where to host the national repository and the final deadline for a long-term repository has been extended multiple times (Wald, 2013). If the Yucca repository is not even option, this deadline may be extended even further -- which could present problems for the nuclear waste currently being stored on-site. Ed Burke, chairman of the waste management committee in Aiken, South Carolina, was quoted as saying, "the department's decision not to make it [Yucca Mountain] the permanent repository suggests the next effort to find a permanent site will be even more lengthy and costly?" (Carr, 2013). A new repository site would have to satisfy many requirements in order to be considered even a possibility. Factors such as seismic activity, groundwater flow, surrounding earth composition, and location of major cities and landmarks are all considered for potential sites (Jonsson, 2012). The required testing and monitoring of the site could take years or even decades. With this in mind, extending the sixty year deadline does not seem improbable. (0205-12 [Lyons, Laura])

Comment: [T]he possibility of a new repository being selected is, to say the least, uncertain. (0205-17 [Lyons, Laura])

Comment: Secondly, it is not certain that a new nuclear waste repository will be found in the next sixty years. (0205-4 [Lyons, Laura])

Comment: It should be becoming clear by now that the "bury it and forget about it" approach to dealing with high level nuclear waste cannot be safely engineered. (0208-7 [Robinson, Herb])

Comment: And that we can't be confident there will be a way to dispose of high-level nuclear waste. That story might change in the next 10 to 20 years, but right now, the confidence just isn't there. Remember, the wisdom to understand what we don't know is the most important part of the problem. (0208-9 [Robinson, Herb])

Comment: In the 1984 Decision, the Commission made five findings. However, significant changes have been made to the findings but the Commission failed to provide convincing explanations. For instance, "[t]he Commission finds reasonable assurance that one or more mined geologic repositories for commercial high-level radioactive waste and spent nuclear fuel will be available by the years 2007-2009" was changed into "[t]he Commission finds reasonable assurance that at least one mined geologic repository will be available within the first quarter of the twenty-first century", and, again, was revised as "[t]he Commission finds reasonable assurance that sufficient mined geologic repository capacity will be available to dispose of the commercial high-level radioactive waste and spent nuclear fuel generated by any reactor when necessary." However, the Commission admitted in the discussion section that a national consensus for the site of a repository will not likely to be reached. The reality is there will not be one in the foreseeable future. (0210-1 [Individual, Anonymous])

Comment: Moreover, the time length of continued spent nuclear fuel storage was revised many times without sufficient support. Originally, the Commission stated, "spent nuclear fuel generated in any reactor can be safely stored at least 30 years beyond the expiration of that reactor's operating license." Later it was changed into "at least 30 years beyond the licensed life for operation (which may include the term of a revised or renewed license) of that reactor;" the added brackets indicate another 20 or 40 years. Finally it was replaced by "at least 60 years beyond the licensed life for operation (which may include the term of a revised or renewed license) of that reactor;" the added brackets indicate an additional 30 or 60 years for Generation III reactors. In summary, the time scale has been changed from about 30 years to up to 300 years. The Commission should provide sufficient evidence to support why we can extend the continued storage period up to 300 years, given that the nuclear waste disposal procedure has not changed much. (0210-2 [Individual, Anonymous])

Comment: I want it to be known that my absence does not mean that I consent to living with a nuclear waste dump well into the foreseeable future. Raising 2 young kids at a time when the Fukushima nuclear power plant situation is nowhere under control, I take nuclear waste very serious. My children deserve to grow up in an area with no Radioactive waste hazards. It is important to have this extremely vulnerable nuclear waste moved away from here as soon as it is reasonably safe to do so. (0217-1 [Vanderwoerd, Jennifer])

Comment: If as believed, a deep geologic repository is feasible and considered the most promising or if the technical reprocessing of spent nuclear material has potential, complete the technology and establish the facility before generating undue quantities of nuclear waste. (0219-10 [Olmstead, Stan])

Comment: The NRC's Victor Dricks says there's just no other place to ship the waste to, so it must remain in place. If that's true, it is a pitiful excuse for both logic and leadership. Had no one

thought of this problem previously? Is that possible? Again, if this is true, it suggests horrible things about the great minds of our society, perhaps our society as a whole. Are we really that stupid? If so, why not start designing one-way manned spacecraft from now on? Let's get our astronauts to Mars -- we don't have to think about how we're going to get them back until they get there. (0220-2 [Degher, Darius])

Comment: No Dump Site for Nuclear Waste. Under the Nuclear Waste Policy Act of 1982, commercial nuclear power reactor waste disposal is limited to no more than 63,000 metric tons at the nation's first nuclear dump site. Additional waste is prohibited at such a location, and a second waste site would be required to dispose of waste in excess of that figure. The NWPA prohibits: "... the emplacement in the first repository of a quantity of spent fuel containing in excess of 70,000 metric tons of heavy metal or a quantity of solidified high-level radioactive waste resulting from the reprocessing of such a quantity of spent fuel until such time as a second repository is in operation ...". The 70,000 metric tons would be 90% commercial nuclear reactor waste, the balance of 10%, or 7000 metric tons, would be waste from nuclear weapons production and nuclear energy research. Therefore, only 63,000 metric tons of commercial irradiated nuclear fuel could be disposed until a second national waste dump becomes available. According to the U.S. Department of Energy's Office of Civilian Radioactive Waste Management, a total of 63,000 metric tons of commercial irradiated nuclear fuel was reached in 2010. So the existing, operating commercial nuclear power reactors have effectively filled the nation's first waste site and are now well into the second. Within the next twenty years, over 80,000 metric tons of irradiated nuclear fuel will have been generated at commercial nuclear reactors in the U.S. This was known well before the NRC's last review of waste confidence in 1999.¹³ [footnote 13 text: U.S. Nuclear Waste Technical Review Board "Disposal and Storage of Spent Nuclear Fuel: Finding the Right Balance," (March 1996)] In fact, the DOE predicted that there would be over 105,000 metric tons of commercial irradiated nuclear fuel by the year 2046. Although the NRC's standard license extension is for 20 years, the DOE's assessment was based on license extensions of only 10 years. Further, DOE's estimate included no new commercial nuclear reactors in the U.S. Therefore, the high-level nuclear waste generated by existing reactors is well on the way to filling twice over a mined geologic repository which the NRC has assumed will be "available when necessary." (0222-11 [Zeller, Lou])

Comment: During the 1980's, I observed the fruitless search to locate a site for a waste repository 20 miles from my home. The history of the Nuclear Waste Policy Act of 1982 as amended in 1987 does not lend confidence in the ability to locate a repository. The US Department of Energy's Office of Civilian Radioactive Waste Management's methodology and conclusions were inadequate to the task. Recently, the President's Blue Ribbon Commission outlined a site search using a warmed over DOE approach. Further, the fundamental environmental justice issues of a volunteer waste site have not been addressed. The Commission should entertain no false confidence in the ability to find a national waste site. (0222-14 [Zeller, Lou])

Comment: The old Waste Confidence Rule merely presumed that waste stored at reactors would go to a waste dump someday, but the government's quest for a permanent waste dump is not only as doubtful as ever, it is a political hot potato and a questionable ethical proposition. (0222-21 [Zeller, Lou])

Comment: The new NRC waste rule has no basis and is contrary to the law. According to the NRC Staff Requirements Memo, SECY-13-0061, the new waste confidence rule will be also be based on an assumption about the availability of a dump site for nuclear waste as follows: 10 CFR 51.23 would be revised to provide the Commission's generic determination on continued

storage of spent nuclear fuel. The proposed amendments would state that the Commission has concluded that the analysis in NUREG-2157, "Waste Confidence Generic Environmental Impact Statement" (DGEIS) generically supports the environmental impacts of continued storage of spent nuclear fuel beyond the licensed life for operation of a reactor; and supports the Commission's determinations that it is feasible to safely store spent nuclear fuel beyond the licensed life for operation of a reactor and to have a mined geologic repository within 60 years following the licensed life for operation of a reactor. To support this assumption, the Waste Confidence Generic Environmental Impact Statement, NUREG-2157, states: [T]he activities of European countries support the technical feasibility of a deep geologic repository. In late 2012, a Finnish nuclear-waste-management company (Posiva) submitted a construction licence application for a geological repository for spent fuel to Finland's Radiation and Nuclear Safety Authority. However, when investigated by our staff, all three "Latest publications" posted to the Posiva website via the following links were unavailable. 6 .They are: 29.10.2013 I Workreport 2013-23 Human Intruder Dose Assessment for Deep Geological Disposal; 29.10.2013 I Workreport 2012-102 Studies on Reference Mires: 1. Lastensuo and Pesansuo in 2010-2011; 29.10.2013 I Workreport 2012-101 Studies of Quaternary Deposits in Investigation Trench OL-TK19 on the Olkiluoto Study Site, Eurajoki, SW Finland. The proposed waste confidence rule appears to be going down the same path as the one it is supposed to replace; i.e., specious claims based on unsupported assumptions. This is not only incongruous; it is contrary to the order of the appellate court. With limited time to justify its predetermined conclusions, the Commission has produced a flawed draft generic EIS and a similarly flawed draft rule. (0222-4 [Zeller, Lou])

Comment: Any place that lets a nuclear reactor be built should be prepared to store the waste safely forever on site. (0226-2 [Garden, Claire])

Comment: My second point is that we in the public are not naive about the siting of a nuclear waste dump. If we site one, it will encourage the nuclear industry to feel free to produce more and more waste as it will itself to do so. (0237-2 [Cullen, Noreen])

Comment: Instead of these assumptions, the NRC should draft a new GEIS to examine: --the probability that a geologic repository will be successfully sited, --the probability that a successfully sited repository will actually contain radiation, --the degree to which a repository may leak radiation, and --the public health and environmental consequences that may occur if a repository is not sited or if it ineffectively contains radioactivity. (0238-2 [Greene, David])

Comment: It is important for the Federal Government to put in place a program to safely dispose of these spent fuel assemblies. (0244-1-3 [Tulenko, James])

Comment: The NRC is correct in concluding that it is feasible to have a mined geologic depository available within 60 years after the licensed operating life of a nuclear power plant. There are no technical obstacles to achieving this, nor are there any financial obstacles given that the Nuclear Waste Fund now has a balance of more than 26 billion. (0244-12-2 [Ratchford, James])

Comment: There is strong scientific -- there is strong international scientific consensus that geologic disposal is the best solution to permanently isolate spent nuclear fuel from the public and the environment. Studies by the National Academy of Scientists and the International Atomic Energy Agency have confirmed this conclusion. In fact, the IAEA concluded in 2003 that geologic disposal is the generally accepted solution in practically all countries faced with the issue. Sweden and Finland are developing geologic -- geologic disposal facilities and are

expected to begin disposal of their spent fuel by the early 2020s. France is making significant progress. They have selected and characterized a geologic region and are now working to identify a specific site. Belgium, China, and the United Kingdom plan to start geologic disposal by 2050 or earlier. (0244-12-3 [Ratchford, James])

Comment: We have the technology to develop a geologic repository for spent nuclear fuel, and we have the money to do so. The only thing blocking the U.S. from building a geologic repository is political decision-making. The analysis contained in the Draft Waste Confidence Generic Environmental Impact Statement supports what the industry has long known. If necessary, used nuclear fuel can continue to be stored in a safe, environmentally sound manner for a long period while we wait for the political process to reach agreement on a disposal solution. (0244-12-6 [Ratchford, James])

Comment: No one knows when that [the eruption of super volcano in Yellowstone National Park] will happen, but it's coming, and it could be tomorrow or it could be in 5000 years. We don't know, but nuclear power -- nuclear spent fuel rods stay radioactive for 250,000 years from what I understand. So we talk about time. The time nuclear power's been going on has only been a few seconds of a tick on a clock compared to the time that the planet's been around, and we've really got to think about those things. (0244-13-6 [Wilson, Greg])

Comment: While nuclear energy is a vital part of our state's electricity portfolio and economy, we recognize the need to address issues related to transportation and safe storage of spent nuclear fuel. It's the Federal Government's statutory responsibility to remove used nuclear fuel from nuclear energy facilities -- this is pursuant to Federal law, and was to have started in 1998, 15 years ago. But so far the Federal Government is yet to remove one spent nuclear fuel assembly. (0244-2-2 [Knowles, Berdell])

Comment: Well, of course the GESMO hearings were canceled by Jimmy Carter's Order, and he created a moratorium on nuclear plant orders that has lasted almost four decades -- that lasted almost four decades. His legacy created the impasse that the nation finds itself in, rewriting its Waste Confidence Rule in light of Senator Harry Reid's personal agenda. It is the rule that is the obvious target of activist groups who use nuclear power as their pet issue. The parallel? In 2008 a new President found himself indebted to Senator Harry Reid. All Reid asked President Obama to do was to let him defund Yucca Mountain. Senator Reid stopped the NRC review of the Yucca Mountain Safety Analysis Report. Five years later here we are in hearings about a well-established process, the storage of nuclear fuel. The simple issue has succeeded in creating more delay and confusion on the Waste Confidence Rule. (0244-4-4 [Rossin, A. David])

Comment: Certainly I think most of us would prefer that the U.S. Department of Energy had complied and would comply with its statutory obligations to take possession of that fuel, but in the absence of that, as the group the students pointed out, it is not a limiting factor. It has not been a limiting factor to the operation of the five reactors in the state for five decades. It's not a limiting factor to the continued operation of them. And, it is not a limiting factor to the development of additional nuclear generation that's currently being proposed in this state. (0244-9-4 [Paul, Jerry])

Comment: The cycle of making waste that we can't dispose of is insanity. There is already enough waste for one Yucca, now we're working on two. We should follow the lead of recent events and bury it. (0245-14-7 [Kurz, Carol])

Comment: I say this because reactors are licensed to operate for 40 years and then they are going to retire. The NRC has allowed reactors to operate up to 60 years and possibly 80. That means it will be 140 years or longer before we figure out where that stuff is going. (0245-19-9 [Smith, Ed])

Comment: In conclusion we certainly hope that the Federal government will meet its long overdue obligation and will soon figure out a solution to long-term storage of spent nuclear fuel. But until then, we are happy that the industry and its Federal and State regulators have determined a strategy that works on many levels, the most important of those is our safety. (0245-2-3 [Wolf, Tom])

Comment: Furthermore, NRC is correct in concluding that it is feasible to have a mined geological repository available in 60 years after the license operating life of a nuclear power plant and the analysis of a short-term impact in the GEIS. There should be no technical obstacles to achieving this, nor are there any financial obstacles given that the nuclear waste fund now has a balance of more than \$26 billion. Despite delays in the process because of political and legal maneuvers, progress is being made in establishing a permanent repository. NRC is resuming the licensing proceedings with the Yucca Mountain application which will further inform efforts in developing a geological repository. Legislation is pending in the Senate to begin the process of selecting alternate sites using a consent-based approach consistent with the recommendations of the Blue Ribbon Commission. This progress supports the conclusion of the draft GEIS. We have the technology to develop a geological repository for spent nuclear fuel. And we have the money to do so. (0245-20-4 [Dunlap, Jeff])

Comment: The only thing blocking the United States from building a geological repository is political decision-making. (0245-20-5 [Dunlap, Jeff])

Comment: Can you believe that we are supposed to believe that nuclear power plants can continue producing waste without an adequate plan for its disposal? This toxic radioactive waste, we're supposed to go along on this gamble, on this grand experiment, that an industry can produce waste in a way when it doesn't know how it's going to handle it. (0245-22-2 [Headington, Vince])

Comment: In the original waste confidence, the decision was published and the NRC believed and assured us that a repository would be available in just 24-25 years into the future. Soon, the belief receded to a repository available 41 years after the Waste Confidence Decision was first articulated. Now, the NRC assures us that a suitable repository will be available when necessary, a term which I took to mean repository availability prior to onsite storage failure. That's just in time, JIT, just in time inventory management. I've always understood that term to be a euphemism for almost too late. (0245-24-3 [Conn, Corey])

Comment: We should locate a geological spent fuel storage repository based on rigid scientific criteria. Maximum efforts should be made to thoroughly investigate the least-damaging location for a permanent repository, and preferably one that allows for retrievable storage. The Blue Ribbon Commission proposed heavy reliance on a consent-based approach, but that reliance may not lead to the safest long-term solution. While local consent is important, that consent should be based on scientific knowledge rather than on improperly perceived opportunity to obtain money, jobs, and other items. (0245-29-5 [Shineflug, Marilyn])

Comment: Illinois is not a waste dump. We don't want any more high-level radioactive waste coming to, or through, Illinois. Nuclear waste is still a problem without a solution. No technology

has been proven capable of containing radioactive waste for the hundreds of thousands of years necessary to protect the environment. Debates continue over whether it is even possible to do so. And unfortunately, the United States has failed even to identify the vital site for nuclear waste repository despite millions of dollars and the Federal mandate to do so. (0245-37-1 [Bilenko, Stephanie])

Comment: The nuclear industry and the Nuclear Regulatory Commission, formerly the Atomic Energy Commission, have had nearly 60 years to come up with a permanent solution for nuclear waste, especially spent nuclear fuel generated by nuclear power plants. I've been involved in nuclear issues to a greater or lesser extent for more than half that time. Some 34 or 35 years ago, I was in a meeting similar to this one. But whether it was called by Commonwealth Edison or an agency set up to oversee and regulate it, I cannot remember. One person commented, made mention of all the methods he knew under consideration for long-term disposal of high-level nuclear waste: shoot it into space, bury it in salt mines, et cetera. Someone from either the NRC or ComEd responded that we have high hopes currently for the VDH concept. A year or so later, I received from the NRC a large book addressing the concerns about high-level nuclear waste. This was in the wake of the accident at Three Mile Island, and I assume that every citizen intervening in a licensing procedure or otherwise involved in the nuclear issue received such a copy. Therein I discovered exactly what VDH meant, a very deep hole. The industry and its watchdog have tried to convince the public for half a century that a solution is on the horizon. They have used jargon and acronyms to sound more authoritative and knowledgeable on the subject than they really are. (0245-42-1 [Rorem, Bridget])

Comment: At this time, there are no facilities for permanent storage of high-level radioactive waste. Since the only way radioactive wastes finally become harmless is through decay, which for some isotopes containing high-level waste can take hundreds and thousands of years. The waste must be stored when we have adequate protection for various point in times, but at this time there are no facilities for permanent storage. That actually comes from the NRC website. So, the industry folks and the politicians who spoke tonight and who stand to personally gain from nuclear power through their paychecks and other issues are talking about the next 50 to 100 years. And even that they cannot predict what is the future as Fukushima has taught us. (0245-43-2 [Michaud, Debra])

Comment: How could anyone have even allowed one reactor to be built with no end plan for waste? Your recommendations are not a solution. There is still no end plan. Interim means indefinite, that's not a plan, except to stockpile in facilities beyond the capacity for which they were built. (0245-6-6 [Headington, Maureen])

Comment: But about the confidence in the Nuclear Regulatory Commission and their ability to safely store spent nuclear fuel following the licensed life of every operator, or of every reactor, excuse me, and 60 years from now, them finding a safe geological repository really is laughable. (0245-7-2 [Chamberlain, Lora])

Comment: Even if we step back and assume that the engineers had the perfect solution both from a long-term and a short-term solution, which I do not have that confidence, even if we assume that, the reality is for any of this to work, we've got to have the policy makers and the funding to pay for this. And I don't think that any of us can say that we have the confidence in our government to put the amount of money behind this that really is going to take to address these issues that are in front of us. And that's really one of my biggest concerns with this is simply that we don't have the policies in place and we won't in the future to address this issue. (0245-8-4 [Fox, Rick])

Comment: Nuclear power plants were never intended to be permanent storage sites for spent fuel. Since 1983, we have paid more than \$29 billion into the nuclear waste fund, yet no permanent storage site has been built. As a result, 13 percent of our nation's spent nuclear fuel remains in temporary storage in Illinois power plants. It's time to open Yucca Mountain or similar long-term storage facilities. (0245-9-3 [Peck, Jerry])

Comment: On the question of long-term repository or centralized storage feasibility, solutions are technically and financially feasible. And, as noted in the Generic Environmental Impact Statement, are being implemented in countries worldwide. This is yet another example of how our international counterparts continue to pass us by in facing the challenges of our modern world. What is lacking here in the U.S. is the societal and political gumption to take ownership of our problems and solve them. (0246-10-4 [Bennett, Nathan])

Comment: Now, as I close, it is unfortunate that the leaders of today continue to kick the can down the road for a myriad of national issues, climate change and nuclear waste policy among them. While this may be flagrantly reckless and a willful abdication of responsibility, it is, nonetheless, the sociopolitical environment of this moment in history. However, as the urgency of these problems continues to mount, my generation will have to confront these issues. We simply don't have a choice. This is why individuals such as myself and others in this room chose this calling. And I have full faith and confidence that we will rise to these challenges. (0246-10-6 [Bennett, Nathan])

Comment: Nuclear waste is a problem without a solution and we really do not have an answer. So, to some extent, the overall premise of how do we move forward is certainly a big challenge. We, obviously, have not identified a centralized repository site and there isn't a clear path to identify one and certainly not a path to identify the likely need for more than one, given the volume of our existing waste. (0246-13-1 [O'Leary, David])

Comment: To me, putting it in the ground is like adding dynamite to the interior of the earth. This sets us up for internal pollution, as well as external pollution, but it is from the normal operation of nuclear plants which emit hundreds of thousands of curies of radioactive gases and elements into the environment every day. This is commonly known as burning the candle at both ends. (0246-15-4 [Minniss, Regina])

Comment: Basically, there was an assumption made decades ago that we would have safe storage and that we would be able to deal with very toxic radioactive waste in the future, but that future has never materialized and it likely will never materialize. Therefore, that assumption upon which everything else has been based has no validity anymore. And because that has no validity, we cannot have confidence that there will ever be any safe storage for any of this nuclear waste that we are creating. (0246-16-2 [Michetti, Susan])

Comment: And any confidence statements that this is going to appear in the future are using the same assumptions that have caused us to be in this very precarious situation that we are in without a place to store any of this waste. (0246-16-4 [Michetti, Susan])

Comment: [We should be looking to] find a permanent repository for spent fuel, rather than imposing some new regulations. (0246-18-6 [Karbowsky, Brad])

Comment: As nuclear energy has progressed through the decades, each generation of enthusiastic nuclear engineers and physicists have promised they would solve the problem of nuclear waste. The problem has not been solved yet. We keep producing more nuclear waste,

as well as new generations of young enthusiastic nuclear engineers who both hope that theirs will be the generation to solve the nuclear waste problem. Nuclear waste is not a sociopolitical problem. It is a problem of science. I hope these young engineers do solve the nuclear waste problem and I hope they stop making more nuclear waste in the interim and focus all their enthusiasm toward a science-based solution and stop the double speak about wanting to find a repository and wanting to reprocess the nuclear fuel. (0246-25-1 [Snyder, Gail])

Comment: A permanent deep, geologic repository that is selected using the best science possible is what is needed to protect us from the over 70,000 tons of nuclear waste that already exists in this country. (0246-25-2 [Snyder, Gail])

Comment: [T]he young man [Diego Garcia], the engineer, and the man from NEIS [Rod McCullum, Nuclear Energy Institute] made comments about us trusting them and them learning to find a solution, which it is obvious there is not a solution yet and there has never been one. And I don't think we should base Waste Confidence on a possible learning curve to find out one. In fact, I'm sure we shouldn't. (0246-26-1 [Sondheim, Steven])

Comment: The second thing is that I have been looking at the coal ash problem around the country lately. For 100 years, we have had a coal ash, a coal waste problem. It is not like radioactive waste but it has its dangers. It has its health problems. And the coal industry has not taken full responsibility for it. They have dumped it in pools, in piles. There have been spills. They still don't even have a way to handle that and they have reneged on their responsibility to fully take care of it. And I see a parallel or even worse situation with nuclear waste. We have nothing that can be done with it at the moment. We are piling it up. We are busting at the seams, especially in the pools. There is no way we should have any Waste Confidence until we know exactly what we are going to do with it. So, I think a generic decision should be no waste confidence. (0246-26-2 [Sondheim, Steven])

Comment: Earlier we heard the NRC say that there is a really brief history of Waste Confidence. And the really brief history of Waste Confidence is 65 years of failure. (0246-29-1 [Hoffman, Ace])

Comment: All containments, even if they were made of gold, they would be inadequate for the lengths of time we are trying to keep this stuff. Hence, the decision that a geological repository is necessary because we really don't have any confidence in any other solution. (0246-29-4 [Hoffman, Ace])

Comment: And so Waste Confidence should not be, as Paul [Michalak, NRC] initially stated earlier, "a small part of the licensing procedure." Instead, it should be a pass/fail. And so far, they have failed. You can't build a house without a sewer. The house would be unlivable soon, the quote from some nuclear physicist in Japan after Fukushima. (0246-29-5 [Hoffman, Ace])

Comment: We [Decommissioning Plant Coalition] are certainly aware, and we are sure that the NRC staff and the Commission are as well, that after the publication of the Rule and the Generic Environmental Impact Statement there would still be a great deal of work to do regarding the nation's used fuel and reactor-generated GTCC management program. The NRC will still be responsible for ensuring that its regulatory programs and policies do not foster indefinite on-site storage and we look forward earnestly to work with you in that regard. (0246-4-3 [Callahan, Mike])

Comment: [T]he judge, effectively we are saying hey, reality does have to raise its head. And that he has made a ruling against the NRC with the radioactive waste. Namely, he was trying to, I feel, force reality into the way radioactive waste is looked at by the NRC. (0246-6-3 [Lewis, Marvin])

Comment: Right now, we don't have a place to put a permanent geological repository and we just can't say, according to the Court, oh, we feel confident that it will be there when we need it. According to the Court, you need more basis, as the lawyers say, basis to say hey, a geological repository will be there when we need it. And the Court said that in a ruling and it still has not answered in two-and-a-half inches of paperwork in the GEIS. (0246-6-4 [Lewis, Marvin])

Comment: Radioactive cleanup is a very misleading phrase. It suggests to ordinary people that we can somehow get rid of radioactive contamination. But we cannot do so, at least not in any absolute terms. All we can do is move the contamination from one place to another. (0246-9-5 [Lewison, Linda])

Comment: Governments and their electorates have been misled by the nuclear industry into believing false notions about nuclear waste. They don't know how to clean up and dispose of nuclear waste, except in a temporary and superficial manner, as other people have already referred to here. Why am I mentioning that at this point? Because we can't take a snapshot of one moment in time without ignoring that these changes take place in radioactive elements at the very basic scientific level, at the subatomic level. (0246-9-6 [Lewison, Linda])

Comment: The residents of the City of St. Charles are concerned about any issue that may potentially impact public safety and the storage and transportation of these materials has been discussed for some time. We believe that it is time to move forward and implement solutions that will ensure their secure storage until such time as the hazard is mitigated. (0247-1 [Rogina, Raymond])

Comment: Finally, there is no place for it to go. There is no approved long-term storage facility. (0249-12 [Dugdale, Jane])

Comment: So this radioactive waste has been made every day of my life. We have nothing to do with it except for letting it pile up. It's piling up where it was made, and if you move it, it's just going to pile up there too. That is all we have for an answer right now. (0250-2-2 [Olson, Mary])

Comment: In closing, folks from all walks of life, race, and age, without hesitation signed our petition at the South Carolina Sierra Club booth at the State Fair; all extremely concerned about nuclear spent fuel piling up onsite above ground in spent nuclear pools with no permanent storage. No, South Carolina does not have confidence in waste, the production of it, the piling up of it in nuclear spent fuel pools and the lack of permanent storage. (0250-20-6 [Cooper, Elaine])

Comment: I brought this cup because today I was in the hospitality room, and they had wonderful food there, but they had no place to put the waste, just like the nuclear waste here. We have no place to put this. Nobody wants it, no state really wants it unless you're getting paid a lot of money, and then some people who have the power to make decisions will go for that. I'm just urging you to listen carefully to everything people say and do what's right when you make your decision for that. And I have one final thing. As a famous person in Russia took their shoe and pounded and said, "Please, do what's right." (0250-22-5 [Hands, Tara])

Comment: There's a few facts that we can all see real clearly. Our society started generating nuclear waste back about in the early 1940s. Let's put 1945 on it as a date. That's when we

dropped atomic bombs on Japan, and we were generating nuclear waste at that time. So, we've known for almost 70 years now that we've got a problem with what are we going to do with all this waste material, all this radioactive crap that we keep generating? In that 70 years, we are no closer to a solution. These papers that these people come out with saying well, we've got a solution on the way, you know. Trust us. Yes, trust me. We've got a solution. Within 60 years they say we will have a permanent repository for these 200,000 year waste products. I don't believe it. You've had 70 years to come up with it so far, and you ain't anywhere near a solution. Yes, what makes me believe that you're going to have a solution in the next 60 years? I don't believe it. I don't trust you, and when you come up with a real solution that the American people can believe in, then we might consider letting you create some more dangerous nuclear materials. But until then, stop the madness, let's not have any more of this junk. One thing we do do with it, since we don't have anywhere else to put it, we put it into bullets and bombs and we drop it on Kosovo, Iraq, Afghanistan, and those people don't want our nuclear waste. (0250-23-3 [Ashe, Kenneth])

Comment: There are no technical barriers to achieving this result, nor are there any financial barriers given the current and growing balance of the Nuclear Waste Fund which contains over \$26 billion to date and continues to grow. (0250-25-4 [Wellwood, Jay])

Comment: These spent fuel rods contain a million times more radiation than they did going into the reactor. We have 80,000 tons of the stuff. If we had continued to build Yucca Mountain it would not be adequate at this time because we have more waste than Yucca Mountain would hold. (0250-29-6 [Rivard, Betsey])

Comment: Are we -- as we consider the Environmental Impact Statement proposed, remember, there's nothing as likely to become permanent as a temporary solution. (0250-30-6 [Patrie, Lewis E.])

Comment: Let me begin by stating that it's hard for me to believe that there's any confidence in the prospect that there is or ever will be an adequate solution to the permanent storage of high-level nuclear waste. I don't see how there could ever be public confidence, judicial confidence, regulatory confidence, industrial confidence, scientific confidence. I don't see how any thoughtful, sane, intelligent person within this room, or outside this room knows intuitively -- doesn't know intuitively that it's impossible to guarantee the monitoring and containment of anything for hundreds of thousands of years, much less corrosive, hot and deadly spent nuclear fuel rods containing plutonium-239-- plutonium-239, with a half-life of 24,110 years, and among the deadliest, most carcinogenic substances known to humankind. (0250-33-1 [Friedman, Avram])

Comment: I say it can be safely stored for the following reason. It is being safely stored under U.S. license by the United States Department of Energy at the Waste Isolation Pilot Project in New Mexico, 2,000 feet underground, actinides are being stored in a salt dome right now as licensed by the United States Government. (0250-35-3 [Cook, Andrew])

Comment: Also, I will say it will be safely stored for the following reason. If you make a dry storage facility underground, water would have to come down through thousands of feet of rock where it's never been, penetrate through stainless steel, come through zirconium, and then try to dissolve a ceramic like this cup, a ceramic like this cup, water doesn't dissolve it. (0250-35-5 [Cook, Andrew])

Comment: Other countries, such as France, Finland, and Sweden have solved this problem and are putting geological repositories in place. (0250-37-3 [Barilla, Frank])

Comment: And just by living in that area and watching Plant Vogtle as they're building two new reactors, it makes you wonder some time, when with all the spent fuel they already have there, that they're going to build two more reactors and put some more spent fuel there, and where is it going? Where are they going to store it at? (0250-38-1 [Howard, Claude])

Comment: However, I do feel that there are a couple of points that were made that deserve to be reiterated that everyone here can share. The first one is, all of us agree there is a huge problem with nuclear waste. I've heard the number 70,000 and 80,000 tons used today. The number I had before I came here was 70,000. That is a significant amount of waste, and we do not have a great long-term plan about how to deal with this. It is not part of the short-term solution provided in the Environmental Impact Statement we have before us. I think we can also agree that we need a plan. Even if you decide to end all nuclear immediately, or keep nuclear going forever, this is a problem we're going to face, and we will need a solution for it. So, what do you do? (0250-43-2 [Causey, Lee])

Comment: According to the Government Accountability Office, the amount of spent storage fuel onsite at commercial nuclear reactors will increase by 2,000 metric tons a year, doubling to about 140 metric tons before it can be moved offsite because storage at disposal facilities may take decades to develop. Then with the centralized and permanent disposal, 15 to 40 years before they get ready for that. We are kicking the can down the road. As a grandma, I'm pleading for the 6,000 generations that will be stuck with this horrible handmade substance. Do you ever sit down and think about the children of Fukushima? I do. I sit there and cry. I can't imagine being the mother of any of these children that are affected by it, so when industry stands up here and tells me it's safe, and industry of the United States built those reactors, it really makes me angry. It's hurtful, and it's embarrassing. So, anyway, I say to you, you should try sitting down and contemplating these kids, try crying. It brings a little blood up to your brain. Maybe that will open your mind. (0250-45-3 [Sorenson, Laura])

Comment: We have a responsibility to the future. That's why we're here tonight. All of us agree that this waste must be safely protected from the atmosphere, from the biosphere, basically forever. This is a very serious proposition. (0250-5-2 [Safer, Don])

Comment: And, even if we stored it deep underground, that is the environment, too. And that stuff has a way of coming to the surface. And some of these elements are hazardous for millions of years. And the geology changes over that period of time. And we don't know what is going to happen to those areas that we're storing it in. So we need to keep it on the surface, where we can keep an eye on it and try to maintain it as best we can. (0250-50-5 [Blevins, Eric])

Comment: I encourage the regulator and our government as a whole to resolve the Waste Confidence remanding promptly and, further, to fulfill statutory federal obligations to relieve individual states of its unnecessary burden and establish a staff and secure permanent repository for the nation's inventory of spent fuel. (0250-56-4 [Murphy, William])

Comment: While onsite storage is a safe option, more permanent options, such as a geologic disposal, are necessary. (0250-57-4 [Jones, Lauren])

Comment: It is certain that the storage of used nuclear fuel is an issue that the industry needs to address. However, it is not an insurmountable handicap. Countries such as France and Finland have been successfully dealing with the byproducts of nuclear generation for decades with fuel recycling, onsite storage, and the development of geologic repositories. The

technology, the professionals, and the support of the industry as a whole exist to put into action a strategy for the disposition of used nuclear fuel. (0250-58-3 [Cagnetta, Matt])

Comment: As soon as Washington begins to care more about the welfare of this country than its elections, we can begin to tackle realistic timelines for solving used nuclear fuel disposal issues with existing technology and personnel. (0250-58-6 [Cagnetta, Matt])

Comment: The U.S. government committed via the Nuclear Waste Policy Act of 1982 to have a national repository for nuclear waste operational by '98. However, the U.S. has consistently missed critical milestones for solving the nuclear waste storage problem. American taxpayers have paid the nuclear waste fund over \$32 billion. Yet, the United States has failed the American people and the world in the matter of nuclear waste. (0250-63-3 [Kasher, Brian])

Comment: It is our understanding that the NRC looks favorably at the granite in the North Carolina mountains as a potential storage site. And that is completely unacceptable. And we will do everything in our power to prevent that from being a solution to this nuclear waste issue. (0250-64-4 [Gupton, William])

Comment: The bottom line is that science has not found a safe way to store nuclear waste. It hasn't found a facility that can hold the amount of waste we have for the amount of time that we need to safeguard it. (0250-66-5 [Hanson, Courtney])

Comment: Geologic repositories can be done safely because they are being done safely in France, Finland, among many other others. We have a logical, safe solution on paper. We have simply temporarily lacked the political will to enact it. (0250-70-4 [James, Andrew])

Comment: Despite more than 30 years of anticipation, there is no permanent off-site waste storage facility for radio-active nuclear waste. There will be none in the foreseeable future. (0252-1 [Golden, Leon] [Goldin, Martha])

Comment: Furthermore, the ephemeral permanent storage place is not likely to materialize during our, our children's and our grandchildren's lives, if ever. (0252-4 [Golden, Leon] [Goldin, Martha])

Comment: While nuclear energy is a vital part of our state's electricity portfolio and economy, I recognize the need to address the transportation, storage and disposal of used nuclear fuel. I also recognize that it is the federal government's statutory responsibility to remove used fuel from nuclear energy facilities. This has been federal law for 15 years now and the federal government has yet to move a single used fuel assembly. (0253-4 [Avilla, Karen])

Comment: I was told it would be taken care of (Yucca Mt.). What do you plan to do with the waste material from this plant that last for so many years & looks like it will remain at Diablo??? (0254-2 [Denneen, Bill])

Comment: I want to make it known that I am part of the ever-expanding list of people who vigorously support the need for re-evaluating policy and practices regarding nuclear power plants and the threats posed by their radioactive waste storage. I affirm my support for comments by Mothers for Peace of San Luis Obispo in their call for a less perilous, more well-considered/science-based handling of the problems of radioactive nuclear waste. For those of us who live in the shadow of these poisonous waste stations, it is vitally important that the NRC act as if their loved ones have nuclear power plants-with overcrowded, unprotected spent fuel pools-looming in their neighborhoods. (0256-1 [Harkins, Lynne])

Comment: The GNAC typically comments only on the technical aspects of a proposed action. However, the public opposition to consolidated or interim spent fuel storage compels us to comment on the societal considerations at play. The predominant problem with spent fuel storage is one of public relations. (0262-11 [Patterson, Karen])

Comment: [W]e certainly hope that the federal government will meet its long overdue obligation and will soon figure out the solution to long term storage of spent nuclear fuel. But until then, we are happy that the industry and its federal regulator have determined a short-term strategy that works on many levels ---the most important of those is our safety. (0275-5 [Wolf, Tom])

Comment: The NRC was to find a permanent, leak tight site for spent fuel. With Yucca off the map, and our nuclear waste growing past 70,000 tons, a federal court ruled in 2012 the NRC could not proceed with new licenses or extensions until they completed an environmental study to show the environmental and health effects over time if spent fuel was not stored in a repository. (0276-4 [Kurz, Carol])

Comment: This cycle of making waste we can't dispose of is insanity. There's already enough waste for one Yucca, now we're working on two. We should follow the lead of the Swedes and the Fins and bury it. (0276-8 [Kurz, Carol])

Comment: Since 1998 the US has been delinquent in supplying a location for final disposal of nuclear spent fuel that the federal government promised when nuclear reactors were being built in the late 1960's. There is currently no place being prepared to take the US nuclear spent fuel. When President Obama shut down Yucca Mountain after nearly 30 years of preparing the site to be a final geologic deposit for all of our nuclear waste for the entire country, America became a deadly accident waiting to happen at 104 reactors. But SONGS sits with everyday a potential to destroy as in Fukushima the land from Oceanside to Laguna Beach, shut down forever. The nuclear reactors built in the 1960's were never built to store the waste on site. No state is willing to accept the nuclear waste. The NRC is now wrongly requiring that the waste is safest being stored on site. These old plants were not designed for that. What other plan is possible? (0280-10 [Magda, Marni])

Comment: Commercial nuclear reactors have been "regulated" by the AEC and now the NRC, since 1954. Almost 60 years have passed, and there is still no solution to the fundamental problem of what to do with the deadly radioactive waste. (0287-1 [Swanson, Jane])

Comment: The problem now is that we are running out of room to store this awful stuff. The U.S. government had promised to find a permanent repository by 1998, and tried to get Yucca Mountain. But that didn't work out. Also, it is not as safe a location as people first thought it was. In fact, it may be that there is no such thing as a safe, permanent repository for all this nuclear waste. And that's because it is radioactive for so long. (0293-4 [Lewis, Sherry])

Comment: Remember that the nuclear danger lasts thousands of years. We do not know what to do with nuclear waste. Protect us and future generations from disaster! (0302-2 [Light, Lillian])

Comment: The geology of the earth is not stable enough to find a repository which will be stable for the length of time needed to spend the radioactive isotopes in the waste. (0310-2 [Oster, Phyllis])

Comment: While cask storage is safe, it would be far better if the federal storage of spent fuel progressed forward. The federal government has failed to fulfill its promise to accept the nations spent fuel and has led to this program of long term on-site storage. (0313-2 [Waage, Edward])

Comment: In accordance with the Nuclear Waste Policy Act of 1982, it is the responsibility of the federal government to secure permanent disposal for spent nuclear fuel. As this task has not yet been completed, the City of San Clemente wants to ensure the health and safety of its residents living in close proximity to the San Onofre Nuclear Generating Station (SONGS) until the spent nuclear fuel can be safely transported out of the area. (0315-1 [Brown, Tim])

Comment: NRC must abandon its Waste Confidence policy and stop using it to license nuclear power plants, because there is no scientifically proven solution for safely disposing of nuclear waste. (0319-1 [Nichols, John])

Comment: The U.S. has failed even to identify a viable site for a nuclear waste repository despite two decades, billions of dollars, and a federal mandate to do so. (0319-5 [Nichols, John])

Comment: And this is a really serious problem-- that we've found ourselves in a situation where it's not really safe to store the waste onsite and it's not really safe to transport it. And we're left in this quandary where a difficult situation has to be addressed as openly and transparently as possible. (0325-1-1 [Headrick, Gary])

Comment: I think we're all a little bit under qualified and searching for answers, and it's no longer acceptable to just have the easy answer of okay, well, we have that waste but it'll be okay someday. When we get there, don't worry about it. We're working on it. That's just not a responsible response. It's reckless. And we need to come together over this issue, and it's not adversarial at all. We have good people like Greg Warnick. I have a good relationship with our onsite inspector. And I know his heart is in the right place, but the system is not working the way it should. And there's no reason we should have waste stored onsite any longer than possible. We're here to basically say you've got to move that stuff off the site away from these people, away from the earthquake hazards, tsunamis, human error, you name it, terrorism. There are so many problems that could really destroy Southern California and beyond that we have to take this problem seriously, take it urgently, get real answers to the questions, and I think transparency is going to be key. (0325-1-2 [Headrick, Gary])

Comment: We all have to put our minds together, work together, and do the right thing. So, there's a lot of details, there's a lot of good thinking going on to resolve this issue, but it's not going to be resolved by kicking the problem down the road. We have a limited time before our dry cask storage or pools are vulnerable to disastrous result, and we've got to move on this fast. So, you're going to hear a lot of other good comments from people in the coalition and the audience, and I appreciate the time to address this. (0325-1-4 [Headrick, Gary])

Comment: While nuclear energy is a vital part of our state's electricity energy portfolio and our economy, we do recognize that there is a need to address the transportation, storage, and disposal of used energy nuclear fuel. It is the Federal government's statutory responsibility to remove the used fuel from nuclear energy facilities. Under Federal law this has gone on for over a decade, but so far we have not seen the Federal government act. (0325-13-5 [Wicks, Tonja])

Comment: The student group believes that the NRC now has the resources and will at its disposal to properly address used nuclear fuel, that the pace and diligence of scientific rigor, which the NRC has been addressing used fuel, has been commendable and in the best interest

of local affected communities and the people of the United States alike. (0325-17-4 [Pearson, Jeremy])

Comment: The student group also believes that any inflation, beyond that which the NRC has concluded in its Draft Generic Environmental Impact Statement or political hastening of the movement of used fuel, together with enactment of the NWAA or similar legislation founded on such assertions prior to a consent base and scientific approach being properly and duly followed, may result in future less-than-effective solution scenarios, similar to that of Yucca Mountain, and may serve to erode and undermine public confidence in communities that are interested in hosting used nuclear fuel and nuclear waste in interim storage or final repository facilities, as well as instill irrational and non-productive fear in those communities that now have used nuclear fuel. (0325-17-5 [Pearson, Jeremy])

Comment: Now, the scenario I would like to be in favor of is restart San Onofre because it's a significant economic value. It was a stabilizing source for the power in Southern California, and it operated with a zero carbon footprint. But that decision is past, and now that forced us into looking for the safe storage of spent fuel rods. And that plan must be put in place before a site cleanup plan can be finalized. This is actually a national problem across the United States, not just for San Onofre alone. (0325-26-2 [Hannaman, Bill])

Comment: Tonight the NRC has explained why they wish Californians to be confident in their proposed waste policy, but even the NRC's hypothesis and prediction is uncertain. We will leave highly radioactive waste fuel assemblies, whether in pool or casks, on a seismically vulnerable coast for your defined short period of 60 years, long-term period of 160 years, or your indefinite term when we'll all be dead. (0325-3-2 [Becker, Rochelle])

Comment: In 2011, the Blue Ribbon Commission on Nuclear Waste recommended a new single-purpose organization to develop a focused integrated program for transportation, storage, and disposal of nuclear waste, yet the NRC appears ready to decide each of those issues in isolation; a decision that could only result in additional cost to California and utility rate payers. (0325-3-3 [Becker, Rochelle])

Comment: You know, a friend of mine says well, let's get some lawyers and then the lawyers will force the Nuclear Regulatory Commission to do the right thing. Well, it's not the Nuclear Regulatory Commission that's going to do the right thing. It's not the lawyers. They can't figure out a way to make nuclear waste safe. Lawyers can't do it. Administrators can't do it. Politicians can't do it. I'm proposing that we have a new Manhattan Project, a project that's going to take care of nuclear waste, and at the same time deal with global warming, some kind of way that we can work towards life on this planet, and not towards more. Let's liberate our energies, and our politicians, and our money towards survival for the next seventh generation. (0325-33-7 [Zigler, Randy])

Comment: I'd like you to know that in the Proposed Rule back in 1979 the NRC states that they would not continue to license reactors if they didn't have reasonable confidence that the waste can and will in due course be disposed of safely. 1984 same Proposed Rule, it says the Commission finds reasonable assurance that one -- I'm sorry. It says that yes, they find reasonable assurance that one or more mined geologic repositories for commercial high-level radioactive waste and spent nuclear fuel will be available by the years 2007 to 2009. We're at 2013, almost 2014 and neither of those statements have even come close to fruition. (0325-34-1 [Waller, Viviane])

Comment: I call on the Federal government to follow through on its obligations to provide a national solution to the permanent storage of spent nuclear fuel, including high-burnup fuel, including mixed oxide fuel. And under Federal law, this was to have started 15 years ago, but so far the Federal government has not moved a single fuel rod. (0325-4-2 [Quinn, Ted])

Comment: After fighting San Onofre for 20 years, I had to put up with an awful lot of people telling me the waste solution is going to be Yucca Mountain. Of course, right now they've just today reopened some of the Yucca Mountain plan, but it's not very likely, and there are a lot of scientific problems. Science. It wasn't politics, it was science that is stopping Yucca Mountain. (0325-7-1 [Hoffman, Ace])

Comment: So, we need to get rid of this waste, and until we closed San Onofre, I don't think anyone here was really very good at thinking about what to do with the waste, but now we've got a room full of people who are very concerned about it. (0325-7-3 [Hoffman, Ace])

Comment: This is no way to run a country. This is no way to run a problem that is the biggest problem this country has ever faced. It's bigger than World War II. We have to get rid of this waste. And, of course, there's nowhere to put it, so we have to think really hard about what we're going to do. (0325-7-7 [Hoffman, Ace])

Comment: We have nuclear waste that can't be stored safely, and can't be moved safely. We have no solutions for it. How can we possibly have any confidence in the waste-- nuclear waste policy that this agency proposes? (0325-9-2 [Reson, Myla])

Comment: Well, I think we all agree, all of us have agreed, that the lack of a permanent disposal policy by the Federal government is a terrible burden on our community. (0326-1-1 [Hill, Adam])

Comment: I don't think anyone here is too keen about having spent fuel stored at Diablo Canyon. That being said, the Department of Energy is the agency that needs to take ownership of this issue. (0326-11-1 [Bean, Judith])

Comment: I support all of you in petitioning our government representatives for finally accepting responsibility for the long-term storage of the nuclear fuel that powers all of our lives. (0326-17-3 [See, Daniel])

Comment: I now believe it's time for the Federal government to step up and promised --what they promised all of us and provide a permanent storage facility for the used fuel. (0326-27-2 [Devitt, Andrea])

Comment: In that same regard, I fear the possibility that we may not be able to come up with a viable solution for the long-term storage and disposable of spent fuel, even if we give ourselves 60 years to figure it out. What cost might that prove to be to our children's children? I respectfully submit that the U.S. NRC reconsider Proposal Rule 10 in that we have a mined geologic repository before the end of the licensed life for operation of any reactor. (0326-33-4 [London, Rick])

Comment: It's informative to hear everybody's views tonight, and I'm glad that I came, and as we look about addressing this challenge; you know, I think we can either choose to live in the problem or choose to live in the solution, and I think the solution in this situation is abundantly clear, and that's that the Federal government needs to establish a permanent disposal facility, and that is it. Period. Once that decision has been made, I think we can go on and continue to live our daily lives. (0326-37-4 [Rethmeier, Blain])

Comment: In the business world, if you're being asked to have confidence in something, to invest in something, you have an opportunity to look at the track record. What's the track record here of the NRC and a long-term repository? After the first reactor was opened in Shippingport in 1955, over a half a century ago, we were promised a high-level waste storage. That did not happen. Now we're being asked again to have confidence that maybe within another 60 years we'll get a break. We'll get brakes applied to this nuclear car. I think fool me once, shame on you, fool me twice, shame on me. (0326-4-1 [Brown, Jerry])

Comment: And so on to the topic of Waste Confidence. As I was preparing, you know, reading through the documents for this meeting, and looking at the history of Waste Confidence issues, it's pretty obvious that the United States has been dealing with this issue since before I was born, and I have two children now, and they're going to be dealing with it if we don't do something about it now, and that's why we're all here. My oldest son is now four. When he gets into a challenging situation, he closes his eyes, and I don't blame him, he's four years old, right? Sometimes I want to do that, too. But when you look at all of the misinformation and the political agendas that have hindered a long-term solution for the storage of nuclear fuel through the years, it seems that we, the people, and we, the government, have been closing our eyes at this difficult issue. And in doing so, we're really handicapping our future generations and leaving our issues for them to deal with later. And as I read more about the history, I see that a lot of these issues are really political and not technical, and that's frustrating. I have a vision for my children, you know, I want them to grow up in a society where we deal with our problems instead of leaving them for the next guy. (0326-41-2 [Zaitz, Kristin])

Comment: The problem now is that we are running out of room to store this awful stuff. The U.S. government has promised to find a permanent repository by 1998 and tried to get Yucca Mountain, but that didn't work out; also, it is not as safe a location as people first thought it was. In fact, it may be that there is no such thing as a safe, permanent repository for all this nuclear waste, and that's because it is radioactive for so long. (0326-44-3 [Lewis, Sherry])

Comment: I think where we would all agree is in the fact that the long-term storage needs to be addressed and that the government, Federal government, has a real responsibility to accept the obligation to provide long-term storage and a long-term strategy that can take advantage of the economies of scale of a national initiative. (0326-49-2 [Connor, Vicki])

Comment: We were lied to when we were told that the toxic nuclear waste storage would be offsite, that there would be a safe permanent storage in the very near future. That was over 30 years ago, as stated in the Nuclear Waste Policy Act of 1982. We were lied to and we still have no confidence in the NRC judgment. (0326-53-3 [McGibney, Patrick])

Comment: And I would hope that all of us, including the NRC, would have the ability to put pressure on the Federal government to follow through with their permanent storage facility plans for all nuclear waste. (0326-60-5 [Spooner, Rena])

Comment: Also, I went to a recent forum on radioactive waste and likely changed my mind about the need for a geologic repository, as compared to any other way to deal with the rad waste. However, making--- no more radioactive waste should be made before they establish the geologic repository. And obviously Yucca Mountain isn't the proper spot, because it's in an active volcanic area and had, I think it was a 5.6 quake on the Ghost Dance faults in the last 10 or 15 years. (0326-63-3 [Campbell, Bruce])

Comment: I've heard that there might be a need for two geologic repositories due to the huge increase in the burning of high-burnup fuel. (0326-63-4 [Campbell, Bruce])

Comment: Commercial nuclear reactors have been regulated, "regulated", by the AEC and now the NRC since 1954. Almost 60 years have passed and there is still no solution to the fundamental problem of what to do with the deadly radioactive waste. (0326-8-1 [Swanson, Jane])

Comment: What if there's never a permanent repository for permanent waste? Oh, you say, it's obviously safe and fine just where it is, right? It's fine. For how long? A hundred years? Three-hundred years? Forever? But don't worry, you people who live near nuclear reactors, we're sure that there will be an underground final repository when it's needed. We say it's needed now, but we know that that's ludicrous because there's nowhere to put it. (0326-9-2 [Seeley, Linda])

Comment: And I think, you know, at this point, this form of -- this way of storing this waste probably is the best that's available. At some point, if the Federal government would get their act together and create a repository that would be the next best thing, but at this point, this is, the technology indicates, the research indicates, that this is probably the best way of storing this material. And I can say having personally, first of all, living in Ottawa County my whole life, and also dealing as a Commissioner with the NRC and the utility that they are constantly -- the NRC is overseeing the utility. Big Brother is watching, and I, for one, as the Board of Commissioners, we support the NRC in their efforts in this process as far as the waste, and dealing with the waste. (0327-1-1 [Sass, Jim])

Comment: It's unconscionable that despite the Federal Court ruling of no confidence, the NRC continues to arbitrarily and capriciously pretend that there is a storage disposal solution for the existing 70,000 metric tons of high-level radioactive waste generated by continued operation of commercial reactors. (0327-11-4 [Kline, Connie])

Comment: Since each reactor produces 2,000 metric tons of radioactive waste a year, by 2050 there will be 150,000 metric tons sitting on the least suitable sites possible. (0327-11-5 [Kline, Connie])

Comment: Now, when this whole game began, perhaps there were hopes that there would one day be a resolution to what to do with the waste. Seventy-one years have passed as of this week and they still do not know what to do with the first cupful of radioactive waste. (0327-2-4 [Keegan, Michael])

Comment: I lived in Port Clinton when Davis-Besse was being built, and I knew engineers and laborers who worked during the construction phase and the startup. I'm intimately aware of the ongoing problems of Davis-Besse, beginning when the reactor was started up initially and it did not go as expected right through to include what to do with the nuclear waste that's been generated all these years. We were assured that we'd have a national repository for all this nuclear waste when the plant was being planned. These promises have turned into lies. We are no closer to finding somewhere to put all this radioactive waste than we ever have been. (0327-25-3 [Crow, Valerie])

Comment: The solution seems to be storing it right where it is, and that option certainly isn't without a whole new set of problems, especially when the casks were substandard, as some at Davis-Besse -- as one at Davis-Besse -- was, and it was only one of 13 other plants that had dry cask issues. And storage onsite is not a solution. It's kicking a very dangerous can down the road. (0327-25-4 [Crow, Valerie])

Comment: [M]y confidence in the NRC has significantly decreased since it has become a political, not a technical, organization. And by political, the example that I give is the previous chairman who is no longer there, thank you, is a political appointment with the idea -- by a president and by the consent of Harry Reid from Nevada -- that they didn't want Yucca Mountain. And so there's nothing wrong with Yucca Mountain, from a technical point of view. It's only a political point of view that that thing has stopped. And, hopefully, it will get restarted when the politics changes. The NRC should go back to their idea of citizens first and not the politicians first. (0327-36-2 [Lamberger, Paul])

Comment: I don't have to tell you that in June of 2012 the Federal courts handed down a ruling that required you to take some, take the time to reconsider your efforts to continue to license and relicense nukes based on the fact that there's been a concern that for all these years there has not been, nor will there ever probably be, a repository suitable for the disposal of high-level radioactive waste. (0327-39-3 [Izant, Carol])

Comment: Members of the NRC with the help of the rest of us must quickly begin the process of adequately isolating the inventory of irradiated fuel rods. Because we do not have the capability of forecasting geologic changes over millions of years, radioactive waste must not be put in inaccessible places, certainly not at this time. (0327-4-4 [Marida, Patricia])

Comment: Apparently, it is not an NRC problem but a public problem now, what to do with spent nuclear waste. I'm appalled by this meeting. Where are the experts in this situation? Are there not people who knew what to do with spent nuclear waste? Our lives, our environment, our world was entrusted to you, the nuclear industry, over the protest of those worried about such matters 40 years ago. How long do we have to figure it out? Forty years? It's not been long enough for the experts, and now it's in our backyard, literally. (0327-42-6 [Faris, Kelly])

Comment: How can we be confident when we have these myths on one hand, and on the other hand we have a reality where we have 70,000 tons of the most radioactive material on the planet that already exists in temporary storage with no permanent repository in sight, and with 56 years of commercial nuclear electricity generation already past. The fact is that reactor site fuel pools, dry cask storage, interim away-from-reactor storage facilities are nothing more than a radioactive shell game designed to manage the thinnest membrane of time that these wastes will be radioactive compared with the longevity of our human created institutions and technological creations. (0327-7-2 [Gunter, Keith])

Comment: In the past 56 years, the U.S. Government, the nuclear industry, and the world's scientific establishment has examined every possible disposal option imaginable, including deep geologic disposal in salt, shale, volcanic tuff, crystalline granite, and even possibly in Antarctica. Seabed disposal has been discussed and rejected. Outer space disposal was discussed until January the 28th, 1986 when space shuttle Challenger blew up over Florida and all such ridiculous conversation came to a halt. (0327-7-3 [Gunter, Keith])

Comment: Now we have a problem with Canada. There's this big, huge nuclear waste depository where they're going to bury it near Lake Huron, seal it up in an underground chamber. There is just some really ridiculous answers to what to do with nuclear waste, and I don't think anybody's got a solution yet. (0327-8-3 [Barnes, Kathryn])

Comment: We all know there is no good final solution to the problem of creating nuclear waste that must be isolated from the environment and all living things for millions of years. If we ever come to a decision on a deep underground depository, that would mean thousands of

shipments moving through towns and cities, endangering populations in the likelihood of accidents. Highways, railways, and water courses would have to be militarized, and shipments would have to be secretive to prevent terrorism. Even if a suitable place could be found, it would be decades before any waste would be interred, and we're producing this waste at more than 2,000 tons per year. We already have well over 70,000 tons of nuclear waste. (0327-9-1 [McArdle, Ed])

Comment: Our nation's Nuclear Waste Policy Act is a complete failure. The defects of the Nuclear Waste Policy Act were first exposed when the 1998 deadline for the removing of nuclear waste to a permanent repository came and went. More than 15 years later, that's still the law of the land, but now it's simply being ignored. (0328-1-6 [Johnson, Ron])

Comment: As a Mdewakanton Dakota, we use the term seven generations to refer to a length of time and the success of generations of our people who can be affected by our actions today, but nuclear waste is more than a seven generation problem. Some of the most dangerous and toxic substances known to mankind, spent nuclear fuel, must be isolated from the environment for tens of thousands of years. (0328-1-8 [Johnson, Ron])

Comment: What I need as a citizen is for the GEIS to create some minimum standards and criterion for long-range at-reactor and indeterminate reactor site storage. I need this GEIS to create a foundation to support the utilities and not avoiding long-range planning, but to do long range planning specifying what technologies, what casks, what facility design, what funding will be in place to insure responsible nuclear waste management; to direct -- to facilitate the ability to support utilities in creating long-term storage fund assurance. (0328-12-4 [Eide-Tollefson, Kristen])

Comment: I grew up playing with a Geiger counter. My father designed part of the Elk River Demonstration Plant. It's not there anymore, it's a garbage burner now, go from one bad to another bad. But he also designed the solar for the zoo, so there's hope there. But we didn't agree on much, but one thing that me and dear old dad did agree on was they really had no plan for what to do with nuclear waste. And he recognized back in the early '60s that they hadn't a clue. Well, still don't have a clue, you don't know what to do. And there are only so many ways, people have done it very eloquently, but there really are so many ways to say that this is bullshit. It's what it is. It's backwards engineered. (0328-14-2 [Overland, Carol])

Comment: Since the plant started operations in 1973, there has not been one used fuel assembly that has left the city's boundaries. Every single spent fuel rod or fuel rod assembly is located either in the spent fuel pool or the casks stored next to the power plant. As of today, there are approximately 40 casks that store spent fuel assemblies, and it is anticipated at the end of the plant's operations there will be well over 100 casks that will store the spent fuel assemblies and any additional waste from decommissioning that cannot be properly disposed of. The continued storage of spent fuel outside the Prairie Island Plant is not something the city or even Xcel bargained for, and they will continue to remain there despite the best efforts of many people without any plausible plan for removal. This is a far-reaching effect that is literally impossible to quantify. It impacts the city and the citizens on every level, and will continue to do so until these casks are removed and the land is restored to its natural habitat. To continue storage now and after operations will have a chilling effect on the city and its long-term urban planning and growth. (0328-2-3 [Rauterkus, Ralph])

Comment: Radioactive waste in the form of spent fuel is a dangerous long-term problem. The D.C. Circuit Court decision we've been discussing here this evening described it as follows.

"Even though it is no longer useful for nuclear power, spent nuclear fuel poses a dangerous long-term health and environmental risk. It will remain dangerous for time spans seemingly beyond human comprehension." The growing volume of spent nuclear fuel which may reach 150,000 metric tons by the year 2050 is a serious problem. It is clear that no one really knows what to do with the waste. That's the dilemma that the NRC finds itself in, the hole that you've dug yourself in. "The delay in finding a permanent repository," said the Circuit Court again, "has required plants to expand storage pools, and to pack spent nuclear fuel more densely within them. The lack of progress on a permanent repository has caused considerable uncertainty regarding the environmental effects of temporary spent nuclear fuel storage and the reasonableness of continuing to license and relicense nuclear reactors." (0328-4-3 [Taylor, Wallace])

Comment: In addition, the Blue Ribbon Commission on America's Nuclear Future has said that we may already be at a point where more than one permanent repository is necessary. If we keep making more nuclear waste, how many repositories are we going to need that we'll never have a place for, and can never solve the problem. (0328-4-4 [Taylor, Wallace])

Comment: We have the technology to safely develop a geologic repository for used nuclear fuel and we have the money to do so. The only thing blocking the United States from building a geologic repository is the political will to move ahead. (0328-5-10 [Pickens, Terry])

Comment: A schedule needs to be established and then adhered to leading to the removal of used nuclear fuel from commercial nuclear power plants in a reasonable period of time. (0328-5-12 [Pickens, Terry])

Comment: Until the Federal government fulfills its obligation to remove the used fuel from our plant sites, we are committed to responsibly operating used fuel storage facilities safely and to ensuring we have adequate funds to decommission our plants, and to safely maintain our storage facilities for as long as used fuel remains at our site. (0328-5-13 [Pickens, Terry])

Comment: We believe that the United States must effectively, efficiently, and safely manage the byproducts associated with the use of nuclear energy, and the Federal action is long overdue. The Federal government is required by contract and law to remove used fuel from our plant sites in Minnesota, and we are committed to working with the Prairie Island Indian Community, the cities of Red Wing and Monticello, the counties of Goodhue, Sherburne, and Wright, and our State and Federal legislators and regulators to see that this is accomplished. Having confidence that the Federal government will live up to its commitment to safely manage and dispose of used nuclear fuel generated at commercial nuclear power plants is essential to our energy security. (0328-5-2 [Pickens, Terry])

Comment: The NRC correctly concluded that it is feasible to have a mined geologic repository available within 60 years after the licensed operating life of a nuclear power plant. There are no technical obstacles to achieving this, nor are there any financial obstacles. Xcel Energy's customers have paid more than \$400 million into the Nuclear Waste Fund, and along with payments from customers of other U.S. nuclear power plants, have accrued a balance in the Nuclear Waste Fund of more than \$26 billion. (0328-5-3 [Pickens, Terry])

Comment: There is strong international scientific consensus that geologic disposal is the best solution to permanently isolate used nuclear fuel from the public and the environment. Studies by the National Academy of Sciences and the International Atomic Energy Agency have confirmed this conclusion. (0328-5-4 [Pickens, Terry])

Comment: Sweden and Finland are developing geologic disposal facilities, and are expected to begin disposal of their used fuel by the early 2020s. France has selected and characterized a geologic region and is working to identify a site. Belgium, China, and the United Kingdom plan to start geologic disposal by 2050. The United States made significant progress towards geologic disposal. The Department of Energy documented its safety case in a license application and Final Environmental Impact Statement submitted to the Nuclear Regulatory Commission in 2008. (0328-5-5 [Pickens, Terry])

Comment: President Obama then appointed a Blue Ribbon Commission to examine nuclear waste management issues. The BERC concluded that a deep geologic repository is the scientifically preferred approach, and it recommended finding two or three alternative sites using a consent-based process. Legislation is pending in the United States Senate to begin the process of selecting alternative sites. (0328-5-7 [Pickens, Terry])

Comment: The Nuclear Regulatory Commission's Waste Confidence principles were struck down by a Federal court, as has been discussed, because there is no foreseeable solution for long-term radioactive waste storage that would meet three necessary requirements; namely, that it be scientifically sound, environmentally responsible, and publicly acceptable. Even the shorter term programs now in place for radioactive waste fail to protect the public, and fail to offer the requisite confidence that would justify continued generation of reactor waste. (0328-9-2 [LaForge, John])

Comment: And I've said this before, but the industry promised us to provide solutions in the future if we put our trust in them, and I think that's great that they're looking for solutions. But there can be no confidence until we have a solution and not only a proposed solution but an identified and tested solution. On that basis alone, there could be no waste confidence. (0329-14-4 [Sondheim, Steven])

Comment: Geological repositories for storing the waste, I don't believe we should be discussing this either because we know now that geology is not something that remains stable. It is unpredictable. Plate tectonics are constantly moving. We may be thinking or you guys may be thinking that you're storing waste into infinity, but things are occurring everyday underground that would make all people understand that putting it into a repository, no matter what state you think you could dump it in, is putting not just the state at risk but the entire country because there's nothing that we can predict anymore, as we're seeing with the super storms and climate changes and earthquakes happening everywhere. I mean, there's been no end in sight. (0329-15-4 [Star, Priscilla])

Comment: [W]e have some of the most amazing minds in the world working on this problem [what to do with the waste]. But the problem is we're not working on it together. And we're not starting from the roots. And the roots come from the Mother Earth. And it comes from the power that we extracted from her. And only the original people that know her well as a citizen to take the time to put everything aside because this is the only thing that is important to the survival of my daughter and myself on this planet right now. And I think we all know that in this room or wherever we are on this planet. We all know that. (0329-19-1 [Vandel, Niki])

Comment: Instead of assuming that spent fuel can be stored safely forever, the NRC should examine the probability that a repository will be successfully sited, the probability that a successfully sited repository will actually contain radiation, the degree to which a repository may leak radiation, and the public health and environmental consequences that may occur if a repository is not sited or if it effectively contains radioactivity. You know, these things are very

likely. The fact that we have not been able to come up with anything so far makes me really question our ability to do so. But, you know, we have to keep trying. But I have no confidence that the current Draft Environmental Impact Statement, the current plans for disposal of the nuclear waste we already have are adequate, safe, or sufficient. (0329-28-6 [Wilansky, Laura])

Comment: [W]e have to put all of our time and energy and greatest minds to dealing with the waste that we have now because we have no adequate safe method to deal with it. (0329-4-6 [Messer, Diane])

Comment: Storing radioactive waste in fuel pools and dry casks for an indefinite period of time, is no answer. We The People -- the American people -- count on our federal agencies to protect us. So protect us! Do your job. (0332-2 [Parks, Eric])

Comment: The costs of failure in cases of putative low-probability events, such as occurred in Fukushima, are too high for us to permit current ad hoc waste management methods to be accepted as justification for construction of more nuclear plants. I am not against developing more nuclear capacity per se, but it should not be done without a bullet-proof system for managing all nuclear waste; this has evaded all attempts thus far, and will never be developed if plant construction is permitted before its completion. (0333-3 [Balke, Karl])

Comment: The NRC should not express confidence in the safety of radioactive waste--rather, it should immediately and aggressively pursue safer storage options for this waste. Relying on a low probability of a catastrophe is a recipe for disaster. (0335-1 [Ehrlich, Jeremy])

Comment: The Nuclear Regulatory Commission's "waste confidence" principle was properly struck down by a federal court because, some 60 years into the commercial atomic age, it is patently obvious that there is no foreseeable "solution" for long-term radioactive waste storage that would attain three necessary and basic goals: scientifically-defensible, environmentally-responsible, and publicly-acceptable. (0336-2 [Lish, Christopher])

Comment: Not only is there no long-term solution for atomic waste in hand or on the horizon, the shorter-term programs now in place are inadequate from a public safety standpoint, and do not offer the requisite confidence to allow continued generation of radioactive waste. (0336-3 [Lish, Christopher])

Comment: This new proposed rule is only perpetuating the inevitable, putting off the proper storage of spent fuel and allowing nuclear reactor facilities to continue waster generation without adequate permanent repositories. (0339-2 [Wilmott, Emily])

Comment: I generally agree that all storage of spent nuclear fuel is generic in nature but with such a potent and powerful substance such as spent nuclear fuel and it's safe storage for what could possibly be longer than planned, all things should be considered. Hopefully we can find long term storage in the near future, but no one knows what the future has in plan for us. (0340-1 [Case, Ed])

Comment: The buildup of hundreds of tons of nuclear waste at sites throughout the nation - some 70,000 tons of high-level spent fuel plus even larger quantities of other nuclear waste product - is a serious problem that absolutely must be dealt with. It is a problem created by many men of good will, but insufficient foresight. Whether due to hubris or excessive confidence, ton after ton of nuclear waste has been generated and now we must deal with the toxic mess we have made. (0341-1-2 [Mermelstein, Richard])

Comment: I am concerned about the future of Duxbury Ma, 10 miles from the Pilgrim Plant. The plant's location near sea level and the recent safety issues are concerns. Also Plymouth never thought the city would become a waste depository. We need better plans and oversight. (0342-1 [Landgren, Nancy])

Comment: The promise of a repository for spent fuel, made 50 years ago was never fulfilled. The problems with such an undertaking have prevented this possibility. Now the "Waste Confidence" document alludes to the future storage possibility within 60 more years. (0344-1 [Heald, Deborah])

Comment: In seventy years of producing nuclear weapons and nuclear energy we have found no way to dispose of the resultant radioactive waste that will not threaten life on earth. There is no permanent waste repository. The Yucca Mountain team consisted of the best people we have with unlimited resources, yet they failed. They didn't fail due to incompetent management, they failed because they were given an impossible task. (0348-1 [Agnew, David] [Roscoe, Lee])

Comment: [T]he Department of Energy has a responsibility to make good on its commitment to receive and safely store the spent fuel for the long term. By doing so, locally stored spent fuel could be safely removed to a single or regional locations controlled by and protected by our national government. Please don't let the anarchists and un-informed anti-energy environmentalists block safe energy production and economic progress. (0350-2 [Martz, Robert])

Comment: In seventy years of producing nuclear weapons and nuclear energy we have found no way to dispose of the resultant radioactive waste that will not threaten life on earth. There is no permanent waste repository. The Yucca Mountain team consisted of the best people we have with unlimited resources, yet they failed. They didn't fail due to incompetent management, they failed because they were given an impossible task. (0352-1 [Roscoe, Lee])

Comment: The NRC must now admit that no safe, permanent repository exists, and that 70,000 tons of accumulated nuclear waste may be permanently stored at reactor sites. The NRC must now thoroughly review Environmental Impacts of onsite storage, and consider safer alternatives to nuclear when licensing decisions come up. In response, the NRC is holding public hearings around the country to garner input on nuclear waste storage and licensing. (0357-1 [Daily, G. Allen])

Comment: 1. Our community was first told that "spent fuel waste" would be stored on-site for no longer than 5 years and no more than 540 assemblies. Today, 40 years later, we are asked to endure the storage of more than 4,400 assemblies for an indefinite period of time! (0358-3 [Schumann, Klaus])

Comment: We have no proven technology for safe storage of radioactive waste, and no national repository. (0368-2 [Mattox, Judy])

Comment: It is however, the Department of Energy's responsibility to make good on its commitment to receive and safely store the spent fuel for the long term. (0372-2 [Salas, Peggy])

Comment: Many are the hazards of nuclear power. Among the most intractable difficulties to resolve is the long-term storage of spent fuel rods. In seventy years of producing nuclear weapons and nuclear energy we have found no way to dispose of the resultant radioactive waste that will not threaten life on earth. There is no permanent waste repository. The Yucca Mountain team consisted of the best people we have with unlimited resources, yet they failed.

They didn't fail due to incompetent management, they failed because they were given an impossible task. (0373-1 [O'Malley, Brian])

Comment: U.S. Conference of Mayors Resolution June, 2012: The U.S. Conference of Mayors called on DOE to focus on storage of radioactive waste on-site, as the best opportunity for communities to avoid further health and environmental impacts from waste from nuclear facilities (0377-2-18 [Cuthbert, Lewis])

Comment: EPRI is pleased to provide the attached bibliography of EPRI publications that provide information and analysis related to NRC's Waste Confidence GEIS. EPRI requests that the relevant NRC Waste Confidence staff review the EPRI publications for potential use in preparing the final Waste Confidence GEIS. *Geologic Disposal of Used Fuel and HLW EPRI Review of Geologic Disposal for Used Fuel and High Level Radioactive Waste: Volume IV—Lessons Learned*. EPRI, Palo Alto, CA: 2010. 1021057.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001021057>

The effective termination of the Yucca Mountain program by the U.S. Administration in 2009 has further delayed the construction and operation of a permanent disposal facility for used fuel and high level radioactive waste (HLW) in the United States. In concert with this decision, the President directed the Energy Secretary to establish the Blue Ribbon Commission on America's Nuclear Future to review and provide recommendations on options for managing used fuel and HLW. EPRI is uniquely positioned to provide an independent scientific and technical perspective on used fuel and HLW management as well as related impacts of alternate nuclear fuel cycles. While there are, in fact, numerous options for managing the wastes associated with the nuclear fuel cycle, all waste management and fuel cycle alternatives eventually require permanent disposal for some form and amount of long-lived radioactive material. The disposal of used fuel and HLW is often mischaracterized as an intractable problem. To the contrary, there exists today an international consensus on the appropriateness and capability of deep geologic disposal to provide long-term isolation of used fuel and HLW from the biosphere. This consensus has emerged from more than five decades of scientific study and peer-review, technical and regulatory developments, and site selection and characterization. This report, *Lessons Learned*, is the final volume of a four-volume series, entitled *EPRI Review of Geologic Disposal for Used Fuel and High Level Radioactive Waste*, which surveys and evaluates past, present, and planned disposal options gleaned from a half-century of geologic disposal efforts in the United States and abroad. EPRI's review of technical and nontechnical elements deemed critical for successful implementation of a repository program has identified a number of lessons learned in the following areas: 1) laws, regulations, and institutional and financial arrangements; 2) site screening, selection, and characterization; 3) repository design concepts; 4) independent peer review and advisory bodies; and 5) stakeholder and public involvement. (0379-13 [Kessler, John])

Comment: *EPRI Review of Geologic Disposal for Used Fuel and High Level Radioactive Waste: Volume III—Review of National Repository Programs*. EPRI, Palo Alto, CA: 2010. 1021614.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001021614>;

Most nations pursuing a permanent disposal path for used fuel and HLW are now considering or implementing a deep geologic disposal program. These programs represent a collective source of experience and knowledge that may prove useful for informing the development of a post-Yucca-Mountain disposal strategy and program in the United States. This report reviews and summarizes the approach, developments, and status of national deep geologic disposal programs in a number of countries. *EPRI Review of Geologic Disposal for Used Fuel and High Level Radioactive Waste: Volume II--U.S. Regulations for Geologic Disposal*. EPRI, Palo Alto,

CA: 2010. 1021384.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001021384>;

This report reviews the development and evolution of U.S. standards, regulations, and siting guidelines for the disposal of used fuel and HLW. The report also highlights important elements and aspects of the U.S. regulatory framework that play a critical role in the development, design, and licensing of a geologic repository for used fuel and HLW and that could inform revision of existing regulations or development of new ones. *EPRI Review of Geologic Disposal for Used Fuel and High Level Radioactive Waste: Volume I—The U.S. Site Selection Process Prior to the Nuclear Waste Policy Amendments Act*. EPRI, Palo Alto, CA: 2010. 1021056.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001021056>;

This report reviews the nuanced history of the process for screening, selecting, and characterizing suitable sites for hosting a permanent deep geologic repository. The report also highlights important elements and aspects of U.S. site selection efforts predating the 1987 Amendment of the NWPA, which effectively ended site selection and moved the United States into exclusive site-specific characterization. *EPRI Yucca Mountain Total System Performance Assessment Code (IMARC) Version 10: Model Description and Analyses*. EPRI, Palo Alto, CA: 2009. 1018712.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001018712>;

This report summarizes EPRI's repository performance assessment code, Integrated Multiple Assumptions and Release Code (IMARC) Version 10, beginning with an overview of the code, followed by detailed descriptions of individual IMARC components, including linkages, testing, and benchmarking. Major IMARC features, events and processes (FEPs) are also described, with emphasis on climate change; net infiltration; focusing of unsaturated zone groundwater flow; groundwater percolation into repository drifts; degradation of drip shields, cladding, and waste packages; waste form dissolution; radionuclide transport through the drifts, unsaturated zone, and saturated zone; and multiple exposure pathways in the biosphere. The report also describes how combinations of embedded numerical sub-models are coupled with stand-alone analyses and lookup tables to evaluate annual radiological doses to the RMEI. Results from selected IMARC 10 analyses and sensitivity studies are presented. (0379-14 [Kessler, John])

Comment: EPRI is pleased to provide the attached bibliography of EPRI publications that provide information and analysis related to NRC's Waste Confidence GEIS. EPRI requests that the relevant NRC Waste Confidence staff review the EPRI publications for potential use in preparing the final Waste Confidence GEIS.

Occupational Risk Consequences of the Department of Energy's Approach to Repository Design, Performance Assessment and Operation in the Yucca Mountain License Application.

EPRI, Palo Alto, CA: 2008. 1018058.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001018058>

This report reviewed the DOE-proposed approach to Yucca Mountain repository design, performance assessment, and operation and identifies elements that may have the potential to increase occupational health risks of nuclear and non-nuclear workers relative to those that would be encountered if the DOE had taken a more realistic approach in its 2008 license application.

Feasibility of Direct Disposal of Dual-Purpose Canisters in a High-Level Waste Repository.

EPRI, Palo Alto, CA: 2008. 1018051.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001018051>

This report evaluates the feasibility and consequences of direct disposal of dual-purpose canisters (DPCs) in a deep geologic repository with respect to long-term performance of the Yucca Mountain repository system.

Feasibility of Direct Disposal of Dual-Purpose Canisters in a High-Level Waste Repository: Options for Assuring Criticality Control. EPRI, Palo Alto, CA: 2008. 1016629.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001016629>
The report presents calculated nuclear reactivities of two dual-purpose spent-fuel canisters to assess the feasibility, with respect to criticality control, of direct disposal of such canisters in a permanent geologic repository without the need for repackaging. Results show that criticality safety cannot always be unequivocally demonstrated through burnup credit alone, except by taking into account a sufficiently large number of neutron-absorbing fission products and reasonable values for biases and uncertainties. However, criticality control for direct disposal can be significantly enhanced with the inclusion of used burnable absorber rods in spent-fuel assemblies and loading patterns that minimize reactivity. (0379-15 [Kessler, John])

Comment: *Program on Technology Innovation: Room at the Mountain: Analysis of the Maximum Disposal Capacity for Commercial Spent Nuclear Fuel in a Yucca Mountain Repository.* EPRI, Palo Alto, CA: 2007. 1015046.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001015046>;
Projected expansion of nuclear power beyond the year 2014 will result in the need for commercial spent nuclear fuel (CSNF) management options in addition to the currently legislated CSNF storage capacity at the proposed Yucca Mountain geological repository. At present, 70,000 MTHM of storage capacity has been authorized, with a projection that 63,000 MTHM would be used for CSNF. This report extends preliminary analyses of the maximum physical capacity of the Yucca Mountain repository, presented in EPRI report 1013523. EPRI is confident that at least four times the current CSNF limit (~260,000 MTHM) and possibly upwards of nine times the limit (~570,000 MTHM) could be emplaced with additional site characterization. *Yucca Mountain Licensing Standard Options for Very Long Time Frames: Technical Bases for the Standard and Compliance Assessments.* EPRI, Palo Alto, CA: 2005. 1011754.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001011754>;
In the existing U.S. Environmental Protection Agency (EPA) and Nuclear Regulatory Commission (NRC) regulations governing the spent nuclear fuel and high-level radioactive waste site at Yucca Mountain, Nevada, the time period of compliance was set at 10,000 years. Recently, a Court ordered that EPA and NRC either revise the regulation on this topic to be "based upon and consistent with" recommendations made by a panel of the National Academy of Sciences, who recommended a time period of compliance out to as long as one million years, or seek congressional relief. This report summarizes the technical issues related to establishing a meaningful, reasonable, and implementable standard for such a long time period of compliance assuming no congressional action is taken. The report also makes a set of recommendations. (0379-16 [Kessler, John])

Comment: I am astounded by the stoic indifference to the obvious fact that after all these years there is no safe solution to the problem of what to do with the nuclear waste we've been accumulating. (0381-2 [Fasten, Susan])

Comment: The Department of Energy has a responsibility to make good on its commitment to receive and safely store the spent fuel for the long term. By doing so, locally store spent fuel could be safely removed to a single or regional locations controlled by and protected by the federal government. (0383-3 [Mordaunt, Brandon] [Mordaunt, Laura] [Mordaunt, Philip])

Comment: However, the Department of Energy has a responsibility to make good on its commitment to receive and safely store the spent fuel could be safely removed to a single or regional locations controlled by and protected by our national government. (0384-2 [Tannler, Sandra])

Comment: I do also think that it is very important for the Department of Energy to fulfill their commitment to receive and safely store spent nuclear fuel for the long run. The great work with on-site storage is much appreciated, but we will not be where we should be as a nation until the long term storage of nuclear fuel is available. Thank you for reading and please keep up the pressure on long term spent fuel storage. (0385-2 [Buckingham, Jeffrey])

Comment: [T]he Department of Energy has a responsibility to make good on its commitment to receive and safely store the spent fuel for the long term. By doing so, locally stored spent fuel could be safely removed to a single or regional locations controlled by and protected by our national government. (0386-2 [Thompson, Lydia])

Comment: While I am convinced that current storage systems at Diablo Canyon are acceptable, I urge the Department of Energy to find solutions to the long term spent fuel storage issue. The DOE must continue its efforts to educate the public about nuclear energy and storage, and support the President's Blue Ribbon Commission recommendations for development of a workable long term storage solution. (0388-3 [Cox, David])

Comment: [T]he Department of Energy has a responsibility to make good on its commitment to receive and safely store the spent fuel for the long term. By doing so, locally stored spent fuel could be safely removed to a single or regional locations controlled by and protected by our national government. (0391-2 [Trahey, Linda])

Comment: There is presently no safe way to transport, store or dispose of high-level radioactive waste, and it is unlikely that there will be in the foreseeable future. (0402-2 [Gross, Cheryl])

Comment: It is repeatedly obvious that there is no foreseeable solution for long-term radioactive waste storage that would attain environmental and public health basic goals. There are no solutions for atomic waste. (0403-1 [Brown, Deborah])

Comment: Yucca mountain leaks. The Finnish repository has been trying to figure out how to tell generations a million years out that they are encountering a nuclear hot spot when no written language or pictographic glyphs have been found in human history from that long ago. Nuke waste is a horrific burden on our children's children (0405-4 [Dugan, Pat])

Comment: I would like to see the Department of Energy take the responsibility to make good on its commitment to receive and safely store the spent fuel for the long term. (0408-2 [Watson, Jeannette])

Comment: The NRC should realize that the government has subsidized the nuclear industry and is partly responsible for the problem of the build up of nuclear waste. No solution is yet available for the safe disposal of this highly toxic substance. (0416-2 [Barnes, Kathryn])

Comment: Dr.Mary Sinclair said the only solution is to monitor it in safe, above -ground containers until it loses its toxicity. The deadly waste can be toxic for hundreds of thousands of years, so we should realize it is a long term problem with no short term solutions. (0416-4 [Barnes, Kathryn])

Comment: There is no scientifically proven solution for safely disposing of nuclear waste. (0417-8 [Clark, Terrence])

Comment: I am very appreciative of the opportunity to share my thoughts on the important topic of waste confidence and its relationship to the new "consent-based" siting approach for nuclear waste management facilities for interim storage and on a permanent geologic repository. The idea of local communities forming partnerships with implementers under the auspices of national governments appears to be gaining traction in countries opting for voluntary siting. Some version of this idea can be found in Sweden, the UK and Canada. The only catch here is that there must be a community that has the infrastructure, the real estate, a knowledgeable workforce, and educated citizens that understand both science and risk. I'm not sure that this community exists. (0421-2 [Clemons, Victoria])

Comment: In the UK, as well as in Canada the nuclear waste leadership role was removed from scientists and engineers, and the leadership was temporarily placed in the hands of very prominent individuals who developed new, radically different, policy proposals that took social aspects seriously and used social science as their tool. (0421-3 [Clemons, Victoria])

Comment: At this time I would also like to add that when discussing a permanent facility there are...in fact...TWO...quite different aspects to consider for storage of nuclear waste in a Geological Repository. The first is providing a place where nuclear waste can be securely stored and monitored in a safe and retrievable fashion ... and the second aspect is abandoning those wastes, closing and sealing the underground facility that will, at some point be, forever after, unmonitored, unmanned, unregulated and eternally beyond human control. (0421-5 [Clemons, Victoria])

Comment: Experience with Yucca Mountain indicates that there can be no confidence that geological storage can ever be available. Yucca Mountain became mired in scientific misconduct and lost the confidence of the neighboring communities. Any alternative site may well face the same fate. Regaining the confidence of the neighboring communities is essentially impossible once faith has been broken, so every proposed site will end up socially impossible. The NRC does not regulate the Department of Energy and thus can not guarantee that scientific misconduct or some other form of corruption will not wreck confidence in another site. The NRC does not regulate Congress and thus can not guarantee that legislative fiat will not wreck confidence in an objective and fair process. Because confidence is so contingent on such outside factors which are essentially social in nature, the NRC itself can have no confidence in the availability of geological storage at any time in the future. (0422-2 [Dudley, Chris])

Comment: Arjun Makhijani comments: "A worst-case event on the surface, especially in a sensitive area like San Onofre, is an order of magnitude more severe than worst case in deep geologic storage. Our goal should be to store waste in a way where the worst-case is not catastrophic. For that reason, we need a deep geological repository. We have done a terrible job on a national repository in this country. We need to work on a repository. All other solutions are much less adequate." Within the environmental community a level of unease has arisen from the sense that as isolated storage proved difficult to site, the GEIS exercise was undertaken to present on-site storage as equally safe and appropriate, thereby reducing or removing any sense of urgency in siting a remote geologic repository. (0431-13 [Pascall, Glenn] [Watland, George])

Comment: Given the total context, the GEIS approach is at best a default position in response to the difficulty of siting a national repository. More fundamentally, the EIS process appears unsuited to assessing the realities of managing long-term nuclear waste storage generally, and specifically in an era of high burn-up fuel use. Our bottom line conclusion: There remains no alternative but to continue the hard and necessary work of work "creating a safe, long-term

solution for managing and disposing of the nation's spent nuclear fuel and high-level radioactive waste," in the words of the NRC's Blue Ribbon Commission, which reported in January 2012. The BRC report recommends "immediate efforts to commence development of at least one geologic disposal facility and at least one consolidated storage facility, as well as efforts to prepare for the eventual large-scale transport of spent nuclear fuel and high-level waste from current storage sites to those facilities." (0431-15 [Pascall, Glenn] [Watland, George])

Comment: We recognize that development of this GEIS was undertaken as a required response to the June 8, 2012 finding of the U.S. Court of Appeals., D.C. Circuit, : that the NRC needed to more fully address impacts in two areas: in failing to secure permanent disposal for spent nuclear fuel and potential spent fuel pool leaks and spent fuel pool fires. Regarding permanent disposal, the NRC definition of Waste Confidence in NUREG 2157 reads as follows: Waste Confidence applies to the storage of spent fuel after the end of the licensed life of a nuclear reactor and before disposal in a permanent repository. The Waste Confidence criterion applies to an interim phase in a complete cycle of nuclear fuel storage. Thus, lack of a permanent repository as the end point makes development of an adequate Waste Confidence policy vastly more difficult and perhaps conceptually impossible. (0431-3 [Pascall, Glenn] [Watland, George])

Comment: We recognize that the current lack of a repository arises not from NRC policy, which We recognize to be supportive, but primarily from difficulties in gaining political and public approval for even a single repository site. Sierra Club policy on geologic storage at one or more remote and isolated sites was adopted by its Board of Directors on May 5, 1984. The policy statement begins, To reduce the grave and unacceptable risks posed by the existing and continued production of high-level nuclear waste without a demonstrated means of final disposition, the Sierra Club supports federal assumption of responsibility for the long-term, least hazardous isolation of spent nuclear fuel and high-level wastes. (0431-4 [Pascall, Glenn] [Watland, George])

Comment: From what I gather, there is no practical solution in sight for a permanent secure storage solution. (0436-2 [Patrick, Kay])

Comment: The most serious unresolved problem is the absence of any repository for the waste. Presently, since the Yucca Mountain site was rejected, there is no place for the spent fuel to be stored. (0437-2 [Kinnaird, Eleanor])

Comment: The NRC must accept that truth and act accordingly - not gloss over the fact that there is no foreseeable "solution" for long-term radioactive waste storage. (0443-6 [Sabo, Betty])

Comment: Even though the NRC has failed to solve where & how to store the waste from US nuclear reactors, they NRC has said they hope there will be a solution in the future. This citizen does not believe the NRC & suggests the NRC must do more than pre-suppose a solution will be found. The NRC has had DECADES to come up with their solution for storing nuclear reactor waste, yet has not offered a legitimate solution for this waste. And the nuclear reactors in America continue to create nuclear waste with no solution on where or how to store this highly toxic material. (0446-1 [Krause, Laurel])

Comment: What has the NRC been doing with their research staff? Do they not regard the need for a safe way to store nuclear reactor waste as important or imperative? Who's in charge at the NRC in this area? (0446-3 [Krause, Laurel])

Comment: unwarranted and unwise deference to the Blue Ribbon Commission by accepting the extreme delays in resolving the final deep geologic disposal of spent nuclear fuel and high level wastes (0447-1-7 [Andrews, Richard])

Comment: Promptly work with all other involved agencies to promptly site, build and commission into operation final deep geologic repositories for SNF and other radioactive wastes, within a time frame not to exceed 10 years from the present (0447-2-14 [Andrews, Richard])

Comment: For my entire life, the federal government has been promising the benefits of nuclear technology, but all we really have to show is piles of studies, massive wastes of public funds, a legacy of broken and false promises, while laying all the radioactive waste problems on our children and grandchildren. When I grew up in Kansas in the 1950s the AEC was planning for nuclear waste disposal in Kansas salt mines. That never happened. Nor has anything to resolve this radioactive waste disposal since. (0447-2-17 [Andrews, Richard])

Comment: The only legitimate reply to the courts should have been that NRC has no confidence that waste repositories will ever be available, and that continued on site storage of dangerous high level and spent fuel at reactor sites should be promptly eliminated to reduce the dangers to the public and the environment. (0447-2-2 [Andrews, Richard])

Comment: A totally different plan for the prompt and final disposal of all spent nuclear fuel and other radioactive wastes must be proposed that is accomplished in no more than ten years. I remind the NRC that the entire development and use of the first atomic weapons occurred in a shorter time frame, less than 4 to 5 years. Surely, with the political will and dedication, the NRC and associated federal agencies can perform within a similar time span. (0447-2-7 [Andrews, Richard])

Comment: It is not realistic to expect the federal government to provide a safe repository for nuclear fuel anytime soon. (0450-3 [Bast, Nancy])

Comment: Consequently, even if all of the nuclear waste which has accumulated until now is placed in hardened dry cask storage as soon as possible, there still will remain the problem of locating and building a permanent National Storage Site. (0454-8 [Waldstein, Joe])

Comment: I am writing to encourage the federal government to uphold their obligation of providing a national repository for used nuclear fuel currently being stored at Diablo Power Plant in San Luis Obispo County. It is currently being managed and safely stored by PG&E but nevertheless I have concerns as does much of the local community. PG & E has been a good steward of the property and I am most appreciative of the economic impact on the area and support Diablo's relicensing. (0457-1 [Burkhead, Elizabeth])

Comment: The storing of nuclear waste is a federal responsibility and the federal government needs to fulfill its obligation to remove the spent fuel. I will be looking to hearing more as to how this process will proceed. (0457-2 [Burkhead, Elizabeth])

Comment: There is strong international scientific consensus that geologic disposal is the best solution to permanently isolate spent nuclear fuel from the public and the environment. Studies by the National Academy of Sciences and the IAEA have confirmed this conclusion. (0461-2 [Pan, Arthur])

Comment: NRC also references international experience when deciding on what is a reasonable timeframe for finding a permanent repository - but there is no repository anywhere, in any country, and therefore no relevant international experience to draw from, and the DGEIS does not clarify what timeframes exactly it found reasonable by comparison. Of the fourteen other nuclear power-generating countries, only a handful intend to use direct disposal like the United States does, including Canada, Finland, Sweden, Spain, and South Korea. Of those, only one - Finland - has selected a repository location and begun construction. Sweden has a confirmed location, but because it was a volunteered location, Sweden's experience is inapplicable to the timeline analysis done by the NRC. Spain is still conducting research on deep disposal and has not selected a location, and South Korea is looking only at interim storage right now, starting in 2016.²¹ [footnote 21 text: World Nuclear Association, "Radioactive Waste Management" (updated Apr. 2012), available at <http://www.world-nuclear.org/info/Nuclear-Fuel-Cycle/Nuclear-Wastes/Radioactive-Waste-Management/> (last accessed Sept. 16, 2013).] Given this limited pool of comparison points, and the fact that no country at all has achieved direct disposal yet, the timeframe laid out by the NRC cannot be characterized as reasonable by comparison to international experience. Moreover, even if other countries had had more success, their experience would not be a basis for concluding that no spent fuel will remain in U.S. pools after 60 years post-licensed life. (0473-12-15 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: There is really no good option for storing nuclear waste for the tens of thousands of years required. (0477-4 [Tache, Jan])

Comment: The Federal Government must act in association with the Energy Companies to secure all spent fuel into permanent (dry cask in Yucca Mtn) storage. (0480-1 [Arnold, James])

Comment: Final deposit geological disposal dry storage casks no matter what the cost must be used for San Onofre spent fuel. We must get it out of here NOW! Not in 2 years, 5 years, 30 years, 60 years. Everyday we are playing Russian Roulette with Southern California's future. (0481-3 [Magda, Marni])

Comment: No nuclear waste should not continue to be stored at San Onofre.....The biggest mistake made was having no place to store nuclear waste and that was a known fact from the get go (0486-1 [Bourgeois, Paula])

Comment: I also feel that long term storage is needed once the isotopes have decayed to a level where the materials are safe to handle and transport without constant immersion in a cooling pond. I feel a deep repository such as Yucca Mountain is the ideal solution. (0488-2 [Watkins, Conor])

Comment: Today no safe and secure national nuclear waste geological repository exists, nor can nuclear fission be safely reversed engineered. (0490-1 [Chin, Rebecca])

Comment: The NRC and federal government failed to design a safe and secure nuclear waste solution, as promised by 1998. The United States has over 72,000 tons of high level radioactive toxic waste which must be stored for tens of thousands of years. (0490-2 [Chin, Rebecca])

Comment: The NRC's "waste confidence" principle was properly struck down by a federal court because, some 60 years into the commercial atomic age, it is patently obvious that there is no foreseeable "solution" for long-term radioactive waste storage that would attain three

necessary and basic goals: scientifically-defensible, environmentally-responsible and publicly-acceptable. (0491-1 [Commenters, Multiple])

Comment: Chairman McFarlane in a answer to questions by Representative Shumkus at a House Energy and Conservation Subcommittee meeting on or about 12/12/2013 stated that many actions and inactions had to await the will and financing of the Congress. I point out that when the Nation is thrown into a sequestration at the whim of one party that there is not much confidence that any safety is assured. That is exactly what has happened recently. I point out that the confidence that the NUREG 2157 and the Waste Confidence rulemaking hangs by a thread on the whims of the Congress. The present DGEIS makes little or no discussion on the appropriate and timely funding of radwaste management from the viewpoint of politics. Will the glaring omission of politics in the funding of safety for radioactive wastes be repaired before the NUREG 2157 issues? (0502-1 [Lewis, Marvin])

Comment: The Western Interstate Energy Board (WIEB) High-Level Radioactive Waste (HLRW) Committee appreciates the opportunity to review and comment on NRC's Waste Confidence Generic Environmental Impact Statement (GEIS) and Proposed Rule. We appreciate NRC's effort to provide opportunity for public input as it formulates its response to the June 2012 D.C. Circuit Court decision. We also appreciate that NRC cannot itself resolve the nation's issue regarding permanent disposal of commercial spent nuclear fuel (SNF); it can only regulate commercial utilities while other federal government branches and agencies attempt to resolve the issue--hopefully following the very sound recommendations made by the Blue Ribbon Commission on America's Nuclear Future (BRC) in January 2012. (0505-1 [Williams, Jim])

Comment: There needs to be an immediate placement of all dry casked fuel into long term storage, preferably at Yucca Mtn. No site is a proven contender for safe storage of spent fuel, however, the public would be better protected if we put all fuel that can be dry casked into that storage and sequester it in a geologically stable area. (0514-5 [Fahey, John])

Comment: You are urged to locate, study, and approve a storage area for spent nuclear fuel in the U.S. (0515-1 [Stennes, Nancy])

Comment: Find a way to store low level and high level nuclear waste on a permanent basis (nearly impossible in principle, since humans only live for 70-80 years or so). Find a safe storage area ASAP. Build it. Use it. (0515-5 [Stennes, Nancy])

Comment: We currently have no technically viable solution for safe, long-term storage (or disposal) of nuclear waste that has accumulated from 60(+) years of commercial nuclear power production -- and from other sources. (0522-1 [Rogers, William])

Comment: Because no Government knows how to handle the spent fuel "hot potato" in the long term, the problem has not even begun to be addressed. There is no good long term solution, but we do have a good short term solution[.] (0529-1 [Claybourne, Ana])

Comment: The new DGEIS means that extended on site spent fuel storage has the potential to become the default means of disposal, which is unacceptable from an environmental and social standpoint. (0531-1-12 [Morgan, Sally])

Comment: The new DGEIS means that extended on site spent fuel storage has the potential to become the default means of disposal, which is unacceptable from an environmental and social standpoint. (0531-2-12 [Morgan, Sally])

Comment: Despite two decades, billions of dollars and a federal mandate to do so, there is still no federal nuclear waste depository. Even if there was a federal repository, as of 2010, nuclear plants had already generated enough spent fuel to fill that repository. We would need a second, and there is no plan or Act of Congress on the table to address the issue. (0531-2-14 [Morgan, Sally])

Comment: If a community in the United State is to step forward and consent to host a repository [or even a centralized interim storage facility] that community must trust in the integrity of political and regulatory systems with which they are to consent. They are in effect entering into a contract on behalf of the safety of their citizens and, especially, in the case of the repository, the safety of their future generations. The Nuclear Waste Policy Act, as amended, that led eventually to selecting Yucca Mountain is such a statutory framework, enacted by Congress. It set forth a process for developing two repositories. This process was to be implemented by the Executive Branch and licensed and overseen by an independent Nuclear Regulatory Commission. Any prospective host community, today, will have to confront soberly the reality that the U.S. Government failed to implement its own nuclear waste law. Absent an Executive Branch willing to carry out a nuclear waste law enacted by the U.S. Congress, and overseen by a safety regulator, perceived as truly independent, how can any community going forward have confidence that this, or any other statutorily mandated path to a repository disposal solution, will, in fact, be honored and implemented? No attempt has been made in this proposal to address the impact of this breakdown in the public's ability to rely on its government or on NRC itself to comply with the Nation's own nuclear waste laws, especially in light of the recent ruling of the U.S. Court of Appeals., D.C Circuit. (0532-16 [Kotra, Janet])

Comment: It is important to recall, however, that the Commission also founded its confidence, both in 1984 and again in 1990, on confidence in the existence of a statutory framework enacted by a bipartisan U.S. Congress, setting forth a process for a path towards for the development of two geologic repositories. (0532-18 [Kotra, Janet])

Comment: Deep geologic disposal of spent nuclear fuel in an underground repository is widely agreed to be the best technical way to provide for that safety and security. It is still National Policy. It is still the Law of the Land. It is time the Commission awoke from its long slumber of disgrace and disregard of its responsibility as Independent Safety Authority in Chief and did its job. (0532-5 [Kotra, Janet])

Comment: The Commission is correct that there exists today a stronger technical basis for confidence in geological disposal. However, the Commission has failed to consider whether there exists sufficient social and political bases for continued confidence that such disposal can be realized and what those inadequacies imply for this rulemaking. Since 1984, the Commission has expressed, and later affirmed, its confidence that deep geologic disposal is feasible. Nothing since has emerged to lessen the NRC's confidence in the technical feasibility of repository disposal. That much is not in dispute. As this rulemaking notes, considerable additional scientific and engineering experience and evidence has reinforced the Commission's initial finding to this effect-much of it contributed quite ably by NRC scientists and engineers and their colleagues at the CNWRA. Also among the reasons for greater confidence are findings and recommendations by the President's Blue Ribbon Commission for America's Nuclear Future, which endorsed disposal in deep geologic repositories when selected using a consent-based process. (0532-7 [Kotra, Janet])

Comment: [First in 1984]"The passage of the Act provides evidence of a strong national commitment to the solution of the radioactive waste management problem." And [then in 1990] "Congress has aggressively demonstrated in both the NWPA of 1982 and the NWPAA of 1987 that is committed to an orderly progression of the repository program and a resolution of the radioactive waste disposal problem." This statutorily mandated process was to be implemented by the Executive Branch and licensed and overseen by an independent Nuclear Regulatory Commission. At no time during the Commission's deliberations leading to the original Waste Confidence Decision in 1984, its update in 1990, or its deferral in 1999, did the respective Commissions involved contemplate that the process laid out in statute would become corrupted and unworkable. Nor did the Commission anticipate that a subsequent Commission would later be unable or unwilling to carry out its statutory obligations as laid out in law. And sadly, no prior Commission could possibly have anticipated that a future chairman of a once revered independent safety regulator would subvert the Nation's Nuclear Waste Law and resign from the Commission in disgrace. (0532-8 [Kotra, Janet])

Comment: Yet, as documented in the recent ruling of the second highest Court in the land, this is precisely what has transpired. Surely, now, the Commission must, at a minimum, consider whether, in the absence of an Executive Branch willing to carry out a Nuclear Waste Law enacted by the U.S. Congress, there can exist any confidence that this or any other statutorily mandated path to a repository disposal solution, will, in fact, be realized. Therefore, because of these developments, the Commission should acknowledge that while it has solid confidence in the technical feasibility of deep repository disposal there exist little or no grounds for confidence in the social and political process necessary for it to be realized, pending new, comprehensive action by the Congress. (0532-9 [Kotra, Janet])

Comment: Spent fuel should be maintained such that it may be retrieved for future use as a potential resource. (0534-3 [Vetter, Richard])

Comment: No safe and secure national nuclear waste geological repository exists, nor can nuclear fission be safely reverse engineered. (0537-1 [Commenters, Multiple])

Comment: The federal government has failed to provide safe and secure nuclear waste solutions, as promised by 1998. Today the U.S. has over 72,000 tons of high level radioactive toxic waste which must be stored for tens of thousands of years. (0537-2 [Commenters, Multiple])

Comment: I am grateful we have a source of energy that supplies so much electricity locally with such a low environmental impact. It is my wish however that we invest more into research and development and eventually find a permanent solution to the nuclear waste issue rather than have on-site storage. (0538-2 [Kaul, Michelle])

Comment: I support the call by the Sierra Club for the NRC to create a safe, long-term solution for managing and disposing of the nation's spent nuclear fuel and high level radioactive waste. (0540-2 [Watland, George])

Comment: The Sierra Club's bottom line conclusion: There remains no alternative but to continue the hard and necessary work of "creating a safe, long-term solution for managing and disposing of the nation's spent nuclear fuel and high level radioactive waste," in the words of the Nuclear Regulatory Commission's Blue Ribbon Commission, which reported in January 2012. (0540-8 [Watland, George])

Comment: Countries like Finland face this very dangerous problem by creating underground storage carved out of solid rock. (0541-3 [Justesen, Evelyn])

Comment: Rule Package, FR 56794, first column towards bottom. The conclusion that repository disposal is feasible within 60 years after reactor operating life is correct, but the best reason for that conclusion should be added. The Yucca Mountain license application and NRC staff review of that application have shown a safe repository to be technically feasible. (0544-17 [Enriquez, Elizabeth])

Comment: GEIS Section 1.1, p. 1-3, lines 5-18. This is a discussion of the court cases that led to the ruling that an EIS was needed to address the effects of failing to secure permanent disposal. It is noted that the law suits were filed "in response to the 2010 [waste confidence] rulemaking." In essence, the Court said that not ever having a geologic repository is a reasonable possibility that must be addressed in an EIS because the NWPA defined path to a geologic repository is not currently available. The lawsuits that led to the 2010 waste confidence rule being overturned would likely have never been filed had NRC not made the unilateral decision to terminate Yucca Mountain licensing. In the interest of openness and transparency, the GEIS should recognize the fact that the Court of Appeals DC Circuit has now ruled that the unilateral actions directed by the former NRC chairman to suspend the Yucca Mountain licensing process were illegal. A writ of mandamus has been issued ordering NRC to restart the licensing process; and NRC has publicly stated it intends to complete and release the final Yucca Mountain Safety Evaluation Report. It is revisionist history to not recognize NRC's actions that led to the most recent waste confidence law suits and the eventual court ruling remanding the 2010 waste confidence rule. (0544-22 [Enriquez, Elizabeth])

Comment: On July 5, 1977 the Nuclear Regulatory Commission denied a petition of the Natural Resources Defense Council to conduct a rule making proceeding to determine whether radioactive wastes could be generated in nuclear power reactors and subsequently disposed of without undue risk to public health and safety.¹ [footnote 1 text: U.S. Nuclear Regulatory Commission. 1977. Natural Resources Defense Council: Denial of Petition for Rulemaking. Federal Register vol. 42, no. 128, p. 34391, et seq. July 5, 1977] The Commission stated in its denial that, as a matter of policy, it " ... would not continue to license reactors if it did not have reasonable confidence that the wastes could and would in due course be disposed of safely." Not long thereafter, the State of Minnesota and the New England Coalition on Nuclear Pollution challenged license amendments that permitted expansion of the capacity of spent fuel storage pools at the Prairie Island and Vermont Yankee nuclear power plants, respectively. In *Minnesota v. Nuclear Regulatory Commission*² [footnote 2 text: U.S. Court of Appeals for the District of Columbia Circuit. 1979. *Minnesota v. Nuclear Regulatory Commission*. No 78-1269. May 23, 1979], the U.S. Court of Appeals for the District of Columbia Circuit in 1979 rejected a ruling of the Atomic Safety and Licensing Appeal Board that under the National Environmental Policy Act, the requirement for a reasonable probability that when the plants' licenses expired an alternative means of disposing of the nuclear wasters would be available, found that such a finding was satisfied by a previous policy determination by the full Commission stating that alternative spent fuel repositories should be presumed to be available when needed. In rejecting this ruling, the Court of Appeals found that this policy statement did not suffice as the finding required under the National Environmental Policy Act, and directed the Commission to consider the question anew, in either an adjudicatory or informal proceeding. The Court of Appeals specified that the questions to be resolved in such a proceeding are (1) whether an alternative fuel disposal technology is reasonably likely to be developed by the expiration date of the plants' licenses, or if not (emphasis added), (2) whether there is reasonable assurance that the fuel can

be stored safely in the plants' spent fuel pools until an alternative technology is reasonably predicted to become available. (0544-3 [Enriquez, Elizabeth])

Comment: GEIS Section B.2.1, p. B-3, lines 30-36 states, "The NRC's review did not identify any issues that would challenge the feasibility of geological disposal." This is based on the analysis contained in Technical Evaluation Reports issued by NRC regarding Yucca Mountain Repository in the areas of safety before and after permanent closure. It should be noted that NRC is now under a writ of mandamus to restart the Yucca Mountain licensing process and NRC announced it will complete the Yucca Mountain Safety Evaluation Report. This GEIS should make a stronger statement about the safety of geologic disposal based on its Yucca Mountain review and if the Yucca Mountain Safety Evaluation Report is available at the time of this Final GEIS, it should be referenced instead of the Technical Evaluation Reports. (0544-31 [Enriquez, Elizabeth])

Comment: While it is agreed that the Yucca Mountain license application and NRC's review showed no technical or safety reasons that a repository could not be developed, the argument that the public support for the feasibility of geologic disposal can be drawn from the experience gained in the review of the Yucca Mountain license application is preposterous. Political actions to prevent the Nuclear Regulatory Commission staff from publishing their regulatory findings serves instead as an omen portending failure should any other repository program get near to the goal of demonstrating that a repository can be developed safely. The recent announcement that NRC will complete the Yucca Mountain Safety Evaluation Report does not change the fact that political manipulation occurred and the restart of the Yucca Mountain licensing process was forced by a court ordered writ of mandamus. (0544-32 [Enriquez, Elizabeth])

Comment: In a concurring opinion, Judge Tamm emphasized that the findings ordered by the court are required by the National Environmental Policy Act and the Atomic Energy Act, and that if the Commission determined that an alternative means of spent fuel disposal is not reasonably expected to be available when the plants' operating licenses expire, the question is then whether the use of spent fuel pools is an acceptable disposal method over an indefinite period of time. The order of the points made by Judge Tamm is significant. The question of whether the use of spent fuel pools was an acceptable method over an indefinite period would only be relevant after the Commission had determined that an alternative means of spent fuel disposal was not reasonably expected to be available when the plants' operating licenses expired. In Judge Tamm's words: "I write separately to emphasize my belief that section 102(2)(C) of the National Environmental Policy Act of 1969 and section 103(d) of the Atomic Energy Act of 1954, mandate the determination that the Commission identified in this case. In addition, if the Commission determines it is not reasonably probable that an offsite waste disposal solution will be available when the licenses of the plants in question expire, it then must determine whether it is reasonably probable that the spent fuel can be stored safely onsite for an indefinite period. Answers to these inquiries are essential for adequate consideration of the safety and environmental standards of the relevant statutes." The original Waste Confidence Decision and the first two updates shared an attribute that made them meaningful as a response to the Natural Resources Defense Council petition and the Minnesota lawsuit; it could be said that the Federal Government at least endeavored to be responsive to the situation that led to the petition and lawsuit. As long as there was a meaningful commitment to disposal, plagued as it was by inefficiency and missteps, a defensible argument could be made that there was evidence of a solution pathway. With the third update of the Waste Confidence Decision in 2010 along with NRC's illegal unilateral action to terminate the Yucca Mountain licensing process, that commitment and evidence was erased. (0544-4 [Enriquez, Elizabeth])

Comment: Technical Feasibility vs Repository Availability Appendix B of the GEIS purportedly addresses two relevant topics from earlier versions of Waste Confidence decisions: the technical feasibility of a repository and availability of repository capacity. The discussion on Technical Feasibility of a Repository suggests that there is scientific consensus that safe geologic disposal is achievable with currently available technology, that it is viable, and that acceptable sites can be identified. Unfortunately, none of those arguments is a sufficient basis for a defensible demonstration that disposal capability will be available in the United States on a schedule consistent with reasonably short storage periods following reactor license termination. Arguments about siting repository facilities in other countries are of little relevance in the United States' situation. Local communities in foreign countries have autonomy in opting to participate in repository development. In the United States the willingness of local communities appears to be overridden by State primacy, and to date, no state has shown willingness to even be considered for repository siting. Further, the stringency of the U.S. regulatory structure is not comparable to that of other countries. (0544-6 [Enriquez, Elizabeth])

Comment: The 2010 NRC waste confidence rule was remanded by the Court of Appeals for the DC Circuit in 2012 primarily because the NRC's analysis leading to that rule did not evaluate the environmental effects of failing to secure permanent disposal. The lack of a permanent disposal option is the direct result of the heads of the NRC and Department of Energy (DOE) taking steps to terminate the Yucca Mountain Repository despite the requirement to continue the program under Federal law in the Nuclear Waste Policy Act (NWPA). In essence, the Court said that not ever having a geologic repository is a reasonable possibility that must be addressed in an EIS because there is no certainty to the NWPA defined path to a geologic repository. The lawsuits that led to the 2010 waste confidence rule being overturned would likely have never been filed had NRC not made the unilateral decision to terminate Yucca Mountain licensing. (0544-7 [Enriquez, Elizabeth])

Comment: Our society is moving in a dark direction when, rather than using our resources to make our mechanized industrial complex of energy and manufacturing safer for all of us, we are following a path to the bottom... profit and mediocrity take the place of common sense and safety for all of our lives. The easiest road seems to be to maintain status quo, even when common sense tells us that it will not lead to our best results in the long-term. This road is supported and fed by those who are most vested in the shorter-term outcomes, without concern for the long-term ones. The more difficult road is that which takes the most short-term resources to form, because it looks at the long-term outcome and forms its basis therein. The easy road is the road to oblivion over time. We are now seeing the consequences of taking the easy road for generations; in skyrocketing cancer and disease rates in our country; in super storms that are just beginning to reveal the onset of symptoms of climate change that scientific consensus is overwhelming that is man-made; in vesting our collective focus on economic profit-motives over protection and safety considerations, that result in all-of-theaforementioned consequences. It is time that our mode of corporate, legislative, regulatory, and social behavior put priorities where we all know that they must reside: --Safety of human life first; --Safety of human social interaction next; --Safety of human economics next. In other words, all the money in the world will not accomodate a wish for millions of unhealthy lives into healthy lives. (0546-1 [Pace, Gregory])

Comment: The NRC should redouble efforts with other federal agencies and Congress to develop a permanent spent fuel repository. (0548-4 [Gibson, Bruce])

Comment: Finally, as you are certainly aware, a nationwide solution for permanent spent fuel storage has been delayed for far too long. The permits for DCPD did not imagine that the

indefinite storage of spent fuel onsite -and such storage is an obvious added risk to residents of this county. We would again urge the NRC to accelerate work with other federal agencies and Congress to advance a permanent solution. (0548-9 [Gibson, Bruce])

Comment: Additionally there is strong international scientific consensus that geologic disposal is the best solution to permanently isolate spent nuclear fuel from the public and the environment. Studies by the National Academy of Sciences and the International Atomic Energy Agency have confirmed this conclusion (0549-2 [Williams, Robert])

Comment: That solution cannot be abandonment in a deep underground dump. (0552-1-12 [Macks, Vic])

Comment: No storage facility has yet been designed that can contain radioactive waste for such periods of time. (0552-1-3 [Macks, Vic])

Comment: No technology has yet been proven capable of containing radioactive waste for the hundreds, thousands, or millions of years necessary to protect people and the environment. We have no experience, beyond 70 years with how highly radioactive spent fuel rods will behave. The U.S. has failed even to identify a viable site for a nuclear waste repository despite two decades, billions of dollars, and a federal mandate to do so. (0552-1-7 [Macks, Vic])

Comment: Notwithstanding, our nation must also pursue an agreed-upon site for permanent disposal. (0555-5 [Contreras, Raquel])

Comment: For over three decades, the NRC has assumed that an offsite permanent repository would be available for licensees to send their spent fuel at the end of the reactor's operations. The assumption has never had any factual basis, and history has proved it was flatly wrong. Nonetheless, the faulty assumption has been embedded in NRC rules, effectively preventing state officials and the public from litigating spent fuel issues in licensing proceedings. In 2012, the D.C. Circuit Court ruled that NRC could no longer presume the existence of a repository and must do an EIS to address the impacts on public health and safety if spent fuel is not deposited in a repository. (0556-1-2 [Lampert, Mary])

Comment: NRC should go back to the drawing-board with a new EIS. Instead of assuming that spent fuel can be stored safely forever, NRC should examine the problem, and provide a proper analysis regarding:

- The probability that a repository for spent fuel will be successfully sited.
- The probability that a successfully sited repository will actually contain radiation and the consequences if it does not.
- The real public health and environmental consequences that may occur if a repository is not sited and storage remains on site, using: site specific analyses; credible and supported assumptions; and PRA using quantitative factors, supplemented by qualitative factors, and a consequence code updated from lessons learned at Fukushima. (0556-3-8 [Lampert, Mary])

Comment: Having said that, it is incumbent upon the Department of Energy to find and implement long term solutions for spent fuel storage. The public needs to be educated on the issue of safe storage of nuclear fuel waste. The DOE needs to support the President's Blue Ribbon Commission recommendations for development of a long-term storage solution. Diablo Canyon is a critical asset in our regions electrical grid and needs to have the long term spent fuel storage system resolved for its longer term viability. (0557-2 [Johnson, Ray])

Comment: While the NRC may hope that a permanent repository for spent nuclear fuel is operational in 60 years, given the history and status of Yucca Mountain, notwithstanding directives of Congress, that belief is not universally held. (0558-3 [Strell, Ethan])

Comment: The Savannah River Site (SRS), located near Aiken, South Carolina, is a Department of Energy facility that historically produced tritium, plutonium, and other nuclear materials. Past disposal practices at the SRS resulted in significant site contamination, and the SRS was placed on the Environmental Protection Agency's National Priorities List in 1989. Site investigations identified contamination in groundwater, sediments and surface water that included arsenic, cadmium, lead, mercury, plutonium, radium, and tritium, among others. Multiple groundwater plumes were discovered, and remediation will take decades to complete. To avoid the risk of similar contamination due to at-reactor or away-from-reactor storage of radioactive spent nuclear fuel, DNR urges the approval and construction of a permanent, geologic repository such as the proposed Yucca Mountain Repository in Nye County, Nevada. (0560-2 [Vejdani, Vivianne])

Comment: Frankly, I can't think of many WORSE places to store nuclear waste than most of the places we are currently storing it nationally: Invariably near population centers, because that's where the energy was/is produced. (0562-10 [Hoffman, Ace])

Comment: Geologic storage, if we choose that route, will not be easy and will not be risk free. And we're nowhere near it at this point. (0562-5 [Hoffman, Ace])

Comment: You are urged to locate, study, and approve a storage area for spent nuclear fuel in the U.S. (0566-1 [Tocornal, John])

Comment: Find a way to store low level and high level nuclear waste on a permanent basis (nearly impossible in principle, since humans only live for 70-80 years or so). Find a safe storage area ASAP. Build it. Use it. (0566-6 [Tocornal, John])

Comment: Nuclear fuel has been stored at reactor sites in the United States for many years and it can remain there for many more years; however, I believe Congress should act to address a permanent storage facility or consider recycling options in a more appropriate and permanent way. (0568-1 [Michael, Edward])

Comment: I would love for you to locate, study, and approve a storage area for spent nuclear fuel in the U.S. which is NOT located adjacent to an operating nuclear generating facility. Since this technology was initially developed for the military, it makes sense to locate it on a military reservation, downwind of the USA, inland, but near the East Coast. (0569-1 [Hulstrunk, Matt])

Comment: The nuclear waste problem cannot be solved by our present technology. We should therefore scrap nuclear energy technology and focus our attention to figuring out a way to safely store the existing nuclear waste (oxymoron). (0572-1 [Fisher, Peter])

Comment: [T]he Department of Energy has a responsibility to make good on its commitment to receive and safely store the spent fuel for the long term. By doing so, locally stored spent fuel could be safely removed to a single or regional locations controlled by and protected by our national government. (0574-2 [French, Walter])

Comment: We have multiple nuclear power sites in the USA, not having a depository for spent fuel reflects negligent management. Let's make this right. Our children's lives are on the line. California is earthquake country, this is a disaster waiting to happen. (0583-2 [Connoy, Gina])

Comment: No one wants spent fuel storage. Why in heaven & hell's names was there no SAFE TRANSPORT & STORAGE established before now when it becomes so critical. (0594-1 [Individual, Anonymous])

Comment: While nuclear energy is a vital part of our state's electricity portfolio and economy, we recognize the need to address the transportation, storage and disposal of used nuclear fuel. It is the federal government's statutory responsibility to remove used fuel from nuclear energy facilities. Under federal law, this was to have started in 1998-15 years ago-but so far, the federal government has not moved a single used fuel assembly. (0598-5 [Wicks, Tonja])

Comment: Additionally there is strong international scientific consensus that geologic disposal is the best solution to permanently isolate spent nuclear fuel from the public and the environment. Studies by the National Academy of Sciences and the International Atomic Energy Agency have confirmed this conclusion. (0601-2 [Manfredi, Timonhy])

Comment: Section 1. The City of San Clemente formally requests the creation of a repository to provide safe storage of nuclear waste. Section 2. Once complete the City of San Clemente requests that the spent fuel rods stored onsite at SONGS be prioritized for relocation to the repository as soon as it is safe to do so, in light of a) the geographic conditions unique to SONGS, b) the dense population surrounding SONGS, and c) the fact that SONGS is being decommissioned. (0605-2 [Baade, Joanne])

Comment: Now is when public safety should be paramount. (0609-6 [Leon, Vicki])

Comment: In June 2012, the U.S. Court of Appeals for the D.C. Circuit vacated the NRC's 2010 Waste Confidence Decision and Temporary Storage Rule and remanded them to the agency for study of the environmental impacts of storing spent fuel indefinitely if no permanent nuclear waste repository is licensed or if licensing of a repository is substantially delayed. Spent nuclear fuel remains highly dangerous for prolonged periods. It has long-lived radioactive materials in it that can seriously contaminate the environment and harm public health if released. Additionally, spent nuclear fuel contains plutonium-239, a radiotoxic element that can be used to make nuclear weapons if separated from the other materials in the fuel. Plutonium-239 has a half-life of over 24,000 years. The development of nuclear power has gone on in this country for at least six decades with the federal government promising that it would soon find a permanent repository for the highly radioactive waste produced by the reactors. It has repeatedly failed to live up to that promise, putting production ahead of disposal issues. The confidence, that has been shown in the past, has not proved to be very trustworthy. Therefore many more years needs to be devoted to looking into securing this nation's spent nuclear fuel waste stream. (0610-4 [Breachin, Vernon])

Comment: The NRC has failed to fully examine: --the probability or improbability that a geologic repository will be successfully sited for storage of spent fuel including high burn up fuel; (0611-10 [Shapiro, Susan])

Comment: [The NRC has failed to fully examine] the probability or improbability a repository may leak radiation (0611-11 [Shapiro, Susan])

Comment: Burial is the only allowed method of disposal of nuclear waste, yet burial for geological reasons untenable. Since Reagan's Executive Order the only permitted method of disposal of radioactive waste has been geologic burial. However to date no safe and secure burial systems have been indentified, developed and constructed by the NRC. Yucca Mountain in Nevada failed because it was found to be geologically unsound for 10,000 years. Current NRC Commissioner Allison McFarland's own study found that Yucca Mountain was to unstable and porous to contain radioactive waste. The Court's held storing 1000's of tons of radioactive waste underground for 100's of year was not safe to human health, and our drinking water supplies. Prior attempts at geological burial have also failed. The Salt mines in Kansas were also found to also be geologically unsound due to prior oil, gas and coal mining drilling making the ground unstable. Imagine what fracking has done to de-stabilize the ground through out the United States today. (0611-26 [Shapiro, Susan])

Comment: Human knowledge is limited, we do not know and cannot know the results of 100's or 1000's of years fission from nuclear waste will have on any containment structures. Yet, to date no safe burial location has been or can be identified because there is no place on earth that is geological stable enough to sequester radiation for hundred of thousands years. Already billions of taxpayer dollars have been wasted on failed attempts to find a national repository. The NRC must accept the reality that geological repository is not a sustainable option. There is not now or nor will there ever be safe burial ground for large quantities of radioactive waste. (0611-28 [Shapiro, Susan])

Comment: The situation in the state of Illinois is such that we have the largest number of reactors with no real solution to the issue of nuclear power plant waste, except to store it at site. With the failure of the federal government to have sane foreign policy or domestic policy, these large masses of spent nuclear waste are NOT SAFE. This is not a question of the soundness of design of the cask that the spent nuclear waste is stored in. It's a question of the fact that it is there at all. (0612-3 [Takarabe, Tamae])

Comment: I find it very difficult to believe anyone can, in good conscience, state that we can safely continue to create nuclear energy at Diablo Nuclear Power Plant when there is no known safe way to dispose of such dangerous waste material. (0613-1 [Blake, Elisabeth])

Comment: Our town shares the same zip code as San Onofre, and now you want us to share the nuclear waste, possibly forever. When the plant was built, you promised that the waste would never remain here, and now you are reneging on that promise. (0618-2 [Johnson, Roger])

Comment: The Tribe has a number of concerns regarding the draft GEIS. And, for reasons we articulate below, we have grave concerns that the conclusions made in the draft GEIS will become the default policy of the United States government-that spent nuclear fuel can safely stored on-site indefinitely-and that there will be no reason to enforce current law (i.e., the Nuclear Waste Policy Act) or pursue new legislation (i.e., recommendations of the Blue Ribbon Commission) that would require the removal of spent nuclear fuel from Prairie Island. (0619-1-1 [Mahowald, Philip R.])

Comment: When nuclear power plants were originally constructed, it was understood by the public and host communities that the plants would operate for 40 years and then, following decommissioning, the site would be released for some other purpose. Under the NRC's short-term scenario, the PINGP and its ISFSI will have been on Prairie Island for at least 121 years, with one license renewal, or 141 years with two renewals. Under the NRC's longer-term scenario, the timeframe would be 221 or 241 years. This was not what was contemplated when

PIN GP Units 1 and 2 were approved, or when the ISFSI was approved. Because the plant is built and the ISFSI is constructed there is nothing host communities can do. (0619-1-11 [Mahowald, Philip R.]

Comment: The draft GEIS optimistically states that the NRC believes that a repository could be available by the end of the short-term (60 years) because the DOE has expressed its intention to provide repository space by 2048. The 2048 date was included in the DOE's strategy to implement the BRC's 2012 recommendations. There is nothing to suggest that the DOE will meet this goal; legislation that could implement the BRC/DOE's recommendations is stalled in the Senate with no companion version in the House. (0619-1-12 [Mahowald, Philip R.]

Comment: We remain frustrated and discouraged that the "temporary" storage facility has become permanent storage. The PINGP ISFSI license will be renewed repeatedly during the longterm and indefinite storage terms, because to deny a license renewal application is, in effect, the same as approving the license renewal application. Denying the application does nothing. The waste stays on site. (0619-1-6 [Mahowald, Philip R.]

Comment: That it is also feasible to have a mined geological repository within 60 years of a reactor's post-operational period repeats the same "confidence" expressed decades ago that a safe and secure repository/dump for the waste then on hand and for the foreseeable future would exist. (0620-3 [Rivera, Evelyn])

Comment: In 1977 my first child was born. At about that same time I began reading about nuclear power plants and nuclear energy in particular. I was horrified then. Particularly about the spent fuel and how or where it was ever going to be safely stored. But I read that even though the technology hadn't been invented then to take care of the waste, research was ongoing and scientists were sure to develop a solution soon. (0625-1 [Mandrell, Rebecca])

Comment: Well, nothing has been developed to store this waste safely and it appears there can never be a safe answer. (0625-3 [Mandrell, Rebecca])

Comment: First, Citizens like me have no confidence that spent nuclear fuel can be safely stored, short of finishing Yucca Mountain and sending it there. (0628-1 [Perkins, V.E.]

Comment: [T]he obstacles to any state (like Nevada) accepting a geologic depository will never disappear. Unless Congress passes legislation FORCING Nevada to accept a permanent depository, (which does not seem too likely), it will not do so. (0628-5 [Perkins, V.E.]

Comment: The only responsible solution is to bury this waste in a geologically safe repository below ground. Finland and Sweden are doing this. We almost did it at Yucca. However, that site had geological and political complications making it a poor choice. The search must continue for a safe site. (0633-2 [Kurz, Carol])

Comment: How irresponsible we have been in creating nuclear waste without having a means of its safe disposal. Perhaps once northern Japan becomes too dangerous for human occupation, it could be used for worldwide nuclear waste disposal. I have no confidence that you will come up with a better idea. (0635-2 [Bernhoft, Eric])

Comment: I am not a scientist but can grasp that we cannot take shortcuts with waste. I suggest continued study with experts, communities, agencies, legislators and all other

stakeholders involved in transparent process to address the waste legacy that will plague generations. (0636-5 [Bluestein, Bonnie])

Comment: But we must first raise again the primary statement in our December 31, 2012 letter commenting on the scoping process for the Waste Confidence Environmental Impact Statement that the Commission must, as its first principle, continue to hold to its long-established tenant that it does not endorse the indefinite on-site storage of Spent Nuclear Fuel (and Greater-Than-Class-C Waste -SNF/GTCC). (0637-2 [Norton, Wayne])

Comment: The Commission and staff should remember that after publication of the rule and GEIS, it will still be responsible for ensuring that its future regulatory programs and policies do not foster indefinite on-site storage, either intentionally or unintentionally. We are aware that the Commission does not set national policy. It must be careful not to do so passively by ignoring its role in setting safety policy and standards for the nation's nuclear licensees and contractors. In this vein, the U.S. government, currently represented by the Department of Energy, is the contractor that is obligated to remove the material from licensee ISFSIs. The Department is long in default of its obligations. The Commission must ensure that its own safety and security policies do not encourage future default into an indefinite timeframe. Such future defaults act to the detriment of the Commission's stated intention. We continue to encourage the Commission and staff to embark upon an analysis and statement of the best practices for storage while we wait for the federal government to fulfill its obligations to your licensees as well as the nation's ratepayers and taxpayers. (0637-5 [Norton, Wayne])

Comment: Of course public safety is not on the NEI's radar, but it needs to be at the center of the waste issue. (0640-9 [Geary, B.])

Comment: Notwithstanding, our nation must also pursue an agreed-upon site for permanent disposal. (0642-5 [Picking, Brian])

Comment: Intelligent people have already spent many hours and millions of U.S. taxpayer monies proving that current U.S. temporary storage of spent nuclear fuel is safe. We must not continue to waste tax monies on continued studies for political reasons. (0644-1 [Chunglo, Steve])

Comment: The 1984 first "Waste Confidence" decision, asserting that safe geologic disposal is technically feasible, that a repository would be available, and the following \$10 Billion U.S. dollar expenditure for mining and testing of the Yucca Mountain repository were all a very successful use of tax and utility funds. We need to get the Yucca Mountain Repository back on track, approve the license, complete the site, and move the spent fuel to the repository. The U.S. needs to quit squandering Tax and Utility funds on political grandstanding which has taken our country technically backwards, and get back to becoming a world leader in the complete nuclear fuel cycle which we lost in the 1970s. (0644-2 [Chunglo, Steve])

Comment: APV strongly disagrees with the NRC's plan for "indefinite storage" at reactor sites. It is ridiculous to ask the public to believe that these deadly materials, many with radioactive half-lives that make them dangerous hundreds of thousands of years into the future, can be left lying around without a serious plan for their ultimate disposal. (0648-5 [Price, Scott])

Comment: Put public safety ahead of industry profits; prevent the NRC from allowing nuclear waste to be stored on site indefinitely. Nuclear waste is forever. (0650-1 [Crowley, Lawrence])

Comment: The reality of being close to safe SNF storage plan has been a con job from day one. (0652-3 [Maurer, William])

Comment: Face it, the current nuclear reactor sites are and will continue to be de facto nuclear waste dump sites for an indeterminable period of time into the future. The NRC, DOE and nuclear energy industry need to man up and tell the truth....you're no closer to having a realistically safe storage plan for the long term (100 + years) or the indefinite term, than you were 50 years ago. (0652-5 [Maurer, William])

Comment: It is time to stop the nuclear waste con and make it a national priority to find real solutions to stop this ticking time bomb before it is too late. (0660-5 [Headrick, Gary])

Comment: Make it a national priority to come up with real solutions to long term nuclear waste storage[.] (0660-6 [Headrick, Gary])

Comment: The repository should be designed to permit ongoing monitoring of containers to prevent leaks into our land, water and air and designed for retrieval and repackaging if leaks occur. Replaceable filters will be used to capture radioactive gas. Ongoing radiation monitors will be used on site as well as a citizens monitoring network in the surrounding communities. A system to deter wildlife will be in place powered by a renewable energy system. Site will be well marked to deter visitors and explanation of site posted in all languages. Site will be well guarded. Site may include separation of dry cask storage waste from liquid/ transuranic wastes to promote easier monitoring and replacement of containers. Repository will not be sited until all nuclear power plants are closed and the generation of nuclear waste at commercial facilities ceases. Time line for this is five years. (0662-9 [McClintock, Francene])

Comment: Why can't it be more than adequately wrapped and packaged to insure safe shipping, protecting it from accidents of any kind. kind, shipped. Then to be stored underground in New Mexico with the rest of the Nuclear Waste. (0664-1 [BojeLebs, Nannette])

Comment: NRC Chairman, Allison Macfarlane, recently expressed in an interview - "I encourage countries embarking on nuclear power to make sure that they have a plan for disposal, before they turn on a reactor!" So ever-mindful of ENVIRONMENTAL JUSTICE, the D.O.E. or our state MUST locate a suitable remote repository for this waste when it's SAFE to transport away from San Onofre. (0665-5 [van Thillo, Grace])

Comment: When our organization was formed over 44 years ago, in response to plans to construct a nuclear plant on the NH Seacoast, we were told confidently that the nuclear industry could handle this waste and that the government would come up with a permanent solution to isolate it for tens of thousands of years. The NRC's "waste confidence" principle was properly struck down by a federal court because, some 60 years into the commercial atomic age, it is patently obvious that there is no foreseeable "solution" for long-term radioactive waste storage that is scientifically defensible, environmentally responsible and publicly acceptable. (0680-1 [Bogen, Doug])

Comment: [T]he Department of Energy has a responsibility to make good on its commitment to receive and safely store the spent fuel for the long term. By doing so, locally stored spent fuel could be safely removed to a single or regional locations controlled by AND protected by our national government until a cost effective way of recycling portions of the stored fuel can be determined and realized. (0682-3 [Adam, Peter])

Comment: [T]he Department of Energy has a responsibility to make good on its commitment to receive and safely store the spent fuel for the long term. By doing so, locally stored spent fuel could be safely removed to a single or regional locations controlled by AND protected by our national government until a cost effective way of recycling portions of the stored fuel can be determined and realized. (0683-3 [Nelson, Bob])

Comment: It is also important to note that the Waste Confidence Decision and Rule depends on a finding that *disposal* capacity will be available. Measurable progress is being made in several countries toward development of a repository as a prudent and viable long term strategy for spent fuel and high-level waste management. A repository is currently prescribed by the Nuclear Waste Policy Act. Deep geologic repositories have been accepted for decades by international experts as a cornerstone of any spent fuel management paradigm. (0685-9 [Davis, Ed])

Comment: It is commonly known that there is no place in the US that currently can provide for the long term storage of the nuclear waste the ancestors of future generations are creating today. The first and only such repository in the world is Onkalo, Finland. The planning for Onkalo began in 1994 and excavation began in 2004. The projected completion of phase 4, the encapsulation and burial of areas filled with spent fuel is projected to begin around 2020. The estimated cost of this project is about 818 million Euros. The State Nuclear Waste Management Fund has currently saved approximately 1.4 billion Euros from charges paid by customers for generated electricity. This cost should be paid for by the industry owners, before profits are distributed to shareholders and not charged to the users of electricity. It is a cost of production that should not be paid for by the government, but the businesses who created the expense. Onkalo is expected to accept canisters of spent fuel for about 100 yrs; around 2120. At that time, the site will be buried and the access tunnel sealed, for Eternity. In 2012, The Royal Institute of Technology in Stockholm Sweden published research suggesting that the copper capsules designed to hold the fuel rods are not as corrosion safe as they were claimed to be. Remedies for this are being studied. Already the world's only repository is needing to be upgraded. Released in 2010, the documentary film INTO ETERNITY's director Michael Madson interviews the Onkalo experts for answers to important questions: How much waste will there be to store? How do you know it can be safely stored for 1000. 100,000 yrs? How long can we keep creating nuclear waste? Can we guarantee even when we store it in bedrock that the earth will remain stable? Can we insure future generations won't disturb Onkalo? Why should we be afraid of human intrusion into Onkalo? Is it possible another Ice Age might occur? What if the knowledge of the existence of Onkalo is lost? Will there ever be another world war like the two in the 20th century that might disturb this site? How many of these sites will the world need? How much will the total cost be? Who should pay these costs? The answers to these questions are critical and need to be taken seriously in making the decision about not continuing the mistakes of the past - the development of nuclear power for providing electricity. Please view this film right away and become educated. When asked if the designers and scientists working on Onkalo had a message for the future generations- their response was: Stay Away; You should not have come to this place; Create a better world for the future." (0686-14 [Malboeuf, Simone])

Comment: The notion that the Federal Government should build/fund a repository for the waste products of this industry that has been highly profitable to shareholders over the past 60 years at least, is wrong. We, the tax payers, are the ones funding the government. This means we, the electricity users, would be funding the costs of the largest expense for the owners/shareholders of the nuclear power industry. That is the oldest trick in the book. You create the mess. You clean it up. Only, you really can't in this scenario. The mess is too big to

be cleaned up. In addition, the idea that this waste should be buried in the Earth is dangerous. We cannot predict what seismic or other "natural disasters" are in store for the Earth in the future. We can only react to them to the best of our ability. What would be the consequence of a nuclear explosion deep within the bedrock of the earth? Nobody knows, not even the smartest and wisest "scientists", though they may be asked to suggest the probability that nothing bad would happen. If paid enough money, people may say anything which may then be promoted as the "truth". What we do to the Earth, we do to ourselves and our future generations. The Earth is a living organism. How much abuse can its environment take before it reacts in self defense? (0686-17 [Malboeuf, Simone])

Comment: Instead of assuming that spent fuel can be stored safely forever, NRC should examine: --the probability that a repository will be successfully sited --the probability that a successfully sited repository will actually contain radiation --the degree to which a repository may leak radiation, and --the public health and environmental consequences that may occur if a repository is not sited or it ineffectively contains radioactivity. (0687-7 [Wilansky, Laura])

Comment: Radioactive waste in the form of spent fuel is a dangerous long-term problem. As the court described it in *New York v. NRC*, supra, at 474: After four to six years of use in a reactor, nuclear fuel rods can no longer efficiently produce energy and are considered "spent nuclear fuel" ("SNF"). Blue Ribbon Commission on America's Nuclear Future, Report to the Secretary of Energy 10-11 (2012). Fuel rods are thermally hot when removed from reactors and emit great amounts of radiation --enough to be fatal in minutes to someone in the immediate vicinity. Id. Therefore, the rods are transferred to racks within deep, water-filled pools for cooling and to protect workers from radiation. After the fuel has cooled, it may be transferred to dry storage, which consists of large concrete and steel "casks." Most SNF, however, will remain in spent-fuel pools until a permanent disposal solution is available. Id. at 11. Even though it is no longer useful for nuclear power, SNF poses a dangerous, long-term health and environmental risk. It will remain dangerous "for time spans seemingly beyond human comprehension." *Nuclear Energy Inst., Inc. v. EPA*, 373 F.3d 1251, 1258 (D.C. Cir. 2004)(per curiam). Determining how to dispose of the growing volume of SNF, which may reach 150,000 metric tons by the year 2050, is a serious problem. See, Blue Ribbon Commission, supra, at 14. And it is clear that no one really knows what to do with that waste. Again, quoting from *New York v. NRC*, supra, at 474: The delay [in finding a permanent repository] has required plants to expand storage pools and to pack SNF more densely within them. The lack of progress on a permanent repository has caused considerable uncertainty regarding the environmental effects of temporary SNF storage and the reasonableness of continuing to license and relicense nuclear reactors. (emphasis added). (0688-6 [Taylor, Wallace])

Comment: In addition, the Blue Ribbon Commission on America's Nuclear Future has said that we may already be at a point where more than one permanent repository is necessary. As noted in *New York v. NRC*, at this point there is no possibility of finding even one permanent repository in sight. Thus, as we continue to make more spent fuel, the problem becomes worse. (0688-7 [Taylor, Wallace])

Comment: The federal government devotes inordinate amounts of time, money and energy to fighting (and eventually paying) legitimate damage claims by utilities, shutting down ongoing licensing reviews (i.e., Yucca Mountain), and addressing regulatory issues like Waste Confidence. Such efforts would be completely unnecessary if the federal government would simply do its job with respect to used fuel management, as called for by the law. (0689-4 [Boyd, David])

Comment: Strong, bipartisan support remains for carrying out the provisions of the NWPA as passed by Congress decades ago, and your input about NRC funding needs would be valued and helpful in making more timely progress. Such actions will go a long way toward giving our members, other stakeholders, and the public the assurance that the federal government will make good on its obligation. (0689-6 [Boyd, David])

Comment: The Federal government to the detriment and harm of citizens throughout the United States has postponed finding a permanent waste removal site for nuclear waste from its nuclear reactor plants and the Hanford Nuclear reservation where nuclear bombs were produced. (0690-1 [Eisman, Val])

Comment: This country must resolve the issue of where to put our existing waste and fuel pools most empty their rods before we see a Fukushima happen in this country. (0690-7 [Eisman, Val])

Comment: These issues include that there is currently no scientifically demonstrated method nor licensed long term nuclear waste management repository for tens of thousands of metric tons of high-level nuclear waste in the United States[.] (0691-2 [Gunter, Paul])

Comment: There is no public or scientifically demonstrated confidence in a likely permanent repository, or repositories, operable in the foreseeable future that can confidently withstand the tens of thousands of years that radioactive waste will be hazardous. (0691-7 [Gunter, Paul])

Comment: •The NRC's errant efforts allowed petitioners in *New York v. NRC*, 681 F.3d 471 (D.C. Cir. 2012) to argue in their opening brief that "over fifty years after beginning the search for a repository, the United States is no further along in finding [a] permanent disposal solution for nuclear waste than it was in the 1970s." The D.C. Circuit Court in its June 8, 2012, ruling in that case went so far as to declare that "[t]he Commission apparently has no long-term plan other than hoping for a geologic repository." It was that June 8, 2012, ruling, decided against the NRC, that precipitated this waste confidence rulemaking. The NRC's actions and inactions provided the National Association of Regulatory Utility Commissioners (NARUC) with powerful ammunition in its successful action against the DOE seeking to discontinue utility payments into the Nuclear Waste Fund (NWF). Absent NRC's enforcement of its own Licensing Board's denial¹⁶ [footnote 16 text: LBP-10-11 dated June 29, 2010; available in ADAMS (<http://adams.nrc.gov/wba/>) at Accession Number ML101800299.] of the DOE motion to withdraw the Yucca Mountain application- creating a fiction that the NWPA had somehow been repealed and therefore that Yucca Mountain was no longer "[a]pprov[ed] . . . for the development of a repository for the disposal of high-level radioactive waste and spent nuclear fuel,"¹⁷ [footnote 17 text: Public Law 107-200.]-the Secretary of Energy was reduced to presenting "an enormous range of possible costs" as a basis for arguing that utility payments into the NWF should continue. In its ruling, dated November 19, 2013, the D.C. Circuit Court held that the Secretary's "presentation reminds us of the lawyer's song in the musical, 'Chicago,' - 'Give them the old razzle dazzle.'" Had the NRC abided by the NWPA, this entire, expensive, time-consuming litigation would have been avoided. (0692-7 [Skov, Jeff])

Comment: •The US stated preference for highly radioactive waste to be safely disposed in a geological repository. •Enough nuclear spent fuel at present, 70,000 tons, to fill a Yucca Mountain sized repository. •No geological repository anywhere in sight and by the time we identify and approve a single one, we will need two repositories. This estimate is based only on the existing reactors and no new ones producing more waste. (0693-1-4 [Warren, Barbara])

Comment: •Original licensing decisions reflected reactor lifetimes of 40 years. Operating for double that time increases the amount of spent fuel generated and stored on-site. •Over 50 years ago, government promoted nuclear energy by assuring the public that nuclear waste was an easy problem to solve. Instead the public has been forced to accept ever increasing inventories of nuclear waste as the government's default position after failing to site a repository. (0693-3-5 [Warren, Barbara])

Comment: •In just 26 years, the NRC changed its predictions of interim on-site storage from a maximum of 70 years to 240+years +, including indefinitely. (0693-3-6 [Warren, Barbara])

Comment: •A repository is not yet sited and approved and yet we have enough waste today to fill a repository the size of the Yucca Mountain proposal, 70,000 tons. By 2050 even with no new nuclear reactors, we will need 2 repositories. (0693-3-7 [Warren, Barbara])

Comment: The truth is that we do NOT have any viable technology for "safely" storing "spent" fuel. (0695-1 [Fast, Wendy])

Comment: The United State's current stockpile of nuclear waste, about 80,000 tons, will remain toxic for thousands of years and scientists have not found a storage facility that will be able to house the amount of waste we have let alone for the amount of time it will need to be safeguarded from the risks of both natural disasters and outside attacks. (0700-1 [Women's Action for New Direction, Georgia])

Comment: Due to Plate Tectonics a Permanent Indefinite Storage Site does not exist on the Planet. (0701-2 [Wilson, Greg])

Comment: A related concern is that the DGEIS and proposed rule accommodates a default position that would result in the stranding of Spent Nuclear Fuel (SNF) at nuclear plants or Independent Spent Fuel Storage Installations (ISFSI) at scores of locations in dozens of states on a permanent basis. Such an outcome would contradict national policy and commitments as set forth in the Nuclear Waste Policy Act of 1982, 42 USC 10101 et seq., and the Standard Contracts entered into between the U.S. Department of Energy (DOE) and our nation's nuclear utilities,³ [footnote 3 text: 10 C.F.R. Part 961 - Standard Contract for Disposal of Spent Nuclear Fuel And/or High-Level Radioactive Waste.] pursuant to which our nation's utility ratepayers have now paid more than \$37 billion to cover the costs of fees charged under the Standard Contract for a permanent repository for the safe and proper disposal of SNF. (0704-3 [Callen, Ronald C.] [Keskey, Donald L.]

Comment: The history of the nuclear waste repository program is replete with failures and demonstrates, as the DC Circuit found, there should be no assurance there will be sufficient mined geologic repository capacity. 1. The first failed efforts. In 1957-1958, the Atomic Energy Commission (AEC) conducted the first site specific study of the disposal of high-level radioactive waste in salt at Hutchinson, Kansas. Between 1961 and 1963, the AEC conducted experiments at the Cary salt mine at Lyons, Kansas. In 1970 the AEC, along with the Kansas governor, announced tentative selection of the Cary salt mine for a demonstration high-level waste repository. Opposition, primarily by the Kansas Geological Survey, and concerns over conditions in the mine, the presence of numerous oil and gas well in the vicinity, and the fact that there was solution mining at an operating adjacent salt mine operated by American Salt Company forced the AEC to abandoned the site by 1972. Following the demise of the Lyons repository effort, the AEC announced in 1972 that it intended to develop a 100-year Retrievable Surface Storage Facility (RSSF). This proposal was opposed by the Environmental Protection

Agency (EPA) and others because in their view it would divert attention and resources from efforts to find a permanent means of geologic disposal. As a consequence of this opposition the Energy Research and Development Agency (ERDA) gave up its plans for a RSSF in 1975. Between 1975 and 1982, ERDA and the DOE continued to search for potential repository sites in various rock types in the states of Michigan, Ohio, New York, Utah, Texas, Louisiana, Mississippi, Washington, and Nevada. Various degrees of resistance from state and local representatives combined with geological and technical problems stalled efforts to find a repository site. In 1976 President Gerald Ford halted the reprocessing of commercial nuclear fuel. In the following year President Jimmy Carter reinforced the ban on commercial reprocessing and tried to halt the development of commercial breeder reactor development. These actions reinforced the need for prompt development of a geologic repository. In 1977 ERDA also announced that it would accept custody of commercial spent fuel and store it at Away From Reactor (AFR) storage facilities. It never happened. (0706-4-15 [Fettus, Geoffrey])

Comment: 2. The IRG Process[.] In the mid-1970s it became clear that commercial spent fuel reprocessing was uneconomical, environmentally unsound, and represented a serious proliferation risk. President Gerald Ford refused to subsidize the completion of the Barnwell reprocessing plant, and then President Jimmy Carter pulled the plug on reprocessing. The actions by Presidents Ford and Carter gave a new urgency to finding a site suitable for geologic disposal of both spent fuel and high-level radioactive waste. In the late 1970s President Carter initiated an Interagency Review Group (IRG) process to solve once and for all the nuclear waste problem in the United States. The IRG process involved numerous scientists, extensive public involvement, and a consultation and concurrence role for the states. The outcome of the IRG effort was a two-track program. The DOE was tasked with the responsibility for identifying the best repository site in the country, and the EPA and the NRC were tasked with developing nuclear waste disposal criteria against which the selection and development of the final repository site would be judged. 3. The Nuclear Waste Policy Act[.] In 1982, Congress enacted the NWPA, which embodied in law the principal recommendations that grew out of the IRG process, including a commitment to geologic disposal, two repositories, and characterization of three sites before final selection of the first repository. The NWPA established a comprehensive program for the disposal of spent nuclear fuel and high-level radioactive waste (HLW) from the nation's commercial reactors and nuclear weapons complex. At the time the NWPA was passed nearly 25 years ago, the U.S. Government enjoyed fairly widespread support from within the Congress, the environmental community and state governments for the site selection and development process proposed by the IRG. Now, decades later, the U.S. Government has little, if any, support from the State of Nevada, and virtually no public support from the environment and public health community for the proposed Yucca Mountain project. (0706-4-16 [Fettus, Geoffrey])

Comment: 4. What else went wrong? A whole host of things, but suffice to say that over the last twenty years, a substantial segment of the environmental community believes the process of developing, licensing, and setting environmental and oversight standards for the proposed repository have been, and continue to be rigged or dramatically weakened to ensure the licensability of the site rather than provide safety for the length of time the waste is dangerous. The site selection process and the radiation standards are examples that illuminate this perspective and conclusively demonstrate that the NRC has no basis for finding reasonable assurance that sufficient mined geologic repository capacity can reasonably be expected to be available at any time, even within 50-60 years beyond the licensed life for operation (which may include the term of a revised or renewed license) of any reactor to dispose of the commercial high-level nuclear waste and spent fuel originating in such reactor and generated up to that time. a. Site Selection[.] First, DOE and then the Congress corrupted the site selection process.

The original strategy contemplated DOE choosing the best four or five geologic media, then selecting a best candidate site in each media alternative, then narrowing the choices to the best three alternatives, and then picking a preferred site for the first of two repositories. Site selection guidelines were strongly criticized as DOE was accused of selecting sites that they had previously planned to pick. In May of 1986 DOE announced that it was abandoning a search for a second repository, and it had narrowed the candidate sites from nine to three, leaving in the mix the Hanford Reservation in Washington (in basalt), Deaf Smith Co., Texas (in bedded salt), and Yucca Mountain in Nevada (in unsaturated volcanic tuff). All equity in the site selection process was lost in 1987, when the Congress, confronted with a potentially huge cost of characterizing three sites, amended the NWPA of 1982, directing DOE to abandon the two-repository strategy and to develop only the Yucca Mountain site. At the time, Yucca Mountain was DOE's preferred site. The abandonment of the NWPA site selection process led directly to the loss of support from the State of Nevada, diminished Congressional support (except to ensure that the proposed Yucca site remains the sole site), and less meaningful public support for the Yucca Mountain project. The situation has only deteriorated since that time. (0706-4-17 [Fettus, Geoffrey])

Comment: b. Radiation Standards[.] The second track of the process has, if possible, fared worse. Section 121 of the NWPA of 1982 directs EPA to establish generally applicable standards to protect the general environment from offsite releases from radioactive materials in repositories and directs the NRC to issue technical requirements and criteria. Unfortunately, it has been clear for years that the projected failures of the geologic isolation at Yucca Mountain are the determining factor in EPA's standards. EPA repeatedly issued standards that are concerned more with licensing the site than establishing protective standards. EPA's original 1985 standards were vacated in part because the EPA had failed to fulfill its separate duty under the Safe Drinking Water Act, 42 U.S.C. §300h, to assure that underground sources of water will not be "endangered" by any underground injection. *Natural Resources Defense Council v. Environmental Protection Agency* (NRDC v. EPA), 824 F.2d 1258 (1st Cir. 1987). EPA's second attempt to at setting standards that allow for a projected failure of geological isolation was again vacated, this time by the United States Court of Appeals for the D.C. Circuit. The D.C. Circuit found that EPA's Yucca Mountain rule (and the corresponding NRC standard), which ended its period required compliance with the terms of those rules at 10,000 years was not "based upon or consistent with" the recommendations of the National Academy of Sciences ("NAS") as required by the 1992 Energy Policy Act and therefore must be vacated. *Nuclear Energy Institute, Inc. v. EPA*, 373 F.3d 1251 (2004). Giving significant deference to the agency, the D.C. Circuit did not vacate EPA's strangely configured compliance boundary for the Yucca Mountain site. See Appendix A to these comments for a map of EPA's compliance boundary (inside the oddly drawn line, the repository need not protect water quality and radiation can leak in any amount). The dramatically irregular line that represents the point of compliance has little precedent in the realm of environmental protection, and its shape is perhaps more reminiscent of gerrymandered political districts. Rather than promulgate protective groundwater standards, EPA pieced together a "controlled area" that both anticipates and allows for a plume of radioactive contamination that will spread several miles from the repository toward existing farming communities that depend solely on groundwater and perhaps through future communities closer to the site. EPA's next proposed and revised rule, issued in 2005, retained the 15 millirem/year and groundwater standards for the first 10,000 years, but then establishes 350 millirem/year standard for the period after 10,000 years and does away with the groundwater standard entirely. This two-tiered standard failed to comply with the law and fails to protect public health, especially if the repository's engineered barriers were to fail earlier than DOE predicts. On October 15, 2008, EPA published the final version of its revised Yucca Mountain rule in the Federal Register ("2008 Yucca Mountain rule," 73 Fed. Reg. 61255-

61289). The 2008 Yucca Mountain rule's two-tiered individual protection annual dose standard establishes an initial 15 millirem first-tier limit, but weakens that limit to 100 millirem in the period after 10,000 years, when EPA projects peak dose to occur. Peak dose could occur significantly earlier if engineered barriers fail earlier than DOE and EPA have projected. (0706-4-18 [Fettus, Geoffrey])

Comment: The final status of EPA's most recent two-tiered rule remains fundamentally uncertain. In an action pending in the District of Columbia Circuit (*State of Nevada v. Environmental Protection Agency*, No. 08-1327, consolidated with No. 08-1345), Nevada has challenged EPA's 2008 Yucca Mountain rule as once again failing to honor EPA's statutory duty to protect public health and safety, and to proceed consistently with the National Academy of Science's recommendations. (0706-4-19 [Fettus, Geoffrey])

Comment: Even more troubling, any continued confidence in a reasonable assurance of a repository being available 50 or 60 years after license expiration of any commercial reactor is contingent entirely upon Congress revising (1) the current law that limits the United States to one repository, the proposed Yucca Mountain site[.] (0706-4-20 [Fettus, Geoffrey])

Comment: [T]he spent fuel and high-level waste stored at this one repository will be limited to 70,000 metric tons of heavy metal equivalent. Therefore, the current, and only repository under review in this country, could not even accommodate all of the spent fuel from existing reactors without new legislation, much less spent fuel from any new reactors that might be built. A second repository would also require new legislation and, as the proposals acknowledge, such a situation would almost certainly require new NRC regulations. Moreover, the NRC has failed to analyze the impact on future repository requirements of this proposed decision which would potentially place no limits on the total inventory of spent fuel generated by existing and future reactors. (0706-4-21 [Fettus, Geoffrey])

Comment: Appendix B is the closest NRC comes to addressing its responsibilities under the AEA. But the NRC's assertion its "underlying conclusions regarding the technical feasibility for continued storage and repository availability... continue to undergird its environmental analysis" has little merit. See Draft GEIS at B-1. NRC asserts repository capacity will be available to dispose of spent fuel. *Id.* at B-2. The last few years alone should be enough to persuade NRC not to put such deep faith or confidence in the availability of a repository and we recommend close scrutiny of Appendix A to these comments. We are far from a publicly accepted process of developing repositories, much a publicly accepted site. Further, generalizations about the technical feasibility of "a" repository do not answer the question of whether repository capacity will be sufficient to accommodate the spent fuel that will be generated in the future by reactors that have not yet been licensed or re-licensed. And the technical feasibility of some repository provides no comfort or guarantee there will be a repository with sufficient capacity available at the necessary time. Thus, the D.C. Circuit directed NRC to comply with NEPA in *New York et al.* In Appendix A to this set of comments, we detail the sad history of failure in attempts to develop repository and storage sites. (0706-4-5 [Fettus, Geoffrey])

Comment: Such a story should ensure the agency commits to do the work necessary to both develop better storage options and do a substantially better job of analyzing the environmental impacts of potentially permanent surface spent fuel storage. (0706-4-6 [Fettus, Geoffrey])

Comment: [T]he US District Court of Appeals threw out the NRC's Confidence Decision on June 8, 2012. The NRC must now admit that no safe, permanent repository exists, and that 70,000 tons of accumulated nuclear waste may be permanently stored at reactor sites. The

NRC must now thoroughly review Environmental Impacts of onsite storage, and consider safer alternatives to nuclear when licensing decisions come up. Given that the court has verified that no permanent, safe storage solution is likely to be found[.] (0707-2 [Werner, Shahla M.]

Comment: The second point I have to make is that radioactive "cleanup" is a misleading expression. It suggests to the listener that we can somehow get rid of radioactive "contamination." But we cannot do so, at least not in any absolute terms. All we can do is move the radioactive contamination from one place to another and find a place to isolate and manage it for a quarter of a million years. Governments and their electorates have been misled by the nuclear industry into believing false notions about radioactive waste. (0708-5 [Lewison, Linda])

Comment: This December 2013 marks 71 years since the first generation of high level nuclear waste and the world still does not know what to do with the very first cupful. (0713-1 [Keegan, Michael J.]

Comment: After 71 years what is known is that there is no good solution. We are left with the lesser of evils. All solutions are temporary and there is no disposal. Simply you can't get rid of it. (0713-3 [Keegan, Michael J.]

Comment: The Jig is up. There may have been a day, several decades ago when it was thought that there would one day be a solution. What is now known is that there is no solution, just bad options with costs which will be borne by thousands of generations to come. This entire process is the next level of the Confidence Game. (0713-5 [Keegan, Michael J.]

Comment: Since the California Commission Report there have been at least two additional failed attempts to locate a geologic repository – one in the Northeast and one in the Southwest (the Yucca Mountain project). There is still, to this day, not a single example of an operational repository for the "disposal" of irradiated nuclear fuel anywhere in the world. (0714-1-11 [Edwards, Gordon])

Comment: The safe permanent disposal of nuclear waste is a dubious concept with no precise scientific meaning. In other words, there are no measurable or scientifically verifiable criteria that will determine whether "safe permanent disposal" has or has not been accomplished. No matter how much scientific effort goes into the preparatory work, or into the post-closure assessment, science has no way of guaranteeing that the containment will not subsequently fail over hundreds of thousands or even millions of years. To dispose of something permanently is to get rid of it "once and for all", but we do not know how to get rid of irradiated nuclear fuel. We only know how to repackage it and relocate it. No doubt we can relocate it to a geologic repository excavated for that purpose, but there is no scientific principle that allows us to determine whether or not it will stay where we put it. Geology is not a predictive science, and human intervention cannot be excluded. (0714-1-12 [Edwards, Gordon])

Comment: Science has confirmed that some geological formations have remained stable for hundreds of millions or even billions of years. But it is impossible to emplace irradiated nuclear fuel in an undisturbed geological formation without first disturbing it. And there is no technology available to restore a disturbed geological formation to its original integrity. (0714-1-13 [Edwards, Gordon])

Comment: Moreover the nuclear wastes themselves are not inert, but active – thermally active, chemically active, and radioactive. Even the possibility of accidental criticality in the underground repository cannot be completely ruled out. Once these active materials have been emplaced in an excavated cavity where the surrounding geological stress field has been

permanently disrupted, these nuclear wastes will embark upon a history all their own – unobserved and uncontrolled by human society. Science is ill-equipped to predict the long-term behavior of such extraordinary materials in a man-made repository under such unprecedented conditions. In fact there are no scientific principles that allow us to test whether or not such predictions are even in the right ballpark when extended over periods of hundreds of thousands of years. Current mathematical knowledge is inadequate to provide bounding estimates for the accumulated computational errors arising from billions of iterative calculations, which can in some unusual circumstances be larger than the numerical answers themselves. (0714-1-14 [Edwards, Gordon])

Comment: But we do not have the ability to wait for tens or hundreds of millennia to see if the predictions of our mathematical models correspond to the actual long-term behavior of the nuclear wastes within a geologic repository, so we are ultimately basing assurances of safety on the unverified hypotheses that are embodied in the mathematical programs. This is a sophisticated form of wishful thinking – a technological "Hail Mary". (0714-1-15 [Edwards, Gordon])

Comment: In a 1978 paper published by the US Geological Survey, Circular 779, entitled "Geologic Disposal of High-Level Radioactive Wastes— an Earth-Science Perspective", the authors point out that even after a million years of storage, the radiotoxicity of the then-projected inventory of irradiated nuclear fuel from US power plants is extraordinarily high. As a hypothetical measuring mechanism, the authors point out that all of the water in the Great Lakes basin would be required to dilute the radioactive contents of the irradiated nuclear fuel to the maximum level of radioactive contamination that is legally allowed for drinking water. Of course we all understand that this hypothetical scenario is not going to happen, but it is a reminder that even 99.99 percent perfect containment of this material is just not good enough. (0714-1-16 [Edwards, Gordon])

Comment: From the earliest days of nuclear power, nuclear proponents have asserted with the utmost confidence that the safe permanent disposal of nuclear waste is not a technical problem, but a public relations problem. The assertion is partly true, at least from the point of view of the nuclear industry, as failure to find a solution to the nuclear waste problem is a major environmental, political and economic obstacle to the expansion of the industry, and is therefore a threat to the continued existence of nuclear power as a commercial energy source. (0714-1-17 [Edwards, Gordon])

Comment: For the NRC has also fallen under the spell of accepting this unverifiable assumption that a safe permanent disposal method exists in the form of a deep underground geologic repository, as if it were a scientifically demonstrated fact. This assumption has distorted the NRC rulemaking function to such an extent that in 2012 a court of law has ordered NRC to review its rules regarding the storage of irradiated nuclear fuel, specifically challenging the NRC notion that a safe permanent disposal method in the form of a geologic repository will become available in the next few decades. In its current efforts to meet the court's challenge, NRC has failed to consider that the industry's fundamental assumption that a solution to the waste problem exists may be incorrect, and to elaborate a set of policies based on that possibility. (0714-1-19 [Edwards, Gordon])

Comment: CCNR [Canadian Coalition for Nuclear Responsibility] considers it irresponsible for NRC to assume that any method exists or will exist for the safe permanent disposal of irradiated nuclear fuel without a precise and verifiable scientific definition of the word "disposal" – complete with detailed scientific criteria for determining when "safe permanent disposal" has been accomplished, and accompanying methodologies for verifying whether those criteria have

or have not been met. Any other approach amounts to drawing the target after the dart has been thrown. (0714-1-2 [Edwards, Gordon])

Comment: And yet, to date --- seventy-one years later --- no site or technology has been discovered that can be guaranteed to be permanent enough to isolate even the first cupful of those long-lived radioactive wastes. As far as anyone has determined, the brilliant minds that carried us into the Atomic Age were never asked if they could get us out. (0715-3 [Drey, Kay])

Comment: Nowhere is the dangerous "compartmentalization" of radioactive waste issues more evident than in political attempts to continue waste manufacture absent a disposal facility. This process has been handed a long-needed opportunity by the 2012 Court decision for the NRC and the industry to take responsibility for truly solving the high-level radioactive waste (HLRW) disposal issue. (0716-7 [Kraft, Dave])

Comment: With little prospect of a central repository or disposal site for decades to come, spent nuclear fuel continues to accumulate at nuclear plants around the country. Currently, there is an inventory of approximately 69,000 metric tons of spent fuel from commercial nuclear plants, the majority of which is being stored in pools at those plants, and this inventory is growing at a rate of 2,000 to 2,400 metric tons per year.⁷⁸ [footnote 78 text: Blue Ribbon Commission on America's Nuclear Future, Disposal Subcommittee, Draft Report to the Full Commission, at 2 (June 1, 2011). Even if the Yucca Mountain disposal site had been licensed and constructed, it could not hold more than 70,000 metric tons of waste.] The Blue Ribbon Commission concluded, "Simply put, it will take years to more than a decade to open one or more consolidated storage facilities and even longer to open one or more disposal facilities. This means that storage of substantial quantities of spent fuel at operating reactor sites can be expected to continue for some time."⁸¹ [footnote 81 text: *Blue Ribbon Commission Report* at 44.] The reality of the situation, demonstrated by these developments, is that the U.S. does not have a comprehensive policy for the removal and disposal of spent nuclear fuel from reactor sites (such as Indian Point), and is far from establishing one. (0718-2-3 [Sipos, John])

Comment: This response provides nothing more than continued insistence that spent radioactive fuel is stored safely. The fundamental requirements of safe storage -- 1) it is scientifically defensible, 2) environmentally responsible and 3) publicly acceptable -- are not yet met 60 years into the "nuclear age", nor is there an actionable plan for meeting these requirements any time soon. (0719-2 [Hibbard, Angela])

Comment: What, for example, could possibly have been the scientific or technical basis for assuming that Yucca Mountain or some other repository would be up and running in the 20th century? Or, now in the 21st century? NRC has not done a technical or licensing review. (0723-2 [Shadis, Raymond])

Comment: Please spend any extra energy and defence federal monies on finding a way to neutralize the concentrated toxicity of spent nuclear fuel as well as finding safer ways to utilize existing energy without creating toxic residuals. (0728-3 [Anonymous, Anonymous])

Comment: Make it a national priority to come up with real solutions to long term nuclear waste storage[.] (0728-4 [Anonymous, Anonymous])

Comment: Why do we continue to produce this waste with ,nuclear power plants,when we haven't found a safe solution in over 50 years and probably will not ever really find a good one. .This waste will be dangerous for hundreds to thousands of years and there is no guarantee that

it can be guarded properly for all those years and that there will not be an earth upheaval that will dislodge it.. (0729-1 [Wolpoff, Deborah])

Comment: I am writing today to express my concern that we finally begin the long put off job of determining the safest way to store our nuclear waste. (0733-2 [Vanderlan, Kelly])

Comment: It is NOT feasible for this highly radioactive material to be safely stored FOREVER. Nor can we expect to find a geologic repository -- Yucca Mountain turned out to be completely wrong -- geologically -- and furthermore, are you suggesting we turn the planet into a radioactive dump? (0734-2 [Hisasue, Carole])

Comment: The problem of what to do with the extraordinarily dangerous and long-lived wastes produced by nuclear fission has perplexed society since the first reactor wastes were produced on December 2, 1942, the day an atomic "pile," composed of graphite and uranium slugs, went critical in a converted squash court at the University of Chicago. More than seventy years later, despite repeated protestations of confidence by regulators that a solution would soon be found, we still have no method for disposing of the high-level wastes (HLW) produced by nuclear power plants, each enormously larger than that first device for releasing the power of the atom. And more nuclear waste is produced every day. (0738-1 [Hirsch, Daniel])

Comment: Perhaps no issue raises more serious questions of inter-generational ethics than whether we should continue to create such extraordinarily hazardous wastes without a solution to their safe disposal. The plutonium-239 in HLW, for example, is one of the most toxic substances on earth; a few millionths of an ounce if inhaled will cause cancer with virtual 100% statistical certainty. Yet we must find a way to successfully isolate from the environment *hundreds of metric tons* of plutonium for its hazardous life—about *half a million years*. (0738-2 [Hirsch, Daniel])

Comment: The NRC, in its proposed new Waste Confidence Rule, puts forward several draft findings. One is that a geological repository is "feasible" within 60 years of the end of the licensed period, with any renewals, of existing reactors. That, of course, is a far cry from being confident that that will happen. It is feasible that one will win the lottery, but not likely, not something one should count on. The evidence put forward by NRC to support this finding is not very robust. After recounting some of the history, in this country and abroad, where plans for opening repositories have repeatedly failed and been put off, NRC then identifies new hoped-for opening dates and says because such dates have been put forward, they are thus feasible. It is a circular argument without foundation. Indeed, the actual data identified—continued failure of all nations with nuclear power plants to open even a single high level waste disposal site—suggest quite clearly the difficulty in having confidence that such a facility will in fact open here in the next decades. (0738-8 [Hirsch, Daniel])

Comment: Make it a national priority to come up with real solutions to long term nuclear waste storage[.] (0741-1 [Giese, Mark M.])

Comment: I am a resident of Laguna Niguel and live quite close to the recently decommissioned San Onofre plant. I am very concerned about the spent fuel rods stored on site and the lack of a plan to adequately and permanently store these contaminated fuel rods. Please, in the interest of public safety, prioritize the prompt removal and permanent storage of these materials. (0742-1 [Burchfield Rhodes, Valerie])

Comment: When SONGS was originally put into service (circa 1965), what was then the Atomic Energy Commission asserted that all nuclear waste would be removed within 30 years (circa 1995) and the contour of the land would be restored to its natural condition. In 2013, we have a what appears to be a permanent nuclear waste dump in San Onofre. You believe the representations of the US Government have any credibility at all? Remove the waste--as promised! (0743-1 [Metcalf, Michael])

Comment: Regardless, the Federal Government, specifically the Department of Energy must be proactive in finding a solution to the long term spent fuel storage issue. This is what they promised the residents of this county and they need to follow through with that promise. PG&E has done their job and continues to do so with transparency and has shown their dedication to this community. I urge the Department of Energy to do the same. (0753-3 [Devitt, Andrea])

Comment: It is time to make it a national priority to find real solutions to stop this ticking time bomb before it is too late. (0757-11 [Lynch, Laura])

Comment: I believe the NRC must [m]ake it a national priority to come up with real solutions to long term nuclear waste storage[.] (0757-12 [Lynch, Laura])

Comment: In June of 2012, in a lawsuit brought by New York state the U.S. Court of Appeals threw out NRC's Waste Storage Rules saying the commission failed to fully evaluate risks associated with its regulations on the storage of spent fuel. The U.S. Court of Appeals ruled that the NRC's conclusion that permanent storage will be available in the future when it's needed didn't account for how its absence could affect the environment now. The commission also failed to fully assess the dangers of storing spent fuel onsite for 60 years after a nuclear plant's license expires, the court said. "The commission's evaluation of the risks of spent nuclear fuel is deficient," Chief Judge David Sentelle wrote for the three-judge panel. Spent fuel "poses a dangerous long-term health and environmental risk." (0757-9 [Lynch, Laura])

Comment: It is time that we deal with the nuclear waste problem. Storing waste in sites such as San Onofre, on a fault line in the way of a possible sunami, is not a solution. (0758-1 [Kuchnia, Margaret])

Comment: I feel it is very important to dispose of nuclear waste in as safe a manner as possible. Please take steps to protect the masses from this very real threat. (0761-1 [Madden, Donna])

Comment: It is time for Yucca Mountain to open, and preparation made to begin receiving the Nation's nuclear waste, immediately. Of course Nevadans are going to object passionately (NIMBY!). But it's the best solution, ceramic can be used to encase before transportation to the location, to minimize the affects of an accident, in the worst case scenario. The time for action is now, before our children are left to deal with this awful legacy. (0766-1 [Poole, Jesse])

Comment: Permanent storage at Yucca Mountain MUST begin. I urge you to do all in your collective power to put that pln into reality. (0766-3 [Poole, Jesse])

Comment: There seems to be no real plan for permanently storing waste either. I would like to see the waste moved to a permanent storage facility. (0770-2 [Maher, Ed])

Comment: I am very much opposed to continuing the storage of spent fuel at the San Onofre site. It is absolutely essential that the NRC find and locate a site for the storage of all of our

spent fuel. It has been so many years since Yucca Mountain was rejected. (0771-1 [Carlton, Paul])

Comment: It is time to stop the nuclear waste con and make it a national priority to find real solutions to stop this ticking time bomb before it is too late. (0774-5 [Revilla, Oscar])

Comment: Make it a national priority to come up with real solutions to long term nuclear waste storage. (0774-6 [Revilla, Oscar])

Comment: Nuclear waste near populated areas with no removal or long term plans is unacceptable. Please move forward on containment and removal plans in a timely manner. (0781-1 [Johnson, Reed])

Comment: However, the City [Red Wing, MN], like many other host communities, is now facing a scenario that it did not, under any set of circumstances, envision: the failure of the Federal Government to honor its contractual agreement with the Company and remove the spent fuel from the PINGP to either an interim storage facility or a long-term or permanent repository. Despite any other contention or disagreement with the Company, the City stands resolute with the Company that the continued storage of spent fuel outside of the PINGP is not a workable solution. With no plan or process in place for its removal, storage, which was to be short (if at all), has become, for all practical purposes, permanent. (0783-1-1 [Harlan, Thomas])

Comment: As to where to put them, I believe scientists would be the best people to answer this question. But I think any American community would fight tooth and nail against it. Therein lies the problem. Where to put the radioactive spent fuel. Wherever is chosen, it should be guarded forever. Placing it in another country is totally unacceptable from a moral and national security perspective. (0786-3 [Dew, Jane])

Comment: Long-term solutions need to be developed for nuclear waste, to eliminate the need for long-term onsite storage of nuclear waste.. (0788-2 [Sattler, Alfred])

Comment: Make it a national priority to come up with real solutions to long term nuclear waste storage[.] (0789-1 [Salto, Don])

Comment: Get this waste out safely. (0790-1 [Richardson, Carlos])

Comment: The Commission should then turn its attention to dealing with the massive amounts of radioactive wastes. This will demand a thorough and thoughtful review of all options for containment of these wastes as well as a warning system that will notify future generations of its fatal toxicity. (0792-3 [Soto, Carol])

Comment: A military style method, as used by the Defense Department for decommissioned nuclear bomb waste in New Mexico deep caverns, is a type of storage that this material needs. Where or how this can be achieved without unnecessary risk I cannot say. But the idea that no attempt will be made to pursue that, and instead it will sit near the city of San Clemente for scores of years is not right. (0793-3 [Sauerheber, Richard])

Comment: Please, please put public safety ahead of industry profits . Find a permanent Place for storage of all this spent nuclear fuel! (0797-1 [Hennessy, Diane])

Comment: Creating dangerous spent radioactive fuel rods and having no real way to move them out of this highly populated area was misjudgement and irresponsible on the NRC's part. Since this garbage is so potent and dangerous[.] (0807-1 [Krimsky, Pam])

Comment: [T]he Department of Energy has a responsibility to make good on its commitment to receive and safely store the spent fuel for the long term. By doing so, locally stored spent fuel could be safely removed to a single or regional location controlled and protected by our national government. (0812-2 [Souza, Celine])

Comment: The toxic waste from Diablo Canyon is too dangerous to be transported anywhere and too long lasting to be considered "safe" in any way! In 30 years no solution has yet been found - its hard to believe these plants ever came into existence in the first place! So many of my friends and neighbors have no confidence in the NRC. Most of us feel that no matter what we say you will do exactly as you please. Please, I beg you, don't let this be an exercise in futility. (0814-1 [Foley, Nancy])

Comment: I have referenced so-called LLRW (considered by the NRC to be less dangerous than spent fuel) above, and there are lessons to be learned from 10CFR61 regarding minimum site suitability requirements, particularly from the NRC Office of Nuclear Material and Safeguards's document "Regulating the Disposal of LLRW A Guide to the NRC's 10CFR61" which contains "Common sense siting requirements which address the natural characteristics of the site and other factors. NRC views the siting requirements as minimum...whether or not engineering enhancements are used. The requirements are primarily directed at aspects to avoided." In this document, the NRC expressed "concerns about storage, including onsite storage, becoming defacto disposal; distraction of reactor management from the safe operation of the reactor ...and the potential for package and waste disintegration." It further states, "There is no way to guarantee that any disposal facility, for any waste, will not release... radioactivity. No structure or site can be guaranteed to contain ... radioactive waste in perpetuity (given the fact) that facilities deteriorate and human institutions may not maintain complete control." (0819-16 [Kline, Connie])

Comment: What is Adaptive Phased Management? Adaptive Phased Management is both a technical method and a management system, with an emphasis on adaptability. Technically, it is centralized containment and isolation of used nuclear fuel in a deep geological repository. The management system involves realistic, manageable phases - each marked by explicit decision points with continuing participation by interested Canadians. It is flexible, allowing for go, no-go decisions at each stage to take advantage of new knowledge or changing societal priorities. Adaptive Phased Management provides an option for shallow underground storage at the central site if some or all of the used fuel needs to be moved before the deep repository is available. It also provides for continuous monitoring throughout implementation and for retrievability for an extended period. (0820-16 [Eide-Tollefson, Kristen])

Comment: Timely federal removal of the waste to a permanent geological repository was, & continues to be, a first condition of support for continued operations in Minnesota. (0820-4 [Eide-Tollefson, Kristen])

Comment: This does not address the overall waste problem of storage and disposal, and it adds to the safety problem and increases the time span. A safe solution has not been found by any nation or the nuclear industry during 65 years of hopeful thinking that doesn't match reality. No solution for the waste exists. All the numerous solutions studied have been found insufficient

for safety. At this point, there is more than adequate justification to conclude that a safe solution for the waste is impossible. (0823-16 [Michetti, Susan])

Comment: The Physical World requires physical world measurements to determine its actual physical properties and safety. Actual physical safety can not be rationally determined by non-specific "generic" conceptualization which introduces distortions that are unreliable, undependable, and untrustworthy from which to claim any public health or environmental "safety." The reality of the physical impossibility of storing this waste for thousands and millions of years is being avoided by flawed rules and insufficient oversight. Wishful thinking that a solution will appear is unacceptable, given the efforts of the last 65 years to identify an actual solution have been without promise, including Yucca Mountain. (0823-56 [Michetti, Susan])

Comment: Moving forward also requires transparency that long-term unknown solutions have the potential to be unsolvable, particularly after 65 years of searching. No place exists for wishful thinking in scientific assessments. (0823-72 [Michetti, Susan])

Comment: Unfortunately, we live under irrational governmental decision-making. In terms of the nuclear industries, these irrational times stem originally from the lack of scientific knowledge and technology to adequately and sufficiently deal with the radioactive waste problem at a harmless end point identifiable prior to generation of lethal waste. Continued irrationality is occurring because governmental decision-makers used a flawed assumption for approximately the last 65 years: they believed inaccurately that the nuclear waste solution so blindly desired would "definitely" appear over time, but that did not happen. (0823-79 [Michetti, Susan])

Comment: Moreover, consideration of a licensing moratorium is not compelled by the AEA. In *NRDC v. NRC*, the Second Circuit explicitly addressed whether operating licenses can be issued in the absence of a definitive agency determination that high-level waste could be permanently disposed of safely.³⁷ [footnote 37 text: 582 F.2d 166 (2d. Cir. 1978).] The Court quoted remarks by Representative Holifield (Chairman of the Special Subcommittee (of the Joint Committee on Atomic Energy) on Radiation) at a hearing on radioactive waste disposal: "from the very beginnings of commercial nuclear power the Congress was aware of the absence of a permanent waste disposal facility, but decided to proceed with power plant licensing."³⁸ [footnote 38 text: *Id.* at 170. The Court also pointed to the enactment of the Energy Reorganization Act of 1974 as further evidence that a moratorium on nuclear power reactor licensing pending an affirmative determination on safe, permanent disposal was not required. It noted that through the Energy Reorganization Act, Congress gave the NRC the authority to review the Department of Energy's future projects regarding long-term storage of high-level waste. *Id.* at 174.] As the Court noted, Congress was (and is) fully aware of the NRC's regulatory scheme, in which the safety of interim storage of spent fuel is determined separately from the safety of a permanent disposal facility.³⁹ [footnote 39 text: *Id.* at 174.] The Court reasoned that if the Commission had interpreted the AEA to require an affirmative determination regarding the feasibility of safe, permanent disposal of high-level waste, no commercial production or utilization facilities would be in operation.⁴⁰ [footnote 40 text: *Id.* at 171.] Ultimately, the Second Circuit found that "Congress did not intend such a condition."⁴¹ [footnote 41 text: *Id.*] Thus, the Court ruled that reactor licensing did not need to be suspended pending the availability of a waste repository. This decision, and the supporting reasoning, continues to hold today. Congress clearly established a separate scheme for waste disposal in the Nuclear Waste Policy Act, and has clearly not objected to reactor licensing actions (and license renewal decisions), notwithstanding the termination of the Yucca Mountain project or implementation of a new program. Moreover, the Secretary of the DOE continues to recognize

and agree to satisfy the government's obligation to provide for disposal of used fuel and high level waste. (0827-1-11 [Ginsberg, Ellen])

Comment: The Conclusions in the SOC articulate that, based on operating experience, technical studies, and physical characteristics of spent fuel pools and dry cask storage systems: (1) a geologic repository is technically "feasible,"¹⁰⁸ [footnote 108 text: 78 *Fed. Reg.* at 56,793.] (2) it is reasonable to assume the availability of a repository within 60 years beyond the licensed life of a reactor (i.e., within the short-term timeframe),¹⁰⁹ [footnote 109 text: *Id.* at 56,794.] and (3) a regulatory framework exists to support a conclusion that spent fuel can be safely stored for at least 60 years beyond a reactor's operating life (the short-term timeframe).¹¹⁰ [footnote 110 text: *Id.* at 56,796.] The NRC appropriately notes that past WCD updates found that a deep geologic repository is a technically feasible means of disposal, and that additional information since past WCD updates further support this conclusion. The NRC also cites the Blue Ribbon Commission Report, experience with Yucca Mountain, and international experience to support the 60-year timeframe for repository availability. (0827-5-8 [Ginsberg, Ellen])

Comment: The NRC has never adequately addressed the question of nuclear waste storage. Dry casks are acceptable for the very short term, but there's been no viable plan for long-term storage. (0834-1 [Thabit, Nick])

Comment: Under the license terms for a given nuclear power plant, the entire plant must be decommissioned and restored to unlimited or partial use within 60 years of the end of operations. This is the underlying "contract" with the public when these plants were installed. Now, the NRC is suggesting in Section 4 that the ISFSIs can remain in operation for centuries. We believe this is WRONG for the NRC to suddenly change this contract with the public. (0836-53 [Davis, Anonymous])

Comment: Nationwide, there is now over 80,000 tons of spent nuclear fuel. No known technology exists to safely store radioactive waste and protect the environment for the period it remains hazardous. There is no known permanent nuclear waste facility in the US in which to store all the existing waste. The use of temporary storage does not create any confidence the waste will be safely or permanently stored for the period required until it is not hazardous. (0840-3 [Taylor, Tom])

Comment: Some have suggested that a permanent, deep-geological high-level radioactive waste disposal facility be built and fully operational to deal with existing waste. The possibility for this material, seeping into a molten area and together with multiple spent fuels, igniting at some point in the future, makes the option impossible to conceive of. Additionally, there is absolutely NO consensus in the scientific community on how to deal with this technology. It is beyond faulty. (0844-5 [Anonymous, Anonymous])

Comment: In geologic repository designs such as the cancelled Yucca Mountain project where the waste containers are expected to corrode over time, the prediction of how much and how fast radionuclides are transported is necessary to estimate the level of groundwater contamination. It came as a surprise to repository designers that low-solubility radionuclides such as plutonium could mobilize and move long distances underground. The cancelled Yucca Mountain repository design did not confine the waste and over time water supplies become contaminated. No community that loves their land or cares about future generations will accept a geologic repository. At the very least, siting a geologic repository will remain politically difficult to achieve. (0851-11 [Thatcher, Tami])

Comment: Commercial nuclear power in the US has generated over 68,000 metric tons heavy metal (MTHM) in spent nuclear fuel.¹ [footnote 1 text: J. C. J. Wagner et al., Categorization of Used Nuclear Fuel Inventory in Support of a Comprehensive National Nuclear Fuel Cycle Strategy, ORNL/TM-2012/308 (FCRD-FCT-2012-00232), Oak Ridge National Laboratory, Oak Ridge, Tenn., December 2012.] This spent fuel storage poses high costs, severe accident risks and technical challenges both above and below ground. Despite the common description of the volume of spent fuel from the entire US commercial nuclear fleet fitting on a football field, there is already enough fuel to fill one Yucca Mountain repository that spans miles and will contaminate the water below ground. (0851-3 [Thatcher, Tami])

Comment: Please put humanity and public safety ahead of Profits and remove deadly waste from San Onofre where it is in the heart of millions of people and in danger of being released by earthquake or a sunami or terrorist attack in one of the most populated areas of the country. (0854-1 [Prosser, Audrey])

Comment: When I learned this past year that nuclear waste at San Onofre is being cooled in pools and then stored in casks indefinitely on site I couldn't believe it. Given the dangerous nature of the fuel and the above mentioned risks, how can this be tolerated? The NRC and the federal government must take immediate steps to address this hazardous situation and move all radioactive material to a remote location as soon as it is safe to do so. This has to become the top priority and primary mission of the NRC. (0855-3 [Holloway, Patricia])

Comment: Regardless of the history of Waste Confidence Proceedings and court cases, it is evident that the NRC by itself cannot make a full, dispositive finding of Waste Confidence. The NRC's statutory authority, staff experience, and mission are well-suited to make technical findings concerning Waste Confidence; but the NRC lacks the authority, the experience, or the clout to make findings about the political activities that have engulfed Waste Confidence or that may affect waste disposal in the future. The Department Of Energy (DOE) might seem better suited to provide waste confidence than the NRC; but in the past few years, the DOE has basically stopped its high level waste program activities due to political direction from the Senate Majority Leader. (0859-1 [Haughney, Charles])

Comment: What should NRC do? The NRC has already begun to finally provide a substantial basis for a technical finding of Waste Confidence by deciding to issue the full suite of Safety Evaluations Reports (SERs) that will document the acceptability of the proposed Yucca Mountain Repository. This SER issuance will demonstrate to the public that the NRC staff has made the requisite findings of acceptability of one type of repository, that of Yucca Mountain. The surrogate Technical Evaluation Report (TER) that has already been published, although lacking the final regulatory conclusions, provides the needed technical basis for a favorable Waste Confidence finding. The TER could be usefully cited in the GEIS in this regard. (0859-2 [Haughney, Charles])

Comment: It is time to stop the nuclear waste con and make it a national priority to find real solutions to stop this ticking time bomb before it is too late. (0860-5 [Headrick, Gary])

Comment: Make it a national priority to come up with real solutions to long term nuclear waste storage (0860-6 [Headrick, Gary])

Comment: The nuclear waste from U.S. power plants is one thing. There is no place to put it. This is a world-wide problem of millennial proportions. Only hubris could give the NRC confidence that they know what to do with the waste. (0861-2 [Boudart, Jan])

Comment: It was recognized early in the development of civilian nuclear energy that the wastes generated from nuclear power plants and laboratories would require careful storage and disposal. The Nuclear Waste Policy Act of 1982 defined the framework under which a large federal repository should be developed to permanently store high level waste, and efforts continue to complete this work today. Recent court rulings¹ [footnote 1 text: United States Court of Appeals for the District of Columbia. *National Association of Regulatory Utility Commissioners v. United States Department of Energy*. No. 11-1066. (19 November, 2013)] and Congressional inquiries² [footnote 2 text: United States House of Representatives Committee on Energy and Commerce. Letter to Ernest Moniz, Secretary of Energy. (11 December 2013) Retrieved from <http://energycommerce.house.gov/sites/republicans.energycommerce.house.gov/files/letters/121113%20DOE%20Yucca%20Implementation%20Letter.pdf>] highlight the importance of finally establishing technically and politically feasible long-term plans for nuclear waste management. Updates to the Waste Confidence Rule play an important role in these long-term plans. (0863-1 [Brinton, Samuel] [Curtis, Daniel])

Comment: The nuclear engineering and geological engineering technical communities are ready to build a repository. Experts surveyed on geologic repositories for spent nuclear fuel demonstrate a consensus that the construction and safe operation of such a repository is completely technically feasible^{6, 7}. [footnote 6 text: Beckjord, Eric et al. *The Future of Nuclear Power: An Interdisciplinary MIT Study*. (2003)] [footnote 7 text: International Atomic Energy Agency. *Scientific and Technical Basis for Geological Disposal of Radioactive Wastes*. IAEA TRS 413. (2003)] Many design lessons were learned during the research and development effort at Yucca Mountain, but all issues raised were resolved before the project was arbitrarily cancelled. The failure of the United States government to provide a permanent storage facility for spent nuclear fuel has been an overwhelmingly political failure, not a technical one. (0863-4 [Brinton, Samuel] [Curtis, Daniel])

Comment: Deep geologic disposal is technically feasible, but politically difficult, and regulatory planning must account for the overwhelming uncertainty over future political developments. (0863-8 [Brinton, Samuel] [Curtis, Daniel])

Comment: From the beginning of the nuclear age, the waste byproducts of nuclear energy production have been recognized as a problem. In the Atomic Energy Act (AEA), Congress promised utilities that the Federal Government would take control of the waste and dispose of it (AEA 1954). A functioning Federal repository program capable of disposing of the waste was a precondition of the manufacture of the materials and continued production of power. Despite this mandate, no real progress has been made in development of a Federal repository program. What appeared to be progress with the Yucca Mountain project was illusory and privatized alternatives like the Private Fuel Storage (PFS) facilities have yet to materialize and may never be built. While the Yucca Mountain Program reached the licensing stage, it is not clear that the license will be granted, nor that a functioning and environmentally acceptable repository and related infrastructure can be constructed. Likewise PFS has been licensed by the NRC but it has yet to overcome judicial, social and political opposition. (0867-1-14 [Griffin, William])

Comment: Additionally, when the AEA was passed, it was assumed that there was a relatively minor technical problem of SNF which would be easily fixed. This has not occurred. For example, there has been no technical development that will actually reduce the radioactivity of these materials. The United States does not reprocess these materials either. As a result, nuclear materials production has created vast amounts of radioactively contaminated materials that continue to cost billions to remediate (Closing the Circle). The essence of radioactive

materials management in the United States is to dispose of the materials by means of a geologic repository, one that is yet to be constructed despite decades of trying. (0867-1-16 [Griffin, William])

Comment: The United States began a program to find a SNF repository in the 1970's. As part of this effort, a variety of different land forms suitable for a geologic repository were studied in a number of different geographic locations. The results were that the Federal government settled on Yucca Mountain as the sole site for a repository. Despite major legislation in 1982 and 1987 that led to the study of Yucca Mountain as the singular repository site, this choice failed by 2010 when the funding for this site was cut. During the decades long time period, there have been no fundamental technological improvements or changes to our ability to manage SNF. That is, there have been no technological breakthroughs that would reduce or modify the human health risks posed by SNF. Additionally, efforts to develop a new reprocessing system have been inconclusive (GNEP). (0867-1-18 [Griffin, William])

Comment: The NRC's failure to take a hard look at its own efforts and to address real environmental, social, economic and political concerns have so far resulted in failure. This experience should be a lesson to the agency and Commission - meaningful analysis under NEPA can provide some means to accomplish the task of siting a facility but failure to address concerns by stakeholders will likewise block or prevent the accomplishment of the desired goal - and should be integrated into its analysis of when and whether a permanent waste repository is likely to be available. However, no such analysis of the basis for the DGEIS conclusion that a waste repository is likely to be in existence within 60 years of the shutdown of the oldest reactor has been conducted (DGEIS p. xxviii). (0867-1-19 [Griffin, William])

Comment: The moving target of a repository construction date is one issue that the NRC has failed to address in the DGEIS. This may be because the issues the NRC failed to address in the DGEIS are too complex and/or that the methodologies used to analyze the waste confidence concept are too simplistic. Such complexities and analytical failures point out deficiencies in a generic approach to the whole of the waste confidence issue. In summary, there is currently no viable program to develop a repository. There is no location for a repository and siting efforts using a wide variety of techniques that continued over the last four plus decades have failed. The fundamental problem remains: What are the environmental impacts at the current wet storage waste locations if there is no repository or no reasonably foreseeable repository? (0867-2-1 [Griffin, William])

Comment: Most people were against storage of the radioactive waste at the site. Most people felt that Diablo should NOT operate until the terrible waste has a place to be stored- a safe site like Yucca Mt. was supposed to be. (0871-1 [Denneen, Bill])

Comment: Will Congress please give the NRC some teeth and make law (1) to find suitable geological storage locations[?] (0881-5 [Szymanowski, Jennifer])

Comment: Thirty years ago I was working in the Records department at Battelle Memorial Institute. We made copies of reports from universities all over the United States. The records were of studies made to try to find a place to store nuclear waste. At the time, the agency called the Office of Nuclear Isolation, was looking for places such as former salt mines or mountains which are stable as a place to store the wastes. It was thought that having the wastes, which take ages to deplete to harmless state, located in places where they would be relatively harmless. (0882-1 [Wright, Margaret Z.])

Comment: These wastes should not be stored near our lakes, rivers, or oceans where they can contaminate our water. (0882-3 [Wright, Margaret Z.])

Comment: We all know there is no good final solution to the problem of creating nuclear waste that must be isolated from the environment and all living things for millions of years. If we ever come to a decision on a deep underground depository that would mean thousands of shipments moving through towns and cities endangering populations as they pass through and the likelihood of accidents. The highways, railways and watercourses would have to be militarized and shipments would have to be secretive to prevent terrorism. Even if a suitable place could be found; it would be decades before any waste would be interred. (0883-1 [McArdle, Ed])

Comment: [T]he Department of Energy has a responsibility to make good on its commitment to receive and safely store the spent fuel for the long term. By doing so, locally stored spent fuel could be safely removed to a single or regional locations controlled by and protected by our national government. (0885-2 [Anderson, Cody])

Comment: [T]he Department of Energy has a responsibility to make good on its commitment to receive and safely store the spent fuel for the long term. By doing so, locally stored spent fuel could be safely removed to single or regional locations controlled by and protected by our national government. I believe it has a duty to do so and encourage them to live up to the commitment they made. (0886-2 [Lind, Jeff])

Comment: Instead, the DGEIS analyzes “scenarios” which assume the unavailability of repository capacity. That is a far cry from analyzing the question of whether the NRC has a technical basis for a reasonable assurance finding regarding the availability of sufficient repository capacity or an environmental risk analysis of the uncertainty surrounding such a prediction. As the Court ruled in *New York*, the NRC must evaluate the “likelihood of nonavailability” of repository capacity unless it is “remote and speculative.” 681 F.3d at 479. And a finding of technical feasibility is a far cry from a finding that sufficient repository capacity will actually be available. The sufficiency of repository capacity is a crucially important consideration in determining whether it is safe for the NRC to continue to allow the generation of spent fuel in licensing decisions. Spent fuel is a highly radioactive substance that must be isolated for many thousands of years in order to protect public health and the environment. Generalizations about the technical feasibility of “a” repository do not answer the question of whether repository capacity will be sufficient to accommodate the spent fuel that will be generated in the future by reactors that have not yet been licensed or re-licensed. As discussed in the attached Makhijani Declaration (pars. 8.4 – 8.13), “[t]he proposed rule’s assertion of the feasibility of a repository does not guarantee that there will be a repository with sufficient capacity to accommodate all the spent fuel envisioned.” In addition, the proposed rule’s failure to address the sufficiency of repository capacity is inconsistent with Congressional policy that disposal of spent fuel in a repository is the only safe means of protecting public health and the environment from spent fuel in the long run. See Section 11 of the Nuclear Waste Policy Act (“NWPA”), which establishes a national policy of disposing of spent nuclear fuel in a deep geologic repository. 42 U.S.C. § 10131 (1982).² [footnote 2 text: The NWPA also clearly distinguishes between storage and disposal. Storage is the “retention of . . . spent nuclear fuel . . . with the intent to recover such waste or fuel for subsequent use, processing, or disposal.” Section 2(25). Disposal is the “emplacement in a [deep geologic] repository . . . with no foreseeable intent of recovery, whether or not such emplacement permits the recovery of such waste.” Section 2(9), (18).] In the proposed rule, the NRC appears to assume that no reasonable assurance finding regarding repository capacity is needed because of its opinion that spent fuel can be stored safely for the long-term or perhaps indefinitely at reactor sites or

away-from reactor storage facilities. Aside from the fact that NRC's opinion is essentially unsupported (see discussion in Section VI.A below), that assumption cannot be squared with the NWPA. (0897-2-14 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Even if the NRC were to attempt to make "reasonable assurance" findings about the availability of sufficient repository capacity or the safety of extended interim storage of spent fuel as required by the Atomic Energy Act, NRC has demonstrated by its own actions that it lacks sufficient information to support such findings. (0897-2-15 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The question of feasibility of spent fuel disposal cannot be evaluated without considering the probability that a repository will safely contain radioactivity for the hundreds of thousands of years required. In order to evaluate that probability, it is necessary to evaluate the environmental impacts of disposing of spent fuel in a range of geologic media. NRC cannot simply presume that a repository is feasible. Disposal impacts are relevant because they are part of the waste confidence finding that a mined geologic repository is feasible. By definition, a "feasible" repository must meet reasonable health and safety standards. (0897-2-16 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Further, sufficient capacity at one or more such sites meeting safety criteria must be available to accommodate spent fuel from any and all commercial light water reactors that may be built. The DGEIS sets no upper limit on the amount of spent fuel to be disposed of. By failing to evaluate spent fuel disposal impacts and the sufficiency of repository capacity (if necessary at more than one site), the NRC has excluded a major part of the picture regarding the feasibility of spent fuel disposal. (0897-2-17 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: In order to comply with the Court's order to analyze the uncertainty associated with its prediction of sufficient spent fuel disposal capacity, the NRC would need to analyze the environmental impacts of spent fuel disposal in an array of geologic media, with an analysis of the uncertainty regarding whether the repositories could meet federal limits for containing radioactivity and how much spent fuel they could accommodate. Makhijani Declaration, pars. 8.2-8.24. The DGEIS does not provide any information about spent fuel disposal impacts, however. Instead, the DGEIS declares spent fuel disposal impacts irrelevant to its analysis and refers the reader to Table S-3. DGEIS at 1-18. (0897-7-9 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The NRC also lacks a factual and scientific basis for a finding of confidence that spent fuel can be disposed of safely within acceptable, legally binding health and safety standards. (0898-1-10 [Curran, Diane] [Makhijani, Arjun])

Comment: As part of this analysis, the NRC should also evaluate the probability that sufficient repository capacity will be available in a timely manner so as to avoid excessive storage risks and costs. Of course, by doing so it would also be calculating the probability that sufficient repository capacity will *not* be available. In the proposed rule, the NRC fails to even address the question of repository capacity. And it only refers to "a" mined geologic repository, as if one were enough. This is a significant deficiency. As we will show, persuasive arguments can be made that two repositories may be needed if there is a resurgence of nuclear power. Appeals to repository programs in Sweden and Finland do not resolve this issue – their nuclear power programs are very small compared to the United States and therefore involve a small amount of spent fuel. (0898-1-23 [Curran, Diane] [Makhijani, Arjun])

Comment: The question of feasibility of spent fuel disposal cannot be evaluated without considering the probability that a repository will safely contain radioactivity for the hundreds of thousands of years required. And, in order to evaluate that probability, it is necessary to evaluate the environmental impacts of disposing of spent fuel in a range of geologic media. NRC cannot simply presume that a repository is feasible. Disposal impacts are relevant because they are part of the waste confidence finding that a mined geologic repository is feasible. By definition of such feasibility, such a repository must meet reasonable health and safety standards. Moreover, we note that Table S-3 at 10 CFR 51.51 is invalid for estimating high-level waste disposal impacts. Among other things, its underlying assumption of disposal in a bedded salt repository for spent fuel disposal was repudiated by the NRC itself in 2008.¹⁶ [footnote 16 text: NRC 2008a, p.59555] Therefore, the NRC must prepare a new disposal impact analysis in the context of its waste confidence decision. Further, *sufficient capacity* at one or more such sites meeting safety criteria must be available to accommodate spent fuel from any and all commercial light water reactors that may be built. The Draft GEIS sets no upper limit on the amount of spent fuel to be disposed of. By failing to evaluate spent fuel disposal impacts, the NRC has excluded a major part of the picture regarding the feasibility of spent fuel disposal. The concept of feasibility also includes cost. What will it cost to isolate spent fuel for many thousands of years? Is the cost affordable when compared with the profit that a nuclear reactor will yield? These questions must be evaluated in order to assess the feasibility of spent fuel disposal. (0898-1-7 [Curran, Diane] [Makhijani, Arjun])

Comment: The NRC's proposed finding that it is feasible to "have a mined geologic repository within 60 years following the licensed life for operation of a reactor"¹¹³ [footnote 113 text: NRC 2013b, p. 56776, italics added to both indefinite articles] is so vague and incomplete that it is essentially meaningless. It is also unsupported in a number of respects. Specifically, the proposed finding is about "a mined repository" – the indefinite article is used. Will it have enough capacity to accommodate all spent fuel from all reactors? Could it safely accommodate all types of spent fuel, including failed high burnup spent fuel? The proposed rule does not say. (0898-4-10 [Curran, Diane] [Makhijani, Arjun])

Comment: The proposed rule's assertion of the feasibility of a repository does not guarantee that there will be a repository with sufficient capacity to accommodate all the spent fuel envisioned. Moreover, the Draft GEIS proposes no upper limit to spent fuel. On the contrary, it includes reactors beyond the existing ones, including new reactor designs such as small modular reactors. The NRC's conclusion that "a" repository is feasible does not provide any assurance that spent fuel from all reactors covered by the Draft GEIS will find space in it. (0898-4-12 [Curran, Diane] [Makhijani, Arjun])

Comment: Every geologic location would have some limit to the amount of spent fuel it can hold due to considerations such as the faults running through the site, natural resources availability, etc. Yucca Mountain, for instance, had a legal limit of 70,000 metric tons (equivalent) of commercial and military waste. Proponents of disposal there argued that the technical limits could be much greater. But no one, so far as I am aware, has asserted that there was no technical limit. Such a limit was considered, for instance, in a paper by Professor Per Peterson of the University of California at Berkeley in the context of a prospective increase in nuclear reactor orders in 2003. He argued that the technical capacity of Yucca Mountain could be increased. This [analysis] suggests a minimum "technical" site capacity of approximately $75 \times 2,000 = 150,000$ MT of spent fuel, with a maximum site capacity greater by perhaps a factor of two or three. *Thus any substantial construction of new U.S. nuclear power infrastructure in the coming decades will almost certainly create a technical requirement (perhaps as soon as 2030 to 2050) either for additional repositories or for the construction of infrastructure for recycling*

spent fuel.¹¹⁵ [footnote 115 text: Peterson 2003, italics added] Thus, one of the most prominent authorities on nuclear power and nuclear waste in the United States,¹¹⁶ [footnote 116 text: Professor Peterson was a member of the Blue Ribbon Commission on America's Nuclear Future which delved into the problem of spent fuel at the behest of then Energy Secretary Steven Chu.] has opined that, in the absence of reprocessing, a second repository may be needed in the United States - and would "almost certainly" be needed in the event of a nuclear power resurgence. (0898-4-13 [Curran, Diane] [Makhijani, Arjun])

Comment: The proposed rule neither puts limits on spent fuel nor assures that there will be sufficient room to dispose of all spent fuel that may arise, including as a result of the government's own actions to promote nuclear energy. Unless there is a specific and reasonable assurance in this regard based on technical and social reality, then spent fuel may well be stranded at reactor sites essentially forever. It is also possible to envisage a case where there is one repository that is insufficient. In that case, there would be impacts both from disposal as well as impacts from indefinite storage at reactors of a part of the spent fuel inventory. (0898-4-15 [Curran, Diane] [Makhijani, Arjun])

Comment: The Draft GEIS has a section on the issue of repository technical feasibility (Section B.2.1) and one entitled "Availability of Repository Capacity" (Section B.2.2).¹¹⁸ [footnote 118 text: NRC 2013a, p. B-2 and p. B-4] These sections appeal to the international consensus that repositories are feasible, to the Waste Isolation Pilot Plant (WIPP) in New Mexico, where transuranic wastes generated by the nuclear weapons program of the Department of Energy are being disposed of, and to the Swedish and Finnish Programs. We consider each of these in turn to show that they are, singly or together, insufficient to establish feasibility in the sense that there will be a repository that will meet specified safety standards and that it will have sufficient capacity. (0898-4-16 [Curran, Diane] [Makhijani, Arjun])

Comment: We note first of all that Yucca Mountain has not been licensed. The State of Nevada raised a host of technical issues¹¹⁹ [footnote 119 text: *See U.S. Department of Energy (High-Level Waste Repository)*, LBP-09-06, 69 NRC 367, aff'd in part and rev'd in part, CLI-09-14, 69 NRC 580 (NRC 2009).] before the DOE informed the NRC that it was withdrawing its application. Yucca Mountain therefore cannot be used to assert repository feasibility, in the sense of meeting the standard that the EPA set forth in 40 CFR 197. (0898-4-17 [Curran, Diane] [Makhijani, Arjun])

Comment: The appeal to WIPP does not provide much assurance. As noted, in paragraph 3.5, the NRC itself has repudiated a salt repository for spent fuel. (0898-4-19 [Curran, Diane] [Makhijani, Arjun])

Comment: The Finnish and Swedish repository programs are more advanced than those in other countries. However, it should be noted that both these countries have very small amounts of spent fuel compared to the United States. Sweden has just ten reactors, with nuclear energy production at about eight percent of the United States. Finland has just four with production, about three percent of the United States.¹²⁰ [footnote 120 text: NRC Information Digest 2013, Appendix T] As noted in paragraph 8.5 above, even one very large repository, accommodating hundreds of thousands of tons of spent fuel may not be sufficient under a nuclear power resurgence scenario. Moreover, size matters, because the larger the repository that is needed, the more constrained the choices for locating it are likely to be. A smaller capacity at a particular site could well mean two repositories. (0898-4-20 [Curran, Diane] [Makhijani, Arjun])

Comment: Showing feasibility in the context of the U.S. power program that may expand considerably beyond the present level means showing that sufficient capacity will exist for all reactors that may be built. It is not enough to say that there will be "a" repository 60 years after the license expiry of "a" reactor. The NRC must specify the amount of spent fuel to be disposed of and show that there will be sufficient capacity to dispose of all of the spent fuel in a manner that would comply with reasonable safety standards. The Draft GEIS has not done that. (0898-4-21 [Curran, Diane] [Makhijani, Arjun])

Comment: The Draft GEIS has considered questions of technical feasibility without actually examining the impact of spent fuel disposal in a repository. This is essential for a waste confidence finding. For instance, the original waste confidence finding in 1978 was connected to Table S-3 in 10 CFR51.51. The latter assumed zero impact after repository closure because the former assumed disposal in bedded salt.¹²¹ [footnote 121 text: We note below in paragraph 8.21 that this was shown to be incorrect five years later in 1983, but it was the NRC's understanding in 1978 when the waste confidence rule was issued. The NRC's understanding today is that radiation doses to the public could be well above the zero exposure assumed in Table S-3.] We show below, in paragraph 8.22 that the NRC itself now acknowledges that radiation doses would, or at least could, be well above zero and even above the Yucca Mountain EPA standard of 100 millirem per year in 40 CFR 197. It is essential that a new waste confidence finding in regard to the feasibility of a repository be based on a contemporary understanding and actual scientifically valid estimates of radiation doses that might be expected at different sites in the United States. (0898-4-22 [Curran, Diane] [Makhijani, Arjun])

Comment: The NRC was explicit about the exclusion of repository impacts in its response to public comments on the scope of the GEIS: The NRC received comments related to spent nuclear fuel disposal. Spent nuclear fuel disposal is outside the scope of the Waste Confidence analysis, which will consider the environmental impacts of continued storage prior to ultimate disposal. The development of a national repository, the licensing of Yucca Mountain or another repository site, *environmental impacts associated with disposal in a repository*, funding issues, recycling, and other waste disposal strategies *are outside the scope of this GEIS*.¹²² [footnote 122 text: NRC Scoping 2013, p. 42; italics added] 8.16. Two of the three scenarios in the Draft GEIS involve repository disposal. It is essential at least for the NRC to demonstrate in the GEIS that one or more sites with sufficient capacity exist in the United States that would likely meet reasonable health and safety rules. (0898-4-23 [Curran, Diane] [Makhijani, Arjun])

Comment: THE DRAFT GEIS DOES NOT SUPPORT THE NRC'S PROPOSED FINDINGS REGARDING THE FEASIBILITY AND SAFETY OF DEEP GEOLOGIC DISPOSAL OF SPENT FUEL. (0898-4-9 [Curran, Diane] [Makhijani, Arjun])

Comment: The question of feasibility of spent fuel disposal is integrally related with the questions of the health and safety standards for disposal and whether any specific repository can comply with them. The Draft GEIS did not evaluate disposal impacts. By excluding them from its scope, the NRC has excluded a major part of the picture regarding the environmental impacts of the back end of the nuclear fuel cycle. (0898-5-19 [Curran, Diane] [Makhijani, Arjun])

Comment: The Draft GEIS has failed to demonstrate the feasibility of a repository in the sense of showing that there is a site in the United States that will meet safety standards with reasonable assurance. (0898-5-20 [Curran, Diane] [Makhijani, Arjun])

Comment: Nor has it demonstrated that there will be sufficient repository capacity, especially given that the Draft GEIS puts no quantitative limits on how much spent fuel can be produced under the proposed waste confidence rule. Persuasive arguments can be made that two repositories may be needed if there is a resurgence of nuclear power. Appeals to repository programs in Sweden and Finland do not resolve this issue ? their nuclear power programs are very small compared to the United States and therefore involve a small amount of spent fuel. Costs of long-term storage and disposal could run into hundreds of billions of dollars. (0898-5-30 [Curran, Diane] [Makhijani, Arjun])

Comment: [T]he Department of Energy has a responsibility to make good on its commitment to receive and safely store the spent fuel for the long term. By doing so, locally stored spent fuel could be safely removed to a single or regional locations controlled by and protected by our national government. (0909-2 [Johnson, Amber])

Comment: [T]he Department of Energy has a responsibility to make good on its commitment to receive and safely store the spent fuel for the long term. By doing so, locally stored spent fuel could be safely removed to a single or regional locations controlled by and protected by our national government. (0911-2 [Stork, Gilbert])

Comment: Power reactor Host States did not envision Long-Term or Indefinite storage of spent nuclear fuel within the State, and the Federal government must assume its responsibility for managing Spent Nuclear Fuel (SNF). The SNF must be permanently disposed of in a geologic repository as recommended by the "Blue Ribbon Commission on America's Nuclear Future" and supported by the Department of Energy. (0913-1 [Bevill, Bernard])

Comment: The indefinite period of storage at an Independent Spent Fuel Storage Installation (ISFSI), either at-reactor or away-from-reactor, accomplishes and assures the temporary storage of SNF in the absence of a permanent geologic repository, albeit less than satisfactory. (0913-3 [Bevill, Bernard])

Comment: The Federal government must insure the process for selecting a permanent disposal facility continues as proposed by the Department of Energy, and that a permanent geologic repository is developed, licensed, and becomes operational. (0913-4 [Bevill, Bernard])

Comment: (XII-6) Sweden has taken an interesting approach to ISFSI design. The Swedes have built the Clab facility, in which spent-fuel pools are located in underground caverns excavated in rock. The Clab facility has been described in a brochure published by SKB, the company that manages Sweden's radioactive waste.¹⁴² [footnote 142 text: SKB, 2006.] That brochure accompanies this declaration as Exhibit #48. One sees from the brochure that the ceiling of each cavern is 32 m below the surface. The intervening rock is granite. (XII-7) The Clab facility will probably not be replicated in the United States. It represents a comparatively expensive approach to managing spent fuel. Also, although Clab is not designed as a repository, there might be political pressure to employ such a facility as a repository if repeated efforts to build a repository were to fail. For that reason, I recommend that interim storage of spent fuel be done at the surface, to reduce the likelihood that an interim storage facility could become a repository by default. (XII-8) The German approach to ISFSI design is to store spent fuel in dry casks that are, with one exception, located within buildings at the surface.¹⁴³ [footnote 143 text: The exception is the Neckarwestheim ISFSI, which consists of two concrete-lined tunnels in the wall of a quarry.] The design of these buildings is described in a conference paper by Thomauske.¹⁴⁴ [footnote 144 text: Thomauske, 2003.] That paper accompanies this declaration as Exhibit #49. Two basic designs are used. One design is by STEAG, and the

other by WTI. Cross-sectional drawings in Thomauske's paper suggest that the STEAG design would be more robust against attack. That observation is confirmed by analyses showing that the STEAG design would be more robust against impact by a large aircraft. (0916-3-17 [Curran, Diane] [Thompson, Gordon R.])

Comment: About the proposed geologic repository for just a few Finnish reactors' irradiated nuclear fuel at Onkalo, immediately adjacent to the Olkiluoto nuclear power plant, the filmmaker interviews only Scandinavian proponents of geologic disposal, such as Finnish and Swedish industry and government officials. No anti-nuclear activists are interviewed. But even the proponents of geologic disposal cannot agree amongst themselves on a number of very basic questions, such as, should the repository be marked, to warn future generations? For, what if future generations want to mine the plutonium in order to make nuclear weapons? If the repository is to be marked as a warning against inadvertent human intrusion, how should it be marked? Current languages will evolve, and/or go extinct, long before the radioactive waste loses its hazard. But even once the gamma hazard dissipates, the nuclear weapons proliferation risk will remain for a much longer period of time - as will the alpha-particle hazard associated with such radiotoxic elements as Pu-239. (0919-2-17 [Kamps, Kevin])

Comment: On Page 1-12, in Figure 1-1, NRC assumes up to 80 years of operations at commercial reactors. That is, two 20-year license extensions, in addition to 40 years of initial operations. But how much high-level radioactive waste would that amount to, if all currently operating U.S. reactors were to continue to generate irradiated nuclear fuel for 80 years? Doesn't this conflict with DOE's assumption of 50 years of operations at commercial reactors, as assumed in its 2002 FEIS on Yucca? The DOE's Yucca FEIS, as at Table A-8 on Page A-16, assumes 105,414 Metric Tons of Heavy Metal in terms of quantities of irradiated nuclear fuel to be generated by the commercial nuclear power industry in the U.S. by 2046. Are NRC's assumptions in this DGEIS compatible with DOE's projections, or not? Wouldn't 80 years of commercial reactor operations result in significantly more irradiated nuclear fuel being generated than DOE assumed in its 2002 Yucca FEIS? (0919-3-2 [Kamps, Kevin])

Comment: Also attached are the announcement of the 2012 Chicago event, its schedule, its roster of speakers, and a 4-page fact sheet I wrote, entitled "Red Gate Woods: History's First Radioactive Dust Bin," about how we have not even figured out what to do with Fermi's first cupful of radioactive waste from 70 years ago. The same is true for commercial radioactive waste. (0924-4 [Kamps, Kevin])

Comment: A permanent repository was the basis of the growth of the nuclear industry and of course is not yet built and used. Both Republican and Democratic politicians have stated at public meetings that there never will be one built. (0933-2 [Anonymous, Janet])

Comment: There is no where safe to put the waste. All of the acrobatics to locate a "safe" storage / disposal site are a hoax - there is no safe way to handle and manage nuclear materials, and I have no confidence that one will be "found". (0936-5 [Laney, Nan S.])

Comment: I support the call by the Sierra Club for the NRC to create a safe, long-term solution for managing and disposing of the nation's spent nuclear fuel and high level radioactive waste. (0944-3 [Pascall, Glenn] [Watland, George])

Comment: The Sierra Club's bottom line conclusion: There remains no alternative but to continue the hard and necessary work of "creating a safe, long-term solution for managing and disposing of the nation's spent nuclear fuel and high level radioactive waste," in the words of the Nuclear Regulatory Commission's Blue Ribbon Commission, which reported in January 2012. (0944-9 [Pascall, Glenn] [Watland, George])

Comment: As history has taught us, temporary plans for nuclear waste are not the answer. (0946-4 [Commenters, Multiple])

Comment: However, the Department of Energy has a responsibility to make good on its commitment to receive and safely store the spent fuel for the long term. By doing so, locally stored spent fuel could be safely removed to a single or regional locations controlled by and protected by our national government. (0949-2 [Commenters, Multiple])

Comment: The Department of Energy has a responsibility to make good on its commitment to receive the spent fuel. Because it has neglected that responsibility, PG&E is supportive of the establishment of the President's Blue Ribbon Commission and its recommendations to advance a workable storage solution. (0949-4 [Commenters, Multiple])

Comment: However, the Department of Energy has a responsibility to make good on its commitment to receive and safely store the spent fuel for the long term. By doing so, locally stored spent fuel could be safely removed to a single or regional locations controlled by and protected by our national government. (0949-7 [Commenters, Multiple])

Comment: We Need YUCCA MOUNTAIN as a Storage Facility for Nuclear Waste: huge amounts of US tax money has already been spent toward this goal. (0967-1 [Kane, Lynne])

Comment: [I]s the radioactive materials national storage site in Moab up and running yet. Or are other sites being considered. (0978-1 [Martin, David])

Comment: Other countries have national rules and regulations regarding the disposal of these materials and some seem to be quite safe. (0986-1 [Wayland, Gregory])

Comment: Each year 2000 metric tons of high-level nuclear waste is generated which only adds to the 58000 tons already stockpiled at existing reactors in the US. Thus, we already have more nuclear waste than can be contained in the Yucca Mountain storage facility even if it did have funding and a license to operate which at this time it does not. (0990-1 [Schilling, Francis])

Comment: Your agency has been remiss in not having guidelines in place already. Your agency needs government oversight, not public comments. Any reactor that does not already have policies in place for retiring its waste and rods, should be handled immediately by the agency that oversees nuclear reactors, as well as their state government, with the possibility of being shut down. (0992-1 [Thaw, Karen])

Comment: Nuclear waste disposal is a mess. First, we must reactivate the Nevada disposal site. That stuff just has to go to some safe place, even if the Nevadans don't like it. (0996-1 [Donaldson, John])

Comment: As yet there is no permanent storage solution - and there is none likely in the foreseeable future, for engineering and political reasons. (0998-3 [Rosanelli, Donald])

38. Comments Concerning the Feasibility of Safe Storage and Regulatory Framework

Comment: While we are working on the solution, I am also concerned that many of our nuclear reactors have over-crowded fuel pools on site. These present safety threats to the communities and industries that surround the plants. The NRC should take immediate action to reduce the number of fuel assemblies in the water-filled pools. (0003-2 [Commenters, Multiple])

Comment: Before transferring the fuel rods to cask storage, the cask storage needs to be examined and reinforced to be able to safely store the fuel rods particularly those that qualify as high burn up fuel. Hardened on-site storage of the casks should become the choice for storage. (0003-3 [Commenters, Multiple])

Comment: Perhaps the best temporary solution would be to require every nuclear reactor location to provide for it's own waste storage on site, which would be secure from earthquake and volcanic damage (or release into any waterway through flood or tsunami) until such time as this problem can be safely resolved. (0006-4 [Van Wicklen, Betty J.])

Comment: I do NOT share the NRC's confidence in the industry's ability to solve the storage and disposal problems inherent in the use of nuclear power to generate electricity here in the US. Having seen far too many instances over the years where the Nuclear Power Industry has failed to properly maintain existing facilities, where human and mechanical failures have released radioactive materials into the environment, it is ludicrous for the NRC to tolerate the less-than-stellar performance on the part of Nuclear Power interests at their 'word', such as it has been. 'Reasonable assurances' from an industry with a record like that don't amount to a whole heck of a lot when you're planning on leveraging the futures of our children and grandchildren....assuming the inevitable mishap doesn't occur sooner than that. (0008-1 [Daly, John])

Comment: Waste from the Mix Oxide Fuel (MOX) technology should not be considered in the Environmental Impact Statement. MOX development and implementation technology has not been completed or licensed, and waste from MOX is not the same composition as uranium spent fuel. (0023-2 [Bridges, Martha])

Comment: I want to ask the NRC to consider can they definitely state with confidence that there is no danger with our current ways of dealing with radioactive waste? And I don't think so. And is there currently a safe way to store the waste? We should wait until a safe method exists, if ever. And I'm not even sure, and none of us are, that deep geological storage is safe. (0030-13-2 [Sondheim, Steven])

Comment: We anticipate that the NRC will continue to assess the adequacy of its current framework for regulating safe storage through its existing processes outside of this rulemaking. Several examples have been mentioned today, including the ongoing work on the ISFSI security rulemaking and staff's recent work on spent fuel pool safety in the Spent Fuel Pool Study. (0030-16-6 [Bonanno, Jerry])

Comment: The industry has shown over the course of decades that it is committed to the responsible, safe and secure storage techniques onsite. And we all know that onsite storage was never intended as a permanent solution, but we also know that the industry was gone to great lengths to make on-site storage a safe and secure process. These structures meet the rigorous requirements that the NRC has already laid out and the industry has invested billions of

dollars and thousands of man hours over the last few years in making these facilities safe and secure. (0030-18-3 [Curtin, Kenneth])

Comment: The truth is that all of the used nuclear fuel ever produced in the United States can be safely stored on the same amount of space required by only a handful of wind turbines. Personally, I feel that's a very small price to pay for nuclear energy which is and will continue to be our largest source of zero-carbon electricity. Furthermore, the U.S. industry has a stellar record of fuel storage and transportation. As has been mentioned, we stored over 1,000 casks safely and the fuel pools remain safe at every site across this country. Under the NRC's guidance we've completed over 3,000 successful shipments of fuel without incident. The NRC oversees many times as many shipments of radiological materials every year from medical, research, and other industrial needs. When it comes to materials management, the responsibility and professionalism shown by the nuclear industry and the NRC is beyond compare and they have shown that they are able to responsibly manage on-site fuel storage for as long as is necessary. (0030-19-3 [Cohn, Jeremy])

Comment: Spent nuclear fuel is currently being stored onsite in well-designed, well-protected facilities and storage casks. These facilities and storage casks are robust structures made out of steel linings and reinforced concrete walls that are several feet thick. Spent fuel pool are often 40 feet deep, steel lined with reinforced concrete walls and the structures are built to seismic standards to protect the pools. The dry storage casks where the fuel is moved are also robust structures made of concrete and steel. For every 10 tons of used fuel a facility uses 100 tons of concrete and steel to form a structure designed to protect the fuel. Over the 30 years nuclear energy facilities have safely and securely stored used fuel in these structures. American nuclear energy is also a highly-regulated industry with operating facilities subjected to on-site inspections by NRC staff 24 hours a day, 7 days a week, 365 days a year. (0030-20-2 [Lapiska, Evan])

Comment: The Council endorses the NRC's fundamental waste confidence conclusion that used fuel can be safely stored at reactor sites or at off-site locations in a time interval between reactor shutdown and ultimate recycling or disposal of the fuel. This conclusion is supported by many decades of safe secure on-site storage of used fuel in spent fuel pools and in dry storage systems, both in the United States and abroad. Nuclear fuel assemblies are robust, corrosion-resistant metal containers designed to maintain their integrity in the high-temperature, high-pressure, high-radiation environment of an operating nuclear reactor core. Conditions experienced by the fuel in storage are far more benign. The decay heat and radiation associated with used fuel decreases with time, and moreover used fuel requires no active cooling systems for long-term heat removal. Finally, the ability of used fuel to maintain its integrity during storage is supported by extensive experience, data, and analysis. (0030-23-6 [Blee, David])

Comment: We heard a little bit about the North Anna earthquake. In fact, what that showed is incredible robustness and integrity and excellence in design of the systems that were deployed at North Anna. (0030-23-7 [Blee, David])

Comment: But until then, our commitment, the regulatory framework, all of the things that are mentioned in the EIS, will keep these materials safe in these robust structures. (0030-6-11 [McCullum, Rod])

Comment: I just want to say a few words on behalf of the folks that I work with on a daily basis, the professional men and women out there who are responsible for managing used nuclear fuel

at our sites, who have compiled a very impressive safety record. We have loaded 1,700 dry cask storage systems with absolutely no release of radioactivity. They have been sitting on the pad, some of them, for as long as 30 years. We have done scientific studies. We have opened one up after over a decade in storage. We have looked inside. We have a tremendous base of evidence to know that these systems were steel, concrete, lead, used 100 tons of protection for every 10 tons of used nuclear fuel -- do provide outstanding protection. (0030-6-2 [McCullum, Rod])

Comment: The individuals I work with every day, they are -- I have been working for NEI for 15 years, and they are probably the biggest reason I keep coming into work every day, because I am so proud of the job they do and the experience that they provide and all of the innovation that has occurred in our industry. We have three vendors providing these casks. These vendors don't just meet regulations. They have to compete. It's like Ford and General Motors and Chrysler except it's Holtec and Transnuclear and NAC. That is, in general, the attitude of the folks I work with on a daily basis at the utilities and at the vendors. We don't just meet regulations; we exceed them. And a lot is said in this EIS about confidence in NRC's regulatory process, and that is how we will know that storage is safe. And, well, yes, the regulatory process is very strict, but it is indeed the nuclear culture that we have that is in place on all of those individuals I know and am speaking out on behalf of here today, as well as I know the ones that will come in the future because you don't get into this business unless you have that conference. (0030-6-3 [McCullum, Rod])

Comment: I think storage of the spent fuel is certainly important, and it seems to be done in a safe manner. We have had nuclear energy in this country for almost 50 years. The worst case scenario was Three Mile Island. Those safety checks and balances worked. (0030-9-2 [Guido, Jeffry])

Comment: I just wanted to be here tonight to let you all know that Sierra Club has no confidence that high level nuclear waste will be safe after nuclear reactors close. (0045-1-1 [English, Becky])

Comment: I'm also not confident that they are fully prepared to store the existing 80,000 metric tons of radioactive waste already sitting at the 104 reactors across the country. (0045-11-4 [March, Leslie])

Comment: It says here, you know, it's feasible to safely store spent nuclear fuel, follow license life of the operator of the reactor. You know, the DOE said it was feasible to build an advanced nitrous filtration plant at Hanford. And they approved a plan to build that plant that was going to cost somewhere between \$3 billion and \$4 billion, that was about ten years ago. That plant by Bechtel is, Bechtel has just turned that into a cash cow. They are currently not completed. They were supposed to be completed by 2014. The completion date has, you know, been moved up to about 2016 at this point and the cost of the thing is \$14.4 billion currently, you know, you can see what's happened there. You know, it's feasible perhaps to build the plant, but it didn't happen, you know. It didn't happen and DOE couldn't make it happen and that cost is incredibly high. That was a way of dealing with nuclear waste. (0045-12-3 [Kinsey, Bob])

Comment: If necessary, spent nuclear fuel can continue to be stored in a safe environmentally sound manner, for a long period of time, while we wait for the political process to reach agreement on a disposal solution. (0045-2-8 [Green, Michael])

Comment: Storing this stuff above ground for decades at plant sites is totally unsafe. (0050-2 [Waterman, Charles])

Comment: Show me the actual tests that prove these canisters won't leak the fission byproducts if an airplane crashes into them. (0050-3 [Waterman, Charles])

Comment: When the Nuclear Industry started terrorism was not a threat and I doubt that even then these plants would ever have received operating licenses if the intent was to store spent fuel in casks above ground at each site! (0050-4 [Waterman, Charles])

Comment: I am writing you because I am concerned about how we store all our hazardous waste, including the radioactive fuel rods from nuclear reactors. We should study and emulate the French example for using this technology. Nuclear power has been highly successful throughout France for many years. There has never been an accident or leak. (0057-1 [Lamont, Dana])

Comment: Remove all dry casks to ISFSI facilities away from populated areas of our country in dispersed arrays to make them less vulnerable to terrorists attacks, and reducing the consequences if attacked (0059-14 [Andrews, Richard])

Comment: Spent nuclear fuel is currently being stored on-site in well-designed, well-protected facilities and storage casks. These facilities and storage casks are robust structures made out of steel linings and reinforced concrete walls that are several feet thick. Spent fuel pools are often 40 feet deep, steel lined with reinforced concrete walls and the structures are built to seismic standards to protect the pools. The dry-storage casks where the fuel is moved are also robust structures made of concrete and steel. For every 10 tons of used fuel, facilities use 100 tons of concrete and steel to form a structure designed to protect the fuel. Over the last 30 years, nuclear energy facilities have safely and securely stored used fuel in these structures. American nuclear energy is also a highly regulated industry, with operating facilities subject to on-site inspections by NRC staff 24 hours a day, seven days a week, 365 days a year. (0060-2 [Lapiska, Evan])

Comment: The industry has shown over the course of decades that it is committed to responsible, safe and secure storage techniques on-site. While we all know that on-site storage was never intended as the permanent solution, we also know that industry has gone to great lengths to make on-site storage a very safe and secure process. These structures meet the rigorous requirements set by the Commission and the industry has invested billions of dollars and thousands of man hours upgrading the physical structure and overall security at nuclear facilities in recent years. (0061-3 [Kirton, Kenneth])

Comment: What exactly are the current safety standards for the spent fuel cooling pools at SONGS? What exactly are the current safety standards for the 42 dry storage casks? What back up is required today to protect the spent fuel pools from an electrical shut down of more than four hours? How many hours without cooling are the spent fuel pools safe? How far away are the back-up generators? Are they sufficient to keep all cooling pools safe for the three days of 90 mile an hour winds that our Santa Ana winds that hit Southern California each year might continue, keeping air support from the cooling pools if firestorm over ran the facility where the spent fuel pools are kept? What safety precautions exist for that circumstance? What is the safety formula for protecting the spent fuel from all disaster possibilities? Firestorm, earthquake, tsunami or terrorists? Such as the reactor domes were "adequate" against a 7.0 earthquake, and five terrorists on the ground. (0063-3 [Magda, Marni])

Comment: We were led to believe that nuclear spent fuel must wait five to seven years to be put in dry storage. No new fuel has been generated at SONGS for two years, so conceivably in

five years all spent fuel at Songs could be in dry storage. Why have only 42 dry storage casks been created in the 30 years the spent fuel has been accumulating at SONGS? Since the shutdown, the public has learned that 16 years ago a dangerous high burn fuel began to be used at SONGS. Who approved of that change? This kind of fuel is considered by the rest of the world too dangerous to use. What environmental impact did this higher burn fuel create have on the ocean? What temperatures changed or volume of ocean water used and dispersed? Who approved of this change of fuel at SONGS? What studies were demanded? Have we stored any of this more deadly spent fuel in dry storage at SONGS in the last 16 years? How? In what kind of storage? Where? Have we moved any of this more deadly high burn spent fuel from the SONGS spent fuel cooling pools? How? Where? How much of the spent fuel in cooling pools at SONGS is not high burn fuel? Is it stored in separate cooling pools from the high burn more dangerous fuel? Since this fuel is older than 16 years, could it all be in dry storage? Is all of it in dry storage? (0063-4 [Magda, Marni])

Comment: How long must the high burn fuel at SONGS remain in cooling pools before it can be stored in dry storage? How long will those dry storage casks last? How long must we wait to put the high burn fuel in final geologic disposal transportable casks? How soon could it be moved to MRS monitored, retrievable storage and how do we begin to get a California solution for MRS high burn fuel? We need it YESTERDAY. It can't wait, 2 years, let alone 20 to 60. SONGS can't keep the spent fuel where it is because of earthquake or tsunami possibilities that could create a Fukushima meltdown here any day. How can spent fuel in cooling pools be moved from Songs to a geological location that would be safe to store the fuel in new cooling pools that are away from earthquake faults, the ocean, and 8.4 million people? This must be done!!!! (0063-5 [Magda, Marni])

Comment: We need final geologic disposal casks that are transportable. Is that the NRC recommendation? We can't leave our grandchildren with the Chernobyl type mess of no money and containment needing to be redone every thirty or so years. (0063-7 [Magda, Marni])

Comment: The short- or interim-term storage of spent fuel is an escalating public safety matter because the United States has failed to identify or build a permanent national spent fuel repository. At nuclear plants across the nation, short-term storage has become defacto long-term storage, and risky wet storage pools are filling beyond their design capacity. Any doubling up on design capacity exacerbates the potential for a radioactive release. (0064-8 [Skud, Bruce])

Comment: Prevention and precaution. The EIS must also compare the variety of possible methods for storing the more than 150,000 tons of highly radioactive irradiated/spent fuel that will be created and housed at nuclear power reactors by 2050. (0072-2 [Black, Ryan])

Comment: We put the sludge from the ponds in 55 gallon drums which were then buried on site. This facility [West Valley, NY] was built on a fault and some of these drums were found in area creeks. Which begs the question just how safe are these storage sites? (0076-3 [Jensen, Phyllis])

Comment: Cooling pools were never meant to store as many dangerously radioactive "spent" rods as they are now doing. Sadly, we have no real way to safely contain these rods, since they will remain radioactively toxic for thousands of years. (0088-1 [Fast, Wendy])

Comment: And what is to be done with all the melted fuel and damaged fuel rods from the meltdowns that have actually occurred (despite NRC's misplaced confidence, probabilistic risk assessments and continued speculating that that can never happen)? According to an article

revealing failure of the concrete storage system for melted and damaged fuel from the Three Mile Island meltdown:

<http://www.platts.com/RSSFeedDetailedNews/RSSFeed/ElectricPower/6002873>; The concrete modules are "showing significant cracking and degradation," even though they were built in 1999 to last for 50 years, NRC said in the letter, [to DOE] which is dated April 7. DOE has analyzed the structural integrity of the modules, which have walls two feet thick, and determined that the problem is getting progressively worse, NRC said. NRC Staff scientists declare that a nuclear fuel fire in fuel exposed to air cannot be ruled out even in the oldest fuel. (0089-3 [Shaw, Sally])

Comment: In the report cited below, U.S.NRC NUREG-1738 Spent Fuel Pool Accidents Risks at Decommissioning Nuclear Power Plants. For Vermont Yankee (BWR), Ref. 1 states that the critical failure mode for the gross structural failure of the pool is an out-of-plane shear failure of the pool floor slab. With this failure mode, the liner will be breached and a large crack will develop through the concrete floor slab within a distance equal to the floor slab thickness from the pool walls. Possibly the entire floor will drop out, but I think that such a gross failure is unlikely. However, the concrete crack will be sufficiently large that the water in the pool will quickly drain out. (0089-4 [Shaw, Sally])

Comment: I am writing to ask that compliance of containment not be left to fuel pools for nuclear waste. This is not secure and vulnerable to terrorists, leaks and area contamination. (0092-1 [Scharin, Lisa])

Comment: It is IMMORAL and UNETHICAL to be so lax with such a dangerous fuel- especially one that can be used to annihilate so many people! I want more responsible, highly contained and monitored systems! (0092-3 [Scharin, Lisa])

Comment: As strange as this may sound, the idea for this paper was given to me by a anti-nuclear environmentalist who in describing various reasons that nuclear power plants should not be built, informed me that some of these casks have "skin temperatures" of three hundred and fifty degrees. I have never been able to confirm this exact figure. The cask manufacturers themselves however, and there are several, advertise the fact that "their casks" can typically store spent fuel safely for one hundred years, while at the same time allowing the latent heat of the fuel rods to gradually cool. (0100-1 [Behling, Steve])

Comment: These storage arrangements need to withstand earthquakes, storms, floods and terrorist acts. (0110-1 [Wolf, Ann])

Comment: Basically, I want to say very briefly about short-term storage of wet storage. Shame on the Nuclear Regulatory Commission for supporting wet storage. Wet storage is inherently less safe than dry storage because it has to be backed up by electrical generation that could fail and dry storage does not require electric generation. (0112-10-6 [Skud, Bruce])

Comment: Right now, right now we have -- we know the detail and characteristics of used nuclear fuel and how to design its containment and its protection. The record is clear from decades of operation in the U.S. and around the world. (0112-12-2 [Garcia, Diego])

Comment: However, on the other side, fuel from our reactors -- and I know some of you are not in agreement -- but fuel from our reactors is currently stored safely. Some in pools and a lot of it is in dry cask storage facilities. And the -- I think that we need to give them credit. And obviously your -- you need to voice concerns when you have them specifically and I think you've

been doing that. But while we don't have a central repository, I think it's important that we have a more than acceptable, a good system, and a safe system for storing the fuel that we have. And I think that this report goes in that direction and I think it's technically acceptable to do that and it does it. (0112-17-4 [Stamm, Steve])

Comment: According to an article revealing failure of concrete storage systems for melted and damaged fuel from the Three-Mile Island meltdown, the concrete modules are showing significant cracking and degradation even though they were built in 1999 to last for 50 years. NRC said in the letter, which is dated April 7th: "The Department of Energy has analyzed the structural integrity of the modules which have walls 2-feet thick and determined that the problem is getting progressively worse," NRC said. NRC staff scientists declared that a nuclear fuel fire and fuel exposed to air cannot be ruled out even in the oldest fuel. (0112-18-4 [Shaw, Sally])

Comment: In the U.S. NRC's NUREG-1738, spent fuel pool accident risks at decommissioning nuclear power plants, for Vermont Yankee boiling water reactor, it states that the critical failure mode for the gross structural failure of the pool is an out-of-plane shear failure of the pool floor slab. With this failure mode the liner will be breached and a large crack will develop through the concrete floor slab within a distance equal to the floor slab thickness from the pool walls. Possibly the entire floor will drop out, but I think that such a gross failure is unlikely. However, the concrete crack will be sufficiently large that the water in the pool would quickly drain out. (0112-18-5 [Shaw, Sally])

Comment: If you read the report itself, there are more other words other than generic that give me some problems. Let's look at spent fuel storage. I looked in vain because people kept saying, "Oh, the NRC has said they're all equally safe, all methods." Well, unless somebody at the NRC can point me to where that is, all I found in the NUREG was that both provide, quote, "adequate protection." What's adequate mean? One definition is barely sufficient. A second is mediocre. (0112-2-3 [Lampert, Jim])

Comment: Spent fuel is currently being stored onsite in well-designed, well-protected facilities in storage casks that are designed to avoid a wide range of threats. That's not to say, that's not to say that we don't look forward to, and are not open to, the evolution of these devices and technologies. (0112-21-1 [Morris, Kelsi])

Comment: Over the last 30 years nuclear energy facilities have safely and securely stored used fuel in these structures. American nuclear energy undergoes the most rigorous safety precautions and inspections in the world with the operating facilities subject to on-site inspections by NRC staff 24 hours a day/7 days a week/365 days a year. (0112-21-2 [Morris, Kelsi])

Comment: As the Commission continues these public hearings, I would just like to reiterate that nuclear energy has shown the utmost commitment to safely and securely storing spent fuel. (0112-21-5 [Morris, Kelsi])

Comment: I do not have to be a nuclear engineer to know that dry cask is safer than an overcrowded spent fuel pool on the banks of my beautiful Connecticut River or on the banks of Massachusetts Bay. I will repeat what was said before, shame on you for ever saying otherwise. I'm going to sound like a mother again, shame on you. (0112-24-4 [Darling, Ann])

Comment: You know, I'm heartened. During the 15 years I've been doing this as the work has shifted from disposing of it in the near term to storing it in dry cask and pools, which we do both

of those things safely, I've had a chance to work with some of the brightest professionals I could have ever imagined meeting. The engineers, the scientists who formed the technical foundation which keep the risks in the casks and the risks in the pool so low. I'm so heartened today to see all these young people who are devoting their careers to the same cause. It is indeed noble work and it is work that has been well done. (0112-25-2 [McCullum, Rod])

Comment: And I think the most powerful testimony of the safety of both pools and casks is Fukushima because those casks were over washed by the tsunami, they were shaken by the earthquake. The pools were not only over washed by the tsunami and shaken by the earthquake, three of them were in buildings that were completely decimated by hydrogen explosions. There's been a lot of rumors spread about what happened in those pools. But if you go on YouTube and look at the video, that fuel is in pretty much the same condition it was before the accident. And it will be there as we safely move it out of the pools as we've done in so many pools before. (0112-25-7 [McCullum, Rod])

Comment: I'd point you to the American Physical Society, the nuclear energy study group had a paper in 2007 that determined independently, unequivocally that with an appropriate schedule of monitoring and inspection, dry storage can be provided for as long as it's needed. (0112-27-2 [Curtis, Daniel])

Comment: I'm also for the dry casks, let me make that very clear. (0112-30-2 [Parks, Sheila])

Comment: So I want to start because there's this assumption out there and it's stated repeatedly that the spent fuel is safe, that it's managed safely, that it's current condition is safe, that the fuel pools are safe, that the reactors are safe. And I would really like the NRC to acknowledge that the current storage of spent fuel pools is not safe. There isn't anything about it that's safe. They're over stacked, they're beyond the design life, beyond the intentions. It can be made safer. I can agree with that. But the assertion that doing nothing but maintaining the status quo is safe is completely untrue and needs to change. So step one is to acknowledge that the spent fuel in the fuel pools is not safe. (0112-31-2 [Johanson, Birgit])

Comment: We should be designing for the worst possible scenarios, not deliberately minimizing the risks. (0112-31-9 [Johanson, Birgit])

Comment: I'm here to express my support and confidence in the storage of spent fuel on-site at nuclear facilities. The industry has shown that over the course of decades it is committed to responsible, safe, and secure storage techniques on-site. Now, we all know that on-site storage was never intended as a permanent solution. And we also know that industry's gone to great lengths to make on-site storage as safe and secure as possible. These facilities meet the standards and rigorous requirements that are set by the NRC. And the industry's invested billions of dollars and hundreds of thousands of man-hours, post 9/11 alone, in securing and reinforcing these facilities. (0112-4-1 [Kirton, Stratton])

Comment: In the phase-out period the radiated nuclear fuel should be stored in concrete and steel dry casks which do not require electricity. Because, according to the Union of Concerned Scientists, they are passively cooled by natural air flow. (0112-6-3 [Wrenn, Nancy])

Comment: Scientists now claim that the irradiated nuclear fuel will degrade with age. This means that when and if a better storage option is possible, transfer of this more radioactive and thermally hot fuel from the casks will be extremely risky. (0112-6-5 [Wrenn, Nancy])

Comment: The fuel pools [at Vermont Yankee Nuclear Power Station] are not protected by any redundant emergency systems or cooling systems nor are they housed in any robust structures. (0112-7-3 [Sachs, Leslie Sullivan])

Comment: In the phase-out period irradiated nuclear fuel should be stored in concrete and steel dry casks, which do not require electricity because, according to the Union of Concerned Scientists, they are passively cooled by natural air flow. (0116-3 [Wrenn, Nancy])

Comment: Scientists now claim that the irradiated nuclear fuel will degrade with age. This means that when and if a better storage option is possible, transfer of this more radioactive and thermally hot fuel from the casks will be extremely risky. (0116-5 [Wrenn, Nancy])

Comment: [F]or the millions of younger people in the area affected by this ticking time bomb, we owe it to THEM to have the chance to live out their lives by using common sense and exercising responsible behavior BEFORE it is too late. We are told that we shouldn't worry because it is less expensive to continue to store the waste as we have been doing, and more business-like than finding a safer way to store the deadly poisons of nuclear waste. And that there is really no danger. The last time I checked the Sunday New York Times Real Estate Section, Three Mile Island, Chernobyl and Fukushima were not places with many listings nor were there any articles indicating that there were customers looking to move to either of these three places. (0117-1 [Amram, David])

Comment: There are those here today who would like to construe the true purpose of this meeting in order to push their own agendas. The fact is that the waste confidence rule has nothing to do with Indian Point. Federal regulators and scientific experts say that it is safe to store spent fuel in pools onsite at Indian point and New York's five other nuclear power plants (0119-1 [Mooney, William])

Comment: I have no confidence under any rules that waste stored at Indian Point will be handled appropriately. (0120-1 [Seeman, Laurie])

Comment: In 2005, NRC and Entergy reported that radioactive water was leaking from IP2's spent fuel pool. Although discovered 20 days earlier, Entergy did not believe a tritium leak posed a serious enough threat to warrant public notification. 2007 a new tritium leak was found - leaks into the ground water and Hudson River. The now over 2,700 tons of high level radioactive waste that contains plutonium will remain deadly for 240,000 years - and it is being stored in ordinary buildings, not dry cask storage. And what about the amount of high burn-up fuel that presents an even far greater threat? How much is being produced? The radioactive material being stored at Indian Point is the equivalent of over 1000 Hiroshima bombs. The spent fuel pools are over-crowded, making an accident far more likely. There is no room for more spent fuel rods - stop producing them! (0121-2 [Skopic, Catherine])

Comment: First, please let me express my support and confidence in the storage of spent nuclear fuel on-site at nuclear facilities. Throughout its history, the nuclear energy industry has proven that it is committed to responsible, safe and secure storage on-site. Although storage of spent fuel on-site at nuclear facilities was not intended as a permanent solution, the industry has committed to making on-site storage a very safe and secure process. All containment structures are required to meet the rigorous requirements set by the Commission and billions of dollars and thousands of labor hours have been invested by the nuclear energy industry. (0122-2 [Bailey, Savannah])

Comment: Dry cask storage is a method of storing high-level radioactive waste, such as spent nuclear fuel that has already been cooled in the spent fuel pool for at least one year. Casks are typically steel cylinders that are either welded or bolted closed. The fuel rods inside are surrounded by inert gas. Ideally, the steel cylinder provides leak-tight containment of the spent fuel. Each cylinder is surrounded by additional steel, concrete, or other material to provide radiation shielding to workers and members of the public. There are various dry storage cask system designs. At Indian Point, the steel cylinders containing the fuel are placed vertically in a concrete vault. The concrete vaults provide the radiation shielding. The steel cylinders are vertically placed on a concrete pad at the dry cask storage site and use both metal and concrete outer cylinders for radiation shielding. Currently there is no long term permanent storage facility, dry cask storage is designed as an interim safer solution than spent pool storage. Indian Point began "dry casking" spent fuel rods in 2008, a "safer alternative", according to the Nuclear Regulatory Commission. Some rods have already been moved to casks from the spent fuel pools, which will be kept "nearly full of spent fuel, leaving enough space to allow emptying the reactor completely should that become necessary." Dry cask storage systems are designed to resist floods, tornadoes, projectiles, temperature extremes, and other unusual scenarios. NRC requires the spent fuel to be cooled and stored in the spent fuel pool for at least five years before being transferred to dry casks. Indian Point stores used fuel rods in two spent fuel pools at the facility. According to the New York State Department of Environmental Conservation, the Indian Point spent fuel pools, which contain more nuclear material than the reactors, "have no containment structure". While the spent fuel pools at Indian Point are not stored under a containment dome like the reactor, they are contained within a 40-foot-deep pool and submerged under 27 feet of water. The spent fuel pools at Indian Point are made of concrete walls that are four to six feet wide with a half-inch thick stainless steel inner liner. According to Jonathan Alter, the pools are located in bedrock, not above-ground as at many other plants including the Japanese ones. (0123-1 [Marzullo, Dominic])

Comment: Secondly, there is no safe place to store spent and radioactive fuel rods. We should not be generating more of them. Storage and liability needs to be the permanent responsibility of the nuclear energy companies. Storage of present fuel rods should, for safety's sake, be in dry casks rather than in pools. (0125-3 [Kidney, Barbara A.])

Comment: Is it possible that the NRC could finally insist that the potential for the very same catastrophe be removed from the United States by requiring dry cask storage, at the very least? (0126-5 [Houston, Ann E.])

Comment: I would remind the Region 1 NRC that the current NRC Chairman was part of a waste storage study in 2003 at MIT that concluded that dry cask storage is less dangerous than wet pool storage. (0136-5 [Shaw, Gary])

Comment: We can be confident that - Commercial Nuclear Fuel in the United States - is safely stored, can be safely stored and will be safely stored. (0138-1 [Cook, Dr. Andrew G.])

Comment: As a physicist and engineer I can say with confidence that used nuclear fuel is, can be and will be safely stored. I know it is safely stored because I have seen the used fuel at our US nuclear energy facilities. Used nuclear fuel is a solid, rock like ceramic, encased in strong metal tubes that are sealed. It is a solid, a rock, that is protected from the environment. It is temporarily stored and cooled in NRC licensed fuel storage pools. I know this fuel is safely stored. I have seen: --the attention to detail and safety exhibited in the design of those storage sites, --the care the operating staffs take with fuel and --the rigorous, independent assurance the on Site Nuclear Regulatory Commission inspectors provide. (0138-2 [Cook, Dr. Andrew G.])

Comment: I also know the fuel is safely stored because it is being safely stored and even recycled by my company at our La Hague France nuclear fuel recycling center. There, using US created technology, we are routinely, today, safely storing nuclear fuel, and safely recycling nuclear fuel. Further, we, today are melting the extremely small amount of left over material into glass. These glass cylinders, about 2 feet by 4 inches in diameter form a solid, water impervious engineered and licensed, environmentally friendly approach for long term underground storage. (0138-4 [Cook, Dr. Andrew G.]

Comment: The EIS must compare methods for storing the more that 70,000 tons of spent fuel that will be created and housed at nuclear plants by 2050, Hardened On-Site Storage (HOSS) of high-level nuclear waste to reduce risk of leakage or terrorist attack. The NRC should take immediate action to reduce the fuel assemblies in spent fuel pools, as well as analyzing the deficiencies of current dry cask storage. (0143-5 [Arauz, Jorge])

Comment: In order to justify its Waste Confidence policy, NRC is relying on the federal government's Plan B: to hide the waste problem by transporting spent fuel away from nuclear reactors to "temporary" storage sites around the country. This means more communities would be at risk from radioactive waste, more nuclear sites would have to be safeguarded, and reactor owners could continue making waste without responsibility for managing it. Temporary storage sites easily could become de facto permanent dumps if it is not politically feasible to site enough repositories to handle the waste. (0147-4 [Fallon, Gloria])

Comment: Spent fuel storage should be maintained locally until a consolidated Federal Depository is established at Yucca Mountain or another Federal depository site. (0148-2 [Ryan, Paul])

Comment: Radioactive waste from nuclear power plants should be stored on-site. This places the risks and costs of storage in the communities that benefit from nuclear power plants. Shipping nuclear waste to other storage sites is an externalization of costs, both economic and risk. (0149-1 [Powell, Michael])

Comment: Spent fuel is currently stored safely at nuclear power plants in either spent fuel pools or dry cask. In 1990 the commission made the generic determination that spent fuel generated in a reactor could be safely stored on site for at least 30 years after licensed life for operation. It was assumed that at the end of the 30 year period a deep repository would be available for long term storage. We now know that may not be the case. It is assumed that at the end of the 60 year period the United States will have a sufficient deep repository for long term storage. As a result of monitoring current storage methods and data collected since the 1990 decision it is evident that safe fuel storage can continue as a regulated activity for 60 years after the end of licensed operation. (0152-2 [Pelletier, David A.]

Comment: The strict guidelines regulating the onsite storage of the spent fuel, whether it be in storage pool or dry cask containers insure the safety of the public and should put any environmental concerns to rest. (0153-2 [Capurso, Thomas])

Comment: There is no truly safe way to store nuclear waste for thousands of years. (0155-1 [Preschle, Gus])

Comment: Think about all the nuclear waste leaking out of Japan into the Pacific Ocean. Now think about the safety of our reactors here and about how we store our most hazardous waste, the radioactive fuel rods from nuclear reactors. Are our communities at risk because of how we

store these radioactive fuel rods? It is also known that many of our nuclear reactors have overcrowded fuel pools on site. (0159-1 [Evjion, Virginia])

Comment: I know how both wet storage pools and dry casks are designed and operated. I know the redundancies in margins of safety in the designs of both types of storage technologies. Beginning in the 1980s the nuclear power plants began moving spent fuel from wet storage to dry storage and have continued to do so safely for nearly 30 years. There is no reason to believe they cannot continue to do so into the future and as long as necessary until the Federal Government starts picking up the fuel. The vast majority of today's dry spent fuel systems, including those at Indian Point are made of fully welded stainless steel canisters stored inside thick concrete casks or modules about two feet around the outside of those. They don't leak. They don't release any reactor material. They're designed to be dropped, tipped over, withstand floods, earthquakes, tornadoes and missiles without leaking an ounce of radioactivity. (0163-11-3 [Gutherman, Brian])

Comment: The technology doesn't exist. The casks that that other person was talking about with all the thickness and everything and the cement, they don't last more than I think 300 years is the max. That's it. It's uncontainable. (0163-14-3 [Schepart, Margot])

Comment: We're here to discuss spent nuclear fuel. Spent nuclear fuel is being stored onsite in well-designed, well-protected facilities in storage casks -- and quite safely at that. These facilities and storage casks are robust structures made of steel linings and reinforced concrete walls that are several feet thick. Spent fuel pools are often 40-feet deep, steel-lined with reinforced concrete walls and the structures are built to seismic standards to protect the pools. The dry storage casks where the fuel is moved are no different. For every ten tons of used fuel, facilities form a robust structure made of 100 tons of concrete and steel to protect the fuel. The industry has been doing this for more than 30 years safely and securely and to ensure safety there is regulation. American nuclear energy is also the high -- is also a highly regulated industry with operating facilities subject to onsite inspections by NRC staff 24 hours a day, seven days a week, 365 days a year. (0163-18-3 [Lapiska, Evan])

Comment: In addition, new technologies create new risks. For the past 16 years the NRC has allowed high burn-up fuel which burns longer and hotter in the reactor. When removed, this fuel needs up to twice as long in cooling pools, as well as more space between fuel rods in an already crowded pool. (0163-20-5 [Gellert, Sally Jane])

Comment: Those high-level radioactive rods and fuel assemblies need to be moved to dry cask storage. They need to be monitored and they need to stay onsite for as long as they are radioactive -- 240,000 years. We used the electricity. It was a fleeting good so-called and now we're stuck with it. And what's the answer? To stop making more. (0163-21-5 [Elie, Marilyn])

Comment: It's my understanding that only about 15 percent of the spent fuel assemblies that have been accumulating at Indian Point for the last 40-plus years have been moved to on site dry cast storage. This directly contradicts what the -- what the report out MIT that included a co-author, who is now the current chairman of the NRC, who said that -- who said that dry casks are much more safe than wet storage. I guess they don't want -- you know, it's just mind-boggling. (0163-22-3 [Shaw, Gary])

Comment: But for millions of younger people in the area affected by this ticking time bomb, we owe it to them to have the chance to live out their lives by using common sense and exercising responsible behavior before it is too late. We're told that we shouldn't worry because it's less

expensive to continue to store the waste as we've been doing, and more business-like than finding a safer way to store the deadly poisons of nuclear waste and that there's really no danger. (0163-26-1 [Amram, David])

Comment: First, please let me express my support and confidence in the storage of spent nuclear fuel on site at facilities. Throughout its history the nuclear energy industry has proven that it is committed to responsible safe and secure storage onsite. (0163-29-4 [Bailey, Savannah])

Comment: Although storage of spent fuel onsite was not intended as a permanent solution, the industry has committed to making it a very safe and secure process. All containment structures are required to meet the rigorous requirement set by the Commission, and billions of dollars and thousands of labor hours have been invested by the nuclear energy industry in recent years to upgrade physical structures and ensure security at nuclear facilities across the country. (0163-29-5 [Bailey, Savannah])

Comment: Throughout the industry's history it has shown that spent fuel can be stored on site safely, securely and cleanly. In the Commission's consideration of both this and future issues I urge them to take into account the incredible clean-air power of nuclear energy and consider ways to strengthen its commitment to clean-air - clean-energy technologies across the U.S. (0163-29-9 [Bailey, Savannah])

Comment: The now over 2,700 tons of high-level radioactive waste that contain plutonium will remain deadly as we've heard over and over again this evening for 240,000 years and is being stored in ordinary buildings, not dry cask storage. (0163-32-2 [Skopic, Catherine])

Comment: And what about the amount of high burn-up fuel that presents an even far greater threat. How much is being produced? I would really like to know. We all would like to know. The radioactive material being stored at Indian Point is the equivalent of over 1,000 Hiroshima bombs. The spent fuel pools are overcrowded, as we've also heard, making an incident far more likely. There is no room for more spent fuel. Stop producing them. (0163-32-3 [Skopic, Catherine])

Comment: We in Oyster Creek also have the problem of the unknown unknowns as was alluded to a couple of times earlier, namely of the high burn-up fuel issue. Just as recently as Monday we've asked the NRC "Do we have high burn-up fuel at Oyster Creek?" And we're assured, no, no. But the document from the U.S. Department of Energy Inventory and Description of Commercial Reactive Fuels in the United States published in March 31, 2011, clearly states we do. And many other reactors do. (0163-36-3 [Brown, Jeffrey])

Comment: Now, the problem with high burn-up fuel for this waste confidence issue in part is that it makes the fuel rods embrittled, much worse than they would be otherwise. Therefore, even handling them becomes more difficult. There's more likelihood of damage. It makes it more difficult to transport, so that the problem is multiplied. And so how can we have confidence that whatever the unknown unknowns that are going to be discovered going forth will be handled. I say we do not. (0163-36-4 [Brown, Jeffrey])

Comment: "The public has been asked to come here today to comment on the U.S. Nuclear Regulatory Commission's Proposed Waste Confidence Rule related to the appropriate and safe storage of used fuel from nuclear power reactors. There are those here today, one of which who you have already heard from, who would like to construe the true purpose of this meeting in order to push their own agendas. The fact is -- the fact is that the Waste Confidence Rule has

nothing to do with Indian Point. Federal regulators and scientific experts say that it is safe to store spent fuel in pools onsite at Indian Point and New York's five other nuclear power plants. (0163-4-1 [Thomas, Richard])

Comment: I'm here to talk about the dry cask storage. It's a method of storing high-level radioactive waste, such as spent nuclear fuel, that has already been cooled in a spent fuel pool for at least one year. Casks are typically steel cylinders that are either welded or bolted closed. The fuel rods inside surrounded by inert gas. Ideally, the steel cylinders -- steel cylinders provide leak-tight containment of the spent fuel. Each cylinder is surrounded by additional steel, concrete, and other material to provide radiation shielding to workers and members of the public. There are various dry storage systems. At Indian Point the steel cylinders contain fuel that are placed vertically in a concrete vault. The concrete vaults provide the radiation shielding. The steel cylinders are vertically placed on the concrete pad and the dry cask storage sites use both metal and concrete outer cylinders for radiation shielding. Currently there is no long-term permanent storage facility. Dry cask design is an interim safer solution than spent fuel pool. (0163-6-1 [Marzullo, Dominic])

Comment: Indian Point began dry casking spent fuel rods in 2008, a safer alternative. According to the Nuclear Regulatory Commission, some rods have already been moved to casks and the spent -- from the spent fuel pools, which they were kept, nearly full of spent fuel leaving enough space to allow emptying the reactor completely should it become necessary. Dry cask storage systems are designed to resist floods, tornadoes, projectiles, temperature extremes, and other unusual scenarios. The NRC requires all spent fuel to be cooled and stored in spent fuel pool for at least five years before being transferred to dry cask. If this was not a safe process, we would not have our employees work and they also live very close to the plant. (0163-6-2 [Marzullo, Dominic])

Comment: One thing that has not been discussed and is not discussed in the GEIS is how much high burn-up waste there is. And high burn-up waste is a really serious question and the NRC will not answer how much there is because that waste takes longer to cool and has to be handled differently, but the NRC will not reveal to anyone how much there is at the plant. (0163-7-1 [Shapiro, Susan])

Comment: Let me just answer your two questions. No. The answer is "No." There is no feasible safe storage following the operation of the reactor. We've seen that with the safe storage at Indian Point 1. (0163-7-10 [Shapiro, Susan])

Comment: I support the NRC 's conclusion that used fuel can be stored safely and without significant environmental effects. This conclusion is very well supported by years of safe storage in the U.S. and elsewhere. (0178-1 [Daniels, John])

Comment: As a former Non-Licensed Operator at Duke Energy's McGuire Nuclear Station, I am comfortable with and familiar with the safe handling and storage of spent fuel. As an employee of AREVA, I am familiar with the safe transportation of nuclear material, which has occurred accident free for decades in this country. I have every confidence that solutions will be available, when needed, for dealing with spent fuel and high-level radioactive waste. (0179-2 [Graham, Susan])

Comment: As an NRC Commissioner, I clearly saw that U.S. nuclear power plant operators take used fuel storage very seriously. Whether stored in a pool, or in a dry canister, that fuel receives the highest level of attention to ensure its long term safety and security. As a result of 9-11 and Fukushima, the nuclear industry has taken a series of measures to enhance the safety

of these facilities. In my view, these efforts have enhanced the high level of assurance that this fuel can be safely managed-on site or off-site after the lifetime of the nuclear plant. (0180-1 [Merrifield, Jeffrey])

Comment: I also believe that temporary-away from reactor storage can be successfully utilized as an interim solution for used fuel. In February of 2006, the NRC issued a license to build the Private Fuel Storage Facility in Utah which was an interim dry storage site for 44,000 metric tons of used fuel 50 miles outside of Salt Lake City. As part of the permitting process, Holtec, the cask manufacturer, conducted testing to successfully demonstrate that these canisters can withstand the direct impact of an F-16 fighter jet. While PFS did not move forward, this licensing process clearly showed the ability of the NRC to review and approve such a site and has prompted a number of communities to consider volunteering to host a similar facility in the future. (0180-3 [Merrifield, Jeffrey])

Comment: Combined with the high quality design and manufacturing that I saw visiting facilities that were fabricating dry storage canisters, I became convinced that dry storage and transportation containers are a safe, demonstrated, and reliable used fuel storage technology. (0180-5 [Merrifield, Jeffrey])

Comment: I have learned through my short career in this business that nuclear power plant owners have safely managed spent nuclear fuel for decades and continue to do so today. There is no reason to believe they cannot continue to do so well into the future, and as long as is necessary for the federal government to begin removing fuel from these sites. The fact that the government has not lived up to its promise to remove fuel from the reactor sites is disturbing, but considering that the current scenario is likely to remain the status quo for decades, I feel confident that nuclear power can safely continue to play a role in U.S. electricity generation, and the necessary storage of spent fuel at the reactor sites gives me no cause for concern. My understanding is that the nuclear industry is the most highly regulated industry, and the NRC has proven that it protects the health and safety of the public. With the excellent safety record the industry has established over the last several decades, I see no reason to believe this will change. The vast majority of today's dry spent fuel storage systems are made of fully welded stainless steel canisters stored inside thick concrete casks or modules. The canisters do not leak and therefore do not release any radioactive material. The concrete casks and the canisters inside are designed to withstand drops and tip-overs, as well as severe environmental conditions, including earthquakes, tornadoes, fires, floods, and wind-borne missiles all without releasing any radioactivity whatsoever. Zero. These storage systems are passive. That is, they require no electric or other source of power and will last a long, long time with minimal maintenance. (0181-2 [Waters, Christine])

Comment: I have learned throughout my career in this business that nuclear power plant owners have safely managed spent nuclear fuel for decades and continue to do so today. There is no reason to believe they cannot continue to do so well into the future, and as long as is necessary for the federal government to begin removing fuel from these sites. The fact that the government has not lived up to its promise to remove fuel from the reactor sites is disturbing, but considering that the current scenario is likely to remain the status quo for decades, I feel confident that nuclear power can safely continue to play a role in U.S. electricity generation, and the necessary storage of spent fuel at the reactor sites gives me no cause for concern. My understanding is that the nuclear industry is the most highly regulated industry, and the NRC has proven it protects the health and safety of the public. With the excellent safety record the industry has established over the last several decades, I see no reason to believe this will change. The vast majority of today's dry spent fuel storage systems are made of fully welded

stainless steel canisters stored inside thick concrete casks or modules. The canisters do not leak and therefore do not release any radioactive material. The concrete casks and the canisters inside are designed to withstand drops and tip-overs, as well as severe environmental conditions, including earthquakes, tornadoes, fires, floods, and wind-borne missiles all without releasing any radioactivity whatsoever. Zero. These storage systems are passive. That is, they require no electric or other source of power and will last a long, long time with minimal maintenance. (0183-2 [Green, Carlyn])

Comment: As long as nuclear reactors generate this waste, would not "interim" waste sites simply create more contaminated sites, while at the same time allow for the production of ever increasing amounts of these dangerous materials for which future generations would have to contend? (0189-2 [Patrie, MD, MPH, Lewis E.]

Comment: Before transferring the fuel rods to cask storage, the cask storage needs to be examined and reinforced to be able to safely store the fuel rods particularly those that qualify as high burn up fuel. (0198-3 [Cerrito, Robert])

Comment: Throughout my career, the Nuclear Professionals I have worked with have displayed one core value that has never changed - which is a focus on safety. Our industry has a demonstrated track record of operating safely. In particular, I note the transportation and storage of spent nuclear fuel where we have decades of experience operating safely, both in the US, and around the world. Safety has been, and is, our highest priority. (0201-3 [Fregonese, Vic])

Comment: Safer on site measures must be taken regarding temporary storage to avoid any and all environmental and human impact. (0202-4 [Hill, Jack])

Comment: Although on-site storage is not appropriate for long-term storage and a national repository does not appear to be available in the present, there are other options. A recent Senate bill discussed the option to have interim repositories which would act as locations where several reactors could consolidate their waste. These would not take the place of a national repository but would act as "buffer locations" until the national repository is accessible (Dolley, 2013). Interim locations are a way of alleviating the problem but are not a permanent solution. (0205-13 [Lyons, Laura])

Comment: On-site storage is not appropriate for long-term, as it can present disastrous effects[.] (0205-16 [Lyons, Laura])

Comment: The first issue is that on-site storage is not necessarily appropriate for long-term nuclear waste storage, as it can present hazardous conditions. (0205-3 [Lyons, Laura])

Comment: The proposed rule states that the Nuclear Regulatory Commission: "has concluded that the analysis in NUREG-2157, "Waste Confidence Generic Environmental Impact Statement" (DGEIS) generically supports the environmental impacts of continued storage of spent nuclear fuel beyond the licensed life for operation of a reactor and supports the Commission's determinations that it is feasible to safely store spent nuclear fuel beyond the licensed life for operation of a reactor and to have a mined geologic repository within 60 years following the licensed life for operation of a reactor." However, the most common methods of on-site storage currently in use are concrete-lined pools or large concrete and steel casks which are not meant for long-term storage (Harnett, 2013). The lifetime of a cask is decades, yet nuclear waste remains dangerous for thousands of years ("Nuclear waste can't," 2013). Moreover, these casks are not in a form that can be stored at a repository -- even if one is found

in the next sixty years (Wald, 2013). Every year reactors in the United States generate about 2000 metric tons of radioactive waste (Kintisch, 2011). As they continue to generate nuclear waste and store it in these casks, they are losing precious storage space every day. (0205-6 [Lyons, Laura])

Comment: Please forward this info to the Waste Confidence people: Article from Power Engineering: Briefer on the DOE's High Burn-Up Used Fuel Demonstration Project; <http://www.power-eng.com/articles/npi/print/volume-6/issue-5/departments/nuclear-world/briefer-on-the-doe-s-high-burn-up-used-fuel-demonstration-project.html>; The NRC should not be allowing the industry to use (and make more of) this type of high burn-up fuel when they do not have either the safe long term storage or the safe transportation of it figured out yet! "Since the 1990s, almost all used fuel being removed from the reactors have burn-ups in excess of 45 to 50 GWd/MTU. This is considerably higher than the burn-up of the PWR assemblies in the initial demos at INL. The higher burn-ups have generated regulatory interest regarding the ability of used fuel that has undergone prolonged storage to remain intact during transportation; there are some concerns that high burn-up fuel could become critical after a transportation accident." In truth, the NRC Waste Confidence environmental impact statement cannot hope to comment on these issue since the potential answers are not even known. (0211-1 [Leichtling, Don])

Comment: The NRC has placed its own safety employees in a catch-22 situation because they allowed the nuclear industry to promote the use of high burn-up fuel before the safe transportation and long term storage were ever considered, in fact until recently the public did not even know that high burn-up fuel was even in use since the 1990's, much less that it required much longer cool down periods after being in use which will surely increase the nuclear "footprint" of nuclear waste located at all NPP using high burn-up fuel! (0211-2 [Leichtling, Don])

Comment: We're here to discuss spent nuclear fuel-not something that is new, and not because of an issue, but because of the way the system works, providing due process to address questions and concerns and ensure the safe operation of nuclear facilities, and the safe storage of fuel after it has been used. Spent fuel is currently being stored safely on-site in storage casks as well as fuel pools. Most importantly, it is being stored safely and securely, as it has been for many years and can be for many more[.] On top of the physical safety measures that are the design of the storage options, the regulation the industry operates under is second to none. American nuclear energy operating facilities are subject to on-site inspections by NRC staff 24 hours a day, seven days a week; 365 days a year. (0212-3 [Lapiska, Evan])

Comment: Spent nuclear fuel is currently being stored on-site at facilities in storage casks that are steel-lined with reinforced concrete walls. These are robust structures--for every 10 tons of used fuel, facilities use 100 tons of concrete and steel to form a structure designed to protect the fuel. Over the last 30 years, nuclear energy facilities have safely and securely stored used fuel in these structures. American nuclear energy is also a highly regulated industry, with operating facilities subject to on-site inspections by NRC staff 24 hours a day, every day of the year. (0213-3 [Coalition, Clean and Safe Energy])

Comment: Leaving spent fuel in fuel pools indefinitely is not acceptable. (0215-2 [Matsuda, Thomas])

Comment: NRC is currently evaluating Edison's requested use of a new dry cask system that crowds 32 fuel assemblies into the same space that currently holds 24 at San Onofre. This new system will increase risk of dangerous radiation releases into the environment. (0218-7 [Borchmann, Patricia])

Comment: Use of High burn-up fuel at San Onofre requires more storage space between fuel assemblies due to higher heat, higher radioactivity, and instability. (RWMA Marvin Resnikoff, PhD.) No transportation casks for high burn-up fuel are approved by NRC, so waste cannot be relocated. Insufficient data exists to approve dry casks for over 20 years. (per NRC Robert E. Einziger, PhD, <http://1.usa.gov/15E8qX5>. High burn-up fuel has unresolved serious waste storage issues. A June 2013 Department of Energy Report states: ".cladding performance issues need to be addressed before this fuel can be loaded into dry casks and transportation systems", and "burnup rates as low as 30 GWd/dMTU can present performance issues including cladding embrittlement under accident conditions as well as normal operations. San Onofre now has 1,123 high burn-up fuel assemblies (which require a longer minimum of 15 years of cooling in spent fuel ponds). (DOE FCRD=NFST-2013-000132, Rev.I; /Fuel Cycle Research & Development-Nuclear Fuel Storage and Transportation 2013,-000132, Rv.1, 6/15/13 <http://222.hsdn.org/abstract&id=739345/>) (0218-8 [Borchmann, Patricia])

Comment: Long-term storage of radioactive waste at nuclear power plant sites should be done in dry, secure canisters. The industry which made the waste and profited from it should manage it. And storage on-site at nuclear power stations represents the least hazard to public health in the areas both near the reactors and along transport routes. (0222-3 [Zeller, Lou])

Comment: The EIS must consider the risks of current dry cask storage. Lack of quality assurance for design and fabrication of dry casks casts doubt on the structural reliability of current casks, most of which are stored outdoors in plain sight, and are not designed to withstand terrorism or severe earthquakes. Accidents with dry casks have occurred. The EIS must consider seismic risks to dry cask storage. (0230-12 [Garb, James])

Comment: Moreover more and more of today's fuel is the radioactively hotter high burn-up fuel. (0233-2 [Dubois, Gwen L])

Comment: The University of Florida is part of a six university consortia which is researching the performance of nuclear fuel which may be stored in airtight dry steel or concrete and steel containers for long periods of time exceeding hundreds of years. This university research consortia is funded by the Department of Energy and is headed by Texas A&M University and includes universities of Florida, Boise State, Illinois, Wisconsin, and North Carolina State. I am the task leader for the thermo creep of nuclear fuel in long-term storage. Our initial studies indicate the satisfactory performance of nuclear fuel in this long-term storage. (0244-1-1 [Tulenko, James])

Comment: I would also like to indicate the research teams from the Electric Power Research Institute and our national nuclear laboratories are also forming consortias which are ensuring the safety of the long-term dry storage of nuclear fuel. (0244-1-6 [Tulenko, James])

Comment: There were seven used fuel pools and nine dry casks on the Fukushima site. They all survived the accident very well. Some of us who were familiar with the details of those pools were talking before the meeting. The pool -- there was concern that we didn't know what was going on in the pools, but when the pools were investigated that fuel was still in good shape, that fuel will be very thoroughly and methodically removed from those pools. And the casks

were over washed by the tsunami and shaken by the earthquake; three of those pools, and they're fine. Three of those pools were in the buildings that suffer the hydrogen explosion. It is perhaps the most dramatic example of how robust its used fuel storage is, what happened at Fukushima. If you look at the videos on YouTube, the data that exists now that we've seen those pools, it is indeed a dramatic counterexample as to why they're not safe but why they are safe. (0244-11-11 [McCullum, Rod])

Comment: Because what we know, based on our experience, that we can safely store used nuclear fuel in both pools and casks, we know we also have to demonstrate that to the public. So it's important for me and for our industry to hear what others are saying. (0244-11-4 [McCullum, Rod])

Comment: Well, if you look at the experience we've had in loading 1,700 casks, in managing 104 spent fuel pools for 40 years, or longer in some cases, and you look at all of the events, these things are all in great detail discussed in the EIS. We don't stop there. Well, we don't say, oh, "Well, past predicts the future," because you never know what can happen. There is a lot of very forward-looking science and it was good to hear a representative of that scientific community speak earlier about how we're always looking, doing research to look further into the future, to keep our headlights safe on the road ahead of us. (0244-11-7 [McCullum, Rod])

Comment: In Waste Confidence the NRC proposes reasonable assurance that the disposal of spent fuel will not pose an undue risk to public health and safety. It does so via the NRC finding and assumption that disposal is technically feasible and can be achieved with no significant environmental impact. The Waste Confidence decision makes a key assumption that spent fuel in the future, when necessary, can be isolated in a repository and no radioactive releases will go to the biosphere. (0244-14-2 [Prescott, Lisa Marie])

Comment: The American Association of Blacks in Energy supports Federal action to develop consolidated facilities for interim storage of high-level radioactive waste until a permanent repository is sited. We urge the NRC to continue its strong, independent oversight of commercial nuclear energy facilities; the operation of existing plants; the licensing of new reactors; the renewing of operating licenses of existing reactors; and the management, transportation, and disposal of spent nuclear fuel. (0244-2-3 [Knowles, Berdell])

Comment: For the many decades which nuclear energy has been use, spent nuclear fuel has been stored safely and securely onsite at Florida's nuclear power plants. With their environmental assessments, the Nuclear Regulatory Commission has shown that the environmental impact of the storage of spent nuclear fuel is small. In addition, research by major universities around the nation have shown the safety of the storage of spent nuclear fuel. (0244-7-3 [Kuntawala, Jitesh])

Comment: Which, quite frankly, is a fairly narrow question, and that is do -- is there confidence that we can safely, and for an extended period of time, store spent nuclear fuel onsite beyond the reactor life. And the simple truth is, is that those who suggest that you can't have suggested that 50 years ago, 40 years ago, 30 years ago, 20 years ago, 10 years ago, and they have always been wrong. They were wrong then and they're wrong now. For five decades in the state of Florida we have operated successfully five reactors, which, quite frankly, have provided -- as I think another engineer pointed out, Mr. Bernard Knowles from American Association of Blacks in Energy -- have provided 98 percent of the emission-free energy in the state of Florida. Those plants have done that by storing their spent nuclear fuel onsite in spent fuel pools and now in dry cask storage. If what the opponents have suggested were true, 50 years ago, 40 years ago,

30 -- 10, 30, 20, 10, and tonight, I wouldn't have been able to say that. I believe we do have confidence in our ability to store fuel onsite for an extended period of time; short term, intermediate term, and indefinitely. (0244-9-3 [Paul, Jerry])

Comment: So, the fundamental question of today's meeting is do we have reasonable assurance that it's safe to store spent fuel beyond the license life of nuclear power plants. And to answer this question, the NRC put out the generic environmental statement which concludes that it is safe to store. And upon reviewing it and using my engineering background and knowledge from the industry, I agree with their conclusions. The fact of the matter is, even if we never get a repository, spent fuel pools and dry casks are both safe options based on their continued performance. In fact, Illinois has the largest inventory of used spent nuclear fuel and has not had a spent nuclear fuel accident. And that's not shortsightedness, that's proven engineering. This is because both technologies are designed to be robust. Everyday we think about what's the worst case scenario. That's what I'm trained to do and we design to protect the health and safety of the public. (0245-12-1 [de Graaf, Brandon])

Comment: So, for example, spent fuel pools are designed with reinforced concrete walls, stainless steel liners, leak-detection systems, redundant monitoring and cooling, and makeup water systems. Dry casks, they are designed with the tight steel cylinders, they're actually welded shut, and they have concrete liners which protect and shield the environment from the radiation. I walk by these things everyday. I've worked in the spent fuel pool buildings. And I still get more radiation from flying on an airplane to visit my sister in the south. The casks are also air-cooled and, have no moving parts, and are not dependent on any operator or system actuation to be safe. (0245-12-2 [de Graaf, Brandon])

Comment: So, on top of all that, the fuel itself is robust. I mean we take materials so that they can handle the harsh environment of the reactor, so it has to be degradation-resistant. So, once it becomes spent nuclear fuel, that's a property that won't actually disappear, it's still degradation-resistant. (0245-12-4 [de Graaf, Brandon])

Comment: But until then, there is reasonable assurance that it is safely stored spent fuel in dry casks and pools. (0245-12-7 [de Graaf, Brandon])

Comment: My final point has to do with a whistleblower right here in the Chicago area, Oscar Shirani, who passed away a number of years ago, who called attention to the shortcuts on safety going on with the Holtec cask design. In a short three-day inspection, he and a team of experts from across the country identified nine categories of quality assurance violation with the Holtecs. These are deployed at Dresden and he questioned the structural integrity of these dry casks sitting still. So, for over a decade now, hundreds of environmental groups have called for the pools to be emptied into hardened onsite storage, a major safety upgrade on the status quo of dry cask storage, fortifications against terrorist attacks, safeguards against accidents. That's what needs to happen. (0245-13-6 [Kamps, Kevin])

Comment: There is talk about Illinois becoming a centralized interim storage site although interim seems to be taking on a new meaning of possibly forever. Maps from Oak Ridge National Laboratory put Illinois number one and all but a few, because of our centralized location. We also have the most reactors and the largest amount of waste. We don't want interim storage here. Fuel should be moved only once on the way to the repository. Interim storage wastes time and money and we'd be a prime destination for terrorists. (0245-14-6 [Kurz, Carol])

Comment: NRC also has not adequately studied the environmental impact of fuel degradation and cask deterioration over time. Finally, since the NRC is doing, engineering, an environmental impact study, the site-specific issues, of which there are several major issues, aren't being addressed. It sounds to me like we're inviting a catastrophe. Is this what we want? (0245-15-3 [McComb, Sandy])

Comment: The storage of spent nuclear fuel has been taking place in Illinois for decades, in fact for half a century since the first commercial reactor went online in Illinois. In that time, there has not been a single breach at a spent fuel storage facility. There has not been a single case of public injury or contamination as a result of spent fuel storage facility failing. There has not been a single incidence where any person or group has been able to obtain spent fuel for nefarious purposes. (0245-16-2 [O'Brien, Doug])

Comment: We can't find the proper solution to deal with this so-called low-level ionizing radiation in the landfill, what the heck are we going to do with the stuff that's sitting in the spent fuel pools, like the 2,363 fuel pools at the Callaway I nuclear reactor that my organization is legally challenging the license extension of. (0245-19-3 [Smith, Ed])

Comment: But we've done pretty well with these and I want to thank the NRC, IEMA, and all those for working with the owners of our nuclear facilities to keep the onsite storage of spent nuclear fuel safe. And it is safe. Unlikely scenarios that are designed to scare people are not productive to the discussion nor to our energy debate in general. Opponents of nuclear energy paint a picture of piles of growing glowing waste sitting out in open air or implying that they're easy targets. All this hyperbole and hot air just obscures the fact that there has never been a single incident where spent nuclear fuel storage has been compromised by any outside individual or group. It's been safely stored for decades and I believe the NRC and IEMA and the owners of nuclear plants can keep it that way for decades to come. Of all the reasons people give for wanting to move away from Illinois, I can say that no one has ever talked to the Chamber about the stored nuclear waste as the reason that they moved out of the state. The tax structure, the pension problem, the high workers comp rates, restructured attitudes in Springfield, those are the major active issues that keep businesses from coming to or growing in our state. (0245-2-2 [Wolf, Tom])

Comment: I'm a manager in the area of spent fuel at Exelon. And I appreciate the opportunity to provide these comments on behalf of Exelon. What we have shown and continue to show as an industry is that we safely store fuel at our sites, both dry and wet storage. (0245-20-1 [Dunlap, Jeff])

Comment: In the interim, for storage at the reactor, as I have said, we continue to safely store fuel in both wet and dry storage. And just to add a little perspective, the amount of storage required is very small. If you stacked all the stored fuel in Illinois up to the height of the average person, it would only fill up half of one football field. The NRC environmental assessment of nuclear fuel storage accurately reflects the environmental impacts, which is small for the continued storage at plant sites and away-from-reactor storage, even with many bounding assumptions that may overstate the impact. This conclusion is based on storage systems for nuclear fuel that are proven technology with robust design and safety features that prevent environmental impacts. The analysis contained in the Draft Waste Confidence Generic Environmental Impact Statement supports what the industry has long known. If necessary, used fuel can be stored in a safe, environmentally sound manner for a long period while we wait for the political process to reach agreement on a disposal solution. (0245-20-6 [Dunlap, Jeff])

Comment: We take our jobs seriously, and its essential to the design, building, maintenance, and security of our spent fuel storage system. Our dry cask storage containers, they're lined, they're steel lined with thick concrete post structures. They are designed to improve and to protect the fuel under the most extreme weather conditions or other destructive forces. I personally have no doubt that this passive technology offers a long-term solution that will protect my colleagues, my family, and my neighbors. (0245-23-2 [Korn, Susan])

Comment: And we know a lot of defective casks arrived from Holtec at Dresden and were loaded after some welding was done without -- in violation of 10 CFR 50 Appendix B, a lot of those casks that lead to the reasonable expectation that they do not have the strength that the original designs have. I'm sure you've heard of -- dirty operation. (0245-24-1 [Conn, Corey])

Comment: An available repository is actually of little value if the thousands of tons of freshly radiated fuel remains precariously perched in elevated pools. It matters not that the waste may also be stored in dry casks as every operating reactor must also have its pool. (0245-24-4 [Conn, Corey])

Comment: I have spent some time in my career working at the nuclear station and I have first-hand experience with spent fuel storage. I personally walk down the dry cask storage area and work next to a loaded dry cask, and I have spent considerable time working near spent fuel pools. Storing fuel in the spent fuel pool or in dry cask storage is very safe. First, I'd like to discuss the spent fuel pool and spent fuel storage, the dry cask storage. I have spent many hours working near spent fuel pools, observing the fuel and the actions of moving the fuel. This is a safe location designed to withstand severe natural accidents including floods, tornadoes, and earthquakes. The safety of the spent fuel pool is ensured by maintaining sufficient water level above the fuel, even during -- This pool is designed to be about 40 feet deep, and to maintain about 20 feet of water above the fuel in an accident condition. Everyone involved with the spent fuel pool recognizes the importance of spent fuel pool. And as an employee, I can tell you we consider safety in every decision that we make. Next, I would like to discuss dry cask storage. Dry cask storage is proven safe technology that is designed for long-term isolation of spent nuclear fuel. The casks themselves are robust concrete in steel structures with no moving parts. These casks are engineered to monitor and protect 10 tons of spent fuel per cask. Over the last 30 years, the nuclear industry has over 1,700 dry cask storage systems. All these systems are still in service and have had zero release of their radioactive contents. I personally have worked near dry casks and I feel confident in their design and safety. Throughout my career, I have learned that Exelon Nuclear values the health and safety of the public above all else. Safety is infused in everything that we do. (0245-26-1 [Kovacs, Ashley])

Comment: So, one thing I did want to respond to that I saw and I heard mentioned a couple of times was in response to criticisms of casks falling through to the bottom of the spent fuel pool. That's a great challenge. So, the question is why the heck would we lift these heavy structures over a spent fuel pool, and the answer is we don't. They're designed so that we don't lift heavy structures near these safety critical systems. And I've actually went over that several times when development plans because we have to keep these, anything over 2,000 pounds, you know, a set distance away from safety critical things such as spent fuel pools. (0245-28-2 [Rosso, Chris])

Comment: The third thing is reduce Illinois' chances of becoming the nation's dump. Illinois already is home to over 9,000 metric tons of used nuclear fuel, more than in any other state. The previous two alternatives would work to minimize Illinois' chances of receiving an even greater proportion of the nation's spent fuel. According to an Oak Ridge National Laboratory

report, as a totally separate analysis, a consolidated independent storage site in Illinois is the single optimized site for an independent spent fuel installation and only SNF reactors is considered relative to siting itself. In other words, it's a lot of tech speak in that particular paragraph but what it's saying is that Illinois is in a position to become the site of one of these independent spent fuel storage facilities. And, of course, we have a nuclear plant already, a nuclear spent fuel facility at Morris, Illinois. (0245-29-4 [Shineflug, Marilyn])

Comment: How can long-term, let alone indefinite, waste storage even be considered credible? How disintegrated will spent fuel rods be, particularly those with high-product fuel when the need for transfer to new casks arises every many years or so? (0245-29-9 [Shineflug, Marilyn])

Comment: And to me, in order to have any kind of waste confidence, confidence in any kind of exclusion, you have to have an underlying risk-management system that makes sense. This doesn't seem to have a system at all. Instead, I think they want to conflate waste confidence with, as my husband terms it, waste arrogance, and that's really all this is, the belief that we can just say, whoosh, we've got a solution, we will continue doing as we are and it will work great and everyone will be happy. Instead, I think about the very real engineering nitpicky details, things like fatigues, stresses on metals that begin to fail, the impacts of corrosion. When things are designed for a 30-year-life or even a 60-year-life, they do not last for 100 years. Otherwise, then they are over-designed and that doesn't serve shareholders so it never, ever happens. (0245-31-6 [Fox, Tracy])

Comment: I'm here speaking on behalf of my nieces and nephews and for future generation in all walks of life. As I was thinking about what I wanted to say here in response to this hearing tonight, I was reminded of a story of a young person with clothes. It's a story of a vain emperor who cares about nothing except wearing and displaying clothes. He hires two swindlers who promised some of the finest best clothes with a fabric invisible to anyone who is unfit for his position or hopelessly stupid. The emperor's ministers could not see the clothing themselves but they pretend that they can for fear of appearing unfit for their positions, and the emperor does the same. Finally, the swindlers report that the suit is finished and they mime dressing the emperor and he marches in procession before his subjects. And the townsfolk played along with the pretense not wanting to appear unfit for their positions or stupid. But then there's a child in the crowd and he's too young to understand the desirability of keeping up this pretense and he blurts out that the emperor is wearing nothing at all. And he frees everyone else in the crowd who start realizing that the emperor is naked. This is a fable that is an apt description of the nuclear industry and the issue before us tonight. It's the feasibility of safely storing nuclear waste. The nuclear industry has dressed this operation in a sham of safety, claiming that nuclear power is safe, and spent fuel rods can be contained, and so posing no threat to life on the planet. But that simply isn't true. The emperor has no clothes. Nuclear power plants produce the most deadly waste imaginable. We have already created enough radioactive waste to destroy life on Earth. And the hard truth is we don't know what to do about it. Fukushima is not hypothetical. It is not theoretical. It is not science fiction or a made-up story. It's real. And it is proof of the fallibility of nuclear power and protection of spent fuel rods. The experts don't know how to keep us safe from it. And yet the NRC and the nuclear industry is acting as if we do. We're looking at the naked emperor and praising his imaginary outfit. (0245-32-1 [Rude, Kathleen])

Comment: This safety one hundred percent translates to our nuclear waste program. I personally work with the dry cask storage campaign at LaSalle and I can testify that those casks are far more robust than you can imagine. Over a hundred tons of steel and concrete form a precisely engineered structure to protect the fuel that we place inside. And I have walked past

those loaded casks many times, and I assure you that I get way more radiation from the sun that's shining down on me than from those casks. They've been proven to survive severe hurricanes and earthquakes, aircraft crashes. They have flown planes into those concrete cask storage and the plane was disintegrated with the cask remaining intact. And we've also tested missiles 30 times more powerful than a typical antitank weapon. And all this has been done to keep the casks intact. (0245-33-2 [Schussele, Samantha])

Comment: Illinois has 50 years of experience managing spent nuclear fuel and has done so safely. And I believe that's only going to get better. Illinois has loaded 120 casks, safely stored in pools for 50 years including the only independent spent fuel storage installation - that is the Morris facility - which was recently relicensed, a very tough, highly specific process like all NRC process just to use an example. (0245-34-1 [McCullum, Rod])

Comment: I want to talk about two things specifically that's been mentioned a lot, the safety culture and climate change. I see these things becoming intertwined. Safety culture is not about rhetoric. It's not about anecdotes. It's not about speculation. It's about facts. It's about analysis. It's about questioning the facts and doing more analysis. This is what nuclear engineers do. This is why the young people who got up here are so confident. This is why we have achieved the safety record we have. (0245-34-3 [McCullum, Rod])

Comment: Nationwide, there is well over 80,000 tons of spent nuclear fuel, with plutonium that will remain toxic for 240,000 years. Other elements in the radiated fuel will be dangerously radioactive for even longer. No storage facility has been designed that can contain radioactive waste for such periods since spent nuclear fuel contains large quantities of fissile fuel or -- material that can be used to make nuclear weapons. So, they also must be safeguarded to prevent theft. (0245-37-3 [Bilenko, Stephanie])

Comment: Proponents of nuclear power treat the radioactive waste as a minor matter. It is not. A nuclear fusion reactor produces waste so lethal that it has to be isolated from the rest of existence for a quarter of a million years. In theory, containing high-level waste is possible. In practice, Murphy's Law is the safer god. In the real world, it is certain that sooner or later things go wrong. By accident or passiveness of nature, that waste is going to leak into the biosphere. And once that happens, anyone and anything that comes into contact with even a few milligrams of it will suffer a miserable death. The more nuclear power we generate now, the more of this ghastly 'gift' will be stockpiling for the people of the far future. A basic concept of morality is that each of us ought to leave the world a better place for those who come after us. If we know better, we ought to do that. One of the essential boundaries of appropriate tech is the boundary between the kinds of matter you can change with tools you have on hand and the kinds you can't. And if you can't change it into something safe, it's a bad idea to produce it in the first place. (0245-37-4 [Bilenko, Stephanie])

Comment: Now, the young lady who came up from Exelon, all the people from Exelon, thank you. You're very nice. I like you. I'm sorry you work for Exelon and I'm glad your organization and company provides you with experiences that you feel make things safe. Exelon gets cited many times for doing wrong things. So, don't forget that. But they have never put you in a situation with a tornado or a typhoon or an earthquake. How about that for pools of radioactive waste? You've never experienced that. So, you really can't stand up and say confidently they have done everything and I do feel safe. (0245-38-2 [Good, Joyce])

Comment: Those of us who live and work in that area, especially someone who is looking to attract new business in the area would not be satisfied with the substantial economic impact that

we gain at the expense of our safety. The Center for Economic Development is also a member of the Braidwood Citizens Advisory Panel and have been fortunate to closely follow the way Braidwood operates. Its culture of safety and security is second to none, and its transition to dry cask storage of spent fuel is a good example. Exelon took the initiative to invest in dry cask storage that provides an added level of safety and security, and we applaud them for taking that step. We also encourage the NRC to continue to work with industry to promote innovations that will improve or enhance operational safety and ultimately lead to the creation of spent fuel repository for the storage of this material. The Will County CED is confident with the safety and security of the storage facilities at Braidwood and we look forward to the continued positive impacts of the station in our community for many years to come. (0245-4-2 [Fleming, Scott])

Comment: I do have confidence in the NRC's rulemaking and policies and procedures. I reside at, well, with this crowd, I don't think I'm going to tell you where I reside it. But, as the crow flies, I live eight miles downwind of Dresden Nuclear Power Plant. And there are nuclear spent fuel storage casks there that have been there for years. And my -- isn't wired shut and I haven't lost any teeth either. I feel safe that the fuel is stored safely and not a threat to my safety or my family's. And I live downwind of the casks. And I represent one of the neighbors and we know the casks. I have witnessed the fuel being put into the casks. I have witnessed the welding of the casks. And I have witnessed the inner cask being put in the outer cask, and I have witnessed the two feet of concrete, the new product concrete poured around the inner casks and the outer lid welded on. I have all the confidence that the NRC's design and engineering will keep the fuel safely stored with all the criteria and the most stringent standards. Each inch is reviewed. The casks are made of neutron material. I have confidence in the NRC's expertise in continuing to develop policies and procedures to protect us as they have done in the past. And I'm not moving. And I challenge the previous speaker who contested the safety of the casks and the building of the casks in the parking lot after this meeting. (0245-40-1 [Schwartz, Robert])

Comment: And nuclear waste continues building up, so nuclear spent fuel is now stored in dry casks at nuclear plants while they work on the problem. It is as simple as this. Everything leaks eventually. Everything leaks. And nuclear matter, when it leaks, contaminates that which contains it and everything far, far beyond. Leakage cannot be controlled or contained. (0245-42-2 [Rorem, Bridget])

Comment: [W]e also recognize the need to address the transportation, storage, and disposal of used nuclear fuel. The issue of developing a solution to the safe and secure storage of high-level radioactive waste and used nuclear fuel is of great importance. NCLS supports Federal action to develop consolidated interim storage facilities to temporarily house high-level radioactive waste inventories until a permanent repository is operational. (0246-1-2 [Husch, Ben])

Comment: We urge the Nuclear Regulatory Commission to continue providing strong, independent oversight of all commercial nuclear plant operations, including plant licensing for new reactors and license extensions for operating reactors and in used fuel and radioactive waste management, transportation, and disposal. (0246-1-3 [Husch, Ben])

Comment: As the Federal government continues to default on its legally mandated responsibility to handle spent nuclear fuel, utilities and the nation's rate payers have been left to foot the bill. The work-around has been dry cask storage, nearly 2,000 of which have been installed in the U.S. with zero release of radiation. This historical track record lent strong support to the rigorous technical evaluations that the Agency has compiled as part of its rulemaking. (0246-10-3 [Bennett, Nathan])

Comment: All of that notwithstanding, the Agency has ample reason to have confidence and remain confident in the fact that a safe disposal option will become available and that continued storage can be accomplished in a safe and environmentally sound manner in the meantime. (0246-14-2 [Ginsberg, Ellen])

Comment: There is no proof that spent fuel stored in dry steel containers inserted into these concrete casks can be safely removed or transported in the future and there is no place for it to go. How can the NRC assure that the containers will be replaced after their 50-year lifetime or before that if they fail? (0246-17-4 [Dugdale, Jane])

Comment: In spite of the risks it poses, cask storage onsite is the least-bad long-term solution to waste containment. (0246-17-6 [Dugdale, Jane])

Comment: The current system of storage has been approved and continues to be studied to find ways to make things more secure and safe. (0246-18-4 [Karbowsky, Brad])

Comment: Dry cask storage systems, they are robust, no moving parts, passively cooled, a hundred tons of concrete and steel and other materials to protect every 10 tons of fuel. Pools are equally robust with 20 feet of water above the fuel, several feet of concrete structures. And of course, the casks are most relevant to the discussion here because over these incredibly long time frames, the fuel will move to the casks, it is decades or less that we tend to do that. Now, I have talked about at some of the other meetings I have had the pleasure to attend and learn from, the robustness of the casks, I have talked about my confidence in the people who manage the casks. It is one of the things that I think is underappreciated in the EIS is the human element and the very dedicated people that do this. (0246-19-2 [McCullum, Rod])

Comment: But what I want to talk today is a little bit more about the robustness of the process. A couple of things have been mentioned. One is high burn-up fuel. That is mentioned in the EIS as an example of how the process works. And I was going to cite a letter that I left back there. But industry has documented its position and in our comments, we will send a letter which we wrote to NRC within the last year that cites 15 different scientific studies, which document the technical basis for the safe and long-term storage of high burn-up fuel. The high burn-up demo project was mentioned previously. That project is intended to confirm, further confirm the findings of those studies. And the results of that project, whatever it be, good, bad, or indifferent, will go into aging management plans. Every 40 years these casks have to be relicensed. The NRC has done a very bounding analysis here, talked about repackaging every 100 years, dry transfer facilities everywhere. We don't think that will happen. But the regulatory process will be what decides what does happen. So, we do have a very robust technical basis for storing high burn-up fuel for addressing other technical concerns. It is very forward looking. (0246-19-3 [McCullum, Rod])

Comment: One of the things about this EIS is it is a snapshot in time. It looks at the world based on what we know today. If you look at the opportunities for learning that go beyond what we hear in these meetings and go through the aging management plans and the scientific investigations, industry has multiple programs in place to look at all the long-term aging characteristics of not just the fuel but the casks. Just like we are looking at high burn-up fuel, we are looking at various cask degradation mechanisms. Everything with dry storage happens slowly. So whatever we find, we will have time to address it. We will take what we learn and we will move on. (0246-19-4 [McCullum, Rod])

Comment: I believe as strongly as anybody we need a permanent disposal solution and I am committed to continuing to work towards that. But until we have that, I know our processes will work. They will continue to learn. And throughout my career in this area, the more we learn about this, the more we know, the safer it looks. (0246-19-5 [McCullum, Rod])

Comment: There is not adequate understanding of the high burn-up fuel that has now, we are hearing, half of the inventory this high burn-up fuel, fuel with more radioactivity has to be cooled longer in the pools. It is not an integral part of the analysis that we have done, even though it is an integral part that we'll continue to generate, so the high burn-up fuel is not adequately addressed in the Environmental Impact Statement. (0246-2-5 [D'Arrigo, Diane])

Comment: Spent fuel is currently being stored safely onsite in storage casks, as well as fuel pools. Most importantly, it is being stored safely and securely, as it has been for many years and can be for many more. On top of the physical safety measures that are design of the storage options, the regulation the industry operates under is second to none. American nuclear energy operating facilities are subject to onsite inspections by NRC staff 24 hours a day, 7 days a week, and 365 days a year. (0246-20-3 [Lapiska, Evan])

Comment: [We don't] need interim storage solutions for nuclear waste. What we need are permanent storage solutions because right now at the beginning of the nuclear waste problem, the fuel is thousands of times more dangerous. (0246-29-10 [Hoffman, Ace])

Comment: And there is no feasible safe storage. And I am talking about something that is going to survive today's environment. There is not a policy decision either that is scientific fact because ionization destroys any containment. The containment, as we have just heard from the last speaker [Mark Leyse], are degrading. (0246-29-2 [Hoffman, Ace])

Comment: Honestly, I think that the whole process is pathetic because the state-of-the-art of high burn-up fuel knowledge is practically zero. Despite the claims that we have been hearing to the contrary, every zirconium fitting is different and maybe one has been tested. And nothing has been tested for very long. The testing just simply hasn't been done. We are talking about engineers who cannot, in 65 years, they haven't been able to solve the transit problems that occurred in Fukushima. And now, two years later, we are still nowhere near a good solution to that. There are gingerly trying to move the fuel. (0246-29-8 [Hoffman, Ace])

Comment: I would like to address the high burn-up fuel, which the NRC is allowing to be used nationwide and they don't even have a safe way to store it. It is a classic case of putting the cart before the horse. And if they are going to do any kind of environmental impact statement, that should have all been done before they approved the use of this high burn-up fuel, period. I mean the NRC needs to step up and take a good look at what they are approving and to make sure they can safely secure what they are allowing utilities to create more of. And right now, there is no safe way to store that. In fact, I am reading off a thing from Power Engineering. They posted, on the internet, a briefer under Department of Energy's high burn-up used fuel demonstration project, which is a \$16 million five-year award to a team led by some different companies, the objective of which is to observe and confirm the long-term characteristics and behavior of high burn-up fuel under real conditions and a full-scale dry storage system. (0246-5-1 [Leichtling, Don])

Comment: So, the NRC needs to immediately address what is happening with high burn-up fuel, how it can be transported safely, how it can be stored, and not let more of it get created until they have this thing worked out, waiting for another 10, 15, 40, 100 years is not a good

answer when they are trying to come up with an Environmental Impact Statement that describes what they are going to do in the future. (0246-5-3 [Leichtling, Don])

Comment: The nuclear energy industry has built a comprehensive system, using state-of-the-art technology to safely and securely contain the spent fuel it creates that keeps both the public and the environment safe. Spent nuclear fuel is currently being stored onsite of facilities in storage casks that are steel-lined with reinforced concrete walls. These are robust structures. For every 10 tons of used fuel, facilities use 100 tons of concrete and steel to form a structure designed to protect the fuel. Over the last 30 years, nuclear energy facilities have safely and securely stored used fuel in these structures. American nuclear energy is also a highly regulated industry with operating facilities subject to onsite inspections by NRC staff 24 hours a day, every day of the year. (0246-8-1 [Vince, Jenny])

Comment: In spite of the risks it poses, cask storage on site is the least bad long term solution to waste containment, because removing and transporting the containers is much too dangerous. (0249-10 [Dugdale, Jane])

Comment: First, regarding Limerick's use of "high-burn" nuclear fuel, evidence suggests its use is far more dangerous than fuel previously used at Limerick. Higher radioactive gas releases; increased corrosion, thinning, and brittleness of fuel cladding; increased radioactivity and decay heat from spent fuels; and increased damage to the fuel rods in the reactor vessels -- all these can result, leading to radiation leaks in the spent fuel pools and casks.; o The public has a right to full and accurate disclosure of the long-term consequences of using "high-burn" nuclear fuel.; o Requests by ACE for this information have gone unanswered. Specifically, ACE wants to know if the NRC has verifiable answers to the following questions: When did Limerick start using this fuel? When was Limerick's license amended to start using this fuel? Does the NRC plan to continue allowing Limerick to use it, despite the increased risks to our region? (0249-5 [Dugdale, Jane])

Comment: There is no proof that spent fuel stored in dry steel containers inserted into these concrete casks can be safely removed or transported in the future. There is no place for it to go. (0249-8 [Dugdale, Jane])

Comment: o Steel Containers for spent fuel at Limerick are only expected to last 50 years. How can the NRC assure that the containers will be replaced after that, or before that, if they fail? (0249-9 [Dugdale, Jane])

Comment: [L]ong-term storage of radioactive waste at nuclear power plant sites should be done in dry, secure canisters. The industry which made the waste and profited from it should manage it, and storage onsite at nuclear power plants represents the least hazard to public health in the area, both near the reactors and along transport routes. (0250-1-3 [Zeller, Lou])

Comment: I believe that the U.S. nuclear facilities will continue to safely handle and store used nuclear fuel for the time frames discussed in the draft Environmental Impact Statement. (0250-10-2 [Tampas, Courtney])

Comment: Yes, it's hard for me to get to the meetings, but I'm on a mission. I want you to know that North Carolina citizens do not want Shearon Harris to continue to store dangerous irradiated nuclear fuel in the overcrowded and unprotected cooling pools. How did North Carolina come to provide a home for the four largest overcrowded cooling pools in the country? Why didn't we get to say something about this before it happened? Most people don't even

know the danger of these pools. But you do, don't you? It's your responsibility to protect the public health by transferring this nuclear waste to dry cast storage. You must make it a national security top priority. (0250-11-2 [Kerr, Julius])

Comment: I appreciate the opportunity to provide input to the important topic of used fuel management. We currently safely store our used fuel assemblies in our used fuel storage pool. We have taken steps to assure the long-term safety of used fuel stored in our pool. In 2003, we replaced all of the storage racks with an improved neutron absorber. We also have an ongoing surveillance program, to monitor the long-term performance of this material during the wet storage of our used fuel. Summer Unit 1 is currently making the transition to dry fuel storage. By being one of several nuclear plants that have yet to implement dry fuel storage, we have been able to take advantage of the successful operating experience of other plants with many years of dry storage experience. We have also been able to take advantage of technical advances in the design and processing of fuel storage systems, and will implement a state-of-the-art dry storage system. Our current plan is to load our first dry storage systems in 2015. (0250-13-1 [Herwig, Bill])

Comment: I firmly believe that we will continue to safely handle and store used fuel in the wet and dry configurations, in the three time frames mentioned in the draft EIS. (0250-13-2 [Herwig, Bill])

Comment: There are no technical barriers to the safe, secure, long-term storage of spent nuclear fuel. (0250-15-6 [Rodack, Tom])

Comment: Right now, however, we are considering whether or not we feel confident that nuclear waste can be handled at our reactor sites. The answer is yes. It has been done for decades, and we have the technical expertise to handle our used nuclear fuel. (0250-18-4 [Lang, Amanda])

Comment: One project recently analyzed used fuel canisters and their storage systems. The casks were much larger than I expected seeing them first hand, on the order of 100 tons, reinforced concrete and steel. These clearly provide the shielding needed to protect the public, as well as providing protection of the used nuclear fuel from hazards posed by not only Mother Nature, but terrorists. In addition, seeing the studies attempted to breach the cask with everything from rocket sleds to military ordinance, my appreciation of the engineering has only increased. My other project focused on fuel storage and repackaging, both short- and long-term in closed casks in storage facilities. We have the technology available to move, store, dispose, recycle used nuclear fuel. The dry transfer systems operated in France and around the world are quite impressive. Overall, our generation is frustrated by lack of political will to move forward with the technically sound commonsense options for nuclear energy production and used fuel management. We want those who are experts to be making rational, not emotional decisions for our future. (0250-19-2 [Howell, Adam])

Comment: The Savannah River Site Citizens Advisory voted no to interim storage at SRS. The SRS Citizens Advisory Board reflected the overwhelming concern that once waste was allowed to be stored at SRS, that perhaps SRS would be considered a permanent depository. This decision shocked me. I've never heard this coming from that area, coming from an area where folks depend on SRS, depend on the nuclear industry for their jobs. This spoke volumes, reflecting the public's concern over nuclear waste piling up onsite and its lack of permanent storage. Basically, I have not experienced such an overwhelming concern about the lack of a

permanent disposal of radioactive waste ever, compared to the many years that I've been going to these meetings from South Carolina rate payers. (0250-20-3 [Cooper, Elaine])

Comment: I loaded fuel in my first dry fuel storage canister in 1996. I'm involved with virtually every aspect of dry cask storage process at reactor sites to date, from performing nearly every physical task associated with the placement and sealing of used fuel canisters, to performing engineering and licensing technical evaluations that document the impact of implementation of dry cask storage systems at numerous reactor sites around the country. I am intimately familiar with the majority of all dry cask storage systems licensed for use in the United States by the Nuclear Regulatory Commission. As you well know, dry cask storage containers have been deployed successfully across these United States since 1986 at both active and decommissioned reactor sites. These containers have been qualified by analytical methods, and proven by rigorous testing to be able to successfully withstand any accident scenario, whether it be natural or a manmade event. (0250-25-2 [Wellwood, Jay])

Comment: The analysis contained in the Waste Confidence draft Generic Environmental Impact Statement support what the Commission and those of us in the industry have long known; if necessary, used fuel can continue to be stored in a safe, environmentally sound manner for a very long period of time while we wait for the political process to reach consensus on a final disposal solution. For nearly 56 years now, American homes, businesses, and government operations have benefitted from electricity generated using nuclear technology safely. In closing, it is my professional opinion that there are simply no indication that even a minimal decrease in safety margin or a challenge to the environment will be experienced by the continued practice of storage of used fuel in dry fuel storage canisters at or away from reactor sites for 60, 160, or even indefinitely. (0250-25-5 [Wellwood, Jay])

Comment: [T]onight I want to expand upon the robustness of dry used fuel systems, which is more than just a bit understated and, in fact, under-documented in the GEIS both for severe accidents and for potential acts of sabotage and terrorism. I will use some selected information presented to the Blue Ribbon Commission in 2010 and 2011. Dry used fuel systems are among the safest of all industrial technologies as presented and discussed by the National Academy of Sciences in two publications. Extensive safety analyses and testing have been performed to conclude that used fuel systems in a license configuration will not release radioactive material under any credible accident conditions. Conservative materials for used package containment boundaries result in about two orders of magnitude more energy absorption capability before failure than is permitted for credit by our current design standards, and that is one reason why the largest conditional consequence doses reported in the GEIS and, in fact, in the NUREG-1864 reference document are incorrect. They greatly overstate what the actual results would be. (0250-27-2 [Pennington, Charlie])

Comment: We face those same threats here where dozens of reactors in the United States or overly loaded fuel ponds are sitting three stories tall. And since they are outside of the containment could contaminate entire states. (0250-28-2 [Embrey, Monica])

Comment: I'm sure the authorities in Japan also considered the potential negative impacts of storing nuclear waste in the pools onsite to be small just as this EIS does, but accidents happen. Because of Fukushima we know the negative effects of storing spent fuel in pools onsite. (0250-29-4 [Rivard, Betsey])

Comment: In my role as chief nuclear officer, I'm accountable for oversight of our current nuclear operations, as well as supporting oversight of our new nuclear construction activities.

South Carolina Electric and Gas owns and operates the V.C. Summer Unit 1 Nuclear Station in Jenkinsville, South Carolina, which is located approximately 30 miles north of Columbia, the state's capitol. This plant has operated safely for 30 years, providing emission-free electric power to customers in our service territory. Since bringing V.C. Summer Unit 1 online in 1984, we have demonstrated the ability to store used fuel safely in our wet fuel storage pool located onsite. We have extremely competent, well-qualified individuals that provide oversight of fuel-related activities, and we have not had any events that have challenged the safety of the public or our employees. We are currently building an integrated spent fuel storage installation that will in the future allow fuel to be transported from our wet spent fuel storage location to a dry storage location when wet storage capacity is exhausted. We have benchmarked extensively with other utilities in the U.S. to ensure we benefit from the knowledge gained by organizations that have implemented dry spent fuel storage successfully for many, many years. The demonstration of safe nuclear plant operation and spent fuel management at V.C. Summer has been a part of the foundation for the strong public support we have received over the years. I'm especially proud of the fact that a recent survey commissioned by the Nuclear Energy Institute, and conducted by Viscon (ph) Research Incorporated, show that 90 percent of our neighbors that live within the ten-mile radius of the plant had favorable impressions of the plant and how it is operated. Our ability to ensure and demonstrate excellence in plant operation was one of the primary drivers in our decision to build two new Westinghouse AP-1000s adjacent to our existing Unit 1 plant. These reactors, V.C. Summer Units 2 and 3, received a combined operating and construction license from the NRC in March of 2012. We expect to bring Unit 2 online in late 2017 or first quarter 2018, and we are well on our way to achieving that goal. Construction activities for V.C. Summer Units 2 and 3 have gone very well, with a number of significant milestones achieved to date. Recently, we completed the foundation preps and required rebar installations for both units, and completed an installation of the first nuclear concrete for both units, having finished the concrete pour for Unit 3 just this morning. (0250-3-2 [Archie, Jeff])

Comment: As long as nuclear reactors generate this waste would not interim waste sites simply create more contaminated sites, while at the same time allow for the production of ever increasing amounts of these dangerous materials for which future generations would have to contend? (0250-30-2 [Patrie, Lewis E.])

Comment: Used nuclear fuel is equally safe in pools or in dry storage located at nuclear energy facilities, and we use both at Vogtle. The NRC has reiterated the safety and security of used nuclear fuel management and post-Fukushima. Used nuclear fuel is well protected from potential natural events and terrorist attacks by a combination of sturdy design and construction, multiple safety systems, ongoing surveillance and inspection, and state-of-the-art security measures. Used fuel pools are large robust structures with reinforced concrete walls several feet thick and steel liners. Water offers superb shielding for radiation, and every fuel pool offers 25 to 30 feet of water for shielding and fuel cooling. The volume of water in the pools is so large that any evaporative process associated with a loss of cooling system would provide ample time for operators to establish backup water supply. All used fuel pools are designed to seismic standards consistent with other important safety-related structures on plant sites. Augmenting already redundant safety systems to insure cooling of fuel assemblies in pools, the industry has added backup cooling water spray systems and placed potable water supply equipment at locations near the pools so they can be available quickly in the event of an emergency. As part of their post-Fukushima safety enhancements, our facilities are also adding instrumentation with improved capabilities to monitor levels in used fuel pools in the face of extreme events, such as Fukushima. Dry storage containers are robust concrete and steel structures with no moving parts. Multiple barriers provide the defense-in-depth protection. More than 100 tons of concrete

and steel forms a precisely engineered structure to protect every 10 tons of used fuel. Over the past 30 years, the nuclear industry has safely loaded more than 1,700 dry storage systems. All these systems are in service today, and there has been zero release of their radioactive contents. To gain license renewal, facilities must put in place stringent Aging Management programs to insure the containers are adequately maintained and inspected. Vogtle has done that and will continue to do so each and every our license is up for renewal. (0250-32-3 [Wesley, Ashleigh])

Comment: I am confident, and you can be confident that nuclear fuel is, can be, and will be safely stored. It is safely stored because the used fuel that is stored at the sites was designed by many of my friends, some of who are here today, using the stringent standards required by the Nuclear Regulatory Commission. (0250-35-1 [Cook, Andrew])

Comment: I have also been to those sites and seen how the operators of those plants have so carefully managed that fuel and continue to prudently manage it, and I have observed the Nuclear Regulatory onsite inspectors who rigorously require that the operators maintain adherence to the Nuclear Regulatory requirements. (0250-35-2 [Cook, Andrew])

Comment: But those of you who do this work, those of you who I have seen safely manage the pools over a 50-year period, safely load over 1,700 dry casks, developed technological innovations in both the pools and the casks to assure safety, you are my inspiration. (0250-36-1 [McCullum, Rod])

Comment: Concerning the Waste Confidence Rule, these dedicated professionals have done analysis to show the storage of the spent fuel and dry storage is safe. Storage either onsite at power plants or offsite is also feasible, and 25 to 35 years is a reasonable estimate for the time period, while a longer term solution is implemented. In addition, spent fuel has been stored safely for decades. The technology is proven, and mature, and well understood, more well understood than the iPods that we're all using tonight to take pictures. (0250-37-2 [Barilla, Frank])

Comment: As an NRC Commissioner, I clearly saw that U.S. nuclear power plant operators took used fuel very seriously. Whether it's stored in a pool or in a dry canister, that fuel receives the highest level of attention to ensure its long-term safety and security. As a result of 9/11 and Fukushima, the nuclear industry has taken a series of measures to enhance the safety of these facilities. In my view, these efforts have reinforced the high level of assurance that this fuel can be safely managed, onsite or off, well after the lifetime of a nuclear plant. (0250-4-1 [Merrifield, Jeffrey])

Comment: I also believe that temporary, away-from-reactor storage can be successfully utilized as an interim solution for used fuel. In February of 2006, the NRC issued a license to build a private fuel storage facility in Utah, which was the interim dry storage site for 44,000 metric tons of used fuel, 50 miles outside of Salt Lake City. While PFS did not move forward, this licensing process clearly showed the ability of the NRC to review and approve such a site, and has prompted a number of communities in our country to consider volunteering to host a similar facility in the future. (0250-4-3 [Merrifield, Jeffrey])

Comment: Misleading and biased information is being given to the public here. The NRC and the industry is ignoring real world multiple risk factors. We all know that waste cannot be contained for as long as it poses a hazard. We see that nuclear plants are becoming permanent waste dumps. This increases the need for a safer storage plan. Irradiated fuel pools are dramatically overcrowded and not protected. (0250-40-1 [Kerr, Beverly])

Comment: At least minimize the risk of storage of irradiated fuel by placing it below ground and get it out of cooling pools like those at Shearon Harris near Raleigh. Shearon Harris' four cooling pools are the largest in the United States, and represent one of the greatest risks at nuclear plants because they are so overcrowded with so much highly irradiated material. (0250-40-2 [Kerr, Beverly])

Comment: Keep nuclear waste onsite where it is created. As soon as it leaves the nuclear plant property, then whose responsibility is it? Is that why the industry wants to move irradiated nuclear waste around and cloud the issue of who pays the bill when an accident occurs? I agree with the Blue Ridge Environmental Defense League who says, "If you make it and profit by it, then you keep it. If you can't maintain it, then stop making it." (0250-40-7 [Kerr, Beverly])

Comment: For those 40 years, we have safely stored spent fuel onsite. (0250-41-2 [Abendano, Juan])

Comment: So I will talk about consolidating the waste around the country at temporary sites with a plan to move to a permanent storage facility. As of 2010, nuclear power plants have already generated 70,000 tons of spent fuel. The industry is moving towards new fuel types, such as MOX and high-burnup fuels, which are more radioactive, dangerous, thermally hot, and difficult to store and transport. Again I will say we have no way to deal with high-level nuclear waste. To say a consolidated storage area is the answer just creates more problems. (0250-49-3 [Gantt, Carol])

Comment: While tragic and avoidable, the event at Fukushima Daiichi examined objectively and dispassionately further demonstrates the robustness and relative passivity of spent fuel storage. The fuel stored in dry cask systems was unaffected while the fuel in the spent fuel pools, even the unit 4 pool of greatest concern, emerged from the event without contributing to offsite releases whatsoever. (0250-56-2 [Murphy, William])

Comment: My biggest concern early on in my career was not about how the power was generated or how safely it was generated but, rather, what happens to the waste. That's the hardest thing for people to understand. As I have learned and observed, used nuclear fuel has been stored safely in used fuel pools and dry storage systems worldwide for many, many years. I visited nuclear power plants, and I have seen the rigor with which it is stored and secured. I have worn a dosimeter near a fuel exchange pool and watched closely as the minimal reading stayed stable. There was no creep up, down, or otherwise. It stayed fully stable. (0250-57-3 [Jones, Lauren])

Comment: In the United States, used nuclear fuel has been safely and securely stored on plant sites for some time. And I support the NRC's evaluations in this regard. Contrary to what some may believe, fuel storage casks are much more than 55-gallon steel drums. They are excruciatingly engineered pieces of equipment weighing 100 tons and designed to shield the population from radiation and the fuel from any number of natural and manmade threats, including floods, earthquakes, and ordnance. (0250-58-4 [Cagnetta, Matt])

Comment: The nuclear industry in general and Duke Energy in particular have extensive operational experience that supports this conclusion. The history of used fuel storage goes back to the beginning of the nuclear enterprise in the 1940's, and there has never been an instance in which a member of the public was harmed by used fuel storage. Duke Energy began its nuclear power plant operations more than 40 years ago. Since that time, we've safely stored used fuel in spent fuel pools, as well as in dry storage facilities. In addition, we safely transported

thousands of fuel assemblies between reactor sites. At no time have these activities resulted in harm to the public or significant adverse environmental impacts. The NRC performed a thorough and extensive evaluation of projected future impacts from used fuel storage, and found them to be small. We agree with the NRC's conclusion. (0250-6-3 [Nesbit, Steve])

Comment: Both methods of storage, wet and dry, have been proven to be safe through analyses, as well as decades of operating experience. (0250-6-5 [Nesbit, Steve])

Comment: So what worries me probably most of all is our current focus on storage in pools, which are at risk from really a lot of -- you know, we've heard terrorist. We have heard natural disasters. (0250-69-4 [Rundle, Steve])

Comment: Storage and transportation can be done safely because they have been done safely for decades. (0250-70-3 [James, Andrew])

Comment: The development of consolidated facilities for interim storage of spent fuel must be pursued until a permanent repository is ready. Over 100 commercial spent fuel pools are or have been in service in the U.S. Most of these pools have safely contained spent fuel for 30 years or longer. This is the equivalent of 3,000 years of operating experience with no significant environmental impact - a record that is very hard to compete with. (0253-5 [Avilla, Karen])

Comment: We need a thorough review of the following: long term storage for spent nuclear fuel, spent fuel fires, and spent fuel pool leakage. The crisis in Japan has shown us that dry casks are less vulnerable than pools. The dry casks at Fukushima survived, whereas, the pools are collapsing. (0257-1 [Abbott, Dana])

Comment: We have a nuclear waste problem from 60 years of power generation. The indefinite storage of nuclear waste at the reactors that generated it is NOT an acceptable storage option. No interim storage policy should be put in place until a geologic waste repository is operational. The alternative allows for the possibility of indefinite storage at generating plants, which is unacceptable to the public. (0259-1 [Katz, Shari])

Comment: Climate change is brining unexpected and unimaginable events that were not part of the resiliency planning for reactor site selection and design. 60 year "short term" storage is not short term, and 100 years long term storage are NOT acceptable storage periods. We should be able to come to a resolution before at least 20 years to get this material into the ground. In the interim, waste should stay where it was generated and not get shipped around to interim storage type locations. Fuel should be moved from cooling pools to concrete storage casks when it has appropriately cooled, as this is a safer storage means. (0259-2 [Katz, Shari])

Comment: We understand that the purpose of a NEPA analysis is to draw conclusions regarding environmental impacts, and that other analyses support safety assessments, however, the safety of spent fuel storage is a concern of the public. Notwithstanding the NRC's request for comments only on the conclusions in the GEIS, the GNAC also notes that used fuel has been stored safely for decades. Storage system designs and operations have become more robust over time; the GNAC expects that spent fuel storage will continue to evolve in the future as it has in the past, enhancing an already safe system. At the same time, the GNAC encourages the NRC to evaluate and validate the sufficiency of the design life of individual used fuel storage systems and facilities in a comprehensive, programmatic manner. (0262-2 [Patterson, Karen])

Comment: There are 94 identified knowledge unknowns or "gaps" in Spent Nuclear Fuel storage and transportation. There are no solutions presented, in addition to incomplete research, for the NRC to validate the Generic EIS conclusion. It seems logical to basically complete NRC and DOE extended storage and transportation research prior to an NRC final EIS report. (0267-2 [Rodarte, Ron])

Comment: The NRC states in Division of Spent Fuel Storage and Transportation Interim Staff Guidance-24, Revision 0, "The Use of a Demonstration Program as Confirmation of Integrity for Continued Storage of High Burnup Fuel Beyond 20 Years" that the NRC has insufficient data to support dry cask licensing for more than an additional 20 years for high burnup SNF. How can the NRC GEIS have confidence in extended storage of high burnup (>45 GWd/MTU) spent nuclear fuel SNF? (0267-3 [Rodarte, Ron])

Comment: How can the NRC GEIS have confidence in extended storage of SNF when their own Interim Staff Guidance 11, Rev 3, "Cladding Considerations for the Transportation and Storage of Spent Fuel" excludes approval of transportation casks for high burnup SNF except on a case by case basis? (0267-4 [Rodarte, Ron])

Comment: The NRC GEIS ignores information about how the level of burnup negatively impacts extended storage in both dry casks and spent fuel pools. "...An additional issue involves advancing corrosion and hydriding of zirconium alloy cladding subject to extended burnup. Diminished low temperature ductility imposes the need for additional care in spent fuel handling operations to avoid any mechanical impact that may cause cladding fracture." This information, a cautionary note from the 1998 IAEA report is excluded in the NRC GEIS. All of the GEIS inspections and characterizations were performed on low-burnup fuel after only 15 or less years of dry storage. No information was offered on inspections conducted on high-burnup fuels to confirm the predictions made about the brittleness or cladding fracturing in highburnup dry storage and long term storage of high-burnup SNF spent nuclear fuel. (0267-5 [Rodarte, Ron])

Comment: I want to thank the NRC for working with the owners of our nation's nuclear facilities to keep the on-site storage of spent nuclear fuel safe. And it is safe. Unlikely scenarios that are designed to scare people or grab headlines are not productive to this discussion nor to our energy debate in general. (0275-2 [Wolf, Tom])

Comment: There's talk of Illinois becoming a centralized interim waste storage site although interim seems to be taking on a new meaning of possibly forever. Maps from Oak Ridge National Laboratory put Illinois #1 on all but a few maps because of our centralized location. We also have the most reactors, and the largest amount of waste. We don't want interim storage here. Fuel should be moved only once--on the way to the repository. Interim storage wastes time and money, and we'd be a prime destination for terrorists. (0276-7 [Kurz, Carol])

Comment: While reviewing the documents for comment, the term "adequate" repeatedly appears regarding the steps currently used to store toxic nuclear waste. Whenever I hear the term used by NRC staff to describe any of the nuclear plants across the country, but in particular Entergy's Palisades Nuclear Plant, I cringe. I am not sure how the use of this term is supposed to be reassuring to the public since it means "good enough." The connotation connected with "good enough" is mediocre. So, I ask you , how safe would you feel with an "adequate" pilot on a turbulent transcontinental flight? Or, how quickly would you employ an "adequate" heart surgeon if you required surgery? Yet, you throw the word "adequate" around to the public like that is supposed to reassure us about the safety of these aging, decrepit

nuclear power plants in this country and what you propose as the generic treatment of high-level radioactive waste storage for a number of years far into the future. (0277-2 [Pierman, Bette])

Comment: But those of us who live and work in the area, and especially someone who is looking to attract new businesses to the area, would not be satisfied with that substantial economic impact if it came at the expense of our safety. The CED is also a member of the Braidwood Citizens Advisory Panel and have been fortunate to closely follow the way Braidwood operates. Its culture of safety and security is second to none. And its transition to dry cask storage of spent fuel is a good example. Exelon took the initiative to invest in dry cask storage that provides an added level of safety and security and we applaud them for taking that step. We also encourage the NRC to continue to work with industry to promote innovations that will further enhance operational safety, and, ultimately, lead to the creation of a spent fuel repository for the storage of this material. The Will County CED is confident in the safety and security of the storage facilities at Braidwood and we look forward to the continued positive impacts of the Braidwood station in our community for many years to come. (0278-2 [Fleming, Scott])

Comment: When decommissioning a plant, get the spent fuel relocated into secure dry storage systems as soon as the fuel is cool enough to do so. Stop allowing the utilities to utilize dry cask systems that are not capable of protecting their contained fuel from an impact from a large aircraft. The Draft GEIS talks about storing fuel in casks for up to several hundred years. The casks need to be able to endure whatever mechanical impacts we can foresee in our current society before we pass the site on to the next seven generations. (0279-2 [Morgal, Richard])

Comment: What exactly are the current safety standards for the spent fuel cooling pools at SONGS? What exactly are the current safety standards for the 42 dry storage casks? What back up is required today to protect the spent fuel pools from an electrical shut down of more than four hours? How many hours without cooling are the spent fuel pools safe? How far away are the back -up generators? Are they sufficient to keep all cooling pools safe for the three days of 90 mile an hour winds that our Santa Ana winds which hit Southern California each year might continue, keeping air support from the cooling pools if firestorm over ran the facility where the spent fuel pools are kept? What safety precautions exist for that circumstance? What is the safety formula for protecting the spent fuel from all disaster possibilities? Firestorm, earthquake, tsunami or terrorists? Such as the reactor domes were "adequate" against a 7.0 earthquake, and five terrorists on the ground. (0280-3 [Magda, Marni])

Comment: We were led to believe that nuclear spent fuel must wait five to seven years to be put in dry storage. No new fuel has been generated at SONGS for two years, so conceivably in five years all spent fuel at Songs could be in dry storage. Why have only 42 dry storage casks been created in the 30 years the spent fuel has been accumulating at SONGS? Since the shutdown, the public has learned that 16 years ago a dangerous high burn fuel began to be used at SONGS. Who approved of that change? This kind of fuel is considered by the rest of the world too dangerous to use. What environmental impact did this higher burn fuel have on the ocean? What temperatures changed or volume of ocean water used and dispersed? Who approved of this change of fuel at SONGS? What studies were demanded? Have we stored any of this more deadly spent fuel in dry storage at SONGS in the last 16 years? How? In what kind of storage? Where? Have we moved any of this more deadly high burn spent fuel from the SONGS spent fuel cooling pools? How? Where? How much of the spent fuel in cooling pools at SONGS is not high burn fuel? Is it stored in separate cooling pools from the high burn more dangerous fuel? Since this fuel is older than 16 years, could it all be in dry storage? Is all of it in dry storage? (0280-4 [Magda, Marni])

Comment: How long must the high burn fuel at SONGS remain in cooling pools before it can be stored in dry storage? How long will those dry storage casks last? How long must we wait to put the high burn fuel in final geologic disposal transportable casks? How soon could it be moved to MRS monitored, retrievable storage and how do we begin to get a California solution for MRS of high burn fuel? We need it YESTERDAY. It can't wait, 2 years, let alone 20 to 60. SONGS can't keep the spent fuel where it is because of earthquake or tsunami possibilities that could create a Fukushima meltdown here any day. How can spent fuel in cooling pools be moved from Songs to a geological location that would be safe to store the fuel in new cooling pools that are away from earthquake faults, the ocean, and 8.4 million people? This must be done!!!! Has MOX been moved from SONGS that wasn't in dry storage casks? How? When? Where? (0280-5 [Magda, Marni])

Comment: We need final geologic disposal casks that are transportable. Is that the NRC recommendation? We can't leave our grandchildren with the Chernobyl type mess of no money and containment needing to be redone every thirty or so years. (0280-7 [Magda, Marni])

Comment: The planning for long-term storage is wholly inadequate given the half-life of some of the material. (0282-3 [Haber, Jim])

Comment: On October 19, the Sierra Club joined the Coalition to Decommission San Onofre in sponsoring a Community Symposium on that topic [High Burn Fuel]. Three nationally regarded experts addressed the challenges and concerns. The expert panel presentations at the Symposium include references to several "high burn" concerns: there appears to be no record of NRC prior approval for use of high burn at San Onofre; workers at the plant were and are unaware high burn was being used; the energy density of the specific form of fuel being used exceeded NRC standards even for high burn; and finally, there is no currently certified or approved technology for storage of high burn on site or its transport to remote sites. (0283-1 [Pascall, Glenn] [Watland, George])

Comment: Dr. Marvin Resnikoff, Senior Associate at Radioactive Waste Management Associates, told the Symposium that at San Onofre spent fuel will need 15 to 20 years to cool in pools before it can be put in dry casks. Edison has said spent fuel will be removed from the pool by 2034. After that, Resnikoff said, "San Onofre will consist entirely of fuel casks or silos in a Stonehenge configuration. What remains? A fuel mausoleum and the conversion of a valuable site into a wasteland." An urgent issue is the use of high burn fuel, brought to the fore by the diligent research of San Clemente activist Donna Gilmore. This fuel permits longer continuous operation before refueling but is twice as radioactive and twice as hot after use. "We should be very concerned about the challenge of storing high burn fuel," Resnikoff said. "There is a long cool-down period for fuel used at 67 megawatt-days per metric ton. How did San Onofre get permission to operate at this level? The question has not been analyzed and San Onofre has put little or no high burn fuel in storage. Indeed, no form of storage has yet been approved for fuel this hot." Resnikoff concluded with a charge to Symposium attendees: "The NRC doesn't have all the answers. Sometimes citizens have to force the issue by getting involved in the proceedings of regulatory agencies. Educate yourselves on the minutiae of safety. Continue to question authority. Work to empower independent voices that have demonstrable expertise. Challenge the NRC and Edison to be sure they are employing the best possible technology in every regard." (0283-5 [Pascall, Glenn] [Watland, George])

Comment: Use of High burn-up fuel at San Onofre requires more storage space between fuel assemblies due to higher heat, higher radioactivity, and instability. (RWMA Marvin Resnikoff, PhD.) No transportation casks for high burn-up fuel are approved by NRC, so waste cannot be

relocated. Insufficient data exists to approve dry casks for over 20 years . (per NRC Robert E. Einziger, PhD, <http://1.usa.gov/15E8gX5>. High burn-up fuel has unresolved serious waste storage issues. A June 2013 Department of Energy Report states: "...cladding performance issues need to be addressed before this fuel can be loaded into dry casks and transportation systems", and "burnup rates as low as 30 GWd/dMTU can present performance issues including cladding embrittlement under accident conditions as well as normal operations. San Onofre now has 1,123 high burn-up fuel assemblies (which require a longer minimum of 15 years of cooling in spent fuel ponds). (DOE FCRD=NFST-2013-000132, Rev.I; /Fuel Cycle Research & Development-Nuclear Fuel Storage and Transportation 2013,-000132, Rv.1, 6/15/13 <http://222.hsdll.org/abstract&did=739345>) (0284-10 [Borchmann, Patricia])

Comment: NRC is currently evaluating Edison's requested use of a new dry cask system that crowds 32 fuel assemblies into the same space that currently holds 24 at San Onofre. This new system will increase risk of dangerous radiation releases into the environment. (0284-9 [Borchmann, Patricia])

Comment: The US government's long delayed commitment to take possession and manage the spent fuel rods now becomes the focus. Recently, the National Conference of State Legislatures said that it supports federal action to develop consolidated facilities for interim storage of high-level radioactive waste until a permanent repository is ready. This is an extension of the current onsite storage facilities which places fuel bundles into casks after about seven years of storage in the spent fuel pools. The casks are stored on the plant sites awaiting transfer to federal facilities. SCE's plan for 20 years is compatible with this time frame. (0286-2 [Hannaman, Bill])

Comment: Nuclear waste can never be stored in a completely safe manner. There is no viable method available for long-term storage. (0288-3 [Wickham, Wendelyn])

Comment: I am here this evening to support the reasoning of many in this county who have great concern over the huge and growing amount of nuclear waste accumulating at Diablo Canyon plant. The high-level waste in the cooling pools is of critical importance. (0290-1 [Brown, Marty])

Comment: There are approximately 70,000 metric tons of commercial spent fuel across our country -78 % of it in pools. These pools have the largest concentration of radioactivity on the planet. The cooling pools literally sit on earthquake faults here, are unprotected from air strikes and are overcrowded even now having 4-5 times the amount of fuel rods than they were designed for. You must demand that PG&E transfer the fuel rods from the cooling pools to dry cask storage starting immediately. (0290-3 [Brown, Marty])

Comment: No one knows how long the dry casts will remain safe. NRC is experimenting with my families health and property value Only 1/3 of the spent fuel is in dry casts - why hasn't PG&G(sic) taken a more aggressive stance to protect the community[.] (0291-2 [Mauter, Nancy])

Comment: I am dismayed that the NRC is allowing PG&E to make more nuclur (sic) waste without PG&E safely storing all the waste in dry casts. The only people who spoke in favor of PG&E nuclear power industry was the employees who benefit financially from the plant. (0291-4 [Mauter, Nancy])

Comment: We are in an impossible situation. When the Spent Fuel Pools were first licensed there were fewer assemblies placed in open racks where water could circulate freely to help cool down the very hot and very radioactive spent fuel rods. Circulating water is the best way to absorb the heat and also to shield against radiation. (0293-1 [Lewis, Sherry])

Comment: But early on, a more highly enriched uranium fuel, we now call high burn-up fuel, was developed. Unfortunately, the waste created from high burn-up fuel is even hotter and also more radioactive than before. (0293-2 [Lewis, Sherry])

Comment: There is currently no safe way to store nuclear waste. There has been a lot of thought and money diverted to this problem for many years, and there is no real answer. Very possibly, we are at a cul-de-sac with this technology. It may be an unsolvable problem. (0297-1 [Fishman, Zelma])

Comment: The Commission simply, so far, has allowed generators to compress the spent fuel rods in the “temporary” on-site cooling pools to such extent that many of these now hold several times more than they were designed to hold. Despite this dangerous overcrowding, the Proposed Rule states, quite cavalierly quite a few times, that the Commission “continues to support the...storage of spent nuclear fuel in spent fuel pools” until a repository becomes available. Though it mentions dry casks, it fails to acknowledge that by far the most of it – some 75 percent – is being kept in the overcrowded pools, very little in the much safer and more stable dry canisters. (0303-3 [Lamberts, Frances])

Comment: However, the FSHCC understands that it is critical that the transportation, storage and disposal of used nuclear fuel are properly and adequately addressed. There are many misconceptions about nuclear energy and we are pleased to see that the NRC is working to educate the public on the important measures that are being taken to ensure that used nuclear fuel is well protected from potential natural events and terrorist attacks, including a combination of strategic design and construction, multiple safety systems, ongoing surveillance and inspection, and state-of-the-art security measures. We also appreciate the NRC's transparency in informing the public around the safety and security of used nuclear fuel management in post-Fukushima. (0307-2 [Fuentes, Julio])

Comment: Although we continue to wait on the political process regarding reaching an agreement on a disposal solution, it is a well-known fact that nuclear fuel can be safely stored in an environmentally sound manner for very long periods of time in the interim. (0307-4 [Fuentes, Julio])

Comment: While nuclear energy is a vital part of our state's electricity portfolio and economy, I recognize the need to address the transportation, storage and disposal of used nuclear fuel. As the political process and debate continues regarding reaching an agreement on a disposal solution, the development of consolidated facilities for interim storage of spent fuel must be pursued until a permanent repository is ready. Over 100 commercial spent fuel pools are, or have been, in service in the U.S. and most of these pools have safely contained spent fuel for 30 years or longer. The safety and security measures taken to maintain these spent fuel pools are unprecedented measures that include a combination of strategic design and construction, utilization of multiple safety systems, ongoing surveillance and inspection, and state-of-the-art security measures. (0308-2 [Weinberg, Luz])

Comment: As many nuclear plants in the U.S. have spent fuel pools containing double the amount of spent fuel rods as originally planned, we are in a dangerous situation. Looking at

what happened and is still happening at Fukushima Daiichi, the contention that these over-packed pools sitting above reactors are a minimal danger is false. Simple loss of coolant due to even temporary energy loss or leaks is a probability that can no longer be easily dismissed as improbable. (0309-1 [Green, Jeanne])

Comment: I am familiar with the issues concerning dry cask storage of spent fuel at nuclear power plants and I believe it is a safe method of long term storage. (0313-1 [Waage, Edward])

Comment: The so-called 'temporary' storage sites could become de facto permanent dumps if it is not politically feasible to site enough repositories to handle the waste. (0319-7 [Nichols, John])

Comment: NRC's Waste Confidence policy assumes that all nuclear waste is the same. This is far from the truth. The industry is moving toward new fuel types, such as MOX and high burnup fuels, which are more radioactive, dangerous, thermally hot and difficult to store and transport safely. (0319-8 [Nichols, John])

Comment: I am opposed to storing used radioactive fuel rods in a pool of water 100 feet above ground level. The imagination runs wild when considering all the bad things that could happen to such a massive object that high up on a manmade structure. (0321-1 [Bagwell, Charles])

Comment: Even without catastrophic accidents like at Chernobyl, our current way of holding spent nuclear fuel at reactor sites, in greatly overcrowded cooling pools, adds a large amount of risk to nuclear power production. (0322-4 [Baker, Hannelore])

Comment: They have to be able to take whatever is this high-burnup fuel, whatever is the real truth about that here, we have to have all these great minds together now creating a solution to get the casks that we need right now today to begin putting that storage in casks that can be moved as soon as we have a place for it. We need Camp Pendleton involved. (0325-12-5 [Magda, Marni])

Comment: Under the nuclear fuel, it's safe in the pool over there. Dry storage works in this country. It's worked for years. Over the past 30 years, the nuclear industry has safely loaded more than 1,700 dry storage caskets. There's been no problems with any of them, no disaster of any kind, any kind has ever bothered any of these caskets. There's no reason not to continue to go on and use this way. These pools are safe. This pool over here across the street has got backup system after backup system. That plant has so many backup systems in it you can't believe it. (0325-14-1 [Sallis, Gary])

Comment: There's so many already redundant systems to ensure cooling and fuel assemblies in the pools, and the industries have backed it up with more. The NRC made more rules after the thing that happened in Japan. They made more rules to make it even better and better. They do this all the time. Don't condemn them. Continue to let them work, and work with them. (0325-14-4 [Sallis, Gary])

Comment: [S]pent nuclear fuel is currently stored onsite at facilities across the country in well designed, well protected facilities and storage casks. Both facilities and storage casks are robust structures made out of steel linings and reinforced concrete walls that are several feet thick. Spent fuel pools are often 40-feet deep and seal lined with reinforced concrete walls. Further, the structures protecting these pools are built to seismic standards. The dry storage casks where the fuel is moved are also strong structures made of concrete and steel. For every 10 tons of spent fuel, facilities use 100 tons of concrete and steel to form a structure designed

for the highest level of protection. Over the last 30 years, nuclear energy facilities have proven that they can safely and securely store spent fuel onsite at facilities in these structures. (0325-16-2 [Bailey, Savannah])

Comment: [I would like to] reiterate that nuclear energy facilities across the country have continued to show the utmost commitment to safely and securely storing spent nuclear fuel. (0325-16-6 [Bailey, Savannah])

Comment: First, dry storage, dry cask storage. Dry cask storage systems have withstood severe earthquakes, hurricanes, and other natural disasters. Nine of these systems were in place in Fukushima, were shaken by the earthquake and over-washed by the tsunami and suffered no damage. Another fun-filled fact about spent fuel pool safety. In the 2011 Fukushima event in Japan, there were seven spent fuel pools. All endured the earthquake and tsunami, three of the pools were in the reactor building also suffered catastrophic hydrogen explosions. Active cooling capacity was lost for several days, yet all the fuel was safely protected. (0325-18-1 [Lemmon, Tom])

Comment: I've collected information about nuclear waste. And what I've learned is a scandal. The nuclear -- the NRC has allowed the nuclear plants to run much more dangerous fuel without having a solution for storing it, even short term. They call it high-burnup fuel and Dr. Einzinger in March said they're not going to license this fuel for more than 20 years because they don't have the data to show its safe in dry cask for over 20 years. And then I find out that there's no transportation approved for this fuel, and we have tons of it at San Onofre. Apparently, the protective cladding becomes brittle and it's subject to shattering and could eventually lead to radiation release. You know, we're talking short-term problems. How can -- if the NRC doesn't have confidence short-term in this fuel, how can this plan possibly say it has confidence for hundreds of years? I mean, this is outlandish. And to call it a generic plan. Sitting by the ocean, we've got metal corrosion going on here with the facility. We're in the ring of fire just like Fukushima, and if we have problems here we're talking national security, we're talking national, international economy, we're talking the food supply for the nation. This is totally unacceptable. The NRC needs to complete their research on extended storage before it completes the EIS, because the research that they've already done shows there's no confidence. And there's -- and the high-burnup issue that I'm talking about, it's not covered -- the research that went into this information is not covered in this document. All the research the NRC has should be evaluated and included in there, and what the DOE has should be part of that. So, there's no confidence here. This is just a bunch of BS, as far as I'm concerned. (0325-2-1 [Gilmore, Donna])

Comment: The U.S. Government, not the NRC, but the U.S. Government's long delayed commitment to take possession and manage the spent fuel rods now becomes the focus. Recently, the National Conference of State Legislators said that it supports Federal action to develop consolidated facilities for interim storage of high-level waste until a permanent repository is ready. I think that satisfies the idea of moving the fuel away from San Onofre to an interim place, but it's really just an extension of the onsite storage facilities, which already takes the fuel bundles in the casks. And there is an issue here of timing. (0325-26-3 [Hannaman, Bill])

Comment: I am very troubled by the use of this high-burnup fuel at San Onofre. It puts my children at a much higher risk, and it puts them at a higher risk for a longer time. Wasn't nuclear waste bad enough to begin with? Did they have to go and find a way to make it worse? And what about the roof that is on that spent fuel pool? Certainly, yes, you have hardened sides and a concrete bottom, and that sounds very good, but the roof? Not much help there. (0325-27-1 [Davis, Patti])

Comment: [H]igh-burnup fuel has changed everything, and has made a terrible challenge a horrendous one. Everything in this process about Waste Confidence needs to stop until there is enough data to reliably manage and monitor the high-burnup fuel. According to NRC's own documents, their assumptions about how high-burnup fuel would react and perform have not proven correct. How can we honestly talk about any plans for storing and managing this waste when the high-burnup fuel problem is not even fully acknowledged and addressed? (0325-28-5 [Branigan, Mary Beth])

Comment: Intense radiation, as you know, breaks down concrete, salt water breaks down metal, no containment will even reliably last for 50 years, much less the hundreds and thousands of years needed to isolate this deadly waste from the environment. And it's everywhere, it's everywhere in our country. (0325-28-6 [Branigan, Mary Beth])

Comment: Spent fuel pools at nuclear power plants are intended to house nuclear waste only until it's cool enough to be transferred to permanent storage. In the U.S., overcrowded cooling pools can contain up to 40 times more nuclear material than the reactor cores. Furthermore, they lack equivalent containment buildings and safety systems for protection. These pools have now become nuclear waste storage sites. (0325-29-2 [Feathers, Jösan])

Comment: Unlike some of the other nuclear power plants to be covered by this Generic EIS, there are known offshore earthquake faults capable of up to an 8.0 magnitude earthquake here. In the event of an earthquake of this size and potential tsunamis, failure similar to Fukushima, Japan are possible. In contrast to spent fuel pools, concrete and steel dry casks are not vulnerable to the loss of the coolant if electricity is disrupted by an earthquake or other natural disaster because they are passively cooled by natural air flow. (0325-29-3 [Feathers, Jösan])

Comment: Rather than invest in dry casks, plant owners continue to fill cooling pools well beyond what they were designed for. Today around 80 percent of U.S. nuclear waste currently is stored in pools. Let me say that again. Today around 80 percent of U.S. nuclear waste currently in pools could be moved to onsite dry casks until permanent storage is available. (0325-29-4 [Feathers, Jösan])

Comment: However, in the case of high-burnup fuel like we have here at San Onofre unbeknownst to us, it's back to the drawing board. At a minimum, the NRC should not approve higher density of fuel assemblies in dry cask systems, and they should stop approving the use of high-burnup fuel in existing plants. (0325-29-5 [Feathers, Jösan])

Comment: Independent experts of the Union of Concerned Scientists and elsewhere agree that the dangerous radioactive waste from spent fuel pools that has cooled sufficiently should be required to be transferred to safer onsite dry cask storage. Dry casks are economically viable and provide a storage alternative for 20 years for high-burnup fuel until an offsite storage facility becomes available. (0325-29-6 [Feathers, Jösan])

Comment: Now we're stuck with a whole lot of nuclear power plants with a whole lot of waste stuff that we don't know what to do with it. There's no answer to safe storage, and the safe transport of this material. It's right here in our backyard. It's threatening us at all times. We don't have a way to deal with it. (0325-33-2 [Zigler, Randy])

Comment: The industry has shown over decades that it has the ability and the technology to safely store spent fuel onsite. Now, we all know that permanent onsite storage is not what was ever intended, and it's not a long-term solution, but we should not punish the nation's largest

source of clean air electricity because of that. These structures have met rigorous standards that have been set out by the NRC and the industry has invested billions of dollars and thousands of man hours in improving these facilities and structures. (0325-5-3 [Kirtan, Stratton])

Comment: The nuclear industry switched to high-burnup fuel because it burns longer in the reactor and increases industry profits. This has further reduced our safety here and across the nation. It turns out that the NRC and the nuclear industry have no safe storage solution for high-burnup fuel, used fuel, even short term, and there's no solution for transporting this waste offsite. So, we're asking the NRC to include in your Generic Environmental Statement and in your document to solve these unsolved problems. (0325-8-2 [Von Thillo, Grace])

Comment: If the NRC won't even approve short-term storage or transport of high-burnup used fuel because you don't have the confidence, then you must stop wasting and making this waste. Your demonstration project with the DOE is still experimenting on the technology and the materials. We want this extremely vulnerable fuel moved away from San Onofre as soon as it is reasonably safe to do so, and storing it longer in this sensitive area where you've heard again we are prone to tsunami, earthquake, our coastal and marine environments, next to California's critical transportation, economic, and military arteries and surrounded by 8.5 million people, increase our concerns and lessen our confidence daily. (0325-8-4 [Von Thillo, Grace])

Comment: I have absolutely no confidence in a regulatory agency that even allows the nuclear industry to continually increase the level of burnup for its fuel. But, essentially, the nuclear power industry wanted to increase profits and be allowed to keep the fuel in the reactors longer, and the NRC gave them the go ahead. And they have been creating an inventory of high-burnup fuel and creating an intractable problem, and that has to end because it amounts to nothing less than the reckless endangerment of the American people. (0325-9-1 [Reson, Myla])

Comment: Some of the areas that we heard from the public that we would like the NRC to better address has to do with the storage and transfer of spent fuel. Concerns are chiefly over the density and configuration of assembly storage and spent fuel pools before they're transferred to dry cask storage. The concern about this practice is that the current allowable density and configuration of highly radioactive material is far more vulnerable to a variety of accidents or even natural disasters, and thus, more threatening to our populations. Thus, my colleagues and I have been asked to urge the Nuclear Regulatory Commission to better address this potential danger to our citizens by creating, adopting, and implementing regulations to further reduce the likelihood and/or better mitigate the potential for any kind of spent fuel disaster. (0326-1-2 [Hill, Adam])

Comment: PG&E has a detailed and regulated spent fuel management program in place. The wet storage fuel pools, where the solid spent fuel is housed, are robust concrete and steel structures designed to withstand extreme events such as earthquakes, floods, hurricanes, and tornados. The most likely of these scenarios for here on the Central Coast is earthquakes, but the NRC's analysis shows that even a powerful earthquake is unlikely to damage a used fuel storage pool to the extent that it would lose water. Even in the case of Fukushima, where there was a loss of all offsite electrical power for weeks, and explosions resulting from hydrogen buildup in containment structures, all seven fuel pools at the Fukushima Power Plant in Japan remained intact and the used fuels in the pools remained safely covered with cooling water. PG&E has been and continues to be a good neighbor in our community. They have layer upon layer of safeguards in place to manage and monitor spent fuel. Like I said earlier, we're none too keen on storing spent fuel at Diablo Canyon, but unless the Federal government follows

through on their responsibility, it's my opinion that PG&E has done everything possible to deal with the situation. (0326-11-3 [Bean, Judith])

Comment: "There are approximately 70,000 metric tons of commercial spent fuel across our country; 78 percent of it in pools. These pools have the largest concentration of radioactivity on the planet. The cooling pools literally sit on earthquake faults here, are unprotected from air strikes, and are overcrowded, even now, having four to five times the amount of fuel rods than they were designed for. You must demand that PG&E transfer the fuel rods from the cooling pools to dry cask storage starting immediately." (0326-14-3 [Brown, Marti])

Comment: It was badly needed here for the county, but something else that's also very badly needed, and that's safer storage of nuclear waste here at the Coast. The proposed -- well, I should say, I was actually a member of the Nuclear Waste Management Committee of San Luis Obispo County from 1996 to 2002, and already, some 12 years ago, we came to the conclusion that the dry cask storage would be a lot safer way to go. (0326-15-1 [Schumann, Klaus])

Comment: For the already existing spent fuel, dry casks are far safer than crowded pools[.] (0326-15-6 [Schumann, Klaus])

Comment: [F]or the already produced spent fuel, certified dry casks for high-burnup fuel is ASAP ; return storage fuels to low density ASAP[.] (0326-15-9 [Schumann, Klaus])

Comment: I'm here to express my support and my confidence in the storage of spent nuclear fuel onsite. The industry has shown, over the course of decades, that it can store spent fuel onsite safely. Now, I think many of us are in agreement that onsite storage was never meant to be a permanent solution and we want a permanent solution, but we shouldn't punish our nation's number one source of greenhouse-gas-free electricity because of a political problem in Washington. Now, these structures meet rigorous requirements that have been set by the NRC, and the industry has invested, literally billions and thousands of man hours over the last few decades, upgrading both the physical structure and the security of these facilities. (0326-16-2 [Kirtan, Stratton])

Comment: For approximately the past two-and-a-half years, I have helped maintain Diablo Canyon as one of the safest plants in the industry. In all the work that I do, safety is at the forefront of my mind, for myself, my co-workers, our friends and families, and the entire community; all of you here. I grew up as the son of a PG&E employee, my mother worked as a meter technician in Stockton for PG&E for 37 years. I've witnessed the company's focus on safety my entire life, throughout the countless training sessions and meetings my mother had to attend, often out of town. I continue to see that same focus at a companywide level and as demonstrated in my interactions with personnel at the plant. The safety of long-term onsite storage is a political issue, not a technical one. (0326-17-2 [See, Daniel])

Comment: Used fuel has been stored safely at nuclear plants for many years and with the engineering technologies we have nowadays, we can continue that for many years in the future. (0326-18-3 [Schrader, Ken])

Comment: I'd also like to thank Representative Diane Feinstein, who I'm relieved to know that she's here. In 2011, after touring the power plants at Diablo and San Onofre, Senator Feinstein commented that what jumps out at you is that some spent nuclear fuel rods are stored in pools, similar to the ones leaking radiation at a crippled Japanese reactor. (0326-19-2 [Carrigan, Milton])

Comment: The NRC is exposing us all to the possibility of a horrendous nuclear accident. The Union of Concerned Scientists state, and I quote, "Tens of thousands of tons of radioactive waste is being stored in unsafe, insecure, overcrowded spent fuel pools, which puts the American people at risk." They call for the accelerated transfer of spent fuel into safer dry casks. There is no scientifically proven solution for safely disposing of nuclear waste. (0326-20-2 [Caulfield, Lee])

Comment: Now, moving to the topic of tonight's discussion, spent nuclear fuel is currently stored onsite at facilities across the country in well-designed, well-protected facilities and storage casks. Both facilities and storage casks are robust structures made out of steel linings and reinforced concrete walls that are several feet thick. Spent fuel pools are often 40-feet deep and steel-lined with reinforced concrete walls. Further, the structures protecting these pools are built to seismic standards. The dry storage casks, where fuel is moved, are also strong structures made of concrete and steel. For every 10 tons of spent fuel, facilities use 100 tons of concrete and steel to form a structure designed to the highest level of protection. While our coalition continues to support a Federal long-term storage solution, over the past 30 years, nuclear energy facilities have proven that they can safely and securely store spent fuel onsite at facilities. Beyond that, the NRC is committed to ensuring American nuclear facilities adhere to the strictest regulations and operate in the best interests of the public. As such, operating facilities are subject to onsite inspections by NRC staff 24 hours a day, 7 days a week, and 365 days a year. (0326-25-2 [Bailey, Savannah])

Comment: PG&E has had a comprehensive fuel management program in place to safely store used nuclear fuel until the time that the Federal government can assume their responsibilities. As a utility, we have long advocated that the Department of Energy act on its commitment to collect used fuel. We support the establishment of the President's Blue Ribbon Commission and its recommendations to advance a workable storage solution that includes, also, the establishment of the interim consolidate storage facilities. In the absence of an existing Federal repository, PG&E will continue to store used fuel assemblies onsite at Diablo Canyon in safe, secure, and Federally monitored storage facilities. With the continued delays in collection of the used nuclear fuel, most nuclear facilities, including Diablo Canyon, have had to develop dry storage facilities, and the need to develop these dry storage facilities is to augment the existing wet storage facilities. (0326-3-1 [Strickland, Gerald])

Comment: Tonight, there will be a number of questions and comments tendered to the NRC associated with high-burnup fuel. PG&E has used fuel that is greater than what's termed 45 gigawatt-days per metric ton of uranium, and that meets the definition of high-burnup fuel. This fuel is safely stored in both our wet and dry storage systems in accordance with the licensed requirement set forth by the Nuclear Regulatory Commission. (0326-3-3 [Strickland, Gerald])

Comment: [B]ut along the way an issue came up, and of course, if you're not going to reprocess the fuel, what are you going to do with it? And of course, re-racking came in and I was in the State Department, so I didn't do any calculations, but of course, the government did calculations about re-racking, but the one thing they didn't know is-- it was 35 years since then, since this took place-- and of course, you exceed what they could have from a safety point of view. Now, these things can be calculated in terms of if you have too many watts per square meter, and how much air circulation you lose if you have too much racking, but it's clear there are, in some cases, you can have uranium fires, so I support moving them out, but I wouldn't say exactly at what point you make that decision, because I don't know; because I have studied it. It's been a long time. But clearly, you should move them into dry cask storage, which is pretty safe. (0326-30-2 [Hafemeister, David])

Comment: To start, I'd like to thank the Nuclear Regulatory Commission for the opportunity for myself, and so many others, to say a few words here tonight. I started working at Diablo Canyon in February of 2009. My first impression of the facility was that it was very safe and open. Everyone watching out for one another. The culture of Diablo Canyon is one that is centered on safety and doing the right thing. I've held various positions at Diablo Canyon in design engineering, mechanical system engineering, and regulatory services, exposing me to a variety of technical and regulatory issues. Throughout them, I've witnessed and participated in some tough decisions. These tough decisions were made to take the high road, the conservative road, the safe road. Rather than letting cost make the call, or schedule pressure make the call, safety always makes the call. With regard to spent nuclear fuel, the NRC has been thorough in their evaluation and then providing a comprehensive and reliable Generic Environmental Impact Statement. This Impact Statement concludes that it is feasible to safely store spent fuel following the licensed operating life of a nuclear facility without significant environmental impact. Having seen the dry cask storage at Diablo Canyon, I believe that it is a safe and secure way to store our spent fuel until a long-awaited permanent repository is available. Having seen the spent fuel pool and worked with reactor engineering during fuel inspections, I believe that the pool is safe and well-designed. I know and worked very closely with the engineers, the operators, security, and training personnel of Diablo Canyon. We work very, very hard in everything we do to ensure the health and safety of the public; of ourselves too. I'm confident that the future of Diablo Canyon is in good and skilled hands. (0326-32-1 [Landreth, Will])

Comment: And then, you need to put that waste into dry cask storage. Give us some confidence. (0326-35-5 [Owen, Linde])

Comment: The only components of the four damaged reactors that survived the earthquake tsunami, loss of coolant, and reactor explosions relatively intact were that portion of the 11,000 fuel rods that were in dry cask storage. According to PG&E's statement that you just heard, only 1/3 of the spent fuel assemblies are now in dry cask storage. (0326-4-4 [Brown, Jerry])

Comment: We are in an impossible situation. When the spent fuel pools were first licensed, there were fewer assemblies placed in open racks where water could circulate freely to help cool down the very hot and very radioactive spent fuel rods. Circulating water is the best way to absorb the heat and also to shield against radiation. But early on, a more highly-enriched uranium fuel, we now call high-burnup fuel, was developed. Unfortunately, the waste created from high-burnup fuel is even hotter and also more radioactive than before. At the same time, the capacity for storing all this waste was becoming a problem. (0326-44-1 [Lewis, Sherry])

Comment: The idea that storing nuclear waste at Yucca Mountain, or Diablo Canyon, or anywhere, is not a resolution. We suggest PG&E and the Federal government go back to the drawing board. These ideas are unacceptable. There is no safe storage for toxic waste. And in the words of the Russian Prime Minister, after the asteroid landed five miles away from a nuclear power plant, he had stated, "Nothing nuclear is safe for the human race." (0326-45-4 [Baker, Crystal])

Comment: I think that this evening we've had a great deal of good articulation about some of the risks of nuclear energy in Diablo Canyon. I guess I'm in the minority though tonight in believing a little bit in the ability of the human spirit and human ingenuity to perhaps find some solutions in the next 250,000 years for some of the problems we've been discussing. Meantime, I think that there is some, at least in my view, a reason for some level of confidence in PG&E's ability to do the right thing or to safely manage the problem in the short term. (0326-49-1 [Connor, Vicki])

Comment: And, for the record, I just want to say I have no confidence in safe storage of nuclear waste. (0326-54-3 [Crimmel, Steve])

Comment: So also I've heard, though I'm for fairly rapid transfer when safe, to dry casks from cooling ponds; however, I also-- I saw-- got an email that said 26 technical data gaps for dry cask storage. And a DOE website stated there are 94 technical data gaps in dry cask storage. Anyway, try to make dry cask storage safer[.] (0326-63-6 [Campbell, Bruce])

Comment: There have been absolutely no studies on the extended storage of nuclear waste, either in spent fuel pools or in dry casks. You need to have those data before you can write a Final EIS, but the research hasn't been done. The dry casks are guaranteed for 20 years. You assume they will last longer, but you don't know because they haven't been tested, and you don't know how high-burnup fuel acts in dry casks. (0326-9-5 [Seeley, Linda])

Comment: Does it embrittle the casing? I understand that you've just started a study on the characteristics of high-burnup fuel in casks, but it won't be finished until 2016. How can you issue a Final EIS before you know the results of that investigation? It's like writing a cookbook before you've even prepared any of the food before you publish the book, except you're dealing with the most lethal substance on Earth, not bread dough. (0326-9-6 [Seeley, Linda])

Comment: Onsite storage facilities for spent nuclear fuel have been designed to withstand potential natural disaster events or terrorist attacks by durable design and construction, ongoing surveillance, inspection, and state-of-the-art security measures. The two methods for storage of spent nuclear fuel have proven to be extremely safe. Dry storage systems used to store spent nuclear fuel have more than 100 tons of concrete and steel forms, precisely engineered, to protect every 10 tons of fuel. And in the past 30 years, over 1,700 dry storage systems have been used by the industry, and there's never been a release of any potential radioactive material. Fuel pools used to store spent nuclear fuel are large structures with reinforced concrete walls and steel liners. At Japan's Fukushima Daiichi site, used fuel was stored in seven fuel pools, and after the severe earthquake, tsunami, and subsequent explosions which occurred none of the spent fuel was compromised. (0327-12-2 [Knisley, Mike])

Comment: In 1994, a couple of good friends of mine, Bill and Alice Hurt, long-time anti-nuclear activists were plaintiffs in a law suit that I filed in the District of Columbia challenging the permission, the rulemaking, that the NRC implemented to allow an exception for the use of the three defective casks that Kevin Kamps mentioned a little while ago. There were three dry casks up for use as storage modules that were defectively ground. They were too thin, they weren't up to spec, and in classic traditional response, the NRC simply made the exception into the rule. We challenged the rulemaking and ran into a brick wall, figuratively, at least. But therein lies the message. Here we are about a generation later and these three casks are sitting there, and the NRC now expects them to last forever. (0327-13-2 [Lodge, Terry])

Comment: I'm here today to voice my opinion on a new concept called "consent-based siting approaches" that you're moving towards for nuclear waste-management facilities, for interim storage and for geological repository. The idea of local communities forming partnerships with the implementers under the auspices of a national government appears to be gaining a lot of traction in countries that are opting for voluntary siting. Some version of this idea has been found in Sweden, the UK, and Canada. The only catch here is that there must be a community that has infrastructure, that has real estate, that has a knowledgeable workforce, that has educated citizens that understand both science and risk. I'm not sure that that community exists at all. (0327-20-1 [Clemons, Victoria])

Comment: We need to contain it onsite, but not at Perry on top of a nuclear fault line, for God's sake. (0327-23-4 [Tolls, Leatrice])

Comment: Maybe we all remember Fukushima, Three Mile Island, and Chernobyl. According to the Union of Concerned Scientists, there are continuing safety concerns, including where to store nuclear waste. In the absence of an interim or permanent repository for spent nuclear fuel, which remains dangerously radioactive for hundreds of thousands of years, plant owners keep it onsite, mostly in overcrowded, relatively unprotected cooling pools. Nearly 75 percent of all spent nuclear fuel sits in these pools. About 120 million United States citizens live within 50 miles of a nuclear plant and continue to be at risk, and we are among them here. (0327-26-1 [Myers, Dan])

Comment: Nuclear facilities have already been required during license renewals to have stringent storage standards and management programs in place to ensure adequate inspection and maintenance of these systems. These requirements ensure that any issue which could have safety ramifications are detected and helps keep our communities safe. (0327-31-5 [Dorans, Rob])

Comment: A decision to do nothing now is not a solution, so I'll say that again. A decision to do nothing now is not a solution. What we actually have is the capability of doing now is the best technology we have to put sufficiently cooled fuel rods into state-of-the-art hardened canisters. How can moving this most deadly of all materials around the country with no solution be a solution? Canisters must be stored as close as safely possible to the sites of generation. Moving it for no purpose is not a solution. (0327-4-5 [Marida, Patricia])

Comment: Do I have confidence? No, I have no confidence because the nuclear waste we have right now is not being handled properly. At Palisades there's a cask that's got a bad weld. I've been at meetings in the past like many others, and I say well, why don't you take the nuclear waste out of this cask with the bad weld which could deteriorate and break, and leak, and contaminate the lake? Why don't you take the fuel rods out of it and put it in a good cask, you know, and monitor it? Well, instead, they've kind of like put casks up around it to kind of buffer it. And they say it's too dangerous, we can't take those rods out. Well, come to find out it's never been done. Those casks were not licensed when they were loaded. And the company got away with that. I mean, do you put a car on the road that might be dangerous - thanks for the one minute - and just run it down and see if it blows up, or if your engine blows 300 feet out ahead, or whatever. No, you don't do that. They don't let anybody do that, but the NRC has let the nuclear industry get away with a lot, and part of it is in the storage of nuclear waste. It's just not safe right now. And I can't see it being safe in the future. (0327-8-2 [Barnes, Kathryn])

Comment: The proposed interim storage sites until a final solution is found makes no sense either. It would just double the shipments and exposures to accidents. And this temporary solution would also take decades to implement. Keeping waste onsite in dry casks also is not a good solution, but seems the best alternative for now to moving the waste multiple times. (0327-9-2 [McArdle, Ed])

Comment: My worst fear, and the worst fear of our people is that we will be forced to abandon our homeland because of an incident at the plant. And to be honest with you, my biggest concern isn't with the plant operations, it's with the nuclear waste packed into the spent fuel pools and the stored aboveground dry casks less than a half mile from our lower Island residential area. (0328-1-4 [Johnson, Ron])

Comment: Allowing for the continued storage of spent nuclear fuel onsite will allow the industry the flexibility to maintain our current supply of spent nuclear fuel in a safe and effective manner until a final repository or alternative solution can be agreed upon without the added pressure on license renewal. It will also lift a burden not only on the industry, but the country as a whole by allowing sites with proven track records to maintain their fuel on site. The industry has shown that it is fully capable of maintaining spent fuel safely and effectively for over 50 years. It can and will continue to do so. (0328-10-3 [Biersdorf, John])

Comment: First, there were some comments earlier, I believe it was Mr. Mahowald talking about degradation. So, I've got this cute little report that I found called, "Premature Degradation of Spent Fuel Storage Cask Structures and Components from Environmental Moisture." And this is specifically dealing with TN casks, which is what we have at Prairie Island, so I want to put that in. And then another one, and I will have more detailed comments. I haven't had any time to really look at this, so I'll have written comments by the 20th. Another one, "Spent Fuel Integrity During Dry Storage," and it talks about things like leaks. And this is about krypton levels, so that can tell if the casks are leaking or not. And they're talking about the work that they've done to determine whether or not casks are leaking. And it says, "Before this test," this is like this one test, "four cask performance tests of similar duration and scope had been performed. Only two indications of release were observed," two out of four. Well, don't we have a problem there? I want to introduce that. And that's a study by M.A. McKinnon. McKinnon has done a lot of these studies. (0328-14-3 [Overland, Carol])

Comment: And then I also want to introduce this -- it's hilarious. It's the Keystone Cops, and I'm sure some of you are familiar with this. I got this in a brown envelope when I was representing Florence Township. INEL did a study where they tried -- well, not a study, an attempt to unload a cask, and it's Keystone Cops. It's -- they tried to pull -- it had been in storage for not that long. They tried to pull it out, and it got stuck. They tried to pull it in, they couldn't get the thing back in. And they tried to pull -- and it sat there for a while until they finally figured out what to do, and they rammed it back in and shut it up, and put it away. As far as I know, no casks have actually been unloaded. Is that -- like have any of the TN-40s on Prairie Island been unloaded since '95? I don't think so. Have any TN-40s anywhere been unloaded or 29s? It's a problem. So, I want to introduce this. (0328-14-4 [Overland, Carol])

Comment: Another problem, do you all remember the exploding cask at Point Beach? This is where they took the cask, filled it up, picked it up, let it sit there. Well, the cask had a zinc basket in it, and it had boric acid sitting in it, and the shift went home. And like 8 hours, 12 hours later the shift -- another shift comes in and they go to load it up, and so you've got fire and zinc and boron which is -- you end up with hydrogen, kaboom. And a big old what, I don't know how many tons it was, 9-inch-thick cover bent up, the shims that were in holding the basket in flew up, landed on the floor. I'm sorry, I don't have confidence in nuclear waste storage if this is the kind of thing that happens. How many of you remember all the failed welds that have been addressed over the years? So, we should have confidence because someone takes an x-ray of it? No, the welds fail, it happens. So, I have no confidence. (0328-14-5 [Overland, Carol])

Comment: My involvement with nuclear, other than playing with the Geiger counter, started in 1994, in December, so we're looking at now almost 19 years. And that was just kind of scary concept for me. And before that, actually at that very time I was still being a truck driver trying to raise money to open up my office, and so this is December '94, and we're having this little meeting sponsored by Northern States Power, and we're trying to figure out where to put the nuclear waste. And, Kristen, remember this? And so we're sitting there trying to figure out, this is an NSP-sponsored committee, and they were describing the casks. And, you know, I'm a truck

driver, and they were talking about the seals on the casks. Well, so I was like excuse me, don't you have to change the seals? Like eh, didn't know what to say. It's like yes, those seals have to be changed. They have to be changed every 20 years. Okay. First cask was loaded 1995, and now here we are, we're coming up on 10 years, 20 years isn't that far away, no cask has been unloaded. How many seals have been changed? What's the process for doing that? Does anybody know? So, you think it can be safely stored there for 100 years? Right. (0328-14-7 [Overland, Carol])

Comment: The uncertainties associated with the long-term storage high-burnup fuel are simply wished away. There are known documented problems associated with high-burnup fuel. The NRC has yet to determine precisely how to monitor those effects during the extended storage periods contemplated in the Draft Generic Environmental Impact Statement. But, yet, we're told that there's no need to worry about cask and cladding degradation or the embrittlement of fuel assemblies and internal cask components because the casks will simply be reloaded every 100 years. (0328-3-2 [Mahowald, Philip])

Comment: What are the effects of high-burnup fuel on fuel rod cladding and fuel assemblies over 100 years, over 200 years, over 300 years? What are the effects of high-burnup fuel on the internal dry cask components themselves, the baskets and the separators, again, over 100 years, over 200 years, over 300 years? (0328-3-4 [Mahowald, Philip])

Comment: Well, maybe we've figured out how to mass produce those gadgets and maybe they won't cost so much, but we've also done a really remarkable job of diversifying the fuel that these reactors are burning. And when you have the higher burnup rates and the mixed oxides in the reactor fuel, and all the other stresses that happen uniquely cask by cask to say nothing about site by site, and then you assume that you're going to be actually able to transfer this waste. What happens if it disintegrates? What happens if one-half of 1 percent of the fuel assemblies at the end of 100 years, or at the end of 150 years, or 200 years, or 20 years, whenever we get to the repository, if we ever get there, what happens if one-half of 1 percent of those fuel assemblies disintegrates? What happens to your assumption then? How do you manage that? (0328-7-5 [Crocker, George])

Comment: The design of fuel assemblies and storage casks have undergone significant developments over the 15 years of my career with a primary goal to improve the safety and security of managing used nuclear fuel. First has been a transition from bolted cask designs to welded canister-based systems. These welded canisters are tested with liquid penetrant exams, radiography, and ultrasonic hydrostatic and helium leakage tests. These designs are now implemented in over 1,600 of the approximately 1,900 loaded storage systems. (0328-8-2 [Cummings, Kristopher])

Comment: Second, there's been an evolution to larger canister-based systems, larger capacities. Canisters that were originally designed to contain 24 PWR assemblies can now hold 37. There's also 40 at the Prairie Island that they can hold. Those that were designed contain 44 BWR assemblies can now hold 89. Higher capacity casks result in a reduced number of handling operations, reduced dose during loading, and eventually a smaller number of shipments (0328-8-3 [Cummings, Kristopher])

Comment: Third, the fuel assembly burnup has steadily increased. Higher burnups allows more energy to be extracted from a fuel assembly for the same amount of volume. This leads to a smaller amount of used fuel that needs to be managed. (0328-8-4 [Cummings, Kristopher])

Comment: Fourth has been the development of more sophisticated cladding materials that can perform under longer exposure times with less susceptibility to cladding breaches. Over the past 20 years, the number of fuel assemblies with leaking rods has been reduced dramatically. The industry now maintains a small fraction of a percent of fuel rods that developed leaks in the reactor. (0328-8-5 [Cummings, Kristopher])

Comment: There's been much discussion of the challenges associated with high-burnup fuel during this comment period. NEI has previously provided information on this issue to the NRC which can be found in ADAMS under the accession number ML13084A045. This letter identifies areas where the industry and NRC are addressing are addressing this challenge to assure the long-term safety of managing high-burnup fuel. (0328-8-6 [Cummings, Kristopher])

Comment: Recent experiments have questioned whether the drying process during storage may cause cladding to become more brittle. However, these experiments have been performed at conditions that are not representative of the majority of used fuel assemblies. First, the hydrogen content in the cladding used in these experiments is at or exceeds the NRC established limit. Second, the simulated drying conditions in these experiments are performed at or above the cladding temperature limit of 400 degrees Celsius. Finally, all of these experiments have been conducted by pinching the fuel rod. In reality, the loading during transportation would be axial compression or bending of the fuel rod which is less severe. In conclusion, the recent experiments are not -- are highly conservative with respect to the fuel condition and structural loads expected during used fuel management, and are not representative of the majority of the fuel in storage or in the spent fuel pools. (0328-8-7 [Cummings, Kristopher])

Comment: Moreover, there are some simple solutions that can be implemented to safely accommodate high-burnup fuel. High-burnup fuel can be placed in individual cans inside the canister. Alternatively, the allowable cladding temperature during drying can be reduced to prevent embrittlement and hydrate reorientation. Additionally, there needs to be a recognition by the NRC that a cask is never loaded with a heat load more than about 90 percent of the licensed limit, thereby reducing the cladding temperature during drying. All of these conclusions are further justification why storage and transportation of used nuclear fuel continues to be conducted in a safe and reliable manner. (0328-8-8 [Cummings, Kristopher])

Comment: The NRC is surely the only regulatory body in the world that would argue that indefinite and essentially permanent storage of highly radioactive waste in cooling pools and dry casks creates confidence that this waste will never threaten the public and the environment with radiological disasters. Neither dry casks, nor cooling pools are designed for permanent high-level radioactive waste storage. Rather than insist on a robust waste management system designed to handle conceivable accidents, whether through equipment failure, natural disasters, operator error, or other causes that could release radioactive materials to the environment, the NRC's draft document ultimately relies on the low probability of an accident to justify its position that reactor licensing and relicensing should resume. (0328-9-4 [LaForge, John])

Comment: What I want to do today is specifically address one thing that was said in the November 19th meeting in Rockville. In that meeting, I was quoted by a Mr. Mark Leyse, and I wanted to address the issue he raised. First of all, I want to thank him for being factual and accurate to a point. He accurately quoted me, and he did cite two documents, and those documents were ML021230367 and ML132568086. What he quoted me saying, which is true, is that I or, in my case, when I was saying this in a previous public meeting that preceded the waste confidence meeting in September, we understand in the industry that we can no longer rely on boraflex. This is absolutely a true statement. I said that in the context of explaining what

industry was doing to replace boraflex, which is a neutron absorber, with more reliable neutron absorbers that will have more longer-term utility. Mr. Leyse then went on to say that there was a documented history of degradation of boraflex at the Indian Point reactor. That's where he cited the two documents. And he then raised that documented history of boraflex degradation as a concern for the safety of that pool. And that's where I do disagree with Mr. Leyse. The two documents he cited are, to me, in fact, evidence of quite the contrary point. If there was not a documented history of boraflex degradation in that pool, then the situation would be that boraflex was degrading and we were either not doing anything about it or not aware of it. The two documents he cites, one a 2001 or 2002 license application, license amendment application which basically removes a lot of credit for the boraflex and puts in place some compensatory measures, and then a 2013 meeting submittal where Indian Point proactively came to NRC and said, okay, here's what we're doing, we're further tracking the boraflex degradation, and here's our plan to replace it with new neutron absorbers. In all cases, the licensee, Indian Point, was within the parameters of their safety analysis. The plant is safe, and a criticality has been and will be prevented. (0329-10-2 [McCullum, Rod])

Comment: The NRC, a couple of times in the Draft Environmental Impact Statement or Generic Environmental Impact Statement has cited examples of how issues are dealt with as being reasons we can have confidence in the regulatory process working, being high burn-up fuel and chloride-induced stress corrosion cracking. Since Mr. Leyse raised it, I'd want to suggest this should be another example. Indeed, we did discover over our experience with boraflex that it degrades, and that has driven the market to develop better neutron absorbers. Those are being deployed throughout industry. And the documented history that Mr. Leyse cites at Indian Point is but one example of how we're doing that and how we're assuring safety while we're doing that. In other words, it is another example of how the regulatory process assures safety as we go forward into longer periods of time. And I believe it should be cited as such. (0329-10-3 [McCullum, Rod])

Comment: But whatever we do, whether it's repackaging or repairing or replacing materials, as long as these things are under NRC license, as long as these things are managed by responsible companies that are held accountable to their shareholders and the citizens around them, as well as the regulators, examples of how we will take the steps to do the things we need to do to manage the inevitable time-dependent degradation mechanisms, and boraflex is probably one of the most extreme examples, those things will continue. So I guess what I've learned from having listened to Mr. Leyse's comment, and I thank him for taking the trouble to listen to what I said earlier, is that, indeed, this is something that should be more strongly emphasized in the Generic Environmental Impact Statement, the extent to which the processes that we have in place can address the effects of time. (0329-10-5 [McCullum, Rod])

Comment: I want to reiterate some things about this high burn-up fuel problem. It's come to my attention lately that an analysis of the high burn-up fuel and its impacts were not a part of the EIS. And I want to ask were they, and I want to request, if they weren't, that there be an analysis based on that. And what I've learned is that they must stay in the pools much longer, up to five years. I've also learned that they put in cask storage. They have to come out, and I've seen estimates as quickly as 20 years. And I've also learned that there was a ruling that they are not transportable. In other words, waste from high burn-up fuel is currently disallowed in terms of transport. And so this, in my mind, shakes up the entire EIS if it did not take those factors into account, and so I ask that be taken into account. (0329-14-1 [Sondheim, Steven])

Comment: I just also think that we should not be making any more spent fuel until we find out what we should do with the existing. All the pools are completely full. They are rack systems of

maybe four times as much fuel, sometimes more than that, than they were designed for. We need to get everybody out of the pool, as the lifeguard says. There's danger. There's danger. (0329-18-4 [Carberry, Mike])

Comment: He [Oscar Shirani] was a lead quality assurance inspector for Commonwealth Edison. And he led a nationwide quality assurance inspection on the Holtec casks. I recently learned at the U.S. Nuclear Waste Technical Review Board meeting a few weeks ago in Washington, D.C. that Holtec has 46 percent of the dry cask storage market in this country, which I hadn't known before that it was such a high percentage, which is truly frightening because in the year 2000, Oscar and a dozen other quality assurance inspectors from a dozen different nuclear industry utility companies that use Holtec casks identified 9 major categories of quality assurance violations having to do with these containers. So Oscar Shirani questioned the structural integrity of the Holtecs sitting still in onsite storage, let alone, as has been mentioned by several commenters today, traveling at 60 miles per hour or greater speeds on the rails in this country as the Holtecs are a rail-sized container. So that's a real problem. And, unfortunately, the Nuclear Regulatory Commission was not there for Oscar as a nuclear industry whistleblower. He did get a few days at the Office of Inspector General to tell his story. The Office of Inspector General at NRC said they did not dispute his insights or observations, but they did not see that NRC had done anything wrong. So this nuclear industry whistleblower was left out to dry, a personal tragedy of great proportions for him, blacklisted from the U.S. nuclear industry for the rest of his life, but perhaps even greater societally is the fact that we have hundreds and at some point thousands of Holtec containers deployed across this country loaded with high-level radioactive waste in all kinds of barrable situations in the onsite storage, let alone discussing the transportation risks that would be involved. (0329-20-3 [Kamps, Kevin])

Comment: I was asking about high-burnup fuel. And I want to ask you if you can answer me or if there's a way we can get an answer, if you can answer me now or if there's a way. All the possible risks of the high-burnup fuel, which has different, different criteria, were those taken into account in the EIS? Do you know? But I would like to be able to get an answer quicker than when the final decision comes out. (0329-22-1 [Sondheim, Steven])

Comment: I want to reiterate that it's looking to us like the plans for both onsite cask storage and transportation do not cover the intensity of the heat and the problems that may come from the high-burnup waste. So we've got a situation that needs attention. (0329-22-2 [Sondheim, Steven])

Comment: And when you're talking about materials that remain deadly dangerous for tens of thousands of years, longer than all of human history, anything less than 100 percent safety is not safe. And we are not infallible. Humans cannot produce something that is infallible. That means that nuclear plants cannot, cannot, cannot be guaranteed to be safe. And anything less than 100 percent safety in taking care of nuclear materials is not good enough. (0329-28-2 [Wilansky, Laura])

Comment: We're suggesting also that the NRC should require nuclear waste to be stored safer on sites where they are produced and to stop the plan for dangerous nuclear waste transport and interim storage when they reach their final conclusions. We've identified a number of transport and interim storage plan problems. Risks are not eliminated from current sites where waste would still be stored, and risks are, in fact, increased with waste spread to more locations throughout the nation, resulting in more targets for potential problems from either natural disasters or terrorist activities. (0329-3-3 [Cuthbert, Lewis])

Comment: Interim storage is a dangerous proposition. It's not good for Nevada. It's not good for any of the interim storage sites. And it's going to put people and the environment at risk. (0329-33-2 [Feldman, Jane])

Comment: Nobody wants it [nuclear waste]. It's dangerous. There is no safe method to contain the waste, and we have created a monster for ourselves. (0329-4-3 [Messer, Diane])

Comment: I have little to no confidence in the NRC in long-term storage. It's not really been looked into good. (0329-9-2 [Martin, David])

Comment: Indefinite storage of high-level radioactive waste in fuel pools and dry casks threatens public health and safety. Casks and fuel pools are not designed for permanent storage. We need a waste management system that is designed to handle myriad possible accidents -- operator error, equipment failure, natural disasters, terrorist attacks, etc. -- as shown at Fukushima, Chernobyl, and Three Mile Island. (0331-1 [Miller, Kirk])

Comment: I see no reason to believe that there is no significant risk to lives and property from the currently-contemplated means of storing radioactive waste. (0333-1 [Balke, Karl])

Comment: To this day, there is no clear evidence that there is any way to safely store nuclear waste indefinitely. Obviously, given the nature of these waste products, storing them for an indefinite period of time is the only real solution. (0334-3 [Nuccio, Theresa])

Comment: I am very concerned about how we store our most hazardous waste-the radioactive fuel rods from nuclear reactors. (0336-1 [Lish, Christopher])

Comment: Over 67,500 metric tons of high-level nuclear waste (or MTU) are being stored at commercial nuclear power plants and that amount is expected to increase at a rate of approximately 2,000 a year or 20,000 MTU each decade. The typical spent fuel pool at a light water reactor now holds the equivalent of about 6 reactor core loads of spent fuel, about 700 MTU. Low-burnup fuel can be transferred from cooling pools into dry casks after 5 years, but high-burnup fuel may need to remain within pool cooling for over 20 years, and the use of high-burnup fuel has been increasing. Transfer of fuel from pool to pad or from wet to dry storage (and back and forth) is an abrupt change of environment for used spent fuel assemblies. Transfer of fuel also involves varying degrees of mechanical stress and dropping risk. Aging effects/mechanisms include: degradation of toughness and strength of materials due to irradiation, including degradation of neutron absorber materials; changes in a mechanical property of materials, including change in dimensions or reconfiguration due to creep and effects of freeze-thaw; loss of preload due to stress relaxation; crack initiation and growth; loss or weakening of material due to corrosion; loss of strength and modulus due to elevated temperature. (0341-1-12 [Mermelstein, Richard])

Comment: Aging effects/mechanisms applicable to high-burnup fuel remain to be determined, but the current engineering consensus is that high-burnup fuel is more subject to cladding radial hydride formation and embrittlement 20-25 years after the high-burnup fuel assemblies are placed in dry storage. And casks for high-burnup fuel are still under development. (0341-1-13 [Mermelstein, Richard])

Comment: America's existing nuclear fleet and the on-site spent fuel pools where most of the high-level spent fuel waste remains stored are aging. It is a fundamental of engineering that as machines and structures age they become subject to age-related deterioration. Aging

effects/mechanisms apply to spent fuel pools and their associated structures. (0341-1-14 [Mermelstein, Richard])

Comment: When the spent fuel pools were originally constructed they were planned to hold spent fuel for a very short term - less than a year. Unlike the reactors, the spent fuel containments are not hardened. The roofs are similar to the roofs commonly built at box top stores. The spent fuel pool structures at nuclear plant sites were never designed, nor built, with the intention of holding large quantities of nuclear material for a decade, much less a century. Data on dry cask performance has been collected for a matter of decades. (0341-1-15 [Mermelstein, Richard])

Comment: I firmly believe that the best solution that can be agreed upon by most parties and implemented in a reasonable time, and that provides the best level of security and protection is a dedicated above ground long-term retrievable storage at a central facility. Idaho National Laboratory meets the general requirements for such a facility. (0343-1 [Blacker, Paul])

Comment: Current on-site interim storage is a terrorist dream waiting to be exploited. Multiple sites, many located near population centers, cannot provide the confidence required for these spent fuel items. (0343-2 [Blacker, Paul])

Comment: I am writing to support the NRC's Spent Fuel Storage Rule, and wish to say that with NRC oversight PG&E has a very detailed and successful spent fuel management program and continues to safely store fuel via both its wet and dry cask storage systems. I am confident that layer upon layer of safeguards are in place to effectively manage and monitor the stored spent fuel. (0350-1 [Martz, Robert])

Comment: Nuclear waste should not be transported and stockpiled in "interim" sites around the country, as the cost to taxpayers and risk to communities of moving this deadly cargo are too great. (0357-5 [Daily, G. Allen])

Comment: For the already produced "spent fuel": a. Certify dry casks for high burn-up fuel a.s.a.p.; b. Return the storage pools to low density a.s.a.p. (0358-13 [Schumann, Klaus])

Comment: Furthermore, the US Dept. of Energy and the NRC's records on spent fuel wastes at the Diablo Canyon Nuclear Power Plant (DCNPP) are dismal and do not inspire any "confidence" in their ability to safely regulate the Nation's nuclear waste. (0358-2 [Schumann, Klaus])

Comment: 4. The decision to allow the use of high burn-up fuel has compounded the problems with storing and transporting spent fuel due to increased radioactivity and embrittlement of the fuel cladding. All these decisions were made for the sake of keeping the industry afloat while ignoring public safety concerns explicitly stated by scientists and concerned citizens alike! (0358-6 [Schumann, Klaus])

Comment: There is not now and never has been safe storage for radioactive waste. (0359-1 [Kushigian, Elizabeth])

Comment: In all these decades, it has become more clear each day that there IS NO SAFE solution to the problem of 'STORING' nuclear waste! (0361-2 [Greenfield, Jan])

Comment: The NRC's Draft NUREG-2157 makes laughable claims about the safety of storing high-level radioactive waste in fuel pools and dry casks: by their very nature, neither casks nor fuel pools are designed for permanent storage. (0362-2 [Schietinger, Helen])

Comment: Temporary storage sites put more communities at risk and create security issues. (0368-3 [Mattox, Judy])

Comment: I support the NRC's Spent Fuel Storage Rule. The NRC oversight of PG&E has a very detailed and successful spent fuel management program and continues to safely store fuel via both its wet and dry cask storage systems. With all the safeguards in place to effectively manage and monitor the stored spent fuel I am confident they will continue to do so. (0372-1 [Salas, Peggy])

Comment: Locally stored spent fuel could be safely removed to a single or regional locations controlled by and protected by our national government. (0372-3 [Salas, Peggy])

Comment: 2. Require nuclear wastes to be stored safer on sites where they were produced (0377-1-12 [Cuthbert, Lewis])

Comment: 5. Would result in additional locations that store these high-level radioactive wastes which are some of the most deadly materials on earth. Nuclear plants would still have this waste on site. (0377-1-14 [Cuthbert, Lewis])

Comment: ACE Strenuously Objects To Nuclear Waste Transport and Interim Storage: -It transfers ownership and costs to the public for transport, plus endless storage and security -It absolves reactor owners of responsibility and liability -It makes room for more lethal wastes for which there is no safe solution. There is no benefit to the public, only unjust increased costs and risks. -The minute deadly radioactive wastes are transported off-site from nuclear plants, the public is forced to bear the astronomical financial burden for nuclear waste transport, storage, and liability forever. (0377-1-15 [Cuthbert, Lewis])

Comment: NRC's Interim Storage scheme creates a misleading illusion of a solution. - This is NOT a solution. In fact, it drastically increases risk of a nuclear waste disaster. -We would end up with more deadly radioactive wastes at more locations throughout our nation, facing devastating consequences from radioactive contamination due to a natural disaster or terrorist attack. - The public would be forced to forever pay for security at all these new locations, to guard this lethal waste from a terrorist attack. -New locations would now also face radioactive contamination from a natural disaster. -Risks are not eliminated from current sites, where wastes would still be stored. (0377-1-17 [Cuthbert, Lewis])

Comment: 3. Stop Limerick's use of high-burn fuel based on unacceptable increased risks from its long term storage. (0377-1-8 [Cuthbert, Lewis])

Comment: Safety Is A Dangerous Illusion - To Claim Otherwise Is Intentional Deceit: NRC cannot guarantee safe transport or storage of high-level radioactive wastes; NRC cannot guarantee transported storage containers will remain safe for 50 years, the time they are expected to last. There is no proof.; NRC cannot guarantee storage containers will be replaced in time to protect public health and safety. There may be no federal funds to do that or a future Congress may refuse to provide funding.; NRC cannot guarantee that increasingly dangerous weather events will not cause a catastrophe in transport or in interim off-site storage; NRC cannot guarantee there will not be a terrorist attack. Moving Nuclear Wastes Won't Solve

Nuclear Waste Problems At Nuclear Plants: It is an outright lie for the nuclear industry and their supporters to claim transport to another location will remove nuclear waste storage threats at nuclear plants -As long as nuclear plants operate, deadly radioactive wastes will pile up on site - Transport won't reduce the number of radioactive waste sites, it just adds enormous risk at more locations, to the already unprecedented threats from high-level radioactive wastes; The evidence shows why it is both indefensible and unreasonable for NRC to suggest that transport and interim storage is a solution; Transport and interim storage is an irrational pea and shell game that ignores the additional unnecessary health and financial risks it presents to the public; Moving wastes only benefits nuclear plant owners, allowing them to avoid accountability for their deadly wastes. (0377-2-17 [Cuthbert, Lewis])

Comment: "High-Burn Nuclear Fuel" Is Not Transportable. Limerick and Other Nuclear Plants Using High-Burn Fuel Must Be Required To Stop: Due to increased radioactivity and decay heat in spent fuel; Due to increased corrosion, thinning, and brittleness of fuel cladding; Due to increased damage and rupture of fuel rods in the reactor vessels, leading to damage in the form of pinhole leaks and small cracks that can lead to breaching of fuel cladding. NRC has known about the potential for damage from this fuel for several years. NRC has NO PROOF use of High-Burn fuel is safe, yet negligently allows its use to continue. NRC's decision to allow this to continue abandons public interests while it further jeopardizes safe storage and transport. It is clearly motivated by economic benefit to the nuclear industry. "Spent fuel that may have degraded after extended storage may present new obstacles to safe transport". According to the National Academy of Engineering of the National Academy of Sciences, The technical basis for the spent fuel currently being discharged (high utilization, burn-up fuels) is not well established". "NRC has not yet granted a license for the transport of the higher burnup fuels discharged from reactors." -This even more dangerous waste could be transported whether or not NRC grants a license for that. Evidence shows why with higher burn-up, nuclear fuel rods undergo several very risky changes that include: Increasing oxidation, corrosion and hydriding of the fuel cladding. Oxidation reduces cladding thickness, while hydrogen (H3) absorption of the cladding to form a hydrogen-based rust of the zirconium metal from the gas pressure inside the rod can cause the cladding to become brittle and fail. Higher internal rod gas pressure between the pellets and the inner wall of the cladding leading to higher fission gas release. Pressure increases are typically two to three times greater. Elongation or thinning of the cladding from increased internal fission gas pressure. Structural damage and failure of the cladding caused by hoop (circumferential) stress. Increased debris in the reactor vessel, damaging and rupturing fuel rods. Cladding wear and failure from prolonged rubbing of fuel rods against grids that hold them in the assembly as the reactor operates (grid to rod fretting). A significant increase in radioactivity and decay heat in the spent fuel. A potentially larger number of damaged spent fuel assemblies stored in pools. Upgraded pool storage with respect to heat removal and pool cleaning. Requiring as much as 150 years of surface storage before final disposal. (0377-2-9 [Cuthbert, Lewis])

Comment: WE URGE NRC TO CHOOSE THE LEAST BAD SOLUTION: STORE IT ON- SITE "SAFER." REQUIRE NUCLEAR PLANT OWNERS TO DRY-STORE HIGH-LEVEL RADIOACTIVE WASTE WHERE IT IS, IN THE SAFEST POSSIBLE WAY (0377-3-4 [Cuthbert, Lewis])

Comment: NRC's Regulatory Oversight Of Fuel Pools Is Failing To Reduce Risks At Limerick and Elsewhere (0377-4-10 [Cuthbert, Lewis])

Comment: WHY THE SAFEST DRY-CASK STORAGE AND MOST STRINGENT REGULATORY OVERSIGHT ARE REQUIRED FOR ON-SITE DRY STORAGE; EVIDENCE

BELOW SHOWS WHY ON-SITE CASK STORAGE AT LIMERICK NUCLEAR PLANT PRESENTS LONG-TERM ENVIRONMENTAL RISKS AND PROVIDES COMPELLING EVIDENCE THAT MUST NOT BE IGNORED BY NRC. CASK ISSUES THAT NEED TO BE CONSIDERED BY NRC: Casks Are Threatened by Natural Disasters like Earthquakes, Tornadoes, and Floods; If air flow vents get clogged from severe weather events and remain clogged for an extended period, rods can overheat and combust; Extremely heavy casks were shifted on their base during the North Anna earthquake; Corrosion of steel holding Limerick's high-level radioactive waste rods is a huge concern. NRC is well aware of Limerick's highly corrosive air as a result of chlorine and other corrosives massively released into the air from Limerick cooling towers with 44 million gallons of steam every day; Corrosion over time may make it impossible to remove rods in the event of a problem with leaking, for transport, or in the event of combustion; Containers are expected to last 50 years - wastes stay dangerous over a million years. What will happen if corrosion makes it impossible to remove the wastes into new containers every 50 years? (0377-4-12 [Cuthbert, Lewis])

Comment: CASK DESIGN FLAWS A SERIOUS CONCERN OVERLOOKED BY NRC: A Nuclear Engineer Warned ACE About Design Flaws In Casks For Storing Limerick's High-Level Radioactive Wastes. ACE Reported The Information To NRC. Sadly, Design Flaws Were Denied Or Ignored. THE NUCLEAR ENGINEER WHISTLE BLOWER CALLED LIMERICK CASK TECHNOLOGY "OLD AND DOWNRIGHT DANGEROUS" 1. Cask Design Flaws: Cement Blocks, Assembled Together, Are Not The Safest Housing For Enclosing Deadly Nuclear Fuel, Not Even Anchored to the Concrete Floor. Industry Workers Claim NUHOMS Concrete Enclosure Falls Apart and Container Is Breached Under a Boeing Airplane Strike. 19 Corrosion of Steel Can Eventually Cause Nuclear Wastes to Collapse On Their Own Safe Storage Depends on Airflow. Air Around Limerick Is Likely Highly Corrosive. It's Only a Matter of Time Before Invisible and Inaccessible Steel Tubes Turn to Rust. 40 Ton Radioactive Waste Containers, "Filled With The Nastiest Of Manmade Stuff", Are Placed And Rest Unfastened On A Set Of Steel Columns. 3. Wastes May Not Be Able To Be Retrieved: Rods Are Being Removed From Pools at Limerick Years Before NRC Regulations First Required. Rods Stored In Casks Too Hot Can Heat Up And Cause Fire. Containers Are Expected To Last 50 Years, While Wastes Are Deadly Hundreds Of Thousands Of Years (0377-4-15 [Cuthbert, Lewis])

Comment: This Nuclear Engineer Said Casks May Be A Sitting Duck In Case of a Crashing Aircraft: PROVEN CORROSION CONCERNS ARE A RECIPE FOR DISASTER: Research validates ACE concerns about corrosion of steel storing deadly wastes at Limerick Nuclear Plant. No one knows how long it will take for nuclear waste storage containers to break down from corrosion and eventually leak It is only a matter of time. How long will it take for steel to corrode that holds high-level radioactive wastes above ground in our back yard at Limerick Nuclear Plant? (0377-4-16 [Cuthbert, Lewis])

Comment: Summary Concerns and Questions About Spent Fuel Stored In Above Ground Casks That NRC Should Address. Clogged air flow vents from natural disasters like earthquakes, tornadoes, or floods, for an extended period, causing rods to overheat and combust. Corrosion of steel holding wastes making it impossible to remove wastes in the event of internal combustion. Containers are expected to last only 50 years - while wastes stay dangerous over a million years, leading to radioactive leaks that could cause future devastating harms. What guarantee is there that aging, corroded containers can or will be replaced? Who will pay? (0377-5-2 [Cuthbert, Lewis])

Comment: NRC SHOULD TAKE IMMEDIATE ACTION TO REDUCE RISKS BASED ON THE FOLLOWING CONCERNS: UNDETECTED CORROSION; INABILITY TO REMOVE IN CASE

OF FIRE OR NATURAL DISASTER; FAULTY CONCRETE; LAX NRC OVERSIGHT AND ENFORCEMENT EASY TERRORIST TARGET (0377-5-5 [Cuthbert, Lewis])

Comment: I also wish to add that my comments on the issue of spent fuel recriticality AKA 'K' factor are also impacted with the issue of the fragility and easy failure of the cladding and ease of fuel pellets forming geometries which support recriticality. I hope that the NRC staff will answer the questions posed by recriticality due to new geometries subsequent to cladding failure. Specifically How will issues such as fragility of cladding, relocation of fuel pellets and many experimental fuels and cladding in spent fuel pools impact chance of recriticality during storage and accidents? (0378-1 [Lewis, Marvin])

Comment: EPRI is pleased to provide the attached bibliography of EPRI publications that provide information and analysis related to NRC's Waste Confidence GEIS. EPRI requests that the relevant NRC Waste Confidence staff review the EPRI publications for potential use in preparing the final Waste Confidence GEIS. Wet and Dry Storage of Used Nuclear Fuel: *Impacts Associated with Transfer of Spent Nuclear Fuel from Spent Fuel Storage Pools to Dry Storage After Five Years of Cooling, Revision 1*. EPRI, Palo Alto, CA: 2012. 1025206. <http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001025206>. In 2010, EPRI performed a study of the accelerated transfer of spent fuel older than five years from pools to dry storage in response to the threat of terrorist activities at nuclear power plants. Following the March 2011 Great East Japan Earthquake and the subsequent accident at the Fukushima Daiichi nuclear power plant, some organizations issued a renewed call for accelerated transfer of used fuel from spent fuel pools (SFP) to dry storage. Their reasoning was that this would lessen the potential consequences from a loss-of-spent-fuel cooling accident by decreasing the heat load and source term available for release. This report revises the 2010 study to evaluate the costs and benefits of accelerating transfer of used fuel from SFPs to dry storage for two scenarios-one taking 10 years to transition the removal of all fuel cooled for at least five years, and the other taking 15 years to complete the transition. EPRI estimated the reduction of the number of assemblies, decay heat, and Cs-137 inventory in the spent fuel pool due to accelerated transfer of fuel older than five years. EPRI also estimated the increased cost and dose to workers caused by accelerated transfer. *Extended Storage Collaboration Program International Subcommittee Report*. EPRI, Palo Alto, CA: 2012. 1026481. <http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001026481>. With the prospect of spent nuclear fuel being stored at reactor sites for the foreseeable future, EPRI established the Extended Storage Collaboration Program (ESCP) in 2009 to investigate aging effects and mitigation options for the extended storage and transportation of spent nuclear fuel. ESCP's International Subcommittee developed this summary of the regulatory status, operational status, fuel inventory, and technical gaps identified for extended storage of spent fuel for each country involved. (0379-1 [Kessler, John])

Comment: Strategy for Managing the Long Term Use of BORAL® in Spent Fuel Storage Pools. EPRI, Palo Alto, CA: 2012. 1025204. <http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001025204>; BORAL® is a neutron poison material commonly used in spent fuel pool storage racks. This report examines the performance of BORAL® based on evaluation of surveillance coupons, identifies the degradation mechanisms for BORAL® in spent fuel pools, and evaluates the impacts of degradation. The report also develops a defense-in-depth strategy for managing BORAL® degradation for long-term use and suggests areas of research for further refinement of the BORAL® management strategy, including a recommended long-term corrosion test program. Summary of EPRI's Early Event Analysis of the Fukushima Dai-ichi Spent Fuel Pools Following the March 11, 2011 Earthquake and Tsunami. EPRI, Palo Alto, CA: 2012. 1025058.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001025058>;
As part of its Fukushima response, EPRI collaborated with experts from nuclear utilities, vendors, and national laboratories to evaluate the key theories and available data in support of EPRI's larger effort to provide timely information to the Tokyo Electric Power Company (TEPCO) and other member utilities on issues relevant to the safe management of spent nuclear fuel. Early products included assessments of the following: 1) re-criticality risk upon reflooding of a dry pool; 2) fuel pool evolution following loss of cooling; 3) likelihood of localized voiding within individual fuel assembly channels, leading to cladding heat-up and oxidation with release of hydrogen gas; and 4) potential significance of hydrogen from radiolysis in a boiling fuel pool. This report compiles individual analyses and assessments developed early in the Fukushima response for the purpose of documentation and for future reference and use. (0379-2 [Kessler, John])

Comment: *Extended Storage Collaboration Program (ESCP)*. EPRI, Palo Alto, CA: 2011. 1022914.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001022914>. EPRI is coordinating the Extended Storage Collaboration Program (ESCP)—a group of organizations representing the nuclear industry, federal government, national laboratories, and suppliers of used fuel dry storage systems—to investigate aging effects and mitigation options for the extended storage and transportation of used/spent nuclear fuel and high-level radioactive waste (HLW). The primary ESCP activity in 2010 through mid 2011 has been significant progress toward completion of technical "gap analyses" conducted by three organizations: U.S. Department of Energy Office of Nuclear Energy (DOE-NE) Used Fuel Disposition (UFD) Program; U.S. Nuclear Waste Technical Review Board (NWTRB); and U.S. Nuclear Regulatory Commission (NRC). *Delayed Hydride Cracking Considerations Relevant to Spent Nuclear Fuel Storage*. EPRI, Palo Alto, CA: 2011. 1022921.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001022921>. In this report, the main features of delayed hydride cracking (DHC) in zirconium alloys are reviewed. The conditions inside fuel rods during dry storage are estimated and used to evaluate whether DHC is possible during dry storage. Although some of the conditions for DHC exist—sufficient hydrogen for hydride formation, cooling from a high temperature, and at long times—crack initiation is unlikely because either the required high stresses or large sharp flaws are absent. In addition, DHC in zirconium alloys at low temperatures is reviewed. The conditions inside fuel rods during wet storage are estimated and used to evaluate whether DHC is possible during pool storage. Crack initiation, and therefore crack growth, is unlikely because the tensile stresses are too low, even if the outside surface of the cladding contains fretting damage from grids of modern design. If cracks were nucleated, they would grow sufficiently quickly that they would be apparent during pool storage. Their absence supports the conclusion that DHC is improbable. (0379-3 [Kessler, John])

Comment: *Industry Spent Fuel Storage Handbook*. EPRI, Palo Alto, CA: 2010. 1021048.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001021048>; The Industry Spent Fuel Storage Handbook "the Handbook") addresses the relevant aspects of at-reactor spent (or used) nuclear fuel (SNF) storage in the United States. With the prospect of SNF being stored at reactor sites for the foreseeable future, it is expected that all U.S. nuclear power plants will have to implement at-reactor dry storage by 2025 or shortly thereafter. The Handbook provides a broad overview of recent developments for storing SNF at U.S. reactor sites, focusing primarily on at-reactor dry storage of SNF. The Handbook provides an overview of current regulations and regulatory guidance for dry storage of SNF; descriptions of dry storage technologies available in the United States, and an overview of the process for planning and implementing an at-reactor storage facility. (0379-4 [Kessler, John])

Comment: *Used Fuel and High-Level Radioactive Waste Extended Storage Collaboration Program*. EPRI, Palo Alto, CA: 2010. 1020780.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001020780>;

The Electric Power Research Institute (EPRI) convened a workshop of over 40 representatives of the nuclear industry, federal government, national laboratories, and suppliers of used-fuel dry-storage systems to discuss the potential issues associated with extended dry storage of used fuel, that is, storage considerably beyond the term of current and recently proposed U.S. Nuclear Regulatory Commission (NRC) regulations. The workshop was held November 18-19, 2009, at EPRI's offices in Washington, DC. *Handbook of Neutron Absorber Materials for Spent Nuclear Fuel Transportation and Storage Applications*. EPRI, Palo Alto, CA: 2009. 1019110.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001019110>;

This handbook is intended to become a single source of information regarding technical characteristics of neutron absorber materials that have been used for storage and transportation of spent nuclear fuel as well as to provide a summary of users' experience. The second edition of this handbook was published in 2006. This third edition, the 2009 Edition, updates materials covered in the 2006 Edition, presents new products introduced since 2006, and reflects recent realignments of neutron absorber suppliers. *Cost Estimate for an Away-From-Reactor Generic Interim Spent Fuel Storage Facility*. EPRI, Palo Alto, CA: 2009. 1018722.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001018722>;

As nuclear power plants began to run out of storage capacity in spent nuclear fuel (SNF) storage pools, many nuclear operating companies added higher density pool storage racks to increase pool capacity. Most nuclear power plant storage pools have been re-racked one or more times. As many spent fuel storage pools were re-racked to the maximum extent possible, nuclear operating companies began to employ interim dry storage technologies to store SNF in certified casks and canister-based systems outside of the storage pool in independent spent fuel storage installations (ISFSIs). Since there will be a need for additional SNF storage capacity for several decades into the future, an alternative to storing SNF at reactor sites would be to store SNF at away-from-reactor interim SNF storage facilities, referred to herein as a "generic interim storage facility" or "GISF." This study provides an overview of the timing and projected costs associated with the design, licensing, construction, and operation of a GISF. (0379-5 [Kessler, John])

Comment: *Climatic Corrosion Considerations for Independent Spent Fuel Storage Installations in Marine Environments*. EPRI, Palo Alto, CA: 2006. 1013524.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001013524>;

It has been clearly demonstrated in laboratory and field studies plus field experience with actual and simulated components that the stress corrosion cracking (SCC) of austenitic stainless steel can occur at ambient temperatures in marine-type environments. This report evaluates the climatic differences among the various independent spent fuel storage installation (ISFSI) sites compared to the reference marine test site at Kure Beach, NC among the various reactor sites that have or plan to have spent fuel storage systems exposed to a marine environment. The typical surface temperature vs. time profiles of spent fuel canisters are also presented as is an evaluation of composition of airborne materials that could deposit on the spent fuel canisters exposed to a marine environment. *Effects of Marine Environments on Stress Corrosion Cracking of Austenitic Stainless Steels*. EPRI, Palo Alto, CA: 2005. 1011820.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001011820>;

It has been clearly demonstrated in laboratory and field studies plus field experience with actual and simulated components that the stress corrosion cracking (SCC) of austenitic stainless steel can occur at ambient temperatures in marine-type environments. There are a number of qualified techniques readily available to mitigate SCC of the proposed spent fuel storage canisters by addressing the tensile stress parameter of the SCC equation. There are also a

number of new emerging techniques for mitigating residual tensile stresses. This report presents information on both established tensile residual stress mitigation techniques and also newer techniques considered by the Yucca Mountain Project and the pressurized water reactor (PWR) industry for mitigation of SCC. *Probabilistic Risk Assessment (PRA) of Bolted Storage Casks: Updated Quantification and Analysis Report*. EPRI, Palo Alto, CA: 2004. 1009691. <http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001009691>; This report describes radiological risks and consequences to individuals from a bolted cask containing spent fuel from a pressurized water reactor while the cask is on-site. The risk to the public from the cask design is extremely low, with no calculated early fatalities and a first year risk of latent cancer fatality of $5.6E-13$ per year per cask. Subsequent year risk to the general public is even lower, attain, with no early fatalities and a cancer risk of $1.7E-13$ per cask per year. (0379-6 [Kessler, John])

Comment: *Technical Bases for Extended Dry Storage of Spent Nuclear Fuel*. EPRI, Palo Alto, CA: 2002. 1003416.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001003416>; In the United States, independent spent fuel storage installations (ISFSIs) were initially licensed for a 20 year-year period. However, delays in developing permanent spent fuel disposal capability require continued ISFSI storage beyond the 20-year term. This report provides a technical basis for demonstrating the feasibility of extended storage of low burnup spent fuel (i.e., < 45 GWD/MTU) in ISFSIs. *Dry Cask Storage Characterization Project*. EPRI, Palo Alto, CA: 2002. 1002882.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001002882>; Nuclear utilities have developed independent spent fuel storage installations (ISFSIs) as a means of expanding their spent-fuel storage capacity on an interim basis until a geologic repository is available to accept the fuel for permanent storage. This report provides a technical basis for demonstrating the feasibility of extended spent-fuel storage in ISFSIs. *Creep as the Limiting Mechanism for Spent Fuel Dry Storage*. EPRI, Palo Alto, CA: 2000. 1001207.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001001207>; Cladding creep is the dominant deformation regime for spent fuel in dry storage, and the evaluation of creep related time-dependent damage is an essential component of spent fuel storage licensing. Several potential damage mechanisms have been postulated for spent fuel in dry storage, which include accelerated (tertiary) creep leading to creep rupture, delayed hydride cracking (DHC), and stress corrosion cracking (SCC). These mechanisms are examined in detail in this report with the objective of determining their effect in potentially limiting the creep capacity of spent fuel cladding in dry storage. It is shown that the sent fuel environment lacks the conditions that are necessary for SCC and DHC mechanisms to become operative in dry storage. *The Castor-V/21 PWR Spent-Fuel Storage Cask: Testing and Analyses*. EPRI, Palo Alto, CA: 1985. NP-4887.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?AbstractId=NP-4887>; In full-scale tests, the 100-t Castor-V/21 cask proved itself both technically sound and practical for on-site storage of spent PWR fuel--a milestone in the qualification of metal casks for dry storage. Moreover, pretest predictions of the cask's thermal performance demonstrated the accuracy of the advanced HYDRA computer code, soon to be available for utility licensing analyses. (0379-7 [Kessler, John])

Comment: *Interim Storage of Greater than Class C Low Level Waste, Rev. 1*. EPRI, Palo Alto, CA: 2003. 1007862.

<http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001007862>; This report serves as a guideline for the safe, interim on site storage of low level radioactive waste (LLW) that exceeds the activity limitations for near-surface disposal set forth in 10 CFR

61.55. The nuclear industry refers to this waste as "greater than Class C (GTTC) waste" as it exceeds the Class C limits in the referenced regulation. At the present time, there is no licensed disposal facility for GTCC waste in the US. This situation forces commercial nuclear reactors to store it on site until a disposal facility is constructed and licensed. *Oxidation of Spent Fuel at Between 250 and 360 C*. EPRI. Palo Alto, CA. 1986. NP-4524 (0379-8 [Kessler, John])

Comment: I see no reason to believe the NRC's reassurances because I know your overly permissive record. As for technical back-up for my failure to believe that nuclear power generation and nuclear waste storage can be safe....need I do more than cite Murphy's Law? (0380-5 [Holt, Joan])

Comment: It is your job to protect this generation and many, many to come from the hazards of the nuclear industry. Your present decisions, actions, non-actions will cause countless deaths, cancers, birth defects, life disruptions, etc. now and generations into the future. 1. Acknowledge that there is no way to safely deal with nuclear waste. (0381-5 [Fasten, Susan])

Comment: The current way to handle the spent rods works. I feel strongly that with the great minds of our young engineers, we will come up with an even better way. (0382-3 [Tognazzini, Randall])

Comment: Due to the NRC watching over PG&E, it has a very detailed and successful spent fuel management program and continues to safely store fuel via both its wet and dry cask storage systems. I am confident that layer upon layer of safeguards are in place to effectively manage and monitor the stored spent fuel. I was on a tour of the Diablo facility and was able to learn and see for myself the safety measures. One way to calm the populace down is to tour the facility. There are so many mistruths flying around. (0383-2 [Mordaunt, Brandon] [Mordaunt, Laura] [Mordaunt, Philip])

Comment: I am writing to support the NRC's Spent Fuel Storage Rule, and wish to say that with NRC oversight PG&E has a very detailed and successful spent fuel management program And continues to safely store fuel via both its wet and dry cask storage systems. I am confident that layer upon layer of safeguards are in place to effectively manage and monitor the stored spent fuel. (0384-1 [Tannler, Sandra])

Comment: I am taking the time to write to share my views and concerns about the storage of spent nuclear fuel. I appreciate the work PG&E and the NRC have done to safely store spent nuclear fuel in wet and dry cask storage systems on site at Diablo Canyon. As a local resident I have taken the time to tour the plant and see the storage systems and to talk with PG&E about the process. I am impressed with the construction methods PG&E has used and the procedures for handling the fuel that have been developed with NRC oversight. Storage of spent nuclear fuel is a very serious issue and I feel it is well worth the time and energy that has been contributed. I'm sure the attention to detail will continue in the future. (0385-1 [Buckingham, Jeffrey])

Comment: I am writing to support the NRC's Spent Fuel Storage Rule, and wish to say that with NRC oversight PG&E has a very detailed and successful spent fuel management program and continues to safely store fuel via both its wet and dry cask storage systems. I am confident that layer upon layer of safeguards are in place to effectively manage and monitor the stored spent fuel. (0386-1 [Thompson, Lydia])

Comment: I have personally toured the Diablo Canyon Nuclear Power Plant and have seen firsthand Pacific Gas & Electric Company's spent fuel storage area and have heard a detailed

description of the management program, directed by the NRC. Safeguards are multilayered, and the monitoring is comprehensive, providing me great confidence in the NRC and PG&E. (0388-2 [Cox, David])

Comment: I am writing to support the NRC's Spent Fuel Storage Rule, and wish to say that with NRC oversight PG&E has a very detailed and successful spent fuel management program and continues to safely store fuel via both its wet and dry cask storage systems. I am confident that layer upon layer of safeguards are in place to effectively manage and monitor the stored spent fuel. (0391-1 [Trahey, Linda])

Comment: I have no doubt that the Nuclear Regulatory Commission will continue its strong, independent oversight of commercial nuclear energy facilities-the operation of existing plants, licensing new reactors, renewing the operating licenses of existing reactors, and the management, transportation and disposal of used nuclear fuel. (0398-2 [Helsel, Adam])

Comment: I have no doubt that the Nuclear Regulatory Commission will continue its strong, independent oversight of commercial nuclear energy facilities-the operation of existing plants, licensing new reactors, renewing the operating licenses of existing reactors, and the management, transportation and disposal of used nuclear fuel. (0399-2 [Sylvester, Richard])

Comment: I have no doubt that the Nuclear Regulatory Commission will continue its strong, independent oversight of commercial nuclear energy facilities-the operation of existing plants, licensing new reactors, renewing the operating licenses of existing reactors, and the management, transportation and disposal of used nuclear fuel. (0400-2 [Blankenmyer, Eric])

Comment: Because there is no place to sent this radioactive waste the atomic power plants have become de facto major radioactive waste-management operations. About 13% of America's 70,000 tons of radioactive wast is being held in water pools or casks at atomic plants in Illinois. This is just crazy. According to Bloomberg News the safest way to store radioactive waste is to put it into "dry casks" (i.e., steel and concrete casts) after the waste has cooled in "cooling pools" for about 5 years. But, 71% of the nation's spent fuel now remains in the water pools which are susceptible to fires that could spread the radiation. (0406-3 [Gerleman, Douglas])

Comment: I have not personally toured the Diablo Power plant run by PG&E. however. I have been to numerous meetings where PG&E spokesmen has discussed the working of the plant and I personally know people who have gone on your tours and were very impressed by your careful handling and management of the spent fuel rods in dry cask storage and wet cask storage which they found very adequate. (0408-1 [Watson, Jeannette])

Comment: By doing so. locally stored spent fuel could be safely removed to a single or regional locations controlled by and protected by our national government. (0408-3 [Watson, Jeannette])

Comment: We live in Santa Barbara County, which is immediately downwind of the Diablo Canyon Nuclear Power Plant. We are concerned about the dangers associated with the operation of the plant and the indefinite storage of radioactive "spent" fuel at the site. The inadequacy of the NRC's studies and proposals for "spent" fuel storage at Diablo and other nuclear plants would be laughable if it weren't so downright terrifying. (0409-1 [Hanson, Lauren] [Jones, Mary])

Comment: Fuel rod storage under water in fuel pools also has the problem of radiolytic hydrogen generation which can react with the zirconium cladding and other metallic components to cause hydride embrittlement. This creates problems for the future handling of the rods in the dry cask systems because the fuel elements become fragile and can break during transfer or repackaging, thereby releasing their contents. It is unclear whether the embrittlement gets worse with continued aging in dry storage. (0410-11 [Nelson, Dennis])

Comment: For maximum safety, present supplies of spent fuel rods should be stored in dry casks on location, rather than transporting them to ad hoc centers where concentrations will be greater, and security will be compounded in new locations. In addition with storage on site, paid for by those who invested in nuclear energy, the real dangers of accidents in transportation are removed (0411-2 [Krumm, Paul])

Comment: Public meetings for the EIS should be in every reactor community and analysis must include: sabotage and terrorist acts; current and future leaks from SFPs. Hardened On Site Storage, with earthen berms to isolate casks, should be required for all High Level Reactor Waste (HLRW) cool enough to store dry. For a greater margin of safety, low density configuration of the SFP should be required for all HLRW not placed in casks. The EIS must consider the risks of pool fires. (0419-13 [Agnew, David])

Comment: The EIS must consider the risk of current dry cask storage. Lack of quality assurance for design and fabrication of dry casks cast doubt on the structural reliability of current casks, most of which are stored outdoors in plain sight, and are not designed to withstand terrorism or severe earthquakes. Accidents with dry casks have occurred. The EIS must consider seismic risks to dry cask storage. (0419-15 [Agnew, David])

Comment: Making matters far worse, years ago the NRC quietly approved burning the fuel in the reactors longer, resulting in "high burnup" waste, which turns out may not actually be safe for storage or transport. High burnup fuel, and its excessive thermal and radioactive heat accelerating the degradation of dry cask storage containers, has not been adequately addressed in the GEIS. While the NRC has licensed the storage of "normal" radioactive fuel for up to 50 years, it can't endorse the storage of high burnup fuel for even 20 years. (0423-2 [Graves, Caryn])

Comment: This rule must be revised to ensure that "high burnup" waste is safely handled and the public is completely protected from any potential injury, especially from an earthquake at San Onofre and Diablo Canyon plants. The NRC should also prohibit any more production of "high burnup" waste until the public is completely protected from any potential injury, (0424-1 [Stewart, Jim])

Comment: The spent nuclear fuel needs to be moved ASAP to a much more remote location prior to finding a permanent storage location. We cannot risk spent fuel pool leaks and spent fuel pool fires. Tsunamis from distant countries can also affect the fuel storage at San Onofre, which has very small sea walls offering poor protection to the spent nuclear fuel storage system. (0425-2 [Individual, Anonymous])

Comment: I also understand that years ago the NRC agreed to burning the nuclear fuel in the reactors longer than normally allowed. This has resulted in "high burnup" waste, that will need to be handled even more carefully in order to not have a destructive nuclear accident, which will negatively affect the 8 million residents of the surrounding area. This high burnup fuel is excessively hot and radioactive, which may cause accelerated degradation of the dry cask

storage containers. This needs to be addressed immediately. The NRC is suppose to be a protector of public safety, that we can count on to do what is right for all the local residents. (0425-3 [Individual, Anonymous])

Comment: The NRC asserts that spent fuel stored indefinitely will not leak radioactivity to the point where human lives will be endangered above allowable limits. I point out that these facilities are mostly unfiltered, surface storage. They are open to weather, endangered by terrorists, inundated by flooding and with whatever else time will impact them. (0427-1 [Lewis, Marvin])

Comment: The low levels of risk reported in the GEIS do not reflect emergent concerns about the challenge of handling high burn-up fuel. The above critique suggests that we find the GEIS approach fundamentally misconceived as a response to the Waste Confidence challenge. The stakes on applying adequate criteria to on-site storage have been raised by the revelation that high burn-up nuclear fuel has been used for an extended period at locations such as San Onofre. This fuel is hotter both thermally and radioactively, thus increasing both the risk of storage on-site and the difficulties of transport to a remote site. Marvin Resnikoff comments: We should be very concerned about the challenge of storing high burn fuel. There is the timing issue of a long cool-down period for fuel used at 67 megawatt-days per metric ton. How did San Onofre get permission to operate at this level? The question has not been analyzed and San Onofre has put little or no high burn fuel in storage. Indeed, no form of storage has yet been approved for fuel this hot. This issue needs maximum attention. We await with interest the outcome of the NRC's technical workshop on storage of high burn-up fuel, held in Washington on November 18-19, 2013. The discovery of high burn-up fuel use, until recently unknown to the concerned public, might qualify as a game-changer if it had been assumed as we do not that on-site storage of spent fuel is a viable option. This has never been the case but the challenge of handling high burn-up fuel makes inescapably obvious the inherently dubious attempt to qualify indefinite on-site storage as an environmentally responsible alternative. (0431-14 [Pascall, Glenn] [Watland, George])

Comment: Find a good place for this radioactive hazard and put this waste there. Do not permit it to sit in casks on faults next to reactors. If you can not see the folly in this approach, you are not qualified to regulate for public well being. (0436-4 [Patrick, Kay])

Comment: Not only is there no long-term solution for atomic waste in hand or on the horizon, the shorter-term programs now in place are inadequate from a public safety standpoint and do not offer the requisite confidence to allow continued generation of radioactive waste. Nothing in the NRC's Draft NUREG-2157 changes truth and fact; it only relies on crossed fingers that no accident occur and the flimsy argument that casks and pools are doing fine. (0443-7 [Sabo, Betty])

Comment: Until final geologic repositories are established and operational, remove all dry casks to remote interim ISFSI facilities away from populated areas of our country, and placed in dispersed hardened and earthen covered or buried arrays to make them less vulnerable to terrorists attacks, and reducing the consequences if attacked (0447-2-13 [Andrews, Richard])

Comment: Spent fuel can be safely stored on-site at nuclear power stations in dry cask storage. This point was well presented by Dr. Rip Anderson and Gwyneth Cravens in the DVD "Power to Save the World," as recorded by the Long Now Foundation. (0448-1 [Moncy, Charles])

Comment: Human error is no trivial consideration. A person's preoccupation with personal or other problems or incorrect reaction to a stressful occurrence can compound events rapidly into catastrophe as history has shown. (0450-5 [Bast, Nancy])

Comment: We own property and reside within Evacuation Zone 3 of the Diablo Canyon Nuclear Power plant in San Luis Obispo, CA. We are seriously concerned about the lack of appropriate, long-term storage for the highly unstable and toxic "nuclear waste" from this plant. Per NRC information at recent hearings held in San Luis Obispo, only one-third of the "nuclear waste" generated at Diablo Canyon, which should have already been transferred into dry cask storage, had been so transferred. The remaining two-thirds of the spent fuel assemblies, which should have been transferred to dry cask storage, still remain in open and overcrowded cooling pools. The Diablo Canyon plant is not only in an active earthquake zone but it is also a highly-rated terrorist target location. In our opinion, the NRC is not exercising responsible and professional oversight when it allows continued generation of nuclear waste at Diablo Canyon without enforcing the transfer of spent fuel assemblies from open pools, designed for short term, cooling period, storage, into dry cask storage until such time as the spent fuel assemblies can be moved to safe, long-term, off-site storage. (0451-1 [Rippner, Sharon] [Rippner, Thomas])

Comment: In our opinion, long term on-site storage of nuclear waste at the Diablo Canyon plant is unacceptable under any circumstances. A plan which approves storage in open pools for longer than the five-year cooling period, without requiring timely removal of the assemblies to dry cask interim storage, is irresponsible in the medium term. (0451-3 [Rippner, Sharon] [Rippner, Thomas])

Comment: Furthermore, your approval of high burnup fuel at San Onofre requires that this waste be stored on-site in crowded spent fuel pools for a minimum of twenty years instead of in safer concrete and steel dry casks. (0453-2 [Feathers, Jösan])

Comment: The dry casks are not vulnerable to the loss of coolant if electricity is disrupted by an earthquake or other natural disaster since they are passively cooled by natural air flow. Spent fuel pools at nuclear power plants are intended to house nuclear waste only until it is cool enough to be transferred to permanent storage. In the U.S., overcrowded cooling pools can contain up to forty times more nuclear material than the reactor cores. Additionally, these pools lack equivalent containment buildings and safety systems for protection. (0453-3 [Feathers, Jösan])

Comment: Dry casks are economically viable and provide a storage alternative for twenty years for high burn up fuel or until an off-site storage facility becomes available, if ever. At a minimum, the NRC should not approve higher densities of fuel assemblies in dry cask systems and should stop approving the use of high burn up fuel in existing plants. (0453-5 [Feathers, Jösan])

Comment: Consequently, the first issue to be addressed should be the reduction in the density of overcrowded spent fuel pools. These are accidents waiting to happen, given how many are now filled to far beyond their original intended capacity. There is no reason to accept this kind of unnecessary risk unless, of course, the focus is on limiting expenses for Station operators. The pools were never meant for long term storage but, given that many old plants have renewed licenses which extend their operation up to 60 years, this has become the norm. Of course, transfer to dry cask storage is not without its own long term risk. There is no doubt that for short term storage, dry casks are more reliable than Spent Fuel Pools. The events at Fukushima after the March 2011 earthquake & tsunami proved this point since there was no damage to the dry

casks present at the site at the time of the multiple accidents. The dangerous condition of the pool at unit #4 speaks volumes about the risk which overcrowding presents. (0454-5 [Waldstein, Joe])

Comment: In our comments submitted during the scoping process for this EIS, we specifically requested that the EIS address the research needs identified by the NRC staff to develop the necessary information to address the risk of long term storage of SNF. Specifically, the staff identified the following high priority research needs: NRC staff concludes that the following potential degradation • Stress corrosion cracking (SCC) of stainless steel canister body and welds; • Corrosion, SCC, embrittlement, and mechanical degradation of cask bolts; • Swelling of fuel pellets due to helium in-growth, and fuel rod pressurization due to additional fuel fragmentation, helium release, and fission gas release during accidents. The items listed in the third bullet, concerning fuel and cladding, are highlighted for early attention because if they are shown to be unlikely to compromise cladding, other cladding-related mechanisms may become less significant. NRC staff also recommends that first priority be given to the following crosscutting areas: • Thermal calculations; • Effects of residual moisture after normal drying; • Development of in-service monitoring methods for storage systems and components. These areas have significance for multiple SCCs and degradation processes. Improvements in thermal calculations, for example, can help enhance understanding of performance of system components both inside (e.g., fuel and cladding) and on the exterior (susceptibility of canisters to SCC). By the same token, residual moisture can affect potential corrosion of cladding or fuel assembly hardware during storage; the potential significance depends on the amount of moisture and how it may interact with the components. (0459-2 [Johnson, Abigail])

Comment: At worst, this dubious policy would put area residents in peril of accidents in spent fuel pools or from long-term decay of dry-cask storage. These perils have been greatly increased by the use of "high burn-up" fuel that is hotter both thermally and radioactively, making it more dangerous to handle and more difficult to store. Currently, high burn-up has no approved means of storage beyond 20 years. (0464-5 [Nelson, Pam])

Comment: We have stored large quantities of spent nuclear fuel 50 miles from where I live for over 50 years with no contamination of the surroundings. This has been the experience at hundreds of reactors worldwide. Even in the extreme case of the spent fuel pool at Fukushima #4, it now appears that the hydrogen explosion there was from hydrogen vented from the neighboring Fukushima #3 plant, not because of any defects of the #4 pool. (0466-2 [Tanner, John])

Comment: The NRC's defense of spent nuclear fuel stored in pools of water to be as safe as dry cask storage is fallacious. Spent fuel pools are vulnerable to leaks due to aging materials, to terrorist acts (dropping of explosives into pool), and to unexpected and unplanned for natural events that damage the pools. (0467-1 [Hynes, H Patricia])

Comment: Making matters far worse, years ago the NRC quietly approved burning the fuel in the reactors longer, resulting in "high burnup" waste, which turns out may not actually be safe for storage or transport. High burnup fuel, and its excessive thermal and radioactive heat accelerating the degradation of dry cask storage containers, has not been adequately addressed in the GEIS. While the NRC has licensed the storage of "normal" radioactive fuel for up to 50 years, you can't endorse the storage of high burnup fuel for even 20 years. (0472-2 [Sheridan, Paul])

Comment: At the time of its decision that it could no longer predict a precise date or time frame for when a repository will become available, the NRC also determined that it needed to look at the environmental and safety implications of storing spent fuel at reactor sites for periods beyond 60 years after plant shutdown because no such analysis had ever been conducted: The Commission, as a separate action, has directed the staff to develop a plan for a longer-term rulemaking and Environmental Impact Statement (EIS) to assess the environmental impacts and safety of long-term SNF and HLW storage beyond 120 years (SRM-SECY-09- 0090; ADAMS Accession Number ML102580229). This analysis will go well beyond the current analysis that supports at least 60 years of postlicensed life storage with eventual disposal in a deep geologic repository. The Commission believes that a more expansive analysis is appropriate because it will provide additional information (beyond the reasonable assurance the Commission is recognizing in the current rulemaking) on whether spent fuel can be safely stored for a longer time, if necessary.; 75 Fed. Reg. at 81040. In its Project Plan for the Regulatory Program Review to Support Extended Storage and Transportation of Spent Nuclear Fuel (June 15, 2010) COMSECY-10-0007, NRC Staff "developed a seven-year plan for enhancing the technical and regulatory basis for extended storage and transportation by FY 2017" to be followed by a rulemaking if warranted. However, there is no mention of that 7-year effort in the current draft GEIS and it is unclear what has happened to those carefully developed research initiatives. (0473-10-2 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The DGEIS has failed to adequately consider the potential additional adverse environmental impacts associated with the use of high burnup fuel. The increasing use of high burnup fuel at reactors is creating problems for spent fuel pools. As of 2008, the NRC allows reactors using uranium fuel to operate at the highest burnup rates of any country in the world.²⁷ [footnote 27 text: Erik Kolstad, Nuclear Fuel Behaviour in Operational Conditions and Reliability, Prepared for IPG meeting-Workshop on Fuel Behaviour, Argonne National Laboratory (Sept. 2008), at 10.] Nonetheless, NRC and others acknowledge that there are many aspects of high burnup fuel that could make their use problematic for spent fuel storage and handling. For instance: * "There is limited data to show that the cladding of spent fuel with burnups greater than 45,000 MWd/MTU will remain undamaged during the licensing period."²⁸ [footnote 28 text: U.S. Nuclear Regulatory Commission, Standard Review Plan for Spent Fuel Dry Storage Facilities, Final Report NUREG-1567 (Mar. 2000), at 6-15. <http://www.nrc.gov/reading-rm/doccollections/nuregs/staff/sr1567/sr1567.pdf>.] * "For the most part, the current licensing basis for dry storage of spent fuel is largely based on fuel examinations and dry storage performance demonstrations performed in the 1980s and 1990s. Spent fuel used in the dry storage performance demonstrations had discharge burnups of ~36 GWd/MTU, or less."²⁹ [footnote 29 text: Electric Power Institute, Dry Storage Demonstration for High-Burnup Spent Nuclear Fuel Feasibility Study (Sept. 2003) at 5-1.] * "the majority of isotopic assay measurements available to date involve spent fuel with burnups of less than 40 GWd/MTU and initial enrichments below 4 wt % 235U, limiting the ability to validate computer code predictions and accurately quantify the uncertainties of isotopic analyses for modern fuels in the high burnup domain."³⁰ [footnote 30 text: NUREG/CR-7013, G. Ilas and I.C. Gauld, Analysis of Experimental Data for High-Burnup PWR Spent Fuel Isotopic Validation— Vandellös II Reactor, ORNL/TM-2009/32 at 1. Available at <http://info.ornl.gov/sites/publications/files/Pub22621.pdf>.] * "Only limited references were found on the inspection and characterization of fuel in dry storage, and they all were performed on low-burnup fuel after 15 years or less of dry storage. Insufficient information is available yet on high- burnup fuels to allow reliable predictions of degradation processes during extended dry storage, and no information was found on inspections conducted on high-burnup fuels to confirm the predictions that have been made."³¹ [footnote 31 text: United States Nuclear Waste Technical Review Board, *Evaluation of the Technical Basis for Extended*

Dry Storage and Transportation of Used Nuclear Fuel, December 10, 2010, available at http://www.nwtrb.gov/reports/eds_execsumm.pdf (last accessed Dec. 17, 2013).] * "the technical basis for the spent fuel currently being discharged (high utilization, burnup fuels) is not well established "the NRC has not yet granted a license for the transport of the higher burnup fuels that are now commonly discharged from reactors. In addition, spent fuel that may have degraded after extended storage may present new obstacles to safe transport."32 [footnote 32 text: National Academy of Engineering, *Managing Nuclear Waste*, Summer 2012, pp 21, 31. <http://www.nae.edu/File.aspx?id=60739>.] (0473-14-4 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: This increase in radioactivity also produces an increase in decay heat as the following chart, based on information from EPRI, demonstrates for a PWR: PWR SNF Assembly Decay Heat (right axis) and Cesium Inventory (left axis) as a Function of Burnup and Cooling Time E. Supko, *Impacts Associated with Transfer of Spent Nuclear Fuel from Spent Fuel Storage Pools to Dry Storage After Five Years of Cooling*, Revision 1, Electric Power Research Institute, (Aug. 2012), Fig. 2-2, available at <http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001025206#!> (last accessed Dec. 20, 2013). The BWR has similar results for the use of high burnup fuel: E. Supko, *Impacts Associated with Transfer of Spent Nuclear Fuel from Spent Fuel Storage Pools to Dry Storage After Five Years of Cooling*, Revision 1, Electric Power Research Institute, (Aug. 2012), Fig. 2-3, available at <http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000000001025206#!> (last accessed Dec. 20, 2013). In terms of the risk of a zirconium fire in the spent fuel pool, increasing decay heat in spent fuel is particularly troublesome where air and steam are present: [the reaction] is strongly exothermic - that is, the reaction releases large quantities of heat, which can further raise cladding temperatures... if a supply of oxygen and or steam is available to sustain the reactions. The result could be a runaway oxidation -referred to as a zirconium cladding fire - that proceeds as a burn front (e.g., as seen in a forest fire or fireworks sparkler)...As fuel rod temperatures increase, the gas pressure inside the fuel rod increases and eventually can cause the cladding to balloon out and rupture.³³ [footnote 33 text: National Research Council, Board on Radioactive Waste Management, Committee on the Safety and Security of Commercial Spent Nuclear Fuel Storage, National Academies Press (2006), p. 38-39. Available at http://www.nap.edu/openbook.php?record_id=11263&page=38, http://www.nap.edu/openbook.php?record_id=11263&page=39 .] NRC has recognized the problem created by high burnup fuel and is not able to establish a generic analysis of it: "it was not feasible, without numerous constraints, to establish a generic decay heat level (and therefore a decay time) beyond which a zirconium fire is physically impossible."³⁴ [footnote 34 text: U.S. Nuclear Regulatory Commission, *Technical Study of Spent Fuel Pool Accident Risk at Decommissioning Nuclear Power Plants*, October 2000, p. ix. available at <http://pbadupws.nrc.gov/docs/ML0104/ML010430066.pdf>.] In addition to increasing the possibility of zirconium fires and making the calculation of their probability on a generic basis impossible, high burnup fuels are also causing problems with the integrity of the spent fuel pools themselves: as nuclear plants age, degradations of spent fuel pools (SFPs), reactor refueling cavities...are occurring at an increasing rate, primarily due to environment-related factors. During the last decade, a number of NPPs have experienced water leakage from the SFPs [spent fuel pools] and reactor refueling cavities. (0473-14-5 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: it is often hard to assess their in situ condition because of accessibility problems...Similarly, a portion of the listed concrete structures are either buried or form part of other structures or buildings, or their external surfaces are invisible because they are covered

with liners.³⁵ [footnote 35 text: U.S. Nuclear Regulatory Commission, "A Summary of Aging Effects and Their Management in Reactor Spent Fuel Pools, Refueling Cavities, TORI and Safety-Related Concrete Structures," NUREG/CR-7111 (2011) at vxiii, available at <http://pbadupws.nrc.gov/docs/ML1204/ML12047A184.pdf>. These structural problems are creating additional risks of criticality accidents at spent fuel pools: The conservatism/margins in spent fuel pool (SFP) criticality analyses have been decreasing...The new rack designs rely heavily on permanently installed neutron absorbers to maintain criticality requirements. Unfortunately, virtually every permanently installed neutron absorber, for which a history can be established, has exhibited some degradation. Some have lost a significant portion of their neutron absorbing capability. In some cases, the degradation is so extensive that the permanently installed neutron absorber can no longer be credited in the criticality analysis.³⁶ [footnote 36 text: U.S. NRC, Office of Nuclear Reactor Regulation, On Site Spent Fuel Criticality Analyses, NRR Action Plan, May 21, 2010. <http://pbadupws.nrc.gov/docs/ML1015/ML101520463.pdf>]. This problem cannot be fixed merely by adding more boron to the spent fuel pool since concrete "could be negatively impacted by adverse environments of borated water or where there is the possibility of alkali aggregate material reactivity."³⁷ [footnote 37 text: NUREG/CR-7111, supra note 35, at xiv.] And adding any equipment to the spent fuel pool (e.g., to control water chemistry or to absorb neutron) is not a viable solution because it restricts water flow in the pool and thus increases the risk of an accident from a loss of adequate cooling. In sum, the DGEIS has failed to adequately consider the potential additional adverse environmental impacts associated with the use of high burnup fuel. Relatedly, the NRC has failed to analyse the extent to which those impacts could be mitigated by, for instance, preventing further use of high burnup fuel at reactors and requiring the immediate transfer of all high burnup spent fuel that is at least 5 years old to dry casks. (0473-14-6 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The Commission has frequently relied on NUREG-0575, including waste confidence decisions.¹¹ [footnote 11 text: The initial waste confidence decision relied, in part, on NUREG-0575 to conclude that storage of spent fuel at reactor sites is acceptable. "The Commission is confident that the regulations now in place will assure adequate protection of the public health and safety and the environment during the period when the spent fuel is in storage (NUREG-0575, 'Final Generic Environmental Impact Statement on Handling and Storage of Spent Light Water Power Reactor Fuel,' Vol. 1, August 1979, at ES-12, 4-10 to 4-17)." 49 Fed. Reg. 34658.] In doing so, the Commission has never recognized that NUREG-0575 was based on several incorrect assumptions. First, it greatly underestimated the "conservative upper bound" to the length of onsite storage: The Commission announcement of September 16, 1975, outlining this study stipulated that the Staff was to examine the period through the mid-1980's. In the absence of a national policy directed to final disposition of spent fuel, the staff extended the time period of this study to year-2000. This extension provided a conservative upper bound to the interim spent fuel storage situation at a date that constituted a practical limit to the forecasting that may logically be used as a basis for today's decisionmaking. Id. at ES-1 (emphasis added). (0473-7-2 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Dry cask storage for older, cooler spent fuel has two inherent advantages over pool storage: (1) It is a passive system that relies on natural air circulation for cooling; and (2) it divides the inventory of that spent fuel among a large number of discrete, robust containers. These factors make it more difficult to attack a large amount of spent fuel at one time and also reduce the consequences of such attacks. *** NAS Study at 6, 8 and 10.; The previous NRC analyses and independent analyses of the safety of spent fuel stored at reactor sites,

particularly the safety of such storage in spent fuel pools, is directly relevant to the task NRC should be undertaking here. (0473-8-7 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Another study was done by the General Accounting Office. GAO-12-797, Spent Nuclear Fuel Accumulating Quantities at Commercial Reactors Present Storage and Other Challenges (August 2012) ("GAO Study"). This study concluded that "the key risk of storing spent fuel at reactor sites is radiation exposure from spent fuel that has caught fire when it is stored in a pool, but it is difficult to quantify the probability of such an event." Id. at 27. The GAO Study also found that "according to the analysis in a February 2001 NRC study [NUREG-1738], assuming a high release of radiation, the release of spent fuel fission products resulting from a pool fire could result in nearly 200 early fatalities, thousands of subsequent cancer fatalities, and widespread land contamination." Id. at 28. The previous NRC analyses and independent analyses of the safety of spent fuel stored at reactor sites, particularly the safety of such storage in spent fuel pools, is directly relevant to the task NRC should be undertaking here. (0473-8-8 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: [W]ell the horse is out of the barn, but how can we safely transport and permanently store the leftovers? One thing for sure, it has to be moved away from the coast and away from the seismic zone. (0474-1 [Bucklin, Christine])

Comment: The key word is PERMANENT. No "interim" storage facilities should be implemented. PERIOD. (0475-4 [Graham, Candace])

Comment: Then there is the problem of the storage of "high burnup" waste, which may not actually be safe for storage or transport at all. High burnup fuel, and it's excessive thermal and radioactive heat accelerating the degradation of dry cask storage containers, has not been adequately addressed in the GEIS. This category of fuel was caused by the NRC quietly approving burning the fuel in the reactors longer, even though the NRC doesn't endorse storing this waste for more than 20 years. (0477-2 [Tache, Jan])

Comment: This amount of radioactive material threatens too many people and too much property when stored in such a densely populated area, it needs to be secure from all threats including man made and natural. Please find another way and place to store it. (0479-1 [Sahagian-Allsopp, Ed])

Comment: Dry case storage is very dangerous, it's on the CA fault line & 90% more radioactive stuff than Chernobyl! Do your job, (0483-2 [Garvey, Lydia])

Comment: When nuclear power plants were first built, the spent fuel pool was designed as a very temporary storage site. The pools were never intended for long term storage. (0484-1 [Olsen, Steven])

Comment: Because no Government knows how to handle the spent fuel "hot potato" in the long term, the interim good solution of Dry Cask has been mostly ignored. Dry Cask everything that can be Dry Casked now. Typically spent fuels that have been cooling for 5 years can be Dry Casked. Until the fuels are put into Dry Cask, there is a risk of a regional economy killing event due to power loss/natural disaster, or terrorist action. There have been far too many close calls in the last few years, in the USA. We are flirting with disaster. Our good judgment in risk control has been decimated by lack of good choices and the hope of a Yucca mountain, always right around the corner. There is a GREAT interim solution, which creates good jobs in

America, and we need that badly, and solves much of the problem, immediately increasing our safety and reducing our risk of terrorist attack. (0484-2 [Olsen, Steven])

Comment: MOX reprocessing IS NOT an answer. MOX reprocessing is attempting to "burn up" the fuel by removing the plutonium from the spent fuel and concentrating it in new fuel rods to be burned in a nuclear plant. There are 2 problems with this. 1) It is much more expensive to process and create the MOX fuel than it is to simply cask it. A study by Princeton presented April 4, 2008 to Congress estimated that processing MOX is about 10 times more expensive than simply Dry Casking. 2) The MOX fuel is far more likely to blow up in a modified nuclear explosion called a Moderated Prompt Criticality, as did occur At Fukushima Reactor 3 which was running MOX. (0484-4 [Olsen, Steven])

Comment: The Dry Cask is proven technology, we can produce them in the USA, we can create jobs in the USA, and we can increase safety, all at an acceptable cost. Most or all of the cost should be borne by the existing utilities, since they had the obligation to decommission their plants. But I also propose that the US Government, using taxpayer dollars, assist the utilities, as it is in our common interest to Dry Cask as soon as possible, by providing 50% of the cost of the cask itself. (0484-5 [Olsen, Steven])

Comment: For the immediate and medium term, I believe that nuclear waste should be stored in a manner that minimizes the risk of its release into the environment. As there is often much more waste on the site of a reactor than active fuel within, I feel this needs to be stored inside a structure just as robust as the reactor containment itself. I also feel that while the highly radioactive isotopes decay, provisions should be made to keep the reactor and spent fuel cool during extended power outages that could be caused by a major disaster such as an earthquake. This could either be done by having backup power or designing systems so that they do not require active cooling (even better). (0488-1 [Watkins, Conor])

Comment: The NRC has confirmed that all U.S. reactors use High Burn Up waste. High Burn Up waste is too hot (radioactive) to handle and too unstable to transport or store. The DOE and NRC have not approved High Burn Up storage casks beyond 20 years. The GEIS contains inaccurate, incomplete and misleading information about High Burn Up waste. (0490-3 [Chin, Rebecca])

Comment: The NRC is surely the only regulatory body in the world that would argue that indefinite -- essentially permanent -- storage of high-level radioactive waste in fuel pools and dry casks provides "confidence" that this waste will never cause a threat to public health and safety. By their very nature, neither casks nor fuel pools are designed for permanent storage. (0491-4 [Commenters, Multiple])

Comment: Storing nuclear waste that may leak into the ground and into our rivers and drinking water is not a gamble I am willing to accept. (0492-3 [Maghakian, Carol])

Comment: There is no proven safe way to store nuclear waste. (0493-1 [Davis, Suzanne] [Davis, Tom])

Comment: I am writing to raise concern about the amount of spent fuel rods "packed" into cooling pools. The number is far beyond the recommended amount and radiation spikes are appearing all around the country, including in my state of Arizona. (0494-1 [Orlinski, Patricia])

Comment: The reality appears to be that there is no place to move the spent fuel at this time, it also appears that dry cask storage while having problems of its own would at least lower the risk of massive radiation danger of a widespread dispersal of contaminating particles should an earthquake damage the holding pool and cause loss of the cooling water with a resulting fire. (0495-2 [Grigg, Richard])

Comment: The risks and costs involved in trying to move these radioactive materials to an interim storage site are prohibitive and prolong the process of achieving safer storage conditions on-site in the short term. (0499-2 [Ramsay, Rebecca])

Comment: The only components of the four damaged reactors that survived the earthquake, tsunami, loss of coolant and reactor explosions relatively intact were that portion of the 11,000 fuel rods which were in dry cask storage. According to PG&E figures, as of this month, November 2013, 67% -- or 1,920 of the Diablo Canyon spent fuel assemblies -- are currently in spent fuel pools serving units 1 and 2. (0501-3 [Brown, Jerry])

Comment: The next issue that seems untouched in the NUREG 2157 is experiments with zirconium cladding. Zirconium cladding has been discussed in NUREG 2157, but issues such as experimental alloys, what has caused many fuel rods to be put into SF pools with little or no use, experiments with alloying, geometries caused by accidents resulting in recriticality, coolant filters packing up with fuel pellets and other debris... Will the above issues with spent fuel be resolved before the final NUREG 2157 issues? (0502-2 [Lewis, Marvin])

Comment: Nuclear waste should not be transported and stockpiled in "interim" sites around the country, as the cost to taxpayers and risk to communities of moving this deadly cargo are too great. (0507-4 [Giese, Mark M.])

Comment: Please, for the sake of future generations of humanity and all other life forms on this beautiful planet enact a safer,workable,more permanent solution to the extreme safety issue of storing spent fuel in temporary fuel pools. Increase dry cask and safer storage and research viable solutions to nuclear waste now. (0508-1 [Marsh, Kathryn])

Comment: The storage of waste generated by the nuclear power industry is one of a series of insurmountable problems for humanity that make the technology unsuitable from its inception. The proposed "determinations" of the impact statement are based on risk: that the storage pools employed by the industry are safe to operate for 60 years past the original lifetime design of the plant. The authors evidently consulted a crystal ball to support their assertion. The recent disaster at Fukushima Dai-ichi proves that nuclear materials are inherently unsafe to store, that there exists no place to securely store them for the time necessary to render them stable. (0509-1 [Longyear, John])

Comment: Nuclear energy cannot be safe and cheap. To have no repository means moving these materials. Every terrorist is now well - aware of the potential vulnerability of stored spent fuel rods. Multiple acts of nature can combine in a number of unforeseeable ways to create fuel fires and uncontrolled releases into the atmosphere of lakes, streams, rivers, aquifers, etc. (0512-3 [Bibb, William])

Comment: Dry Casking the spent fuel that can be stored that way is our best option at present. Spent Fuel pools are not safe. Look at the ongoing horrible crisis at Fukushima, Look what it has done and continues to do to the sea life in the pacific ocean. Think about the safety of your children and grandchildren. Act now while you still can. (0513-1 [Riesterer, Zita-Ann])

Comment: The methods and practices used by the US in storing spent fuel indicate that the NRC is an irresponsible agency in dealing with this issue. It is genocidal to permit the storage of fuel in such poorly protected pools at reactor sites that in most cases have enough fuel to destroy the entire planet's human population. It is suicidal to put spent fuel in places where the additional risks of reactor meltdowns can disable the safety systems to keep the fuel cooled. You apparently have your heads in the sand when it comes to both reactor and fuel safety. (0514-1 [Fahey, John])

Comment: The way spent fuel is stored is a crime against humanity and the human genome= genocide on nameless people who will pay for this incompetence with their genome damage. The spent fuel pool original capacities should be rolled back at the very least. The decision to allow some utilities to store more fuel in tighter racks is madness. To allow MOX fuel to be used and stored in common pools is madness. The pools just do not have the multiple safety systems, safe locations or reliability to safely store this deadly material. Spent fuel should NEVER be stored on reactor sites. The containment concept has been shown to be a fraud, as gasses produced during accidents can detonate and destroy containment structures, they are released instead. (0514-3 [Fahey, John])

Comment: Multiple and I mean X 5! ways to produce emergency cooling for spent fuel pools must be mandated ASAP. All pools should be underground and be offsite reactor facilities. (0514-6 [Fahey, John])

Comment: Do not allow the use of dangerous MOX fuel; (0515-8 [Stennes, Nancy])

Comment: Fukushima disaster shows the storage of spent fuel, as currently done, can have national and global radiation fallout in event of disruption of the storage process. The "60 years" mentioned as a timeline for a mined geologic repository is just kicking the can down the road in the hopes a technology will some day be created; this is currently what is occurring in Japan with their fuel storage issues and radiation damages. (0517-2 [Anonymous, JEC])

Comment: I didn't know there was or is a safe way to store spent nuclear fuel. Oh right, there isn't a way to store this menacing material. Human error always wins along with corrosion. (0519-1 [Bernstein, Patricia])

Comment: High burnup fuel, and it's excessive thermal and radioactive heat accelerating the degradation of dry cask storage containers, has not been adequately addressed in the GEIS. (0528-2 [Brown, Susan])

Comment: Years ago the NRC quietly approved burning the fuel in the reactors longer, resulting in "high burnup" waste, which turns out may not actually be safe for storage or transport. High burnup fuel, and it's excessive thermal and radioactive heat accelerating the degradation of dry cask storage containers, has not been adequately addressed in the GEIS. While the NRC has licensed the storage of "normal" radioactive fuel for up to 50 years, they can't endorse the storage of high burnup fuel for even 20 years. STOP high burn up fuel now. (0529-5 [Claybourne, Ana])

Comment: MOX reprocessing IS NOT an answer. MOX reprocessing is attempting to "burn up" the fuel by removing the plutonium from the spent fuel and concentrating it in new fuel rods to be burned in a nuclear plant. There are 2 problems with this. 1) It is much more expensive to process and create the MOX fuel than it is to simply cask it. A study by Princeton presented April 4, 2008 to Congress estimated that processing MOX including the costs of the MOX facility and decommissioning the MOX facility is about 10 times more expensive than simply Dry

Casking. 2) The MOX fuel is far more likely to blow up in a modified nuclear explosion called a Moderated Prompt Criticality. Even in the 1940's it was theorized that a nuclear explosion could happen in a nuclear reactor, and in the 1950's Argonne National Laboratory did a series of experiments that were filmed and proved that even with normal nuclear fuel rods, under the right conditions, and uncontrolled criticality could blow up the reactor. With MOX, enriched with bomb making plutonium, this type of nuclear explosion is much more likely, as Japan found out in their Reactor 3 at Fukushima, which was running MOX. The amount of Uranium detected by the EPA in Saipan, Guam, Honolulu, and California could only be caused by one thing...an explosion from within the reactor vessel, that launched the inventory into the air. MOX can turn a 80 foot tall reactor with 6" steel walls into a "Canon" which can launch the entire inventory. (0529-6 [Claybourne, Ana])

Comment: The NRC's Waste Confidence policy assumes that all nuclear waste is the same, when different fuel types, such as high-burnup fuels and MOX have different storage considerations and implications for safety. (0531-1-11 [Morgan, Sally])

Comment: The NRC's Waste Confidence policy assumes that all nuclear waste is the same, when different fuel types, such as high-burnup fuels and MOX have different storage considerations and implications for safety. (0531-2-11 [Morgan, Sally])

Comment: Using temporary storage sites around the country while waiting for a federal repository means more communities would be at risk from radioactive waste, more nuclear sites would have to be safeguarded, and reactor owners can continue making waste without being responsible for managing it. (0531-2-18 [Morgan, Sally])

Comment: Some irradiated fuel pools in the US have been found to be holding up to 9 times the amount of spent fuel for which they were designed[.] (0531-2-20 [Morgan, Sally])

Comment: An independent study should be undertaken to determine the best course of action for at-reactor storage, centralized storage, or some other configuration or location. (0534-5 [Vetter, Richard])

Comment: The NRC has confirmed that all U.S. reactors generate HIGH BURN UP waste. HIGH BURN UP waste is too hot (radioactive) to handle, too unstable to transport or store. The DOE and NRC have not approved storage casks for HIGH BURN UP beyond 20 years. The GEIS contains inaccurate, incomplete, and misleading information about HIGH BURN UP waste. (0537-3 [Commenters, Multiple])

Comment: I would like to submit my support of on site waste storage until a future alternative is found. I do not feel this is a threat to our community and support the operation of the Diablo Canyon Nuclear Power Plant. (0538-1 [Kaul, Michelle])

Comment: At worst, this dubious policy would put area residents in peril of accidents in spent fuel pools or from long-term decay of dry-cask storage. These perils have been greatly increased by the use of "high burn-up" fuel that is hotter both thermally and radioactively, making it more dangerous to handle and more difficult to store. Currently, high burn-up has no approved means of storage beyond 20 years. (0540-6 [Watland, George])

Comment: Having the highly radioactive "waste" stored in relative unprotected dry cask storage containers as well as the cooling pools not being protected by cement domes as the reactors are, leaves one with complete no confidence in the task the GEIS has attempted to fulfill. (0541-6 [Justesen, Evelyn])

Comment: Start by not whitewashing the "relative safety" of highly radio waste. Start all over again by considering the communities that are vulnerable to the dangers of this waste. Start by taking us and this problem seriously. (0541-7 [Justesen, Evelyn])

Comment: Fourth, nowhere in my state of Minnesota is a good place for a radioactive waste dump. No place in the USA is a good place for a radioactive waste dump. No place on earth is a good place for a radioactive waste dump. We do not want any more high-level radioactive wastes coming "to or through" our state. We do not want to see more high-level, long-lived radioactive waste coming to proposed "centralized interim storage" waste facilities here or anywhere else. (0543-4 [Senkiw, Sheryl])

Comment: The waste confidence documents should also be very clear that centralized interim storage financed by the Federal government (the away from reactor scenario analyzed in the subject GEIS) is not allowed under current Federal law. (0544-10 [Enriquez, Elizabeth])

Comment: Our Board appreciates the opportunity to comment on your Waste Confidence Rule update and trust that your Commission will require all nuclear plant operators to handle spent fuel in a manner most protective of the residents of the communities where these plants are located. (0548-10 [Gibson, Bruce])

Comment: We further understand that the pools at DCPD are now storing spent "high burn-up" fuel assemblies material possibly not considered in the original design. We would request a thorough examination of the thermal and mechanical consequences of high burn-up fuel being present in spent fuel pools. (0548-7 [Gibson, Bruce])

Comment: I have no doubt that the Nuclear Regulatory Commission will continue its strong, independent oversight of commercial nuclear energy facilities --the operation of existing plants, licensing new reactors, renewing the operating licenses of existing reactors, and the management, transportation and disposal of used nuclear fuel. (0549-3 [Williams, Robert])

Comment: Consolidated Storage away from reactor sites creates more problems, not solutions. In order to justify its Waste Confidence policy, NRC is relying on the federal government's plan (Senate bill 1240) that mandates transporting spent fuel away from nuclear reactors to "temporary" storage sites around the country until a central repository is built. This means more communities would be at risk from radioactive waste, more nuclear sites would have to be safeguarded, and reactor owners could continue making waste without responsibility for managing it. Temporary storage sites easily could become de facto permanent dumps if it is not politically feasible to site enough repositories to handle the waste. (0552-1-10 [Macks, Vic])

Comment: NRC's Waste Confidence policy assumes that all nuclear spent fuel is the same. This is far from the truth. The industry is moving toward new fuel types, such as MOX (mixed oxide) and high-burnup fuels, which are more radioactive, dangerous, thermally hot and difficult to store and transport safely. (0552-1-13 [Macks, Vic])

Comment: High burnup fuel problems:(citations follow): Dangerously unpredictable and unstable in storage--even short-term. Over twice as radioactive and over twice as hot. The

higher the burnup rate and the higher the uranium enrichment, the more radioactive, hotter and unstable. Requires a minimum of 7 to 20 years of cooling in spent fuel pools. San Onofre's 1123 high burnup fuel assemblies require at least 15 years to cool in the pools. Years of cooling depend on burnup rate, percent of uranium enrichment and other factors as defined in the dry cask system's technical specifications.³ Lower burnup fuel requires a minimum of 5 years in cooling pool. Requires more storage space between fuel assemblies due to the higher heat, higher radioactivity, and instability,⁴ yet the NRC approves higher densities of fuel assemblies in dry casks systems. San Onofre requested use of a new dry cask system that crowds 32 fuel assemblies into the same space that currently holds 24.⁵ This new system will increase the risks of dangerous radiation releases into the environment. The NRC should NOT approve the NUHOMS® 32PTH2 cask system for high burnup, but is considering doing so this year. Diablo Canyon now uses a 32 fuel assembly cask system. No transportation casks for high burnup are approved by the NRC,⁶ so the waste cannot be relocated. Approved for only 20 years in dry cask storage and assumptions about how high burnup fuel reacts in the first 20 years of storage are proving incorrect.⁷ Insufficient data to approve dry casks for over 20 years, per Dr. Robert Einziger, Senior Materials Scientist, NRC Division of Spent Fuel Storage and Transportation. 8 citations: 1 GAO-12-797 SPENT NUCLEAR FUEL Accumulating Quantities at Commercial Reactors Present Storage & Other Challenges, August 2012.

The Coalition to Decommission San Onofre 10/18/2013 SanOnofreSafety.org. (0552-1-14 [Macks, Vic])

Comment: Some irradiated fuel pools in the U.S. currently hold up to 9 times the amount of spent fuel for which they were designed. (Lochbaum) The pools are not protected by redundant emergency makeup and cooling systems or housed within robust containment structures having reinforced concrete walls several feet thick. (Lochbaum). Lochbaum, David, Director, Nuclear Safety Project, testimony Before the Senate Committee on Energy and Natural Resources, July 20, 2013. http://www.energy.senate.gov/public/index.cfm/files/serve?File_id=89dbc888-171c-4f77-8ecf-83a0055fcfb9 5. Principles of Safeguarding Nuclear Waste at Reactors or Hardened On-Site Storage (HOSS) <http://www.nirs.org/radwaste/policy/hossprinciples3232010.pdf>. (0552-1-22 [Macks, Vic])

Comment: NRC has not dealt with the very real risk that the irradiated nuclear fuel will so degrade with age that such transfer operations could not be carried out safely or smoothly. This is especially a risk with "high burn-up fuel," that has spent more time in an operating reactor core, and is thus significantly more radioactive and thermally hot. (0552-1-26 [Macks, Vic])

Comment: The advantages of dry cask storage over pool storage is further documented by a team of experts on the hazards of spent fuel pools which includes the current chair of the Nuclear Regulatory Commission, Allison Macfarlane.(Alvarez) There is a substantial reduction in the risk to the population if the spent fuel is transferred to casks: "The risk reduction is undeniable: the contaminated land area is reduced from 9,400 square miles to 170 square miles and the number of people displaced from their communities for a long time drops from 4,100,000 to 81,000." (Lochbaum). Robert Alvarez, Jan Beyea, Klaus Janberg, Jungmin Kang, Ed Lyman, Allison Macfarlane, Gordon Thompson, and Frank N. von Hippel, Reducing the Hazards from Stored Spent Power-Reactor Fuel in the United States, Science and Global Security, 11:1-51, 2003.

Lochbaum, David, Director, Nuclear Safety Project, testimony Before the Senate Committee on Energy and Natural Resources, July 20, 2013. http://www.energy.senate.gov/public/index.cfm/files/serve?File_id=89dbc888-171c-4f77-8ecf-83a0055fcfb9 5. Principles of Safeguarding Nuclear Waste at Reactors or Hardened On-Site Storage (HOSS) <http://www.nirs.org/radwaste/policy/hossprinciples3232010.pdf>. (0552-1-29 [Macks, Vic])

Comment: Failure to compare relative hazards of high-density pool storage with dry cask storage: Instead the authors pick a scenario which may not even reflect real world situations relative to the different storage configurations at U.S. nuclear power stations. According to estimates developed in 2007 for the Nuclear Regulatory Commission's Emergency Operation Center, for purposes of emergency planning and response, a major earthquake near the San Onofre Nuclear Generating Station in California might cause a spent fuel cladding fire releasing approximately 40 million curies of Cs-137 and causing life-threatening radiation doses to people within a 10-mile radius. By contrast, according to the same NRC document, a cask rupture would result in the release of 2,500 times less radioactivity. This is underscored by real world experience at the Fukushima Daiichi site where all the nine dry spent fuel casks were unscathed by the earthquake and tsunami. (NRC, 2007), (Talbot). U.S. Nuclear Regulatory Commission, Office of Nuclear Security and Incidence Response, RASCAL 3.0.5 Descriptions of Models and Methods, NUREG-1887, August 2007. Talbot, David, "The Case for Moving U.S. Nuclear Fuel to Dry Storage", MIT Technology Review, April 14, 2011. (0552-2-27 [Macks, Vic])

Comment: THE NRC HAS APPROVED UNSAFE HOLTEC STORAGE/TRANSPORT CASTS THAT ARE NOW DEPLOYED AND IN USE (0552-3-3 [Macks, Vic])

Comment: <http://www.gao.gov/assets/600/593745.pdf> describes complex unresolved issues regarding dry cask storage, unresolved issues regarding storage of high burn up spent fuel, dismantled cooling pools leaving no way to transfer spent fuel to new casks, casks used that are not suitable for transportation, spent fuel that can be stranded in deteriorating casks without provision for transfer to new casks, expectation of deteriorated spent fuel rods and no provision for management of such degraded spent fuel rods, and has no data base of its studies, etc. (0552-3-4 [Macks, Vic])

Comment: Federal policy makers must act now to develop consolidated facilities for interim storage, as recommended by the President's Blue Ribbon Commission on America's Nuclear Future and supported by a bipartisan group of Congressmen. (0555-4 [Contreras, Raquel])

Comment: Reactors in marine environments have a higher probability of corrosion from exposure to chloride than, obviously, those not in marine environments. (IN 2013-07 April 16, 2013 Premature Degradation Spent Fuel Storage Cask Structures and Components from Environmental Moisture) (0556-1-19 [Lampert, Mary])

Comment: Reactors vary in number of spent fuel assemblies that are defective and/or damaged. Therefore the potential storage challenges and environmental impact will differ. For example: Pilgrim has operated, and most likely will continue to operate with defective fuel assemblies. Pilgrim began operations in 1972 with defective fuel. The Massachusetts Department of Public Health's *Southeastern Massachusetts Health Study 1978-1986* stated, "Pilgrim, which began operations in 1972, had a history of emissions during the 1970s that were above currently "acceptable EPA guidelines as a result of a fuel rod problem." *Southeastern Massachusetts Health Study 1978-1986*, Morris M.S., Knorr R.S., Executive Summary, Massachusetts Department of Health (October, 1990). In the March 2005 and April 2006 Pilgrim SALP (Systematic Assessment of Licensee Performance, performed by the NRC) Reports, NRC Resident Inspector, William Raymond, stated that Pilgrim operated in 2004 and 2005 with defective radioactive fuel -- that is, fuel with perforated cladding. Fuel cladding provides the first barrier to prevent radionuclides from getting out and harming workers and the public. Degraded fuel is an ongoing issue for the industry. NRC Commissioner Merrifield has admitted nearly 1/3 reactors now have failed fuel, and the trend is increasing, not decreasing. *Briefing on Nuclear Fuel Performance*, Transcript, p.4, (February 24, 2005), <http://www.nrc.gov>. Use of degraded fuel varies and will impact the environment by increasing exposure to the public, workers and natural resources. For example, according to the NRC, 'a plant operating with 0.125 percent pin-hole fuel cladding defects showed a general five-fold increase in whole- body radiation exposure rates in some areas of the plant when compared to a sister plant with high-integrity fuel (<0.01 percent leaks). Around certain plant systems the degraded fuel may elevate radiation exposure rates even more.' United States Nuclear Regulatory Commission, Information Notice No. 87-39, *Control Of Hot Particle Contamination At Nuclear plants*, (August 21, 1987). (0556-1-37 [Lampert, Mary])

Comment: *NRC Generic Letter 94-04 Boraflex Degradation in Spent Fuel Storage racks*, June 26, 1996: Only some licensees use Boraflex as a neutron absorber in its spent fuel racks and some may not have the capability to maintain a 5percent sub-criticality margin because of current or projected future Boraflex degradation. When Boraflex is exposed to gamma radiation, the material shrinks and is subject to tears or gaps in the material. A second factor that may impact storage rack service life occurs when Boraflex is subjected to long-term exposure to gamma irradiation in the wet pool environment, the silicon polymer matrix becomes degraded and silica filler and boron carbide are released. The boron carbide loss can result in a significant increase in the reactivity of the storage racks. (GL, p. 3) Reactors with Boraflex present potential environmental impacts; and reactors vary in attention to mitigation for this problem. Plants with Boraflex are listed in the GL. (0556-1-38 [Lampert, Mary])

Comment: 10. NRC staff failed to perform a relative risk comparison with dry casks. There is not a peep from the NRC on this topic. 11. No mention that the dry casks at the Fukushima Dai-ichi site remained unscathed. 12. The Study assumes there is no risk to casks (Chapter 10) but provides no empirical justification. Casks, like spent fuel pools, are vulnerable. (Table IV-1, p., 32 above) For example, Holtec Hi-Storm 100's can be breached from a shaped charge delivered from either onsite or from off-site. The Performance of US Army Shaped Charges, M3 and M2A3 were described in Table IV-3.³¹ [footnote 31 text: Ibid]) [Table Submitted with Correspondence ML13354A021] Holtec Hi-Storm 100 casks have a 0.5" (1.27 cm) steel canister and a concrete outer wall measuring 26.75" (67.945 cm). The assemblies are protected by

68.445 cm, easily penetrable based on the capability of a shaped charge. Consequences: We know that a typical BWR cask contains approximately half the Cesium-137 that was released at Chernobyl. (0556-4-8 [Lampert, Mary])

Comment: 13. The Study never asked the important question: "Which is safer, pools or casks?" The report did not specifically answer this question but facts contained in the report actually lead to the conclusion that dry cask storage is safer and more secure than cramming more spent fuel rods into pools that weren't designed to accommodate that much material. The Study says that a fire in a densely packed spent fuel pool at the Peach Bottom plant could contaminate thousands of square miles with radioactive material, force the long-term displacement of millions of people, and cause tens of thousands of cancer deaths. Also the Earthquake Study failed to evaluate plants closer to major urban areas than Peach Bottom, such as the Indian Point plant near New York City or Pilgrim near Boston and Providence where the consequences of a similar event could be even greater. However, the Study shows that removing spent fuel older than five years from the pool could reduce the amount of radioactive cesium released by factor of 80, the number of cancers by a factor of 10, and the total amount of land that would be uninhabitable by a factor of 50. The bottom line--reinforced by the details in the NRC study--is that the public is better protected by reducing the amount of spent fuel storage in pools at U.S. reactors by moving it to dry storage. Doing so is an important defense-in-depth measure, which would significantly reduce the radiological risk to the public from spent fuel pool fires. 14. No analysis of age degradation of the pool and refueling cavity for the 60 years following license expiration. Pilgrim for example was built in the late 60's when Lyndon Johnson was President and the NRC Confidence Decision assumes that the pool would have structural integrity through 2092. There is neither industry experience to rely on nor any other basis for that determination. Engineers explain the aging phenomenon by using what is known as the "Bathtub Curve." The curve is a graph of failure rate according to age. The failure rate is relatively high in the beginning when "kinks" are being worked out; it flattens out during the middle life phase; and it rises again sharply in the end-of-life or at the "wearout phase." On average, 20 to 30 years usually marks the beginning of the wear-out phase. And the rate of corrosion is not linear over time.[FIGURE 1 - THE BATHTUB CURVE] [Figure Submitted with Correspondence ML13354A021] (0556-4-9 [Lampert, Mary])

Comment: Both the DGEIS and the Earthquake Study are key documents that provide the basis for the Proposed Waste Confidence Rule. Although the Proposed Rule explains that the Earthquake Study is not referenced in the DGEIS, it is for all practical purposes one of its foundations. It was developed side-by-side with the Proposed Rule to justify its conclusions. The authors admit that "the staff is aware of the conclusions in the draft Study and worked closely with the authors who developed the draft Study to prepare the relevant sections of the draft GEIS." (Draft Rule, p. 56783, emphasis added) PW's analyses of both the DGEIS and draft Earthquake Study show precisely why the draft rule by extension has no factual basis and why PW disagrees with its findings. (0556-5-1 [Lampert, Mary])

Comment: Dry Casks are Safer than Spent Fuel Pools • Casks have the advantage of passive cooling via airflow, unlike pools, which require mechanical functioning and human intervention to provide flow of cool water to cover the assemblies. Therefore casks are less vulnerable to natural disaster and sabotage. • Pools are not protected by redundant emergency makeup and cooling systems or housed in robust containment structures having reinforced concrete walls several feet thick. Pilgrim's pool, like other Mark I BWRs' has two feet thick external walls, where the primary containment is five feet thick. The roof is very thin, as it is designed to give in an accident. • Casks can withstand environmental disasters that pools cannot. At Fukushima the casks survived at 9.0 earthquake and the tsunami that flooded them. Pools are attractive terrorist

targets, not studied by the NRC in preparing the proposed rule. Casks are less vulnerable, also, because terrorists would have to target several casks to have the same amount of radiation released as the pool. Casks could be far safer if NRC required the casks to be spread out and surrounded by earthen berms. • Pool Accidents: NRC's economic consequence analyses (inexplicably for any reason other than the potential cost to the industry of dealing with the issue) continue to ignore the consequences of a spent fuel accident. No rational analysis could do so. • The importance of a spent fuel accident is illustrated by pointing to Pilgrim, where a spent fuel pool fire could release more than 44,010,000 curies of Cs-137, an amount 8 times more than a core release. Further, a spent fuel pool fire would result in releases going higher into the air and significantly impacting locations at greater distance with denser populations. Dr. Beyea estimated for the MA AGO the cost of a 10% release from a spent pool fire to be between \$105 and \$175 billion; and that a 100% release of C-137 would cost somewhere between \$342 and \$488 billion. (Beyea, p. 10). Entergy's LRA SAMA, based on currently approved NRC models, considered only the release of a relatively small amount of C-137 from the reactor core³⁵ [footnote 35 text: The Massachusetts Attorney General's Request for a Hearing and Petition for Leave to Intervene with Respect to Entergy Nuclear Operations Inc.'s Application for Renewal of the Pilgrim Nuclear Power Plants Operating License and Petition for Backfit Order Requiring New Design Features to Protect Against Spent Fuel Pool Accidents, Docket No. 50-293, May 26, 2006 includes a Report to The Massachusetts Attorney General on the Potential Consequences of a Spent Fuel Pool Fire at the Pilgrim or Vermont Yankee Nuclear Plant, by Jan Beyea, Ph.D., May 25, 2006.]. • Vulnerability: A wealth of government and independent reports show high-density, closed-frame spent fuel storage pools are vulnerable to catastrophic fires that may be caused by accidents or intentional attacks. NRC's safe storage finding does not qualify as a generic licensing determination under the AEA or NEPA. (0556-5-3 [Lampert, Mary])

Comment: • There is a substantial reduction in risk to the population if fuel is transferred to casks. "The risk reduction is undeniable: the contaminated land area is reduced from 9,400 square miles to 170 square miles and the number of people displaced from their communities for a long time drops from 4,100,000 to 81,000.³⁷," [footnote 37 text: David Lochbaum, Director, Nuclear Safety Project, Union of Concerned Scientists, Testimony before the Senate Committee on Energy and Natural Resources, July 20, 2013 http://www.energy.senate.gov/public/index.cfm/files/serve?File_id=89dbc888-171c4f77-Becf-83a0055fcfb9] • NRC knows that dry casks are safer than pools. In its Lessons Learned from Fukushima, NRC issued Orders regarding spent fuel pools but none for dry casks. The danger presented by spent fuel is the reason that the NRC recommended that all Americans within 50 miles of Fukushima be evacuated. (0556-5-5 [Lampert, Mary])

Comment: I am writing to address the NRC's Spent Fuel Rule. I have lived in the region of Diablo Canyon for over 27 years and as the former economic developer for our county, have a good understanding of the operations at Diablo Canyon Nuclear Power Plant. I have toured the facility and have sat in numerous detailed briefings by their staff, Pacific Gas and Electric has developed a spent fuel storage system that is well within the guidelines of the commission. They have set in place a multi-layered system of safeguards and have a comprehensive monitoring program to ensure proper safety of the region. I am convinced we are well protected by their ongoing efforts. (0557-1 [Johnson, Ray])

Comment: At the very least, all the used reactor cores (aka "spent" or "used" fuel) in California should be consolidated into ONE protected location, the best one possible, wherever we decide that is -- with DC shut down, of course, so no more waste is being produced here. There is reason for California to wait for a national repository -- it could be centuries away. The fuel should be retrievable in case a permanent national repository does become available. (0562-12 [Hoffman, Ace])

Comment: Instead, we've apparently chosen to practically randomly assign approximately 75 sites around the country to be nearly-permanent or virtually-permanent (100s of years, which only George Orwell and the NRC can call temporary) nuclear waste dumps. (0562-6 [Hoffman, Ace])

Comment: The U.S. has tens of thousands of tons of spent nuclear fuel sitting in waste storage ponds and spent fuel pools. This is a disaster in the making. It has the makings of an event of Biblical proportions. The potential consequences of the failure of one of these pools is unthinkable, and could destroy the Northern Hemisphere, if not the entire world. (0566-4 [Tocornal, John])

Comment: Do not allow the use of dangerous MOX fuel (0566-8 [Tocornal, John])

Comment: Storing spent fuel rods in a heavily populated area is social suicide! Is the NRC crazy, or just uninterested in the health and safety of the very taxpayers who feed their inoperable machine? Storing is no longer an option. (0567-1 [Taylor, Jeff])

Comment: The U.S. has many thousands upon thousands of tons of spent nuclear fuel sitting in spent fuel pools. This is a disaster, at a global scale, just waiting to happen. And for what? 19% of the power generating of the US? This is quite foolish, irrational and insane. (0569-2 [Hulstrunk, Matt])

Comment: I have NO Confidence in the continued storage of Spent Nuclear fuel because we have no Actual deep repository. (0571-1 [Young, Jane])

Comment: I am writing to support the NRC's Spent Fuel Storage Rule, and wish to say that with the NRC oversight PG&E has a very detailed and successful spent fuel management program and continues to safely store fuel via both its wet and dry cask storage systems. I am confident that layer upon layer of safeguards are in place to effectively manage and monitor the stored spent fuel. (0574-1 [French, Walter])

Comment: These fuels must be stored far away from the plants. (0580-1 [Shinker, Carol])

Comment: I think is completely to for storage as long as it is monitored and Government regulated. (0592-1 [Conrad, Chad])

Comment: We cannot pretend that leaving it where it is for 60 years is unreasonable, irrational and irresponsible and not to do everything possible to maintain if safely till it can be moved before the next quake would be the better choice. (0593-1 [Raimondi, Frank])

Comment: I'm sure that the Nuclear Regulatory Commission will continue its strong, independent oversight of commercial nuclear energy facilities--the operation of existing plants, licensing new reactors, renewing the operating licenses of existing reactors, and the management, transportation and disposal of used nuclear fuel. (0601-3 [Manfredi, Timothy])

Comment: You talk of making nuclear waste safe, having confidence in where it is buried. There is no such thing as safe nuclear waste. (0602-1 [Parks, Sheila])

Comment: Miss-Assumption Regarding Degradation Of Spent Fuel During Storage Periods. Over time, metals degrade. The more stressful the environment is, the more rapid the rate of degradation. Stress factors include thermal cycling, season following season; corrosion due to exposure to water; liquid metal embrittlement, metal creep, neutron bombardment, atmospheric

deposition corrosion, and other degradation modes upon which metallurgists could expound. These stress factors will cause some fraction of the irradiated fuel stored in casks to degrade. The degradation may cause stored waste fuel assemblies to warp and twist so that it is not possible to lift them out of an old cask and insert them into a new one. The degradation may cause fuel rod cladding to rupture, thereby causing waste fuel pellets to spill to the bottom of casks. Waste fuel pellets on the bottom of waste storage casks due to ruptured cladding may accumulate in patterns that cause criticality events. (0608-13 [Crocker, George])

Comment: Perhaps someday fuel rods can be made safer by better cladding, as preliminary studies seem to show. But "someday" isn't now. (0609-5 [Leon, Vicki])

Comment: Nationally 70,000 tons of radioactive waste is the current inventory. At the current rate each year another 2,000 tons is produced. In addition, over the past years high burn up fuel is now included in the waste inventories of nearly every reactor in the nation. (0611-4 [Shapiro, Susan])

Comment: The GEIS does not address the need reduce densely packed spent fuel pools to design basis standards. (0611-42 [Shapiro, Susan])

Comment: The GEIS does not address High Burn Up waste which takes at least seven to ten (7-10 years) to cool in the spent fuel pools, instead of the five (5) required by conventional spent fuel. Studies on High Burn Up waste are now, for the first time, being conducted by the DOE with regard to requirements for safe handling and storage of High Burn Up waste. These studies are incomplete and inconclusive, therefore not enough scientific information exists for the NRC to make an informed determination as to methodology and safety requirements necessary for storage of High Burn Up waste. What is known is that High Burn up waste is much hotter for a longer period of time, contain higher levels of radioactive isotopes than conventional spent fuel and causes embrittlement faster. (see Exhibit B: attached the Coalition to Decommission San Onofre). (0611-5 [Shapiro, Susan])

Comment: The NRC cannot rely on the current GEIS as a valid Environmental Impact Statement ("EIS") as it omits consideration of the significant waste storage issues related to High Burn Up waste. When and if scientific investigations regarding storage of high burn up waste are completed, a new or supplemental GEIS must be conducted to meet the requirements of NEPA. (0611-7 [Shapiro, Susan])

Comment: No state is a waste dump! We don't want any more high-level radioactive wastes coming "to or through" our state. The entire approach to nuclear waste endangers public and environmental health; the idea of transporting high-level, long-lived radioactive waste coming to proposed so-called "centralize interim storage" waste facilities ("parking lot dumps") is unsound. (0617-4 [Zure, Lisa])

Comment: Here is a suggestion: The government owns millions of acres of land, much of it isolated and remote, much of it on secure military facilities. There are many possibilities for temporary storage sites on such remote locations. Sites could be regional or state-specific to avoid federal issues. What is required is only a pad, not an elaborate repository. This would be designated as a temporary waste storage facility until a permanent repository is opened. (0618-6 [Johnson, Roger])

Comment: Current nuclear power plants were never designed to be long term (anything over 20 years) waste storage facilities. San Onofre especially is totally unsuitable and it cannot be turned into a long term storage facility just by changing its name. (0618-7 [Johnson, Roger])

Comment: Moving waste to remote sites has many powerful advantages: (1) Waste can be removed from tsunami and earthquake prone areas; (2) Waste can be stored far from population centers; (3) waste can be stored in secure areas away from public access; (4) waste stored in a remote temporary site would be mostly immune from terrorist threats since terrorists would not be interested in targets far from population zones. (0618-8 [Johnson, Roger])

Comment: High Burn-up Fuel: Section 2.1.1.3 provides a general description of the reactor designs (i.e., boiling water or pressurized water) and the fuel used (i.e., low burnup, high burnup, mixed oxide, etc.). The PINGP Units 1 and 2 have been using high burn-up fuel since the 1990s and it is estimated that 69 of the 98 casks that will eventually be stored on-site will contain high burnup fuel. If PINGP Units 1 and 2 are relicensed for a second renewal term, an additional 33 casks of high burnup fuel will be filled (for a total of 102 high burnup fuel casks). Page 2-7 of the draft GEIS states "For purposes of analysis in this draft GEIS, the NRC relies for impact analysis on the larger reactor lifetime amount of spent fuel discharged at low burn-ups (i.e., 1,600 MTU) unless otherwise stated in the description of environmental impact." It is further stated that this has to do with the fact the lower burn-up fuel takes up more space (i.e., more fuel, more casks, larger ISFSI). This statement ignores the potential public health impacts from the continued storage of high burn up fuel. The problems, concerns and uncertainties associated with high burnup fuel-cladding and cask component degradation, embrittlement, etc. -are well documented. The final GEIS must be revised to include a discussion of public health and environmental impacts from the high burnup fuel. (0619-1-15 [Mahowald, Philip R.])

Comment: Statements that it is feasible to safely store high-level irradiated fuel on-site, densely packed in pools of water (many perched precariously above the reactor) and in cement/steel casks (neither of which were designed for long-term storage) for 100 years provide no confidence. (0620-2 [Rivera, Evelyn])

Comment: I oppose the continued storage of spent nuclear fuel. There is no safe storage! Accidents/disasters do happen and the costs of remediation far outweigh the benefits. An example is the TEPCO's spent nuclear fuel in Fukushima, In Japan, no amount of money or existing technology can stop the ticking time bomb two years later. What folly to think we could do any better. Let their tragedy guide you in your decision-making. Please deny the continued storage of spent nuclear fuel. (0627-1 [Tognini, Dana])

Comment: Third, considering the fact that the meltdown at Chernobyl has not been safely contained and that the disaster at Fukushima-Daiichi continues to present a totally unacceptable risk to Japan, to the Pacific Ocean's ecosystem, and really to the entire world (due to radioactive fallout), any reasonably sane person would be obliged to conclude that the people running the nuclear industry and the individuals comprising the Nuclear Regulatory Commission are completely INSANE, to think that radioactive waste can be safely managed in the U.S.A. (0628-4 [Perkins, V.E.])

Comment: Spent fuel needs to be dealt with. The idea of storing spent fuel indefinitely at reactor sites obviously carries huge risk given what is currently happening at Fukushima. Cask storage would be a great start, after that store in locations that are not prone to dangerous weather situations. (0630-1 [Anonymous, Jeff])

Comment: I believe everyone agrees that nuclear spent fuel rods will be radioactive for 10's of 1000's of years. If that is the case, then how can this waste be stored "safely" above ground, either next to reactors or at some interim storage site (where "interim" is an undetermined length of time---decades, centuries??). (0633-1 [Kurz, Carol])

Comment: Spent fuel cannot be stored safely above ground in dry casks indefinitely for 100's of years--or forever. The casks do not last that long; the cost of moving the fuel to new casks would be prohibitive. The high burn up fuel being introduced doesn't last longer than 20 years in a dry cask further complicating such a scenario. (0633-3 [Kurz, Carol])

Comment: Nuclear waste is the problem. Rods have to be stored in fuel pools until they are "cool" enough for casks. Our spent fuel pools are already more crowded than Fukushima's pools. Shall we continue to create more fuel to bury? How many "holes" will we need? (0633-6 [Kurz, Carol])

Comment: There is no safe place to store waste in the interim or long-term. I am perplexed at a plan to endanger more communities. Nuclear waste has already contaminated nuclear plant sites and effected surrounding areas. (0636-2 [Bluestein, Bonnie])

Comment: We again assure you that we are dedicated to keeping the spent fuel and Greater-Than-Class-C-Waste that remains at our sites safe and secure. (0637-12 [Norton, Wayne])

Comment: Additionally, we find it inconceivable that the federal government's continued default has put the Commission and the nuclear industry in the position where Waste Confidence is only achievable with reliance on extended at reactor storage with the potential for repackaging of SNF and HLW until the Government actually meets its contractual obligation. We believe that under any test of best long-term safety and security practices and policies that one or more consolidated interim storage facilities are a necessary part of the nation's SNF/GTCC management strategy, and that all federal government entities having an official role in this matter ought to so state. (0637-4 [Norton, Wayne])

Comment: Dry cask tests have failed (e.g., at Aberdeen Proving Grounds).. But we cannot afford even one failure of a loaded dry cask. (0640-6 [Geary, B.])

Comment: Fortunately, American nuclear providers have successfully demonstrated that they can safely store nuclear waste while we wait for the federal government to enact a long-term solution. (0642-3 [Picking, Brian])

Comment: Federal policy makers must act now to develop consolidated facilities for interim storage, as recommended by the President's Blue Ribbon Commission on America's Nuclear Future and supported by a bipartisan group of Congressmen. (0642-4 [Picking, Brian])

Comment: How would you feel to see your child drink water contaminated with nuclear waste? How would you feel to know you set a plate of food before your child and it was contaminated with nuclear waste but you had nothing else to feed them even though you know they will surely get sick and possibly die. I want each one of you to think about this because you are educated people. You have been informed of how "we can safely store nuclear waste" yet each one of you read the news or watch it then turn your head. You know of the thousands of animals dead from this waste, the high rise of cancers in the areas of storage wherein your "safe nuclear waste storage facility" leaked or the nuclear plant that failed caused so much death and destruction to all people and animals, and the land is no longer safe to even walk upon. (0645-1 [Britz, Joan])

Comment: ANA supports interim storage of high-level waste and spent nuclear fuel as close to the point of generation as possible, as safely as possible. (0646-2 [Hanson, Courtney])

Comment: ANA opposes consolidated spent nuclear fuel storage facilities. Consolidated SNF storage facilities are inconsistent with the first principle of safe storage that it be as close as possible to the generation site. Consolidated storage requires nuclear waste transportation, which is costly and endangers millions of people along shipping routes. (0646-4 [Hanson, Courtney])

Comment: Consolidated storage is not disposal, but it could become de facto disposal. Consolidated storage does not "solve" SNF storage at reactors, because operating reactors will continue to generate more waste. (0646-6 [Hanson, Courtney])

Comment: What happens if the material so degrades over time as to be too dangerous or costly to handle. This is of particular concern in regard to so-called "high burn-up fuel," that has spent more time in an operating reactor core, and is thus significantly more radioactive, thermally hot and prone to actually catching fire. What manner of catastrophe exactly are the bureaucrats at the NRC so glibly bequeathing to generations far in the future? (0648-7 [Price, Scott])

Comment: Millions of your fellow citizens depend upon you doing your job of protecting our health & safety. Storage of spent nuclear fuel in earthquake prone locations is simply not logical. I implore you to remove spent fuel storage to unpopulated areas. (0654-1 [Cash, Joy])

Comment: [P]lease immediately remove all nuclear waste and nuclear power plants from any zones with seismic activity and possible tsunami threat. (0655-1 [Moffroid, Jenn])

Comment: It is a ticking time bomb to have nuclear waste stored indefinitely in high seismic zones, in densely populated areas or on the coast. San Onofre is all, so it poses a triple threat. Fukushima has already taught us that the spread of radioactivity through the ocean is something that should be prevented, period. Storing waste at San Onofre is a HUGE toxic accident just waiting to happen that would cost hundreds of billions of dollars and would likely not be containable. (0659-1 [Stanick, Kim])

Comment: This report only reinforces the growing mistrust of nuclear regulators who would play down the risk of storing nuclear waste wherever it may be presently, apparently bending to the will of the industry they are supposed to regulate. Suggesting that we will be able to rely on unproven or non-existent technology for safe storage of nuclear waste for thousands of years puts the future of our entire nation at risk. (0660-3 [Headrick, Gary])

Comment: Immediately reduce spent fuel pool density to original design standards, without exemptions[.] (0660-8 [Headrick, Gary])

Comment: Unfortunately, there are not many options and no idea is really safe everlasting forever. (0664-3 [BojeLebs, Nannette])

Comment: Plus, with our emerging understanding of high burn-up fuel WASTE with its long-term onsite storage and transporting challenges; and "the Department of Energy reports that burnups "as low as 30 GWd/MTU can present performance issues including cladding embrittlement under accident conditions as well as normal operations," DEMAND specific

research and solutions. <http://sanonofresafety.org/nuclear-waste/> and <http://sti.srs.gov/fulltext/SRNL-STI-2011-00228.pdf> (0665-4 [van Thillo, Grace])

Comment: The government must come to the aid of its population, they can no longer just gloss over or hide the ongoing dilemma that will eventually arise from continually neglecting the storage of spent fuel rods. Surely its kind of criminal to not keep the people informed as to their health and safety. (0667-1 [Mitchell, Steve])

Comment: MOVE NUCLEAR WASTE NOW!!!! (0668-4 [Gordon, Mark] [Gordon, Michelle])

Comment: All spent fuel should be put in dry cask storage on site. (0671-1 [Conley, Pam])

Comment: MOX fuel is a bad idea & should not be used or created. (0671-2 [Conley, Pam])

Comment: [R]ight now we are considering if we feel confident that nuclear waste can be handled at our reactor sites. The answer is yes. It has been done for decades and we have the technical expertise to handle our nuclear used fuel. (0674-4 [Lang, Amanda])

Comment: STARS has participated in the development of Reference 2 and endorses the comments contained therein. In particular, STARS agrees with NEI's responses to the four specific questions the NRC posed in the Federal Register Notice. Furthermore, STARS endorses the industry position that dry storage of spent fuel is a safe means for long term storage. [Letter from the Nuclear Energy Institute with Comments on Waste Confidence, to be submitted on December 20, 2013] (0675-1 [Bauer, Scott])

Comment: The State of New York recommends that before the NRC takes any further action on the proposed rule and the draft GEIS, that the Commissioners perform a transparent study to examine the durability of spent fuel assemblies (including high burnup fuel) and establish the precise lifetime and replacement cycle of ISFSI facilities, spent fuel canisters and casks, and dry transfer system buildings. (0681-12 [Peterson, Alyse])

Comment: It is not adequate to fabricate a lifetime for critical spent fuel storage systems. Most especially for the long-term storage and indefinite storage timeframes, the safety and security of spent nuclear fuel relies heavily on the storage systems containing this waste on site. The NRC is relying solely on site owners to detect the degradation of spent fuel pools, casks, and ISFSIs. Furthermore, it is irresponsible to wait for the degradation of in-use spent fuel storage systems to determine a replacement cycle. (0681-2 [Peterson, Alyse])

Comment: As presently licensed and configured, many of the Independent Spent Fuel Storage Installation facilities at the nuclear plants in New York do not have sufficient capacity to hold all the spent nuclear waste that has been generated and will be generated by those plants during extended operating license terms. That means that, absent a change in policy, at the end of a plant's commercial operation, spent nuclear fuel will remain in the plant's spent fuel pool -- and will remain in a dense storage configuration in those pools. Those ISFSIs have been designed to house the excess spent nuclear fuel that cannot fit into (full and densely-packed) fuel pools on site. Reducing the inventory of spent nuclear fuel in the densely-packed spent fuel pools will require the construction of additional independent spent fuel storage installations along with the purchase of additional dry cask storage. (0681-4 [Peterson, Alyse])

Comment: I am in complete support of the NRC's Spent Fuel Storage Rule and have witnessed firsthand that with NRC oversight PG&E has a very detailed and successful spent

fuel management program who continues to safely store fuel via both its wet and dry cask storage systems. Through my personal tour of the facility, I am confident that numerous safeguards are in place to manage and monitor the stored spent fuel. (0682-2 [Adam, Peter])

Comment: I am in complete support of the NRC's Spent Fuel Storage Rule and have witnessed firsthand that with NRC oversight PG&E has a very detailed and successful spent fuel management program who continues to safely store fuel via both its wet and dry cask storage systems. Through my personal tour of the facility as Chief of Staff, I am confident that numerous safeguards are in place to manage and monitor the stored spent fuel. (0683-2 [Nelson, Bob])

Comment: There is no way to guarantee 100% safety when using this technology, and when it comes to materials that remain deadly dangerous for tens of thousands of years, longer than all of human history, anything less than 100% safety cannot be considered safe. We humans are not infallible, and neither is anything we produce. This means that nuclear plants cannot, simply cannot be guaranteed to be safe. And when it comes to nuclear materials, anything less than 100% safety is just not good enough. (0687-3 [Wilansky, Laura])

Comment: Furthermore, the fuel pools have an excess of rods and are severely overloaded. The failure to find a safe fuel depository is putting our entire nation at risk a la Japan and Fukushima. (0690-3 [Eisman, Val])

Comment: There is no public or scientifically demonstrated or public confidence for "temporary" or "interim" storage at reactor or away from reactor centralized storage sites that can isolate more and more nuclear waste for time frames of extending out to one hundred years and beyond, given that after more than a half century of search a likely high-level radioactive waste repository has not been established. (0691-8 [Gunter, Paul])

Comment: •An enormous backlog of spent fuel being stored on-site at nuclear reactors temporarily because there is nowhere else for it to go. In spent fuel pools, the assemblies are currently extremely overcrowded—most pools handling 3 or 4 times the amount of spent fuel the pool was originally designed for. Eventually reactor operators are forced to store spent fuel on site in dry casks, when there is no more capacity in the pools. •When reactors were licensed, no one envisioned—not the public, elected officials or reactor operators—that nuclear waste would be stored on-site for decades into the future. (0693-1-5 [Warren, Barbara])

Comment: •NRC decided that all nuclear fuel used at reactors is similar and therefore NRC did not discuss the significant differences in fuel as part of the GEIS. High burnup fuel is more radioactive and hotter, requiring a long time period in a spent fuel pool, approximately twenty years. This obviously affects the ability to transfer the material to dry casks. (0693-3-13 [Warren, Barbara])

Comment: NRC will not approve dry cask storage beyond 20 years and has not approved a transport cask for high burnup fuel. The Blue Ribbon Commission raised concerns about high burnup fuel and the need to monitor dry casks for their performance and degradation. (0693-3-14 [Warren, Barbara])

Comment: MOX fuel includes plutonium in the fuel mix, a very different fuel that NRC also did not thoroughly evaluate. (0693-3-15 [Warren, Barbara])

Comment: •Original licensing decisions included a design basis for the spent fuel pool. •Spent fuel pools in the US currently contain 3- 4 times the amount of spent fuel the pool was designed for. (0693-3-4 [Warren, Barbara])

Comment: Reactor licensees, including TVA, continue to develop and successfully use onsite SNF storage capacity in the form of SFPs and dry cask storage in a safe and environmentally sound fashion. Substantial technical understanding and decades of experience demonstrate the technical feasibility of safe storage of spent fuel in SFPs and in dry casks, based on their robust physical integrity over long periods of time. (0694-1-6 [Shea, Joseph])

Comment: The storage of SNF in any combination of SFPs or dry casks will continue as a licensed activity under regulatory controls and oversight. Regulatory oversight continues to enhance the safety of both wet and dry spent fuel storage as concerns and information evolve over time. For example, events such as the September 11, 2001 terrorist attacks and the March 2011 Fukushima Dai-ichi accident have led to numerous security and safety enhancements. Safe and environmentally-sound spent fuel storage would continue, if necessary, beyond 60 years after the end of the reactor's licensed operating life under an NRC-approved aging management program to ensure that monitoring and maintenance are adequately performed. The DGEIS assumes that, at an appropriate time, ISFSI structures, systems, and components ("SSCs") would be replaced as part of an approved aging management program. Continued experience with storing spent fuel will guide and inform aging management plans. (0694-1-7 [Shea, Joseph])

Comment: TVA has implemented the additional security measures applicable to SFPs. These activities provide additional assurances of the safety of continued storage of spent fuel. (0694-2-23 [Shea, Joseph])

Comment: [T]he WBN ISFSI will be under institutional control for the duration of SNF storage at WBN. Additionally, as demonstrated by its experience with its Browns Ferry and Sequoyah nuclear plants, TVA will demonstrate that the future WBN ISFSI will comply with relevant requirements. (0694-2-26 [Shea, Joseph])

Comment: TVA also agrees with NEI's comments that the NRC should add further discussion to the GEIS of the lessons learned from the Fukushima event regarding the robustness of SFP and ISFSI storage, and that this operating experience is significant evidence of the substantial safety assurance provided by SFPs and dry cask storage. (0694-2-28 [Shea, Joseph])

Comment: These regulatory requirements and the NRC's continued oversight and evolution of the requirements in response to new information or developments provide additional assurance that spent fuel will be stored and managed in a safe and secure manner. (0694-3-13 [Shea, Joseph])

Comment: •Reactor licensees, including Entergy, continue to develop and successfully use onsite SNF storage capacity in the form of SFPs and dry cask storage in a safe and environmentally sound fashion. Substantial technical understanding and decades of experience demonstrate the technical feasibility of safe storage of spent fuel in SFPs and in dry casks, based on their robust physical integrity over long periods of time.⁷ [footnote 7 text: See Proposed Rule, 78 Fed. Reg. at 56,799.] (0697-1-7 [Bessette, Paul] [Kuyler, Raphael])

Comment: Entergy also agrees with NEI's comments that the NRC should add further discussion to the GEIS of the lessons learned from the Fukushima event regarding the

robustness of SFP and ISFSI storage, and that this operating experience is significant evidence of the substantial safety assurance provided by SFPs and dry cask storage.⁷² [footnote 72 text: NEI Comments.] (0697-2-8 [Bessette, Paul] [Kuyler, Raphael])

Comment: One reason I do not share your confidence is because of what I learned from Commonwealth Edison/Exelon whistleblower Oscar Shirani, about the quality assurance (QA) violations involving Holtec casks. A "Summary of Oscar Shirani's Allegations of Quality Assurance Violations Against Holtec Storage/Transport Casks" is pasted in below. This Summary is also posted online at:

<http://www.nirs.org/radwaste//atreactorstorage/shiranialeg04.htm>. Although dated July 2004, to the best of my knowledge, NRC has never taken action on Oscar Shirani's revelations. In fact, quite to the contrary, NRC instead rubber-stamped the Private Fuel Storage, LLC construction and operating license in 2005-2006. Targeted at the Skull Valley Goshute Indian Reservation, a very serious environmental justice violation, PFS LLC would have deployed a whopping 4,000 Holtec casks onto the roads, rails, and/or waterways -- more shipments of high-level radioactive waste than have yet been carried out in the U.S., since the beginning of the Atomic Age in 1945. The 4,000 Holtecs that would have been de facto permanently parked on Skull Valley Goshute land would have been more than twice as many dry casks as are currently parked at U.S. atomic reactor sites presently (some 1,700). That is how flippantly NRC took Oscar Shirani's dire warnings. Fortunately, PFS LLC pulled the plug a year ago today, and will not be happening, despite NRC's ready rubber-stamp. (0698-3 [Kamps, Kevin])

Comment: Oscar Shirani was made to pay dearly for his integrity, and outspoken refusal to simply shut up about the Holtec QA violations. He endeavored to get Exelon to place a Stop Work Order on the manufacture of Holtecs. Instead, Exelon subjected him to harrassment by his own supervisors, and eventually ran him out of the company, and Exelon, and the U.S. nuclear power industry, blacklisted him for the rest of his life. Oscar Shirani alleged that he never signed off on the audit form granting Holtecs a clean bill of health. Oscar Shirani alleged that his signature on that audit report was forged. Neither the U.S. NRC nor the U.S. Department of Labor provided any support, relief, or assistance to Oscar Shirani, abandoning him to his fate, to both agencies' eternal shame. I attended, and bore witness at, a two-day NRC Office of Inspector General interview with Oscar Shirani, regarding his whistleblowing allegations concerning the Holtec casks. OIG's final report did not challenge Oscar Shirani's observations or conclusions, but it did find, incredibly, that NRC had done nothing wrong in the matter, and closed the case. Thus, no action was taken by NRC's OIG, nor by NRC itself, to defend or assist Oscar Shirani as a safety conscious whistleblower, nor to investigate the merits of his allegations against the Holtec casks, or take any safety enforcement action whatsoever. (0698-4 [Kamps, Kevin])

Comment: Oscar Shirani's QA allegations against the Holtec casks are very safety significant. Oscar Shirani questioned the structural integrity of Holtecs sitting still, going zero miles per hour, in on-site/at-reactor storage. But NRC has certified Holtecs for transport. The destructive forces they would face, traveling 60 mph, or even faster, down the rail lines, and potentially subjected to severe, high-speed crashes; long-duration, high-temperature fires; prolonged and/or deep underwater submersions; and perhaps even terrorist attacks; exacerbates the risks of Holtec QA violations even more. The significance of Oscar Shirani's QA whistleblowing against the Holtecs is even more significant, considering how widely deployed they are. On November 20, 2013, Josh Jarrell, R&D Staff, Used Fuel Systems, Nuclear Fuels Storage and Transportation, Planning Project (NFST), Oak Ridge National Laboratory, presented at the U.S. Nuclear Waste Technical Review Board meeting held in Washington, D.C. During his presentation, entitled "Integrating Standardization into the Nuclear Waste Management System," Dr. Jarrell

documented that Holtec has supplied a full 46% of the dry cask storage market in the U.S. up to the current point. Thus, the risks inherent in the QA violations revealed by Oscar Shirani are widespread across the U.S., in dry cask storage ISFSIs located throughout the country. They will increase in significance as Holtecs are transported, by barge on waterways, by heavy haul trucks on roads, or by trains on the railways, during shipments to centralized interim storage facilities, or final repositories. (0698-5 [Kamps, Kevin])

Comment: Nuclear, nuclear, nuclear waste Put it in casks There's no other place The spent fuel pools Have run out of space For the nuclear All the nuclear For the nuclear waste[.] (0699-5 [Lee, Michel])

Comment: Consolidated storage of nuclear fuel, which the Blue Ribbon Commission on America's Nuclear Future has officially recommended, would mean taking nuclear waste from the country's reactor sites to a temporary storage facility and then moving it again, decades later, to a more permanent facility. Consolidated storage is creating a bigger problem, rather than moving toward a solution. Transporting waste away from nuclear reactor sites to a temporary facility would put dangerous waste on our roads, rails and waterways and expose more communities to radioactive waste. Meanwhile, the companies producing the waste would be off the hook for managing it and the new temporary storage sites would require additional funds for security measures. High level nuclear waste should only be moved once and it should be kept as near as possible to the site that produced it. (0700-3 [Women's Action for New Direction, Georgia])

Comment: NRC's Waste Confidence policy assumes that all nuclear waste is the same, but new forms of waste, such as Mixed Oxide Plutonium fuel, slated to be produced as the Savannah River Site in South Carolina are more radioactive and dangerous as well as more difficult to transport and store. (0700-4 [Women's Action for New Direction, Georgia])

Comment: The proposed DGEIS and rule appear to countenance the stranding or storage of SNF at or near plant sites for up to 150 years or more, and contain no effective provisions to ultimately ensure the safe and proper disposal of SNF. The Commission's rule also contains a questionable premise -- that long-term SNF storage at current sites or perhaps some centralized sites (for 150 or more years) is safe and feasible merely on the basis of the limited experience involving SNF storage to date, particularly at ISFSI's, and at fewer locations with lower quantities of SNF, compared to what would exist over such a long time span. (0704-6 [Callen, Ronald C.] [Keskey, Donald L.]

Comment: There are several problems posed by high-burnup fuel and NRC must provide a detailed environmental analysis. The National Academy of Engineering of the National Academy of Sciences has expressed concern regarding the viability of long term storage and management of high-burnup fuel. The Academy noted: "the technical basis for the spent fuel currently being discharged (high utilization, burnup fuels) is not well established" the NRC has not yet granted a license for the transport of the higher burnup fuels that are now commonly discharged from reactors. In addition, spent fuel that may have degraded after extended storage may present new obstacles to safe transport.⁴² [footnote 42 text: See National Academy of Engineering, *Managing Nuclear Waste*, Summer 2012, pp 21, 31. <http://www.nae.edu/File.aspx?id=60739>.] Further, Mr. Robert Alvarez, at the Institute for Policy Studies, has authored a recent report in which he criticized the NRC for taking a "leap of faith" with respect to the safe operation of reactors and the storage and disposal of spent nuclear fuel" with higher burnup fuel.⁴³ [footnote 43 text: See *Reducing the Hazards of High-Level Radioactive Waste in Southern California: Storage of Spent Power Reactor Fuel at the San*

Onofre Nuclear Station, Robert Alvarez, (June 25, 2013) at 12. Commissioned by Friends of the Earth; http://libcloud.s3.amazonaws.com/93/22/3/3024/SONGS_Spent_Fuel_FINAL.pdf.] With the higher burn rates, Mr. Alvarez notes nuclear fuel rods undergo significant changes meriting more study and treatment under this Draft EIS. Such changes include: increasing oxidation, corrosion and hydriding (i.e., hydrogen absorption) of the fuel cladding; oxidation reduces cladding thickness, while hydrogen (H₂) absorption of the cladding to form a hydrogen-based rust of the zirconium metal from the gas pressure inside the rod can cause the cladding to become brittle and fail; higher internal rod gas pressure between the pellets and the inner wall of the cladding leading to higher fission gas release; pressure increases are typically two to three times greater; elongation or thinning of the cladding from increased internal fission gas pressure; structural damage and failure of the cladding caused by hoop (circumferential) stress; increased debris in the reactor vessel, damaging and rupturing fuel rods; cladding wear and failure from prolonged rubbing of fuel rods against grids that hold them in the assembly as the reactor operates (grid to rod fretting); a significant increase in radioactivity and decay heat in the spent fuel; a potentially larger number of damaged spent fuel assemblies stored in pools; upgraded pool storage with respect to heat removal and pool cleaning; and requiring as much as 150 years of surface storage before final disposal. *Id.* (citations found in report and omitted here). (0706-3-18 [Fettus, Geoffrey])

Comment: In short, there is significant evidence that with higher burn-ups nuclear fuel cladding may be inadequate as a primary barrier to prevent escape of radioactivity, especially during dry storage, and therefore the NRC needs to include these problems specific to high burnup fuel in the impact analysis in the draft GEIS. (0706-3-19 [Fettus, Geoffrey])

Comment: Page 2-14. Assumption of ability to move and no dual purpose dry casks have been certified. NRDC Comment[.] With the acknowledged absence of licensed dual purpose casks or canisters and no operational experience with the moving and management challenges raised by high burnup SNF, we suggest the agency has significant research for the final GEIS to provide any meaningful support for an impacts analysis. (0706-3-21 [Fettus, Geoffrey])

Comment: Page 2-18. "In January 2013, DOE published its response to the Blue Ribbon Commission recommendations titled, "Strategy for the Management and Disposal of Used Nuclear Fuel and High-Level Radioactive Waste" (DOE 2013). This strategy implements a program over the next 10 years that, with congressional authorization, will: • site, design, construct, license, and begin operation of a pilot interim storage facility by 2021 with an initial focus on accepting spent fuel from shutdown reactor sites; • advance toward the siting and licensing of a larger interim storage facility to be available by 2025 with sufficient capacity to provide flexibility in the waste-management system and allow for acceptance of enough spent fuel to reduce expected government liabilities; • make demonstrable progress on the siting and characterization of repository sites to facilitate the availability of a geologic repository by 2048. The Federal government's support for interim storage supports the NRC's decision to consider this type of facility as one of the reasonably foreseeable interim solutions for spent fuel storage pending ultimate disposal at a repository." NRDC Comment[.] The history of the nuclear waste repository program is a series of failures and demonstrates, as the DC Circuit found, there should be no assurance there will be sufficient mined geologic repository capacity.⁴⁴ [footnote 44 text: See Appendix A of these comments on the failure of the efforts to manage and dispose of nuclear waste and *How Safe is Yucca Mountain*, Remarks of Thomas B. Cochran, Senior Scientist, NRDC, At the Symposium: Uncertainty in Long-Term Planning- Nuclear Waste Management, a Case Study, Vanderbilt University, January 7, 2008; http://docs.nrdc.org/nuclear/files/nuc_08010701A.pdf.] NRDC further suggests the failure of efforts to site interim storage facilities have been at least as problematic as the failed efforts to

develop a final repository solution. See NRDC's Testimony on S. 2140, the current proposed legislation before the United States Senate Committee on Energy & Natural Resources (<http://www.nrdc.org/nuclear/gfettus-13073001.asp>). In that testimony, we noted current legislation pending before a Senate Committee (S.1240) risks sending the nation down another dead-end road by severing the link between storage and disposal and thereby allowing for a storage site to become a de facto repository. NRDC Testimony at 3. (0706-3-22 [Fettus, Geoffrey])

Comment: In the U.S. and elsewhere, the trend is to increase the burnup of fuel assemblies; this is done by extending the length of time the assemblies spend producing energy in the reactor core and/or by increasing the power levels of nuclear power plants ("NPP"). Some power uprates—"the process of increasing the licensed power level at a commercial [NPP]"⁴ [footnote 4 text: NRC, "Review Standard for Extended Power Uprates," RS-001, Revision 0, December 2003, Background.]—in the U.S. have been substantial; in 2006, the NRC approved a 20 percent power uprate for Vermont Yankee Nuclear Power Station. (0706-5-10 [Fettus, Geoffrey])

Comment: In 1999, burnup levels for spent pressurized water reactor ("PWR") fuel and spent boiling water reactor ("BWR") fuel were approximately 45 gigawatt-days thermal per metric ton⁵ [footnote 5 text: 1000 kilograms] of enriched uranium ("GW·d/t U") and 37 GW·d/t U, respectively; in the U.S., by 2021, "[b]urnup levels for spent PWR fuel are anticipated to rise to ~55 GW·d/t U [and] burnup levels for spent BWR fuel will likely increase to over 40 GW·d/t U."⁶ [footnote 6 text: IAEA, "Impact of High Burnup Uranium Oxide and Mixed Uranium-Plutonium Oxide Water Reactor Fuel on Spent Fuel Management," No. NF-T-3.8, 2011, p. 9.] (0706-5-11 [Fettus, Geoffrey])

Comment: When high burnup (and other) fuel rods are discharged from the reactor core and loaded into the SFP, the fuel cladding can have local zirconium dioxide (ZrO₂) "oxide" layers that are up to 100 microns ("µm") thick (or greater);⁷ [footnote 7 text: IAEA, "Impact of High Burnup Uranium Oxide and Mixed Uranium-Plutonium Oxide Water Reactor Fuel on Spent Fuel Management," No. NF-T-3.8, 2011, p. 30.] there can also be local crud layers on top of the oxide layers, which can sometimes also be up to 100 µm thick.⁸ [footnote 8 text: IAEA, "Impact of High Burnup Uranium Oxide and Mixed Uranium-Plutonium Oxide Water Reactor Fuel on Spent Fuel Management," No. NF-T-3.8, 2011, p. 29.] (0706-5-12 [Fettus, Geoffrey])

Comment: Local heavy oxide and/or crud layers would partly impede the local steam or air "coolant" flow through the spent fuel assemblies in a SFP boil-off accident or complete SFP LOCA, respectively, in at least the following aspects: 1) the amount of either steam or air "coolant" in the vicinity of the spent fuel cladding that had local heavy oxide and/or crud layers may be substantially less than if the cladding were clean; 2) the amount of either steam or air coolant flow past the vicinity of the spent fuel cladding that had local heavy crud and oxide layers may be substantially less than the flow past clean cladding; 3) if there were rapid oxidation, local growth of oxide layer thicknesses and increased degradation of the fuel cladding would further obstruct either the steam or air "coolant" flow. (0706-5-13 [Fettus, Geoffrey])

Comment: Partly impeded local cooling, caused by local heavy oxide and/or crud layers, could cause local fuel-cladding temperatures to increase up the point at which zirconium would begin to rapidly chemically react with steam or air—at approximately 1000°C (1832°F) or 900°C (1652°F),⁹ [footnote 9 text: Allan S. Benjamin et al., Sandia Laboratories, "Spent Fuel Heatup Following Loss of Water During Storage," NUREG/CR-0649, March 1979, p. 47.] respectively. In a SFP accident, partly impeded local cooling, caused by local heavy oxide and/or crud layers, could decrease the time to the ignition of zirconium in either steam or air. (0706-5-14 [Fettus, Geoffrey])

Comment: As stated above, when high burnup (and other) fuel rods are discharged from the reactor core and loaded into the SFP, the fuel cladding can have local zirconium dioxide (ZrO₂) "oxide" layers that are up to 100 µm thick (or greater); there can also be local crud layers on top of the oxide layers, which can sometimes also be up to 100 µm thick. (And medium to high burnup fuel cladding typically has a "hydrogen concentration in the range of 100-1000 wppm [weight parts per million];" "[z]irconium-based alloys, in general, have a strong affinity for oxygen, nitrogen, and hydrogen..."¹⁰ [footnote 10 text: K. Natesan, W.K. Soppet, Argonne National Laboratory, "Hydrogen Effects on Air Oxidation of Zirlo Alloy," NUREG/CR-6851, October 2004, (ADAMS Accession No. ML042870061), pp. iii, 3.]) (0706-5-16 [Fettus, Geoffrey])

Comment: High burnup fuel rods have thinner cladding, because a higher quantity of their zirconium content has oxidized during the operation of the reactor.¹¹ [footnote 11 text: IAEA, "Impact of High Burnup Uranium Oxide and Mixed Uranium-Plutonium Oxide Water Reactor Fuel on Spent Fuel Management," No. NF-T-3.8, 2011, pp. 29, 50.] The thermal conductivity of oxide layers and crud layers is low—especially crud layers. (It is noteworthy that an EPRI report states that "[i]n some instances, BWR rods have been known to dislodge so much crud when moved around in [SFPs] that diminished pool clarity occurred."¹² [footnote 12 text: Electric Power Research Institute, "Technical Bases for Extended Dry Storage of Spent Nuclear Fuel," 1003416, December 2002, p. 3-8.] Tenacious crud would not become dislodged from fuel rods in this fashion.) (0706-5-17 [Fettus, Geoffrey])

Comment: And, as the burnup of fuel rods increases, there is an increase in their total *internal* thermal resistance. There is greater internal thermal resistance in high burnup fuel, because: 1) the thermal conductivity of the fuel pellets degrades, partly due to cracking and 2) there is an increased release of fission gas that degrades the thermal conductivity of the gap between the fuel pellet and the cladding.¹³ [footnote 13 text: NRC, "Letter to GE-Hitachi Nuclear Energy Americas (GEH) Regarding Nuclear Fuel Thermal Conductivity Degradation Evaluation," March 23, 2012, (ADAMS Accession No. ML120680571), Enclosure 2, "NRC Staff Assessment of General Electric-Hitachi Nuclear Energy and Global Nuclear Fuel—Americas Codes and Methods with Regard to Thermal Conductivity Degradation," March 23, 2012, (ADAMS Accession No. ML120750001), pp. 1-2.] (A 2011 IAEA report states that "[t]he fission gas released from the fuel pellets to the fuel cladding gap will increase *as much as ten-fold* for high burnup fuel over lower burnup fuel"¹⁴ [footnote 14 text: IAEA, "Impact of High Burnup Uranium Oxide and Mixed Uranium-Plutonium Oxide Water Reactor Fuel on Spent Fuel Management," No. NF-T-3.8, 2011, p. 50.][emphasis added].) A 2012 NRC document states that "[t]he gap [thermal] resistance can "increase because of pellet densification (which increases the gap size) and/or degradation of the helium-gap gas conductivity by the addition of noble fission gases (xenon and krypton) released from the fuel pellets."¹⁵ [footnote 15 text: NRC, "Letter to GE-Hitachi Nuclear Energy Americas (GEH) Regarding Nuclear Fuel Thermal Conductivity Degradation Evaluation," March 23, 2012, (ADAMS Accession No. ML120680571), Enclosure 2, "NRC Staff Assessment of General Electric-Hitachi Nuclear Energy and Global Nuclear Fuel—Americas Codes and Methods with Regard to Thermal Conductivity Degradation," March 23, 2012, (ADAMS Accession No. ML120750001), pp. 1-2.] (0706-5-18 [Fettus, Geoffrey])

Comment: It is noteworthy that the fuel-cladding gap size does not necessarily increase in high burnup fuel; an October 2003 paper states that "[i]nner surface cladding oxidation and subsequent mechanical bonding between the fuel pellet and the cladding are well-known phenomena of high burnup and high duty fuels."¹⁶ [footnote 16 text: Sven Van den Berghe *et al.*, "Observation of a Pellet-Cladding Bonding Layer in High Power Fuel," presented at "Advanced

Fuel Pellet Materials and Designs for Water Cooled Reactors: Technical Committee Meeting," 20–24 October 2003, p. 307.] (0706-5-19 [Fettus, Geoffrey])

Comment: During the operation of a reactor, the thermal resistance of crud and/or oxide layers on cladding increases the internal pressure of fuel rods. Regarding this phenomenon, a 2003 NRC document states: Clad[ding] oxidation can lead to significantly increased fuel rod internal pressures. ... In addition to oxidation causing increases in rod internal pressures, crud deposition has a similar effect since crud is a poor conductor of heat. Keeping crud deposition to a minimum also reduces the impact on rod internal pressures.¹⁷ [footnote 17 text: NRC, "Safety Evaluation by the Office of Nuclear Regulation, Topical Report WCAP-15604-NP. REV. 1, 'Limited Scope High Burnup Lead Test Assemblies' Westinghouse Owners Group, Project No. 694," 2003, (ADAMS Accession No. ML070740225 (See Section A), p. 4.) (0706-5-20 [Fettus, Geoffrey])

Comment: During the operation of a reactor, the fuel-cladding gap of high burnup fuel rods may reopen "when [the] internal pressure in the [fuel] rod exceeds [the] reactor coolant system pressure."¹⁸ [footnote 18 text: NRC, "NRC Information Notice 98-29: Predicted Increase in Fuel Rod Cladding Oxidation," August 3, 98, (ADAMS Accession No. ML003730714), p.1.] When the fuel-cladding gap reopens there is also thermal resistance caused by the extremely low thermal conductivity of the gases in the fuel-cladding gap. Regarding this phenomenon, the 2012 NRC document states: Should the gap [between the fuel pellet and the cladding] reopen, the increased thermal resistance will result in higher fuel pellet temperatures, resulting in higher fission gas release. The increased fission gas release will degrade gap conductivity while increasing the rod internal pressure, thus increasing pellet temperature and widening the gas gap further. The onset of gap reopening results in a runaway process of increasing gap opening until cladding failure.¹⁹ [footnote 19 text: NRC, "Letter to GE-Hitachi Nuclear Energy Americas (GEH) Regarding Nuclear Fuel Thermal Conductivity Degradation Evaluation," March 23, 2012, (ADAMS Accession No. ML120680571), Enclosure 2, "NRC Staff Assessment of General Electric-Hitachi Nuclear Energy and Global Nuclear Fuel—Americas Codes and Methods with Regard to Thermal Conductivity Degradation," March 23, 2012, (ADAMS Accession No. ML120750001), p. 8.] (0706-5-21 [Fettus, Geoffrey])

Comment: Regarding the heating of the fuel cladding in a complete SFP LOCA, a 1979 Sandia Laboratories report states that "[v]ariations in temperature from rod to rod in an assembly might occur as a result of variations in decay heat or differences in the thickness of the oxide coating, but these factors are difficult to predict and have not been accounted for" ²⁰ [footnote 20 text: Allan S. Benjamin *et al.*, Sandia Laboratories, "Spent Fuel Heatup Following Loss of Water During Storage," NUREG/CR-0649, SAND77-1371, March 1979, (ADAMS Accession No. ML120960637), p. 40.][emphasis added]. And, discussing research and development priorities regarding the dry storage of spent fuel assemblies, which would also pertain to SFP accidents, a 2012 Pacific Northwest National Laboratory ("PNNL") report states that "[d]etermining actual clad emissivities²¹ [footnote 21 text: Emissivity is "[t]he ratio of the power per unit area radiated by a surface to that radiated by a black body at the same temperature. A black body therefore has an emissivity of 1 and a perfect reflector has an emissivity of 0." A black body is "[a] hypothetical body that absorbs all the radiation falling on it. ...While a true black body is an imaginary concept, a small hole in the wall of an enclosure at uniform temperature is the nearest approach that can be made to it in practice." See Alan Isaacs *et al.*, "A Concise Dictionary of Physics," Oxford Reference, 1990, pp. 22, 88.] as a function of oxide and crud layer thicknesses under dry storage conditions is necessary to calculate actual temperature profiles..."²² [footnote 22 text: Brady Hanson *et al.*, "Gap Analysis to Support Extended Storage of Used Nuclear Fuel." PNNL-20509, Rev. 0, Pacific Northwest National Laboratory, January 31, 2012, p. 88.] The PNNL report observes that this would be a "difficult and expensive task."²³ [footnote 23 text: *Id.*] (0706-5-22 [Fettus, Geoffrey])

Comment: In a boil-off accident, the thermal resistance of crud (corrosion products) and/or oxide layers on fuel-cladding would slightly decrease the radial heat losses of fuel assemblies to the external environment—slightly impeding the local cooling of the fuel assemblies. The thermal resistance of crud and/or oxide layers would primarily serve to decrease radial heat losses at the outer perimeters of the fuel assemblies; this effect would not be significant because the heat flux (rate of heat transfer from the fuel rods) would be relatively low. In fact, a 1979 Sandia Laboratories report states that "[a] calculation was made to determine whether a 100 micron [crud] Fe₂O₃ coating on the BWR fuel pins would affect the heatup of these pins during a pool drainage accident, and it was found that the overall effect on the fuel pin temperature was less than one degree."²⁴ [footnote 24 text: Allan S. Benjamin *et al.*, Sandia Laboratories, "Spent Fuel Heatup Following Loss of Water During Storage," NUREG/CR-0649, SAND77-1371, March 1979, (ADAMS Accession No. ML120960637), p. 78.] (0706-5-23 [Fettus, Geoffrey])

Comment: It is doubtful that the Sandia Laboratories calculation used the lowest possible value that the thermal conductivity of crud layers can have; the morphology of crud plays more of a role than its chemical content does in determining the degree of its thermal resistance²⁵ [footnote 25 text: NRC, Advisory Committee on Reactor Safeguards, Reactor Fuels Subcommittee Meeting Transcript, September 30, 2003, (ADAMS Accession No. ML032940295), p. 240.] (this was not necessarily known in 1979). It is also doubtful that a calculation done in 1979 or earlier would have accurately modeled (or attempted to model) the internal thermal resistance of spent fuel rods. (In fact, today, in 2013, the computer safety model the NRC uses for SFP accident analyses—MELCOR—does not model the gap between the fuel cladding and fuel pellets. MELCOR also replaces the thermo-physical properties of UO₂ fuel with properties of compacted magnesium oxide (MgO). In SFP-fire experiments conducted at SNL—used to benchmark MELCOR—zirconium cladding is packed with solid magnesium oxide filler.²⁶ [footnote 26 text: Jeffrey Cardoni, Sandia National Laboratories, "MELCOR Model for an Experimental 17x17 Spent Fuel PWR Assembly," SAND2010-8249, November 2010, p. 4.]) Furthermore, the burnups of spent fuel assemblies were far lower in 1979 than they are today. Nonetheless, the Sandia Laboratories calculation results are instructive: the overall effect of the degraded thermal conductivity of high burnup fuel rods in a SFP accident would be slight (unless such fuel rods were involved in a criticality accident²⁷ [footnote 27 text: Fission—the splitting of atoms in the nuclear fuel—occurs in a criticality accident.]). (0706-5-24 [Fettus, Geoffrey])

Comment: Contention 1 - Phenomena Regarding How High Burnup Fuel and High Burnup Fuel Cladding Would Affect the Progression of a SFP Accident Are Not Considered in NUREG-2157, Appendix F, "Spent Fuel Pool Fires." 5. SFPs store fuel assemblies (essentially bundles of fuel rods, comprised of zirconium alloy cladding sheathing uranium dioxide (UO₂) fuel pellets) after they are discharged from the reactor core. If there were a loss of SFP cooling, the water in the pool would be heated by the fuel assemblies' decay heat (heat generated by the radioactive decay of the fuel's fission products) until it reached the boiling point; then the water would boil away, uncovering the fuel assemblies. (0706-5-8 [Fettus, Geoffrey])

Comment: Fuel assemblies that had a higher burnup² [footnote 2 text: Burnup is the thermal energy produced per unit mass of enriched-uranium in the fuel.]—whose enriched-uranium fuel had been converted into energy to a greater extent in the reactor core—would produce greater quantities of decay heat; "[i]n general, the higher the burnup, the higher the heat load generated and the more heat rejection [cooling] capability is required."³ [footnote 3 text: IAEA, "Impact of High Burnup Uranium Oxide and Mixed Uranium-Plutonium Oxide Water Reactor Fuel on Spent Fuel Management," No. NF-T-3.8, 2011, p. 18.] (0706-5-9 [Fettus, Geoffrey])

Comment: The NRC should take immediate action to reduce the fuel assemblies in spent fuel pools, as well as analyzing the deficiencies of current dry cask storage. (0707-5 [Werner, Shahla M.])

Comment: High Burn-up[:] How can the NRC GEIS have confidence in extended storage of high burn-up (>45 GWd/MTU) highly radioactive spent nuclear fuel when the NRC currently will not approve dry cask storage beyond 20 years^{xiv} [footnote xiv text: *Status of NRC Research on High Burnup Fuel Issues* (Slide 7) Dr. Robert E. Einziger <http://1.usa.gov/15E8gX5>.] for high burn-up waste and has not approved transportation casks^{xv} [footnote xv text: NRC Interim Staff Guidance 11, rev 3, *Cladding Considerations for the Transportation and Storage of Spent Fuel* <http://www.nrc.gov/reading-rm/doc-collections/isg/isg-11R3.pdf>.] for high burnup waste? The fuel is over twice as radioactive as lower burnup fuel and is hotter, requiring up to a minimum 20 years cooling in spent fuel pools.^{xvi} [footnote xvi text: Appendix A to CoC No.1029, Technical Specifications for the Advanced Nuhoms® System (Table 2.12) <http://pbadupws.nrc.gov/docs/ML0515/ML051520131.pdf>.] The fuel is proving unstable in storage and there are no current solutions to these problems. The NRC GEIS^{xvii} [footnote xvii text: NRC Draft Waste Confidence Generic Environmental Impact Statement NUREG-2157, September 2013 <http://pbadupws.nrc.gov/docs/ML1322/ML1322A106.pdf>.] even quotes one study (Pages B-13 and B-23) regarding the problems of fuel cladding embrittlement with high burn-up waste, yet ignores the potential consequences of this - shattering of the embrittled, fragile fuel cladding, which could release radiation into the environment. (GEIS Pages B-12 and B-23)[.] (0711-10 [Olson, Mary])

Comment: How can the NRC GEIS have confidence in extended storage when the NRC and Department of Energy (DOE) have not completed their research on extended storage and transportation? The NRC does not have the research data (let alone the solutions) to analyze and validate the draft Generic EIS conclusions. The DOE has identified 94 critical technical data gaps in knowledge of "used" nuclear/irradiated fuel storage and transportation.[†] [footnote † text: DOE Review of Used Nuclear Fuel Storage and Transportation Technical Gap Analyses, 7/31/2012 <http://1.usa.gov/1bQr5xO>.] NRC and DOE extended storage and transportation research should be completed before the NRC completes their EIS. (0711-29 [Olson, Mary])

Comment: How can the NRC GEIS have confidence in extended storage of high burn-up (>45 GWd/MTU) highly radioactive spent nuclear fuel when the NRC currently will not approve dry cask storage beyond 20 years[‡] [footnote ‡ text: *Status of NRC Research on High Burnup Fuel Issues* (Slide 7) Dr. Robert E. Einziger <http://1.usa.gov/15E8gX5>.] for high burnup waste and won't approve transportation casks[§] [footnote § text: NRC Interim Staff Guidance 11, rev 3, *Cladding Considerations for the Transportation and Storage of Spent Fuel* <http://www.nrc.gov/reading-rm/doc-collections/isg/isg-11R3.pdf>.] for high burnup waste? How long does high burn-up fuel have to be actively cooled in liquid? How does burn-up impact the amount, rate and percentage of plutonium generated? How about burn-up and the other transuranics (amount, rate, percentage)? How does burn-up change the "biological effectiveness" (dose) of exposure to fuel particles? (0711-30 [Olson, Mary])

Comment: What is the profile of hydride generation in dry storage? Is there a correlation between hydride generation and burnup? Is there a correlation between hydride generation and time? (0711-34 [Olson, Mary])

Comment: CCNR [Canadian Coalition for Nuclear Responsibility] finds that NRC assurances of the safety of temporary storage measures for spent nuclear fuel under both wet and dry storage regimes are not supported by adequate analysis of the consequences of using high

burn-up fuel in commercial reactors. CCNR recommends that NRC refrain from all licensing decisions that may add to the inventory of high burn-up fuel in temporary storage pending the outcome of a public review process based on a thorough analysis of all safety implications of high burnup fuel vis-à-vis such things as accelerated cladding degradation, added criticality potential, obstacles to safe transport of spent fuel, deterioration of spent fuel handling equipment, alterations in isotopic composition (source terms), as well as increased radioactivity and heat generation in any geologic repository or surface facility. (0714-1-5 [Edwards, Gordon])

Comment: The NRC has also failed to address in an adequate manner the environmental risks associated with continuing the current management practices of wet storage in spent fuel pools and dry storage in canisters, particularly in light of the unexamined implications of NRC's decision to allow licensees to use high burnup nuclear fuel which adds significantly to the fission product inventory and heat loadings associated with the resulting irradiated fuel, thereby invalidating analyses that were carried out years ago based on lower burn-up. (0714-1-8 [Edwards, Gordon])

Comment: The inherent dangers in storing irradiated nuclear fuel have been compounded by recent practices. Since the 1990s, NRC has allowed its licensees to increase the burn-up of the uranium reactor fuel dramatically by increasing the concentration of uranium-235. The resulting irradiated nuclear fuel has a higher fission product inventory and generates significantly more decay heat. The unique characteristics of high burn-up irradiated fuel have major implications for the potential environmental consequences of storage of such nuclear waste in spent fuel pools, in dry storage casks, and even in a geologic repository, yet NRC has failed to carry out a thorough and exhaustive study of these important implications resulting from its own licensing actions over the last 2 decades. As of 2008, the NRC allows reactors using uranium fuel to operate at the highest burn-up rates of any country in the world. (0714-2-3 [Edwards, Gordon])

Comment: The NRC also has an obligation not to add to that burden [of indefinite storage of nuclear fuel] unnecessarily. For this reason the NRC policy allowing licensees to use high burn-up fuels should be thoroughly reexamined and reconsidered with an opportunity for full public input. (0714-2-6 [Edwards, Gordon])

Comment: A 2003 peer-reviewed article by Robert Alvarez, a Senior Scholar at Princeton University's Institute for Policy Studies and a former Senior Policy Advisor to the U.S. Secretary of Energy, concluded that the dense packing of spent fuel in cooling pools does not provide a sufficient safety margin in the event of a pool breach and consequent water loss from an accident or terrorist attack.³⁷ [footnote 37 text: *See Reducing the Hazards from Stored Spent Power-Reactor Fuel in the United States*, Science and Global Security, Vol. 11:1-51 ("Reducing the Hazards") (2003).] In such cases, the fuel most recently placed in the pool could heat up enough to ignite its zirconium cladding, possibly resulting in the release of large amounts of radioactivity to the environment.³⁸ [footnote 38 text: *Id.*] To reduce this risk, the Alvarez article recommended moving spent fuel that had cooled for five years to dry-cask storage.³⁹ [footnote 39 text: *Id.* at 27.] The graph below, taken from the Alvarez article, shows that several days after being removed from the reactor, nuclear fuel is releasing 100 kilowatts of radioactive heat per metric ton of uranium (kWt/tU).⁴⁰ [footnote 40 text: *Id.* at 12.] [Figure inserted] Gordon Thompson of the Institute for Resource and Security Studies has also issued reports concluding that increased storage of spent fuel in dry casks would allow lower-density packing of spent fuel pools and decrease the risk of pool fires.⁴¹ [footnote 41 text: *See, e.g.,* Gordon R. Thompson, *Environmental Impacts of Storing Spent Nuclear Fuel and High-Level Waste from Commercial Nuclear Reactors: A Critique of NRC's Waste Confidence Decision and Environmental Impact Determination*, at 49-50 (Feb. 6, 2009).] But, as yet, only 22% of spent nuclear fuel is stored in

dry casks.⁴² [footnote 42 text: Nuclear Regulatory Commission, *Spent Fuel Storage in Pools and Dry Casks Key Points and Questions and Answers* (Apr. 29, 2011). Available at: <http://www.nrc.gov/waste/spent-fuelstorage/faqs.html>.] Other scientists and engineers have raised similar points.⁴³ [footnote 43 text: *See Damages from a Major Release* (discussing accident costs at Indian Point and four other sites).] NRC disagreed with Reducing the Hazards and criticized Alvarez and the Institute for Policy Studies for questioning NRC's and industry's reliance on densely packed spent fuel pools. (0718-1-15 [Sipos, John])

Comment: Indeed, has NRC ever found any difficulties in any approach to waste handling and storage insurmountable? Now, really, not even the part where Wiley Coyote pushes the Volkswagen bus full of nuclear waste over the cliff, but Roadrunner catches it al in a hot tub full of ginger ale? Sorry, but in the face of NRC's insult to the intelligence approach thus far, I couldn't help this comparison. (0723-4 [Shadis, Raymond])

Comment: NRC chooses to declare that spent fuel pool storage are equally(that is presumably beneath regulatory concern) "safe", therefore, says NRC, there is no urgency whatsoever in moving spent fuel from over-packed spent fuel pools to dry cask storage. At the same time, an NRC taskforce is grimly engaging in recalculating the risk of criticality accidents should neutron absorbing materials required in over-packed spent fuel pools fail. I would ask NRC to consult with NUREG – 1738 – Spent Fuel Pool Accident Risk in Decommissioning Nuclear Power Plants and the NRC studies that precede it and feed into it. NUREG-1738 advises in reference tables that as many as 25,000 latent fatalities out to a distance of 500 miles may result from a spent fuel pool fire –even if the emergency planning zone is 95% evacuated. NUREG-1738 advises a rapid oxidation reaction may occur no matter how long fuel has cooled. NUREG-1738 advises that a BWR Mark I containment would present no substantial obstacle to aircraft penetration (these being commercial aircraft of modest weight and speed). NUREG-1738 advises that the probabilities of acts of terror or sabotage are incalculable. NUREG-1738 advises that BWR Mark I spent fuel pools (Vermont Yankee, in particular, could under severe seismic shock tear open laterally corner to corner. Or, in a most severe event, the entire bottom could simply drop out. I say, the intense radiation from a mass of unshielded fuel would then preclude adding water until robotic equipment could be brought to play; by then too late to stop an exothermic reaction. NUREG-1738 advises that an exothermic reaction in a spent fuel pool could, if uninterrupted, propagate through the entire mass of fuel – in many reactors-the equivalent of five or more full reactor cores. No such propagation capability exists for dry cask storage. How then can NRC credibly equate risk for wet and dry storage? (0723-8 [Shadis, Raymond])

Comment: It is extremely unsafe to continue to store the Spent Nuclear Fuel at the San Onofre site because of the vulnerability of the site location at the ocean's edge and the lack of adequate storage at the site. What could possibly happen would affect approximately 7.5 million residents and Southern California's major cites and render uninhabitable vast lands of the area and all of the wildlife. I strongly support finding a safe and permanent storage elsewhere. (0725-1 [Barker, Lauren])

Comment: Immediately reduce spent fuel pool density to original design standards, without exemptions[.] (0728-6 [Anonymous, Anonymous])

Comment: Radioactive waste is dangerous, and needs to be stored properly. Fukushima is a glowing example of danger of nuclear materials. People have died, and now talking about it has been ruled to be criminal. We can only make so many STUPID moves as a human race in the future. Storing nuclear fuel in a poor manner cannot be one of these moves .Even our sailors

who assisted during Fukushima meltdown are now sick - just after a few days being around the area. Find a better storage - period. (0732-2 [Green, Jeane])

Comment: In particular, storing nuclear waste next to rivers such as the Altamaha and the Savannah Rivers in Georgia is a very bad idea, and shuffling radioactive waste around to "interim" storage facilities is even worse. (0739-2 [Quartermann, John S.])

Comment: Immediately reduce spent fuel pool density to original design standards, without exemptions[.] (0741-3 [Giese, Mark M.])

Comment: Dry cast storage systems are manufactured by several competitive vendors in the United States, including AREVA. The competition in the market fosters a cycle of innovation and development, which continues to drive technological progress for evolving systems with increased safety margins. The statement "improvement based on research and operating experience, and licensee compliance with regulatory requirements is important to the continued safe storage of spent nuclear fuel" (78 Fed. Reg. 56,788) represents a substantial underrepresentation of the basis and market for continued safe spent fuel storage options available today. AREVA requests that the staff augment this statement to better reflect and represent the existing competitive market for spent fuel storage. (0745-3 [Kelley, Devin])

Comment: I urge you to store nuclear waste in dry casks and safely keep in the nuclear plant site. (0751-2 [Temlock, Ayumi])

Comment: In 2011 I had an opportunity to tour Diablo Canyon Nuclear Power Plant. I am confident that the spent fuel storage area provided by PG& E is safe and acceptable based on what I saw and the information I was provided during that tour. (0753-2 [Devitt, Andrea])

Comment: Other issues such as water storage and onsite rod storage have been nightmares in disguise that due to the Fukushima Japan event are clear and present dangers. (0755-4 [Calnan, Christopher])

Comment: How can the NRC GEIS have confidence in extended storage when the NRC and the Department of Energy (DOE) have not completed their research on extended storage and transportation? The NRC does not have the research data (let alone the solutions) to validate the draft Generic EIS conclusions. The DOE has identified 94 critical technical data gaps in knowledge of spent nuclear fuel (SNF) storage and transportation.¹ [footnote 1 text: DOE Review of Used Nuclear Fuel Storage and Transportation Technical Gap Analyses, 7/31/2012, <http://1.usa.gov/1bQr5xO>] NRC and DOE extended storage and transportation research should be completed before the NRC completes their EIS. (0756-1 [Gillmore, Donna])

Comment: The NRC has not approved short-term storage and transportation because numerous scientific reports have shown these high burnup fuel problems: •Unstable and unpredictable in storage [.] •The protective Zirconium metal cladding around the low enriched (up to 5% U-235) uranium fuel is becoming brittle, making it fragile and subject to shattering. If the radiation breaches the cladding, it can also breach the steel canister and cement cask, release radiation into the environment. •High burnup fuel reacts with the Zirconium cladding resulting in hydrides, adding the risk of a hydrogen explosion. •Hotter and over twice as radioactive •Requires up to a minimum cooling of 20 years in spent fuel pools (instead of 5 years for lower burnup fuel).¹⁰ [footnote 10 text: No. 1029 Technical Specifications for Advanced NUHOMS® System Operating Controls and Limits, Appendix A Table 2-12 (page 2-16) <http://pbadupws.nrc.gov/docs/ML0515/ML051520131.pdf>.] Fuel cladding temperature must be

400 C (752° F) or less before moving fuel assemblies to dry storage.¹¹ [footnote 11 text: NRC Spent Fuel Project Office Interim Staff Guidance - 11, Revision 3, Cladding Considerations for the Transportation and Storage of Spent Fuel, Nov 17, 2003 <http://www.nrc.gov/reading-rm/doc-collections/isg/isg-11R3.pdf>.] •Requires over double the storage space (of lower burnup fuel) in a permanent geological repository and there are no geological repository designs for high burnup fuel.¹² [footnote 12 text: RWMA Marvin Resnikoff, PhD: The Hazards of Generation III Reactor Fuel Wastes May 2010 <http://bit.ly/19dVRsY>.] The NRC has known for decades of high burnup fuel problems,¹³ [footnote 13 text: NRC Agency Program Plan for High-Burnup Fuel, To NRC Commissioners, July 6, 1998 <http://bit.ly/19R1i2L>.] yet continues to approve use of this fuel. In some cases, it has approved burnup levels up to 75 GWd/MTU.¹⁴ [footnote 14 text: Catawba Nuclear Station, Environmental Assessment & Finding of No Significant Impact, Federal Register Vol 75, No. 142, Docket 50-413 & 50-414; NRC-2010-0260, 7/26/10 <http://www.gpo.gov/fdsys/pkg/FR-2010-07-26/html/2010-18241.htm>.] (0756-10 [Gilmore, Donna])

Comment: The independent U.S. Nuclear Waste Technical Review Board December 2010 report, *"Evaluation of Technical Basis for Extended Dry Storage and Transportation of Used Nuclear Fuel,"*¹⁵ [footnote 15 text: U.S. Nuclear Waste Technical Review Board (NWTRB) *Evaluation of Technical Basis for Extended Dry Storage and Transportation of Used Nuclear Fuel*, December 2010 <http://bit.ly/1jfl1Sn>.] states *"Argonne scientists reported high burn-up fuels may result in fuel rods becoming more brittle over time." And "...insufficient information is available on high burnup fuels to allow reliable predictions of degradation processes during extended dry storage."* It also states *Only limited references were found on the inspection and characterization of fuel in dry storage, and they all were performed on low-burnup fuel after only 15 years or less of dry storage. Insufficient information is available on high-burnup fuels to allow reliable predictions of degradation processes during extended dry storage, and no information was found on inspections conducted on high-burnup fuels to confirm the predictions that have been made. The introduction of new cladding materials for use with high-burnup fuels has been studied primarily with respect to their reactor performance, and little information is available on the degradation of these materials that will occur during extended dry storage.* (0756-11 [Gilmore, Donna])

Comment: There is no technology to monitor conditions inside dry casks.¹⁶ [footnote 16 text: Fancy New Lids for Nuclear Waste Casks, As Contents Get Hotter, Jeff McMahon, May 2, 2013 <http://www.forbes.com/sites/jeffmcmahon/2013/05/02/fancy-new-lids-for-nuclear-waste-casks-as-contents-get-hotter/?view=pc> Division of Spent Fuel Storage and Transportation Interim Staff Guidance-24, Revision 0, *The Use of a Demonstration Program as Confirmation of Integrity for Continued Storage of High Burnup Fuel Beyond 20 Years* <http://pbadupws.nrc.gov/docs/ML1305/ML13056A516.pdf>; *Briefer on the DOE's High Burn-Up Used Fuel Demonstration Project*, John Kessler EPRI, Power Engineering 10/11/2013 <http://www.power-eng.com/articles/npi/print/volume-6/issue-5/departments/nuclear-world/briefer-on-the-doe-s-high-burn-up-used-fuel-demonstration-project.html>.] According to Argonne scientists, this requires sensors with (1) the ability to endure temperatures above 200 degrees C, (2) the ability to endure radiation levels higher than 1000 rads per hour, (3) a means of "harvesting" the energy inside the container, and (4) batteries that will power the sensors for more than 10 years, and (5), a way to wirelessly transmit the sensor data out of the cask. Statistics from the Nuclear Energy Institute (NEI): - High burnup fuel has been stored in dry casks in the U.S. since 2003 •Approximately 200 loaded-casks contain high burn-up fuel •Most fuel in pools for future loading is high burn-up.¹⁷ [footnote 17 text: Cask Storage of High Burn-up Fuel, NEI, Marc Nichol 7/25/2012 presentation Slide 3 <http://sanonofresafety.files.wordpress.com/2013/06/nei-highburnupslide2012-07-25.pdf>.] (0756-12 [Gilmore, Donna])

Comment: How can the NRC GEIS have confidence in extended storage of high burnup (>45 GWd/MTU) spent nuclear fuel (SNF) when the NRC states they have insufficient data to support dry cask licensing for more than an initial 20 years for high burnup SNF? See Division of Spent Fuel Storage and Transportation Interim Staff Guidance-24, Revision 0, *The Use of a Demonstration Program as Confirmation of Integrity for Continued Storage of High Burnup Fuel Beyond 20 Years*² [footnote 2 text: Division of Spent Fuel Storage and Transportation Interim Staff Guidance-24, Revision 0, *The Use of a Demonstration Program as Confirmation of Integrity for Continued Storage of High Burnup Fuel Beyond 20 Years*, <http://pbadupws.nrc.gov/docs/ML1305/ML13056A516.pdf>; *Status of NRC Research on High Burnup Fuel Issues* (Slide 7) Dr. Robert E. Einziger <http://1.usa.gov/15E8gX5> Hear 3/13/2013 Conference session on Storage and Transportation of High Burnup Fuel. Dr. Einziger's presentation starts at minute 39:50. <http://www.nrc.gov/public-involve/conference-symposia/ric/past/2013/docs/audio/w24.mp3>.] (0756-2 [Gilmore, Donna])

Comment: How can the NRC GEIS have confidence in extended storage of SNF when their own Interim Staff Guidance 11, rev 3, *Cladding Considerations for the Transportation and Storage of Spent Fuel* excludes approval of transportation casks for high burnup SNF (except on a case by case basis)?³ [footnote 3 text: NRC Interim Staff Guidance 11, rev 3, *Cladding Considerations for the Transportation and Storage of Spent Fuel* <http://www.nrc.gov/reading-rm/doc-collections/isg/isg-11R3.pdf>.] The fuel is over twice as radioactive as lower burnup fuel and is hotter, requiring up to a minimum 20 years cooling in spent fuel pools.⁴ [footnote 4 text: Appendix A to CoC No.1029, Technical Specifications for the Advanced Nuhoms® System (Table 2.12) <http://pbadupws.nrc.gov/docs/ML0515/ML051520131.pdf>.] The fuel is proving unstable in storage and there are no current solutions to these problems. The NRC GEIS⁵ [footnote 5 text: *NRC Draft Waste Confidence Generic Environmental Impact Statement NUREG-2157*, September 20 <http://pbadupws.nrc.gov/docs/ML1322/ML13224A106.pdf> <http://www.nrc.gov/waste/spent-fuel-storage/wcd/pub-involve.html>.] quotes one study (Pages B-13 and B-23) regarding the problems of fuel cladding embrittlement with high burnup SNF, yet ignores the potential consequences of this - shattering of the embrittled fragile fuel cladding, which could release radiation into the environment. (See Attachment A for details). (0756-3 [Gilmore, Donna])

Comment: How can the NRC GEIS have confidence in extended storage of SNF when the independent U.S. Nuclear Waste Technical Review Board (NWTRB) December 2010 report, "Evaluation of Technical Basis for Extended Dry Storage and Transportation of Used Nuclear Fuel,"⁶ [footnote 6 text: U.S. Nuclear Waste Technical Review Board (NWTRB) *Evaluation of Technical Basis for Extended Dry Storage and Transportation of Used Nuclear Fuel*, December 2010 <http://bit.ly/1jfl1Sn>] states "Argonne scientists reported high burn-up fuels may result in fuel rods becoming more brittle over time." And "...insufficient information is available on high burnup fuels to allow reliable predictions of degradation processes during extended dry storage." The NRTWB report also states: *Only limited references were found on the inspection and characterization of fuel in dry storage, and they all were performed on low-burnup fuel after only 15 years or less of dry storage. Insufficient information is available on high-burnup fuels to allow reliable predictions of degradation processes during extended dry storage, and no information was found on inspections conducted on high-burnup fuels to confirm the predictions that have been made. The introduction of new cladding materials for use with high-burnup fuels has been studied primarily with respect to their reactor performance, and little information is available on the degradation of these materials that will occur during extended dry storage.* (0756-4 [Gilmore, Donna])

Comment: Why did the NRC GEIS choose to ignore information about how the level of burnup negatively impacts extended storage in both dry casks and spent fuel pools? Most of the cases made in the GEIS are for lower burnup fuel. Information for high burnup fuel is consistently ignored or downplayed. Here is one example. See Attachment A for details on this example and other examples. In the paragraph starting on Line 22 of Page B-8, the GEIS cherry picks a paragraph of a 1998 IAEA report⁷ [footnote 7 text: IAEA-TECDOC-1012 Durability of spent nuclear fuels and facility components in wet storage, April 1998, http://www-pub.iaea.org/MTCD/Publications/PDF/te_1012_prn.pdf] and concludes "*the database for zirconium alloys supports a judgment of satisfactory wet storage in the time frame of 50 to 100 years or more.*" However, in the same paragraph of that 1998 IAEA report (Summary, Page 1), the GEIS chose to exclude this caution about high burnup fuel and details about Zircaloy cladding corrosion. *However, it is necessary to place into perspective the advancing corrosion that has occurred on Zircaloy clad uranium metal fuel from the Hanford N Reactor. The otherwise durable Zircaloy was mechanically damaged during reactor discharge, exposing uranium metal, that is vulnerable to aqueous corrosion in the temperature range encountered in wet storage environments. An additional issue involves advancing corrosion and hydriding of zirconium alloy cladding subject to extended burnup. Diminished low temperature ductility imposes the need for additional care in spent fuel handling operations to avoid any mechanical impact that may cause cladding fracture.* In addition, see attached document "*High Burnup Nuclear Fuel: No short-term storage or transport solutions*", SanOnofreSafety.org. More information is available at <http://sanonofresafety.org/nuclear-waste/>.] (0756-5 [Gilmore, Donna])

Comment: The NRC should stop approving high burnup fuel. The NRC should not approve the Waste Confidence Generic Environmental Impact Statement, since they do not have sufficient data on extended storage of high burnup to have confidence this waste can be safely stored or transported. (0756-6 [Gilmore, Donna])

Comment: The DOE and NRC should take a leadership role in finding both short and long term storage and transport solution for high burnup spent fuel, and not depend on the nuclear industry to put safety over profits. This should take priority over research for new reactors and nuclear waste reprocessing. Congress should provide adequate funding to find a solution that puts safety above industry profits. (0756-7 [Gilmore, Donna])

Comment: The Nuclear Regulatory Commission (NRC) states they have no safe short-term storage or transportation solutions for high burnup^{1,2} [footnote 1 text: Low enriched uranium (up to 5% U-235) fuel that has burned over 45 gigawatt-days per metric ton of uranium is high burnup (>45 GWd/MTU). Spent fuel assemblies with average burnups exceeding 45 GWd/MTU are only approved for transport on a case-by-case basis. NRC Spent Fuel Project Office Interim Staff Guidance - 11, Revision 3, Cladding Considerations for the Transportation and Storage of Spent Fuel, Nov 17, 2003 <http://www.nrc.gov/reading-rm/doc-collections/isg/isg-11R3.pdf>; footnote 2 text: Division of Spent Fuel Storage and Transportation Interim Staff Guidance-24, Revision 0, *The Use of a Demonstration Program as Confirmation of Integrity for Continued Storage of High Burnup Fuel Beyond 20 Years* <http://pbadupws.nrc.gov/docs/ML1305/ML13056A516.pdf>; NRC Dr. Robert E. Einziger: insufficient data to support licensing dry casks for >20 years, (slide 7) Status of NRC Research on High Burnup Fuel Issues, March 13, 2013 Regulatory Information Conference session on W24-Storage and Transportation of High Burnup Fuel. Dr. Einziger is Senior Materials Scientist, NRC Division of Spent Fuel Storage & Transportation <http://1.usa.gov/15E8gX5>, Audio of Dr. Einziger's presentation starts at minute 39:50: <http://www.nrc.gov/public-involve/conference?symposia/ric/past/2013/docs/audio/w24.mp3>.] spent nuclear fuel: •Insufficient data to approve high burnup dry cask storage for over 20 years,³ [footnote 3

text: Ibid] and •No approved transportation casks to safely move high burnup spent nuclear fuel offsite. Exceptions approved on a case-by-case basis.⁴ [footnote 4 text: NRC Spent Fuel Project Office Interim Staff Guidance - 11, Revision 3, Cladding Considerations for the Transportation and Storage of Spent Fuel, Nov 17, 2003 <http://www.nrc.gov/reading-rm/doc-collections/isg/isg-11R3.pdf>.] San Onofre⁵ [footnote 5 text: NRC Inspection Report: San Onofre Independent Spent Fuel Storage Installation (ISFSI), May 20, 2011. Attachment 2 LOADED CASKS AT THE SONGS ISFSI (last 3 pages of document). <http://pbadupws.nrc.gov/docs/ML1114/ML111430612.pdf>.] and Diablo Canyon⁶ [footnote 6 text: NRC Inspection Report: Diablo Canyon Independent Spent Fuel Storage Installation (ISFSI), May 20, 2013. Attachment 2 LOADED CASKS AT THE DIABLO CANYON POWER PLANT ISFSI (last 2 pages of document) <http://pbadupws.nrc.gov/docs/ML1314/ML13140A430.pdf>.] nuclear power plants both use high burnup fuel as do other U.S. nuclear power plants.⁷ [footnote 7 text: DOE Inventory and Description of Commercial Reactor Fuels within the United States, March 31, 2011 (Table 7) <http://sti.srs.gov/fulltext/SRNL-STI-2011-00228.pdf>.] The NRC approved high burnup fuel about 15 years ago.⁸ [footnote 8 text: GAO-12-797 SPENT NUCLEAR FUEL: Accumulating Quantities at Commercial Reactors Present Storage and Other Challenges, August 2012 <http://www.gao.gov/assets/600/593745.pdf>.] (0756-8 [Gilmore, Donna])

Comment: High burnup fuel stays in the reactor longer, thus increasing industry profits, but makes us less safe. The NRC defines "high burnup" as fuel that has burned over 45 gigawatt-days per metric ton of uranium (>45 GWd/MTU). However, according to a June 15th, 2013 Department of Energy (DOE) report, experimental data suggests fuel with burnup as low as 30 GWd/MTU shows signs of premature failure.⁹ [footnote 9 text: DOE FCRD-NFST-2013-000132, Rev. 1; Fuel Cycle Research & Development-Nuclear Fuel Storage and Transportation-2013-000132, Rev. 1, June 15, 2013 <http://www.hsd.org/?abstract&did=739345>.] (0756-9 [Gilmore, Donna])

Comment: [I believe the NRC must:] Immediately reduce spent fuel pool density to original design standards, without exemptions[.] (0757-14 [Lynch, Laura])

Comment: No state is a waste dump! We don't want any more high-level radioactive wastes coming "to or through" our states. We do not want to see more high-level, long-lived radioactive waste coming to proposed so-called "centralized interim storage" waste facilities (a.k.a., "parking lot dumps") here or anywhere else. (0757-8 [Lynch, Laura])

Comment: No state is a waste dump! We don't want any more high-level radioactive wastes coming "to or through" our state. I do not want to see more high-level, long-lived radioactive waste coming to proposed so-called "centralized interim storage" waste facilities (a.k.a., "parking lot dumps") here or anywhere else. I want to feel confident and comfortable encouraging my children to have children. I want to believe our voices will be heard. I want to believe those making these laws are awake enough to make proper decisions. I want to believe we have acknowledged how much damage we have already done to the human race and life as we've known it, and that we will stop the madness. (0763-4 [Freeman, Susan])

Comment: HIGH BURNUP FUEL - Too hot to handle[.] No short-term storage or transportation solutions for high burnup fuel waste. •The NRC and DOE are concerned with the instability of high burnup nuclear waste in both storage and transport, yet the NRC continues approving this dangerous fuel for U.S. reactors. •The NRC won't approve high burnup dry cask storage over 20 years because they have NO CONFIDENCE it can be stored longer without releasing radiation into the environment, even though it must be safely stored for tens of thousands of years. •The NRC won't approve transportation of high burnup used fuel because they have NO

CONFIDENCE it can be transported without releasing radiation into the environment. •San Onofre's high burnup used fuel is so hot and radioactive, it requires up to a MINIMUM 20 YEARS cooling in the crowded spent fuel pools, instead of the minimum 5 years for lower burnup fuel. (0764-2 [Gilmore, Donna])

Comment: As a resident of South Orange County I feel it is entirely unacceptable to store nuclear waste permanently at a facility so close to this highly populated and desirable area. A failure in the storage containers with any kind of failure in the future could produce disastrous effects to one of the most lovely areas in North America. This must not be done. (0765-1 [Tucker, Alison])

Comment: If a company undertakes to use nuclear material to produce energy it must have a SAFE method of disposing of it, not near the ocean or any other area which might affect the people and ecosystem in close proximity. The waste must be MOVED and disposed of SAFELY. (0765-2 [Tucker, Alison])

Comment: After seeing what has happened to Fukushima, it is clear that the storage of spent fuel rods within a reactor is pure folly. Actually, nuclear is pure folly, but that's for another discussion. At least for now, spent fuel needs to be put in dry cask. (0772-1 [Bogdan, Andrew])

Comment: The waste is not safe in the spent fuel pools nor far below in the ground in big amounts. (0773-2 [Dupont, Alice])

Comment: This report only reinforces the growing mistrust of nuclear regulators who would play down the risk of storing nuclear waste wherever it may be presently, apparently bending to the will of the industry they are supposed to regulate. Suggesting that we will be able to rely on unproven or non-existent technology for safe storage of nuclear waste for thousands of years puts the future of our entire nation at risk. (0774-3 [Revilla, Oscar])

Comment: Immediately reduce spent fuel pool density to original design standards, without exemptions. (0774-8 [Revilla, Oscar])

Comment: No state is a waste dump! We don't want any more high-level radioactive wastes coming "to or through" our state. The entire approach to nuclear waste endangers public and environmental health; the idea of transporting high-level, long-lived radioactive waste coming to proposed so-called "centralize interim storage" waste facilities ("parking lot dumps") is unsound. (0775-4 [Zure, Lisa])

Comment: 1) It's more costly to process and create the MOX fuel than to cask it. A study by Princeton presented April 4, 2008 to Congress estimated that processing MOX including the costs of the MOX facility and decommissioning the MOX facility is about 10 times more expensive than simply Dry Casking! 2) The MOX fuel is far more likely to explode in a Moderated Prompt Criticality. In the 1950's Argonne National Lab conducted a series of experiments that proved that even with normal nuclear fuel rods, an uncontrolled criticality could blow up the reactor. With MOX, enriched with bomb making plutonium, this type of nuclear explosion is much more likely, as occurred in Japan @ Fukushima Daiichi unit 3 which was running MOX. The amount of Uranium detected by the EPA in Saipan, Guam, Honolulu and California could only be caused by one thing...an explosion from within the reactor vessel that launched the inventory into the air. MOX is too dangerous! MOX can turn a 80 foot tall reactor with 6" steel walls into a "Canon" which can launch the entire inventory. (0778-2 [Sorgen, Phoebe])

Comment: The Dry Cask is proven technology that can be produced in the USA, creating jobs in the USA and increasing safety, all at an affordable cost, which should be covered by the utilities because they had the obligation to decommission the reactors. If necessary, the US Government could assist the utilities by providing half the cost of the cask. (0778-3 [Sorgen, Phoebe])

Comment: The Draft GEIS should also add while the NRC has experience with licensing and spent fuel storage from the 1950's, dry cask storage has not extended back that far and the technology associated with higher burn rates for fuel assemblies has changed. A Draft GEIS should specifically reference that the storage being determined by the Draft GEIS was never contemplated and therefore is unique in both analysis and application. (0783-2-3 [Harlan, Thomas])

Comment: Lastly, the repository for the spent fuel has never approved and it appears as though it never will be. The waste should be transferred to dry cask storage and moved away from this heavily populated area to a location away from the coast ASAP. Please don't allow this Southern California coastal community to live with the thread of a nuclear disaster a day longer than absolutely necessary. (0785-4 [Korsen, Alan])

Comment: There needs to be a long term storage solution or nuclear power is just an accident waiting to happen. It isn't acceptable to continue to store the spent fuel on site in either wet or dry storage. Not only is it a environmental concern, it is also a national security nightmare waiting to happen. And though these plants need a coolant to keep them from overheating, another way should be found as we risk our water supply and the associated health problems of introducing additional radioactive materials into our environment. (0786-1 [Dew, Jane])

Comment: Nuclear waste needs to be stored in an area MADE for waste storage. Leaving it in an area that is not made for storage is inexcusable. Have you imagined if a terrorist got hold of waste? Send it somewhere built out and protected. PROTECT US! (0787-1 [Iwashita, Thomas])

Comment: Immediately reduce spent fuel pool density to original design standards, without exemptions[.] (0789-3 [Salto, Don])

Comment: No state is a waste dump! I don't want any more high-level radioactive wastes coming "to or through" our state. I do not want to see more high-level, long-lived radioactive waste coming to proposed so-called "centralized interim storage" waste facilities here or anywhere else. (0791-4 [Mierzwicki, Tony])

Comment: My understanding is this high burn-up fuel is going to be stored in dry casks for decades to come at San Onofre. But this has never been done before and thus is an ongoing experiment. This puts the city at an unnecessary risk. We have opposed the presence of this plutonium generating facility since before it was ever constructed, and now we are expected to accept its waste indefinitely anyway. The land on which the plant sits is useless because of this. The risk of even a small scale hydrogen gas explosion or fire from electrolysis of any moisture that ever gains entry into the casks is unacceptable. The material needs to be placed in a safer facility a substantial distance from populated areas, a substantial distance from earthquake faults, and a substantial distance from any shoreline. (0793-2 [Sauerheber, Richard])

Comment: I am especially concerned about the proposed plan for storing nuclear waste. The high burnup fuel used at San Onofre is twice as radioactive as lower burnup fuel, and there is

no approved method for safely storing it in dry casks for more than 20 years. Nor is there any approved method for transporting it. (0796-2 [Hanna, Helen])

Comment: To allow any reactor in the US to store this waste in fuel pools is irresponsible and reckless and now is the time to force industry to deal with the waste permanently. (0798-3 [deBruler, Gregory])

Comment: The menace of enormous amounts of highly radioactive materials in insecure locations is an unacceptable risk to the United States and the entire world. If anything would cause the breakdown of the storage system, especially on the west coast of the United States, a giant swath of our country would no longer be inhabitable and millions of people would die or be severely impacted. We will lose giant acreages of agricultural land and our economy would be devastated. You must take your responsibility seriously to protect America from even a remote possibility of release of radioactive materials from our power plants. (0800-1 [Renzoni, Dante])

Comment: End the madness of the overstocked spent fuel pools. The spent fuel pools should contain only the minimum inventory required for safe operation of the NPP, plus the inventory that is less than 5 years old and is too hot to remove. This should be made an operating requirement. (0801-5 [Magyar, Michael])

Comment: Require that the spent fuel pool situation begin improving immediately. Regulate the industry so that any refueling activity must result in a net improvement of the situation. Require that for each kilogram of new fuel delivered to the NPP site, 2 kilograms of spent fuel must be taken out of the spent fuel pool and put in dry cask storage. (0801-6 [Magyar, Michael])

Comment: First, NextEra believes that its strong record of safely storing spent nuclear fuel, along with that of the rest of the nuclear industry, is compelling evidence that spent fuel can and will be stored safely and securely in the period following a reactor's period of licensed operations. The NRC's proposed TSR revision accurately reflects this high level of assurance in its finding that it is "feasible to safely store spent nuclear fuel following the licensed life for operation of a reactor." (0808-1 [Petro, James])

Comment: I am writing to support the NRC's Spent Fuel Storage Rule, and wish to say that with NRC oversight PG&E has a very particular and successful spent fuel management program. PG&E continues to safely store fuel via both its wet and dry cask storage systems. I am confident that regulations of safeguards are in place to effectively manage and monitor the stored spent fuel. (0812-1 [Souza, Celine])

Comment: First, it [spent fuel] should be passively safe. The waste should remain safe without relying on electricity, cooling water or a human crew. This does not apply to continued storage in spent fuel pools, which require a continuous flow of cooling water and other active maintenance. (0815-4 [Gunter, Keith] [Izant, Carol])

Comment: Third, the waste should be decentralized; that is, stored on the sites of nuclear plants, not at a centralized facility, and dispersed around each reactor site if possible. (0815-6 [Gunter, Keith] [Izant, Carol])

Comment: Despite NRC's assurances that dry cask storage is safe for up to 100 years, problems began surfacing almost immediately with dry casks. The NRC allowed manufacturers to build casks before issuing a certificate of compliance. There have been numerous quality control and quality assurance problems as well as documented departures from design and

technical specifications, use of potentially inferior materials, structural integrity issues, weld failures, problems with the concrete pads, themselves, and their location on unstable, sandy, erosion-prone soils etc. etc.. Perhaps the most serious and disturbing issues have involved the "hydrogen ignition incidents" (explosions) and problems with the VSC-24 casks. Here in Ohio at Davis Besse, fully loaded NUHOMS casks were built below technical specifications with poor quality aggregate in the outer concrete shells, and the shells, themselves, were ground too thin. At the Surry plant in Virginia, a loaded Transnuclear TN-32 cask developed six inch long cracks in its outer concrete shield, loose bolts, and a helium leak. (0819-12 [Kline, Connie])

Comment: If an arid, unpopulated, desert location like Yucca Mountain is unsuitable for permanent disposal of reactor spent fuel, how can reactors that don't meet the siting requirements for LLRW disposal because they are located on potable and environmentally sensitive bodies of water, on high groundwater tables, in seismic and geologically unstable areas subject to erosion, flooding, earthquakes etc. possibly be considered as permanent spent fuel repositories??? Let's be realistic here for a moment. These are the least suitable sites for nuclear power plants PERIOD! Only the NRC's faulty, illogical, circular reasoning could conclude, based on unsubstantiated assumptions, that it is perfectly acceptable to leave spent fuel permanently in defacto dumps on reactor sites. (0819-22 [Kline, Connie])

Comment: This problem will only worsen with the increased use of high burn-up fuel and the continued corrosion and disintegration of pipes, unless the NRC orders every reactor to locate and replace the miles-long maze of buried, leaking pipes so they can be inspected and monitored, and contamination can be contained. (0819-9 [Kline, Connie])

Comment: The refusal of the NRC to require existing wet pool storage to be returned to design level densities destroys the credibility of the DGEIS as recognizing an immediate safety concern that must be solved to allow continued operation of some reactor designs. (0821-7 [Paddock, Brian])

Comment: Now are you going to be part of the problem that continues or are you going to be part of the solution that says no more! We can no longer afford to utilize this Nuclear Waste and we certainly can not afford to store it because there is no man made container that can isolate and keep any isotope from doing harm. Since the containers will eventually leak there WILL BE MORE HARM and instead of continuing in such way I use my vote to find another better way! (0822-2 [Soldier, Wolf])

Comment: The French tout their ability to recycle their nuclear waste, but only 1% can be reprocessed into plutonium (MOX) fuel, per Sierra Club, John Muir Chapter's *Nuclear Energy: A Bad Bargain for Wisconsin*, 2013. MOX fuel is the most dangerous and the most insidious ionizing isotopes with the greatest safety problems and with the longest lifespans. (0823-15 [Michetti, Susan])

Comment: Reactor owners have increased the risk of serious environmental threat by using high-density storage racks in fuel pools. Decreasing the risk of environmental threat requires decreasing the fuel density stored in pools. Spent fuel in high density pools is accumulating dangerously at every nuclear power plant site in the USA. Such waste pools pose a serious risk of catastrophic fire. It is irrational to continue this practice after the Fukushima catastrophic fires that continue to rage out-of-control for nearly three years now. Pertinent to safety of on-site storage pools, unacceptable safety problems exist during plant operation and generation of the fuel waste with insufficient oversight and enforcement. Natural earthquakes, volcano eruptions, tsunamis, hurricanes, tornados, and high winds are points of vulnerability that can damage

nuclear plant facilities or take down the electric grid upon which these nuclear reactors and fuel pools depend to prevent threats to the public. It is insufficient for the NRC to claim that these dangerous high density stacked fuel pools, which, in turn, require continual energy to cool, are being permitted to continue for 60 years after the operation ends, without scientific proof that they will be ever be safe during this period as well as throughout their cumulative half-lives life spans that far exceed this arbitrary time period. (0823-31 [Michetti, Susan])

Comment: Keep it in the place where it was generated and have the companies who make it pay for the sequestering of it for the thousands of years it will be toxic. (0824-3 [Ingram, Gwen])

Comment: The surrounding community should not be forced to live with another 50 years of spent nuclear fuel residing in pools because the owner/operator sees a centralized high level waste facility being built 50 years from now averting the costs associated with building dry cask storage systems. The suggestion is to make the owner/operator transfer all the spent fuel on site into dry casks before the owner/operator gains access to decommissioning funds will reduce the surrounding community's exposure to a potential catastrophic nuclear accident. Its bad enough to have to impact the surrounding community with on-site dry cask storage for up to 200+ years but to allow the plant owner to keep spent fuel pools operational for half a century in a speculative venture is not fair to the surrounding community and has national security risks. The NRC must not allow the spent fuel pools to become part of the owner/operator's short-term (60 year) spent fuel storage strategy. (0826-18 [Morgal, Rick])

Comment: The operation of the nation's nuclear power plants has evolved over the last fifty years. Initially, a reactor's spent fuel pool was designed and built to hold a single core's worth of spent nuclear fuel with the stated operational procedure involving the removal of the spent fuel core before the next core was depleted. Historically this rarely, if ever, happened due to the US nuclear industry's inability to determine how to manage spent fuel. Now these same spent fuel pools, built years ago, have new racks allowing them to hold six to eight times as much nuclear waste as initially designed to hold. A typical spent fuel pool in the US holds more than one million of pounds of spent fuel. These pools must actively water-cool their contents to prevent the nuclear fuel from spontaneously combusting when in prolonged contact with air. The above-described incremental changes in the nation's nuclear spent fuel management policies negatively impact communities near nuclear power plants by significantly increasing the quantities of spent nuclear fuel stored at each nuclear power plant site. (0826-7 [Morgal, Rick])

Comment: NEI also agrees with NRC's statement that the current regulatory framework is adequate for multiple cask renewal periods.⁴⁷ [footnote 47 text: 78 Fed. Reg. at 56,782.] In accordance with this framework, industry has conducted and will continue to conduct confirmatory studies as necessary to support future license renewals so that existing casks may remain in service for as long as needed - even if their use extends to hundreds of years. Examples of these studies include the Idaho National Laboratory Dry Storage Characterization Project completed in 2001,⁴⁸ [footnote 48 text: "Dry Storage Characterization Project - Phase I: CASTOR V/21 Cask Opening and Examination," INEEL/EXT-0100183, August 2001.] ongoing canister inspections being conducted by EPRI at a number of sites,⁴⁹ [footnote 49 text: Regulatory Issue Resolution Protocol Screening Form and Resolution Plan for Chloride-Induced Stress Corrosion Cracking (RIRP-N-10-01), May 31, 2013.] and the ongoing DOE/EPRI High Burn-up Dry Storage Cask Research and Development Project.⁵⁰ [footnote 50 text: DOE Contract No. DE-NE-0000593, April 16, 2013.] Dry storage casks are robust concrete and steel structures with no moving parts. Multiple barriers provide defense-in-depth protection. Over 100 tons of concrete and steel forms a precisely engineered structure to protect every 10 tons of spent fuel. Over the last 30 years the nuclear industry has safely loaded over 1700 dry cask

storage systems. All of these systems are still in service today and there has been no release of their radioactive contents. As long as these systems continue to be licensed for storage, their owners will continue to meet NRC requirements by following strict aging management plans. (0827-2-3 [Ginsberg, Ellen])

Comment: The GEIS appropriately addresses concerns being raised by staff about the integrity of high burnup fuel in storage as an example of the diligence in assuring long-term safety that is inherent in the regulatory process. The significant efforts that industry has already taken, and is continuing to take, to address these concerns should also be mentioned. Specifically, NEI's March 22 letter to NRC (*Industry Analysis and Confirmatory Information Gathering Program to Support the Long-Term Storage of High Burnup Fuel*, ML13084A045), information provided by Calvert Cliffs and Prairie Island in support of their ISFSI license renewal applications, and the joint DOE/EPRI High Burn-up Dry Storage Cask Research and Development Project (DOE Contract No.: DE-NE-0000593) should be referenced. The body of work contained in these references rules out gross degradation of high burnup fuel (HBF) cladding⁹⁰ [footnote 90 text: Electric Power Research Institute, *R&D Insights and Perspectives on Storage and Transportation of High Burnup Fuel*, Albert J. Machiels, presentation to RIC 2013, March 13, 2013.] and provides significant technical basis for the further evaluation of cladding performance over time. The DOE demonstration program is intended to gather confirmatory data on actual high burnup fuel in storage in support of this evaluation. Industry is committed to continually apply the results of ongoing scientific programs such as this to further assure the safety of high burnup fuel in storage and transportation, through aging management programs that support the renewal of storage system licenses. For example, in response to NRC questions asked as part of the license renewal process for the ISFSI at the Calvert Cliffs site, Constellation Energy outlined a two-pronged approach to long term storage of HBF. This approach consisted of an aging management program involving the aforementioned DOE demonstration program and documentation of the "substantial" safety margin that exists to assure *that fuel currently in storage is at low risk of suffering from the aging mechanisms associated with HBF during the additional time that will be required for the DOE program to conduct the first HBF inspection."⁹¹ [footnote 91 text: Calvert Cliffs Nuclear Plant, *Response to Request for Additional Information, RE: Calvert Cliffs Independent Spent Fuel Storage Installation License Renewal Application*, Material License No. SNM-2505, Docket 72-8, Letter Gellrich to NRC Document Control Desk, April 24, 2013.] (0827-3-7 [Ginsberg, Ellen])

Comment: NRC should add a discussion of the lessons learned from the March 2011 events at Fukushima Daiichi regarding the robustness of spent fuel in storage. Due to the fact that there were rumors about the condition of spent fuel at the Fukushima site during the event that later proved to be false, there is considerable misunderstanding on this topic. This continuing misunderstanding was evident in a number of statements made at the public meetings held during the comment period. On the day the earthquake and tsunami struck Japan, there were 10,149 spent fuel assemblies at the Daiichi site in seven pools and nine dry casks.⁹² [footnote 92 text: Tokyo Electric Power Company, *Operating Experience in Spent Fuel Storage Casks*, IAEA-CN-178/KN27 June 3, 2010.] All of these pools were subject to the full force of the earthquake and three of them were inside buildings that were catastrophically damaged by hydrogen explosions associated with the reactor accidents. The dry casks were also over-washed by the tsunami. Yet, observations conducted since the accident consistently confirm that the stored spent fuel was largely unaffected by these occurrences and is still safely containing its radioactive inventory. The spent fuel that was of greatest concern during the accident, which was contained in the Unit 4 pool, remains in good condition and is suitable for handling using normal means. Accordingly, it is now being transferred out of the badly damaged building into another pool on site. The manner in which spent fuel withstood the effects of that

tragic accident is perhaps the most dramatic evidence yet of the robust safety assurance provided by the spent fuel pool and dry cask storage. (0827-3-8 [Ginsberg, Ellen])

Comment: The SOC should continue to express reasonable assurance that safe disposal of high-level radioactive waste and spent nuclear fuel in a mined geologic repository is technically feasible. This conclusion tracks to prior Finding 1 and is supported by the prior WCDs. As stated in the SOC for the proposed rule, no new information challenges this conclusion. Although NEI's recommended rule language would state the Commission's reasonable assurance that a repository can be available "when necessary," the SOC (and draft GEIS) should continue to express the Commission's conclusion that it is reasonable to assume that a mined geologic repository will be available within 60 years beyond the licensed life for operating and planned new reactors.¹¹⁶ [footnote 116 text: The record supports the Commission's belief that the availability of a geologic repository within this timeframe is very likely. However, as discussed above, given the societal and political uncertainties surrounding the establishment of a repository, the rule would express the Commission's reasonable assurance that a mined geologic repository can be available when necessary.] This conclusion tracks to prior Finding 2 and is supported by international and national experience that the time period needed to develop a repository is approximately 25-35 years. (0827-6-4 [Ginsberg, Ellen])

Comment: The SOC for the rule should also clearly articulate the basis for the Commission's conclusion of reasonable assurance that spent fuel can continue to be safely managed in spent fuel pools and dry casks until a geologic repository is available. This basis includes technical studies and industry experience to date. The SOC could additionally acknowledge - as it does currently - that regulatory oversight further ensures that aging management programs continue to be updated to address the monitoring and maintenance of structures, systems, and components that are important to safety. This conclusion tracks to prior Finding 3. (0827-6-5 [Ginsberg, Ellen])

Comment: RULE Discussion, C.3.a, 56795, Col. 3: NRC appropriately addresses concerns being raised by staff about Stress Corrosion Cracking (SCC) of dry storage canisters, citing the manner in which these concerns are being resolved as an example of how the regulatory process responds to changes and new information. The significant efforts that industry has already taken, and is continuing to take, to address this concern and assure the longevity of these canisters should also be mentioned. Specifically, actions being taken in accordance with Regulatory Issue Resolution Protocol N-10-01¹¹⁹ [footnote 119 text: "Regulatory Issue Resolution Protocol Screening Form and Resolution Plan for Chloride-Induced Stress Corrosion Cracking (RIRP-N-10-01)," Letter from R. McCullum (NEI) to D. Pstrack (NRC), May 31, 2013.], information provided by Calvert Cliffs in support of their ISFSI license renewal application, and EPRI's comprehensive Failure Modes and Effects Analysis effort should be referenced. (0827-7-20 [Ginsberg, Ellen])

Comment: Each State needs to take care of their own nuclear waste. Don't send it to other states! (0830-1 [Sanders, John])

Comment: We shouldn't storage high radioactive spent fuels at San Onofre Nuclear Generating station. It is within such high density populated areas in Southern California. Also, it's within Tsunami zone and San Andreal fault near by. California is a earthquake state. (0831-1 [Collins, Yoko])

Comment: I've seen what happened at reactor #4 at Fukushima Daiichi nuclear power plant where had spent fuel cooling pool and the building had exploded 2 years and 9 months ago.

We, public know about its danger, even just storing high radioactive nuclear fuels. We can't take a chance. We need to remove the spent fuels from the SONGS as soon as possible. We can't wait 20 or more years to remove them. (0831-2 [Collins, Yoko])

Comment: Vitrification only lasts 100 years in most cases and when it breaks down all the waste will pool together and perhaps achieve criticality. (0834-2 [Thabit, Nick])

Comment: The recently proposed "temporary" waste storage sites will become permanent, once the waste is sited there; no one will have the political leverage to get it moving again, once all the construction and transportation contracts are fulfilled. (0834-4 [Thabit, Nick])

Comment: It is a good point, what is the difference between a deep geologic repository and the NWOs that you propose to scatter around the country? Is there a reason the experts have pushed for a site like Yucca Mountain and have not proposed leaving it in casks, exposed to the elements and wartime or terrorist attack? Of course there is, but if you use the logic of this GEIS, the fuel will never be moved to such a repository, because you say that there is no problem with leaving it where it is. YOUR DOCUMENT MUST REVEAL THESE DANGERS! (0836-21 [Davis, Anonymous])

Comment: There is not any viable solution for the Standard Spent Fuel and the High Burnup Nuclear Fuel is much more dangerous. (0836-3 [Davis, Anonymous])

Comment: The independent U.S. Nuclear Waste Technical Review Board December 2010 report, "Evaluation of Technical Basis for Extended Dry Storage and Transportation of Used Nuclear Fuel,"15 states "Argonne scientists reported high burn-up fuels may result in fuel rods becoming more brittle over time." And "...insufficient information is available on high burnup fuels to allow reliable predictions of degradation processes during extended dry storage." It also states Only limited references were found on the inspection and characterization of fuel in dry storage, and they all were performed on low-burnup fuel after only 15 years or less of dry storage. Insufficient information is available on high-burnup fuels to allow reliable predictions of degradation processes during extended dry storage, and no information was found on inspections conducted on high-burnup fuels to confirm the predictions that have been made. The introduction of new cladding materials for use with high-burnup fuels has been studied primarily with respect to their reactor performance, and little information is available on the degradation of these materials that will occur during extended dry storage. There is no technology to monitor conditions inside dry casks. According to Argonne scientists, this requires sensors with (1) the ability to endure temperatures above 200 degrees C, (2) the ability to endure radiation levels higher than 1000 rads per hour, (3) a means of "harvesting" the energy inside the container, and (4) batteries that will power the sensors for more than 10 years, and (5), a way to wirelessly transmit the sensor data out of the cask. (0836-4 [Davis, Anonymous])

Comment: Page 2-26, Lines 32+, you consider "aging effects" and list a few that are related only to the canisters, casks, and overpacking, but not the aging of the fuel assemblies and fuel contained by them. The use of "high burnup fuel" is extremely prevalent and the implications in terms of aging are really unknown. This is yet another example of a pesky "issue that requires resolution"... we really don't know what will happen to the fuel assemblies after 100 years (or even 20 years) of containment in a ISFSI, but they certainly must be contained in your list of aging issues. (0836-44 [Davis, Anonymous])

Comment: We must continue to point out that a NWO DOES DIFFER from a deep geologic repository. YOU NEED TO DESCRIBE THAT DIFFERENCE AND BE HONEST ABOUT THE RISKS! (0836-48 [Davis, Anonymous])

Comment: The document sidesteps the key issue... These NWOs are not as safe as a deep geologic repository due to the obvious risk of terrorist or wartime attack. THIS ISSUE CANNOT BE LEFT OUT! And if you are honest, you will decide that there is no way we can continue to license new plants and extend the licenses of old plants, particularly those with Mark-I containments, which have fuel pools above grade and much easier to attack and cause a problem than one that is built at ground level. (0836-68 [Davis, Anonymous])

Comment: The DOE and NRC should take a leadership role in finding both short and long term storage and transport solution for high burnup spent fuel, and not depend on the nuclear industry to put safety over profits. This should take priority over research for new reactors and nuclear waste reprocessing. Congress should provide adequate funding to find a solution that puts safety above industry profits. (0836-7 [Davis, Anonymous])

Comment: We do not know how to contain nuclear waste. We do not know how to store it so it does not harm our natural environment because every environment we put it into it irreparably alters and changes that environment. Let's be responsible with that knowledge first and foremost, before we listen to all the great projects coming down the pike. Thank you for being super smart, responsible people of the highest ethical calling and let's do this right. (0838-9 [Clermont, Elaine])

Comment: NRC's Waste Confidence policy assumes that all nuclear waste is homogeneous. The reality is that the use of MOX and high burn-up fuels are more radioactive, dangerous, thermally hot, and difficult to store and transport safely. These realities do nothing less than undermine confidence that waste can be safely handled and stored. (0840-4 [Taylor, Tom])

Comment: No state is a waste dump! We don't want any more high-level radioactive wastes coming "to or through" our state. We do not wish to share our highways, roadways and oceans with nuclear waste. Storing it in hospital basements and on the edge of small towns is terrible. The entire approach to nuclear waste endangers public and environmental health; the idea of transporting high-level, long-lived radioactive waste coming to proposed so-called "centralize interim storage" waste facilities ("parking lot dumps") is unsound. (0844-4 [Anonymous, Anonymous])

Comment: In 2012, the National Academy of Sciences raised concern about the increasing use of high-burnup fuels currently being discharged because of reduced cladding integrity.⁶ [footnote 6 text: National Academy of Engineering, Managing Nuclear Waste, Summer 2012, pp 21, 30. <http://www.nae.edu/File.aspx?id=60739>] This complicates storage and transport, as does aging. And it is not the NRC's or the nuclear industry's problem because the ownership of the fuel is transferred to the DOE and will be funded by taxpayers. (0851-8 [Thatcher, Tami])

Comment: A consolidated interim storage just requires "concrete, steel and fences" according to some nuclear boosters. But even predominantly Republican Utah would not accept an interim spent fuel storage facility in their state despite one being licensed by the Nuclear Regulatory Commission in Skull Valley. And symbolically, the DOE's Citizens Advisory Board at the Savannah River Site in South Carolina recently voted against being a potential interim storage site, fearing their site could become the permanent home for the waste.⁷ [footnote 7 text: "Advisory panel votes not to store nuclear waste at Savannah River Site"]

<http://www.timesfreepress.com/news/2013/jul/24/advisory-panel-votes-not-store-nuclear-waste-savan/> and more discussion at <http://www.nukewatch.org/media2/postData.php?id=2873>] (0851-9 [Thatcher, Tami])

Comment: I oppose any plan for transportation and/or "temporary storage" of existing nuclear waste. We do not at this time have -- or reasonably foresee -- any technology to make transport or storage safe. We do know that moving nuclear waste through an area, and siting it in an area, will inflict life-destroying damage that is for all intents and purposes permanent. (0852-1 [Ein, Mark])

Comment: My family lives in San Clemente, California, approximately 6 miles from the San Onofre Nuclear Generating Station. I am writing to thank you for shutting down the nuclear plant, and to implore you to move the tons of radioactive waste accumulating on site to a safer location far from population centers. (0855-1 [Holloway, Patricia])

Comment: Immediately reduce spent fuel pool density to original design standards, without exemptions (0860-8 [Headrick, Gary])

Comment: NRC proposed plans call for the movement of spent nuclear fuel to dry cask storage systems (DCSS) if storage is necessary for more than 60 years after the end of operating licenses. The long term safety and security of DCSS is therefore essential to the proposed rule system update. The response of new or mildly aged dry casks to a wide range of external events is very well understood^{3, 4}, [footnote 3 text: United States Nuclear Waste Technical Review Board. *Evaluation of the Technical Basis for the Extended Dry Storage and Transportation of Used Nuclear Fuel*. (December 2010) Retrieved from <http://www.nwtrb.gov/reports/eds-final.pdf>] [footnote 4 text: Saegusa, Toshiaki et al. *Experimental Studies on Safety of Dry Cask Storage Technology of Spent Fuel: Allowable Temperature of Cladding and Integrity of Cask under Accidents*. (March 1996)] and the best available technical analysis and experimental evidence indicate that continued storage of spent nuclear fuel can be made acceptably safe by use of dry cask storage systems and appropriate schedules of inspection, repair, and replacement (SIRR)⁵ [footnote 5 text: American Physical Society Nuclear Energy Study Group. *Consolidated Interim Storage of Spent Nuclear Fuel*. (February 2007) Retrieved from <http://www.aps.org/policy/reports/popa-reports/upload/Energy-2007-ReportInterimStorage.pdf>]. The proposed NRC updates accurately reflect this technical consensus that dry cask storage systems can be used to safely store spent nuclear fuel. (0863-3 [Brinton, Samuel] [Curtis, Daniel])

Comment: Many uncertainties in the analysis of dry cask aging and lifetimes remain poorly quantified. The uncertainty on the overall safe lifetime of DCSS in different environments, or with different levels of stored fuel burnup, requires additional research to more effectively quantify. This research could make substantial strides in the short term, given currently available experimental results, technical analysis, and performance data. The results could be used to establish appropriate margins for schedules of inspection, repair, and replacement with greater confidence. Ongoing research is necessary to analyze dry cask system performance data over time and reduce the uncertainties described above. The Nuclear Waste Technical Review Board has already called for similar research in their recent technical basis evaluation³. [footnote 3 text: United States Nuclear Waste Technical Review Board. *Evaluation of the Technical Basis for the Extended Dry Storage and Transportation of Used Nuclear Fuel*. (December 2010) Retrieved from <http://www.nwtrb.gov/reports/eds-final.pdf>] (0863-6 [Brinton, Samuel] [Curtis, Daniel])

Comment: And finally, ongoing research is needed to quantify and reduce the uncertainties associated with the lifetimes of dry cask storage systems. (0863-9 [Brinton, Samuel] [Curtis, Daniel])

Comment: As we saw at Fukushima, the dry casks survived-they did not explode, burn, or leak as the fuel pools did. In addition, dry casks do not need a continual inflow of liquid to prevent further destruction; they are instead passively cooled by airflow. (0864-10 [Gellert, Sally Jane])

Comment: In addition, new technologies create new risks; for the past 16 years you have allowed "high-burn-up fuel", which burns longer and hotter in the reactor; when removed, this fuel needs up to twice as long in cooling pools as well as more space between fuel rods in the already-crowded pool. When a colleague asked about the percentage of high-burn-up fuel at Indian Point, it was suggested to her that that information might not be released for reasons of "national security". However, local security must also be considered: without enough of an estimate to understand whether the irradiated fuel rods are being stored safely, I am concerned that Woodcliff Lake and the area surrounding Indian Point and other reactors are even more at risk than they inherently are simply because of the nuclear reactors. I therefore request that this information be made public and that priority be given to ensuring that neighbors of these installations have all the information we need to ensure that all that can be done to protect our health and property is in fact being done. (0864-5 [Gellert, Sally Jane])

Comment: There is currently not a realistic plan for centralized national storage, and I would prefer to see efforts being spent not on trying to create one, but instead on providing the safest possible storage on site at reactors across the country. I realize that this means permanent storage of Indian Point waste less than 50 miles from my home, but that is a consequence of decisions made that cannot be reversed. (0864-7 [Gellert, Sally Jane])

Comment: Spent fuel is currently eligible to be removed from a fuel pool and moved into dry storage after five years. The NRC here assumes that there will be money, equipment, available expertise and an ISFSI capable of handling the waste. Additionally, the NRC assumes waste can be safely held in the fuel pool for 55 years. The reality is that fuel pools are filling or full to capacity and everyday operations create more and more inventory that must be addressed in the near future. (0867-2-6 [Griffin, William])

Comment: The DGEIS assumes that spent fuel remains intact as time passes. This may not be the case. Recent work prepared by the Pacific Northwest Laboratory (PNL) indicates that the properties of spent nuclear fuel are not well understood at the current levels of burnup (exceeding 45 gigawatt-days per metric ton of uranium [GWd/MTU]). The report concluded that: "Because limited information is available on the properties of high burnup fuel, and because much of the fuel currently discharged from today's reactors exceeds this burnup threshold, a particular emphasis of this program is on high burnup fuels assumptions that are not appropriate for generic appraisal" (PNL p. viii). The fuel being discharged from operating nuclear power plants has properties that are not currently well understood. It is not clear that the NRC has a basis for making future projections about the indefinite handling of spent nuclear fuel, given the absence of reliable technical information. (0867-3-14 [Griffin, William])

Comment: The proposed interim storage sites until a final solution is found makes no sense either. It would just double the shipments and exposure to accidents. This temporary solution would also take decades to implement. Keeping the waste on site in dry casks also is not a good solution but seems the best alternative for now to moving the waste multiple times. (0883-2 [McArdle, Ed])

Comment: Of course, some sites are not appropriate for cask storage such as the Palisades nuclear station where they are placed on unstable sand dunes. It should be realized that there is a special problem at Fermi 2. They are unable to transfer the radiated waste from the fuel pools to casks because of defects in the original construction. (0883-4 [McArdle, Ed])

Comment: Meanwhile, the NRC continues to allow waste to be stored in the fuel pools way beyond the design capacity. There is now over 620 tons of the most dangerous substances on earth stored in a pool five stories above. This is more irradiated fuel there than all the Fukushimas put together. (0883-5 [McArdle, Ed])

Comment: The author attached the following reports she referred to in the 00328-14 Minnetonka transcript: McKinnon, M.A. 1995. "Spent Fuel Integrity During Dry Storage." PNL-SA-25969, Pacific Northwest Laboratory, Richland, WA. Nuclear Regulatory Commission. 2013. "Premature Degradation of Spent Fuel Storage Cask Structures and Components from Environmental Moisture." NRC Information Notice 2013-07, Washington, D.C. Available at <http://pbadupws.nrc.gov/docs/ML1232/ML12320A697.pdf>. And 2 Idaho National Environmental Laboratory reports concerning a stuck fuel assembly: "Experiences in Transfer of Canisters from the TN-24P Cask to the VEC-17 Concrete Cask" (1990); (unreadable microfiche). "Evaluation of Options, Associated Costs, and Recommendations for (A) The "Stuck" Fuel Canister in the TN-24P Cask (B) Related Cask Move Operations, and (C) Resolution of VSC-17 Pressure Behavior" (1990); (unreadable microfiche). (0884-1 [Overland, Carol])

Comment: I am writing to support the NRC's Spent Fuel Storage Rule. In my view, with NRC oversight, PG&E has a very detailed and successful spent fuel management program for its Diablo Canyon nuclear power plant (Diablo). PG&E continues to safely store fuel via both its wet and dry cask storage systems. Without the federal government providing a permanent geologic storage facility, as required by law, PG&E has designed and implemented an interim, on-site system for the interim storage of the spent fuel assemblies. After removal from the reactors, the used fuel is placed in storage pools to cool for approximately five (5) years. After sufficient cooling, the used fuel assemblies are placed in sealed, Helium-filled canister and set inside a 20 foot tall, concrete-filled, steel storage cask. The storage casks are stored in a secure protected area proximate to the plant. Unlike other nuclear plants, the casks in the storage area are bolted to a seven and-a-half-foot thick steel-reinforced concrete pad to ensure it is seismically stable. This system has proved safe and effective. There is no reason to believe that this interim storage system would not remain viable after the Diablo plant's licensing period. I am confident that layer upon layer of safeguards are in place to effectively manage and monitor the stored spent fuel. (0885-1 [Anderson, Cody])

Comment: I am writing to support the NRC's Spent Fuel Storage Rule. PG&E has been a vital and crucial part of the community here on the Central Coast of California for decades with an impeccable safety record. I believe that with NRC oversight PG&E has a very detailed and successful spent fuel management program that continues to safely store fuel via both its wet and dry cask storage systems. I am confident that with multiple layers of safeguards in place stored spent fuel is being handled in a safe manner. (0886-1 [Lind, Jeff])

Comment: In fact, the DGEIS flouts both NEPA and the Court's application of NEPA in *New York*, 681 F.3d 481 (D.C. Cir. 2012) in multiple ways: The DGEIS' analysis of the environmental impacts of extended spent fuel storage ignores the fact that NRC knows very little about the behavior of spent fuel in long-term or indefinite storage conditions, especially the potentially significant effects of long-term dry cask storage on high burnup fuel integrity. In violation of

NEPA, the NRC makes no attempt to quantify these uncertainties. (0897-1-9 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: It will take a long time, potentially well over a decade, to collect the data needed to make scientifically valid impact analyses for high burnup fuel stored for long periods. Necessary research tasks include development of a sound database for a scientifically valid evaluation of the environmental impacts of prolonged storage of spent fuel, including high burnup spent fuel up to 62.5 GWd/MTU and MOX spent fuel. In addition, there are essentially no data available for high burnup spent fuel that has been stored in dry casks for extended periods of time. The deficiencies in the NRC's understanding of spent fuel characteristics and behavior under long-term storage conditions are further addressed in the attached declaration of Dr. Arjun Makhijani, pars. 4.1-4.35. (0897-2-20 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: In his declaration, Dr. Makhijani lists a number of spent fuel degradation phenomena that could affect the safety of spent fuel during long-term storage. Safety parameters that could be compromised include confinement, criticality, retrievability, shielding, structural, and thermal. Makhijani Declaration, par. 4.18. Impacts of spent fuel degradation could be serious enough to result in environmental releases during spent fuel inter-cask transfer and could result in more severe impacts in cases of accidents. *Id.* For instance, little is known about the extent to which microbiologically induced corrosion could corrode seals and/or the cask body that affect containment. Laboratory work and examination of spent fuel of different levels of burnup stored for long periods in spent fuel pools followed by long-term storage in dry casks is needed. Makhijani Declaration, par. 4.19. Other phenomena that may cause degradation include stress corrosion cracking, delayed hydride cracking, and low temperature creep. The NRC Draft Report on Technical Information Needs notes that "All three mechanisms depend on a source of stress that would come from pellet swelling. If the stress is not present, the mechanisms become benign. If operative, these mechanisms could increase the source term and increase cladding stress. The latter could affect containment, especially if other degradation processes have compromised the canister." Makhijani Declaration (quoting Draft Report at 6-2). In other words, the NRC does not know at present whether corrosion of seals or the canister body may occur to an extent that compromises containment. Damage to canisters could set the stage for severe releases either during inter-cask transfer or because the canister itself degrades. Makhijani Declaration, par. 4.20. (0897-4-10 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Dr. Makhijani also observes that high burnup fuels tend to build up much thicker levels of oxide during the in-reactor period as well as much higher levels of hydrogen in the cladding. Figure 2 of Dr. Makhijani's declaration shows that the typical increase in outer oxide layer thickness increases from about 20 microns at 30 GWd/MTU to about 100 microns at about 62 or 63 GWd/MTU at discharge from the reactor. Moreover, the spread in the oxide layer thickness increases with burnup, indicating that some fraction of fuel rods may be at a much greater risk of failure. Makhijani Declaration par. 4.21 (citing NWTRB 2010, Figure 20). (0897-4-11 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The NWTRB has issued the following caution about prolonged spent fuel pool storage: Cladding may already have some small defects like tiny holes or hairline cracks, internal and external corrosion that has decreased the original metal wall-thickness, absorbed hydrogen, and hydride precipitation; however, it is very rare that new defects are detected while in the pool. Significant cladding defects can be detected during wet storage by monitoring stack off-gas for fission product gas leaks; if leaks are found, then assemblies are further inspected and breached fuel-rods are canned if necessary. Generally, a visual inspection is made of

assemblies to identify fuel assemblies that may need to be classified as damaged and require special handling. If the cladding is functionally undamaged, there is an insignificant risk of expected fuel oxidation [at the time of transfer to dry storage]. Given undamaged cladding and the visible transfer of assemblies into and out of wet storage, the fuel-assembly containment criterion is deemed satisfied. Thus, during wet pool storage, used fuel is not expected to experience significant deterioration before dry storage. *If pool storage of fuel is continued for an extended period, it will be necessary to assess and evaluate the effects on intact or damaged fuel.*⁸ [footnote 8 text: NWTRB 2010, p. 60, italics in the original.] Makhijani Declaration, par. 4.23 (citing NWTRB 2010, p. 60). Although the DGEIS assumes that pool storage could continue for periods approaching 140 years (the first spent fuel discharged during 80 years of licensed operation, plus 60 years of post-operating license storage), it has not included any uncertainty analysis relating to impacts of damage that may occur in some fraction of the spent fuel during such prolonged storage. *Id.* (0897-4-12 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The NWTRB has identified hydriding, creep and stress corrosion cracking to be “[t]he most significant potential degradation mechanisms affecting the fuel cladding during extended storage.” Makhijani Declaration, par. 4.25 (quoting NWTRB 2010, p. 10). These phenomena can lead to “failed fuel” under certain conditions. Fuel failure occurs when there is a rupture in the fuel cladding, allowing fuel pellets direct contact with the environment around the fuel, the reactor coolant, spent fuel pool water, the canister environment, or the general environment during inter-cask transfer of failed fuel. If detected during cask loading, failed fuel is normally put in a “can,” which is a special sleeve, prior to loading into the cask. But if failure occurs after dry storage commences, some fuel pellets could be exposed to the environment during transfer. The NRC has refused to state how it would transfer failed spent fuel. It plans to figure it out when the problem arises. Makhijani Declaration, par. 4.24. The DGEIS concludes that the phenomena leading to failed fuel (*i.e.*, hydriding, creep and stress corrosion cracking) are unlikely to cause significant problems in the “short-term.” DGEIS at B-13. With respect to long-term storage, the NRC claims to be ignorant of any studies “that would cause it to question the technical feasibility of continued safe storage of spent fuel in dry casks.” *Id.* But the Draft Study of Technical Needs admits that the level of knowledge regarding galvanic corrosion, stress corrosion cracking, low-temperature creep and propagation of existing flaws is “low”; and that knowledge of delayed hydride cracking is only “medium.” The NRC’s amnesia regarding its own study undermines the credibility and integrity of the DGEIS. Makhijani Declaration, par. 4.25. Incredibly, the only explicit mention of failed fuel in the DGEIS is in the context of spent fuel pool leaks: Impacts from spent fuel pool leakage occur from radionuclide contaminants present in spent fuel pool water. The sources of radionuclide contaminants in spent fuel pool water are activation products and fission products. Activation products are elements formed from the neutron bombardment of a stable element and fission products are elements formed as a byproduct of a nuclear reaction and radioactive decay of other fission products. *The sources of activation products are corrosion and wear deposits (including corrosion films on the fuel bundle surfaces).* Fission products come from bundles with rods that failed in-reactor or from intact bundles that adsorbed circulating fission products.⁹ [footnote 9 text: DGEIS at E-10 (emphasis added).] DGEIS at E10 (emphasis added). The NRC’s limitation of its consideration of failed fuel to short-term storage conditions is grossly insufficient, given that the principal long-term risks are likely to arise after prolonged storage has resulted in serious fuel degradation of some fraction of the fuel rods, notably in the case of high burnup spent fuel. Makhijani Declaration, par. 4.26. (0897-4-13 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The NRC’s failure to address the effects of failed fuel on safety and environmental risk is all the more remarkable in the context of the NRC’s own admission that it does not yet know how it will transfer such failed spent fuel. The NRC has no experience in transferring

failed fuel from one cask to another. By NRC's own admission, it has not even developed the procedures to do so. Makhijani Declaration, par. 4.27. The NRC also has no basis in data or experience in estimating how much additional damage could be done to failed fuel by transferring it between casks. This would apply even to damaged medium burnup fuel stored for short or moderate periods of time (up to two or three decades) in dry casks. It is a *fortiori* true of high burnup spent fuel that has been stored for many decades or even a few hundred years, given the considerations about such spent fuel discussed in the rest of this section. Makhijani Declaration, par. 4.28. Indeed, in this context, Dr. Makhijani observes that no spent fuel bundle, damaged or not, has ever been transferred from one dry cask to another. Further, while the DGEIS postulates a Dry Transfer System for fuel inspection, repackaging and transfer, such a facility has never been built in the United States. The NRC even refuses to say how it would handle and repackage failed fuel. This makes the lack of discussion of the impacts of the transfer of failed spent fuel bundles even more problematic since the NRC lacks sufficient empirical basis for estimating the probabilities and consequences of the spread of radioactivity during transfers in the normal case. Makhijani Declaration, par. 4.29. In failing to address the issue of failed spent fuel inter-cask transfers, the NRC also has ignored the fact that failed spent fuel bundles are already stored in dry casks, but have never had to undergo inter-cask transfers. For instance, there are 95 failed spent fuel bundles stored in 15 dry casks at San Onofre Nuclear Generating Station alone. Makhijani Declaration, par. 4.30. (0897-4-14 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: As discussed above, NWTRB has proposed an extended research program to address the lack of data regarding spent fuel characteristics. It is also important to have dry storage performance data on the newer cladding materials that have been developed to enable high fuel burnup, which is a relatively recent practice (since about the turn of the century). There are practically no such data. Indeed, even the research has been focused mainly on in-reactor behavior of high burnup fuels rather than on degradation during prolonged storage. Makhijani Declaration, par. 4.31. (0897-4-15 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Safety and environmental risks of storing other forms of spent fuel are ignored or tossed off with scant attention in the DGEIS. For instance, the U.S. is building a MOX plant to convert weapons grade plutonium into commercial reactor fuel. There is no significant experience with irradiation of such MOX fuel in a commercial reactor in the United States. Only lead test assemblies have been irradiated. Therefore there is essentially no experience with storage of commercial MOX spent fuel in the United States in wet or dry storage for any length of time. France, which has the most experience with MOX spent fuel, stores it in pools and has no dry storage. The DGEIS simply assumes away the problem of MOX spent fuel with the following statement: Because the MOX fuel that would be generated at the Mixed Oxide Fuel Fabrication Facility is substantially similar to existing light water reactor fuel and is, in fact, intended for use in existing light water reactors in the United States, MOX fuel from this project is within the scope of this DGEIS.¹⁰ [footnote 10 text: DGEIS at 2-8.] Contrary to the claim in the DGEIS MOX fuel is decidedly *not* "substantially similar to existing light water reactor fuel." In the former the fissile material is plutonium, which has different nuclear characteristics (a smaller delayed neutron fraction, for instance) than current low-enriched uranium reactor fuel. Even more importantly for the present purposes, the characteristics of the spent fuel will be different. For instance, uranium spent fuel from a PWR with initial 4.25 percent enrichment and burnup of 50 GWd per metric ton would have about 1 percent plutonium isotopes in it at discharge, including about half-a-percent plutonium-239. For the same burnup MOX fuel would typically have 8.46 percent total plutonium to start with. The spent fuel from a PWR would have about five times as much total plutonium, and about three- and-half-times as much plutonium-239. Makhijani Declaration, par. 4.32. In the example provided (50 GWd per metric ton burnup in a

PWR), the MOX spent fuel would have about six-and-a-half-times the amount of plutonium-241 as the uranium spent fuel. Plutonium-241 decays into americium-241 relatively rapidly with a half-life of just 14.4 years. Americium-241 has a half-life of 432 years.¹¹ [footnote 11 text: Properties of radionuclides, including half-lives and dose conversion factors can be found in FGR 13 CD 2002.] Unlike plutonium-239 and plutonium-241, americium-241 is a powerful gamma radiation emitter; it would pose special problems during spent fuel transfer, long after the main gamma-emitting fission product, cesium-137 (half-life about 30 years), would have decayed away. These problems associated with americium-241 gamma radiation dose would extend to post-accident recovery in case of release of radionuclides from the spent fuel. Makhijani Declaration, par. 4.33. It stretches credulity that the NRC staff is not aware of these critical differences that would make a significant difference between impacts of MOX spent fuel and uranium spent fuel. In any case, the DGEIS assertion that there the two are substantially similar is wrong. A specific impact analysis is needed for MOX spent fuel. Makhijani Declaration, par. 4.34. (0897-4-16 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Similarly, the DGEIS pays little heed to the environmental impacts of extended storage of stainless steel fuel cladding. As Dr. Makhijani points out, stainless steel was used as fuel cladding early in the history of U.S. commercial reactors. By 1994, only one reactor had any stainless steel clad fuel in its core. By 1992, a total of 679 metric tons of spent fuel (uranium heavy metal content) had been generated from the stainless steel clad fuel. Further, the use of stainless steel cladding was discontinued partly because of in-reactor degradation of stainless steel cladding. For instance, the stainless steel cladding in the Connecticut Yankee reactor "experienced a number of fuel element failures" between 1977 and 1980, even though it had performed well in this regard prior to that time. The degradation characteristics of stainless steel fuel are different than zircaloy fuel and needed to be explicitly considered in the DGEIS. The DGEIS catalogs the amount of stainless steel spent fuel but does not discuss the failed fuel or its transfer from one dry cask to another. It does not discuss whether accidents involving such failed fuel would have more or less severe consequences than failed zircaloy-clad fuel. Makhijani Declaration, par. 4.35. (0897-4-17 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The DGEIS cites just one study (Billone et al. 2013) that has evidence about the deterioration of high burnup spent fuel during drying and subsequent storage. DGEIS at B-13. Even so, the lessons contained in this study, such as the implications of degradation for accident consequences or the differences between risks of various zirconium alloys used as cladding material are not discussed in the Draft GEIS. (0897-4-2 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The DGEIS omits any mention of the fact that elsewhere, the NRC has acknowledged that it has a serious lack of information about the behavior of spent fuel stored for long periods. Makhijani Declaration, par. 4.8. In May 2012, the NRC published a *Draft Report for Comment: Identification and Prioritization of the Technical Information Needs Affecting Potential Regulation of Extended Storage and Transportation of Spent Nuclear Fuel* ("Draft Report on Technical Information Needs" or "Draft Report"). This report catalogs what is known, as well as the gaps in knowledge, of spent fuel degradation mechanisms. Some of the gaps will require extensive new data and a considerable amount of time to fill. The Draft Report on Technical Information Needs was based on a number of prior reports, data from physical examination of some "lower burnup" spent fuel, and extrapolation from this data to 80 years. Based on this data, the Draft Report concluded:The current regulatory framework supports at least the first 80 years of dry cask storage (i.e., a 40-year initial licensing term, followed by a license renewal for a term of up to 40 years, although many of the existing facilities were licensed for an initial term of 20 years under the regulations in place at the time). The technical

basis for the initial licensing and renewal period is supported by the results of a cask demonstration project that *examined a cask loaded with lower burnup fuel* (approximately 30 GWd/MTU [gigawatt-days per metric ton uranium] average; all fuel burnup in this paper is given as peak rod average value). Following 15 years of storage, the cask internals and fuel did not show any significant degradation (Einziger et al., 2003). The data from this study can be extrapolated to maintain a licensing safety finding that *low burnup SNF* can be safely stored in a dry storage mode for at least 80 years with an appropriate aging management program that considers the effects of aging on systems, structures, and components (SSCs). (0897-4-3 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Makhijani Declaration, par. 4.8 (emphasis added). Note that the existing licensing and license extension procedures are based on examination of a single cask of relatively low burnup uranium dioxide spent fuel that had been in dry storage for only 15 years. The Draft Report lists data extensive requirements for extending this analysis to: • high burnup spent fuel that would be stored from 120 years to 300 years; • spent fuel burnups up to about 62.5 GWd/MTU; • mixed oxide (MOX) spent fuel (which has plutonium-239 instead of uranium-235 as the fissile material that sustains the chain reaction); and • new cladding, fuel compositions, and assembly designs that have been and will continue to be put into use. Makhijani Declaration, par. 4.9 & Table 6-1. In the Draft Report, the NRC proposed to undertake a seven-year study of the phenomena identified in the Draft Report; but the plan was deferred when resources were diverted to the preparation of the Waste Confidence DGEIS. Makhijani Declaration, par. 4.12. As Dr. Makhijani observes, the NRC's failure to mention in the DGEIS the agency's own previously expressed concerns about the data gaps essential to understanding high burnup and MOX spent fuel and spent fuel with new cladding materials is an egregious technical omission. The missing data are critical to assessing the health and environmental impacts of spent fuel; gathering the data will need extensive additional research. Whenever a scientist lacks sufficient information to evaluate an issue, it is essential to identify the missing information and, at the very least, conduct an uncertainty analysis. Neither of those steps was taken by the NRC in the DGEIS. On the contrary, the one study that the NRC cited to justify its conclusion that impact accident consequences would be low explicitly did not consider uncertainties. The NRC's failure to mention its own documented concerns about spent fuel characteristics seriously compromises the scientific integrity of the DGEIS. Makhijani Declaration, par. 4.12. (0897-4-4 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The NRC's failure to acknowledge the amount of information that is lacking regarding spent fuel behavior over the long-term is all the more disturbing in light of the fact that the Nuclear Waste Technical Review Board ("NWTRB") has expressly acknowledged the dearth of information regarding spent fuel integrity and degradation. Makhijani Declaration, par. 4.13. NWTRB confirms that at present no U.S. data are available for high burnups (up to 62.5 GWd/MTU) for any of the NRC's storage scenarios, or for periods of storage anywhere comparable to the long timeframe of hundreds of years that the NRC will have to consider in its Waste Confidence EIS in one or more scenarios. Predictions, estimates or projections that the NRC may make of the effects of high burnup spent fuel storage, particularly over long-term periods, in its Waste Confidence EIS cannot be validated with scientific data or observations with presently available information. Such validation is essential for reliable and scientifically acceptable estimates of the environmental and health impacts of long-term storage and transportation. Makhijani Declaration, par. 4.13. (0897-4-5 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: The NWTRB also commented on the lack of information about interactions between different degradation mechanisms as well as the possible effect of high burnup on those

interactions: These [degradation] mechanisms and their interactions are not well understood. New research suggests that the effects of hydrogen absorption and migration, hydride precipitation and reorientation, and delayed hydride cracking may degrade the fuel cladding over long periods at low temperatures, affecting its ductility, strength, and fracture toughness. *High-burnup fuels tend to swell and close the pellet-cladding gap, which increases the cladding stresses and can lead to creep and stress corrosion cracking of cladding in extended storage.* Fuel temperatures will decrease in extended storage, and cladding can become brittle at low temperatures.⁷ [footnote 7 text: NWTRB 2010, p. 11, italics added.] Makhijani Declaration, par. 4.14 (quoting NWTRB Report, p. 11, italics added). Hence, high burnup could possibly combine with other factors to create conditions that would result in severe, if not catastrophic, releases of radioactivity. This possibility must be studied. *Id.* (0897-4-6 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Besides the NRC staff's 2012 proposal, the NWRTB has also proposed an extended research program to address the problem of the lack of data. The NWTRB research and development recommendations include: • Understanding the ultimate mechanical cladding behavior and fuel-cladding degradation mechanisms potentially active during extended dry storage, including those that will act on the materials introduced in the last few years for fabrication of high-burnup fuels • Understanding and modeling the time-dependent conditions that affect aging and degradation processes, such as temperature profiles, in situ material stresses, quantity of residual water, and quantity of helium gas • Modeling of age-related degradation of metal canisters, casks, and internal components during extended dry storage • Inspection and monitoring of fuel and dry-storage systems to verify the actual conditions and degradation behavior over time, including techniques for ensuring the presence of helium cover gas • Verification of the predicted mechanical performance of fuel after extended dry storage during cask and container handling, normal transportation operations, fuel removal from casks and containers, off-normal occurrences, and accident events • Design and demonstration of dry-transfer fuel systems for removing fuel from casks and canisters following extended dry storage (0897-4-7 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: Dr. Makhijani also points out that other institutions have also analyzed the critical data gaps regarding high burnup degradation and its implications for storage, transport and disposal. For instance, a 2012 paper published by the National Academy of Engineering noted the following: Based on its assessment, the study board concluded that the technical basis for the spent fuel currently being discharged (high utilization, burnup fuels) is not well established and that the possibility of degradation mechanisms, such as hydriding, will require more study. The NWTRB recommended periodic examinations of representative amounts of spent fuel to ensure that degradation mechanisms are not in evidence. (0897-4-8 [Curran, Diane] [Goldstein, Mindy] [Kysor, Jillian])

Comment: In fact, the available evidence suggests that both long-term storage and disposal of spent fuel could pose significant safety and environmental risks. Further, the costs of long-term storage and disposal could run into hundreds of billions of dollars. The NRC should prepare a new Draft GEIS that meaningfully examines these risks. (0898-1-11 [Curran, Diane] [Makhijani, Arjun])

Comment: The study cited by the NRC for public health impact only considered spent fuel stored in a pool for 10 years followed by dry storage for 20 years.⁵¹ [footnote 51 text: Billone et al. 2013, p. 431] The experiments of Billone et al. on high burnup fuel – the only study cited in the Draft GEIS regarding damage to spent fuel as a result of high burnup – showed significant damage to high burnup fuel upon drying: Pre-storage drying-transfer operations and early stage

storage subject cladding to higher temperatures and much higher pressure-induced tensile hoop stresses relative to in-reactor operation and pool storage. Under these conditions, radial hydrides may precipitate during slow cooling and provide an additional embrittlement mechanism as the cladding temperature decreases below the ductile-to-brittle transition temperature (DBTT).⁵² [footnote 52 text: Billone et al. 2013, p. 431] Photographs in Billone et al. show clear damage, including significant cracks in the cladding. The Draft GEIS statement that this “could influence the approach used for repackaging spent fuel” is so limited in scope as to provide almost no insight into the environmental impacts during accidents, further degradation during prolonged storage, and during handling and transfer operations. Repackaging is far from the only or even the most important issue from the environmental point of view. We note that the NRC has yet to demonstrate how it will transfer damaged spent fuel from one cask to another (see paragraph 4.27 below). Figure 1 shows the trends in burnup for PWRs and BWRs. It shows that high burnup fuel (more than 45 GWd per metric ton) started being discharged from reactors only around the turn of the century. Most of this is still in spent fuel pools. Examination of high burnup spent fuel after dry storage of 15 years, as was done for low burnup Surry fuel,⁵³ [footnote 53 text: Einziger et al. 2003] is not yet possible, though some experimental work with high burnup fuel cladding has been done.⁵⁴ [footnote 54 text: Billone et al. 2013] **(0898-1-16** [Curran, Diane] [Makhijani, Arjun])

Comment: The Draft GEIS assumes that spent fuel bundles can be stored for millennia and repeatedly transferred hundreds of times from one cask to another without large releases of radioactivity. But the Draft GEIS contains almost no information about spent fuel characteristics that could cause adverse safety risks and environmental impacts in case of long-term or indefinite storage, both during storage and during the many transfers that must take place. As noted in paragraph 4.5 above, even drying upon removal from the spent fuel pool and early dry cask storage drying induce significant embrittlement in high burnup spent fuel. Further, Billone et al. also found that the degradation is dependent upon the specific zirconium alloy used in the cladding material. Specifically, there was a significant difference in radial hydriding and the ductile-to-brittle transition temperature between ZIRLO and zircaloy-4 cladding subjected to high burnup.⁵⁵ [footnote 55 text: Billone et al. 2013, p. 446] The Draft GEIS says nothing about the significance of these findings for accident impacts, inter-cask transfer operations, or transportation risks. Further, little-understood factors affecting the safety of spent fuel storage include the degree to which spent fuel and its host containers corrode and degrade over a prolonged period of time, the phenomenon of “failed fuel,” and the effect of high burnup fuel on the integrity of cladding and storage containers. The Draft GEIS contains no analysis of how spent fuel characteristics may contribute to the risk of an accidental release of radioactivity during extended storage of dry casks; or how these factors may contribute to accident risks during the many transfers that would take place over an extended period of time, i.e., transfers between pools and casks, transfers between storage casks, transfers between storage and transportation casks, and transfers between transportation casks and casks used for ultimate disposal of spent fuel. **(0898-1-17** [Curran, Diane] [Makhijani, Arjun])

Comment: The NRC has cited just one study (Billone et al. 2013) that has evidence about the deterioration of high burnup spent fuel during drying and subsequent storage.⁵⁶ [footnote 56 text: NRC 2013a, p. B-13. Two of the four other studies cited, Bare et al. 2001 and Einziger et al. 2003, deal with low burnup fuel that has been stored – in fact, they relate to an examination of the same low burnup fuel from the Surry plant in Virginia. The third, IAEA 2006, makes a general assertion that international experience indicates that dry storage is satisfactory and only “a few” rod failure have been detected by sampling of cover gases. The study also refers to the same Surry cask examination as the other two as evidence of storage (IAEA 2006, p. 21). It does not deal explicitly with safety issues that might arise with high burnup fuel, though it notes

that there is “a strong interest in extending the technical basis to license storage of power reactor fuel assemblies with burnups above 45 000 MW•d/MTU.” (IAEA 2006, p. 21). The fourth, EPRI 1998, was prepared early in the high burnup era. Even so it flagged concerns about high burnup spent fuel at several points, including at the very start: “As the utilities push to higher and higher burnups, eventually the behavior of the fuel in storage of any duration will need to be considered.” The document goes on to identify a number of concerns (EPRI 1998, p. iv). The EPRI study notes that high burnup spent fuel had not been studied “to date.” (EPRI 1998, p. 6-7).] Even so, the lessons contained in this study, such as the implications of degradation for accident consequences or the differences between risks of various zirconium alloys used as cladding material are not discussed in the Draft GEIS. (0898-1-18 [Curran, Diane] [Makhijani, Arjun])

Comment: However, the NRC has acknowledged elsewhere that it has a serious lack of information about the behavior of spent fuel stored for long periods. In May 2012, the NRC published a *Draft Report for Comment: Identification and Prioritization of the Technical Information Needs Affecting Potential Regulation of Extended Storage and Transportation of Spent Nuclear Fuel* (Draft Report on Technical Information Needs).⁵⁷ [footnote 57 text: NRC 2012a] This report catalogs what is known, as well as the gaps in knowledge, of spent fuel degradation mechanisms. Some of the gaps will require extensive new data and a considerable amount of time to fill. 4.8. The Draft Report on Technical Information Needs was based on a number of prior reports, data from physical examination of some “lower burnup” spent fuel, and extrapolation from this data to 80 years. Based on this data, the Draft Report concluded as follows:The current regulatory framework supports at least the first 80 years of dry cask storage (i.e., a 40-year initial licensing term, followed by a license renewal for a term of up to 40 years, although many of the existing facilities were licensed for an initial term of 20 years under the regulations in place at the time). The technical basis for the initial licensing and renewal period is supported by the results of a cask demonstration project *that examined a cask loaded with lower burnup fuel* (approximately 30 GWd/MTU [gigawatt-days per metric ton uranium] average; all fuel burnup in this paper is given as peak rod average value). Following 15 years of storage, the cask internals and fuel did not show any significant degradation (Einziger et al., 2003). The data from this study can be extrapolated to maintain a licensing safety finding that *low burnup SNF* can be safely stored in a dry storage mode for at least 80 years with an appropriate aging management program that considers the effects of aging on systems, structures, and components (SSCs).⁵⁸ [footnote 58 text: NRC 2012a, p. 1-1, italics added] (0898-1-19 [Curran, Diane] [Makhijani, Arjun])

Comment: Note that the existing licensing and license extension procedures are based on examination of a single cask of relatively low burnup uranium dioxide spent fuel that had been in dry storage for only 15 years. The paper lists data requirements for extending this analysis to: • high burnup spent fuel that would be stored from 120 years to 300 years⁵⁹ [footnote 59 text: NRC 2012a, p. 1-2] – that is from about six times to about 16 times longer than the total 19-year storage time (15 years of dry storage plus four years of wet storage) of the spent fuel that was examined in Einziger et al. 2003;⁶⁰ [footnote 60 text: The wet storage time was about 3.7 years (Einziger et al. 2003, p. 6); it has been rounded to four years for this calculation.] • spent fuel burnups up to about 62.5 GWd/MTU,⁶¹ [footnote 61 text: NRC 2012a, p. 3-1] about double the irradiation of the spent fuel that was examined; • mixed oxide (MOX) spent fuel (which has plutonium-239 instead of uranium-235 as the fissile material that sustains the chain reaction), even though there are hardly any data on MOX fuel degradation after dry storage; MOX fuel may be “more susceptible” to some forms of degradation, according to the Nuclear Waste Technical Review Board;⁶² [footnote 62 text: NRC 2012a, p. A2-2, A2-4, and A4-3, for instance] • “new cladding, fuel compositions, and assembly designs that have been and will continue to be put into use.”⁶³ [footnote 63 text: NRC 2012a, p. 3-1] (0898-1-20 [Curran, Diane] [Makhijani, Arjun])

Comment: The data requirements are extensive even by the NRC staff's own accounting. According to Table 6-1 in the Draft Report on Technical Information Needs, there are 23 different degradation phenomena that have a ranking of "high" in terms of "the need for further research"⁶⁴ [footnote 64 text: NRC 2012a, p. 6-1 and Table 6-1] in addition to the data available from the lower burnup/short storage time evaluations. (0898-1-21 [Curran, Diane] [Makhijani, Arjun])

Comment: The NRC's failure to mention in the Draft GEIS the agency's own previously expressed concerns about the data gaps essential to understanding high burnup and MOX spent fuel and spent fuel with new cladding materials is an egregious technical omission. The missing data are critical to assessing the health and environmental impacts of spent fuel; gathering the data will need extensive additional research, which appears essential for a credible impact analysis, including placing operationally meaningful uncertainty bounds on impacts. Without this basic information, the NRC has an inadequate foundation for scientifically sound predictive safety findings regarding the behavior of high burnup spent fuel in long-term storage conditions. The Draft GEIS made no attempt to place uncertainty bounds on impacts. On the contrary, as noted in paragraph 4.4 above, the one study that the NRC cited to justify its conclusion that impact accident consequences would be low explicitly did *not* consider uncertainties. The explicit reason cited in that study for not estimating uncertainties was that "the uncertainty of the database" was such that it "may introduce large errors..." in the analysis.⁶⁶ [footnote 66 text: NRC Pilot 2007, p. D-19, italics added] The data gaps relevant to long-term storage of high burnup fuel are much greater than those considered in the Pilot Study. The problem of putting bounds on the impacts is therefore much more serious, in light of the issues listed in Table 6-1 above. The NRC's failure to mention its own documented concerns about spent fuel characteristics seriously compromises the scientific integrity of the Draft GEIS. (0898-1-22 [Curran, Diane] [Makhijani, Arjun])

Comment: In addition, the Draft GEIS contains almost no information about spent fuel characteristics that could cause adverse safety risks and environmental impacts during long-term or indefinite storage. That is perhaps due to the fact that, in other contexts, the NRC itself has acknowledged that it currently lacks sufficient information to reach informed conclusions about the behavior of spent fuel in storage over the long term. Little-understood factors affecting the safety of spent fuel storage include the degree to which spent fuel and its host containers corrode and degrade over a prolonged period of time, the phenomenon of "failed fuel," and the effect of high burnup fuel on the integrity of cladding and storage containers. (0898-1-3 [Curran, Diane] [Makhijani, Arjun])

Comment: For instance, although high burnup fuel now makes up a significant portion of spent fuel inventories, there is no explicit consideration of long-term dry storage and disposal of failed high-burnup fuel. The cladding of such fuel degrades much more during reactor operation than low burnup fuel; continued degradation appears likely during prolonged storage. The NRC currently has little or no empirical data regarding its behavior under extended dry storage conditions. The NRC itself identified the data gaps in a Draft Study of Technical Needs in 2012¹³ [footnote 13 text: NRC 2012a] but failed to note these gaps in the Draft GEIS. The NRC's amnesia regarding its own study undermines the credibility and integrity of the Draft GEIS. The Draft GEIS contains no analysis of how high burnup spent fuel characteristics may contribute to the risk of an accidental release of radioactivity from spent fuel that has been stored for a long period in dry casks, preceded by prolonged (60 to 120 years) of storage in spent fuel pools; or how degradation may contribute to accidental releases and radiation exposure risks during the many transfers that would take place in case of long-term or indefinite storage. The NRC should factor in its own prior acknowledgement of the potential for degradation of high burnup spent

fuel and the low state of knowledge of a number of critical factors prior to declaring its confidence in the safety of long-term or indefinite spent fuel storage.¹⁴ [footnote 14 text: The Draft GEIS makes just one explicit substantive statement about degradation of high burnup fuel and that related to the “short-term” time frame: “This [reduced ductility] phenomenon could influence the approach used for repackaging spent fuel but the NRC is not aware of information that would require it to conclude that high-burnup fuel would need to be repackaged during the short-term timeframe defined in the Draft GEIS. Should spent fuel cladding be more brittle, greater care could be required during handling operations, regardless of when repackaging would occur, to limit the potential for damage to spent fuel assemblies that could affect easy retrievability of the spent fuel and complicate repackaging operations.” (NRC 2013a, p. B-13) (0898-1-4 [Curran, Diane] [Makhijani, Arjun])

Comment: The NRC’s failure to acknowledge the amount of information that is lacking regarding spent fuel behavior over the long-term is all the more disturbing in light of the fact that the Nuclear Waste Technical Review Board (NWTRB) has expressly acknowledged the dearth of information. In 2010, NWTRB reported with respect to spent fuel integrity and degradation: Only limited references were found on the inspection and characterization of fuel in dry storage, and they all were performed on low-burnup fuel after only 15 years or less of dry storage. *Insufficient information is available on high-burnup fuels to allow reliable predictions of degradation processes during extended dry storage, and no information was found on inspections conducted on high-burnup fuels to confirm the predictions that have been made.*⁶⁷ [footnote 67 text: NWTRB 2010, p. 11, italics added] Thus, NWTRB confirms that at present no U.S. data are available for high burnups (up to 62.5 GWd/MTU) for any of the NRC’s storage scenarios, or for periods of storage anywhere comparable to the long time frame of hundreds of years that the NRC will have to consider in its waste confidence GEIS in one or more scenarios. Predictions, estimates or projections that the NRC may make of the effects of high burnup spent fuel storage, particularly over long-term periods, in its waste confidence GEIS cannot be validated with scientific data or observations with presently available information. Such validation is essential for reliable and scientifically acceptable estimates of environmental and health impact of long-term storage and transportation. (0898-2-1 [Curran, Diane] [Makhijani, Arjun])

Comment: The Draft GEIS cites an at-reactor dry storage facility at Surry as a successful example of dry storage.⁷³ [footnote 73 text: NRC 2013a, p. B-12] The spent fuel from Surry that was examined after about 15 years of dry storage was found upon inspection to be functionally undamaged.⁷⁴ [footnote 74 text: Einziger et al. 2003, p. ix] Hence one can safely assume that the spent fuel was also functionally undamaged at the time of transfer from wet to dry storage. The results of the Surry study are unlikely to be applicable to fuel that has developed some damage during irradiation, for instance, due to higher burnup, or during spent fuel pool storage. Lack of damage during much more prolonged dry storage of high burnup fuel also cannot be assumed based on the Surry study. The NWTRB has issued the following caution about prolonged spent fuel pool storage: Cladding may already have some small defects like tiny holes or hairline cracks, internal and external corrosion that has decreased the original metal wall-thickness, absorbed hydrogen, and hydride precipitation; however, it is very rare that new defects are detected while in the pool. Significant cladding defects can be detected during wet storage by monitoring stack off-gas for fission product gas leaks; if leaks are found, then assemblies are further inspected and breached fuel-rods are canned if necessary. Generally, a visual inspection is made of assemblies to identify fuel assemblies that may need to be classified as damaged and require special handling. If the cladding is functionally undamaged, there is an insignificant risk of expected fuel oxidation [at the time of transfer to dry storage]. Given undamaged cladding and the visible transfer of assemblies into and out of wet storage,

the fuel-assembly containment criterion is deemed satisfied. Thus, during wet pool storage, used fuel is not expected to experience significant deterioration before dry storage. *If pool storage of fuel is continued for an extended period, it will be necessary to assess and evaluate the effects on intact or damaged fuel.*⁷⁵ [footnote 75 text: NWTRB 2010, p. 60, italics in the original] Though Draft GEIS assumes that pool storage could continue for periods approaching 140 years (the first spent fuel discharged during 80 years of total licensed operation, plus 60 years of post-operating license storage), it has not included any uncertainty analysis relating to impacts of damage that may occur in some fraction of the spent fuel during such prolonged storage. (0898-2-10 [Curran, Diane] [Makhijani, Arjun])

Comment: Fuel failure occurs when there is a rupture in the fuel cladding, allowing fuel pellets direct contact with the environment around the fuel, the reactor coolant, spent fuel pool water, the canister environment, or the general environment during inter-cask transfer of failed fuel. If detected during cask loading, failed fuel is normally put in a "can," which is a special sleeve, prior to loading into the cask. But if failure occurs after dry storage commences, some fuel pellets could be exposed to the environment during transfer. The NRC has refused to state how it would transfer failed spent fuel. It plans to figure it out then, as noted in paragraph 4.27 below. (0898-2-11 [Curran, Diane] [Makhijani, Arjun])

Comment: In the NWTRB study described above, NWTRB identified hydriding, creep, and stress corrosion cracking to be "[t]he most significant potential degradation mechanisms affecting the fuel cladding during extended storage."⁷⁶ [footnote 76 text: NWTRB 2010, p. 10] These phenomena can lead to "failed fuel" under certain conditions.⁷⁷ [footnote 77 text: NRC 2012a, pp. A1-6 and A1-7] The Draft GEIS concludes that these phenomena are unlikely to cause significant problems in the "short-term."⁷⁸ [footnote 78 text: NRC 2013a, p. B-13] With respect to long-term storage, the NRC claims to be ignorant of any studies "that would cause it to question the technical feasibility of continued safe storage of spent fuel in dry casks."⁷⁹ [footnote 79 text: NRC 2013a, p. B-13] But Table 6-1 of the Draft Study of Technical Needs admits that the level of knowledge regarding galvanic corrosion, stress corrosion cracking, low-temperature creep, and propagation of existing flaws is "low"; and that knowledge of delayed hydride cracking is only "medium." The NRC's amnesia regarding its own study undermines the credibility and integrity of the Draft GEIS. (0898-2-12 [Curran, Diane] [Makhijani, Arjun])

Comment: The only explicit mention of failed fuel in the Draft GEIS is in the context of spent fuel pool leaks: Impacts from spent fuel pool leakage occur from radionuclide contaminants present in spent fuel pool water. The sources of radionuclide contaminants in spent fuel pool water are activation products and fission products. Activation products are elements formed from the neutron bombardment of a stable element and fission products are elements formed as a byproduct of a nuclear reaction and radioactive decay of other fission products. *The sources of activation products are corrosion and wear deposits (including corrosion films on the fuel bundle surfaces).* Fission products come from bundles with rods that failed in-reactor or from intact bundles that adsorbed circulating fission products.⁸⁰ [footnote 80 text: NRC 2013a, p. E-10, italics added] This is grossly insufficient, since the principal long-term risks are likely to arise after prolonged storage has resulted in serious fuel degradation of some fraction of the fuel rods, notably in the case of high burnup spent fuel. (0898-2-13 [Curran, Diane] [Makhijani, Arjun])

Comment: The NRC's failure to address the effects of failed fuel on safety and environmental risk is all the more remarkable in the context of the NRC's own admission that it does not yet know how it will transfer such failed spent fuel. The NRC has no experience in transferring failed fuel from one cask to another. By NRC's own admission, it has not even developed the procedures to do so, as illustrated by the following 2001 decision by the NRC's technical staff:

The NRC staff believes that the petitioner has identified a valid concern regarding the potential recovery of fuel assemblies that unexpectedly degrade during storage. However, in this unlikely event, the NRC staff has concluded that there is reasonable assurance that a licensee can safely unload degraded fuel or address other problems. This conclusion is based on the NRC's defense-in-depth approach to safety that includes requirements to design and operate spent fuel storage systems that minimize the possibility of degradation; requirements to establish competent organizations staffed with experienced, trained, and qualified personnel; and NRC inspections to confirm safety and compliance with requirements. The NRC staff finds acceptable these procedures for detecting degraded fuel through sampling and, on the basis of the sample results, the implementation of appropriate recovery provisions that reflect the ALARA (as low as is reasonably achievable) requirements. The NRC staff's acceptance of this approach is based on the fact that the spent fuel storage cask can be maintained in a safe condition *during the time needed to develop the necessary procedures and to assemble the appropriate equipment before proceeding with cask unloading.* The NRC staff also relies on the considerable radiological safety experience available in the nuclear industry in its assessment that appropriately detailed procedures can be prepared for the specific circumstances in a timely manner.⁸¹ [footnote 81 text: NRC 2001, p. 9058, italics added] While this "kicking the can down the road" may have been a legally valid response to the petition, it can no longer be sustained in the context of the waste confidence GEIS. The issue is material to environmental impacts, which the NRC is obliged to estimate. (0898-2-14 [Curran, Diane] [Makhijani, Arjun])

Comment: The NRC also has no basis in data or experience in estimating how much additional damage could be done to failed fuel by transferring it between casks. This would apply even to damaged medium burnup fuel stored for short or moderate periods of time (up to two or three decades) in dry casks. It is *a fortiori* true of high burnup spent fuel that has been stored for many decades or even a few hundred years, given the considerations about such spent fuel discussed in the rest of this section. (0898-2-15 [Curran, Diane] [Makhijani, Arjun])

Comment: In failing to address the issue of failed spent fuel inter-cask transfers, the NRC has ignored the fact that failed spent fuel bundles are already stored in dry casks, but have never had to undergo inter-cask transfers. For instance, there are 95 failed spent fuel bundles stored in 15 dry casks at San Onofre Nuclear Generating Station alone.⁸² [footnote 82 text: NRC 2011b, p. 11] (0898-2-17 [Curran, Diane] [Makhijani, Arjun])

Comment: As discussed above, NWTRB has proposed an extended research program to address the lack of data regarding spent fuel characteristics. It is also important to have dry storage performance data on the newer cladding materials that have been developed to enable high fuel burnup, which is a relatively recent practice (since about the turn of the century⁸³ [footnote 83 text: NWTRB 2010, p. 72]). There are practically no such data. Indeed, even the research has been focused mainly on in-reactor behavior of high burnup fuels rather than on degradation during prolonged storage: Because of the more severe conditions created by burning fuel to higher levels, new cladding materials have been developed for in-reactor service and employed by vendors such as Areva's M5 alloy, Westinghouse's optimized ZIRLO, Siemen's Duplex, and Mitsubishi's M-MDA material. Currently there is much more behavioral data available on Zircaloy-2 and -4 cladding, but work is ongoing to study the new cladding materials (mostly proprietary). From the limited information reviewed it appears new cladding research is focused primarily on in-reactor behavior and not behavior during extended storage.⁸⁴ [footnote 84 text: NWTRB 2010, p. 52] (0898-2-18 [Curran, Diane] [Makhijani, Arjun])

Comment: The NWTRB also commented on the lack of information about interactions between different degradation mechanisms as well as the possible effect of high burnup on those

interactions: These [degradation] mechanisms and their interactions are not well understood. New research suggests that the effects of hydrogen absorption and migration, hydride precipitation and reorientation, and delayed hydride cracking may degrade the fuel cladding over long periods at low temperatures, affecting its ductility, strength, and fracture toughness. *High-burnup fuels tend to swell and close the pellet-cladding gap, which increases the cladding stresses and can lead to creep and stress corrosion cracking of cladding in extended storage.* Fuel temperatures will decrease in extended storage, and cladding can become brittle at low temperatures.⁶⁸ [footnote 68 text: NWTRB 2010, p. 11, italics added] Hence, high burnup could possibly combine with other factors to create conditions that would result in severe, if not catastrophic, releases of radioactivity. This possibility must be studied. (0898-2-2 [Curran, Diane] [Makhijani, Arjun])

Comment: Besides the NRC staff's 2012 proposal, the NWTRB has also proposed an extended research program to address the problem of the lack of data. The NWTRB research and development recommendations include:⁶⁹ [footnote 69 text: The bullet points are quoted from NWTRB 2010, p. 14] • Understanding the ultimate mechanical cladding behavior and fuel-cladding degradation mechanisms potentially active during extended dry storage, including those that will act on the materials introduced in the last few years for fabrication of high-burnup fuels • Understanding and modeling the time-dependent conditions that affect aging and degradation processes, such as temperature profiles, in situ material stresses, quantity of residual water, and quantity of helium gas • Modeling of age-related degradation of metal canisters, casks, and internal components during extended dry storage • Inspection and monitoring of fuel and dry-storage systems to verify the actual conditions and degradation behavior over time, including techniques for ensuring the presence of helium cover gas • Verification of the predicted mechanical performance of fuel after extended dry storage during cask and container handling, normal transportation operations, fuel removal from casks and containers, off-normal occurrences, and accident events • Design and demonstration of dry-transfer fuel systems for removing fuel from casks and canisters following extended dry storage[.] As discussed above, a valid impact analysis requires collection of this information at least to a sufficient extent to make a central estimate of impacts and to put meaningful uncertainty bounds on those impacts. (0898-2-3 [Curran, Diane] [Makhijani, Arjun])

Comment: Other institutions have also analyzed the critical data gaps regarding high burnup degradation and its implications for storage, transport and disposal. For instance, a 2012 paper published by the National Academy of Engineering noted the following: Based on its assessment, the study board concluded that the technical basis for the spent fuel currently being discharged (high utilization, burnup fuels) is not well established and that the possibility of degradation mechanisms, such as hydriding, will require more study. The NWTRB recommended periodic examinations of representative amounts of spent fuel to ensure that degradation mechanisms are not in evidence.⁷⁰ [footnote 70 text: Kadak 2012, p. 30] As concerning as the serious data gaps is the fact that as recently as 2012 neither the NRC nor the nuclear power industry had implemented the periodic examinations of spent fuel recommended by the NWTRB in 2010. (0898-2-4 [Curran, Diane] [Makhijani, Arjun])

Comment: In Table 6-1 above (reproduced in paragraph 4.9 from the NRC Draft Report on Technical Information Needs (NRC 2012a)), all of the categories of "regulatory significance" of the 23 degradation phenomena -- confinement, criticality, retrievability, shielding, structural, and thermal -- are relevant to estimating environmental impacts, some of which could be serious. Such impacts could arise because some of the spent fuel could be degraded badly enough to result in (i) environmental releases during spent fuel inter-cask transfer and (ii) more severe impacts in cases of accidents. (0898-2-6 [Curran, Diane] [Makhijani, Arjun])

Comment: For instance, in the case of microbiologically induced corrosion, Table 6-1 states that "little is known" about the conditions under which it "could corrode seals and/or the cask body that affect containment." Laboratory work and examination of spent fuel of different levels of burnup stored for long periods in spent fuel pools followed by long-term storage in dry casks is needed. It is only on this basis that models to extrapolate the environmental impacts of storage, followed by transportation (and in all but one scenario) disposal can be evaluated and extrapolated in a manner that can be scientifically validated. (0898-2-7 [Curran, Diane] [Makhijani, Arjun])

Comment: As another example, consider phenomena listed near the top of Table 6-1: stress corrosion cracking, delayed hydride cracking, and low temperature creep. The NRC Draft Report on Technical Information Needs notes that "[a]ll three mechanisms depend on a source of stress that would come from pellet swelling. If the stress is not present, the mechanisms become benign. If operative, these mechanisms could increase the source term and increase cladding stress. The latter could affect containment, especially if other degradation processes have compromised the canister."⁷¹ [footnote 71 text: NRC 2012a, p. 6-2] In other words, the NRC does not know at present whether corrosion of seals or the canister body may occur to an extent that compromises containment. Damage to canisters could set the stage for severe releases either during inter-cask transfer or because the canister itself degrades. This is an example of a case where the present state of knowledge is so low that the uncertainties appear to be so large as to be operationally meaningless. (0898-2-8 [Curran, Diane] [Makhijani, Arjun])

Comment: Figure 3 shows that the maximum wall thickness hydrogen content increases from 200 ppm to 800 ppm at discharge over approximately the same burnup range as in Figure 2. In both cases the variability is also much greater at the higher burnup. For instance, Figure 3 shows oxide layer thicknesses for a burnup of 30 GWd/metric ton ranging from roughly 12 microns to (at most) 35 microns -- a spread of 23 microns. At 63 GWd per metric ton the thickness range from about 70 microns to 130 microns, a spread of 60 microns. In fact these data show that the *variability* in oxide layer thickness at 63 GWd/MT burnup is almost *twice as large as the maximum* thickness at 30 GWd/MT. The oxidation and hydriding in-reactor data point to (i) a higher probability of failure and (ii) more severe failures in some fraction of the rods in cases when failures occur upon prolonged spent fuel pool and dry storage for high burnup spent fuel. High oxide and hydrogen levels in cladding create a host of vulnerabilities in spent fuel, including increased brittleness upon drying, high hoop stresses, and other phenomena that could cause fuel to fail -- that is, to develop cracks and fissures that are significant enough to cause release of fission products. Reasonable confidence in the integrity of spent fuel after long periods of storage would not only require examination of typical high burnup fuel rods but also the ones at the higher levels of initial degradation that are clearly indicated by currently available information of in-reactor performance. (0898-2-9 [Curran, Diane] [Makhijani, Arjun])

Comment: The United States is building a MOX plant to convert weapons-grade plutonium into commercial reactor fuel. There is no significant experience with irradiation of such MOX fuel in a commercial reactor in the United States. Only lead test assemblies have been irradiated. There is essentially no experience with storage of commercial MOX spent fuel in the United States in wet or dry storage for any length of time. France, which has the most experience with MOX spent fuel, stores it in pools and has no dry storage. The Draft GEIS simply assumes away the problem of MOX spent fuel with the following statement: Because the MOX fuel that would be generated at the Mixed Oxide Fuel Fabrication Facility is substantially similar to existing light water reactor fuel and is, in fact, intended for use in existing light water reactors in the United States, MOX fuel from this project is within the scope of this draft GEIS.⁸⁵ [footnote 85 text: NRC 2013a, p. 2-8] Contrary to the claim in the Draft GEIS, MOX fuel is decidedly not "substantially

similar to existing light water reactor fuel." In the former the fissile material is plutonium, which has different nuclear characteristics (a smaller delayed neutron fraction, for instance) than current low-enriched uranium reactor fuel. Even more importantly for the present purposes, the characteristics of the spent fuel will be different. For instance, uranium spent fuel from a PWR with initial 4.25 percent enrichment and burnup of 50 GWd per metric ton would have about percent plutonium isotopes in it at discharge, including about half-a-percent plutonium-239. For the same burnup MOX fuel would typically have 8.46 percent total plutonium to start with. The spent fuel from a PWR would have about five times as much total plutonium and about three-and-half-times as much plutonium-239.⁸⁶ [footnote 86 text: IAEA 2007, Tables 18 and 25, pp. 65 and 70 respectively. The MOX fuel in this case started with reactor-grade plutonium. MOX fuel made with weapon-grade plutonium would have a somewhat different mixture of plutonium isotopes in the spent fuel, but it would, in any case, be much higher than the total plutonium in uranium dioxide spent fuel.] (0898-3-1 [Curran, Diane] [Makhijani, Arjun])

Comment: In the example provided (50 GWd per metric ton burnup in a PWR), the MOX spent fuel would have about six-and-half-times the amount of plutonium-241 as the uranium spent fuel. Plutonium-241 decays into americium-241 relatively rapidly with a half-life of just 14.4 years. Americium-241 has a half-life of 432 years.⁸⁷ [footnote 87 text: Properties of radionuclides, including half-lives and dose conversion factors can be found in FGR 13 CD 2002.] Unlike plutonium-239 and plutonium-241, americium-241 is a powerful gamma radiation emitter; it would pose special problems during spent fuel transfer, long after the main gamma-emitting fission product, cesium-137 (half-life about 30 years), would have decayed away. These problems associated with americium-241 gamma radiation dose would extend to post-accident recovery in case of release of radionuclides from the spent fuel. (0898-3-2 [Curran, Diane] [Makhijani, Arjun])

Comment: It stretches credulity that the NRC staff is not aware of these critical differences that would make a significant difference between impacts of MOX spent fuel and uranium spent fuel. In any case, the Draft GEIS assertion that the two are substantially similar is wrong. A specific impact analysis is needed for MOX spent fuel. (0898-3-3 [Curran, Diane] [Makhijani, Arjun])

Comment: Stainless steel fuel cladding was used as fuel cladding early in the history⁸⁸ [footnote 88 text: EIA 1994, p. 23] of U.S. commercial reactors. By 1994, only one reactor had any stainless steel clad fuel in its core.⁸⁹ [footnote 89 text: EIA 1994, p. 23] By 1992, a total of 679 metric tons spent fuel (uranium heavy metal content) had been generated from the stainless steel clad fuel.⁹⁰ [footnote 90 text: EIA 1994, Table 9 (p. 27) and Table 10 (p. 28)] Further, the use of stainless steel cladding was discontinued partly because in-reactor degradation of stainless steel cladding. For instance, the stainless steel cladding in the Connecticut Yankee reactor "experienced a number of fuel element failures" between 1977 and 1980, even though it had performed well in this regard prior to that time.⁹¹ [footnote 91 text: Rivera and Meyer 1980, p.1] The degradation characteristics of stainless steel fuel are different than zircaloy fuel and needed to be explicitly considered in the Draft GEIS. The Draft GEIS catalogs the amount of stainless steel spent fuel but does not discuss the failed fuel or its transfer from one dry cask to another. It does not discuss whether accidents involving such failed fuel would have more or less severe consequences than failed zircaloy-clad fuel. (0898-3-4 [Curran, Diane] [Makhijani, Arjun])

Comment: NUREG/CR-6835 considered risks only from uranium spent fuel with various enrichment levels up to 5 percent.⁹⁴ [footnote 94 text: NUREG/CR-6835 (2003), p. 3] It did not consider MOX spent fuel. As noted in paragraph 4.32 and 4.33, MOX spent fuel contains several times more plutonium-239 than uranium spent fuel with the same burnup. Since the

Draft GEIS includes MOX spent fuel in its scope, it should address criticality risks of such spent fuel in dry storage and during transportation as well. (0898-3-7 [Curran, Diane] [Makhijani, Arjun])

Comment: I provide some examples of impacts that were ignored in the Yucca Mountain EIS loss of institutional control scenario that must be included in the waste confidence GEIS.[...] The Yucca Mountain EIS was completed before any physical evaluation of high burnup fuel that had been in dry storage for any length of time. This aspect needs to be included in the waste confidence GEIS. (0898-4-6 [Curran, Diane] [Makhijani, Arjun])

Comment: The Draft GEIS contains almost no information about spent fuel characteristics that could cause adverse safety risks and environmental impacts during long-term or indefinite storage. In other contexts, the NRC itself has acknowledged that it currently lacks sufficient information to reach informed conclusions about the behavior of spent fuel in storage over the long term. Yet, it failed to note the data gaps identified as recently as 2012 in its Draft GEIS. The NRC's amnesia regarding its own study undermines the credibility and integrity of the Draft GEIS. Little-understood factors affecting the safety of spent fuel storage include the degree to which spent fuel and its host canisters corrode and degrade over a prolonged period of time, and the effect of high burnup fuel on the integrity of cladding and storage canisters. (0898-5-15 [Curran, Diane] [Makhijani, Arjun])

Comment: For instance, although high burnup fuel now makes up a significant portion of spent fuel inventories, there is no explicit consideration of long-term dry storage and disposal of failed high-burnup fuel. The NRC currently has little or no empirical data regarding its behavior under extended dry storage conditions. The Draft GEIS contains no analysis of how high burnup spent fuel characteristics may contribute to the risk of an accidental release of radioactivity during extended storage in pools, followed by long-term storage in dry casks. The one study of high burnup spent fuel degradation that the Draft GEIS cites (Billone et al. 2013) found that different high burnup fuel cladding material degrade at markedly different rates. The Draft GEIS took no account of this finding, which indicates that a generic analysis may not be sufficient to estimate impacts unless it is designed to be bounding, having taken such differences explicitly into account. (0898-5-16 [Curran, Diane] [Makhijani, Arjun])

Comment: In view of the lack of factual and analytical basis for assessing the impacts of long-term or indefinite storage of high burnup spent fuel, the NRC should not permit the further production of high burnup spent fuel until such a time that it is able to evaluate the long-term spent fuel management issues related to that fuel. (0898-5-28 [Curran, Diane] [Makhijani, Arjun])

Comment: In addition, Table S-3 does not cover MOX fuel use, though the waste confidence rule purports to cover it.¹³⁵ [footnote 135 text: NRC 2013a, p. xxix] It is clear that Table S-3 does not give the NRC the basis for a waste confidence statement that includes MOX spent fuel. (0898-5-4 [Curran, Diane] [Makhijani, Arjun])

Comment: Dry casks are only guaranteed for 20 years so monitor for a million as it costs twice as much to have it in pools and dry casks are the part that withstood Fukushima. (0901-2 [Anderson, Janet M.])

Comment: I am writing to you today to show support for PG&E's successful spent fuel management program and the NRC's Spent Fuel Storage Rule. As a 6th generation San Luis Obispo County resident, I take great pride in knowing that PG&E is actively taking precaution to keep us safe and their site at Diablo Canyon safe for both residents and their work force for generations to come. With NRC oversight, PG&E has a very detailed and successful spent fuel

management program and continues to safely store fuel via both its wet and dry cask storage systems. I am confident that layer upon layer of safeguards are in place to effectively manage and monitor the stored spent fuel. (0909-1 [Johnson, Amber])

Comment: On Page 2-16, in the discussion of dry cask use and description, WHY HAVE OUR INQUIRIES RESULTED IN INFORMATION THAT PALISADES NOW HAS BOTH VERTICAL AND HORIZONTAL DRY CASKS IN USE? WHY?? WHAT ARE COMPARATIVE FACTS SHOWING OF SAFETY/PERMANENCE/REPLACEMENTS [100 YEARS.... HOW, WITH CASK 4 STILL NOT REPLACED/RELOADED BECAUSE OF THE CRACK, OR OTHER?? (0910-11 [Carey, Corinne])

Comment: I am writing to you today to show support for PG&E's successful spent fuel management program and the NRC's Spent Fuel Storage Rule. As a sixty-six year San Luis Obispo County resident, I take great pride in knowing that PG&E is actively taking precaution to keep us safe and their site at Diablo Canyon safe for both residents and their work force for generations to come. With NRC oversight, PG&E has a very detailed and successful spent fuel management program and continues to safely store fuel via both its wet and dry cask storage systems. I am confident that layer upon layer of safeguards are in place to effectively manage and monitor the stored spent fuel. (0911-1 [Stork, Gilbert])

Comment: Consolidated, temporary, interim away-from-reactor storage must be available by the end of the Short-Term period, pending the availability of the geologic repository. Consolidated storage presents an overall safer storage environment and a more economical approach to the storage problem by eliminating significant duplication of costly construction (for example, at-reactor Dry Transfer Systems [DTS]) and staffing that will increase costs. Consolidated Storage will reduce the added burden to State and local governments supporting these long term activities. (0913-2 [Bevill, Bernard])

Comment: Aging Management Program[:] The draft GEIS indicates that an aging management program is required by the NRC, however, no specifics are provided. *Recommendation:* Provide information on facility/storage aging management program on specifically how: (i) the integrity of dry storage system components will be monitored during a 100year storage time frame, and (ii) the potential emissions specific to dry storage systems will be monitored during the 100-year storage time frame. (0915-10 [Bromm, Susan E.])

Comment: The draft GEIS discusses cladding degradation issues of high burnup fuel and, should cladding degradation occur, notes that "greater care could be required during handling operations" (p. B13). However, the draft GEIS does not provide information to clarify what specific measures would be taken during handling operations. Furthermore, we expect that cladding conditions of some assemblies would be such that it would not be safe to transfer fuel without cladding rupture, regardless of any additional handling measures. In this case, it may be safer to leave the fuel in the "old" cask instead of risking the spread of radioactive materials due to cladding rupture. EPA believes that such a "leave as is" sub-scenario is not speculative because: (i) the data on fuel conditions exists only for 12 rods after 15 years of storage in a fully controlled experimental environment while the draft GEIS assumes a 100-year long storage period, (ii) there are significant uncertainties concerning the potential for future accidents and off-normal conditions during loading and transfers at a storage site, and (iii) there is no data on fuel conditions after long-term storage that is similar to the data for low burnup fuel. Accidents and off-normal conditions may cause beyond the design basis conditions, i.e., beyond those for which the storage systems are licensed. One example is an assembly mislead caused by a human error, which can lead to cladding temperatures increasing beyond the design basis limit.

In addition, with hundreds of thousands of assemblies to be loaded and transferred, even a low frequency of misload events may cause a release of radioactive materials during the lifetime of one or several independent spent fuel storage installations (ISFSIs). (0915-14 [Bromm, Susan E.]

Comment: High Burnup Fuel[:] The draft GEIS states that it is expected that industry will utilize fuel to higher burnups in the near future, but does not distinguish low and high burnup fuels in its analyses, except for pool fires. The draft GEIS indicates that its analyses are for low burnup fuel because these fuels will require more space for storage in the future. This position would not have much significance if the condition of the high burn up fuel deteriorates significantly more than low burnup fuel in long-term storage. However, while data exists for low burnup fuel conditions after 15 years of dry storage, no data exists for high burnup fuel after 15-years of dry storage. We recognize that high burnup fuel studies are on-going (Billone, 2013) and that no definitive results are currently available. *Recommendation:* Discuss how forthcoming information on high bumup fuel conditions after long-term storage will be addressed in future licensing actions. (0915-2 [Bromm, Susan E.]

Comment: The draft GEIS states that studies performed to date have not identified any issues that would call into question the technical feasibility of the long-term use of dry storage for low burnup spent fuel, however, it is not clear that long-term storage would be feasible for high-burnup fuel. *Recommendation:* Provide information on the projected amount of high-bumup fuel that will be stored, repackaged, and transferred at DTS/ISFSI facilities for the three scenarios. In addition, provide information on whether there are any potential issues regarding the technical feasibility of long-term use of dry storage for high burnup spent fuel. (0915-3 [Bromm, Susan E.]

Comment: The NRC's Interim Staff Guidance "The Use of a Demonstration Program as Confirmation of Integrity for Continued Storage of High Burnup Fuel Beyond 20 Years" (NRC ISG-24 (2013)) indicates that data supporting readily retrievable storage of high-burnup fuel beyond 20 years is not presently available. The guidance also recommends that a demonstration program could provide an acceptable method for an applicant to demonstrate compliance with regulations for storage of high-burnup fuel for periods of greater than 20 years. This demonstration program appears to require a cladding inspection at the end of 20 years. If a reactor license is terminated and a pool is not available, this cladding inspection is likely to include cutting the canisters open and inspecting the cladding for degradation, which would then potentially require construction and operation of a DTS for all three time frame scenarios. *Recommendation:* Provide information on whether high-burnup fuel will likely be inspected every 20 years. If this is the case, discuss how such inspections and associated operations and transfers may impact the assumption that no DTS is needed for 100-year storage period, especially when reactor licenses are terminated and pools are no longer available. (0915-4 [Bromm, Susan E.]

Comment: (XII-3) The most effective option in Table XII-1 is to re-equip the pool with low-density, open-frame racks. In the case of BWR fuel, a corollary action could be the removal of channel boxes from the fuel. When nuclear power plants in the present US fleet first entered service, their spent-fuel pools were equipped with low-density, open-frame racks. The margin of safety provided by this configuration was lost when the nuclear industry adopted high-density racks as a way to minimize short-term costs. (0916-3-15 [Curran, Diane] [Thompson, Gordon R.]

Comment: As woefully inadequate as NRC shipping container safety regulations are, NRC's storage-only container safety regulations are even worse. Thus, an earthquake plunging one or more storage-only casks underwater at Palisades is even more problematic a risk than a barge

shipment sinking a transport cask, at least in terms of the safety standards applied to each type of container for survival of an underwater submersion, that is. To drive the point home, I attended an NRC-industry technical meeting several years ago, regarding the risks of underwater submersion to the particular casks in use at Palisades (as well as at Point Beach nuclear power plant on the Wisconsin shoreline of Lake Michigan, as well as at Arkansas Nuclear One, ANO, nuclear power plant), namely, VSC-24s (for Ventilated Storage Casks holding 24 Pressurized Water Reactor irradiated nuclear fuel assemblies). (0919-1-16 [Kamps, Kevin])

Comment: In fact, NRC's WC DGEIS, at Table G-4, "ISFSIs with General Licenses under Part 72," Pages G-9 to G-11, confirms that VSC-24s are in use at Palisades (as well as at Point Beach and ANO). The industry representatives at the meeting represented cask vendor BNG Fuel Solutions (as confirmed in WC DGEIS Table G-4), which acquired ownership of the VSC-24 license from Sierra Nuclear. BNG Fuel Solutions is now a part of EnergySolutions of Salt Lake City, Utah. NRC staff had 65 RAIs (Requests for Additional Information) for EnergySolutions regarding the risk of inadvertent criticality in VSC-24s due to underwater submersion. Thus, it became clear to me that the earthquake risk described by Dr. Landsman as early as 1994 is quite significant. Dr. Landsman, now retired from NRC, served as NIRS and Don't Waste Michigan's expert witness in the Palisades license extension proceeding. (0919-1-17 [Kamps, Kevin])

Comment: There is no permanent repository for the nuclear waste which would be generated at Palisades after 2010. (0919-1-8 [Kamps, Kevin])

Comment: At Page 2-7 (lines 24-27) to 2-8 (lines 1-2), NRC states "For purposes of analysis in this draft GEIS, the NRC relies for impact analysis on the larger reactor lifetime amount of spent fuel discharged at low burnups (i.e. 1,600 MTU), unless otherwise stated in the description of environmental impacts. This is because many of the environmental impacts (e.g., land use, geology and soils, and terrestrial resources) will depend upon the greater amount of space needed to store the larger amounts of spent fuel that would be generated a low burnups." The aspect that NRC seems to not comprehend is that high burnup irradiated fuel very likely will require, as compared to low burnup fuel, more space and time in the storage pool for sufficient thermal cooling and radioactive decay; and/or more space and time in dry cask storage - perhaps with enhanced features, such as added cooling features, and/or radiation shielding; and/or more space in a repository setting. This, due to the added heat and radioactivity emanating from high burnup fuel. (0919-3-12 [Kamps, Kevin])

Comment: Re: NRC's Section 3.8.3, Wildlife, what about wildlife being attracted to the warmth given off by ISFSIs? What about the risk to the stored irradiated fuel by wildlife nesting in or near ISFSIs, to take advantage of the warmth? Could the convection current flow paths be blocked, as by nesting debris? In North Korea, at the Yongbyon nuclear power plant, frogs and other wildlife were reported to be inhabiting the indoor irradiated fuel pool. Is there a risk of U.S. irradiated fuel storage pools being neglected to such a point during the post-reactor operations timeframe? (0919-5-16 [Kamps, Kevin])

Comment: Please find attached a three-page fact sheet I wrote in January 2012 entitled "Catastrophic Risks of GE BWR Mark I High-Level Radioactive Waste Storage Pools." (0926-1 [Kamps, Kevin])

Comment: A lesson to be learned from Fukushima Daiichi is that dense storage of irradiated nuclear fuel in storage pools, as done in the U.S., is a mega-catastrophe just waiting to happen,

whether sparked by a natural disaster, accident (such as heavy load drop), or intentional attack (in this sense, these pools are unimaginably large dirty bombs in our backyards. At this point, NRC is guilty of a cover up, and complicity with industry, regarding the mega-risk represented by densely-packed pools filled to capacity with ultra-hazardous, high-level radioactive waste, pools that NRC does not even require be connected to back-up power for running cooling water circulation pumps. Although NRC is considering requiring it, incredibly, even at this late point in time, nearly three years after the Fukushima Daiichi catastrophe began, with its horrific images or helicopters dropping water, and fire trucks spraying water, in desperate, ad hoc attempts to ensure cooling water was present in severely damaged, catastrophically vulnerable high-level radioactive waste storage pools, NRC still does not yet require that storage pools here even have in place make-up water supplies or capacities. (0926-4 [Kamps, Kevin])

Comment: Require a low-density, open-frame layout for fuel pools: fuel pools were originally designed for temporary storage of a limited number of irradiated fuel assemblies in a low density, open frame configuration. As the amount of waste generated has increased beyond the designed capacity, the pools have been reorganized so that the concentration of fuel in the pools is nearly the same as that in operating reactor cores. If water is lost from a densely packed pool as the result of an attack or an accident, cooling by ambient air would likely be insufficient to prevent a fire, resulting in the release of large quantities of radioactivity to the environment. A low density, open-frame arrangement within fuel pools could allow enough air circulation to keep the fuel from catching fire. In order to achieve and maintain this arrangement within the pools, irradiated fuel must be transferred from the pools to dry storage within five years of being discharged from the reactor. (0927-6 [Kamps, Kevin])

Comment: In support of public comments I just filed by email to Rulemaking.Comments@nrc.gov at 4:40PM, Dec. 20, 2013 [subject line: Docket ID No. NRC-2012-0246, public comments on NRC WC DGEIS --Oscar Shirani's whistleblowing revelations on Holtec dry cask QA violations], please find attached a copy of a three-page Memorandum, from Dr. Ross Landsman, now-retired NRC dry cask storage inspector for NRC Region 3, to his superior, Bruce Jorgenson, Chief, Decommissioning Branch. In the memorandum, Dr. Landsman expresses his full support for Commonwealth Edison/Exelon whistleblower Oscar Shirani, and Shirani's quality assurance allegations against the Holtec storage/transport casks. (0928-1 [Kamps, Kevin])

Comment: I do not share your confidence, expressed in your Waste Confidence Draft Generic Environmental Impact Statement (WC DGEIS, NUREG-2157), that dry cask storage of irradiated nuclear fuel is currently safe and sound, and will remain so not only for up to 80 years of reactor operations, up to 60 years beyond reactor operations during so-called "short-term storage," up to 100 years beyond that during so-called "long-term storage," and up to forevermore beyond that, during so-called "indefinite storage" (infinite storage?!). (0929-1 [Kamps, Kevin])

Comment: Manufacturers of dry cask systems must go through the NRC's "certificate of compliance" (CoC) process. This covers a host of issues, including the development of the cask design technical specifications, operational limits, maximum radiation dose limits and the condition of irradiated fuel that can be stored inside. As of Feb. 5, 2003, NRC had approved 16 different dry cask storage systems for general use at or away from reactors (see <http://www.nrc.gov/waste/spent-fuel-storage/designs.html>). NRC cask certification is valid for 20 year intervals, with reviewed extensions available. NRC has stated that dry cask storage is safe and reliable for up to 100 years. However, problems with dry casks have surfaced not after decades or a century, but almost immediately in the first few years, raising serious questions

about the NRC cask certification process itself. Evidence documents that the NRC's CoC process has been taken over by cask manufacturers' and nuclear utilities' profit-driven pressure for expediency. The consequent lack of rigorous regulatory oversight has resulted in a complete lack of field testing of cask designs, NRC approval for exemptions allowing manufacturers to build casks before receiving the certificate of compliance, and mounting evidence of poor quality assurance and quality control of cask manufacturing. In fact, a whistleblower fired by the largest nuclear utility in the U.S. alleges major quality assurance (QA) violations involving Holtec storage/transport containers. Oscar Shirani served as a lead QA inspector for Commonwealth Edison/Exelon of Chicago for many years, earning impeccable credentials. A consortium of nuclear utilities invited Shirani to lead a QA inspection of Holtec cask design and manufacturing in 2000. Shirani identified 9 major QA violations (such as unauthorized welding, large numbers of departures from design specifications, and use of potentially shoddy materials), leading him to question the structural integrity of the containers, especially under severe transportation accident conditions. Shirani's discovery followed an NRC-led QA inspection just months earlier that had identified no problems with the Holtec casks, casting huge doubt upon the competence and credibility of NRC's QA regulatory oversight. Shirani sought a "stop work order" against the manufacture of the Holtec casks until the QA violations were rectified. Instead, Exelon harassed and ultimately fired him. Shirani has been blacklisted from the nuclear industry ever since, and his allegations have never been addressed. Frighteningly, Holtec casks are already in use at 33 U.S. nuclear reactors (see locations under "Spent Fuel Systems Division" at <http://www.holtecinternational.com/>). Numerous technical problems with fully loaded dry casks are popping up around the country at an alarming rate, leading to charges from concerned citizens living nearby that ISFSI's (pronounced "is-IF-sees") are very "iffy," and represent "nuclear experiments" in their backyard. (0929-10 [Kamps, Kevin])

Comment: The explosion within the VSC-24 took place immediately above 24 irradiated fuel assemblies already loaded into the cask, containing the equivalent amount of long-lasting radioactivity released by 240 Hiroshima-sized atomic bombs; the nearby "spent" fuel pool held the full inventory of high-level radioactive waste generated at that plant over the course of decades. Although the NRC and utility reported that no radiation was released, no damage was done to the irradiated fuel assemblies in the cask, and no one was injured by the blast, the forceful explosion occurred near the plant's "spent" fuel pool, not a place to "play with fire" or make mistakes with objects weighing many tons. Loaded dry storage casks, weighing more than 100 tons, are among the heaviest loads moved within a reactor during power operation. Human error and equipment failure raise issues of worker and public safety during cask handling and moving activities. Dropping either a loaded or unloaded cask inside the fuel pool building can severely damage plant safety equipment, jeopardizing reactor operation and the cooling of irradiated fuel in the storage pond. On May 13, 1995 a loaded TN-40 cask became stuck in the hoisted position above the Prairie Island, Minnesota plant's irradiated fuel storage pool for 16 hours. This incident occurred just after NRC had granted Northern States Power (now Xcel Energy) an exemption from regulatory requirements for reviewing cask loading procedures. Over 120 tons of metal storage cask and irradiated fuel assemblies dangled precariously over 22 years' worth of the reactor's accumulated irradiated fuel assemblies in the pool below—many hundreds of tons of deadly nuclear waste. This dangling "sword of Damocles" risked dropping back into the pool, damaging irradiated fuel stored there, or punching a hole in the pool leading to a loss of coolant accident and potentially catastrophic consequences. Luckily, nothing happened—that time. Some reactor designs, such as in G.E. boiling water reactors, have placed the irradiated fuel storage pools several stories up in the reactor building. Consequently, cask movement can place heavy loads up to ten stories high inside the reactor building. A cask drop would send the heavy load crashing down through several floors of the building which house vital safety systems, with untold consequences. (0929-12 [Kamps, Kevin])

Comment: These widespread problems make clear that NRC's high-level waste storage and handling regulations are dangerously inadequate and in need of comprehensive review. Despite this, NRC continues to expedite ISFSI licenses: there are scores of nuclear power reactors in dozens of states planning to open ISFSI's in the next several years due to the fact that their indoor storage pools are completely filling up. In addition, NRC continues to allow vendors to manufacture casks before they have received their certificates of compliance. Once casks are already built, the pressure is on NRC to help "fix" any problems that surface via an "efficient and effective" (i.e., quick, cheap and easy) CoC amendment process, which again locks out involvement of concerned citizens, and leads to changes on the casks that leave NRC itself unsure that its "Safety Evaluation Report" still applies. The nuclear industry has even pushed for NRC permission to "fix" cask problems without even notifying the federal agency charged with protecting public health and safety and the environment! As more and more utilities quickly run out of pool space and seek to store fuel in dry casks or even to transport fuel off-site, NRC certification of cask designs is accelerating: in February, 2000 alone, NRC was engaged in certifying five new cask designs, and beginning review of an additional three applications for cask certification. As Bill Brach, director of the NRC's Spent Fuel Project Office (which is in charge of cask certification) cheerfully reported to the NRC Commissioners in February, 2000, "We've been extremely busy." Given the history of past mistakes and the current rush job, future certification, manufacturing, and operational mistakes are inevitable. (0929-13 [Kamps, Kevin])

Comment: Incredibly, not a single dry storage cask, once loaded, has ever been unloaded in the U.S. This has led critics to charge that no safe unloading procedure exists. In May, 1993 local environmental groups and the State of Michigan filed for an injunction in federal court against the loading of VSC-24's at Palisades, alleging that there was no proven safe method for unloading the casks. The NRC and Consumers Energy assured the court that in an emergency, casks could be safely unloaded simply by reversing the loading procedure. The court denied the injunction and allowed the casks to be loaded. Just over a year later, in August, 1994 Consumers Energy discovered that its fourth loaded VSC-24 dry cask had weld flaws. To demonstrate its commitment to public safety and the environment, as well as to live up to its promise to the court, Consumers announced it would unload the irradiated fuel in the cask back into the storage pool. Only then were the difficulties discovered. Reintroducing the 400 degree Fahrenheit fuel assemblies back into the 100 degree fuel pool water would result in a radioactive steam flash hazardous to workers, and would thermally shock the fuel assemblies threatening to further degrade them. Also, the welded-shut inner canister would have to be cut open in a timeframe of less than 50 hours, for the cooling process could not be maintained during the unloading procedure and the fuel within would begin to overheat. In addition, there was no procedure yet developed to remove steel shims that were pressure fit inside the cask lid. Rather than leading to a pause for reflection, however, Consumers rushed to immediately load nine more VSC-24's, a move taken by local concerned citizens to be in very bad faith. Ten years after Consumers announced it would unload the defective cask #4, it still sits fully loaded on the Lake Michigan shoreline, alongside two dozen more fully loaded VSC-24's of questionable structural integrity. The failure to safely unload dry casks has concerned other neighbors next to reactors. The Prairie Island Mdewakanton Dakota Tribe in Minnesota petitioned the NRC to prohibit Northern States Power from loading any more TN-40 casks until a safe unloading procedure had been demonstrated, but to no avail. 17 dry casks sit fully loaded just several hundred yards from the nearest homes and a tribal child care center on this tiny island on a flood plain in the middle of the Mississippi River. Recently, Xcel Energy pressured the Minnesota state legislature to permit it to load scores more casks at Prairie Island, violating an agreement made in 1994 to limit the number of casks to 17. Adding further to worries about cask unloading, corrosion between the metallic inner canister and the metallic lining of the outer shell of VSC-24's could cause a bonding together that would be very difficult to pry apart. Even

if the casks were to malfunction, or the waste to leak, or a repository to open that could accept the wastes, it remains unclear whether dry casks could be safely unloaded back into fuel storage pools or into transport casks for shipment off-site. (0929-14 [Kamps, Kevin])

Comment: High-level nuclear waste presents us with an unprecedented dilemma--poisons that remain deadly for hundreds of thousands of years. If dry cask storage is so problematic, why not keep the wastes in wet storage pools? Wastes are dangerous there too, for cooling pumps must operate 24 hours per day, 7 days per week, for decades. Without pumps circulating cooling water, the thermally hot waste could boil away the pool water in a matter of hours. A recent NRC report admitted that even decades-cooled irradiated fuel could spontaneously combust if overheated or put in contact with air. A pool fire could release disastrous amounts of radioactivity to the environment. A puncture of a pool and consequent loss of water could lead to similar catastrophic consequences. So could a simple loss of power, causing the cooling and water circulation pumps to stop working. A raccoon at the Fermi reactor in Michigan once caused such a loss of power to the cooling pumps. For these reasons, many see dry cask storage as safer than wet pool storage. Dry casks have no moving parts, and individually contain smaller amounts of high-level waste than cram-packed pools. The word "safer" is relative, for high-level nuclear waste is dangerous no matter how or where it is stored. (0929-15 [Kamps, Kevin])

Comment: A May 28, 1996 explosion at the Point Beach reactor in Wisconsin jolted public confidence in the dry cask storage program. While sealing shut a VSC-24 (a Ventilated Storage Cask built by Sierra Nuclear Corporation (SNC) holding 24 irradiated fuel assemblies; this cask design has now been taken over by British Nuclear Fuels, Ltd.), a welding torch ignited pent up hydrogen gas with enough force to dislodge the cask's 4,000 pound shield lid several inches in the air and tilt it ajar on top of the cask. After allowing SNC to manufacture several VSC-24 units even before its CoC, NRC certified the cask design in May, 1993. The explosion was later determined to result from an electro-chemical reaction between an anti-corrosion zinc liner within the cask and the borated "spent" fuel pool water. The chemical reaction between zinc and boric acid to generate explosive hydrogen gas--familiar to many high school chemistry students--somehow escaped the notice of all the "experts" at NRC, the cask manufacturer, and the nuclear utility company. Over a dozen VSC-24 casks had already been loaded around the country before the explosion. Utility employees had observed bubbles in the "spent" fuel pools during these loadings, yet had failed to understand that they were flammable hydrogen gas and did not report them to the NRC. In fact, a blue flame was observed burning within another VSC-24 loaded at Point Beach previous to the explosion, but had been shrugged off by employees as resulting from excess cleaning solvents and went unreported. The explosion led to NRC inspecting SNC's cask manufacturing facility, revealing confusion, inadequate testing, and poor quality control. It also led to a three year halt on the loading of VSC-24's in the U.S. so that the NRC, nuclear utilities, and the cask manufacturer could get a grip on the situation. However, the next VSC-24 to be loaded, at Palisades in June, 1999 again experienced two separate "hydrogen ignition incidents." Again there was a breakdown in administrative controls. The NRC inspectors, thinking all was in order, had already gone home for the day before the "burns" occurred. A welder ignited a "burn" but did not report it, which led inevitably to a welder on the next shift igniting a second "burn". Days passed before NRC was notified. Just the next week later, a suspicious fire in the dry cask storage administrative office trailer at Palisades destroyed many documents, including those about the recent "burns". Concerned citizens cried foul, but NRC did not cite Palisades for any violations of regulations. In 2001, Palisades officials admitted to the NRC that the very same irradiated fuel that was involved in the hydrogen "burns" had actually cooled for less than five years in the storage pool. Loading it in dry casks had been in violation of the casks' technical design specifications, and thus federal regulations. Suspiciously,

the less-than-five-years-cooled fuel had been evenly distributed between a number of casks, leading critics to charge that the "mistake" had in fact been intentional. However, records pertaining to the suspect loading procedure had been destroyed in the earlier suspicious office fire (for which fire inspectors never ruled out the possibility of arson). Shortly thereafter, a VSC-24 cask loading at the Trojan nuclear plant in Oregon had to be suspended when so many hydrogen bubbles were generated in the fuel pool that workers could not see well enough to complete the job. In June, 2000 NRC cited the VSC-24's new owner, British Nuclear Fuels, for poor quality control and assurance in cask manufacturing and maintenance. Obviously, four years since the Point Beach explosion (1996-2000) was not long enough for NRC and industry to resolve problems with the VSC-24. (0929-19 [Kamps, Kevin])

Comment: A March, 1997 NRC inspection report revealed another defect with VSC-24's: delayed cracking in welds supposed to seal shut the multiple shield lids on casks at Palisades, Point Beach, and Arkansas One nuclear plants. Such cracks can allow the inert helium gas within the cask to escape, making the irradiated fuel assemblies vulnerable to contact with air, oxidation, and deterioration. Such degradation could lead to serious irradiated fuel handling and transportation problems in the future. Again, weld failure in shield lids was unanticipated and unanalyzed by industry and the NRC. Over the past several years, NRC has identified serious problems in other dry cask systems. Three NUHOMS casks, manufactured by VECTRA Technologies (now owned by Transnuclear, Inc., a subsidiary of the French nuclear giant COGEMA) and fully loaded at the Davis-Besse nuclear plant in Ohio, were discovered to have been built below technical specifications: the aggregate used to fabricate the casks' outer concrete shells was poor quality, and the shells themselves were ground too thin. In January, 2000 NRC reported that a TN-32 cask (manufactured by Transnuclear, containing 32 irradiated fuel assemblies) at the Surry nuclear plant in Virginia had developed six inch long cracks in its outer concrete shield, loose bolts, and a helium leak. In late May, 2000 NRC discovered an unreported flaw with the neutron shielding material supplied to New Jersey-based cask manufacturer Holtec International by Nuclear Assurance Corporation. Holtec hopes to deploy no less than 4,000 HI-STORM dry casks for use at the proposed Private Fuel Storage, LLC high-level nuclear waste dump targeted at the tiny impoverished Skull Valley Goshutes Indian Reservation in Utah. Transportation of irradiated fuel rods to Utah in Holtec HI-STAR containers-the first dual purpose storage/transport cask to be certified by NRC--from Eastern, Southeastern, and Midwestern reactors would traverse dozens of States, past the homes of millions of Americans, raising unprecedented safety concerns. In April, 2001 the Sacramento Municipal Utility District halted loading its first Transnuclear West Nuhoms dry storage cask at the Rancho Seco reactor in California due to an unexpected mishap. A faulty O-ring leaked air underwater in the irradiated fuel storage pool during loading operations, threatening to contaminate the fuel-holding inner canister with radioactive pool water. In Sept., 2001 an Exelon Corporation spokesman at the Dresden nuclear reactors in Illinois admitted to a visiting group of nuclear power officials touring the plant's new dry cask storage facility that the NRC had granted Dresden an exemption when its recently, poorly poured dry cask storage concrete pad did not meet specifications. (0929-20 [Kamps, Kevin])

Comment: Please find attached an 8-page fact sheet [Get the Facts on High-Level Atomic Waste Storage Casks!] I first wrote in 2000, but updated, as you will see, on July 15, 2004. It lists many problems with dry cask storage that I was aware of at that time. Of course, the fact sheet needs to be updated. Many more problems with dry cask storage have been documented since 2004. But to the best of my knowledge, the problems I cited in 2004 have yet to be adequately addressed by NRC, if they have been addressed -or even acknowledged -at all. So please explain to me how you can have such confidence in dry cask storage, from now until the

end of time, as you do in your WC DGEIS, given the many problems documented in the attached fact sheet? (0929-4 [Kamps, Kevin])

Comment: "Spent" nuclear fuel is a misleading term. Irradiated nuclear fuel rods discharged from commercial nuclear power plants are highly radioactive, a million times more so than when they were first loaded into a reactor core as fresh fuel. If unshielded, irradiated nuclear fuel just removed from a reactor core could deliver a lethal dose of beta, gamma and neutron radiation to a person standing three feet away in just seconds. Even after decades of radioactive decay, a few minutes unshielded exposure time would be enough to deliver a lethal dose. Certain radioactive elements (alpha emitters such as plutonium-239) in "spent" fuel will remain hazardous to humans and other living beings for hundreds of thousands of years. Military high-level radioactive wastes--the highly radioactive liquid and sludge "leftovers" from reprocessing irradiated fuel rods to extract the uranium and plutonium for making nuclear bombs--has the same hazardous characteristics as "spent" commercial fuel. Irradiated fuel rods and high-level nuclear wastes are perhaps the most hazardous poisons ever created. There is the added danger that fissile materials still present in highly radioactive wastes will form a "critical mass," causing an inadvertent nuclear chain reaction that could radiate a deadly beam of neutrons and possibly even generate enough heat to melt through the container within which it is held. Thus, these wastes must be shielded for centuries, prevented from going critical, and isolated from the living environment for hundreds of millennia. (0929-5 [Kamps, Kevin])

Comment: With every operational cycle of 18 to 24 months at a U.S. nuclear power plant, the reactor is shut down and approximately one-quarter to one-third of its now extremely radioactive fuel assemblies are removed. These thermally hot and highly radioactive fuel assemblies are then transferred into the plant's irradiated fuel storage pool. These large, indoor water-filled storage ponds shield much of the high radiation underwater, and allow the assemblies to thermally cool down from the reactor's high operational temperatures. These pools were originally designed for temporary storage only. Nuclear utilities assumed their high-level wastes would be shipped off for reprocessing to extract fissionable uranium and plutonium for making new fuel rods, or else transported for dumping at a "permanent geologic disposal site" --an underground national sacrifice area. However, reprocessing of commercial wastes was abandoned in the 1970's as economically unfeasible and a threat of nuclear weapons proliferation (not to mention a source of serious radioactive pollution into water and air), and geologic disposal remains mired in technical and political controversy. Consequently, high-level waste inventories at commercial U.S. nuclear reactors have dramatically mounted in storage pools. After decades of "re-racking" to cram pools as full as possible, growing numbers have filled to capacity. This has complicated continued operations and waste generation at certain reactors, while at the growing number of closed down reactors, irradiated fuel assemblies sit in their storage pools even while the plant sites are dismantled and "decommissioned" around them. (0929-6 [Kamps, Kevin])

Comment: As pools have filled, the nuclear industry and the U.S. Nuclear Regulatory Commission (NRC) have developed dry cask storage systems, or Independent Spent Fuel Storage Installations (ISFSI's), to expand "interim" storage of wastes both on-site at plants and away from reactors. As of March, 2003 there were 28 operating licensed ISFSI's located in 22 different States. Numerous additional potential ISFSI sites in many more States may open in the near future (see U.S. Nuclear Regulatory Commission Spent Fuel Project Office's March, 2003 map of ISFSI locations at <http://www.nrc.gov/waste/spent-fuel-storage/locations.html>, as well as its "Nuclear Fuel Pool Capacity" graph at <http://www.nrc.gov/waste/spent-fuel-storage/nuc-fuel-pool.html>, showing the growing number of pools filling to capacity, an indication of impending moves to opening ISFSI's at those reactors). After a minimum of five years of thermal cooling in

"wet" storage pools, irradiated fuel assemblies can be transferred to NRC certified "dry" storage casks made of concrete, steel alloy, and neutron shielding materials. Resembling a giant metallic thermos (solid on one end, open on the other), inner canisters are loaded underwater (to shield workers from the high radiation). The pool water is then pumped out, multiple shield lids are welded or bolted on to seal shut the open end, and the interior of the canister is filled with inert gas (such as helium) intended to prevent deterioration of the fuel rods from oxidation with air, as well as to conduct heat away from the waste. These canisters are then transported to concrete storage pads either immediately nearby the reactor (an on-site ISFSI), or else away from the reactor at an off-site ISFSI. They are loaded into either horizontal "bunkers" or vertical silos (depending on the dry cask system design) made of concrete, which provide shielding against the gamma and neutron rays that emanate out from within the surprisingly thin metallic inner canister. Natural convection through vents in the concrete silo or "bunker" provides passive air cooling, but the inner metal canister can still reach temperatures of 400 degrees Fahrenheit or higher due to the waste's on-going radioactive decay. NRC approved ISFSI sites can accept irradiated fuel from more than one reactor. (0929-7 [Kamps, Kevin])

Comment: It is a good point, what is the difference between a deep geologic repository and the NWOs that you propose to scatter around the country? Is there a reason the experts have pushed for a site 2 3 4 like Yucca Mountain and have not proposed leaving it in casks, exposed to the elements and wartime or terrorist attack? Of course there is, but if you use the logic of this GEIS, the fuel will never be moved to such a repository, because you say that there is no problem with leaving it where it is. YOUR DOCUMENT MUST RE.EAL THESE DANGERS. (0930-1-14 [Lutz, Ray])

Comment: Page 2-26, Lines 32+, you consider "aging effects" and list a few that are related only to the canisters, casks, and overpacking, but not the aging of the fuel assemblies and fuel contained by them. The use of "high burnup fuel" is extremely prevalent and the implications in terms of aging are really unknown. This is yet another example of a pesky "issue that requires resolution"... we really don't know what will happen to the fuel assemblies after 100 years (or even 20 years) of containment in a ISFSI, but they certainly must be contained in your list of aging issues. (0930-2-18 [Lutz, Ray])

Comment: We must continue to point out that a NWO DOES DIFFER from a deep geologic repository. YOU NEED TO DESCRIBE THAT DIFFERENCE AND BE HONEST ABOUT THE RISKS. (0930-2-22 [Lutz, Ray])

Comment: It is expected that the fuel pool will be the storage site for a hundred years, destined to remain a waste dump. And an overloaded pool is an added risk for a fire which could be catastrophic. (0933-8 [Anonymous, Janet])

Comment: The NEI's scoping comments termed as "speculative" the possibility of analyzing an alternative with a centralized interim storage area for radwaste. However, given that the Yucca Mountain earlier-proposed repository is in an active volcanic and seismic area along the Ghost Dance Fault, and seeing that I have not heard of any progress being made toward a geologic repository for commercial nuclear power spent fuel waste at another location, thus I contend that it is at least as speculative to claim that there will be a permanent geologic repository for this kind of radwaste. (0937-25 [Campbell, Bruce])

Comment: There was concern that the "Mobile Chernobyl" bill might be brought up in in D.C. in December, but it was put off until the new year. Establishing centralized interim storage is taking legislative form while the push for a geologic repository is lagging. Thus, one could conclude

that in the next few decades it is much more likely to have centralized interim storage than a geologic repository that isn't in that horrible location in an active volcanic and seismic area in Nevada. Thus, the arguments that centralized interim storage is speculative is poorly supported. (0937-26 [Campbell, Bruce])

Comment: Despite what the producers of this document were told by their guiding lawyers, there is clearly and inherently a serious risk in the short, mid, and long-term storage of radioactive wastes whether in spent fuel cooling ponds, in racks, in dry casks, or in other arrangements wherever they may be at a nuclear reactor site, at some centralized or regional locale which is supposed to be awaiting a more permanent solution, or awaiting or eventually being placed in a more permanent geologic repository. (0937-29 [Campbell, Bruce])

Comment: High BurnUp Fuel -The DGEIS must be redone. Not fully evaluated in DGEIS and There is no determination of isolation from other waste, amount and location, or studies to address the problems. Must stay 20 years in pools Only 20 years in casks No transport allowed Reference:

<http://sanonofresafety.files.wordpress.com/2013/11/wasteconcommentsdgilmoreshubmitted2013-12-19docketnrc-2012-0246.pdf> (0938-14 [Sondheim, Steven])

Comment: The EIS must also compare the variety of possible methods for storing the more than 150,000 tons of highly radioactive irradiated/spent fuel that will be created and housed at nuclear power reactors by 2050. (0938-3 [Sondheim, Steven])

Comment: The storage and transport of high-burnup fuel must be fully evaluated in the EIS. (0938-6 [Sondheim, Steven])

Comment: No state is a waste dump! I don't want any more high-level radioactive wastes coming "to or through" my state. I do not want to see more high-level, long-lived radioactive waste coming to proposed so-called "centralized interim storage" waste facilities (a.k.a., "parking lot dumps") here or anywhere else. (0939-4 [Marschak, Cheryl])

Comment: Exelon believes that the NRC appropriately addresses concerns being raised about Stress Corrosion Cracking (SCC) of dry storage canisters by citing the manner in which these concerns are being resolved as an example of how the regulatory process responds to emerging events. The significant efforts that the industry has already taken, and is continuing to take, to address this concern and assure the longevity of these canisters should also be mentioned. (0942-7 [Helker, David P.])

Comment: Exelon considers that dry used fuel storage and transportation are among the safest of all industrial activities, as tens of thousands of tons of used fuel have been stored and shipped around the world in many thousands of storage and transportation packages, without a radiation-induced injury or fatality. Used fuel and radioactive material packages have a unique characteristic among all other hazardous material packages (i.e., the need for gamma radiation shielding). Gamma-shielding materials are dense and strong, and since the shielding, by regulation, must remain attached even following accident conditions, it therefore, provides enhanced robustness with larger structural safety margins than other packages. (0942-8 [Helker, David P.])

Comment: At best, permanent on-site storage would take these sites out of use for any purpose other than housing waste storage in above ground concrete "mausoleums." At worst, this dubious policy would put area residents in peril of accidents in spent fuel pools or from long-

term decay of dry-cask storage. These perils have been greatly increased by the use of "high burn-up" fuel that is hotter both thermally and radioactively, making it more dangerous to handle and more difficult to store. Currently, high burn-up has no approved means of storage beyond 20 years. (0944-7 [Pascall, Glenn] [Watland, George])

Comment: I am writing in full support of the NRC's Spent Fuel Storage Rule, and wish to say that with NRC oversight PG&E has a very detailed and successful spent fuel management program and continues to safely store fuel via both its wet and dry cask storage systems. I am confident that layer upon layer of safeguards are in place to effectively manage and monitor the stored spent fuel. (0949-1 [Commenters, Multiple])

Comment: PG&E has a very detailed and regulated spent fuel management program in place to safely store the fuel until such time as the federal government acts on its responsibility to take ownership and remove the spent fuel to a repository or allows for it to be recycled and reused. (0949-3 [Commenters, Multiple])

Comment: The wet storage pools, where the solid (not liquid) spent fuel is immediately housed after being removed from the reactors, were built with seismic-safety in mind and are constructed out of steel-reinforced concrete built into bedrock, with steel liners serving as an added safety barrier. They are an integral part of the storage process, giving the used fuel an opportunity to cool from its reactor temperature to a more modest temperature before being transported to dry cask storage. When the spent fuel assemblies are ready to be moved from wet storage, they are taken to a seismically reinforced dry cask storage facility located on-site. Here the assemblies are stored in a secure, protected area until they can be transferred to a federal government location or to a recycler for reprocessing and ultimate reuse as a fuel source (a process that is currently not being utilized in the United States). These two on-site interim storage methods are part of a safe, effective, and regulated system that follows industry best-standards. (0949-5 [Commenters, Multiple])

Comment: I am writing to support the NRC's Spent Fuel Storage Rule. In my view, with NRC oversight, PG&E has a very detailed and successful spent fuel management program for its Diablo Canyon nuclear power plant (Diablo). PG&E continues to safely store fuel via both its wet and dry cask storage systems. Without the federal government providing a permanent geologic storage facility, as required by law, PG&E has designed and implemented an interim, on-site system for the interim storage of the spent fuel assemblies. After removal from the reactors, the used fuel is placed in storage pools to cool for approximately five (5) years. After sufficient cooling, the used fuel assemblies are placed in sealed, Helium-filled canister and set inside a 20 foot tall, concrete-filled, steel storage cask. The storage casks are stored in a secure protected area proximate to the plant. Unlike other nuclear plants, the casks in the storage area are bolted to a seven and-a-half-foot thick steel-reinforced concrete pad to ensure it is seismically stable. This system has proved safe and effective. There is no reason to believe that this interim storage system would not remain viable after the Diablo plant's licensing period. I am confident that layer upon layer of safeguards are in place to effectively manage and monitor the stored spent fuel. (0949-6 [Commenters, Multiple])

Comment: Then we need strong regulations for on-site storage and for transporting waste. (0996-2 [Donaldson, John])

Comment: On-site storage in cooling pools is a bad idea because it leaves the radioactive materials spread across dozens of sites in poorly-secured locations, and requires that power be available - without significant interruption - to the cooling water pumps. (0998-4 [Rosanelli, Donald])

Comment: It is impossible to state that the NRC or anyone else for that matter can guarantee 100% that radioactive waste can safely be stored, any where, any how. The problem will only get worse when other countries try and solve their nuclear waste problem. Nature will have a way of making it impossible. (0999-1 [Kirschbaum, Saran])

Comment: The NRC is surely the only regulatory body in the world that would argue that indefinite -- essentially permanent -- storage of high-level radioactive waste in fuel pools and dry casks provides "confidence" that this waste will never cause a threat to public health and safety. MORE NRC CRIMINALITY. AND THE DELUSIONAL NRC JUST KEEP ON KILLING. (1004-6 [Dimondstein, Carla])

Comment: While on-site fuel ponds are clearly the more dangerous choice and dry cask storage would be incrementally preferable, neither provides adequate assurance of acceptable risk to public health and safety, and neither is designed for permanence. (1007-1 [Diamond, Jim])

39. Comments Concerning Spent Fuel Pool Fires

Comment: NRC downplays the risks of pool fires by assuming that surrounding populations will be successfully evacuated. But nuclear utilities are allowed to store HLRW in pools for many decades after reactors permanently shutdown, in order to defer the costs of dry cask storage as far off into the future as possible, despite the inherent risks. At the same time, NRC allows utilities, via exemptions from regulations, to do away with 10-mile radius emergency planning zones (EPZs) within as soon as 12 to 18 months post-reactor shutdown. This, despite the lingering risk of storing HLRW in pools at such shutdown reactor sites. How can populations be evacuated, if EPZs have been dismantled?! (0002-6 [Commenters, Multiple])

Comment: NRC also downplays the risks of pool fires by assuming that a pool drain down accident (or attack) involves the complete drain down of the pool. However, as environmental coalition expert witness Dr. Gordon Thompson of the Institute for Resource and Security Studies (IRSS) has pointed out, any technically competent person paying attention to the issue should have known since 1979 that a partial drain down of the pool is actually a worse-case scenario, for the leftover water in the bottom of the pool would block convection current air flow which would help cool the irradiated nuclear fuel, leading to faster heat up to the ignition point. (0002-7 [Commenters, Multiple])

Comment: Metal containment casings for nuclear fuel rods will burn spontaneously if exposed to air. When the outside burns, the inside burns and releases the radioactivity. If a water-storage fuel pool drains down, it will burn. A HRLW fire could cause huge latent cancer fatalities as far as 500 miles downwind. (0023-9 [Bridges, Martha])

Comment: I'd like to talk about the metallurgy of zirconium, Zircaloy, and fires. First of all, yes, it's true we've been very lucky with controlling fires and we've been very, very lucky with controlling fires in spent fuel pools. We don't know what's going to happen with these spent fuel pools, but now that we've got the higher compaction due to the fact that we don't have any place to put this spent fuel, the radioactive waste -- and we do not really -- I have looked at the data that the NRC has gotten on zirconium, Zircaloy, and fires. They don't look at surface conditions. They don't look at alloying, accidental alloying, or alloying at the surface very much. And there's a chance that instead of a small fire, we can go to a different kind of fire. In other words, instead of having water react with the zirconium to release hydrogen and zirconium oxide, we can go to a very fast, much faster fire where due to temperature and pressure the zirconium can react with the oxygen and air at a much, much faster rate. And I do not know if that actually happened

at Fukushima. All I saw in the news was the roof tops heading out toward a higher altitude and I do not know which kind of fire and whether the higher rate of fire was actually occurring there. (0030-14-4 [Lewis, Marvin])

Comment: In terms of the risks of pool fires, Fukushima Daiichi Unit Number 4 is the most obvious example of the potentially catastrophic risks of pool fires. If that building were to collapse, lose its cooling water supply, and catch fire, the magnitude would be an order of magnitude or greater than what we have already seen in terms of radioactivity releases at Fukushima Daiichi. (0030-2-7 [Kamps, Kevin])

Comment: I agree with NRC Chairwoman Allison Macfarlane when she wrote, along with a team of authors, in 2003 that the risks of pool fires at commercial nuclear power plants in the United States are so great that expedited transfer into hardened onsite storage dry casks is a very important national security priority. (0030-2-8 [Kamps, Kevin])

Comment: [T]he spent fuel pool fires, I think the most relevant piece of data there is what is in NRC's most recently issued spent fuel pool study, which showed that the fuel is only hot enough to burn -- even if you drain all of the water out of the pool -- I mean, you can noodle the scenarios about what causes it to drain or what doesn't cause it to drain, but it is only hot enough to burn for the first two months after it comes out of the reactor. That's not the time periods we're interested in here. (0030-6-5 [McCullum, Rod])

Comment: The EIS is inadequate in that it does not really fully analyze the -- what the Court required, an analysis of the fire scenario, what would cause a fire, and simply because your guess is that your estimate -- expert estimate is that it is unlikely, the full consequences of a fire are not really analyzed. They are analyzed for one specific reactor, but it's not an adequate scenario for a situation like Indian Point or places that have very high populations. (0030-8-4 [D'Arrigo, Diane])

Comment: I join with NRC Chairwoman Allison Macfarlane, who, along with a team of authors, published a study in 2003 warning about the potentially catastrophic risks of storage pool fires, and calling for the wastes to be transferred to dry cask storage on an expedited basis. (0034-5 [Wagner, Jim and Virginia])

Comment: From all that I have read, I believe that there is significant risk of fire in storing spent fuel in densely packed pools, particularly those in pools above ground. We all know that the pools were designed to hold many fewer rods but have been allowed to hold many more since we don't have a national storage facility. Fukushima showed us the danger in losing pumps to circulate the water around the spent fuel pool rods. This could happen here! (0048-1 [Davidson, Judith])

Comment: U.S. Congressman Edward Markey has sought to understand the lessons of Fukushima. Here are some facts about the inadequate regulation of U.S. spent fuel storage pools Rep. Markey and his staff have uncovered, in the report Fukushima Fallout: Regulatory Loopholes at U.S. Nuclear Plants; (<http://markey.house.gov/docs/05-12-11reportfinalsmall.pdf>) Spent fuel pools contain no protection from hydrogen explosions such as the hardened vents that the NRC misleadingly pretended made US reactors invulnerable to hydrogen explosions (Fukushima reactors had hardened vents too, but the loss of electrical power made them inoperable!). NRC does not require any form of hydrogen mitigation at spent fuel pools. Spent fuel pools at offline reactors (such as those undergoing refueling) require no secondary emergency generating capacity. Thus the conditions that led to the Fukushima Unit 4 fuel pool

meltdown are legal under NRC regulations. NRC has no requirement that reactor hardened vents must be operable, and there has never been a requirement in place for hardened vents in spent fuel pool buildings. US fuel pools are holding, on average, 4 times more spent fuel than they are designed for and are densely compacted. (0089-5 [Shaw, Sally])

Comment: In 1997 a report for the NRC by Brookhaven National Laboratory found that a severe pool fire could render about 188-square miles uninhabitable, cause as many as 28,000 cancer fatalities, and cause 59 billion -- cost \$59 billion in damage. Based on a technical study of spent fuel pool accident risk at decommissioning nuclear power plants in 2000, the U.S. NRC conceded that the possibility of a Zirconium fire cannot be dismissed even many years after a final reactor shutdown. Yet the NRC is confident that what has happened at three reactors in Japan due to loss of power, loss of cooling capability, and hydrogen explosions could never happen here in reactors of nearly identical age and design. And because they think it could never happen they do not really consider the consequences. This is faith-based science. (0112-18-1 [Shaw, Sally])

Comment: The risks are incredibly low on both sides. The spent fuel study, so called earthquake study [NRC-2013-0136], that has been cited here on several occasions the fundamental conclusion of this study is that after a couple months out of the reactor the fuel is coolable in air. And you can vary the assumption to that study and months can become days. But over the time periods we're not worried. It's not a big concern for these time periods. (0112-25-6 [McCullum, Rod])

Comment: The problems with the earthquake study [NRC-2013-0136] are multiple. I would refer you to the analysis by Dr. Gordon Thompson submitted by Diane Curran. The highlights of what's wrong are as follows: The study did not consider geometry. It didn't look at or compare high-density to low-density storage, which is very important element. It's limited in its consideration of water loss. Looks at complete water loss. And in actuality, NUREG-1738 that was put out in 2000, finally, and I see admitted the total drainage was the most -- was not the most severe, rather partial drainage. But the study doesn't look at partial drainage. It's limited in consideration of initiating events. It doesn't consider an attack, only earthquake. It makes no linkages amongst reactor accident and pool accident. There's no analysis of cask drops. Misleading statements about mitigating actions. It simply says that adding water or reshuffling how the assemblies are in the pool. But it gives no data how many reactors have water-spray systems. How did they test whether adding water at a certain point to a burning assembly would exacerbate fire, not correct it? As far as duration goes, it only considers up to seven days of a boil fire accident. Has nobody figured Fukushima? (0112-3-4 [Lampert, Mary])

Comment: Also it [NRC-2013-0136] uses MELCOR. And there's been no demonstration that MELCOR has -- is able to look at heat transfer and other important elements to do a real empirical study, not start with a conclusion and pretend to have a study. (0112-3-5 [Lampert, Mary])

Comment: For residents nearby, the possibility of a fire in a spent fuel pool is hardly inconsequential. It would be disastrous. (0163-20-4 [Gellert, Sally Jane])

Comment: I will be submitting comments on the spent fuel fires issue, which Chairman Macfarlane has co-authored a study stating that the densely packed fuel pools at Indian Point, for example, are at great risk of fire. (0163-7-8 [Shapiro, Susan])

Comment: Experts Agree NRC should Ignore Staff Recommendation and Follow NRC Chair's 2003 Call to Curb Risk of Nuclear Reactor Pool Fire Catastrophe, noting that Reactor Fire Danger is Far Greater Than Reactor Meltdown. A Press Release by Alex Frank (afrank@hastingsgroup.com) indicated that NRC Chair Allison MacFarlane and two co-authors prepared an important 2003 Report (Dr. Gordon R. Thompson and Robert Alvarez); "Reducing the Hazard from Stored Spent Power-Reactor Fuel in United States, Science and Global Security, 11:1-51 2003). In this 2003 Report, authors acknowledge the danger of a terrorist attack, and warned effects of a pool fire could be worse than the Chernobyl accident. The paper further proposed that "to reduce both consequences and probability of a spent-fuel pool fire, all spent fuel should be transferred from wet to dry storage within five years of discharge". Now a decade later after the Fukushima disaster, NRC is about to decide whether to require licensees to halt their use of high-density spent fuel pools, and instead use open-frame pool storage combined with dry storage, which would significantly decrease risk of a pool fire. Unlike reactors, spent fuel pools are not protected by a containment dome or structure to prevent escape of radioactivity, and are not required to have independent redundant cooling. Dr. Thompson recently indicated (October 2, 2013), that NRC staff is proposing to rely on a "Draft Consequence Study" to recommend against expediting transfer of spent fuel out of high-density storage pools into low density open racks and dry storage. But the Draft Consequence Study is totally inadequate for that purpose, because it is too narrow in scope, and because it lacks scientific rigor or integrity. The Draft Consequence Study should be scrapped, and NRC should start again with an actual science based study of pool fire risks. NRC admits that storing spent fuel in dry casks pose far less hazards. However, NRC staff argues that a switch to dry storage would impose a major expense for America's again reactor fleet, now facing stiff competition from other electricity sources. As recently as October 2, 2013, these two expert co-authors just recently reaffirmed the following findings from the 2003 Report co-authored by Chair Macfarlane:

- >In it, NRC chair joined the view that terrorist attacks are a significant threat to fuel pools, but the Draft Consequence Study does not consider that threat.
- >Chair Macfarlane joined the view that consequences of a pool fire are so great that NRC should not forego action based on probability calculations alone.
- >Chair Macfarlane joined the view that NRC should take steps to reduce density of fuel stored in pools.
- >Chair Macfarlane joined the view that NRC should be held accountable for failure to take action on risks posed by pool fires. (0218-3 [Borchmann, Patricia])

Comment: The EIS must consider the risks of pool fires. (0230-11 [Garb, James])

Comment: The dangers include just simply dropping one of these heavy loads through the floor of the pool as Linda mentioned. The scenario of partial drain-down is the worst case scenario where you have no air cooling whatsoever. And you could have radioactive inferno in just a few hours time which would dwarf what we've seen at Fukushima Daiichi thus far. (0245-13-4 [Kamps, Kevin])

Comment: Is it true that the hazards and its security of pool storage are so great that they must sacrifice security? Could anyone possibly believe that redacted material supports NRC's finding of those significant impacts? We require a much larger margin of safety about spent fuel pool fire to make better decisions about plutonium, NRC should perform Court-ordered analysis. (0245-24-7 [Conn, Corey])

Comment: We are very concerned about risks of fuel and a fire in fuel pools. (0246-16-8 [Michetti, Susan])

Comment: In addition to the dangers of a fuel fire, which are not adequately addressed -- they are simply documented and then dismissed by saying it is low probability -- that the radiation effects from routine operations, from routine release, and through routine management of fuel, as well as from the long-term or the more devastating impacts from accidents, are not fully, adequately being assessed. And this looks like a rubber stamping saying that there is low impacts when, in fact, we don't really know, and more likely, there will be. (0246-2-7 [D'Arrigo, Diane])

Comment: The study failed to fully consider the vulnerability of high-density spent fuel storage pools to catastrophic fire or the risks of undetected leakage from pools and other reactor components. The GEIS must include a full examination of these risks. This is what the Court intended and that is what is required for the EIS to be in compliance with NEPA. (0246-22-4 [Fisher, Allison])

Comment: Not all nuclear waste is the same. It's highly flammable[.] (0250-29-7 [Rivard, Betsey])

Comment: Remember while flooding and risk of leakage threatens our vital drinking water supplies, we must also be concerned about water loss from earthquakes, dropping of fuel casks, aircraft impact, accidental fires, and explosions. Any and all of these threats could easily lead to an irradiated fuel fire. (0250-40-3 [Kerr, Beverly])

Comment: Everyone agrees there's no argument that a radiological release from a pool fire could dwarf that of a nuclear meltdown[.] (0250-40-4 [Kerr, Beverly])

Comment: Attached article entitled "EXPERTS: NRC SHOULD IGNORE STAFF AND FOLLOW CHAIR'S 2003 CALL TO CURB RISK OF NUCLEAR REACTOR POOL FIRE CATASTROPHE--Cutting Corners for Uncompetitive U.S. Nuclear Industry? Nuclear Regulatory Commission Draft Staff Report Urges Action Directly Contradictory to 2003 Paper by Chair Macfarlane; Reactor Fire Danger Far Greater Than Meltdown, Could Displace 4 Million Americans" was submitted anonymously. EXPERTS: NRC SHOULD IGNORE STAFF AND FOLLOW CHAIR'S 2003 CALL TO CURB RISK OF NUCLEAR REACTOR POOL FIRE CATASTROPHE Cutting Corners for Uncompetitive U.S. Nuclear Industry? Nuclear Regulatory Commission Draft Staff Report Urges Action Directly Contradictory to 2003 Paper by Chair Macfarlane; Reactor Fire Danger Far Greater Than Meltdown, Could Displace 4 Million Americans. Listen to the 10.02.13 news event here ... WASHINGTON, D.C.-October 2, 2013 -A pending Nuclear Regulatory Commission (NRC) staff recommendation that the beleaguered U.S. nuclear power industry should be allowed to continue packing already high-density fuel reactor pools should be rejected in favor of the safer approach of "dry" cask storage embraced in a 2003 paper by then MIT researcher Allison Macfarlane, who is now chair of the NRC. Two of her coauthors of the 2003 paper are urging the NRC to scrap an inadequate draft study of the spent-fuel storage issue and to go back to the drawing board. That was the call today from Macfarlane's 2003 report co-authors: Dr. Gordon R. Thompson and Robert Alvarez. Dr. Thompson is executive director of the Institute for Resource and Security Studies, Cambridge, MA. He also serves as a senior research scientist at the George Perkins Marsh Institute, Clark University, Worcester, Massachusetts. Alvarez is senior scholar at the Institute for Policy Studies, where he is focused on nuclear disarmament, environmental, and energy policies. From 1993 to 1999, Alvarez served as a senior policy advisor to the Secretary of Energy and Deputy Assistant Secretary for National Security and the Environment. The 2003 paper in question is Alvarez et al., Reducing the Hazard from Stored Spent Power-Reactor fuel in the United States, Science and Global Security, 11:1-51, 2003. In it, Macfarlane and her co-authors acknowledged the danger of a terrorist attack and warned that the effects of a pool fire could be

worse than the Chernobyl accident. Further, the paper proposed that "[t]o reduce both the consequences and probability of a spent-fuel-pool fire," all spent fuel should be "transferred from wet to dry storage within five years of discharge." The paper is available online at https://www.princeton.edu/sgs/publications/sgs/pdf/11_1Alvarez.pdf. A decade later in the wake of the Fukushima disaster, the NRC is about to decide whether to require licensees to halt their use of high-density spent fuel pools and instead use open-frame pool storage combined with dry storage, which would significantly decrease the risk of a pool fire. Spent fuel is currently stored in high-density pools at every reactor in the U.S. Originally intended for short-term cooling of five years or less, reactor pools now hold four to-five times more than their original designs and contain some of the largest concentrations of artificial radioactivity in the world. [ARTICLE CONTINUED IN NEXT COMMENT] (0281-1 [Individual, Anonymous])

Comment: [CONTINUATION OF ARTICLE ENTITLED: "EXPERTS: NRC SHOULD IGNORE STAFF AND FOLLOW CHAIR'S 2003 CALL TO CURB RISK OF NUCLEAR REACTOR POOL FIRE CATASTROPHE" submitted anonymously.] Spent fuel pools are susceptible to accidents -such as Fukushima -and are prime targets for terrorists. Unlike reactors, spent fuel pools are not protected by a containment structure to prevent the escape of radioactivity and are not required to have independent redundant cooling. NRC admits that a pool fire could release far more radioactivity than a meltdown and displace more than four million people from their homes. After both 9/11 and the Fukushima accident, the NRC recognized the potential for a catastrophic pool fire. Furthermore, the NRC's Office of Nuclear Security and Incident Response uses a predictive tool to aid emergency responders during nuclear accidents which indicates that the radiological release from a pool fire following an earthquake would dwarf that of a reactor meltdown. It also indicates that the consequence of the breach of a dry cask is thousands of times less severe. The NRC admits that storing spent nuclear fuel in dry casks pose far less hazards. However, NRC staff argues that a switch to dry storage would impose a major expense for America's aging reactor fleet, now facing stiff competition from other electricity sources. Thompson said: "The NRC staff is proposing to rely on a 'Draft Consequence Study' to recommend against expediting the transfer of spent fuel out of high-density storage pools into low-density open racks and dry storage. But the Draft Consequence Study is totally inadequate for that purpose, because it is too narrow in scope and because it lacks scientific rigor or integrity. The Draft Consequence Study should be scrapped and the NRC should start again with an actual science-based study of pool fire risks." Alvarez said: "The NRC staff study lacks integrity because it examines only complete drainage of a pool and ignores the more severe case of partial drainage-despite being warned about this hazard by the National Academy of Sciences in 2004. It's a remarkable coincidence the NRC staff comes up with assumptions it has already adopted for several years without the benefit of its current scientific analysis. By reverting to the discredited assumption that complete pool drainage is the worst case, the NRC undermines the credibility of the Study. The Study also is too narrow because it significantly underestimates risk by considering only one type of initiating event- an earthquake -and ignoring other credible initiating events that are at least as probable. For instance, the Study ignores the impacts of aging and the potential for an attack on a pool and/or adjacent reactor to initiate a pool fire. Vulnerability of spent fuel storage pools to terrorist attack is perhaps the greatest risk of all and cannot be defined away by probability statistics or cost-benefit analysis" Diane Curran, attorney, Harmon, Curran, Spielberg & Eisenberg, L.L.P., said: "The NRC Commissioners have stated that they intend to make a decision this fall. The NRC Staff's Draft Consequence Study is supposed to provide the primary technical basis for the Commission's decision. Our purpose today is to discuss the reasons we believe the Staff's analysis is seriously deficient, and inconsistent with a previous independent technical study by the NRC's current chair, Allison Macfarlane, while she was affiliated with MIT. We are calling upon Dr. Macfarlane to apply her expertise and lead the Commission to a decision that protects

the public and the environment from the unacceptable. risk of a pool fire." [CONTINUED IN NEXT COMMENT] (0281-2 [Individual, Anonymous])

Comment: [CONTINUATION OF ARTICLE ENTITLED: "EXPERTS: NRC SHOULD IGNORE STAFF AND FOLLOW CHAIR'S 2003 CALL TO CURB RISK OF NUCLEAR REACTOR POOL FIRE CATASTROPHE" submitted anonymously.] Thompson and Alvarez noted that the NRC has never conducted a valid scientific study of pool fire risks, although it has had the capability since prior to 1990. Instead, over a period exceeding three decades, NRC published one bad analysis after another that ignored important characteristics and behavior of high-density fuel storage pools and falsely concluded the pools were safe. Early in 2001, the NRC admitted that it had not fully understood the potential for a catastrophic pool fire. Yet, after the 9/11 attacks, the NRC systematically hid its analyses behind a veil of secrecy. The Draft Consequence Study is the first public study the NRC has released since before September 11 -but it simply perpetuates the same bad science of the period before 9/11. In calling for the Draft Consequence Study to be scrapped in favor of a bona fide scientific review of the pool fire issue, Thompson and Alvarez noted the following about the 2003 paper co-authored by Chair Macfarlane: -In it, the NRC chair joined the view that terrorist attacks are a significant threat to fuel pools- but the Draft Consequence Study does not consider that threat. -Chair Macfarlane joined the view that the consequences of a pool fire are so great that the NRC should not forego action based on probability calculations alone. -Chair Macfarlane joined the view that the NRC should take steps to reduce density of fuel stored in pools. -Chair Macfarlane joined the view that the NRC should be held accountable for failure to take action on risks posed by pool fires. MEDIA CONTACT: Alex Frank, (703) 276-3264 or afrank@hastingsgroup.com. EDITOR'S NOTE: A streaming audio replay of a related news event will be available on the Web at <http://bit.ly/reactorpoolfire> as of 5 p.m. EDT on October 2, 2013. (0281-3 [Individual, Anonymous])

Comment: Before the public meeting began, I spoke with Paul Michalak (NRC- Generic DEIS Manager), about my questions regarding Executive Summary, page 1ix, Section ES. 16.2 Spent Fuel Pool Fires. The Executive Summary concludes the "risk of a spent fuel fire is low because even though the consequence would be high, the probability would be low." This conclusion by NRC is in contrast to a press release by Alex Frank (703 276-3264, or afrank@hastingsgroup.com, dated 10-02-13. I've enclosed a copy of this 3-page press release by Alex Frank (attached), titled "Experts: NRC Should Ignore Staff and Follow Chair's 2003 Call to Curb Risk of Nuclear Reactor Pool Fire Catastrophe" On page 1, paragraph 6, first sentence states- "NRC admits that a pool fire could release far more radioactivity than a meltdown, and displace more than four million people from their homes." (0284-13 [Borchmann, Patricia])

Comment: Experts Agree NRC should Ignore Staff Recommendation and Follow NRC Chair's 2003 Call to Curb Risk of Nuclear Reactor Pool Fire Catastrophe, noting that Reactor Fire Danger is Far Greater Than Reactor Meltdown. A Press Release by Alex Frank (afrank@hastingsgroup.com) indicated that NRC Chair Allison MacFarlane and two co-authors prepared an important 2003 Report (Dr. Gordon R. Thompson and Robert Alvarez); "Reducing the Hazard from Stored Spent Power-Reactor Fuel in United States, Science and Global Security, 11:1-51 2003). In this 2003 Report, authors acknowledge the danger of a terrorist attack, and warned effects of a pool fire could be worse than the Chernobyl accident. The paper further proposed that "to reduce both consequences and probability of a spent-fuel pool fire, all spent fuel should be transferred from wet to dry storage within five years of discharge". Now a decade later after the Fukushima disaster, NRC is about to decide whether to require licensees to halt their use of high-density spent fuel pools, and instead use open-frame pool storage combined with dry storage, which would significantly decrease risk of a pool fire. Unlike reactors, spent fuel pools are not protected by a containment dome or structure to prevent

escape of radioactivity, and are not required to have independent redundant cooling. Dr. Thompson recently indicated (October 2, 2013), that NRC staff is proposing to rely on a "Draft Consequence Study" to recommend against expediting transfer of spent fuel out of high-density storage pools into low density open racks and dry storage. But the Draft Consequence Study is totally inadequate for that purpose, because it is too narrow in scope, and because it lacks scientific rigor or integrity. The Draft Consequence Study should be scrapped, and NRC should start again with an actual science based study of pool fire risks. NRC admits that storing spent fuel in dry casks pose far less hazards. However, NRC staff argues that a switch to dry storage would impose a major expense for America's aging reactor fleet, now facing stiff competition from other electricity sources. As recently as October 2, 2013, these two expert co-authors just recently reaffirmed the following findings from the 2003 Report co-authored by Chair Macfarlane: In it, NRC chair joined the view that terrorist attacks are a significant threat to fuel pools, but the Draft Consequence Study does not consider that threat. Chair Macfarlane joined the view that consequences of a pool fire are so great that NRC should not forego action based on probability calculations alone. Chair Macfarlane joined the view that NRC should take steps to reduce density of fuel stored in pools. Chair Macfarlane joined the view that NRC should be held accountable for failure to take action on risks posed by pool fires. (0284-3 [Borchmann, Patricia])

Comment: Spent fuel is highly flammable as well as about one million times more reactive than when placed in the reactor, yet is primarily stored in densely packed pools of water that contain several times more fuel than the nuclear reactor itself. If a fuel pool is damaged or loses its cooling system, fuel rods could be exposed, overheat, and catch fire, releasing massive quantities of radioactive material, creating a far greater disaster than a meltdown of the reactor. (0319-10 [Nichols, John])

Comment: According to a report by Robert Alvarez entitled, it's kind of a long title, "Reducing the Hazards of High-Level Radioactive Waste in Southern California," published by the Friends of the Earth that, "If an airplane was successful in starting a spent fuel pool fire in one of the two cooling pools at San Onofre and only 30 percent of the pool's contents were to burn, the radioactive release from this event would be comparable to 10 Chernobyls." That's what is there right now. I read the Generic Environmental Impact Statement or study and it estimates that the largest number of early -- of fatalities to be 191 people for a spent fuel accident. Latent fatalities are estimated to be 20,000 to 27,000 people. These data points have been taken from the NRC document NUREG-1738 and put into this Environmental Impact Statement. That Nuclear Regulatory 1738 was published in January 2001 before September 11th, 2001. Repeatedly, people have challenged this, including the Attorney General of California, and the Attorney General of Massachusetts. And the NRC states that this report, 1738, is valid, 191 people. Crazy. Clearly, there's a huge difference in opinion on what could happen based on this concept of probability of an event occurring. I believe the NRC is aware of the possibility of a catastrophic event occurring from a spent fuel pool fire, but the NRC is unwilling to entertain the fact that this probability is anything but an extremely remote possibility. (0325-22-2 [Morgal, Richard])

Comment: The NRC downplays the risks of pool fires by assuming that surrounding populations will be successfully evacuated. But nuclear utilities are allowed to store HLRW in pools for many decades after reactors permanently shutdown in order to defer the costs of dry cask storage as far off into the future as possible, despite the inherent risks. At the same time, the NRC allows utilities, via exemptions from regulations, to do away with 10-mile radius emergency planning zones (EPZs) within as soon as 12 to 18 months post-reactor shutdown,

despite the lingering risks of storing HLRW in pools at such shutdown reactor sites. How can populations be evacuated, if EPZs have been dismantled?! (0336-10 [Lish, Christopher])

Comment: The NRC also downplays the risks of pool fires by assuming that a pool drain down accident (or attack) involves the complete drain down of the pool. However, as Dr. Gordon Thompson of the Institute for Resource and Security Studies has pointed out, any technically competent person paying attention to the issue should have known since 1979 that a partial drain down of the pool is actually a worse-case scenario, for the leftover water in the bottom of the pool would block convection current air flow which would help cool the irradiated nuclear fuel, leading to faster heat up to the ignition point. (0336-11 [Lish, Christopher])

Comment: 3. The decision to allow DCNPP's spent fuel pools getting filled to high density capacity has unnecessarily added two more potential sources for major nuclear disasters. Pool fires are now a possibility where there were none before. (0358-5 [Schumann, Klaus])

Comment: Hi, attached are comments in the form of a Powerpoint regarding the Waste Confidence issue. This Powerpoint is a slide show originally done to show how a meltdown and fuel pool fire would affect agricultural areas that we buy organic grapes from to make into wine. It may be educational regarding waste confidence rulemaking. Similar fallout could happen from each nuclear power plant near where you live. [Power Point slides attached to comment-ML13345A069] (0366-1 [Frey, Paul])

Comment: Health and Economic Impacts Of Extended Loss of Water In Spent Fuel Pools Like Limerick's: Limerick's design is similar to reactors in meltdowns at Fukushima. Roof-top fuel pools are highly vulnerable to loss of power and cooling water from an earthquake or other natural disasters, in addition to a variety of attacks by terrorists (0377-3-6 [Cuthbert, Lewis])

Comment: NRC downplays risks of pool fires by erroneously assuming that surrounding populations will be successfully evacuated. (0377-6-2 [Cuthbert, Lewis])

Comment: NRC also downplays risks of fuel pool fires by inaccurately assuming that a drain down accident (or attack) involves the complete drain down of the fuel pool. -Dr. Gordon Thompson, Institute for Resource and Security Studies (IRSS) pointed out, any technically competent person should have known since 1979 that a partial drain down of the pool is actually a worsecase scenario, for the leftover water in the bottom of the pool would block convection current air flow which would help cool the irradiated nuclear fuel, leading to faster heat up to the ignition point (0377-6-4 [Cuthbert, Lewis])

Comment: Fuel rods in cooling pools suffer from the same vulnerability as those in a reactor accident. Any sustained loss of electrical power could result in a loss of cooling, evaporation of the cooling water, exposure of the fuel assemblies to air, spontaneous ignition of the zirconium cladding and widespread dispersion of radioactive particles. Once contamination of the surrounding area has occurred it becomes virtually impossible to perform damage control to prevent further escalation of the event and to conduct remediation and clean-up efforts because of the high ambient radiation levels. This is particularly problematic if there are several contiguous facilities which may contaminate each other when impacted by the same event. Different radioisotopes have different volatilities and therefore different propagation characteristics in the event of a fire. The size of the particles also determines the distance they travel in the event of an accidental release. (0410-8 [Nelson, Dennis])

Comment: The draft report contains some serious estimated consequences for the volatile ruthenium group of radionuclides in fuel newly removed from the reactor if it should be released by a spent fuel fire. The NRC attempts to rationalize this into a less serious event by postulating an early and complete evacuation of people after the accident. (0410-9 [Nelson, Dennis])

Comment: NRC downplays the risks of pool fires by assuming that surrounding populations will be successfully evacuated. But nuclear utilities are allowed to store HLRW in pools for many decades after reactors permanently shutdown, in order to defer the costs of dry cask storage as far off into the future as possible, despite the inherent risks. At the same time, NRC allows utilities, via exemptions from regulations, to do away with 10-mile radius emergency planning zones (EPZs) within as soon as 12 to 18 months post-reactor shutdown. This, despite the lingering risk of storing HLRW in pools at such shutdown reactor sites. How can populations be evacuated, if EPZs have been dismantled?! (0412-1 [Individual, Anonymous])

Comment: Even partially loss of cooling water or pool level could create a disastrous radioactive plume, and a zirconium fuel rod cladding oxidation fire releasing far more radioactivity than exists in the reactor core. In NRC reports, as much as 100% of the Cs-137 is estimated to be vulnerable to release from the inventory of SNF in a storage pool. These are documented facts available in many NRC publications, and in independent studies, including one co-authored by the current chairperson Allison Madfarlane of the NRC (Alvarez et al, 2003). (0447-1-16 [Andrews, Richard])

Comment: A subsequent report by Robert Alvarez (IPS, May 2011) published shortly after the Fukushima disaster began further supports the potentially disastrous consequences of a spent fuel fire. New modeling was not performed in this report but the reality of Fukushima catastrophe and the actual destruction of the SNF structures and buildings should serve as a lesson. (0447-1-17 [Andrews, Richard])

Comment: I have recently completed a RASCAL 4.3 modeling of a spent fuel pool release for the Indian Point Unit 2 spent fuel pool inventory under a drained-uncovered pool fuel scenario. This plant was chosen as representative of a plant in proximity to a major high population density urban setting. The current inventory of SNF at Unit #1, 2 and 3 of Indian Point is estimated to be approximately 234 million Curies (Alvarez, IPS 2011; Yucca Mtn DOE/EIS-0250), about 94 million Curies as Cesium-137, approximately 40% of the total radioactive source. My extrapolated estimate of Unit #2 Nov 2013 SNF inventory is about 1487 fuel assemblies, actually 113 more than original design pool capacity, increasing at the rate of about 38 assemblies per year. Status of non-operating Unit #1 spent fuel pool is not known, nor is amount of SNF that has moved to ISFSI dry cask. Total estimated Unit #2 pool radioactive source is approximately 133 million Curies total and 53 million Curies of Cs-137. The RASCAL 4.3 (Sept 2013) database and summary of activity released to the atmosphere by the model is 26 million Curies total and 15 million Curies of Cs-137, reflecting built in model assumptions of release factor reductions from an uncovered and drained pool fire event. In other words the RASCAL model does not assume 100% of the spent fuel radioactive inventory is released in a fire. According to the model documentation the release factor is assumed at 0.3 for Cs and Rb. The model also reduces effective inventory loss and radioactivity by age categories since off loading from the core. For the RASCAL model assumed wind speeds were ranging from 6 to 9 mph, predominantly from north 15 degrees down the Hudson River. A fresh off-load of spent fuel from the core was assumed to have been made. The source term release was assumed to happen over an approximate 24 hour period, zirconium cladding fire and failure assumed to initiate 2 hours after drained pool condition occurred and fuel temperatures reach 1200 F. Using EPA defined Protective Action Guide (PAG) dose action ranges for Total Effective Dose

Equivalents (TEDE), the model impact zone areas were 247S sq miles(> 2 rem), and 3300 sq miles for >0.2 rem, for 1st year phase. For the 2nd year phase, impact areas were 3,87S and 1,775 sq miles for > zero and >5 rem TEDEs, respectively. For Cs137 surface contamination at levels greater than 15 uCi/m2 the impact area was 2850 sq miles. For Cs-137 surface contamination greater than SO uCi/m2, the impacted area was 2,200 sq miles. To put this in perspective, the Chernobyl permanent evacuation zone of the radiation control area was set at Cs137 contamination of >15 uCi/m2, and encompassed a land area of approximately 3,860 sq miles (10,000 km2),; calculated out to a radius of 36 miles. For Chernobyl the zone at >50uCi/m2 is reported as an area with >0.7% chance of radiation caused cancer deaths from a lifetime external radiation exposure. For Chernobyl the area greater than SO uCi/m2 was determined to be approximately 1,200 sq miles (3,100 km2). This is not understood to include other exposures such as internal ingestion of contaminated foods, or water, so the hazards are much higher. The Chernobyl disaster was actually much smaller in impact contamination and land areas than the possible impacts from a single spent nuclear fuel pool release from any of the U.S. nuclear power plant sites, particularly when one considers the conservative aspects of the RASCAL model regarding reduced magnitude of spent fuel source terms and other model assumptions. (0447-1-19 [Andrews, Richard])

Comment: Now consider that this area of CS-137 surface concentrations covers virtually all of New York City metropolitan area, major parts of Long Island, major parts of New Jersey, eastern Pennsylvania, and even Western parts of Connecticut, with significant fallout into the Atlantic seaboard oceans, estuaries, and bays. Slightly different meteorological conditions with more northeasterly winds could blanket contaminate nearly all of New Jersey and Philadelphia as well, or with westerly winds the contamination plume could cover nearly all of Connecticut, Rhode Island, Massachusetts, and the southern parts of Vermont and New Hampshire and Maine. In the present model the plume of greater than 100 uCi/m2 Cs-137 contamination actually goes well beyond the 100 mile radius from the Indian Point plant down into Delaware, but the model cuts off at 100 miles in its calculations. The impacts and consequences from such an event are simply hard to fathom they are so devastating to one of the most dense population areas of the United States. I have not made estimates of numbers of people impacted but it is likely 10s of millions, nor have I estimated the immediate deaths and lifelong health and fatality effects due to insufficient time in preparing this analysis and comments, but this could be done using U.S. census data and local land/property value, and land use data overlaid on the modeled plume contours. In effect, such an event would dwarf most displaced person and refugee events experienced in major wars experienced in the last half century. But the effects of a radiological land contamination event are much longer in duration, certainly many decades long until long half life isotopes decay such as Cs-137, to essentially permanent for some land and human occupancy uses, and for impacts on natural biological systems and agricultural lands. The wind direction and meteorological conditions, coupled with the immediately fresh off load of spent fuel from the core do make this case study a near worst case scenario, but for an intelligent and committed terrorist, that person may just select his target and timing and weather conditions to do the most damage he can inflict. Due to certain conservative aspects of the RASCAL model on assumed percentage release of SNF inventory from a SNF fire, the actual contamination levels and doses may be much larger than calculated by the RASCAL model. Also the duration of the release from such a fire is considered to be relatively brief, measured in a few hours beyond the assumed initial 2 hours to reach zirconium cladding ignition temperatures, and consequently insufficient time to allow for an orderly mass evacuations to occur. The Fukushima disaster involving spent fuel pool at Unit 4 may however lead us to understand that the source material release duration could be much longer, and could involve conditions nearly impossible to bring under any control once initiated for very long time frames, also leading to greater total radioactive material releases to the atmosphere, soil, water, and

general environment. As another conservative assumption, this RASCAL modeled case only involves Unit #2 SNF pool at Indian Point, not the SNF stored in Unit #1 or Unit #3 pools, or materials in dry storage casks, nor any releases from the reactor cores. The status of Unit #1 pool is unknown to this author since that reactor discontinued power output in the 1970s. (0447-1-20 [Andrews, Richard])

Comment: To illustrate the radioactive dispersion impact areas attached are several of the map overlays of contamination plume patterns for the RASCAL 4.3 model of an Indian Point Unit 2 spent fuel pool fire event and associated radionuclide source term release. Included are maps of total effective dose equivalent (TEDE) zones at various concentration ranges and phases of exposure (immediate, 1 year, 2 year and 50 year), surface contamination (total and Cs-137), and thyroid committed dose equivalent. Please take the time to study these maps and visualize the land areas and people affected. (0447-1-21 [Andrews, Richard])

Comment: The June 2013 NRC report on how earthquakes could affect BWR Mark I SFPs claims that in the event of a complete SFP LOCA, the fuel assemblies would not be air coolable for 10 percent of a two year operating cycle (the approximate time interval between the loading of each reactor core discharge into the SFP); that is, the fuel assemblies would not be air coolable for 73 days. However, the June 2013 NRC report states that in a partial BWR Mark I SFP LOCA, the airflow could be impeded if there were channeled fuel assemblies in the SFP, which would “*increase the time to coolability*”⁵⁶ [footnote 56 text: NRC, “Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I Boiling Water Reactor: Draft Report,” Appendix B, p. B-10.] [emphasis added]. Elsewhere, the June 2013 NRC report states that a partial BWR Mark I SFP LOCA is *assumed not* to be air coolable for an entire two year operating cycle (730 days).⁵⁷ [footnote 57 text: Id., Appendix D, p. D-13.] In other words, partial BWR Mark I SFP LOCAs, in which “the rack baseplate is not cleared and airflow is impeded,”⁵⁸ [footnote 58 text: Id.] are *assumed not* to be air coolable during a reactor’s entire life of operation, in which reactor core discharges would be loaded into the SFP every two years. As stated, the baseplates also would not be cleared in SBO boil-off accidents—another reason such accidents could lead to SFP fires. (0463-1-10 [Leyse, Mark])

Comment: According to the Electric Power Research Institute (“EPRI”), in a boil-off accident, “the temperature on the operating floor of the SFP...would also, at best, be tolerable from the standpoint of temperature and humidity for only a short period even with the help of protective clothing;”⁵⁹ [footnote 59 text: Electric Power Research Institute (“EPRI”), “Severe Accident Management Guidance Technical Basis Report,” Volume 2: “The Physics of Accident Progression,” 1025295, October 2012, Appendix EE, p. EE-2.] which “may require a special suit and a breathing apparatus.”⁶⁰ [footnote 60 text: Robert E. Henry, Fauske & Associates, “Additions and Changes to TBR Volume 2: Physics of Accident Progression,” NRC Briefing on SAMG TBR, November 7, 2012, (ADAMS Accession No: ML12318A080), p. 66.] EPRI also states: [T]he possibility of increased radiation levels on the refueling floor would be a key concern since some emergency actions could involve installing hoses or pipes on the refueling floor to refill the pool. From the safety perspective, the SFP water depth absorbs the gamma rays emitted by the decay heat from reactor fuel. The gamma rays are attenuated exponentially as a function of the water depth...; [I]f the initial water depth is decreased by a factor of two [50 percent], the radiation intensity would increase by 300 to 1000 times [from typical values]. When the radiation level increases to this extent, only minimal time should be spent on the refueling floor. Furthermore, the radiation level will increase exponentially with a further decrease in the SFP water level.⁶¹ [footnote 61 text: EPRI, “Severe Accident Management Guidance Technical Basis Report,” Volume 2: “The Physics of Accident Progression,” 1025295, Appendix EE, pp. EE-1, EE-2.]; In fact, personnel access “should be limited when the [SFP water] level is

significantly reduced and prohibited when the water level is below one-half of the nominal value.”⁶² [footnote 62 text: Id., Appendix EE, p. EE-2.] (0463-1-11 [Leyse, Mark])

Comment: Station Blackout Boil-Off Scenarios Could Lead to Spent Fuel Pool Fires. SFPs store fuel assemblies (essentially bundles of fuel rods, comprised of zirconium alloy cladding sheathing uranium dioxide (UO₂) fuel pellets) after they are discharged from the reactor core. (See Figure 1.) If there were a loss of SFP cooling, the water in the pool would be heated by the fuel assemblies’ decay heat (heat generated by the radioactive decay of the fuel’s fission products) until it reached the boiling point; then the water would boil away, uncovering the fuel assemblies.; [See Figure 1. Fuel Assembly, Fuel Rod, and Uranium Dioxide Fuel Pellets in Original Letter in NRC Adams Database ML13351A310]⁷¹ [footnote 71 text: NRC, Image from “Fact Sheet: Storage of Spent Nuclear Fuel.”]; SFPs have various depths; PWR and BWR SFPs typically have depths in a range from 38.0 feet to 40.0 feet.⁷² [footnote 72 text: NRC, “Regulatory Analysis for the Resolution of Generic Issue 82, ‘Beyond Design Basis Accidents in Spent Fuel Pools’,” NUREG-1353, April 1989, (ADAMS Accession No. ML082330232), p. 4.5.] And spent fuel assemblies typically have heights of approximately 13 feet 4 inches,⁷³ [footnote 73 text: EPRI, “Severe Accident Management Guidance Technical Basis Report,” Volume 2: “The Physics of Accident Progression,” 1025295, October 2012, Appendix EE, p. EE-8.] so there is typically less than 27 feet of water above the top of the fuel assemblies in SFPs. (In BWR Mark I and II designs, SFPs are typically located at the level of the operating floor, approximately 100 to 150 feet above ground level; and in PWR and BWR Mark III designs, SFPs are typically located at ground level.⁷⁴) [footnote 74 text: NRC, “Regulatory Analysis for the Resolution of Generic Issue 82, ‘Beyond Design Basis Accidents in Spent Fuel Pools’,” NUREG-1353, p. 4.6.] (0463-1-14 [Leyse, Mark])

Comment: A number of factors would determine the “heat load” in the SFP, including how recently some of the fuel assemblies stored there had been discharged from the reactor core, because the amount of heat generated by decay heating progressively declines (nonetheless, decay heating remains a significant heat source for years). A 2011 IAEA report states that “[t]he heat load in spent fuel soon after irradiation is primarily due to the fission products [that is, primarily due to the decay heat generated by the fission products]. Much later in life it is due to the decaying actinides,”⁷⁵ [footnote 75 text: IAEA, “Impact of High Burnup Uranium Oxide and Mixed Uranium-Plutonium Oxide Water Reactor Fuel on Spent Fuel Management,” No. NF-T-3.8, 2011, p. 18.] predominantly uranium, a small percentage of plutonium, and traces of other actinides. And the NRC states that the heat load in the SFP decreases rapidly over time from its peak value.”⁷⁶ [footnote 76 text: NRC, “Review Standard for Extended Power Upgrades,” RS-001, Revision 0, December 2003, Attachment 2 to Matrix 5, (located at <http://www.nrc.gov/reactors/operating/licensing/powerupgrades/rs-001-rev-0-dec2003.pdf>), p. 2.] The length of time prior to commencing movement of the fuel assemblies from the reactor core after shutdown to the SFP should also be considered in accessing SFP accidents. At some NPPs, the time before commencing fuel movement after shutdown has been reduced; for example, in 2002, PSEG Nuclear, the owner of Salem Nuclear Generating Station, Units 1 and 2, requested that the time prior to commencing fuel movement after shutdown at Salem be *reduced from 168 hours to 100 hours*.⁷⁷ [footnote 77 text: D.F. Garchow, PSEG Nuclear, “Request for Changes to Technical Specifications for Refueling Operations: Fuel Decay Time Prior to Commencing Core Alterations or Movement of Irradiated Fuel at Salem Nuclear Generating Station, Units 1 and 2,” June 28, 2002, (ADAMS Accession No. ML021920053), p. 1.] Of course, the heat load in the SFP would also be determined by the quantity of fuel assemblies stored in the SFP. With high-density storage there are greater heat loads. If there were a loss of SFP cooling, the heat load in the SFP would affect how long it took for the water to reach the boiling point and boil away, uncovering the fuel assemblies. As an accident

progressed, *local* heat up rates would be affected by fuel rack loading patterns—how the most recently discharged fuel assemblies were arranged with ones discharged over a year previously. In the SFP, fuel assemblies might be arranged within checkerboard configurations; there may be one more recently discharged fuel assembly out of every four cells; the other three could contain older fuel assemblies. In *certain* boil-off scenarios, the water in a “typical” SFP⁷⁸ [footnote 78 text: Generic analyses of SFPs are limited. See J.H. Jo, P.F. Rose, S.D. Unwin, V.L. Sailor, Brookhaven National Laboratory, “Value/Impact Analyses of Accident Preventive and Mitigative Options for Spent Fuel Pools,” NUREG/CR-5281, March 1989, (ADAMS Accession No. ML071690022), p. 5.] that had been loaded five days prior with a 1/3 core discharge, would heat from 51.7°C (125°F) to 100°C (212°F) in 11.2 hours and boil dry in 125.0 hours; and a typical SFP that had been loaded five days prior with a full core discharge, would heat from 66°C (150°F) to 100°C (212°F) in 3.1 hours and boil dry in 49.3 hours. (All of these values are for a SFP already stocked with 20 years of accumulated core discharges.)⁷⁹ [footnote 79 text: NRC, “Regulatory Analysis for the Resolution of Generic Issue 82, ‘Beyond Design Basis Accidents in Spent Fuel Pools’,” NUREG-1353, p. 4-25.] (0463-1-15 [Leyse, Mark])

Comment: In a SBO boil-off accident, if there were partial uncovering of the fuel assemblies, the water level would be above the baseplates, essentially blocking the flow of air through the fuel assemblies and impeding the transfer of heat away from the fuel; the poor heat transfer conditions would cause “the fuel to heat up at a higher rate than if natural circulation [were] occurring.”⁸³ [footnote 83 text: Zachary I. Franiewski et al., Pennsylvania State University, “Spent Fuel Pool Analysis of a BWR-4 Fuel Bundle Under Loss of Coolant Conditions Using TRACE,” p. v.] A March 1979 report, NUREG/CR-0649, observes that in partial-uncovering scenarios, the “heat transfer advantages...gained by converting decay heat to boiling energy would be minimal,” because the (boiling) water level would be “far” below the elevations of the fuel assemblies that had the maximum fuel-cladding temperatures and heatup rates.⁸⁴ [footnote 84 text: Allan S. Benjamin et al., Sandia Laboratories, “Spent Fuel Heatup Following Loss of Water During Storage,” NUREG/CR-0649, March 1979, p. 40.] There would also be partial cooling of the fuel cladding from the steam that was generated by the boiling water;⁸⁵ [footnote 85 text: NRC, “Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I Boiling Water Reactor: Draft Report,” p. 118.] saturated steam would enhance the natural convection of heat away from the fuel assemblies because it has a high heat capacity.⁸⁶ [footnote 86 text: Allan S. Benjamin et al., Sandia Laboratories, “Spent Fuel Heatup Following Loss of Water During Storage,” NUREG/CR-0649, March 1979, p. 40.] However, in partial-uncovering scenarios, the heat-transfer benefits of steam would be minimal compared to how the blockage of air flow through the fuel assemblies would impede the transfer of heat away from the fuel rods; in terms of heat transfer, partial uncovering is considered “the worst case scenario.”⁸⁷ [footnote 87 text: Zachary I. Franiewski et al., Pennsylvania State University, “Spent Fuel Pool Analysis of a BWR-4 Fuel Bundle Under Loss of Coolant Conditions Using TRACE,” p. v.] (0463-1-16 [Leyse, Mark])

Comment: (In a complete SFP LOCA, complete uncovering of the fuel assemblies (with the water level dropping far enough below the bottom of the SFP baseplates,⁸⁸ [footnote 88 text: “[T]he distance between the pool floor liner and the bottom of the rack baseplate is...on average...26 centimeters (cm) (10.25 in.), depending on adjustments made to the leveling pad during installation.” See NRC, “Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I Boiling Water Reactor: Draft Report,” p. 76, Footnote 1.] which have holes) would enable air to flow through the fuel assemblies, entering at the base and exiting at the top. NUREG/CR-0649, states that, in complete SFP LOCA scenarios, “the baseplate hole size can exert a marked effect on the heatup of the spent fuel, since a small baseplate hole tends to constrict the flow at the inlet to the fuel assembly. ...if the

temperature of self-sustaining clad oxidation is not attained, the peak clad temperature tends to reach a steady-state maximum value that remains essentially invariant with time. If a sufficiently high temperature is achieved, however, the clad oxidation reaction can become self-sustaining, leading to a temperature divergence that results in local clad melting. The temperature at which clad oxidation becomes self-sustaining is a function of the storage configuration, but tends to occur around 900°C.”⁸⁹ [footnote 89 text: Allan S. Benjamin et al., Sandia Laboratories, “Spent Fuel Heatup Following Loss of Water During Storage,” NUREG/CR-0649, SAND77-1371, March 1979, p. 47.] (0463-1-17 [Leyse, Mark])

Comment: A June 2013 NRC report on how earthquakes could affect BWR Mark I SFPs claims that in the event of a complete SFP LOCA, the fuel assemblies would not be air coolable for 10 percent of a two year operating cycle (the approximate time interval between the loading of each reactor core discharge into the SFP); that is, the fuel assemblies would not be air coolable for 73 days. However, the same June 2013 NRC report states that a partial BWR Mark I SFP LOCA “with channeled fuel could impede airflow and increase *the time to coolability*”⁹⁰ [footnote 90 text: NRC, “Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I Boiling Water Reactor: Draft Report,” Appendix B, p. B-10.] [emphasis added]. (The same poor heat transfer conditions would occur in a SBO boil-off accident, if there were partial uncovering of the fuel assemblies.) Elsewhere, the June 2013 NRC report states that a partial BWR Mark I SFP LOCA is assumed not to be air coolable for an entire two year operating cycle (730 days).⁹¹ [footnote 91 text: Id., Appendix D, p. D-13.] In other words, partial BWR Mark I SFP LOCAs, in which “the rack baseplate is not cleared and airflow is impeded,”⁹² [footnote 92 text: Id.] are assumed not to be air coolable during a reactor’s entire life of operation, in which reactor core discharges would be loaded into the SFP every two years. As stated, the baseplates also would not be cleared in SBO boil-off accidents. (0463-1-18 [Leyse, Mark])

Comment: A 2013 PSU report, “Spent Fuel Pool Analysis of a BWR-4 Fuel Bundle Under Loss of Coolant Conditions Using TRACE,” states that “[t]he time required for a SFP to reach temperatures high enough [827°C (1520°F)]⁹³ [footnote 93 text: Zachary I. Franiewski et al., Pennsylvania State University, “Spent Fuel Pool Analysis of a BWR-4 Fuel Bundle Under Loss of Coolant Conditions Using TRACE,” p. 2.] to result in fuel overheating could range from several days to weeks.”⁹⁴ [footnote 94 text: Id., p. 1.] The 2013 PSU report is referring to partial SFP LOCAs; however, the same applies to SBO boil-off scenarios. (0463-1-19 [Leyse, Mark])

Comment: For certain boil-off scenarios, after the fuel assemblies were partly uncovered, the upper exposed elevations of the cladding of the fuel rods would initially heat up very slowly, at local rates possibly lower than 0.01°C/sec (0.018°F/sec) (lower than 36°C/hour (64.8°F/hour)).⁹⁵ [footnote 95 text: Id., p. 19.] (These values are based on results of computer simulations conducted with the NRC TRACE computer safety model. The TRACE simulations were conducted to help Sandia National Laboratories (“SNL”) develop a full-scale boil-off experiment, simulating a rapid partial SFP LOCAs, in which “the water level in the SFP drains below the top of the fuel bundle.”⁹⁶ [footnote 96 text: Id., p. 1.] In the TRACE simulations of *particular* SFP LOCAs, with particular accident parameters, the initial temperature of the fuel cladding is 27°C (80°F); in a slower SBO boil-off scenario the initial temperature of the fuel cladding would be approximately 100°C (212°F) at the water surface. In the TRACE simulations, the local fuel-cladding temperature heated up from 27°C (80°F) to 827°C (1520°F) in less than 25 hours.⁹⁷ [footnote 97 text: Id., p. 19.] (See Figure 2.) [See Figure 2. Local Cladding Temperature vs. Time in the TRACE Simulation in Original Letter in NRC Adams Database ML13351A310]⁹⁸ [footnote 98 text: Graph from “Spent Fuel Pool Analysis of a BWR-4 Fuel Bundle Under Loss of Coolant Conditions Using TRACE;” see Zachary I. Franiewski et al., Pennsylvania State

University, “Spent Fuel Pool Analysis of a BWR-4 Fuel Bundle Under Loss of Coolant Conditions Using TRACE,” p. 19.] (0463-1-20 [Leyse, Mark])

Comment: According to EPRI, for certain PWR boil-off scenarios, after the fuel assemblies—with a decay heat of 42,334 watts per assembly—were partly uncovered, the upper exposed elevations of the cladding of the fuel rods would have local heatup rates of approximately 0.13°C/sec (0.23°F/sec).⁹⁹ [footnote 99 text: EPRI, “Severe Accident Management Guidance Technical Basis Report,” Volume 2: “The Physics of Accident Progression,” 1025295, Appendix EE, p. EE-10.] This is still a relatively slow heatup rate; however, it is more than 10 times faster than that of the TRACE simulation example. If the local fuel-cladding heatup rate were 0.13°C/sec (0.23°F/sec), (without considering any additional heat that would be contributed by the zirconium-steam reaction) local fuel-cladding temperatures would heat from 100°C (212°F) to 827°C (1520°F) in approximately 1.6 hours. (0463-1-21 [Leyse, Mark])

Comment: EPRI SFP accident guidance states that in a SBO boil-off accident, “should the water level decrease to 2/3 of the [spent fuel assembly] height, the overheating of the top of the fuel assemblies would approach 2000°F (1093°C).”¹⁰¹ [footnote 101 text: EPRI, “Severe Accident Management Guidance Technical Basis Report,” Volume 2: “The Physics of Accident Progression,” 1025295, October 2012, Appendix EE, p. EE-17.] In a SBO boil-off accident, a SFP fire would possibly commence (*in a steam atmosphere*) if the fuel cladding reached local temperatures between approximately 1000°C (1832°F) and 1200°C (2192°F). *In air*, a SFP fire would most likely commence if the fuel cladding reached local temperatures between approximately 827°C (1520°F)¹⁰² [footnote 102 text: Zachary I. Franiewski et al., Pennsylvania State University, “Spent Fuel Pool Analysis of a BWR-4 Fuel Bundle Under Loss of Coolant Conditions Using TRACE,” pp. iv, 2, 3, 8, 13.] and 900°C (1652°F).¹⁰³ [footnote 103 text: Allan S. Benjamin et al., Sandia Laboratories, “Spent Fuel Heatup Following Loss of Water During Storage,” NUREG/CR-0649, March 1979, p. 47.] (0463-1-22 [Leyse, Mark])

Comment: In a SBO, EDGs are inoperable and “reactor cooling is *temporarily provided* by systems that do not rely on ac power, such as turbine-driven pumps that are driven by steam from the reactor. Batteries also are used to provide direct current (dc) power to control the turbine-driven pumps and to power instrumentation”³⁵ [footnote 35 text: NRC, “Modeling Potential Reactor Accident Consequences,” NUREG/BR-0359, January 2012, (ADAMS Accession No: ML12026A470), p. 11.] [emphasis added]. Backup batteries would become depleted in four hours—for some reactors, eight hours. Without a timely restoration of ac power, a SBO will lead to a reactor core meltdown at each affected NPP unit, as occurred at Fukushima Dai-ichi. And, if there were freshly discharged fuel assemblies in a spent fuel pool (“SFP”), its water could heat up and boil off in 49.3 hours or 125.0 hours (depending on whether there had been a 1/3 or full core discharge, five days prior);³⁶ [footnote 36 text: NRC, “Regulatory Analysis for the Resolution of Generic Issue 82, ‘Beyond Design Basis Accidents in Spent Fuel Pools’,” NUREG-1353, April 1989, (ADAMS Accession No. ML082330232), p. 4-25.] pools densely-packed with fuel assemblies would be likely to incur SFP fires. “Fukushima Fallout,” also states that “[a] review of the NRC’s Standard Technical Specifications for nuclear power plants³⁷ [footnote 37 text: “Fukushima Fallout: Regulatory Loopholes at U.S. Nuclear Plants” (p. 13, note 46) states “[s]ee for example ‘Standard Technical Specifications General Electric Plants, BWR/4’ and ‘Standard Technical Specifications for Westinghouse Plants.’”] indicates that spent fuel pools at nuclear reactors whose cores do not contain nuclear fuel (for example, because they [are] in the process of being refueled) do NOT require the presence of operable secondary emergency generation capacity” [emphasis not added], explaining that “licensees often perform maintenance on their [EDGs] when the reactors are undergoing refueling outages.”³⁸ [footnote 38 text: The Staff of Congressman Edward J. Markey,

“Fukushima Fallout: Regulatory Loopholes at U.S. Nuclear Plants,” May 12, 2011, p.13. “Fukushima Fallout” (p. 13, note 47) states that the sources of this information are from “[p]rivate communications from an individual working inside an operating nuclear power plant obtained by Rep. Markey’s office and discussions with nuclear safety experts.”] (0463-1-5 [Leyse, Mark])

Comment: Large-scale, long-term power outages would lead to SBO scenarios in which the water in the pools heated up and boiled off, uncovering the fuel assemblies; severe earthquakes would lead to different scenarios. NUREG-2157 states that in the event of a beyond-design-basis earthquake with a magnitude significantly larger than what a SFP could withstand that “water would rapidly drain out of the pool. Only a small amount of water would remain and the spent fuel would be uncovered and exposed to the air.”⁵¹ [footnote 51 text: Id., p. 4-81.] Contrary to NUREG-2157, a May 2013 Pennsylvania State University (“PSU”) report claims that it is *unlikely* in the event of a SFP loss-of-coolant accident (“LOCA”) that all the water would rapidly drain, except a small amount, completely uncovering the fuel assemblies and exposing them to air over their entire length.⁵² [footnote 52 text: Zachary I. Franiewski et al., Pennsylvania State University, “Spent Fuel Pool Analysis of a BWR-4 Fuel Bundle Under Loss of Coolant Conditions Using TRACE,” NucE431W S2013, May 2013, p. 3.] The 2013 PSU report opines that *partial* SFP LOCAs—in which “the water level in the SFP drains below the top of the fuel bundle”⁵³ [footnote 53 text: Id., p. 1.]—would be more likely. (0463-1-7 [Leyse, Mark])

Comment: In a SFP LOCA, partial fuel assembly uncover would be a greater threat to safety than complete uncover of the fuel assemblies. Complete uncover of the fuel assemblies (with the water level dropping far enough below the bottom of the SFP baseplates,⁵⁴ [footnote 54 text: “[T]he distance between the pool floor liner and the bottom of the rack baseplate is...on average...26 centimeters (cm) (10.25 in.), depending on adjustments made to the leveling pad during installation.” See NRC, “Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I Boiling Water Reactor: Draft Report,” p. 76, Footnote 1.] which have holes) would enable air to flow through the fuel assemblies, entering at the base and exiting at the top. This would help cool the fuel assemblies. There would not be the same advantage if there were partial uncover of the fuel assemblies. If the water level remained above the baseplates, it would essentially block the flow of air through the fuel assemblies and “effectively reduce the heat transfer rates from the fuel, causing the fuel to heat up at a higher rate than if natural circulation [were] occurring.”⁵⁵ [footnote 55 text: Zachary I. Franiewski et al., Pennsylvania State University, “Spent Fuel Pool Analysis of a BWR-4 Fuel Bundle Under Loss of Coolant Conditions Using TRACE,” p. v.] (0463-1-8 [Leyse, Mark])

Comment: SBO boil-off accidents resemble partial SFP LOCAs in that in both accidents there would be times in which there was partial uncover of the fuel assemblies; the water level would be above the baseplates, essentially blocking the flow of air through the fuel assemblies and impeding the transfer of heat away from the fuel. The poor heat transfer conditions of SBO boil-off accidents make it more probable that they would lead to SFP fires. (0463-1-9 [Leyse, Mark])

Comment: III.E. Spent Fuel Pool Zirconium Fires in Steam and Air: Regarding the initiation and consequences of a SFP zirconium fire, a September 2013 NRC document, NUREG-2157, states: If cooling of the spent fuel were not reestablished, the fuel could heat up to temperatures on the order of 1,000°C (1,832°F). At this temperature, the spent fuel’s zirconium cladding would begin to react with steam or air in a highly exothermic chemical reaction called a runaway zirconium oxidation reaction or autocatalytic ignition. This accident scenario is often referred to as a “spent fuel pool zirconium fire.” Radioactive aerosols and vapors released from the damaged spent fuel could be carried throughout the spent fuel pool building and into the

surrounding environment. This release could lead to exposures of the surrounding population and contamination of property (e.g., land or structures) in the vicinity of the site.¹⁸⁰ [footnote 180 text: NRC, "Waste Confidence Generic Environmental Impact Statement: Draft Report for Comment," NUREG-2157, September 2013, (ADAMS Accession No. ML13224A106), Appendix F, p. F-2.] (Runaway zirconium oxidation would be more likely to commence in steam at local fuel-cladding temperatures between approximately 1000°C (1832°F) and 1200°C, (2192°F); and to commence in air at lower local fuel-cladding temperatures of 827°C (1520°F)¹⁸¹ [footnote 181 text: Zachary I. Franiewski et al., Pennsylvania State University, "Spent Fuel Pool Analysis of a BWR-4 Fuel Bundle Under Loss of Coolant Conditions Using TRACE," pp. iv, 2, 3, 8, 13.] or 900°C (1652°F).¹⁸² [footnote 182 text: Allan S. Benjamin et al., Sandia Laboratories, "Spent Fuel Heatup Following Loss of Water During Storage," NUREG/CR-0649, March 1979, p. 47.]) (See Figure 4.) [See Figure 4. Zirconium Fuel Rod Simulators that Incurred Runaway Oxidation in NRC Adams Database ML13351A310] (0463-2-11 [Leyse, Mark])

Comment: III.E.1. In a Spent Fuel Pool Boil-Off Accident, a Zirconium Fire Could Ignite in Steam if Fuel-Cladding Temperatures Reached 1000°C (1832°F) In a SBO boil-off accident, if the fuel assemblies were uncovered, the fuel cladding's zirconium content would initially chemically react with the steam produced by the boiling water in the SFP.¹⁸³ [footnote 183 text: Randall Gauntt et al., Sandia National Laboratories "Fukushima Daiichi Accident Study: Status as of April 2012," SAND2012-6173, August 2012, p. 183.] And if the water level in the SFP decreased to an elevation at approximately 66 percent of the height of the fuel assemblies, local fuel-cladding temperatures in the upper regions of the fuel assemblies would approach 2000°F (1093°C).¹⁸⁴ [footnote 184 text: EPRI, "Severe Accident Management Guidance Technical Basis Report," Volume 2: "The Physics of Accident Progression," 1025295, Appendix EE, p. EE-17.] When local fuel cladding temperatures increased to approximately 1000°C (1832°F), the fuel cladding would incur significant additional heating from the exothermic (heat-generating) zirconium-steam reaction. The zirconium-steam reaction produces zirconium dioxide, hydrogen, and energy; the equation for the reaction is written as $\text{Zr} + 2\text{H}_2\text{O} \rightarrow \text{ZrO}_2 + 2\text{H}_2 + \text{energy}$. The energy (heat) generated by the reaction is approximately 6.45 megajoules per kilogram (kg) of Zr reacted.¹⁸⁵ [footnote 185 text: NRC, "Compendium of ECCS Research for Realistic LOCA Analysis," NUREG-1230, 1988, (ADAMS Accession No. ML053490333), p. 8-2.] When zirconium reacts in steam it is possible for the reaction to become steam-starved, which occurs when hydrogen produced by the zirconium-steam reaction locally replaces steam (to varying degrees) at the surface of a fuel rod. This will mitigate oxidation rates or completely prevent oxidation. (0463-2-12 [Leyse, Mark])

Comment: The fuel-cladding outer surfaces of spent fuel assemblies are coated with varying thicknesses of zirconium dioxide layers (oxide layers). Oxide layers form on the fuel rods' cladding over the course of three or more years of operation in the reactor core, at elevated temperatures: typical BWR and PWR coolant temperatures are 540-550°F and 540-620°F, respectively.¹⁸⁶ [footnote 186 text: IAEA, "Assessment and Management of Ageing of Major Nuclear Power Plant Components Important to Safety: BWR Pressure Vessels," IAEA-TECDOC-1470, October 2005, p. 7; and IAEA, "Assessment and Management of Ageing of Major Nuclear Power Plant Components Important to Safety: PWR Pressure Vessels," IAEA-TECDOC-1120, October 1999, p. 5.] There are also local crud (corrosion products) deposits on the outer surfaces of fuel cladding. Higher burnup fuel cladding typically has thicker oxide layers, and a higher hydrogen content. In a SFP accident the outer fuel-cladding oxide layer can function as a protective layer; the oxidation of zirconium at elevated temperatures *could* be "controlled by the diffusion of oxygen through the oxide [layer, with] the reaction rate [being] inversely proportional to the oxide thickness."¹⁸⁷ [footnote 187 text: S. Hagen, H. Malauschek, S. O. Peck, K.P. Wallenfels, "Temperature Escalation in PWR Fuel Rod simulator Bundles due

to the Zircaloy-Steam Reaction: Test ESBU-1: Test Results Report,” KfK-3508, December 1983, p. 4.] However, if the cladding temperature increases, the temperature may become the dominating factor that drives the zirconium-oxidation reaction, causing a rapid cladding-temperature escalation.¹⁸⁸ [footnote 188 text: Id., p. 5.] (In the PHEBUS B9R-2 test—conducted with a pre-oxidized test bundle—oxide layers did not prevent a rapid fuel cladding temperature escalation from commencing in steam at a relatively low temperature: 1027°C (1880°F); PHEBUS B9R-2 is discussed in Section F.2.a.) (In air, nitrogen-related breakaway oxidation behavior would cause the protective oxide layer to degrade at approximately 800°C; and oxidation rates would begin accelerating.¹⁸⁹ [footnote 189 text: C. Duriez, T. Dupont, B. Schmet, F. Enoch, “Zircaloy-4 and M5 High Temperature Oxidation and Nitriding in Air,” Journal of Nuclear Materials 380 (2008), pp. 30, 39, 40, 43, 44.]) (0463-2-13 [Leyse, Mark])

Comment: A SFP fire is *primarily a zirconium fire*: the *runaway* chemical reaction between zirconium and steam (or zirconium and air): *runaway zirconium oxidation*. Runaway zirconium oxidation causes *thermal runaway*, because zirconium oxidation is exothermic: the heat produced by the zirconium-steam reaction increases the local fuel-cladding temperature, which in turn increases the reaction rate, further increasing the local fuel-cladding temperature, and so on. Once runaway zirconium oxidation commences in steam (typically at local fuel-cladding temperatures between approximately 1000°C (1832°F) and 1200°C (2192°F), local fuel-cladding temperatures increase rapidly, leading to temperature increases of tens of degrees Fahrenheit per second. Hence, local fuel-cladding temperatures can escalate up to the point where zirconium melts—above 1816°C (3300°F)¹⁹⁰ [footnote 190 text: NRC, “Feasibility Study of a Risk-Informed Alternative to 10 CFR 50.46, Appendix K, and GDC 35,” June 2001, (ADAMS Accession No: ML011800519), p. 3-1.]—within a few minutes. (0463-2-14 [Leyse, Mark])

Comment: III.E.2. In a SFP Boil-Off Accident, a Zirconium Fire Might Not Ignite in Steam if Fuel-Cladding Temperatures Reached 1000°C (1832°F) or Greater; In SBO boil-off accident, it is possible that there would not be a temperature escalation, if local fuel-cladding temperatures increased to approximately 1000°C (1832°F), because the initial heatup rate of the fuel cladding would be very slow, as discussed in Section C. After the fuel cladding were uncovered it would *initially* heat up *very slowly*, in some scenarios, at local rates lower than 0.01°C/sec (0.018°F/sec);¹⁹¹ [footnote 191 text: Zachary I. Franiewski et al., Pennsylvania State University, “Spent Fuel Pool Analysis of a BWR-4 Fuel Bundle Under Loss of Coolant Conditions Using TRACE,” p. 19.] in other scenarios, local heatup rates would be approximately 0.13°C/sec (0.23°F/sec).¹⁹² [footnote 192 text: EPRI, “Severe Accident Management Guidance Technical Basis Report,” Volume 2: “The Physics of Accident Progression,” 1025295, Appendix EE, p. EE-10.] Regarding the zirconium-steam reaction in the reactor core, a 1999 paper, “Current Knowledge on Core Degradation Phenomena, a Review,” states that if the initial fuel-cladding temperature heat-up rate is 0.2°C/sec or lower, the heat-up rate will become 3.0°C/sec or lower if fuel-cladding temperatures reach 1200°C, because of the heat that would be contributed from the exothermic zirconium-steam reaction. The same paper also states that if the initial fuel-cladding temperature heat-up rate is 1.0°C/sec or greater, the heat-up rate will become 10.0°C/sec or greater if fuel-cladding temperatures reach 1200°C, because of the heat that would be contributed from the exothermic zirconium-steam reaction.¹⁹³ [footnote 193 text: P. Hofmann, “Current Knowledge on Core Degradation Phenomena, a Review,” Journal of Nuclear Materials, 270, 1999, p. 205.] An initial fuel-cladding temperature heat-up rate of 1°C/sec or greater means that there will be a thinner oxide thickness on the fuel cladding *for a particular temperature*; hence, oxidation rates become greater at fuel-cladding temperatures at which the exothermic zirconium-steam reaction contributes significant heat (6.45 megajoules per kg of Zr reacted).¹⁹⁴ [footnote 194 text: R. R. Hobbins, D. A. Petti, D. J. Osetek, and D. L. Hargman, Idaho National Engineering Laboratory, EG&G Idaho, Inc., “Review of Experimental Results on

LWR Core Melt Progression,” in NRC “Proceedings of the Eighteenth Water Reactor Safety Information Meeting,” NUREG/CP-0114, Vol. 2, 1990, (ADAMS Accession No. ML042250131), p. 7.] (0463-2-15 [Leyse, Mark])

Comment: (It is noteworthy that if there were one or more criticality accidents in a SBO boil-off accident, after the fuel assemblies were uncovered, the heat generated from fission would cause rapid local fuel-cladding temperature increases.¹⁹⁵ [footnote 195 text: Zachary I. Franiewski et al., Pennsylvania State University, “Spent Fuel Pool Analysis of a BWR-4 Fuel Bundle Under Loss of Coolant Conditions Using TRACE,” NucE431W S2013, May 2013, pp. 1-2.] Hence, it would be possible for initial heatup rates of the fuel cladding to be 1.0°C/sec or greater. If fuel-cladding temperatures that had initial heatup rates of 1.0°C/sec or greater were to increase to between approximately 1000°C (1832°F) and 1200°C (2192°F) *in a steam environment*, runaway zirconium oxidation would most likely commence.) (0463-2-16 [Leyse, Mark])

Comment: Regarding the fact that the CORA experiments conducted with lower heat-up rates did not have temperature escalations, a 1996 European Commission report states: The CORA experiments performed with lower heat-up rates demonstrated clearly that no temperature escalation took place. The chemical interaction energy evolved caused only an increased heat-up rate between [1200°C (2192°F)] and [1800°C (3272°F)] of about [1.0°C/sec (1.8°F/sec)]. The oxide layer which has formed on the cladding outer surface during heat-up delays the chemical interactions between Zircaloy and steam since the diffusion of oxygen through the ZrO₂ layer is the reaction rate-determining step. The Zircaloy will be almost completely oxidized, or at least converted into .-Zr(O), before reaching the melting point of oxygen-poor (as-received) Zircaloy at about [1760°C (3200°F)]¹⁹⁶ [footnote 196 text: Zirconium melts at temperatures above 1816°C (3300°F). See NRC, “Feasibility Study of a Risk-Informed Alternative to 10 CFR 50.46, Appendix K, and GDC 35,” June 2001, (ADAMS Accession No: ML011800519), p. 3-1.]].¹⁹⁷ [footnote 197 text: T.J. Haste et al., “In-Vessel Core Degradation in LWR Severe Accidents,” European Commission, Report EUR 16695 EN, 1996, p. 27.] The PHEBUS B9 test is an example of an experiment that did *not* have a rapid fuel-cladding temperature escalation that commenced at relatively low fuel-cladding temperatures, because *it had a low initial heatup rate*. In PHEBUS B9, conducted in December 1986, the initial fuel-cladding temperature heatup rate was 0.2°C/sec (0.36°F/sec); the test bundle heated up to 1547°C (2816°F) at a very slow rate, without a rapid fuel-cladding temperature escalation. At 1547°C (2816°F) a fuel-cladding temperature escalation of 5°C/sec commenced.¹⁹⁸ [footnote 198 text: C. Gonner et al., “PHEBUS Severe Fuel Damage Program Main Experimental Results and Instrumentation Behavior,” Proceedings of the Seminar of the Phebus-FP (Fission Product) Project, Chateau Cadarache, St. Paul-Lez-Durance, France, June 5-7, 1991, p. 113.] (0463-2-17 [Leyse, Mark])

Comment: The CORA-2 test is an example of an experiment that *had* a rapid fuel-cladding temperature escalation that commenced at relatively low fuel-cladding temperatures, because *it did not have a low initial heatup rate*. CORA-2 had an initial fuel-cladding temperature heatup rate of approximately 1.0°C/sec (1.8°F/sec). In CORA-2, a PWR-type test conducted with 25 fuel rods (16 heated and 9 unheated rods), an “uncontrolled temperature escalation started at about [1100°C (2012°F)].”¹⁹⁹ [footnote 199 text: T.J. Haste et al., “In-Vessel Core Degradation in LWR Severe Accidents,” European Commission, Report EUR 16695 EN, pp. 15, 16.] And the LOFT LP-FP-2 experiment is another example of an experiment that *had* a rapid fuel-cladding temperature escalation that commenced at relatively low fuel-cladding temperatures, because *it did not have a low initial heatup rate*. LOFT LP-FP-2, heated with “actual fission-product decay heating of the core,”²⁰⁰ [footnote 200 text: S. R. Kinnersly, et al., “In-Vessel Core Degradation in LWR Severe Accidents: A State of the Art Report to CSNI,” p. 3.23.] had an initial fuel-cladding

temperature heatup rate of approximately 1.0°C/sec (1.8°F/sec).²⁰¹ [footnote 201 text: T. J. Haste et al., “Degraded Core Quench: A Status Report,” August 1996, p. 13.] In LOFT LP-FP-2, “[t]he first recorded and qualified rapid temperature rise associated with the rapid reaction between Zircaloy and water occurred at ...1400 K [1127°C (2060°F)] on a guide tube.” Hence, an analysis of LOFT LP-FP-2 “concluded from examination of the recorded temperatures that the oxidation of Zircaloy by steam becomes rapid at temperatures in excess of 1400 K (2060°F).”²⁰² [footnote 202 text: J. J. Pena, S. Enciso, F. Reventos, “Thermal-Hydraulic Post-Test Analysis of OECD LOFT LP-FP-2 Experiment,” International Agreement Report, NUREG/IA-0049, April 1992, (ADAMS Accession No: ML062840091), pp. 30, 33.] (0463-2-18 [Leyse, Mark])

Comment: III.E.2.a. The PHEBUS B9R Test had a Low Initial Heatup Rate and a Rapid Fuel-Cladding Temperature Escalation at Relatively Low Temperatures. It needs to be clarified that even if there were a low initial heatup rate of the fuel cladding, it is still possible for a rapid fuel-cladding temperature escalation to commence at relatively low fuel-cladding temperatures. The PHEBUS B9R-2 test is an example of an experiment that *had* an unexpected rapid fuel-cladding temperature escalation that commenced at relatively low fuel-cladding temperatures, even though *it had a low initial heatup rate*. The PHEBUS B9R test was conducted in a light water reactor—as part of the PHEBUS severe fuel damage program—with an assembly of 21 UO₂ fuel rods. The B9R test was conducted in two parts: the B9R-1 test and the B9R-2 test.²⁰³ [footnote 203 text: G. Hache, R. Gonzalez, B. Adroguer, Institute for Protection and Nuclear Safety, “Status of ICARE Code Development and Assessment,” in NRC “Proceedings of the Twentieth Water Reactor Safety Information Meeting,” NUREG/CP-0126, Vol. 2, 1992, (ADAMS Accession No: ML042230126), p. 311.] A 1996 European Commission report states that the B9R-2 test had an unexpected fuel-cladding temperature escalation in the mid-bundle region; the highest temperature escalation rates were from 20°C/sec (36°F/sec) to 30°C/sec (54°F/sec).²⁰⁴ [footnote 204 text: T.J. Haste et al., “In-Vessel Core Degradation in LWR Severe Accidents,” European Commission, Report EUR 16695 EN, p. 33.] Discussing PHEBUS B9R-2, the 1996 European Commission report states: The B9R-2 test (second part of B9R) illustrates the oxidation in different cladding conditions representative of a pre-oxidized and fractured state. This state results from a first oxidation phase (first part name B9R-1, of the B9R test) terminated by a rapid cooling-down phase. During B9R-2, an unexpected strong escalation of the oxidation of the remaining Zr occurred when the bundle flow injection was switched from helium to steam while the maximum clad temperature was equal to 1300 K [1027°C (1880°F)]. *The current oxidation model was not able to predict the strong heat-up rate observed even taking into account the measured large clad deformation and the double-sided oxidation (final state of the cladding from macro-photographs). ... No mechanistic model is currently available to account for enhanced oxidation of pre-oxidized and cracked cladding*²⁰⁵ [footnote 205 text: Id., p. 126.] [emphasis added]. (0463-2-19 [Leyse, Mark])

Comment: The fact that PHEBUS B9R-2 was conducted with a pre-oxidized test bundle makes its results particularly applicable to SFP fires. The results of PHEBUS B9R-2 indicate that it is unpredictable as to whether or not rapid fuel-cladding temperature escalations would commence *in steam*, in a SFP accident, at relatively low fuel-cladding temperatures. Spent fuel rods would also be “pre-oxidized”: when high burnup (and other) fuel rods are discharged from the reactor core and loaded into the SFP, the fuel cladding can have local zirconium dioxide (ZrO₂) “oxide” layers that are up to 100 µm thick (or greater); there can also be local crud layers on top of the oxide layers, which can sometimes also be up to 100 µm thick. And medium to high burnup fuel cladding typically has a “hydrogen concentration in the range of 100-1000 wppm [weight parts per million];” “[z]irconium-based alloys, in general, have a strong affinity for oxygen, nitrogen, and hydrogen...”²⁰⁶ [footnote 206 text: K. Natesan, W.K. Soppet, Argonne

National Laboratory, "Hydrogen Effects on Air Oxidation of Zirlo Alloy," NUREG/CR-6851, October 2004, (ADAMS Accession No: ML042870061), p. iii, 3.] (0463-2-20 [Leyse, Mark])

Comment: According to an October 2000 OECD Nuclear Energy Agency report, the initial heatup rate in PHEBUS B9R-2 was less than 0.1°C/sec up to 727°C (1340°F) (during the pure helium phase of the experiment).²⁰⁷ [footnote 207 text: OECD Nuclear Energy Agency, "In-Vessel Core Degradation Code Validation Matrix Update 1996-1999," NEA/CSNI/R(2000)21, October 2000, p. 97.] However, according to a graph with a plot of fuel-cladding temperature values at the 0.6 meter "hot level" of the PHEBUS B9R-2 test bundle, the initial heatup rate in PHEBUS B9R-2 was approximately 1.0°C/sec up to 727°C (1340°F); however, the heatup rate decreases to lower than 0.2°C/sec between approximately 877°C (1610°F) and 1002°C (1835°F).²⁰⁸ [footnote 208 text: G. Hache, R. Gonzalez, B. Adroguer, Institute for Protection and Nuclear Safety, "Status of ICARE Code Development and Assessment," in NRC "Proceedings of the Twentieth Water Reactor Safety Information Meeting," NUREG/CP-0126, Vol. 2, 1992, (ADAMS Accession No: ML042230126), p. 312.] (See Figure 5.) As stated, the cladding-temperature escalation commenced at approximately 1027°C (1880°F). [See Figure 5. Local Cladding Temperature vs. Time in the PHEBUS B9R-2 Test in NRC Adams Database ML13351A310]²⁰⁹ [footnote 209 text: Id.] (0463-2-21 [Leyse, Mark])

Comment: (It is noteworthy that a September 2013 NRC document, NUREG-2157, states that if local fuel-cladding temperatures were to increase to approximately 1000°C (1832°F) in a SFP accident, a runaway zirconium oxidation reaction—a *SFP zirconium fire*—would commence *in steam*.²¹⁰ [footnote 210 text: NRC, "Waste Confidence Generic Environmental Impact Statement: Draft Report for Comment," NUREG-2157, Appendix F, p. F-2.] However, regarding zirconium alloy fuel-cladding behavior *in steam*, in a reactor LOCA, in October 2012, the NRC stated that "autocatalytic [zirconium oxidation] reactions have not occurred at temperatures less than 2200 degrees F,"²¹¹ [footnote 211 text: NRC, "Draft Interim Review of PRM-50-93/95 Issues Related to Conservatism of 2200 degrees F, Metal-Water Reaction Rate Correlations, and 'The Impression Left from [FLECHT] Run 9573' ," October 16, 2012, (ADAMS Accession No: ML12265A277), p. 2.] that is, runaway zirconium oxidation reactions have not commenced in experiments when fuel-cladding temperatures were lower than 1204.4°C (2200°F). (0463-2-22 [Leyse, Mark])

Comment: Hence, the NRC claims that runaway zirconium oxidation would commence at 1000°C (1832°F) *in steam*, in SFP accidents, which would have low initial heatup rates (except in certain criticality accident scenarios). Nonetheless, the NRC also claims that runaway zirconium oxidation would *not* commence below 1204.4°C (2200°F) *in steam*, in reactor LOCAs, which could have *high* initial heatup rates, exceeding 5.6°C/sec (10.0°F/sec). Perhaps the NRC's statement regarding runaway zirconium oxidation in steam, in reactor LOCAs, is influenced by the fact that the NRC requires the maximum fuel-cladding temperature in a postulated reactor LOCA to not exceed 2200°F— 10 C.F.R. § 50.46(b)(1) peak fuel-cladding temperature limit. If the NRC acknowledged that runaway zirconium oxidation *in steam* could commence in reactor LOCAs at fuel cladding temperatures below 2200°F, the NRC might realize that it needed to lower its Section 50.46 peak fuel-cladding temperature limit.²¹² [footnote 212 text: Full disclosure: in November 2009, the author of this report submitted a rulemaking petition (PRM-50-93) to the NRC, requesting that the NRC revise 10 C.F.R. § 50.46(b)(1) to require that the calculated maximum fuel element cladding temperature, in a reactor LOCA, not exceed a limit based on data from multi-rod (assembly) severe fuel damage experiments. The author argued that data from multi-rod (assembly) severe fuel damage experiments (for example, the LOFT LP-FP-2 experiment) indicates that the current 10 C.F.R. § 50.46(b)(1) PCT limit of 2200°F is non-conservative.]) (0463-2-23 [Leyse, Mark])

Comment: III.E.3. In a Spent Fuel Pool Boil-Off Accident, a Zirconium Fire Would Most Likely Ignite in Air if Fuel-Cladding Temperatures Reached 900°C (1652°F) or Lower. In a SFP boil-off accident, after the fuel assemblies were uncovered, the fuel cladding's zirconium content would initially chemically react with the steam produced by the boiling water in the SFP. At some point, as more water boiled off and the water level decreased further (below the elevation at 66 percent of the height of the fuel assemblies), the fuel cladding would be exposed to local mixtures of steam and air. When zirconium is exposed to local mixtures of steam and air, the zirconium-oxygen reaction will dominate.²¹³ [footnote 213 text: C. Bals et al., "Modelling of Accelerated Cladding Degradation in Air for Severe Accident Codes," The 3rd European Review Meeting on Severe Accident Research (ERMSAR-2008), Bulgaria, September 23-25, 2008, pp. 4, 5.] Then, as the water level dropped down even closer to the baseplates, the upper regions of the fuel assemblies would predominately be exposed to air. (After the fuel assemblies were uncovered there would be various local conditions; for example, there could be local steam starvation and local oxygen starvation.) If there had been initial heatup rates that were very low (that is, if there had not been any criticality accidents that caused faster initial heatup rates) and a zirconium fire had not commenced *in steam*, a zirconium fire would most likely commence *in air*, provided water covered the baseplates at the lower end of the fuel assemblies. (If "water [is] above the base plate of the racks...the water at the bottom of the pool acts as a "plug," which prevents cooling of the assemblies by natural air circulation."²¹⁴ [footnote 214 text: Randall Gauntt et al., Sandia National Laboratories "Fukushima Daiichi Accident Study: Status as of April 2012," SAND2012-6173, August 2012, p. 183.]) (0463-2-24 [Leyse, Mark])

Comment: III.E.4. Exothermic Reactions in Air: Zirconium Oxidation and Zirconium Nitriding: Runaway zirconium oxidation commences *in air* at lower local fuel-cladding temperatures—827°C (1520°F)²¹⁵ [footnote 215 text: Zachary I. Franiewski et al., Pennsylvania State University, "Spent Fuel Pool Analysis of a BWR-4 Fuel Bundle Under Loss of Coolant Conditions Using TRACE," pp. iv, 2, 3, 8, 13.] or 900°C (1652°F)²¹⁶ [footnote 216 text: Allan S. Benjamin et al., Sandia Laboratories, "Spent Fuel Heatup Following Loss of Water During Storage," NUREG/CR-0649, March 1979, p. 47.]—than it does in steam; and the zirconium-oxygen reaction in air produces approximately twice as much energy (per kg of Zr reacted) as the zirconium-steam reaction. The zirconium-oxygen reaction in air produces zirconium dioxide and energy; the equation for the reaction is written as $\text{Zr} + \text{O}_2 \rightarrow \text{ZrO}_2 + \text{energy}$. The energy (heat) generated by the reaction is approximately 12.0 megajoules per kg of Zr reacted.²¹⁷ [footnote 217 text: National Research Council, Committee on the Safety and Security of Commercial Spent Nuclear Fuel Storage, "Safety and Security of Commercial Spent Nuclear Fuel Storage: Public Report," 2005, p. 38.] And the zirconium-nitrogen reaction produces approximately 30 percent of the quantity of energy (per kg of Zr reacted) produced by the zirconium-oxygen reaction in air. The zirconium-nitrogen reaction produces zirconium nitride and energy; the equation for the reaction is written as $\text{Zr} + 1/2\text{N}_2 \rightarrow \text{ZrN} + \text{energy}$. The energy (heat) generated by the reaction is approximately 3.76 megajoules per kg of Zr reacted.²¹⁸ [footnote 218 text: V. L. Sailor et al., Brookhaven National Laboratory, "Severe Accidents in Spent Fuel Pools in Support of Generic Safety Issue 82," NUREG/CR-4982, July 1987, p. 109.] In *April 2000*, the ACRS told the NRC Staff that "nitrogen from air depleted of oxygen will interact exothermically with zircaloy cladding. The reaction of zirconium with nitrogen is exothermic by about 86,000 calories per mole of zirconium reacted. Because the heat required to raise zirconium from room temperature to melting is only about 18,000 calories per mole, the reaction enthalpy with nitrogen is ample" ²¹⁹ [footnote 219 text: Dana A. Powers, Chairman of ACRS, Letter to Richard A. Meserve, Chairman of NRC, Regarding ACRS Recommendations for Improvements to the NRC Staff's "Technical Study of Spent Fuel Pool Accident Risk at Decommissioning Nuclear Power Plants," April 13, 2000, (ADAMS Accession No. ML003704532), pp. 3-4.] [emphasis added]. (A July 1987 NRC document, NUREG/CR-4982,

states that the reaction of zirconium and nitrogen releases approximately 82,000 calories per mole of zirconium reacted.²²⁰ [footnote 220 text: V. L. Sailor et al., “Severe Accidents in Spent Fuel Pools in Support of Generic Safety Issue 82,” NUREG/CR-4982, p. 109.] An August 2012 SNL report, “Fukushima Daiichi Accident Study” states that “[i]f inadequate cooling is provided, then the cladding will heat up and will rapidly oxidize (i.e., burn) and to a lesser extent, nitride (i.e., combine with nitrogen if no oxygen or steam are available). *Since the oxidation and nitride processes are exothermic*, the fuel rods could heat to melting conditions and structurally degrade”²²¹ [footnote 221 text: Randall Gauntt et al., Sandia National Laboratories “Fukushima Daiichi Accident Study: Status as of April 2012,” SAND2012-6173, August 2012, p. 183.] [emphasis added]. (0463-2-25 [Leyse, Mark])

Comment: III.E.5. Nitrogen Accelerates the Oxidation and Degradation of Zirconium Fuel-Cladding in Air. The nitrogen gas (in air) affects the oxidation of zirconium in air.²²² [footnote 222 text: K. C. Wagner, R. O. Gauntt, Sandia National Laboratories, Analysis and Modeling Division, “Mitigation of Spent Fuel Pool Loss-of-Coolant Inventory Accidents and Extension of Reference Plant Analyses to Other Spent Fuel Pools,” SANDIA Letter Report, Revision 2, November 2006, (ADAMS Accession No. ML120970086), p. 12; and L. Fernandez-Moguel, J. Birchley, European MELCOR User’s Group, “PSI air oxidation model in MELCOR: Part 2: Analysis of experiments and model assessment,” Stockholm, May 2013, which states: “Neither MELCOR nor SCDAP [a severe accident computer safety model] are able to predict a nitride reaction.”] The presence of nitrogen accelerates the oxidation (burning) and degradation of zirconium fuel-cladding *in air*,²²³ [footnote 223 text: J. Stuckert, M. Große, Z. Hózer, M. Steinbrück, Karlsruhe Institute of Technology, “Results of the QUENCH-16 Bundle Experiment on Air Ingress,” KIT-SR 7634, May 2013, p. 1; and O. Coindreau, C. Duriez, S. Ederli, “Air Oxidation of Zircaloy-4 in the 600-1000°C Temperature Range: Modeling for ASTEC Code Application,” Journal of Nuclear Materials 405, 2010, p. 208.] which would affect the progression and severity of a SFP accident, including radioactive releases, “most notabl[y] ruthenium.”²²⁴ [footnote 224 text: J. Stuckert et al., “Results of the QUENCH-16 Bundle Experiment on Air Ingress,” p. 1.] (“Ruthenium has a biological effectiveness equivalent to that of Iodine-131;”²²⁵ [footnote 225 text: Dana A. Powers, Chairman of ACRS, Letter to Richard A. Meserve, Chairman of NRC, Regarding ACRS Recommendations for Improvements to the NRC Staff’s “Technical Study of Spent Fuel Pool Accident Risk at Decommissioning Nuclear Power Plants,” April 13, 2000, (ADAMS Accession No. ML003704532), p. 2.] Ruthenium-106 has half-life of 373.6 days.) (0463-2-26 [Leyse, Mark])

Comment: A 2010 Journal of Nuclear Materials paper observes that “[t]he complexity of air oxidation of Zircaloy arises out of the simultaneous oxidation and nitriding processes.”²²⁶ [footnote 226 text: O. Coindreau, C. Duriez, S. Ederli, “Air Oxidation of Zircaloy-4 in the 600-1000°C Temperature Range: Modeling for ASTEC Code Application,” p. 207.] And a May 2013 report, “Results of the QUENCH-16 Bundle Experiment on Air Ingress,” discusses experimental data demonstrating that porous nitrides form inside oxide layers *under local or full oxygen-starvation conditions*.²²⁷ [footnote 227 text: J. Stuckert et al., “Results of the QUENCH-16 Bundle Experiment on Air Ingress,” p. 10.] (When zirconium reacts in air it is possible for the reaction to become oxygen-starved; however, if zirconium is locally oxygen-starved in air, nitrogen will react with it.) The porous, degraded condition of an oxide layer facilitates accelerated oxidation rates if additional oxygen becomes locally available; and any additional oxygen will react with the zirconium nitride (ZrN) within an existing oxide layer and form zirconium dioxide (ZrO₂) in a fast exothermic reaction.²²⁸ [footnote 228 text: Emilie Beuzet et al., “Modelling of Zry-4 Cladding Oxidation by Air Under Severe Accident Conditions using MAAP4 Code,” International Conference Nuclear Energy for New Europe 2009, Slovenia, September 2009, p. 3.] (0463-2-27 [Leyse, Mark])

Comment: A 2008 Journal of Nuclear Materials paper, “Zircaloy-4 and M5 High Temperature Oxidation and Nitriding in Air,” explains that “once initiated, the nitride-assisted degradation will be a self-sustaining process, because ZrN conversion into oxide leaves nitrogen trapped in the oxide scale and available for further nitriding, and because the oxide formed is undoubtedly non-protective. Where nitriding has initiated, the bright α -Zr(O) layer is thin, confirming the faster progression of the oxidation front there. The self-sustainability of the nitriding-reoxidation sequence may also favor the lateral progressive propagation of the breakaway.”²²⁹ [footnote 229 text: C. Duriez, T. Dupont, B. Schmet, F. Enoch, “Zircaloy-4 and M5 High Temperature Oxidation and Nitriding in Air,” Journal of Nuclear Materials 380 (2008), p. 43.] Regarding nitrogen-induced breakaway oxidation, the 2008 Journal of Nuclear Materials paper explains that “[b]reakdown and loss of the dense scale protective effect occur and result in an accelerated degradation;” furthermore, the transition to nitrogen-induced breakaway oxidation occurs *earlier with pre-oxidized fuel cladding than with fresh non-oxidized fuel cladding*—“nitriding is favored by the ‘corrosion’ scale.”²³⁰ [footnote 230 text: Id., p. 44.] (0463-2-28 [Leyse, Mark])

Comment: It is clear that in air, in a SFP accident, a significant degree of zirconium oxidation would occur, because spent fuel rods would be “pre-oxidized.” When high burnup (and other) fuel rods are discharged from the reactor core and loaded into the SFP, the fuel cladding can have local zirconium dioxide (ZrO₂) “oxide” layers that are up to 100 μ m thick (or greater); there can also be local crud layers on top of the oxide layers, which can sometimes also be up to 100 μ m thick. And medium to high burnup fuel cladding typically has a “hydrogen concentration in the range of 100-1000 wppm [weight parts per million];” “[z]irconium-based alloys, in general, have a strong affinity for oxygen, nitrogen, and hydrogen...”²³¹ [footnote 231 text: K. Natesan, W.K. Soppet, Argonne National Laboratory, “Hydrogen Effects on Air Oxidation of Zirlo Alloy,” NUREG/CR-6851, October 2004, (ADAMS Accession No: ML042870061), p. iii, 3.] Regarding the fact that air oxidation causes a fast progression of the oxidation front, the 2008 Journal of Nuclear Materials paper states: At 800°C and above, continuous acceleration is observed, as the consequence of a complex process involving nitride formation and re-oxidation, as well as dissolution of nitrogen in the zirconia anion sub-lattice. Important volume mismatches of the ZrO₂ and ZrN compounds, together with zirconia phase transformations lead to *growth of a highly cracked, porous, non-protective oxide. It results in fast progression of the oxidation front, as well as strong deformation of the cladding.* The barrier against fission product release provided by the fuel cladding is lost much earlier than during accident under steam atmosphere²³² [footnote 232 text: C. Duriez, T. Dupont, B. Schmet, F. Enoch, “Zircaloy-4 and M5 High Temperature Oxidation and Nitriding in Air,” Journal of Nuclear Materials 380 (2008), p. 44.] [emphasis added].; And regarding the fact that cladding degradation can be even much faster in oxygen starved situations (in air), the 2008 Journal of Nuclear Materials paper states: Kinetic data of this study have been obtained mainly in high air flow conditions. *In real accidental situations, where oxygen starved situations are likely to occur, cladding degradation can be even much faster than predictable from these high air flow data*, because of early initiation of the nitriding process, as shown by the few tests performed at the highest temperatures with insufficient air flow rate. All in all, more experimental investigations are required to address the various conditions that can be encountered in accidental situation.²³³ [footnote 233 text: Id., p. 44.] (0463-2-29 [Leyse, Mark])

Comment: III.E.6. The Axial and Radial Propagation of a Spent Fuel Pool Fire; Regarding the axial propagation of the zirconium-steam reaction from its point of initiation, a 1990 Karlsruhe report, KfK 4378, states: [T]he temperature escalation starts at the hottest position in the bundle [of fuel rod simulators], at an elevation above the middle. From there, slowly moving fronts of bright light, which illuminated the bundle, were seen, indicating the spreading of the temperature

escalation upward and downward.²³⁴ [footnote 234 text: S. Hagen, P. Hofmann, G. Schanz, L. Sepold, “Interactions in Zircaloy/UO₂ Fuel Rod Bundles with Inconel Spacers at Temperatures above 1200°C (Posttest Results of Severe Fuel Damage Experiments CORA-2 and CORA-3),” Forschungszentrum Karlsruhe, KfK 4378, September 1990, p. 41.]; And regarding axial and radial propagation of the zirconium-oxygen reaction (in steam and/or air), a September 2013 NRC document, NUREG-2157, states: Under certain conditions, the high temperature runaway zirconium oxidation reaction occurring in one part of the pool could also spread to other spent fuel in the pool. The proximity of fuel assemblies to one another, combined with the effects of [radiative] heat transfer when these assemblies are at very high temperatures, could allow the runaway oxidation reaction to spread from spent fuel with high decay heat to spent fuel with lower decay heat that would otherwise not have begun burning.²³⁵ [footnote 235 text: NRC, “Waste Confidence Generic Environmental Impact Statement: Draft Report for Comment,” NUREG-2157, p. F-2.]; As fuel rods heated up to melting temperatures, “the steel racks supporting the fuel assemblies will also heat due to convection and radiation from the fuel assemblies.”²³⁶ [footnote 236 text: K. C. Wagner, R. O. Gauntt, Sandia National Laboratories, Analysis and Modeling Division, “Mitigation of Spent Fuel Pool Loss-of-Coolant Inventory Accidents and Extension of Reference Plant Analyses to Other Spent Fuel Pools,” SANDIA Letter Report, Revision 2, p. 12.] In the worst-case scenario, a SFP fire would propagate “throughout the entire spent fuel inventory in the pool”²³⁷ [footnote 237 text: J.H. Jo, P.F. Rose, S.D. Unwin, V.L. Sailor, Brookhaven National Laboratory, “Value/Impact Analyses of Accident Preventive and Mitigative Options for Spent Fuel Pools,” NUREG/CR5281, March 1989, (ADAMS Accession No. ML071690022), p. 8.]; The zirconium-air reaction would propagate away from its point of initiation more rapidly than the propagation of the zirconium-steam reaction, because: 1) the heat produced by zirconium oxidation in air is greater than that in steam; 2) the nitrogen content in air would accelerate zirconium oxidation in air; and 3) heat would also be contributed by the exothermic zirconium-nitrogen reaction. (0463-3-1 [Leyse, Mark])

Comment: MELCOR Does Not Model How Nitrogen Accelerates the Oxidation and Degradation of Zirconium Fuel-Cladding in Air: MELCOR also *does not simulate* how nitrogen gas (in air) affects the oxidation of zirconium in air.²⁵⁸ [footnote 258 text: K. C. Wagner, R. O. Gauntt, Sandia National Laboratories, Analysis and Modeling Division, “Mitigation of Spent Fuel Pool Loss-of-Coolant Inventory Accidents and Extension of Reference Plant Analyses to Other Spent Fuel Pools,” SANDIA Letter Report, Revision 2, p. 12; and L. Fernandez-Moguel, J. Birchley, European MELCOR User’s Group, “PSI air oxidation model in MELCOR: Part 2: Analysis of experiments and model assessment,” Stockholm, May 2013, which states: “Neither MELCOR nor SCDAP [a severe accident computer safety model] are able to predict a nitride reaction.”] This is a serious flaw because the presence of nitrogen accelerates the oxidation (burning) and degradation of zirconium fuel-cladding *in air*,²⁵⁹ [footnote 259 text: J. Stuckert, M. Große, Z. Hózer, M. Steinbrück, Karlsruhe Institute of Technology, “Results of the QUENCH-16 Bundle Experiment on Air Ingress,” KIT-SR 7634, May 2013, p. 1; and O. Coindreau, C. Duriez, S. Ederli, “Air Oxidation of Zircaloy-4 in the 600-1000°C Temperature Range: Modeling for ASTEC Code Application,” p. 208.] which would affect the progression and severity of a SFP accident, including radioactive releases, “most notabl[y] ruthenium.”²⁶⁰ [footnote 260 text: J. Stuckert et al., “Results of the QUENCH-16 Bundle Experiment on Air Ingress,” p. 1.] (“Ruthenium has a biological effectiveness equivalent to that of Iodine-131,”²⁶¹ [footnote 261 text: Dana A. Powers, Chairman of ACRS, Letter to Richard A. Meserve, Chairman of NRC, Regarding ACRS Recommendations for Improvements to the NRC Staff’s “Technical Study of Spent Fuel Pool Accident Risk at Decommissioning Nuclear Power Plants,” p. 2.] Ruthenium-106 has half-life of 373.6 days.) Hence, the NRC’s MELCOR simulations of SFP accidents *under-predict* the severity of such accidents. (0463-3-10 [Leyse, Mark])

Comment: A 2010 Journal of Nuclear Materials paper observes that “[t]he complexity of air oxidation of Zircaloy arises out of the simultaneous oxidation and nitriding processes.”²⁶² [footnote 262 text: O. Coindreau, C. Duriez, S. Ederli, “Air Oxidation of Zircaloy-4 in the 600-1000°C Temperature Range: Modeling for ASTEC Code Application,” p. 207.] And a May 2013 report, “Results of the QUENCH-16 Bundle Experiment on Air Ingress,” discusses experimental data demonstrating that porous nitrides form inside oxide layers *under local or full oxygen-starvation conditions*.²⁶³ [footnote 263 text: J. Stuckert et al., “Results of the QUENCH-16 Bundle Experiment on Air Ingress,” p. 10.] (When zirconium reacts in air it is possible for the reaction to become oxygen-starved; however, if zirconium is locally oxygen-starved in air, nitrogen will react with it.) The porous, degraded condition of an oxide layer facilitates accelerated oxidation rates if additional oxygen becomes *locally* available; and any additional oxygen will react with the zirconium nitride (ZrN) within an existing oxide layer and form zirconium dioxide (ZrO₂) in a fast exothermic reaction.²⁶⁴ [footnote 264 text: Emilie Beuzet et al., “Modelling of Zry-4 Cladding Oxidation by Air Under Severe Accident Conditions using MAAP4 Code,” International Conference Nuclear Energy for New Europe 2009, Slovenia, September 2009, p. 3.] (0463-3-11 [Leyse, Mark])

Comment: As quoted above, an April 2000 ACRS letter states that “[m]uch more is known now about air interactions with cladding;”²⁶⁵ [footnote 265 text: Dana A. Powers, Chairman of ACRS, Letter to Richard A. Meserve, Chairman of NRC, Regarding ACRS Recommendations for Improvements to the NRC Staff’s “Technical Study of Spent Fuel Pool Accident Risk at Decommissioning Nuclear Power Plants,” p. 3.] however, a 2008 Journal of Nuclear Materials paper, “Zircaloy-4 and M5 High Temperature Oxidation and Nitriding in Air,” states: Oxidation of zirconium alloys at high temperature for severe accident analysis has been widely studied in steam, however, the existing data regarding air oxidation in the temperature range of interest are scarce. ...the exact role of zirconium nitride on the cladding degradation process is poorly understood. It remains unclear to [what] extent the nitrogen effect is responsible for the kinetic acceleration of the oxidation process that has been observed by these authors. Further[more], it should be stressed that most of the existing data have been obtained with bare [non-oxidized] samples.²⁶⁶ [footnote 266 text: C. Duriez, T. Dupont, B. Schmet, F. Enoch, “Zircaloy-4 and M5 High Temperature Oxidation and Nitriding in Air,” Journal of Nuclear Materials 380 (2008), p. 30.] Regarding nitrogen-induced breakaway oxidation, the 2008 Journal of Nuclear Materials paper explains that “[b]reakdown and loss of the dense scale protective effect occur and result in an accelerated degradation;” furthermore, the transition to nitrogen-induced breakaway oxidation occurs *earlier with pre-oxidized fuel cladding* than with fresh *non-oxidized fuel cladding*—“nitriding is favored by the ‘corrosion’ scale.”²⁶⁷ [footnote 267 text: Id., p. 44.] (0463-3-12 [Leyse, Mark])

Comment: It is clear that *in air*, in a SFP accident, a significant degree of zirconium oxidation would occur, because spent fuel rods would be “pre-oxidized.” When high burnup (and other) fuel rods are discharged from the reactor core and loaded into the SFP, the fuel cladding can have local zirconium dioxide (ZrO₂) “oxide” layers that are up to 100 µm thick (or greater); there can also be local crud layers on top of the oxide layers, which can sometimes also be up to 100 µm thick. And medium to high burnup fuel cladding typically has a “hydrogen concentration in the range of 100-1000 wppm [weight parts per million];” “[z]irconium-based alloys, in general, have a strong affinity for oxygen, nitrogen, and hydrogen...”²⁶⁸ [footnote 268 text: K. Natesan, W.K. Soppet, Argonne National Laboratory, “Hydrogen Effects on Air Oxidation of Zirlo Alloy,” NUREG/CR-6851, October 2004, (ADAMS Accession No. ML042870061), p. iii, 3.] (0463-3-13 [Leyse, Mark])

Comment: Regarding limitations of air oxidation models, the May 2013 report, “Results of the QUENCH-16 Bundle Experiment on Air Ingress,” states that “[t]he models for air oxidation do not yet cover the whole range of representative conditions. The main aims of new bundle tests should be the investigation of areas where data [are] mostly missing.”²⁶⁹ [footnote 269 text: J. Stuckert et al., “Results of the QUENCH-16 Bundle Experiment on Air Ingress,” p. 1.] And, a 2009 paper, regarding needed development for MELCOR *in the area of air ingress*, states that “air oxidation cannot be reliably predicted (or even described conservatively) by any of the models used in the currently available codes. A new modeling approach and an appropriate database are therefore necessary.”²⁷⁰ [footnote 270 text: S. Guntay, J. Birchley, “MELCOR Further Development in the Area of Air Ingress and Participation in OECDNEA SFP Project to Be Performed in the Time Frame 2009-2012,” April 2009, p. 4.] Additionally, information about the French Mozart Program to study the zirconium-air reaction states that “[b]ibliographic reviews reveal wide scattering of the existing kinetic data concerning the oxidation of Zircaloy-4 by air in the temperature range concerned [600°C to 1200°C]. *For recent alloys, such as M5 and Zirlo, there is virtually no data published in the open literature*”²⁷¹ [footnote 271 text: IRSN, website description of the Mozart Program; available at: <http://www.irsn.fr/EN/Research/Research-organisation/Research-programmes/SOURCE-TERM/MOZART/Pages/The-MOZART-programme-on-the-PWR-fuel-cladding-oxidation-in-air-3238.aspx> (last visited 10/22/13).] [emphasis added]. (0463-3-14 [Leyse, Mark])

Comment: In a June 2013 document, the NRC explained that a new air oxidation kinetics model was added to MELCOR version 1.8.6 (2005) that is based on data from *isothermal*²⁷² [footnote 272 text: The tests ANL were *isothermal tests*, in which “a [zirconium alloy] specimen was held at constant temperature and the weight gain associated with oxidation as a function of time was measured.” See NRC, “Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I Boiling Water Reactor: Draft Report,” p. 93.] air zirconium-oxidation experiments conducted at Argonne National Laboratory (“ANL”). The ANL data (published in 2004) demonstrated that “air oxidation can be observed at temperatures as low as 600 K [327°C (620°F)];” and that the breakaway phenomenon that occurs when zirconium is oxidized in air causes “a sharp increase” in reaction and heatup rates in the post-breakaway regime. Apparently, MELCOR version 1.8.6 “provide[s] a better prediction of the measured data, including a transition to accelerated post-breakaway oxidation kinetics.”²⁷³ [footnote 273 text: NRC, “Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I Boiling Water Reactor: Draft Report,” pp. 93-94.] (0463-3-15 [Leyse, Mark])

Comment: MELCOR version 1.8.6 may provide a “better prediction” of the measured air oxidation data, than older versions. However, the Paul Scherrer Institute (“PSI”) recently assessed MELCOR 1.8.6’s ability to predict fuel-cladding behavior in accidents involving air ingress into the reactor vessel—which is pertinent to MELCOR’s ability to predict zirconium-air reaction rates in SFP accidents—and “concluded that development of MELCOR was needed *to capture the accelerated cladding oxidation that can take place under air ingress conditions* (characterized by transition from formation of a protective oxide film to non-protective ‘breakaway’ oxidation at a significantly higher rate)”²⁷⁴ [footnote 274 text: S. Guntay, J. Birchley, “MELCOR Further Development in the Area of Air Ingress and Participation in OECDNEA SFP Project to Be Performed in the Time Frame 2009-2012,” April 2009, p. 2.] [emphasis added]. PSI has also explained: Although there was not, [in] the 1980’s, any systematic treatment of air oxidation, correlations had been developed on the basis of limited data²⁷⁵ [footnote 275 text: A. Benjamin et al., “Spent Fuel Heatup following Loss of Water during Storage,” NUREG/CR-0649, SAND77-1371, March 1979, (ADAMS Accession No. ML120960637); and V. Sailor et al., “Severe Accidents in Spent Fuel Ponds in Support f

Generic Issue 82”, NUREG/CR-4982, July 1987.] and these had been adapted for use in MELCOR in [an] attempt to provide a conservative statement of the thermal response to an air ingress scenario. A feature of all these correlations was that the controlling processes were similar to those which govern steam oxidation. The US-NRC later commissioned experimental studies²⁷⁶ [footnote 276 text: K. Natesan, W.K. Soppet, Argonne National Lab (ANL), "Air Oxidation Kinetics for Zr-Based Alloys," NUREG/CR-6846, July 2004, (ADAMS Accession No. ML041900069).] [the ANL isothermal experiments] to obtain data with which to establish a credible physical basis for using the correlations. *More recent experiments*²⁷⁷ [footnote 277 text: These recent experiments are discussed in the four following reports: 1) M. Steinbrueck, U. Stegmeier, T. Ziegler, "Prototypical Experiments on Air Oxidation of Zircaloy-4 at High Temperature," FZK 7257, January 2007; 2) G. Schanz et al., "Results of QUENCH-10 Experiment on Air Ingress," FZKA 7057, May 2006; 3) Ch. Duriez et al., "Separate effect Tests on Zirconium Cladding Degradation in Air Ingress Situations," Proceedings of 2nd ERMSAR Conference, Karlsruhe, Germany, 2007; and 4) A. Auvinen et al., "Progress on ruthenium release and transport under air ingress Conditions," Nuclear Engineering and Design, 238, 2008, pp. 3418–3428.] *demonstrated that the processes that govern air oxidation are quite different from those which apply to steam oxidation*²⁷⁸ [footnote 278 text: S. Güntay, J. Birchley, "MELCOR Further Development in the Area of Air Ingress and Participation in OECDNEA SFP Project to Be Performed in the Time Frame 2009-2012," p. 4.] [emphasis added]. (0463-3-16 [Leyse, Mark])

Comment: Clearly, the NRC’s conclusions from its Post-Fukushima MELCOR simulations are non-conservative and misleading, because their conclusions underestimate the probabilities of large radiological releases from SFP accidents. By overlooking the deficiencies of its Post-Fukushima MELCOR simulations, the NRC undermines its own philosophy of defense-in-depth, which requires the application of conservative models.²⁷⁹ [footnote 279 text: Charles Miller et al., NRC, "Recommendations for Enhancing Reactor Safety in the 21st Century: The Near-Term Task Force Review of Insights from the Fukushima Dai-ichi Accident," SECY-11-0093, July 12, 2011, (ADAMS Accession No. ML111861807), p. 3.] (0463-3-17 [Leyse, Mark])

Comment: The NRC’s Recent Non-Conservative Post-Fukushima MELCOR Simulations; A recent NRC Post-Fukushima MELCOR (version 1.8.6 of the code²⁸⁰ [footnote 280 text: The SFP models in MELCOR versions 1.8.6 and 2.1 are functionally the same. See NRC, "Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I Boiling Water Reactor: Draft Report," pp. 92-93.]) simulation of *a particular* BWR Mark I SFP fire scenario ("Unsuccessful Deployment of Mitigation for Moderate Leak (OCP3) Scenario"²⁸¹ [footnote 281 text: NRC, "Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I Boiling Water Reactor: Draft Report," p. 142.]) found that in the central area of the SFP, "Radial Ring 1"—where the newly discharged, hottest, fuel assemblies were stored—the peak fuel-cladding temperature would reach approximately 1800 K (1527°C) (2780°F) at "Axial Level 4."²⁸² [footnote 282 text: For MELCOR "[t]he core is nodalized into a number of axial levels and radial rings (each ring represents a collection of assemblies)," and "MELCOR core models were originally designed for the reactor core. Because of the code flexibility, the same modeling approach can be used for the spent fuel pool (with the addition of the rack as a separate component)." See NRC, "Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I Boiling Water Reactor: Draft Report," p. 95, and p. 95, Note 12.] However, the same simulation also found that "[a]fter the peak temperature [is reached] at [Axial] Level 4, the peak temperature in the zirconium fire front decreases with each successive [axial] level. Radial heat transfer²⁸³ [footnote 283 text: "MELCOR attempts to model a multidimensional geometry with a simplified two-surface radiation model." See NRC, "Consequence Study of a Beyond-Design-

Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I Boiling Water Reactor: Draft Report,” p. 110, Note 23.] from the fuel racks to the SFP wall..., *the buildup of the oxide layer on the fuel, and the depletion of the oxygen in the reactor building...cause the clad temperature to decrease*. After 24 hours, the fuel temperatures in [Radial] Ring 1 are relatively stable”²⁸⁴ [footnote 284 text: NRC, “Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I Boiling Water Reactor: Draft Report,” pp. 142-143.] [emphasis added]. (In this scenario there is a depletion of the oxygen in the reactor building, because the reactor building was *not* breached by a hydrogen explosion (a total of four reactor buildings were breached by hydrogen explosions in the Fukushima Dai-ichi accident²⁸⁵ [footnote 285 text: In the Fukushima Dai-ichi accident, hydrogen detonated in and essentially destroyed the secondary containments of Units 1, 3, and 4, causing large releases of radiation. And the secondary containment of Unit 2 was breached: a hydrogen explosion that occurred in the Unit 1 reactor building “caused a blowout panel in the Unit 2 reactor building to open, which resulted in a loss of secondary containment integrity.” See INPO, “Special Report on the Nuclear Accident at the Fukushima Dai-ichi Nuclear Power Station,” INPO 11-005, November 2011, p. 24.])). This recent NRC MELCOR simulation—in which there is a depletion of the oxygen in the reactor building—would have had *different results* if it had modeled: 1) how nitriding would degrade the fuel-cladding’s “protective” oxide layer and accelerate the zirconium oxidation, which would contribute additional heat; 2) the nitriding of zirconium under oxygen-starvation conditions; and 3) the significant additional heat that would be contributed from the exothermic nitrogen-zirconium reaction. (0463-3-18 [Leyse, Mark])

Comment: In other recent NRC MELCOR simulations of BWR Mark I SFP accident/fire scenarios, the reactor buildings were breached by hydrogen explosions, so there was more available oxygen to facilitate zirconium oxidation. However, those simulations would have had *different results* if they had modeled: 1) how nitriding would degrade the fuel-cladding’s “protective” oxide layer and accelerate the zirconium oxidation, which would contribute additional heat and 2) the significant additional heat that would be contributed from the exothermic nitrogen-zirconium reaction.²⁸⁶ [footnote 286 text: NRC, “Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I Boiling Water Reactor: Draft Report.”] In actual SFP fires, there would be quicker fuel-cladding temperature escalations, releasing more heat, and quicker axial and radial propagation of zirconium fires than MELCOR indicates. (0463-3-19 [Leyse, Mark])

Comment: Zirconium Hydriding: It is widely known that hydrogen can detonate in air; hydrogen can also chemically react with zirconium. The reaction between hydrogen and zirconium *is exothermic*. Zirconium hydriding “can occur with [a] hydrogen-rich atmosphere and at [a] moderate temperature... The exothermic reaction is able to lead to *severe temperature escalations* in the temperature range of [627°C (1160°F) to 1127°C (2060°F)]”²³⁸ [footnote 238 text: T.J. Haste et al., “In-Vessel Core Degradation in LWR Severe Accidents,” European Commission, Report EUR 16695 EN, 1996, p. 36.] [emphasis added]. (This information is based on data from an experiment—PHEBUS SFD C3—that was conducted under conditions very different than those that would occur in a SFP accident. PHEBUS SFD C3 “was performed with...high pressure (3.5 MPa [508 psia]), pure steam-starved conditions (pure hydrogen coolant) and very low cladding oxidation.”²³⁹ [footnote 239 text: Id., p. 33.]); Hydriding can occur when there are steam-starved conditions; however, there can also be simultaneous oxidation and hydriding.²⁴⁰ [footnote 240 text: Id., pp. 70-71.] In a SFP accident, hydriding would primarily occur at locations of the spent fuel rods that had freshly exposed zirconium as a result of fuel rod ballooning and rupturing; oxide layers inhibit hydrogen uptake. (0463-3-2 [Leyse, Mark])

Comment: Recent Sandia National Laboratory Spent Fuel Pool Accident Experiments Are Unrealistic because They Were Conducted with Clean Non-Oxidized Cladding. Recent Sandia National Laboratory (“SNL”) SFP accident experiments are unrealistic because they have been conducted with clean non-oxidized bundles of zirconium fuel rod simulators;²⁸⁷ [footnote 287 text: E. R. Lindgren, Sandia National Laboratory, “Characterization of Thermal-Hydraulic and Ignition Phenomena in Prototypic, Full-Length Boiling Water Reactor Spent Fuel Pool Assemblies After a Postulated Complete Loss-of-Coolant Accident,” NUREG/CR-7143, March 2013, (ADAMS Accession No. ML13072A056).] the spent fuel assemblies stored in SFPs have oxide layers. When high burnup (and other) fuel rods are discharged from the reactor core and loaded into the SFP, the fuel cladding can have local zirconium dioxide (ZrO₂) “oxide” layers that are up to 100 µm thick (or greater); there can also be local crud layers on top of the oxide layers, which can sometimes also be up to 100 µm thick. And medium to high burnup fuel cladding typically has a “hydrogen concentration in the range of 100-1000 wppm [weight parts per million];” “[z]irconium-based alloys, in general, have a strong affinity for oxygen, nitrogen, and hydrogen...”²⁸⁸ [footnote 288 text: K. Natesan, W.K. Soppet, Argonne National Laboratory, “Hydrogen Effects on Air Oxidation of Zirlo Alloy,” NUREG/CR-6851, October 2004, (ADAMS Accession No: ML042870061), p. iii, 3.] Regarding nitrogen-induced breakaway oxidation, the 2008 Journal of Nuclear Materials paper explains that “[b]reakdown and loss of the dense scale protective effect occur and result in an accelerated degradation;” furthermore, the transition to nitrogen-induced breakaway oxidation occurs *earlier with pre-oxidized fuel cladding than with fresh non-oxidized fuel cladding*—“nitriding is favored by the ‘corrosion’ scale.”²⁸⁹ [footnote 289 text: C. Duriez, T. Dupont, B. Schmet, F. Enoch, “Zircaloy-4 and M5 High Temperature Oxidation and Nitriding in Air,” Journal of Nuclear Materials 380 (2008), p. 44.] It is clear that *in air*, in a SFP accident, there would be a significant degree of zirconium oxidation, because the spent fuel rods in the pool would be “pre-oxidized.” This phenomenon of nitrogen attacking pre-oxidized zirconium alloy cladding is not simulated in SNL’s experiments. Hence, data from SNL’s SFP accident experiments is inadequate for benchmarking MELCOR. Benchmarking a computer safety model with data gathered from unrealistic experiments undermines the NRC’s philosophy of defense-in-depth, which requires the application of conservative models.²⁹⁰ [footnote 290 text: Charles Miller et al., NRC, “Recommendations for Enhancing Reactor Safety in the 21st Century: The Near-Term Task Force Review of Insights from the Fukushima Dai-ichi Accident,” SECY-11-0093, p. 3.] (0463-3-20 [Leyse, Mark])

Comment: Oxidation Models Are Not Able to Predict the Fuel-Cladding Temperature Escalation that Commenced at “Low Temperatures” in the PHEBUS B9R Test: As stated above, the PHEBUS B9R test was conducted in a light water reactor—as part of the PHEBUS severe fuel damage program—with an assembly of 21 UO₂ fuel rods. The B9R test was conducted in two parts: the B9R-1 test and the B9R-2 test.²⁹¹ [footnote 291 text: G. Hache, R. Gonzalez, B. Adroguer, Institute for Protection and Nuclear Safety, “Status of ICARE Code Development and Assessment,” in NRC “Proceedings of the Twentieth Water Reactor Safety Information Meeting,” NUREG/CP-0126, Vol. 2, 1992, (ADAMS Accession No: ML042230126), p. 311.] A 1996 European Commission report states that the B9R-2 test had an unexpected fuel-cladding temperature escalation in the mid-bundle region; the highest temperature escalation rates were from 20°C/sec (36°F/sec) to 30°C/sec (54°F/sec).²⁹² [footnote 292 text: T.J. Haste et al., “In-Vessel Core Degradation in LWR Severe Accidents,” European Commission, Report EUR 16695 EN, 1996, p. 33.] Discussing PHEBUS B9R-2, the 1996 European Commission report states: The B9R-2 test (second part of B9R) illustrates the oxidation in different cladding conditions representative of a pre-oxidized and fractured state. This state results from a first oxidation phase (first part name B9R-1, of the B9R test) terminated by a rapid cooling-down phase. During B9R-2, an unexpected strong escalation of the oxidation of the remaining Zr occurred when the bundle flow injection was switched from helium to steam while the maximum

clad temperature was equal to 1300 K [1027°C (1880°F)]. *The current oxidation model was not able to predict the strong heat-up rate observed* even taking into account the measured large clad deformation and the double-sided oxidation (final state of the cladding from macro-photographs). ... *No mechanistic model is currently available to account for enhanced oxidation of pre-oxidized and cracked cladding*²⁹³ [footnote 293 text: Id., p. 126.] [emphasis added]. Today, in 2013, oxidation models still cannot accurately predict the local fuel-cladding temperature escalation that commenced in PHEBUS B9R when local fuel-cladding temperatures were 1027°C (1880°F). The PHEBUS B9R results indicate that the currently used zirconium-steam reaction correlations, such as the Cathcart-Pawel and Urbanic-Heidrick correlations, are inadequate for use in computer safety models like MELCOR. (0463-3-21 [Leyse, Mark])

Comment: “Low Temperature” Oxidation Rates Are Under-Predicted for the CORA16 Experiment: When Oak Ridge National Laboratory (“ORNL”) investigators compared the results of the CORA-16 experiment—a BWR core severe fuel damage test, simulating a meltdown, conducted with a multi-rod zirconium alloy bundle—with the predictions of computer safety models, they found that the zirconium-steam reaction rates that occurred in the experiment were under-predicted. The investigators concluded that the “application of the available Zircaloy oxidation kinetics models [zirconium-steam reaction correlations] causes the low-temperature [1652-2192°F] oxidation to be underpredicted.”²⁹⁴ [footnote 294 text: L. J. Ott, Oak Ridge National Laboratory, “Report of Foreign Travel of L. J. Ott, Engineering Analysis Section, Engineering Technology Division,” ORNL/FTR-3780, October 16, 1990, p. 3.] (0463-3-22 [Leyse, Mark])

Comment: It has been postulated that cladding strain—ballooning—was a factor in increasing the zirconium-steam reaction rates that occurred in the CORA-16 experiment.²⁹⁵ [footnote 295 text: L. J. Ott, W. I. van Rij, “In-Vessel Phenomena—CORA: BWR Core Melt Progression Phenomena Program, Oak Ridge National Laboratory,” CONF-9105173-3-Extd.Abst., Presented at Cooperative Severe Accident Research Program, Semiannual Review Meeting, Bethesda, Maryland, May 6-10, 1991.] However, it is unsubstantiated that cladding strain actually increased reaction rates. To help explain how cladding strain could have been a factor in increasing the zirconium-steam reaction rates that occurred in CORA-16, the NRC has pointed out that an NRC report, NUREG/CR-4412,²⁹⁶ [footnote 296 text: R. E. Williford, “An Assessment of Safety Margins in Zircaloy Oxidation and Embrittlement Criteria for ECCS Acceptance,” NUREG/CR-4412, April 1986, (ADAMS Accession No: ML083400371).] “explain[s] that under *certain* conditions ballooning and deformation of the cladding can increase the available surface area for oxidation, thus enhancing the apparent oxidation rate”²⁹⁷ [footnote 297 text: NRC, “Draft Interim Review of PRM-50-93/95 Issues Related to the CORA Tests,” August 23, 2011, (ADAMS Accession No: ML112211930), p. 3.] [emphasis not added]. Regarding this phenomenon, NUREG/CR-4412 states: Depressurization of the primary coolant during a LB LOCA or [severe accident] will permit [fuel] cladding deformation (ballooning and possibly rupture) to occur because the fuel rod internal pressure may be greater than the external (coolant) pressure. In this case, oxidation and deformation can occur simultaneously. This in turn may result in an apparent enhancement of oxidation rates because: 1) ballooning increases the surface area of the cladding and permits more oxide to form per unit volume of Zircaloy and 2) the deformation may crack the oxide and provide increased accessibility of the oxygen to the metal. However deformation generally occurs before oxidation rates become significant; i.e., below [1832°F]. Consequently, the lesser importance of this phenomenon has resulted in a relatively sparse database.²⁹⁸ [footnote 298 text: R. E. Williford, “An Assessment of Safety Margins in Zircaloy Oxidation and Embrittlement Criteria for ECCS Acceptance,” p. 27.] (0463-3-23 [Leyse, Mark])

Comment: NUREG/CR-4412 states that there is a *relatively sparse database* on the phenomenon of cladding strain enhancing zirconium-steam reaction rates.²⁹⁹ [footnote 299 text: Id., pp. 27, 30.] NUREG/CR-4412 also explains that “it is possible to make a very crude estimate of the expected average enhancement of oxidation kinetics by deformation;”³⁰⁰ [footnote 300 text: Id., p. 30.] the report provides a graph of the “rather sparse”³⁰¹ [footnote 301 text: Id.] data. The graph indicates that the general trend is for cladding strain enhancements of zirconium-steam reaction rates to *decrease as cladding temperatures increase*.³⁰² [footnote 302 text: Id., p. 29.] NUREG/CR-4412 has a brief description of the rather sparse data; in one case, two investigators (Furuta and Kawasaki), who heated specimens up to temperatures between 1292°F and 1832°F, reported that “[v]ery small enhancements [of reaction rates] occurred at about [eight percent] strain at [1832°F].”³⁰³ [footnote 303 text: Id., p. 30.] In fact, NUREG/CR-4412 states that only one pair of investigators (Bradhurst and Heuer) conducted tests that encompassed the temperature range—1652°F to 2192°F—in which zirconium-steam reaction rates were under-predicted for CORA-16. Bradhurst and Heuer reported that “[m]aximum enhancements occurred at slower strain rates. ... However, the overall weight gain or average oxide thickness in [the Zircaloy-2 specimens] was only minimally increased because of the localization effects of cracks in the oxide layer.”³⁰⁴ [footnote 304 text: Id.] A second report states that “Bradhurst and Heuer...found no direct influence [from cladding strain] on Zircaloy-2 oxidation outside of oxide cracks.”³⁰⁵ [footnote 305 text: F. J. Erbacher, S. Leistikow, “A Review of Zircaloy Fuel Cladding Behavior in a Loss-of-Coolant Accident,” Kernforschungszentrum Karlsruhe, KfK 3973, September 1985, p. 6.] (In CORA-16, in the temperature range from 1652°F to 2192°F, cladding strain would have occurred over a very brief period of time, because cladding temperatures were increasing rapidly.) (0463-3-24 [Leyse, Mark])

Comment: Clearly, it is unsubstantiated that the estimated cladding strain accurately accounts for why reaction rates for CORA-16 were under-predicted in the temperature range from 1652°F to 2192°F. First, there is a relatively sparse database on how cladding strain enhances reaction rates. Second, the little data that is available indicates that cladding strain *may* only *slightly* enhance reaction rates at cladding temperatures of 1832°F and greater.³⁰⁶ [footnote 306 text: R. E. Williford, “An Assessment of Safety Margins in Zircaloy Oxidation and Embrittlement Criteria for ECCS Acceptance,” p. 30.] Furthermore, ORNL papers on the BWR CORA experiments do not report that any experiments were conducted in order to confirm if in fact cladding strain actually increased zirconium-steam reaction rates and accounted for why reaction rates were under-predicted in the 1652°F to 2192°F temperature range for CORA-16. (0463-3-25 [Leyse, Mark])

Comment: There is also one phenomenon NRC did not consider in its 2011 analysis of CORA-16: “[t]he swelling of the [fuel] cladding...alters [the] pellet-to-cladding gap in a manner that provides less efficient energy transport from the fuel to the cladding,”³⁰⁷ [footnote 307 text: Winston & Strawn LLP, “Duke Energy Corporation, Catawba Nuclear Station Units 1 and 2,” Enclosure, Testimony of Robert C. Harvey and Bert M. Dunn on Behalf of Duke Energy Corporation, “MOX Fuel Lead Assembly Program, MOX Fuel Characteristics and Behavior, and Design Basis Accident (LOCA) Analysis,” July 1, 2004, ((ADAMS Accession No: ML041950059), p. 43.] which would cause the local cladding temperature heatup rate to decrease as the cladding ballooned, moving away from the internal heat source of the fuel. The CORA experiments were internally electrically heated (with annular uranium dioxide pellets to replicate uranium dioxide fuel pellets), so in CORA-16, the ballooning of the cladding would have had a mitigating factor on the local cladding temperature heatup rate, which, in turn, would have had a mitigating factor on zirconium-steam reaction rates. CORA-16 is an example of an experiment that had zirconium-steam reaction rates that were under-predicted in the “low temperature” range from 1652°F to 2192°F by computer safety models. The CORA-16 results

indicate that the currently used zirconium-steam reaction correlations, such as the Cathcart-Pawel and Urbanic-Heidrick correlations, are inadequate for use in computer safety models like MELCOR. (0463-3-26 [Leyse, Mark])

Comment: The Boron Carbide Contained in the Spent Fuel Racks: The boron carbide (“B4C”) contained in the Boral and Boraflex neutron-absorber materials that are placed in spent fuel racks would melt before it could oxidize in the racks. EPRI SFP accident guidance states that it should be assumed that Boral and Boraflex materials would melt and relocate downward to the bottom of the SFP.²⁴¹ [footnote 241 text: EPRI, “Severe Accident Management Guidance Technical Basis Report,” Volume 2: “The Physics of Accident Progression,” 1025295, Appendix EE, p. EE-9.] However, if some of the boron carbide were to oxidize (in dry air) later in the accident, the heat released—50,155 kJ/kg per kg of B4C reacted—would be approximately 7.7 times greater (per gram) than the heat released by the oxidation of zirconium in steam—approximately 6500 kJ per kg of Zr reacted.²⁴² [footnote 242 text: L. Belovsky, “Heat Release from B4C Oxidation in Steam and Air,” paper from “Behaviour of LWR core materials under accident conditions,” IAEA-TECDOC-921, Proceedings of a Technical Committee meeting held in Dimitrovgrad, Russian Federation, 9-13 October 1995, p. 57.] (0463-3-3 [Leyse, Mark])

Comment: Chemical Interactions between Zirconium and Inconel at “Low Temperatures;” Data from experiments studying severe reactor accidents can pertain to SFP accidents— as the NRC report NUREG-1738 concludes²⁴³ [footnote 243 text: NRC, “Technical Study of Spent Fuel Pool Accident Risk at Decommissioning Nuclear Power Plants,” NUREG-1738, February 2001 (ADAMS Accession No. ML010430066), Appendix 1 B, p. AI B-2.]—including information about the eutectic chemical interactions between materials that would occur in both types of accidents. Such experiments have demonstrated that eutectic chemical interactions between Inconel and Zircaloy occur at temperatures as “low” as 1832°F; hence, analysts have concluded that “[g]rid spacers can have a significant impact on the progression of damage in a reactor core during a severe accident. ...in a reactor core with Inconel grid spacers the meltdown of the core may begin at the location of the grid spacers.”²⁴⁴ [footnote 244 text: L.J. Siefken, M.V. Olsen, “A Model for the Effect of Inconel Grid Spacers on Progression of Damage in Reactor Core,” Nuclear Engineering and Design 146, 1994, p. 427.] It is pertinent that in the CORA severe reactor accident experiments, simulating meltdowns, “[i]n all cases, the damage of the bundle was initiated due to Zircaloy/stainless steel and Zircaloy/Inconel interactions. Localized liquefaction of these components started around 1200°C.”²⁴⁵ [footnote 245 text: P. Hofmann, “Current Knowledge on Core Degradation Phenomena, a Review,” Journal of Nuclear Materials, 270, 1999, p. 202.] In the CORA-2 and -3 experiments, “the meltdown of the Inconel spacer [took] less than one minute...[and] an enhanced melting in the midsection...shift[ed] the axial hot spot to the bottom of the bundle.”²⁴⁶ [footnote 246 text: S. Hagen, P. Hofmann, G. Schanz, L. Sepold, “Interactions in Zircaloy/UO2 Fuel Rod Bundles with Inconel Spacers at Temperatures above 1200°C (Posttest Results of Severe Fuel Damage Experiments CORA-2 and CORA-3),” Forschungszentrum Karlsruhe, KfK 4378, September 1990, p. 6.]; (Inconel is an alloy that has a higher percentage of nickel (Ni) than stainless steel; for example, Inconel 600 is composed of 76.0 percent nickel by weight, 15.0 percent chromium by weight, 8.0 percent iron (Fe) by weight, and small percentages of other elements. Stainless steel is a metal alloy with contents of chromium and iron greater than 11.5 percent by weight and 50 percent by weight, respectively; stainless steel also contains nickel, manganese, and small percentages of other elements.); The ballooning of zirconium fuel cladding would augment its contact with the Inconel grid spacers. If local temperatures were to increase to approximately 1200°C, the cladding-to-grid contact would initiate the eutectic chemical reaction between zirconium and Inconel. Hence, one could reasonably speculate that in a SFP boil-off accident,

if a fuel assembly had Inconel grid spacers, the first location it liquefied would be in the vicinity of an upper Inconel grid spacer. (0463-3-4 [Leyse, Mark])

Comment: Chemical Interactions Between Zircaloy and Stainless Steel at “Low Temperatures;” Discussing chemical interactions between Zircaloy and stainless steel (and comparing them to those between Zircaloy and Inconel), “Current Knowledge on Core Degradation Phenomena, a Review” states: In a first approach, the reaction behavior of Zircaloy with Inconel 718 is comparable to that with Type 316 stainless steel.²⁴⁷ [footnote 247 text: P. Hofmann, M. Markiewicz, “Chemical Interactions between As-Received and Pre-Oxidized Zircaloy and Inconel 718 at High Temperatures,” Kernforschungszentrum Karlsruhe, KfK 4729, 1994.] At temperatures <1100°C, Inconel attacks the Zircaloy faster than stainless steel; above 1100°C, the situation is the reverse. In both cases, the melting of a relatively large quantity of Zircaloy with limited melting of the adjacent stainless steel or Inconel takes place. During heat-up of the stainless steel/Zircaloy...reaction [system], a sudden and complete liquefaction of the specimens occurs at temperatures slightly above 1250°C. This may be the reason [one of the locations] that melt progression in a fuel rod bundle initiates [is] at absorber rod cladding (stainless steel)/Zircaloy guide tube contact areas.²⁴⁸ [footnote 248 text: P. Hofmann, “Current Knowledge on Core Degradation Phenomena, a Review,” p. 202.]; And discussing the affects of zirconium oxide (ZrO₂) layers on the chemical interaction between Zircaloy and stainless steel, “Current Knowledge on Core Degradation Phenomena, a Review” states: Oxide layers on the Zircaloy cladding outside diameter delay the chemical interactions between Zircaloy and steel, but they cannot prevent them. The influence of oxide layers becomes less important at temperatures >1100°C, since the dissolution of the protecting ZrO₂ layers occurs rather fast and the stainless steel is then in contact with metallic Zircaloy or oxygen-stabilized α -Zr(O).²⁴⁹ [footnote 249 text: Id.] (0463-3-5 [Leyse, Mark])

Comment: Molten Core Concrete Interaction in Spent Fuel Pool Accidents: For the SFP, the term “molten-core-concrete interaction” (“MCCI”) is a misnomer; MCCI refers to molten fuel assemblies chemically interacting with the SFP’s concrete content, after being relocated to the bottom of the SFP. MCCI would commence after the SFP’s stainless steel liner melted; then the molten fuel assemblies would chemically interact with concrete, generating hydrogen and carbon monoxide gases.²⁵⁰ [footnote 250 text: M. Kowalik et al., “Severe Accident Analyses for Shutdown Modes and Spent Fuel Pools to Support PSA level 2 Activities,” Eurosafe 2013 Seminar 1, p. 5.]; Regarding the MCCI that could occur in a SFP accident, a June 2013 NRC report on how earthquakes could affect BWR Mark I SFPs states: MCCI may occur in selected scenarios in which the fuel relocated to the bottom of the pool following the failure of the rack baseplate and its temperature exceeded the concrete ablation temperature [approximately 1227°C (2240°F)]. These cases involve large-scale debris relocation and large releases of volatile fission products. Even without MCCI, the fuel in debris form continues to release fission products resulting in very large releases of volatiles.²⁵¹ [footnote 251 text: NRC, “Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I Boiling Water Reactor: Draft Report,” June 2013, (ADAMS Accession No. ML13133A132), p 26.] (0463-3-6 [Leyse, Mark])

Comment: MELCOR Does Not Model the Exothermic Zirconium-Nitrogen Reaction: The NRC has recently performed a number of post-Fukushima computer simulations of SFP accidents with the Sandia National Laboratories (“SNL”) MELCOR computer safety model. However, MELCOR *does not simulate* the generation of heat from the chemical reaction of zirconium and nitrogen; neglecting to model a heat source that would affect the progression and severity of SFP accidents is a serious flaw. (0463-3-7 [Leyse, Mark])

Comment: Regarding limitations of the NRC's MELCOR computer safety model, in 2006, a SNL report observed that *MELCOR does not model the nitriding of zirconium alloy fuel cladding*, stating that fuel cladding would "combine with nitrogen if no oxygen or steam are available" and that the nitriding process is exothermic (heat-generating).²⁵³ [footnote 253 text: K. C. Wagner, R. O. Gauntt, Sandia National Laboratories, Analysis and Modeling Division, "Mitigation of Spent Fuel Pool Loss-of-Coolant Inventory Accidents and Extension of Reference Plant Analyses to Other Spent Fuel Pools," SANDIA Letter Report, Revision 2, p. 12.] And in August 2012 a different SNL report, "Fukushima Daiichi Accident Study" stated: "If inadequate cooling is provided, then the cladding will heat up and will rapidly oxidize (i.e., burn) and to a lesser extent, nitride (i.e., combine with nitrogen if no oxygen or steam are available). *Since the oxidation and nitride processes are exothermic*, the fuel rods could heat to melting conditions and structurally degrade"²⁵⁴ [footnote 254 text: Randall Gauntt et al., Sandia National Laboratories "Fukushima Daiichi Accident Study: Status as of April 2012," SAND2012-6173, August 2012, p. 183.] [emphasis added]. (0463-3-8 [Leyse, Mark])

Comment: In an April 2000 letter from Dana A. Powers, Chairman of the Advisory Committee on Reactor Safeguards ("ACRS"), to Richard A. Meserve, Chairman of the NRC, the ACRS advised the NRC Staff that an NRC report on SFP accident risk "relied on relatively geriatric work" for its *analysis of the interaction of air with zirconium fuel cladding*, stating that "[m]uch more is known now about air interactions with cladding," including knowledge gained "from studies being performed as part of a cooperative international program (PHEBUS FP)²⁵⁵ [footnote 255 text: PHEBUS FP is an experimental program that researched severe-accident reactor core damage.]) in which NRC is a partner." The ACRS told the NRC Staff that "[a]mong the findings of this work is *that nitrogen from air depleted of oxygen will interact exothermically with zircaloy cladding*. The reaction of zirconium with nitrogen is exothermic by about 86,000 calories per mole of zirconium reacted. Because the heat required to raise zirconium from room temperature to melting is only about 18,000 calories per mole, the reaction enthalpy with nitrogen is ample"²⁵⁶ [footnote 256 text: Dana A. Powers, Chairman of ACRS, Letter to Richard A. Meserve, Chairman of NRC, Regarding ACRS Recommendations for Improvements to the NRC Staff's "Technical Study of Spent Fuel Pool Accident Risk at Decommissioning Nuclear Power Plants," April 13, 2000, (ADAMS Accession No. ML003704532), pp. 3-4.] [emphasis added]. As early as 1987, a report that was prepared for the NRC, "Severe Accidents in Spent Fuel Pools in Support of Generic Safety Issue 82," stated that zirconium nitriding in air is an exothermic reaction, "releasing approximately 82 kcal/mole"—approximately 3.76 megajoules per kg of Zr reacted,²⁵⁷ [footnote 257 text: V. L. Sailor et al., Brookhaven National Laboratory, "Severe Accidents in Spent Fuel Pools in Support of Generic Safety Issue 82," NUREG/CR-4982, July 1987, p. 109.] which is approximately 30 percent of the quantity of energy (per kg of Zr reacted) produced by the zirconium-oxygen reaction in air. Unfortunately, more than 25 years later, the NRC's Post-Fukushima MELCOR simulations still do not model how the nitrogen content of air would affect the progression of a SFP accident. (0463-3-9 [Leyse, Mark])

Comment: Finally, the NRC is looking at expedited transfer of spent fuel to dry casks. Instead of properly examining expedited transfer of spent fuel to dry casks as an alternative in the DGEIS, the NRC examined expedited fuel transfer to dry casks using other documents such as the Spent Fuel Pool Study, which was finalized after the draft DGEIS was released, is not cited or explicitly referenced in the DGEIS, but somehow already incorporated into the DGEIS and apparently the NRC seeks to reference it in the DGEIS at a later date. See, e.g, NRC, Two Separate NRC Efforts Address Spent Fuel Safety, <http://public-blog.nrc.gov/2013/06/24/two-separate-nrc-efforts-address-spent-fuel-safety/> (June 24, 2013)("The draft GEIS does not explicitly reference the pool study, though the waste confidence staff worked closely with the staff preparing the pool study while developing relevant chapters of

the draft GEIS. If a final version of the study is published before the final waste confidence GEIS, the staff will incorporate a reference to it in the final GEIS." In response to comments New York submitted on the Spent Fuel Pool Study, the NRC was clear that "[t]his research study does not authorize any licensee action or set regulatory requirements. This study also does not establish any Commission policy." Spent Fuel Pool Consequence Study, Response to Comment #72. Yet, Staff has indicated that the DGEIS will incorporate the results of this study. Failure to explicitly reference documents upon which the DGEIS relies violates NEPA and the APA. (0473-11-13 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: NRC's Analysis of Spent Fuel Pool Fires Relies Heavily Upon NUREG-1738 Without Considering NUREG-1738's Limitations. The DGEIS Appendix F explains: "A significant portion of the NRC's analysis for spent fuel pool fires during the short-term storage timeframe is derived from NUREG-1738, "Technical Study of Spent Nuclear Fuel Pool Accident Risk at Decommissioning Nuclear Power Plants (NRC 2001)." DGEIS at F-2. NRC states that this twelve year old, pre-Fukushima study "represents the NRC's current judgment as to the expected impacts from a spent fuel pool fire during the short- term storage timeframe." Id. As explained in the International Safety, Inc. ("ISR") report submitted under separate cover by the New York State Office of the Attorney General ("ISR Report"), NRC's use of NUREG-1738 is flawed for several reasons. First, ISR points out that the DGEIS fails to acknowledge NUREG-1738's assumptions and the stated limitations of a generic approach to spent fuel pool fires. ISR Report at 6-8. Because NUREG-1738 was a study performed in connection with a decommissioning rulemaking, it relied on a series of Industry Decommissioning Commitments and Staff Decommissioning Assumptions, which, if not carried out, could invalidate the analysis. Id. at 7-8. As described in more detail in the ISR Report, these decommissioning assumptions include assumptions regarding the age of the fuel beyond which a spent fuel pool fire can be ruled out (p. 2-1, NUREG-1738); the pool fire frequencies for all initiators (p. 3-7, NUREG-1738); the possibility for air cooling following damage caused by severe weather (p. 3-10, NUREG-1738); the low initiating event frequency for the loss of pool inventory (p. 3- 12, NUREG-1738); the probability of loss of cooling, loss of inventory, and loss of off- site power (p. 3-12, NUREG-1738); and the assumption that leaks are self-limiting. ISR explains how the DGEIS used vague language and largely ignored these specifics in NUREG-1738. With respect to frequency, NUREG-1738 uses the average frequencies for the seismic events (p. 3-9) and acknowledges that site-specific values could be ten times higher or lower (p. 3-7). ISR Report at 15. The DGEIS does not even mention examples of sites with lower or higher seismic frequencies. Again, it fails to use a conservative bounding analysis. A recent statement from Chairman Allison M. Macfarlane supports site-specific review: There's one additional item I'd like to raise with respect to our ongoing post-Fukushima work that may be of particular interest to you. We're reviewing the updated information from our licensees concerning external flooding and seismic events. Logic dictates that with such diverse topography and climate in this country, we must apply different assumptions when considering hazards for plants in California than those we apply for plants in Pennsylvania. Prepared Remarks of NRC Chairman Allison M. Macfarlane, State Liaison Officers Conference, Tuesday, November 5, 2013, Rockville, Maryland. This is another flaw that should be dealt with in a site-specific manner. The DGEIS also uses these average probabilities in Table F-1 (DGEIS at F-4). The total probability of pool drainage from NUREG-1353 (2×10^{-6} events per year) is based on best estimates of the frequency of various event sequences and is dominated by the seismic risk of structural failure (p. 4-36, NUREG-1353). (0473-13-4 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: As the ISR Report explains, the consequence assessment presented in the DGEIS is based on CRAC2 calculations, MACCS calculations, and MACCS2 calculations. The most detailed set of data comes from NUREG-1738 and is based on MACCS2 calculations. The central purpose of the Spent Fuel Pool Consequence Study is to determine if it is cost-beneficial to expedite the transfer of spent fuel from high-density spent fuel pools (reference) to dry storage casks (alternative) by analyzing the probabilities and consequences of severe accidents originating from a spent fuel pool. It likewise relied on MACCS2 calculations to determine the collective dose and various economic costs (i.e., costs associated with decontamination, interdiction and property condemnation). None of these consequence analyses constitutes a conservative bounding analysis. Indeed, they fail to account for the consequences at sites other than the reference site. (0473-13-8 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: In addition, the analysis in COMSECY-13-0300 and its primary technical document, the Consequence Study, suffer from substantial limitations. First the basis for the study of the consequences of a spent fuel accident was a reactor whose characteristics and surrounding demographics are considerably less likely to produce large accident consequences than many other reactors. For example, Indian Point, located only 35 miles north of New York City has an average population density within 50 miles of over 2,000 persons per square mile (Generic Environmental Impact Statement for License Renewal of Nuclear Plants Supplement 38 Regarding Indian Point Nuclear Generating Unit Nos. 2 and 3, NUREG-1437 (December 2010) at 2-124), while the Consequence Study assumed a population density out to 50 miles of only 722 people per square mile (Consequence Study at D-31) and COMSECY-13-0300 at 99-100, Tables 53 and 55 assumed an average population of only 300 persons per square mile, creating that average by using reactor sites with a maximum population density of 722 and ignoring any mention of the Indian Point site. (0473-8-3 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Second, both studies assumed that the event that would initiate the release was an earthquake or other site-specific event like a cask drop where the configuration of the spent fuel pool could affect the consequences of the cask drop. Consequence Study at 9 and COMSECY-13-0300, Cover Memorandum at 7. But not included was the risk of a malevolent act, the probability of which cannot be calculated. (0473-8-4 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: Third, both studies ignored the many unique, site-specific and as-yet-unevaluated problems created by the use of high burnup fuel in reactors. The use of high burnup fuel causes special problems, including a greater chance of accidents and an increased chance of structural failure of the fuel rods such that transfer to dry casks is more difficult, more dangerous, and more expensive. See e.g. NUREG-1738 at ix, 3-1. (0473-8-5 [Dean, Janice] [Griffin, William] [Mahowald, Philip R.] [Snook, Robert] [Springer, Darren])

Comment: The NRC continues to downplay the risk of storage ponds. If fuel rods are exposed, they can overheat, catch fire, and release massive quantities of radioactive material. The NRC continues to consider the environmental impact of these pools "low", even over the course of "indefinite" time periods, over which an accident is all but inevitable. (0531-2-19 [Morgan, Sally])

Comment: Pools are not protected by redundant emergency makeup and cooling systems[.] (0531-2-21 [Morgan, Sally])

Comment: The risk and consequences of a collapse of a spent fuel pool was explicitly ignored in the GEIS. No attempt was made to incorporate this type of possible accident into the risk assessment for spent fuel pool fires. The current, ongoing situation at Fukushima Dai-ichi unit #4 tells us that this particular hypothetical scenario is a very real possibility. (0552-2-17 [Macks, Vic])

Comment: The 2013 GEIS references a seriously out-dated spent fuel pool study: "Regulatory Analysis for the Resolution of Generic Issue 82, 'Beyond Design Basis Accidents in Spent Fuel Pools'" (NRC 1989). The information in this report is at least 24 years old. A new regulatory analysis should be done, with the inclusion of the experience from Fukushima, and should include a risk analysis of spent fuel pools containing irradiated MOX (mixed oxide) fuel rods. (0552-2-18 [Macks, Vic])

Comment: As of 2012, spent fuel pools are overcrowded, packed beyond their originally engineered capacity by as much as 9 times. (Union of Concerned Scientists), (Lochbaum). Lochbaum, David, Director, Nuclear Safety Project, testimony Before the Senate Committee on Energy and Natural Resources, July 20, 2013.
http://www.energy.senate.gov/public/index.cfm/files/serve?File_id=89dbc888-171c-4f77-8ecf-83a0055fcfb9 (0552-2-2 [Macks, Vic])

Comment: The Draft Consequence Study lacks scientific integrity because it examines only complete drainage of a pool and ignores the more severe case of partial drainage. Based on the canard that complete drainage is the worst case, the NRC ignored spent fuel pool accident risks for decades. Then in 2001, in NUREG-1738, the NRC admitted that the most severe accident risk is posed by prolonged disruption of air or water circulation over the spent fuel assemblies. The point was confirmed by a panel of the National Academy of Science in 2004. By reverting to the discredited assumption that complete pool drainage is the worst case, the NRC fatally undermines the integrity and credibility of the Study. (Curran), (NAS). Curran, Diane. "Mothers for Peace Attorney Diane Curran urges public participation in Sept. 18 NRC meeting", San Luis Obispo Mothers for Peace, <http://mothersforpeace.org/data/mothers-for-peace-attorney-diane-curran-urges-public-participation-in-sept.-18-nrc-meeting>. National Academy of Sciences (NAS), "Safety and Security of Commercial Spent Nuclear Fuel Storage: Public Report" (2006). http://www.nap.edu/download.php?record_id=11263. (0552-2-20 [Macks, Vic])

Comment: The Study is too narrow because it significantly underestimates risk by considering only one type of initiating event--an earthquake--and ignoring other credible initiating events that are at least as probable. For instance, the Study ignores the impacts of aging and the potential for an attack on a pool and/or adjacent reactor to initiate a pool fire. Vulnerability of spent fuel storage pools to terrorist attack is perhaps the greatest risk of all. Further, the Study does not analyze the potential for a core melt accident to cause or contribute to a pool fire. For instance, radiation released during a core melt accident could preclude access to the pool to supply emergency cooling. (Curran). Curran, Diane. "Mothers for Peace Attorney Diane Curran urges public participation in Sept. 18 NRC meeting", San Luis Obispo Mothers for Peace, <http://mothersforpeace.org/data/mothers-for-peace-attorney-diane-curran-urges-public-participation-in-sept.-18-nrc-meeting> (0552-2-21 [Macks, Vic])

Comment: The Study is misleading and biased because it only pretends to consider the relative merits of low-density storage. The Study purports to evaluate whether low-density pool storage of irradiated fuel would be cost-effective and safer than high-density storage. But NRC misleadingly uses the phrase "low-density" to refer to closed high-density racks that contain fewer fuel assemblies, not true low-density fuel storage in open-frame racks. The NRC decided

not to consider true open-rack low-density storage because it was assumed to be too expensive (see page 23). The Draft Consequence Study shows an appalling lack of scientific integrity by including the result of the study as an assumption: the question of whether a return to open-frame low-density storage is justified is the very question the NRC set out to answer in the Study. (Curran).Curran, Diane." Mothers for Peace Attorney Diane Curran urges public participation in Sept. 18 NRC meeting", San Luis Obispo Mothers for Peace, <http://mothersforpeace.org/data/mothers-for-peace-attorney-diane-curran-urges-public-participation-in-sept.-18-nrc-meeting>. (0552-2-22 [Macks, Vic])

Comment: Ignoring real world multiple risk factors. The draft NRC study has been done in a vacuum that excludes the hazards of a concurrent reactor accident that are known to impact the safety of spent fuel pool systems. Dr. Thompson correctly points out, "the physical proximity of spent-fuel pools to operating reactors, and their sharing of safety systems, means that the use of high-density racks creates strong linkages between reactor risk and pool risk." This fact is underscored in a 1990 NRC-sponsored study that points out that a long-term station blackout at the Peach Bottom nuclear station would cause "deflagrations to occur in the reactor building and refueling bay.." This is exactly what occurred at the Fukushima reactors, which caused significant damage to the spent fuel pools. (Thompson, 2013). Thompson, Gordon. Comments on the US Nuclear Regulatory Commission's Draft Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a US Mark I Boiling Water Reactor, August 2013. (0552-2-23 [Macks, Vic])

Comment: Aging and deterioration of Spent Fuel Pool Systems. The NRC staff dismisses this problem by ignoring a 2011 NRC-sponsored study that concludes, "as nuclear plants age, degradations of spent fuel pools (SFPs), reactor refueling cavities...are occurring at an increasing rate, primarily due to environment-related factors. During the last decade, a number of NPPs (nuclear power plants) have experienced water leakage from the SFPs [spent fuel pools] and reactor refueling cavities." Instead the NRC staff points to a study done 25 years ago, before aging effects were being observed. (NRC, 2011). U.S. Nuclear regulatory Commission (NRC), A summary of Aging Effects and Their Management in Reactor Spent Fuel Pools, Refueling Cavities, TORI and Safety-Related Concrete Structures, NUREG/CR-7111 (2011). P. vxiii.<http://pbadupws.nrc.gov/docs/ML1204/ML12047A184.pdf>. (0552-2-24 [Macks, Vic])

Comment: Failure to meet the NRC's Technical Safety Information Standard for Final Safety Analysis Reports (10 CFR 52.157). The draft study does not comport with the NRC's own technical information safety analysis standard for reactor operators. According to this regulation, safety analyses must incorporate all key reactor station components including the reactor operations and spent fuel handling and storage functions. (0552-2-25 [Macks, Vic])

Comment: Failure to compare the risks of high density versus open rack configurations: The draft study examines a reduction of spent fuel assemblies while allowing racking configurations that allow for high density storage to remain. Specifically, the study does not address the removal of neutron-absorbing panels that allow for closer spacing. It's been noted in a previous study that these panels can interfere with air convection during a pool drainage event and thus can enhance the heat-up of the nuclear fuel. In effect, they could become de facto "thermos bottles." Open rack storage would allow for free convection cooling and thus reduce the risk of ignition. (Alvarez). Robert Alvarez, Jan Beyea, Klaus Janberg, Jungmin Kang, Ed Lyman, Allison Macfarlane, Gordon Thompson, and Frank N. von Hippel, Reducing the Hazards from Stored Spent Power-Reactor Fuel in the United States, Science and Global Security, 11:1-51, 2003. (0552-2-26 [Macks, Vic])

Comment: Water loss in the spent fuel pool could lead to a catastrophic spent fuel pool fire. "Water could be lost from a spent-fuel pool through leakage, boiling, siphoning, pumping, displacement by objects falling into the pool, or overturning of the pool. These modes of water loss could arise from events, alone or in combination, that include: (i) acts of malice by persons within or outside the plant boundary; (ii) an accidental aircraft impact; (iii) an earthquake; (iv) dropping of a fuel cask; (v) accidental fires or explosions; and (vi) a severe accident at an adjacent reactor that, through the spread of radioactive material and other influences, precludes the ongoing provision of cooling and/or water makeup to the pool."(Thompson). Thompson, Gordon. Comments on the US Nuclear Regulatory Commission's Draft Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a US Mark I Boiling Water Reactor, August 2013. (0552-2-3 [Macks, Vic])

Comment: NRC also downplays the risks of pool fires by assuming that a pool drain down accident (or attack) involves the complete drain down of the pool. As Dr. Gordon Thompson of the Institute for Resource and Security Studies (IRSS) has pointed out, any technically competent person paying attention to the issue should have known since 1979 that a partial drain down of the pool is actually a worse-case scenario, for the leftover water in the bottom of the pool would block convection current air flow which would help cool the irradiated nuclear fuel, leading to faster heat up to the ignition point. (0552-2-30 [Macks, Vic])

Comment: The evaluation of the spent fuel pool fire risk in the GEIS relies on the spent fuel pools having only 3.5 spent fuel cores. Currently, spent fuel pools contain as many as 9 cores. (Lochbaum). The NRC estimates the spent fuel pool capacity for some reactors to be as high as 16.7 cores. (DGEIS G4). The ACTUAL over-loading of the fuel pools renders the probabilistic risk assessment invalid. Lochbaum, David, Director, Nuclear Safety Project, testimony Before the Senate Committee on Energy and Natural Resources, July 20, 2013.http://www.energy.senate.gov/public/index.cfm/files/serve?File_id=89dbc888-171c-4f77-8ecf-83a0055fcfb9 (0552-2-31 [Macks, Vic])

Comment: NRC downplays the risks of pool fires by assuming that surrounding populations will be successfully evacuated. But nuclear utilities are allowed to store high level radioactive withdrawn fuel rods in pools for decades after reactors permanently shutdown, in order to defer the costs of dry cask storage as far off into the future as possible, despite the inherent risks. At the same time, NRC allows utilities, via exemptions from regulations, to do away with 10-mile radius emergency planning zones (EPZs) as soon as 12-18 months post-reactor shutdown despite the lingering risk of storing high level nuclear waste in pools at such shutdown reactor sites. How can populations be evacuated if EPZs have been dismantled?! (0552-2-4 [Macks, Vic])

Comment: Spent fuel is highly flammable as well as radioactive, yet is primarily stored in densely packed pools of water that contain several times more fuel than the nuclear reactor itself. If a fuel pool is damaged or loses its cooling system, fuel rods could be exposed, overheat, and catch fire, releasing massive quantities of radioactive material. NRC refuses to address the incredible risks these facilities pose, pretending the low likelihood of an accident makes the extreme consequences irrelevant. (0552-2-6 [Macks, Vic])

Comment: 75% of the total (72,000 metric tons, plus 2,000 tons more per year) of spent fuel is in fuel pools and allowed to remain there for as much as 60 years beyond licensed life of reactor operations. The GEIS underestimates the risk of fuel pool fires and ignores the safer alternative of hardened on site storage at the nuclear plant sites. (0552-2-8 [Macks, Vic])

Comment: Also, the NRC has "classified" studies that are not available to the GAO, the National Academy of Sciences or the public!!! Why?? What is it that the NRC knows that they refuse to tell us?? How can the NRC move forward with this GEIS without resolving those issues? Why is it that the NRC does not have access to its own data base of past studies? How is it that the NRC could not/did not make available to the GAO that data base of past studies? How can the NRC function in the public interest without access to its own archive of studies? (0552-3-5 [Macks, Vic])

Comment: Environmental consequences vary considerably depending on the reactors proximity to high- population centers. Pilgrim and Indian Point are classic examples, with huge consequences of a spent fuel pool fire. The Massachusetts Attorney General in 2006 found Pilgrim's densely packed pool vulnerable and estimated that a spent fuel pool fire at Pilgrim would cost up to \$488 billion dollars, result in 24,000 latent cancers, and could contaminate hundreds of miles downwind⁴. [footnote 4 text: The Massachusetts Attorney General's Request for a Hearing and Petition for Leave to Intervene With respect to Entergy Nuclear Operations Inc.'s Application for Renewal of the Pilgrim Nuclear Power Plants Operating License and Petition for Backfit Order Requiring New Design features to Protect Against Spent Fuel Pool Accidents, Docket No. 50-293, May 26, 2006 includes a Report to The Massachusetts Attorney General On The Potential Consequences Of A Spent Fuel Pool Fire At The Pilgrim Or Vermont Yankee Nuclear Plant, Jan Beyea, PhD., May 25, 2006] Boston, Providence, smaller cities, and densely populated suburbs are within 50 miles. (0556-1-23 [Lampert, Mary])

Comment: Further, in estimating environmental impact, it cannot be limited to 50 miles as the DGIS did in its analysis.⁵ [footnote 5 text: National Academy of Sciences Safety and Security of Commercial Spent Nuclear Fuel Storage Public Report, National Academy of Sciences, April 2005, <http://www.nap.edu/books/0309096472/html/> said, Such (zirconium cladding) fires would create thermal plumes that could potentially transport radioactive aerosols hundreds of miles downwind under appropriate atmospheric conditions." (NAS, p. 50)] This points out yet another serious methodological weakness of the DGEIS and -- by extension -- the proposed rule. (0556-1-24 [Lampert, Mary])

Comment: NRC's analysis referenced and relied upon previous studies/reports that were outdated. They did not incorporate lessons learned from Fukushima and used outdated consequence codes to estimate environmental impacts of severe accidents. (0556-2-15 [Lampert, Mary])

Comment: NRC and the industry assume that the only radioactive release that needs to be considered is an atmospheric (forget about aqueous) release from the core (forget about the spent fuel pool), and even then only noble gasses and a small fraction of the Cs-137 in a core need be taken into consideration. (0556-2-18 [Lampert, Mary])

Comment: Similarly, there is no rational basis for the NRC DGEIS and referenced studies to assume that a radioactive release will only affect a very limited geographic area defined by an outdated straight-line Gaussian plume; and only out to 50 miles. (0556-2-19 [Lampert, Mary])

Comment: Clean-up and Decontamination is an enormously expensive job, extending over decades. Hosing down buildings and plowing fields under does not clean up or decontaminate. The NRC cannot rely on reports that continue to ignore: that there is no clean-up standard; that clean-up can take more than one year; that it has given no consideration to what can and must be done to the tons of contaminated soils and other wastes; that clean-up after a nuclear explosion is not comparable to clean-up after a nuclear reactor accident; and that forests, wetlands and water simply cannot be cleaned and will re-contaminate areas. (0556-2-20 [Lampert, Mary])

Comment: Also NRC adapted the MELCOR code, version 1.8.6, to examine the physical and chemical phenomena directly associated with a pool fire. (Section 6 NRC's Draft Consequence Study) Dr. Thompson²³ [footnote 23 text: Comments of the US NRC's Draft Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a US Mark I Boiling Water Reactor, by Dr. Gordon Thompson, submitted to the NRC's Cindy Bladey, Chief of Rules, Announcements, and Directives Branch, Office of Administration August 1, 2013, by Diane Curran (of Harmon, Curran, Spielberg & Eisenberg LLP).] at 20 explains that, "1. MELCOR has no capability to model the deformation of fuel cladding as temperature rises. Yet, NUREG-1738 predicted that cladding would balloon and burst in a temperature range of 700-850°C. That outcome could reduce heat transfer and promote ignition of cladding. NRC says that these effects would not be significant, but rests that claim on secret, unpublished studies.⁴⁵ [quoted footnote not included in comment] 2. Radioactive heat transfer is an important consideration in pool-fire modeling. Yet MELCOR employs a simplified approach to modeling this mode of heat transfer." In this context, NRC says:⁴⁶ [quoted footnote not included in comment] "It should be noted that there is a temperature gradient within each ring, and MELCOR attempts to model a multidimensional geometry with a simplified two-surface radiation model." Dr. Thompson also questions NRC's input assumptions. (Thompson, pp. 20-23) For example, how closely does the pool layout assumed by NRC correspond with actual practice in the nuclear industry? (0556-2-23 [Lampert, Mary])

Comment: The second document supporting the DGEIS and the Proposed Waste Confidence Rule is the US Nuclear Regulatory Commission's *Draft Consequence Study of a Beyond-Design-Basis Earthquake Affecting the Spent Fuel Pool for a US Mark I Boiling Water Reactor* (herein after "Earthquake Study"). Although the Proposed Rule explains that the Earthquake Study is not referenced in the DGEIS, it is for all practical purposes basic to the rule. In fact it was developed side-by-side to justify the DGEIS' and Proposed Rule's conclusions. The proposed Rule admits that "the staff is aware of the conclusions in the draft Study and worked closely with the authors who developed the draft Study to prepare the relevant sections of the draft GEIS": The DGEIS does not specifically reference the draft "Consequence Study Of A Beyond Design-Basis Earthquake Affecting The Spent Fuel Pool For A U.S. Mark Boiling Water Reacto"...If the NRC publishes a final study before the final GEIS is published, it will be added to the final GEIS. Although it did not specifically reference the draft Study in the DGEIS, the staff is aware of the conclusions in the draft Study and worked closely with the authors who developed the draft Study to prepare the relevant sections of the draft GEIS. The conclusions of the draft Study do not contradict the conclusions in the DGEIS and are consistent with the consequences reported in previous studies on spent fuel pool accidents. (Draft Rule, p. 56783, emphasis added). Therefore it is important to understand that the draft Earthquake Study is not a credible scientific document to provide any basis for the DGEIS's and Proposed Rule's conclusions. While the study purports to be a broad scientific inquiry into pool fire phenomena, instead it is a very narrow study that ignores basic pool fire phenomena, important pool fire accident contributors, and avoids evaluation of all mitigation strategies. Statements in the so-called Earthquake Study are unsupported by analysis. It says that a severe earthquake causing complete draining of a fuel pool is the primary source of risk to a spent fuel pool, assumes that the risk of pool fire is low and assumes that open-rack low-density pool storage is not any safer without even studying it. (0556-4-1 [Lampert, Mary])

Comment: The cost benefit analysis in the earthquake study was done prematurely because: (a) The analysis was done using pre-Fukushima MELCOR code prior to updating it based on Fukushima; (b) The National Academy has been called in by the U.S. Congress to determine the adequacy of NRC's safety regulation in light of the ongoing Fukushima nuclear disaster, with a specific emphasis on the advisability of current spent nuclear fuel pool practices at U.S. power

reactors. It seems to me that members of Congress should halt the NRC's fast moving train, relative to its continuing approval of high-density SNF pool storage, until the Academy finishes its quality assurance review. (0556-4-10 [Lampert, Mary])

Comment: NRC REFERENCED STUDIES: NRC referenced studies for spent fuel pool fires (Appendix F) in the DGEIS fail to include readily available assessments by independent experts, including studies authored by the Chairman of the NRC Allison Macfarlane; but instead NRC relied on outdated and inadequate studies performed by the NRC or its government contractor Brookhaven. The faults and defects of the selected documents relied upon by NRC are analyzed in full by Dr. Gordon R. Thompson in *Environmental Impacts of Storing Spent Nuclear Fuel And High-Level Waste From Commercial Nuclear Reactors: A Critique of NRC's Waste Confidence Decision And Environmental Impact Determination*, February 6, 2009 (pages 19-21 and 22-26); and in his *Comments on the US Nuclear Regulatory Commission's Draft Consequence Study of a BeyondDesign- Basis Earthquake Affecting the Spent Fuel Pool for a U.S. Mark I BWR*, August 1, 2013 (Section 3, A Brief History of Pool Fire Analysis). Perhaps, NRC also relied on other studies of spent fuel fire risk not referenced. It is possible that NRC managed to find secret studies of spent fuel fire risk that they could not find for GAO when asked to produce them. The August 2012 GAO Report said, "NRC could not easily identify, locate or access...because it does not have an agency-wide mechanism to ensure that it can identify and locate such classified studies³²." [footnote 32 text: GAO-12-797, Spent Nuclear Fuel; Accumulating Quantities at Commercial Reactors Present Storage and Challenges, August 2012, highlights] (0556-4-11 [Lampert, Mary])

Comment: Highlights -- What's Wrong with the Earthquake Study? 1. Pretence of considering low-density storage: The Study does not consider the risk implications of reverting to low-density, open-frame racks. Its authors did not model scenarios that compared the current high-density closed frame design to the safer low-density, open frame design. They compared only a full pool to one with total water loss. They studied only water loss, not geometry--closed or open frame. The reason, NRC explains, is that replacing storage racks would be expensive. NRC's mandated role is to protect public health and safety, not industry's finances. 2. Limited consideration of water-loss scenarios: The Study focuses its analysis only on water-loss scenarios that involve total drainage. By so doing, the Study ignores a substantial part of the pool-fire risk. For example, the Study makes no effort to determine how the presence of residual water could affect fuel ignition, despite the fact that NUREG 1738 (October 2000) reversed NRC's position that total drainage was most severe. Consideration of partial water loss would substantially increase the estimated risk. There have been several accidents due to other causes where spent fuel pools experienced a partial drain-down. In 1984, a ruptured refueling cavity seal drained 200,000 gallons at the Connecticut Yankee nuclear plant. In 1986 an inflatable seal at the Hatch plant in Georgia failed, causing 140,000 gallons to drain from its spent fuel pool. BWR pools typically hold about 400,000 gallons of water. 3. Limited consideration of initiating events: The Study considers only one type of initiating event--an earthquake. That narrow focus reflects a pre-determined conclusion that earthquake is the dominant contributor to the risk of a pool fire. (0556-4-2 [Lampert, Mary])

Comment: No analysis of risk linkages among pools and reactors: The Study identifies the potential for risk linkages, but does not properly analyze them. For example, the Study does not analyze a situation in which onsite radioactive contamination and other impacts of a reactor core melt would preclude mitigating actions that might prevent a pool fire. Yet, the probability of a core melt at an adjacent reactor is at least equal to the probability of the severe earthquake that the Study does consider. Thus, the Study significantly under-estimates pool-fire risks. (0556-4-4 [Lampert, Mary])

Comment: No Analysis of Cask Drops: Goutam Bagchi, NRR, in a February 12, 2001 08:25 AM email to Diane Jackson and George Hubbard, NRR, regarding the SFP Study: Structural and Seismic questions said: [TEXT BOX HERE ON CASK DROP EFFECT and CASK DROPS INSIDE THE POOL] [Text Box Image Submitted with Correspondence ML13354A021] (0556-4-5 [Lampert, Mary])

Comment: Misleading statements regarding mitigating actions: The feasibility and effectiveness of mitigation, such as the ability to provide make-up water to the pool. But the Study only considers "human reliability" and equates human error problems to mitigation failure. The Study acknowledges its limitation for considering only one variable. It ignores, for example, analyzing the effectiveness of spray systems and answering whether in fact they are installed and have been tested in all reactor pool and ignores the possibility that radiation fields and other onsite impacts of a reactor core melt could preclude mitigation for an extended period. Despite limiting mitigation to human reliability, the Study makes unsupported unequivocal statements about the feasibility of mitigation that reflects pre-determined conclusions. 8. Duration: NRC claims that the probability of a spent fuel pool problem causing water loss that could go longer than 7 days is negligible, indicating that lessons were not learned from Fukushima. There, radiation levels precluded personnel from full access to the site for a long period of time, and the full consequences remain un-mitigated. (0556-4-6 [Lampert, Mary])

Comment: NRC uses the MELCOR code to model phenomena related to a pool fire - including heat transfer, cladding ignition, and fire dynamics. Yet, the validity of MELCOR for this type of analysis, and the appropriateness of NRC's input assumptions, has not been tested. For example, independent analysts point to MELCOR's simplified treatment of radioactive heat transfer. (0556-4-7 [Lampert, Mary])

Comment: NRC incorrectly finds the probability of a pool fire to be so low that it concludes such an event is "inconsequential." However, because the consequences are so huge, irrespective of the odds of a fire any risk is unacceptable. (0556-5-12 [Lampert, Mary])
