1.0 INTRODUCTION

This report provides the background water quality characterization for the Fernald Environmental Management Project (FEMP), located in southwestern Ohio approximately 18 miles northwest of Cincinnati. This characterization includes an evaluation of groundwater quality in the regionally extensive Great Miami Aquifer and the local perched groundwater, as well as surface water quality in the adjacent Great Miami River and Paddys Run. This characterization is required for the remedial investigations (RIs) and feasibility studies (FSs) currently being conducted at the FEMP.

1.1 BRIEF HISTORY OF THE SITE

The Feed Material Production Center was a contractor-operated federal facility where pure uranium materials were produced for the U.S. Department of Energy (DOE) between 1951 and 1989. The site is located on 1050 acres in a rural area of Hamilton and Butler counties (Figure 1-1). Production of pure uranium metal at the facility was suspended in July 1989. In February 1991, the DOE announced its intention to formally end production and submitted a closure plan to Congress, which became effective in June 1991. In August 1991, the site was renamed the Fernald Environmental Management Project in accordance with the new environmental cleanup and restoration mission.

On March 9, 1985, the U.S. Environmental Protection Agency (EPA) issued a Notice of Noncompliance to the DOE identifying EPA's major concerns over potential environmental impacts associated with the FEMP's past and ongoing operations. On July 18, 1986, a Federal Facility Compliance Agreement (FFCA) pertaining to environmental impacts associated with the FEMP was signed by the DOE and EPA. The FFCA was entered into, pursuant to Executive Order 12088 (43 FR 47707), to ensure compliance with existing environmental statutes and to implement regulations such as the Clean Air Act, the Resource Conservation and Recovery Act (RCRA), and the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA).

Consistent with the requirements of Section 120 of CERCLA, a Consent Agreement was signed by the DOE and EPA in April 1990 and became effective June 29, 1990. This 1990 Consent Agreement amended the CERCLA portion of the 1986 FFCA. The 1990 Consent Agreement defined five "operable units" at the FEMP and surrounding area. The site was divided into operable units to more effectively manage the ongoing CERCLA investigations. These operable units are as follows:

- Operable Unit 1 - Waste Pit Area
- Operable Unit 2 - Other Waste Units
- Operable Unit 3 - Former Production Area
- Operable Unit 4 - Silos 1-4
- Operable Unit 5 - Environmental Media

5644

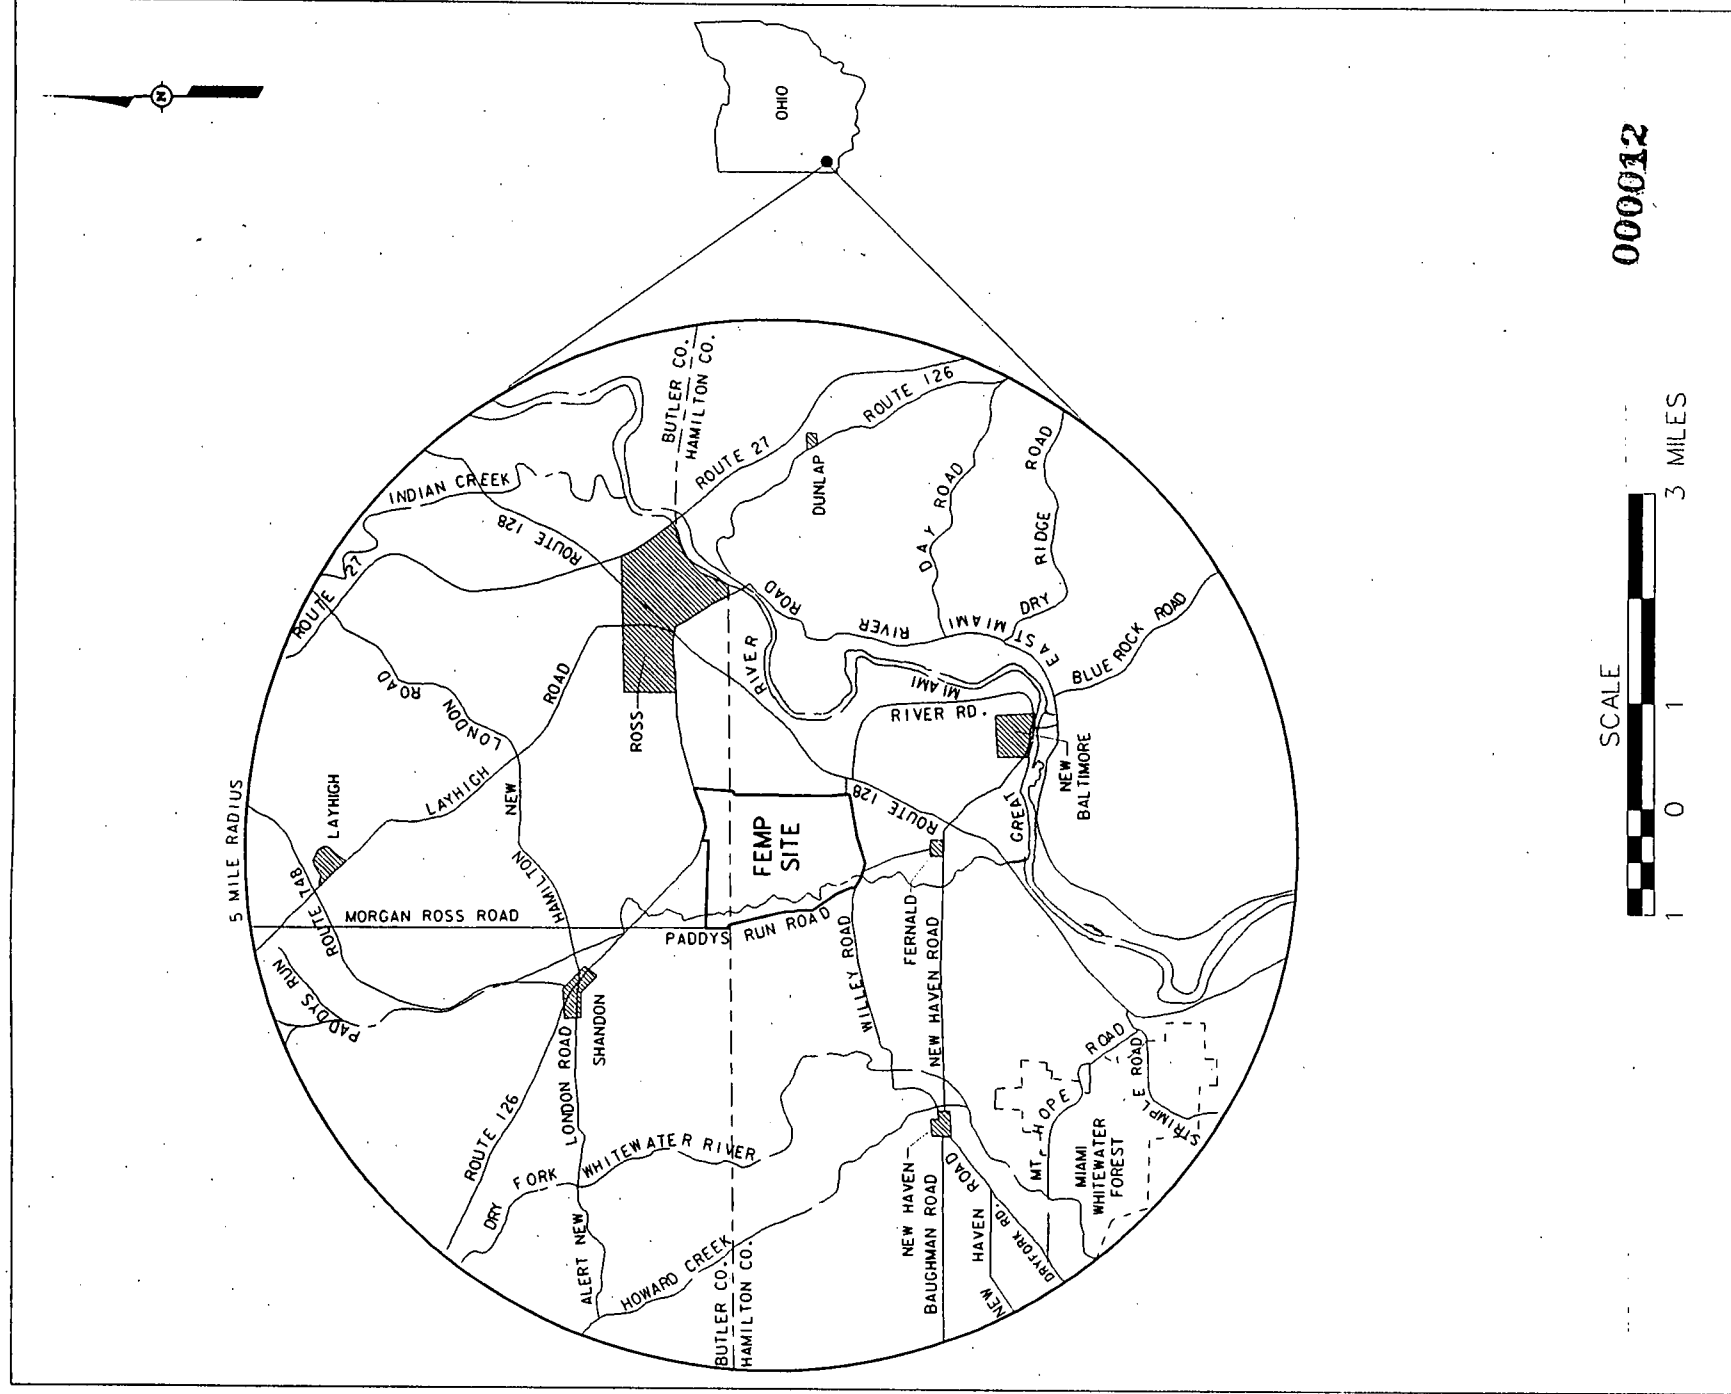

FIGURE 1-1. FEMP SITE LOCATION MAP

In general, the operable units address specific areas or facilities at the site and were defined by their location or the potential for similar technologies to be used in the ultimate cleanup. In September 1991, an Amended Consent Agreement was signed by the DOE and EPA. This Amended Consent Agreement established new schedules for completion of the ongoing RI/FS, identified 14 removal actions to abate immediate threats to the environment, and established a site-wide operable unit encompassing Operable Units 1 through 5 to ensure that actions taken under the individual operable units are protective to human health and the environment.

The 1986 FFCA between the DOE and EPA also stipulated that the site would comply with RCRA regulations and requirements. The DOE entered into a Consent Decree with the State of Ohio on December 2, 1988, which outlined specific actions necessary to attain compliance with RCRA and the Clean Water Act. This Consent Decree included the characterization and proper management of hazardous waste, groundwater monitoring of RCRA-regulated units, and the control of wastewater and surface water runoff. In 1990, negotiations between the State of Ohio and DOE resulted in an Amended Consent Decree, which was finalized and signed in January 1993. The 1993 Amended Consent Decree outlines many requirements for managing RCRA facilities at the FEMP. The RCRA groundwater monitoring requirements are outlined in the Director's Final Findings and Orders issued by the Ohio Environmental Protection Agency (OEPA) in September 1993.

1.2 PURPOSE

The purpose of this report is to gather and statistically evaluate data on background surface water and groundwater quality near the FEMP facility. The data used for this statistical evaluation are derived from RI/FS samples collected through December 31, 1993. This evaluation is intended to satisfy the requirements of the ongoing CERCLA RI/FS investigations and to provide supporting information for the RCRA groundwater monitoring program.

Background surface water and groundwater quality must be established for three principal reasons:

- To differentiate between naturally occurring concentrations of constituents and contaminant levels attributed to site sources
- To identify potential chemicals of concern for the risk assessment process
- To comply with RCRA monitoring requirements

In order to evaluate the potential impacts of the FEMP on water quality, it is necessary to determine the natural characteristics of all surface water bodies and groundwater zones that could potentially be affected. At the FEMP, surface water includes the Great Miami River, which flows along the eastern and southern boundaries of the site, and one of its tributaries, Paddys Run, an on-property stream which receives surface runoff and glacial overburden seepage from the FEMP. Groundwater occurs

locally as perched water in the glacial overburden under the FEMP and regionally in the underlying Great Miami Aquifer. The interrelationship of these water bodies is discussed in Section 1.4.

1.3 GEOLOGIC SETTING

The bedrock in the FEMP area is flat-lying, calcareous shale and thin-bedded limestone of Late Ordovician age (approximately 450 million years ago). During the mid-Pleistocene Epoch (125,000 to 450,000 years ago), continental glaciers advanced as far south as the FEMP area. Concurrent with the advances of the continental ice sheets, the sea level fell approximately 300 feet as an increasing amount of water was stored in the ice sheets. The combined effect of melting ice fronts and lowered sea level produced deep erosional valleys in the Ordovician bedrock in southwestern Ohio.

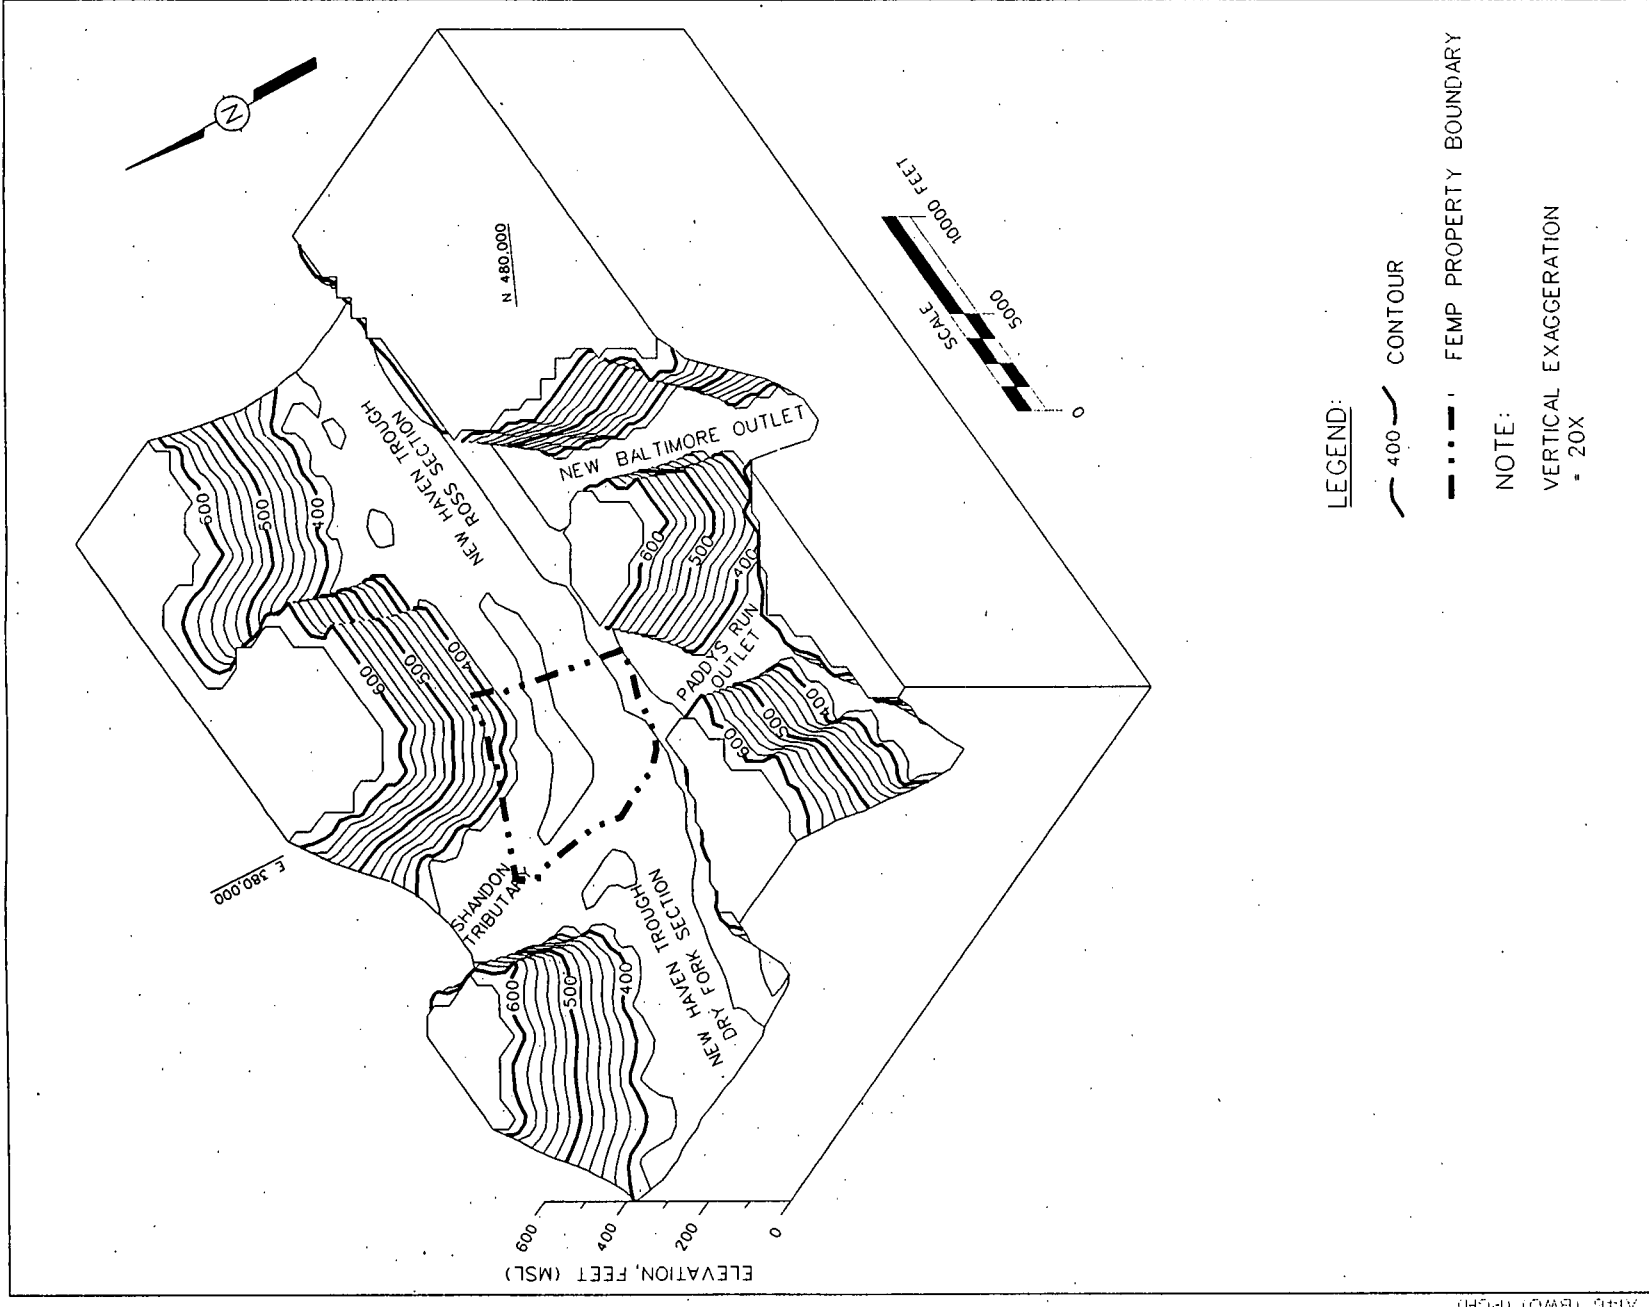

Figure 1-2 shows the depth of the valleys carved in the Ordovician bedrock before they were filled.

As the continental glaciers retreated and sea level rose, these deep erosional valleys were partially filled with well-graded sand and gravel outwash deposits. Many of the deep valleys that were carved during the Pleistocene are presently occupied with surface streams, such as the Ohio River and the Great Miami River. These rivers recharge the outwash deposits creating aquifers which contain large quantities of water. This network of partially filled valleys comprises the principal water supply aquifer system in southwestern Ohio. Generally, groundwater is not found in usable quantities in the Ordovician bedrock.

The FEMP is located over a portion of a Pleistocene valley that does not have a present-day surface stream. This valley segment extends from the Great Miami River Valley south of Ross westward toward Harrison, Ohio, and is called the New Haven Trough (Figures 1-2 and 1-3). During the last stage of continental glaciation (approximately 11,000 to 70,000 years ago), a small lobe of the Wisconsin ice sheet pushed across the New Haven Trough down what is now the valley occupied by Paddys Run. As the ice advanced, it deposited a layer of clay-rich till. As the ice retreated, fluvial, lacustrine, and loess deposits were deposited on top of the till. Collectively, this younger till and sediments are referred to as glacial overburden.

The glacial overburden deposits in the FEMP area have a thickness that ranges up to 50 feet; however, the thickness is usually between 20 and 30 feet. The glacial overburden has been removed where the Great Miami River, Paddys Run, and the Storm Sewer Outfall Ditch (SSOD) have stripped off the glacial overburden as they carved their present channels. The regionally extensive valley sand and gravel fill deposits that make up the Great Miami Aquifer are referred to as glacial outwash.

Figure 1-3 is a schematic cross section showing the relative distribution of geologic materials beneath the FEMP. Relatively impermeable Ordovician bedrock comprises the valley floor and walls. Glacial outwash deposits fill the valley forming the Great Miami Aquifer. Within the glacial outwash

under the FEMP, there is a low-permeability clay interbed ranging from 5 to 20 feet thick that divides the aquifer into upper and lower portions, with approximately the upper 20 feet being unsaturated.

1.4 HYDROLOGIC SETTING

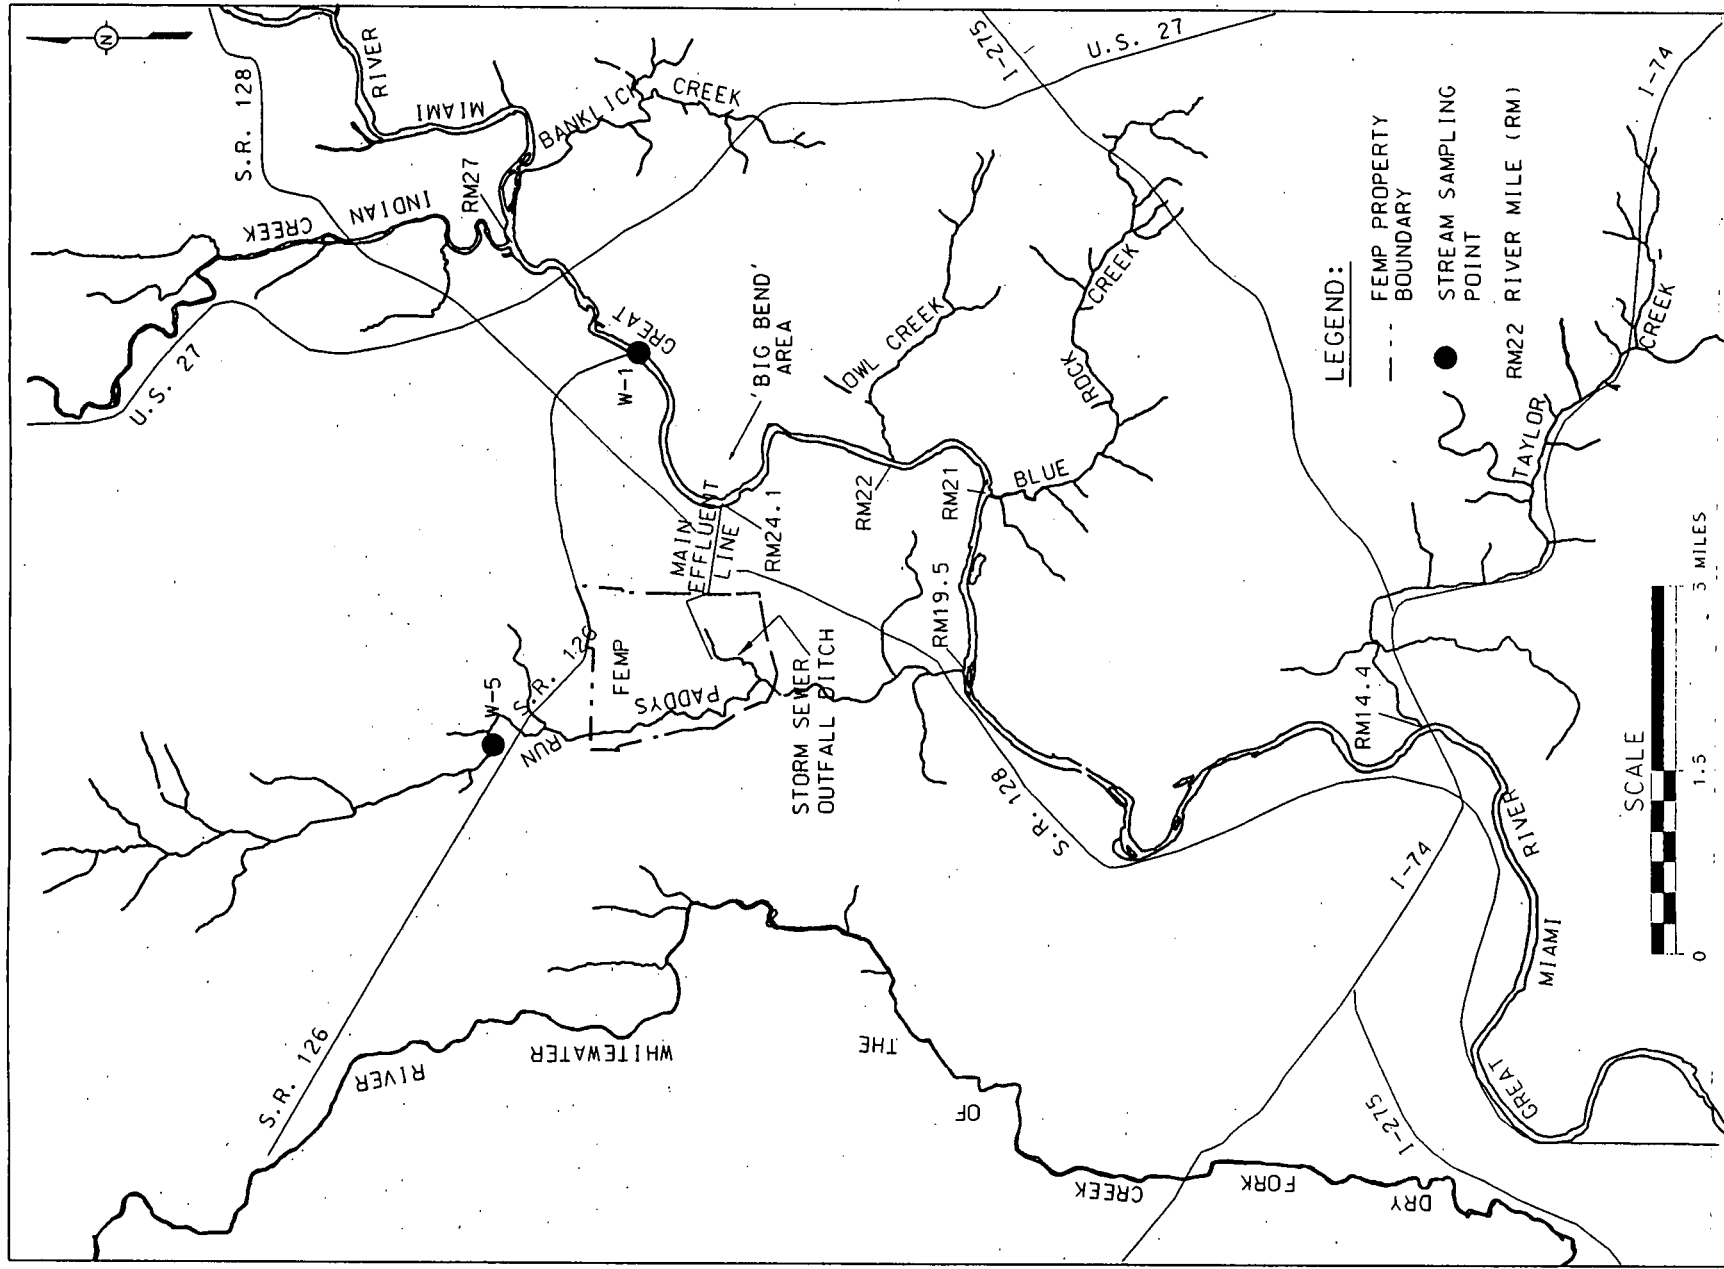

The Great Miami Aquifer is composed of several deep Pleistocene valleys filled or partially filled with outwash sands and gravel that are primarily recharged by the Great Miami River and its tributaries. In the FEMP area, these tributaries include the Dry Fork of the Whitewater River and Paddys Run (Figure 1-4). The New Haven Trough is the section of the Great Miami Aquifer that is of primary interest to the FEMP. The New Haven Trough is filled with 120 to 200 feet of sand and gravel. The glacial outwash deposits receive recharge in the FEMP area from a deep valley tributary on the north called the Shandon Tributary, as well as from the Dry Fork Section on the west (Figure 1-2).

The Dry Fork of the Whitewater River is a surface stream that flows perpendicular to the axis of the New Haven Trough and provides recharge to the Great Miami Aquifer west of the FEMP throughout most years. Paddys Run is a smaller, intermittent stream that flows from north to south along the western portion of the FEMP and recharges the aquifer during the winter and early spring. The general groundwater flow direction within the New Haven Trough from the Dry Fork of the Whitewater River is to the east toward the FEMP and on to the Great Miami River.

Individual water-supply wells in the Great Miami Aquifer are capable of yielding 1000 to 3000 gallons per minute (gpm). Since the outwash deposits are virtually the only usable aquifer in the region, they have been highly developed as a source of industrial and drinking water supply. Overlying the Great Miami Aquifer are glacial overburden deposits which contain perched groundwater. Perched water in the glacial overburden occurs at a depth of approximately 3 to 14 feet below the land surface.

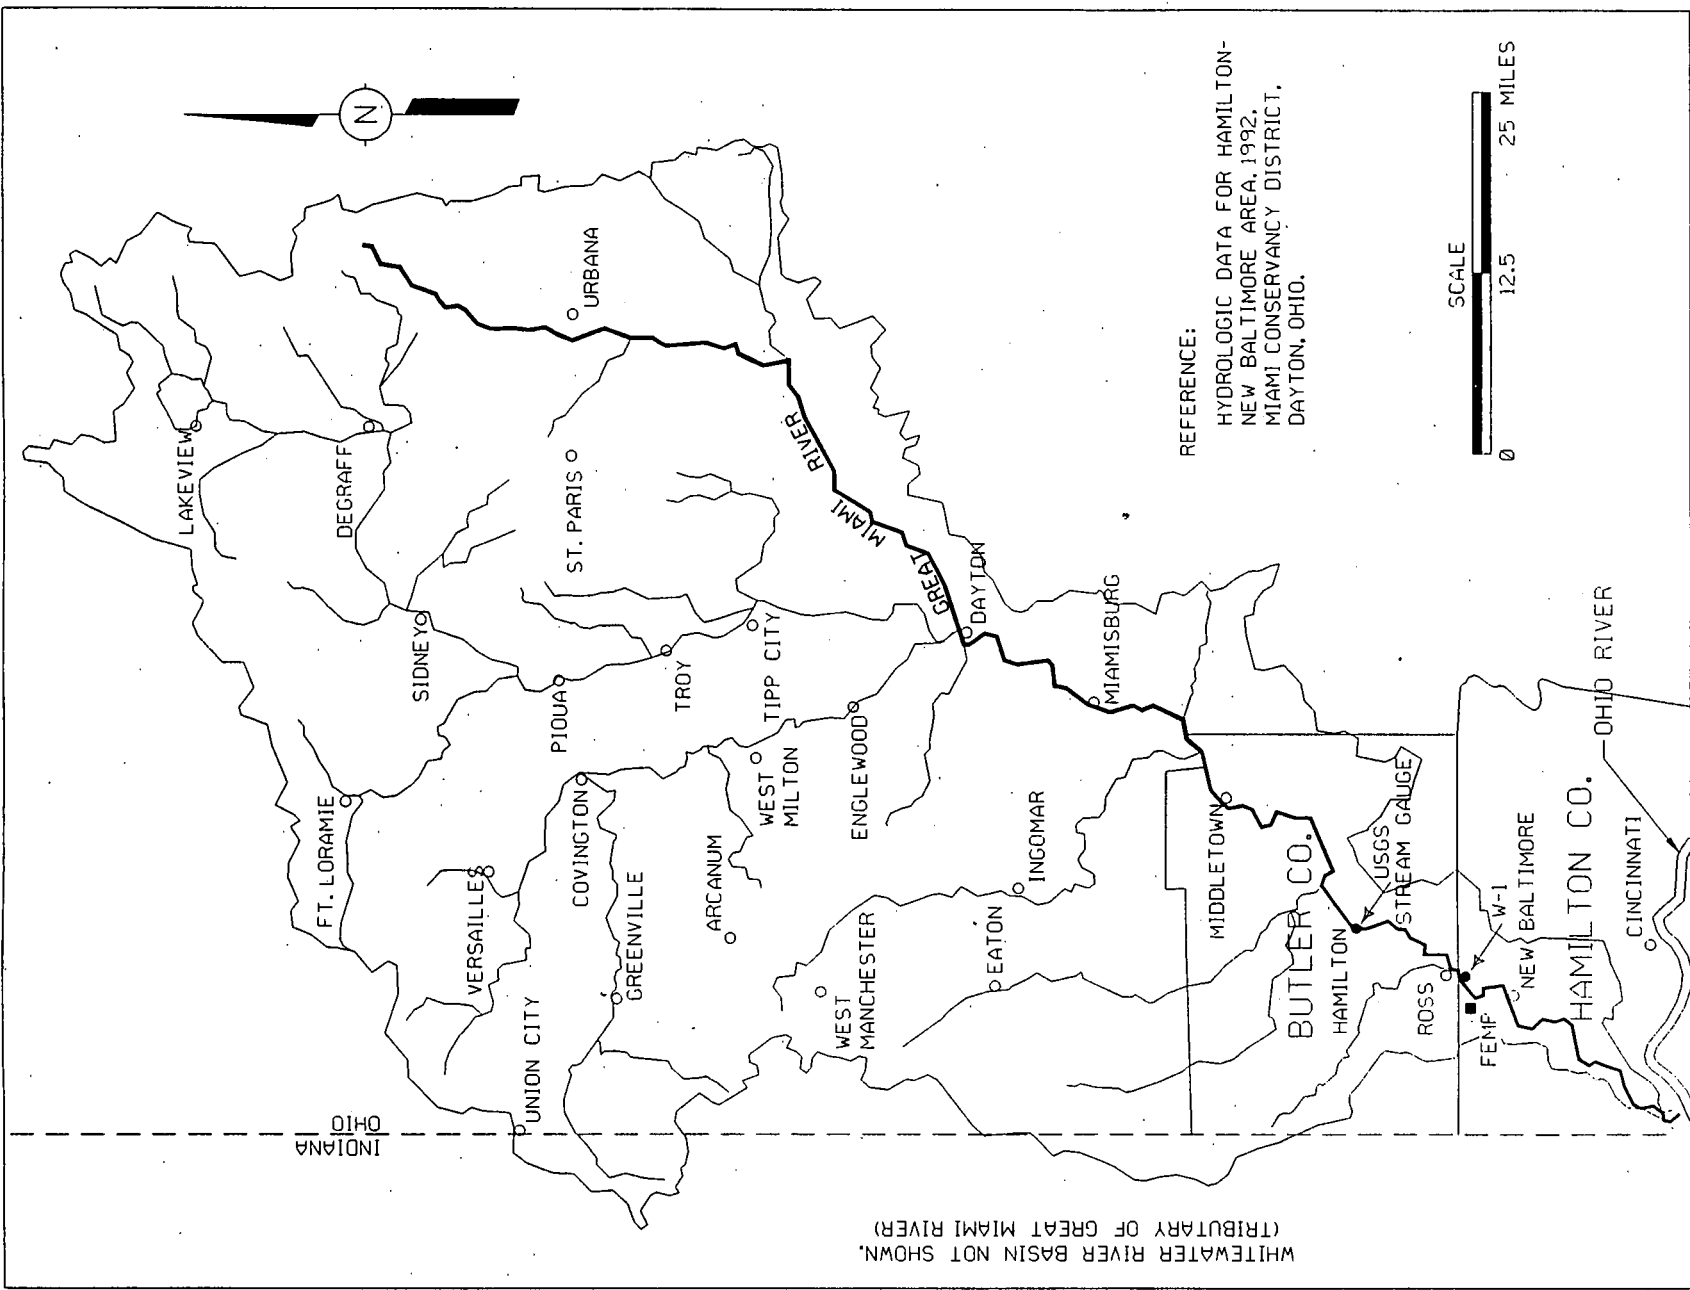

1.4.1 Great Miami River

The FEMP is located within the Great Miami River drainage basin, which is one of the largest watersheds in southern Ohio (Figure 1-5). The river has a total length of 170 river miles and drains an area of approximately 5400 square miles in southwestern Ohio and southeastern Indiana. The drainage basin includes the Whitewater River, which is a major tributary that joins the Great Miami River downstream of the FEMP six river miles above the Ohio River. The headwaters of the Great Miami River are located in west-central Ohio. The river flows southwestward and empties into the Ohio River, downstream of Cincinnati, west of the junction of Ohio, Indiana, and Kentucky. The Great Miami River flows within 3800 feet of the eastern boundary of the FEMP and approximately one mile south of the southern boundary (Figure 1-4).

DAYTON, OHIO.

SCALE
0 12.5 25 MILES

FIGURE 1-5. GREAT MIAMI RIVER BASIN

The U.S. Geological Survey (USGS) operates a flow gauging station on the Great Miami River approximately 10 miles upstream of the FEMP (approximately nine miles upstream of sampling point W-1) at Hamilton, Ohio (Figure 1-5). This point is about 136 miles downstream of the river source. The corresponding drainage area is approximately 3630 square miles, and roughly 90 percent of the Ohio portion of the watershed area lies upstream of the Hamilton gauging station. The average discharge of the Great Miami River at Hamilton, based on 55 years of record, is 3305 cubic feet per second (cfs). The maximum discharge recorded, since the construction of flood control facilities upstream of Hamilton in 1922, was 108,000 cfs (Dove 1961). The 10-year flood discharge is estimated to be approximately 81,455 cfs. Peak flow rates tend to occur in the late winter and spring.

Numerous studies at the FEMP prior to the RI/FS investigations have used sampling point W-1 as the background monitoring point on the Great Miami River. W-1 is located at the State Route 126 bridge, which crosses the river near Ross, Ohio (Figures 1-4 and 1-5). All surface water runoff or discharges from the FEMP site enter the river downstream of this sampling location. Location W-1 is downwind of the FEMP; however, the possible effects of airborne contaminants on water quality at W-1 are not expected to be measurable. This will be discussed further in Section 3.1.1 (Sampling Locations - Surface Water).

1.4.2 Paddys Run

Paddys Run is an ungauged ephemeral tributary of the Great Miami River. The stream is 8.8 river miles long and drains an area of 16 square miles (Dames & Moore 1985). The headwaters of Paddys Run are located about five miles north-northwest of the FEMP and about three miles north of the town of Shandon, Ohio (Figure 1-4). The stream originates in a bedrock upland area, travels through an agricultural area near the town of Shandon, and then flows southward along the western edge of the FEMP to the Great Miami River.

The channel of Paddys Run has an average gradient of about 20 feet per mile. Paddys Run flows on the glacial overburden between Shandon and the FEMP. The Paddys Run channel has cut entirely through the glacial overburden at a point about 3500 feet south of the northern boundary of the FEMP and provides recharge to the Great Miami Aquifer.

Several small tributaries drain the northern and western edges of the FEMP and flow into Paddys Run. A large drainage channel, the SSOD, drains the eastern and southern sides of the FEMP and enters Paddys Run about 500 feet north of the southern boundary of the FEMP (Figure 1-4). Prior to the present controls, surface water drainage flowed primarily to Paddys Run. Surface water drainage from the former production area and the waste storage area is presently controlled at the FEMP and is discharged to the Great Miami River after settling. Before the chambers of the retention basin were built in 1986 and 1988, Paddys Run received the majority of the storm sewer flow from the former production area via the SSOD.

Paddys Run is intermittent and in the summer months may flow briefly in response to storm events. From December through May, there is typically a small flow in the stream due to snowmelt, rainfall runoff, and groundwater base flow.

Sampling point W-5 has historically been used as a background monitoring point for Paddys Run. This point is located north of the intersection of State Route 126 and Paddys Run (Figure 1-4). Sampling point W-5 is not downwind of the FEMP, so the effect of airborne contaminants on stream water quality is not a concern at this sampling location.

1.4.3 Great Miami Aquifer

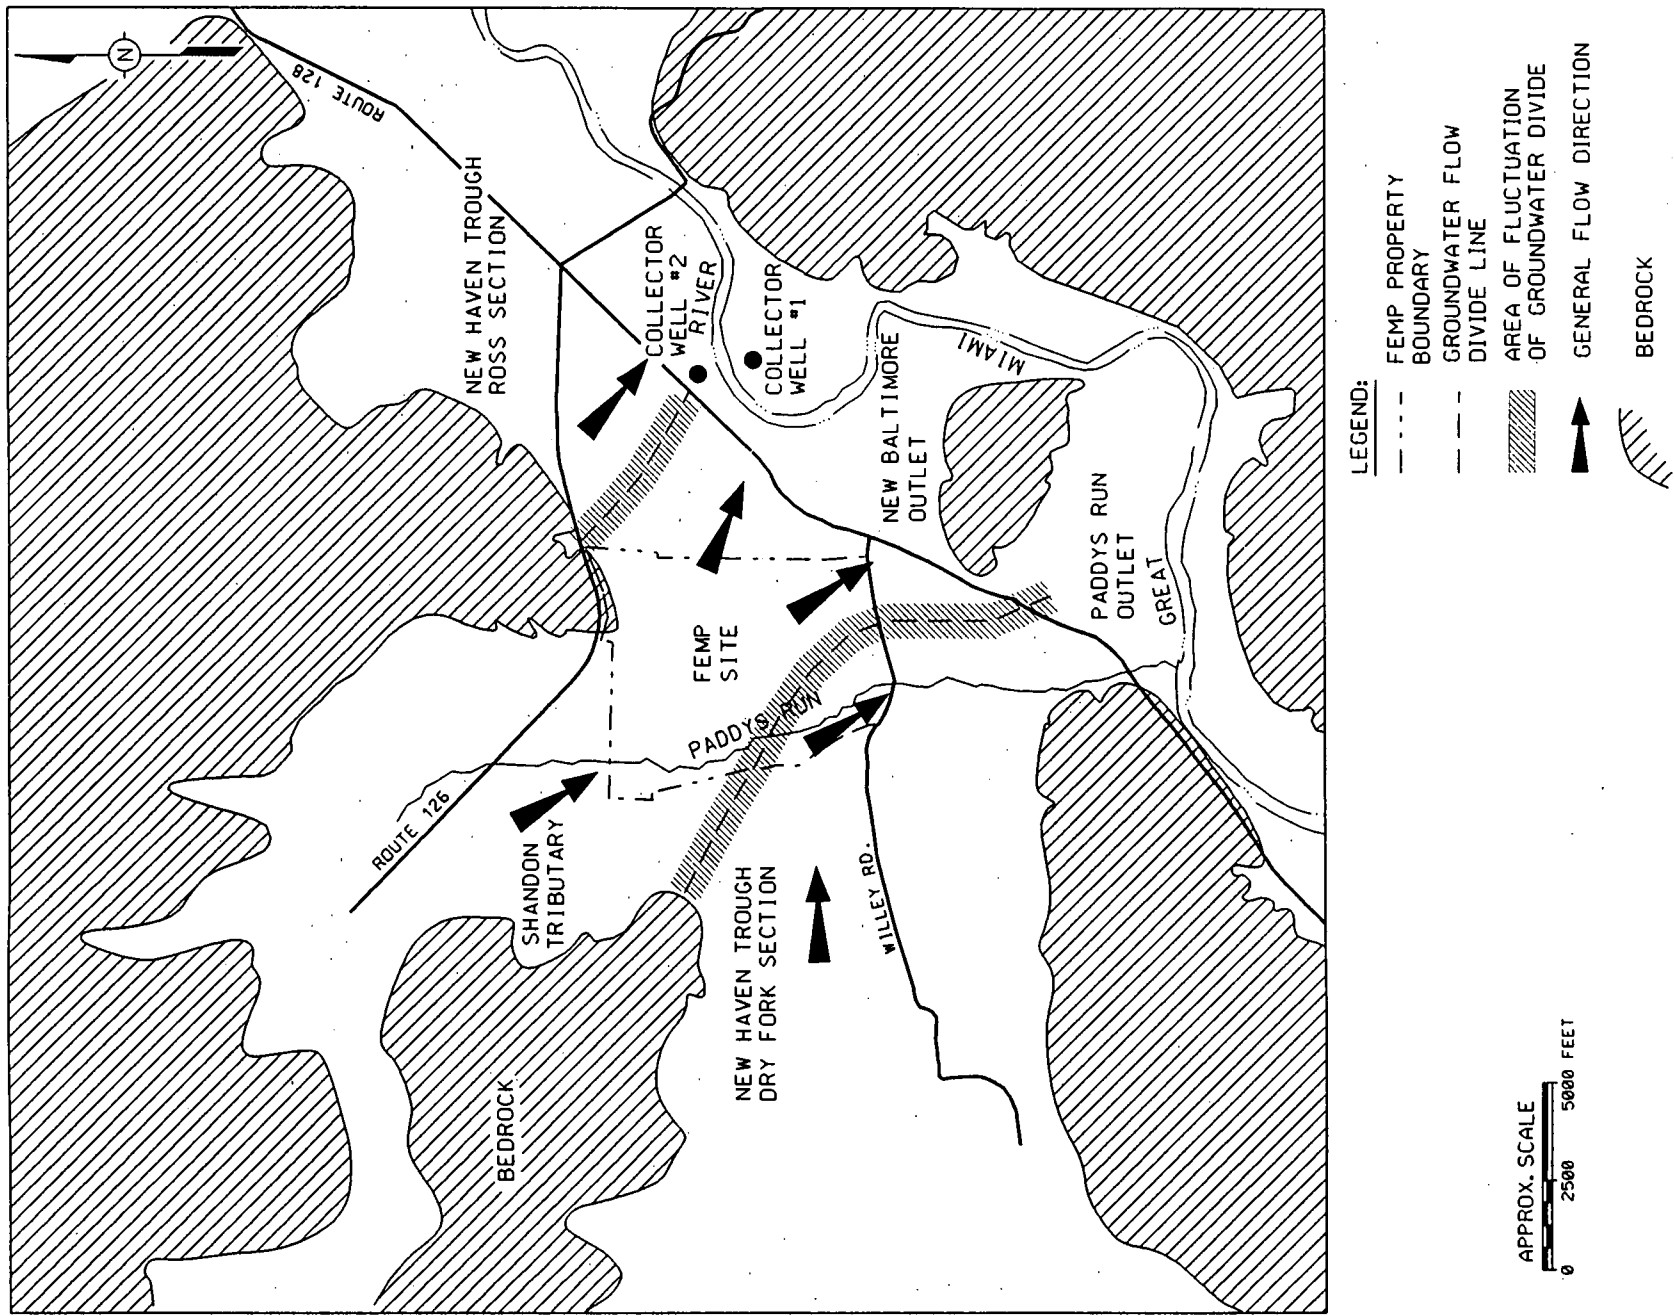

Figure 1-6 shows the conceptual model for groundwater flow in the vicinity of the FEMP. This model is based on water-table measurements collected by the FEMP on a local scale, and regional water levels collected by the Miami Conservancy District (DOE 1993a). Figure 1-6 shows the three flow regions within the Great Miami Aquifer system that are of concern to the FEMP. The bedrock walls bounding the glacial outwash restrict flow to within the valleys.

The Ross section of the New Haven Trough, northeast of the FEMP, has virtually no interaction with groundwater flow from under the FEMP. There are two large collector wells operated by the Southwestern Ohio Water Company which create a cone of depression across the width of the Ross section of the New Haven Trough, effectively forming a barrier to flow. The approximate location of the groundwater divide formed by the cone of depression is shown on Figure 1-6.

The Shandon Tributary to the New Haven Trough provides groundwater that flows under the northern portion of the FEMP and discharges into the Great Miami River east and south of the FEMP. The groundwater flow moves southeasterly through the New Baltimore Outlet from the New Haven Trough. The Shandon Tributary is the source area for groundwater moving under the waste storage and former production areas of the FEMP in the Great Miami Aquifer.

To the west, the Dry Fork section of the New Haven Trough is the source area for groundwater moving under the southwestern portion of the FEMP. The west to east flow turns south and leaves the New Haven Trough via the Paddys Run Outlet to join the Great Miami River. The Dry Fork area is therefore the recharge area for groundwater flowing in the Great Miami Aquifer under the southwestern portion of the FEMP.

A complicating factor in this model is the seasonal flow and resulting recharge from Paddys Run. Figure 1-6 shows the location of the groundwater divide when there is no recharge from Paddys Run. When recharge occurs, the location of the groundwater divide shifts to the south and west and lies directly under Paddys Run as far south as Willey Road.

FIGURE 1-6. GREAT MIAMI AQUIFER CONCEPTUAL FLOW MODEL

1.4.4 Glacial Overburden

Monitoring wells in the glacial overburden were generally constructed with well screens that are 2 to 10 feet long. The screens usually penetrate more than one type of glacial overburden material. Because the silt, sand, and gravel deposits in the glacial overburden are more permeable than the silty clay till, it is highly likely that most movement of the groundwater (laterally or vertically) is through the coarser-grained materials. However, since the well screens are completed in more than one type of material, the hydraulic heads and water quality measured in each well cannot always be assigned with confidence to a single type of overburden material. Hence the data for each well, such as hydraulic heads and water quality, are representative of the undifferentiated glacial overburden.

Rainfall and snowmelt infiltrate into glacial overburden except where the ground surface is covered by a building, parking lot, or other impermeable man-made structures. Perched groundwater in the overburden flows laterally toward the nearest drainage ditch, stream channel, or storm drain. Contouring of water levels in the glacial overburden wells shows that potential flow is from northeast to southwest. Since Paddys Run and the SSOD have eroded completely through the glacial overburden, it is not possible for perched water to travel laterally beyond either surface feature. Groundwater levels are also depressed in the vicinity of storm drains running through the former production area, indicating that shallow groundwater is flowing laterally into the drains. Studies to date indicate perched groundwater flow involves relatively small localized areas and velocities are low compared to flow volumes and velocities that exist in the Great Miami Aquifer.

1.4.5 Monitoring Wells

A three-dimensional monitoring well network was established for the FEMP RI as shown in Figure 1-7. Each well used in the RI has a unique number in which the left digit indicates the well type followed by a three or four-digit location number. Figure 1-7 illustrates each type of well.

Wells that are screened in the glacial overburden are classified as Type 1 wells. Within the Great Miami Aquifer, monitoring wells placed at and just below the water table are classified as Type 2 wells, and are installed with five feet of screen above and 10 feet of screen below the water table. Intermediate depth monitoring wells are placed just above the clay interbed or at the equivalent elevation and are classified as Type 3 wells. Wells completed near the base of the aquifer are classified as Type 4 wells. Figure 1-7 also shows Type 6 wells installed for Paddys Run Road Site investigations. Type 6 wells monitor the zone between Type 2 and Type 3 wells.

Private wells sampled during the FEMP RI monitoring program have been classified according to the same numbering scheme. When possible, the depth of each well was measured or obtained from well records and the wells were given numbers which conform to the Type 1 through Type 4 numbering scheme.

FIGURE 1-7. CLASSIFICATION SCHEME FOR MONITORING ~~000024~~

More than 700 monitoring wells and private wells have been completed in the Great Miami Aquifer and glacial overburden that have been used to study groundwater quality in and around the FEMP. Wells were selected to characterize background groundwater quality if they were located outside and upgradient of the FEMP property or at least away from the effects of any operations.

1.5 EPA GUIDANCE ON BACKGROUND CHARACTERIZATION

Characterization of background surface water and groundwater quality is necessary for both RCRA and CERCLA site investigations. Several documents have been published by the EPA that discuss procedures to select numbers and locations of sampling points, data quality objectives, data validation procedures, statistical methods for evaluating data, and the final end use of background data and statistics.

The general procedures to be used in a CERCLA RI/FS are outlined in "Guidance for Conducting Remedial Investigations and Feasibility Studies under CERCLA" (EPA 1988a). In this document the EPA states that sampling should be conducted in areas perceived to be upgradient from the contaminant source in order to identify background levels and to determine if there are contributions of contaminants from other sources. However, no details are given about the amount of data, quality of data, or methods of data evaluation necessary for background characterization.

These topics are discussed in more detail in the document "Risk Assessment Guidance for Superfund Human Health Evaluation Manual, Part A, Interim Final" (EPA 1989a). In this document, it is stated that: "Background samples are collected at or near the hazardous waste site in areas not influenced by site contamination. They are collected from each medium of concern in these off-site areas. That is, the locations of background samples must be from areas that could not have received contamination from the site, but that do have the same basic characteristics as the medium of concern at the site." The Risk Assessment Guidance for Superfund (RAGS) also suggests that statistics may be used in some cases to test the hypothesis that "there is no difference between contaminant concentrations in background areas and on site." This is commonly referred to as the null hypothesis.

If statistics are to be used, the RAGS further states that: "The number of background samples collected at a site should be sufficient to accept or reject the null hypothesis with a specified likelihood of error." However, the statistical procedures needed to perform the hypothesis testing are not specified in the RAGS. Instead, it defers to another document, "Statistical Analysis of Ground-Water Monitoring Data at RCRA Facilities, Interim Final Guidance" (EPA 1989b), for details concerning statistical procedures.

Guidance on background characterization for RCRA-related studies is more clearly defined and is provided in the following documents:

- "RCRA Ground-Water Monitoring Technical Enforcement Guidance Document" (EPA 1986)
- "Statistical Methods for Evaluating Ground-Water Monitoring from Hazardous Waste Facilities, Final Rule" (EPA 1988b)
- "Statistical Analysis of Ground-Water Monitoring Data at RCRA Facilities, Interim Final Guidance" (EPA 1989b)
- "Statistical Analysis of Ground-Water Monitoring Data at RCRA Facilities, Addendum to Interim Final Guidance" (EPA 1992)

Details of statistical procedures are discussed in Chapter 4 and Appendix F of this report. In summary, the procedures include the following:

- Identification and treatment of high nondetect data
- Identification and treatment of outliers
- Averaging multiple data from the same sampling event (i.e., duplicate, triplicates, etc.)
- Testing for data distribution (normal and lognormal)
- Calculation of descriptive statistics (parametric and nonparametric)
- Comparison of populations

1.6 SUMMARY OF REVISIONS MADE TO THE DRAFT REPORT (MAY 1993)

A draft version of "Characterization of Background Water Quality for Streams and Groundwater" was submitted to the EPA and OEPA in May 1993. The draft report was subsequently approved by those agencies, pending incorporation of comment responses and inclusion of new data collected during the field programs conducted in the spring and summer of 1993. The revisions that have occurred between the draft document and the current report are discussed in Appendix G. Where appropriate, some significant revisions are described in the pertinent sections of the report text.

The major change that has occurred for this document is that more validated RI/FS data are available, particularly for surface water sampling points W-1 and W-5 on the Great Miami River and on Paddys Run, respectively. Additionally, data from the spring and summer 1993 field programs are also available for background groundwater sampling locations. Furthermore, for the 1993 field programs, analysis of both filtered and unfiltered samples were performed for inorganic and radiological parameters. Background water quality data from these analyses are included in the revised report.

Minor changes have occurred to the number and location of wells used to characterize background water quality in the Great Miami Aquifer. In the draft report, 25 Type 2, Type 3, and Type 4 wells were used to characterize the aquifer. Based on further review of data for these wells, three of the wells initially selected to characterize background (2383, 2384, and 3044) have been discarded. They have been discarded because they are located close to Paddys Run where the stream has eroded

through the glacial overburden, and the wells may therefore be influenced by surface water that has infiltrated from the stream.

Two wells have been added since the draft report. No data were available for well 2728 prior to the 1993 sampling program. New data for this well enables its use for background characterization. Well 2105 was disqualified previously because of one anomalous sample. The data from the one sample has been excluded and the remainder of the data appear similar to other data from the Great Miami Aquifer. Therefore, well 2105 was considered usable.

Altogether there was a net reduction of one well used to characterize the Great Miami Aquifer. The wells used to characterize the background water quality in the glacial overburden have not changed; the same five wells are used in this report because they are the most appropriate. The process for evaluating and selecting wells is described in Chapter 3.

Several steps were performed on the compiled potential background data set prior to statistical analysis:

- 1) nonvalidated data were removed
- 2) high nondetect values were removed
- 3) data outliers were identified and removed
- 4) data for replicate samples were averaged

Steps 1 and 2 were performed during the preparation of both the draft report and for this revision. Steps 3 and 4 were performed for the revised document. These procedures were added in order to remove possibly inappropriate data from the background data set and to reduce potential sample bias caused by replicate sampling (i.e., duplicates, triplicates). The data evaluation procedures are discussed in Chapter 4 and Appendix G.

Once the modifications to the background data set were complete, statistical analyses of each data group were performed. The types of statistical analyses performed on the data and the list of descriptive statistics provided have changed slightly from those presented in the draft report. Most notably:

- The one-sided 95 percent upper tolerance limit (UTL) has been replaced by the 95th percentile.
- The two-sided 95 percent upper confidence limit (UCL) has been replaced by the one-sided 95 percent UCL.
- For data groups having lognormal distributions, the geometric mean has been replaced by an "estimated mean" and the geometric standard deviation was replaced by an "estimated standard deviation."

In general, the reason for these modifications is to limit the reported statistical results to those most useful and appropriate for the particular data distribution. Further discussion is provided in Appendix G. The protocol and equations for calculating the new statistics as well as those presented previously are included in Appendix F.

Additional changes to the draft "Background Water Quality" document involve incorporating comment responses as discussed in DOE's correspondence with EPA and OEPA, dated August 31, 1993. Some minor revisions were also made to the description of site setting, groundwater monitoring, sampling and analysis programs, and data validation to promote consistency with the Operable Unit 5 RI Report.

2.0 PREVIOUS STUDIES

Numerous studies have been performed at the FEMP in the past in which background surface water or groundwater quality was investigated. In addition, characterization work continues to be performed at the site for the RCRA, CERCLA, and Environmental Monitoring (EM) Programs. Only the validated CERCLA RI/FS data set is being evaluated to establish background water quality in this document. The nonvalidated background data from the previous studies and other ongoing monitoring programs are useful for comparative purposes. This chapter provides a brief overview of the many sampling programs that have contributed to the overall background data for the FEMP. Summaries of the background data that were collected in these studies are found in Appendix A.

2.1 ENVIRONMENTAL MONITORING PROGRAM

The EM Program began before RCRA and CERCLA regulations were instituted. Surface water and sediment sampling were initiated to measure the effects of routine discharges of treated effluent into the Great Miami River, and the periodic discharge of untreated surface water runoff into the SSOD and Paddys Run. The program was developed by National Lead of Ohio, Inc. (NLO), the first operator of the site for the DOE. There were three sampling points initially established on the Great Miami River. Sampling point W-1 was established upstream by 1954 to provide background data for the river (Figure 1-4). The other two original sampling points were located downstream and are not representative of background water quality.

On Paddys Run, sampling point W-5 was established in 1979 at an upstream point (about 0.5 mile north of the FEMP) and has been monitored routinely to provide background data on Paddys Run (Figure 1-4). All the other EM sampling points on Paddys Run are adjacent to or downstream of the FEMP property and are not representative of background water quality.

In late 1981, above-background concentrations of uranium were found in several private wells near the FEMP, and NLO initiated the EM Private Well Program. By 1984, 19 private wells were being sampled on a monthly basis. The program continued to grow and as of 1991, 41 individual private wells had been sampled (Figure 2-1); however, not all these wells are sampled every year (Westinghouse Environmental Management Company of Ohio [WEMCO] 1992). Monthly samples are analyzed for total uranium; one monthly sample per year is also analyzed for 16 metals. Data for wells upgradient of the FEMP are summarized in Appendix A, Tables A-1 and A-2.

2.2 U.S. GEOLOGICAL SURVEY SURFACE WATER MONITORING

A USGS stream gauging station is located about 10 miles upstream of the FEMP at Hamilton, Ohio (Figure 1-5). From July 1963 to November 1973, stream water samples were collected between one and four times per month. These samples were analyzed for a wide variety of inorganic constituents and a few organic constituents. Although this sampling point is 10 miles upstream, the large amount

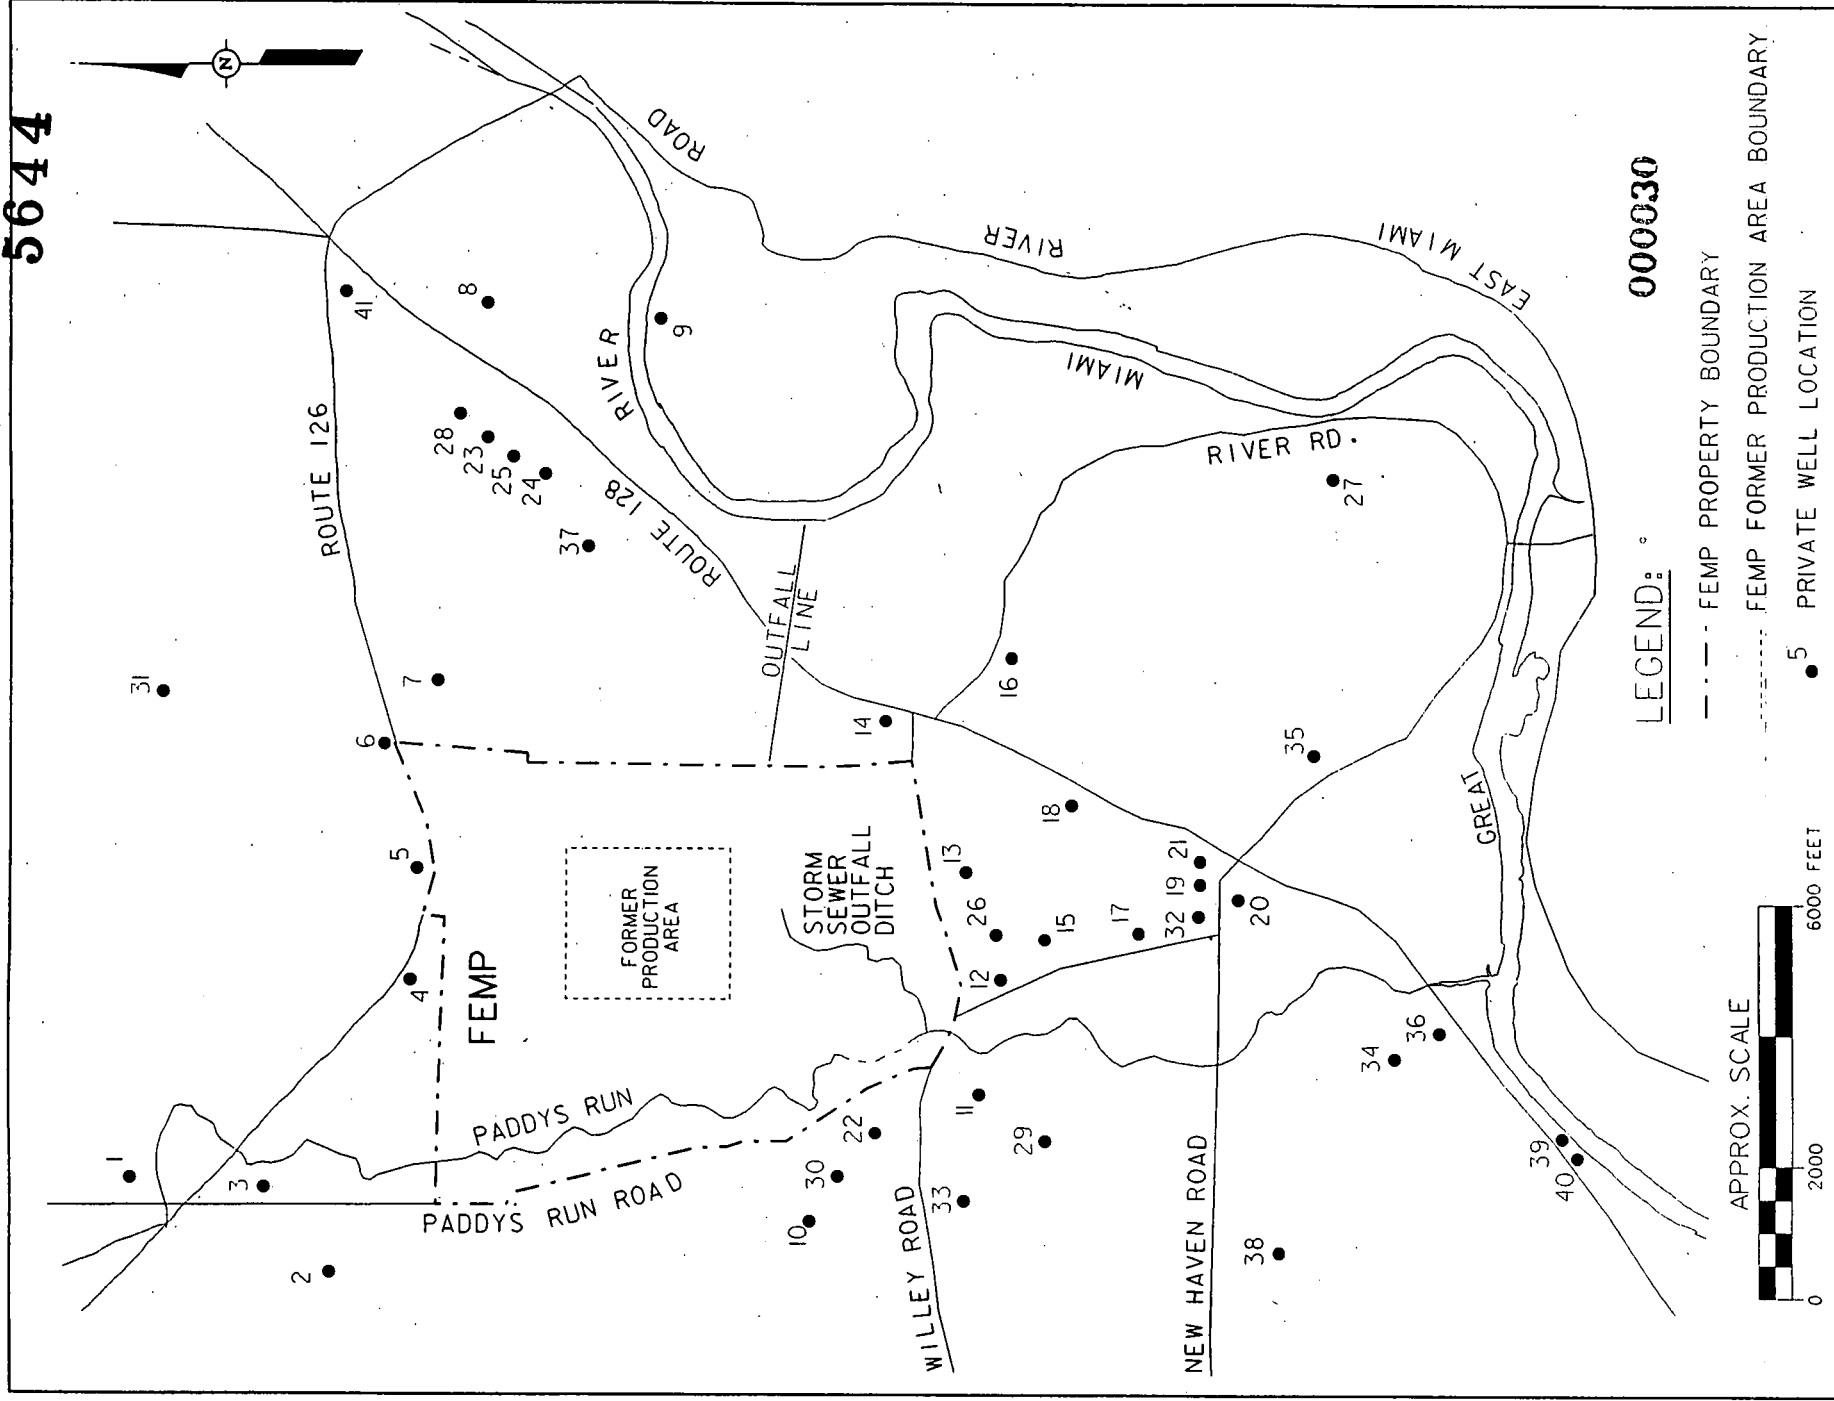

FIGURE 2-1. LOCATIONS OF PRIVATE WELLS SAMPLED FOR THE FEMP ENVIRONMENTAL MONITORING PROGRAM

of data available is useful for comparative purposes. USGS stream water quality data are summarized in Appendix A, Table A-3.

2.3 U.S. GEOLOGICAL SURVEY GROUNDWATER STUDY

The USGS conducted a one-time collection of samples from private wells adjacent to the FEMP in August 1982 (Sedam 1984). A total of 33 well samples were collected, but many of these were analyzed only for total uranium. Of the 33 samples collected, 9 were from wells located on the west or southwest side of the FEMP that can be considered upgradient of the FEMP (Figure 2-2). The depths of these wells range from 70 to 90 feet and they are completed in the upper part of the Great Miami Aquifer. The data for the nine wells located upgradient of the FEMP are summarized in Appendix A, Table A-4. It has been determined that wells designated H-101, H-102, H-103 correspond to EM wells 10, 30, and 22, respectively. In addition, wells H-101 and EM-10 are also the same as well 2104.

2.4 IT CORPORATION FINAL INTERIM REPORT

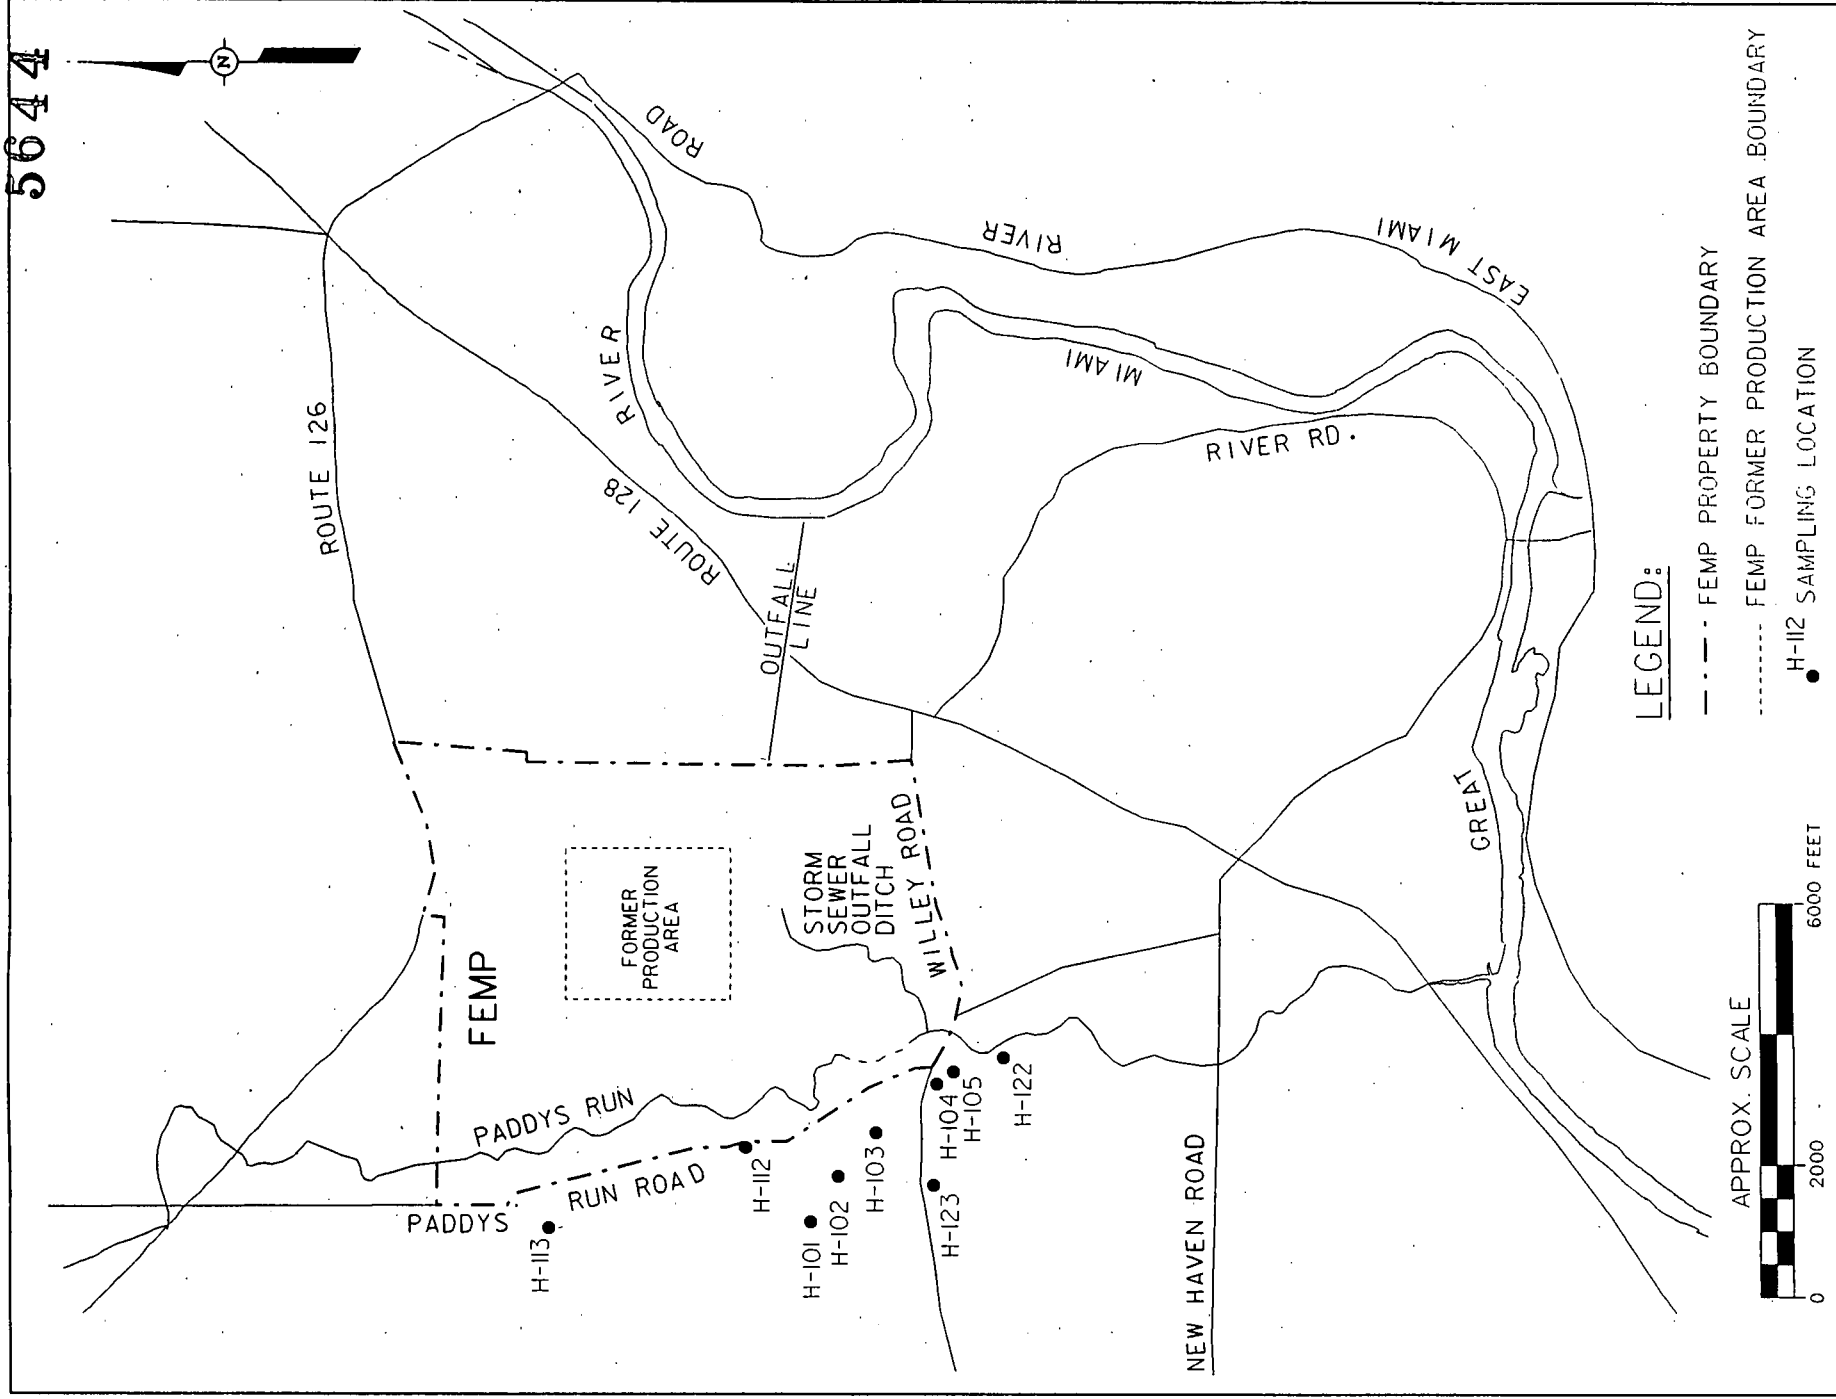

This study (IT 1986) was conducted in 1985 and 1986 to estimate the extent of off-property contaminant migration from the FEMP and to assess the associated health risks. During this study, six new monitoring wells were drilled and water samples were collected from numerous surface water and groundwater monitoring points. Paddys Run was sampled once at W-5, and the Great Miami River was sampled twice at upstream sampling point W-1 (Figure 1-4). Groundwater samples were collected from a large number of wells, many of which are upgradient of the FEMP (Figure 2-3). Many of these samples were analyzed for an array of organic, inorganic, and radiological constituents. Data for well samples collected upgradient of the FEMP are summarized in Table A-5 of Appendix A.

2.5 ARGONNE NATIONAL LABORATORY ENVIRONMENTAL SURVEY

An environmental survey of the FEMP was performed in 1986 by Argonne National Laboratory under the direction of DOE. The results of the sampling and analysis are reported in "FMPC Sampling and Analysis Report" (DOE 1988a). During this study, one water sample was collected from sampling point W-1 on the Great Miami River and was analyzed for a variety of organic, inorganic, and radiological constituents (Table A-6, Appendix A).

2.6 OHIO DEPARTMENT OF HEALTH

In January 1985, the DOE, through a cooperative agreement, requested that the Ohio Department of Health (ODH) collect samples of drinking water from private wells in the vicinity of the FEMP. Groundwater samples were collected primarily in 1985 and 1986, with additional samples collected up to January 1988. These samples were analyzed for gross alpha, gross beta, and total uranium. Approximately 246 private well samples were collected and analyzed (ODH 1988).

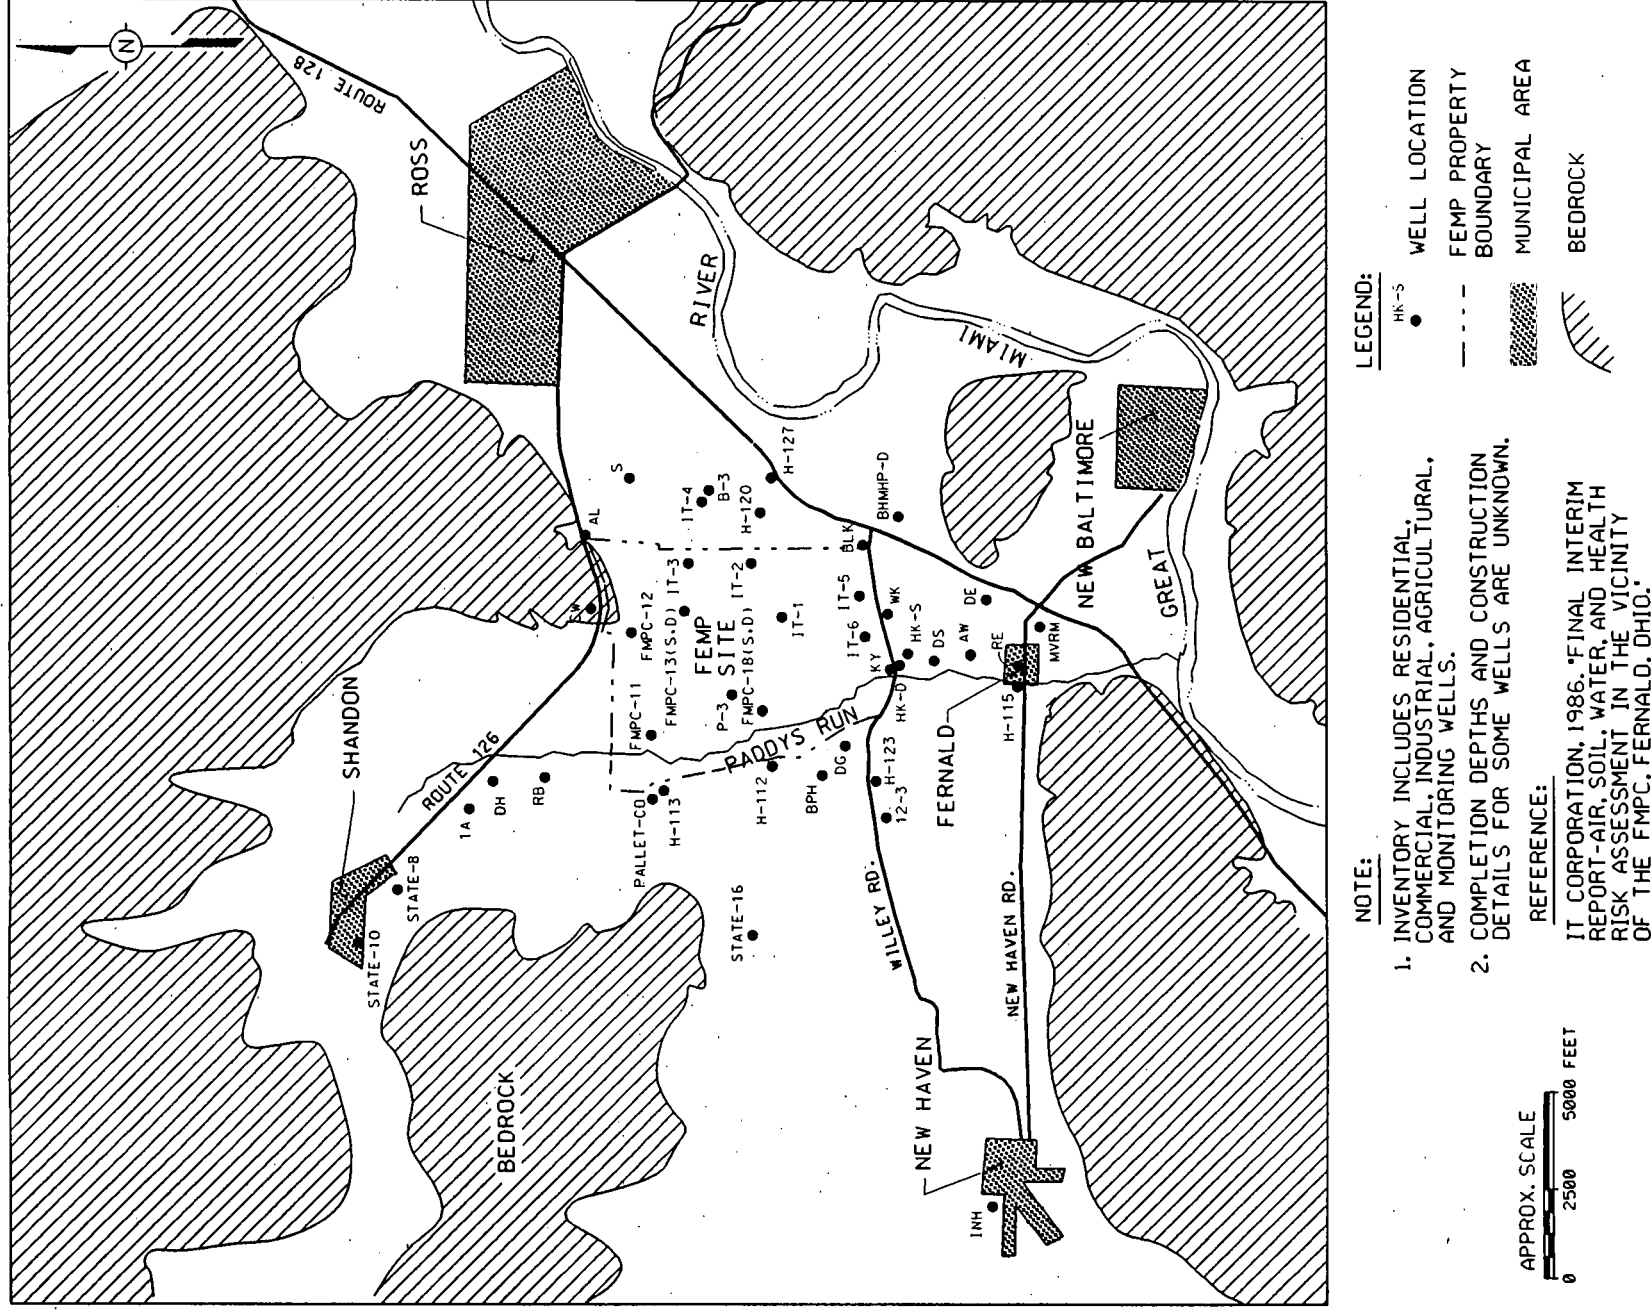

FIGURE 2-3. LOCATIONS OF WELLS SAMPLED BY IT CORPORATION IN 1986

2.7 OEPA STUDY OF THE GREAT MIAMI RIVER

The OEPA conducted a study of water quality in the Great Miami River in 1989. During this investigation, seven water samples were collected from sampling point W-1 and analyzed for numerous metals and general water quality constituents (Table A-15, Appendix A).

2.8 PREVIOUS RI/FS BACKGROUND STUDIES

The RI/FS program for the FEMP began in 1986. The objective was to study the nature and extent of environmental contamination at the site and to assess the potential for adverse human health and environmental effects. Groundwater and surface water sampling was initiated in early 1988 following the plans and procedures contained in an EPA-approved Work Plan (DOE 1988b).

During the progression of the remedial investigation, two reports have been written in which background water quality was addressed. In both cases, incomplete data sets and nonvalidated data were used to derive background water quality characteristics. Additionally, the statistical approaches and procedures employed, well locations chosen, and data sets used to calculate background concentrations in each media were different.

In the draft "Groundwater Report" (DOE 1990a), data from samples collected between April 1988 and March 1989 were evaluated. The data were separated into four groups: glacial overburden and the Ross, Shandon, and Dry Fork sections of the Great Miami Aquifer. The specific wells used to represent background for each of these four groups were:

- Glacial overburden - wells 1024, 1059, 1060, and 1065
- Ross section, Great Miami Aquifer - wells 2026, 2121, 2122, 3063, 3099, and 3100
- Shandon section, Great Miami Aquifer - wells 2050, 2056, 2066, and 2105
- Dry Fork section, Great Miami Aquifer - wells 2036, 2057, and 2123

Arithmetic means of background values calculated for each of these four groups are listed in Appendix A, Tables A-7 through A-10. Means were calculated for 17 radionuclides and 31 inorganic constituents.

A similar exercise was performed later during preparation of the "Site-Wide Characterization Report" (DOE 1993c). The same wells were used in the "Groundwater Report"; however, two additional wells, 1052 and 2043, were included in the characterization of the glacial overburden and the Shandon section background values, respectively.

The background groundwater quality statistics presented in the "Site-Wide Characterization Report" are in Appendix A, Tables A-11 through A-14.

2.9 RCRA GROUNDWATER MONITORING

A RCRA Detection Monitoring Program was initiated at the FEMP in 1985 due to the disposal of barium chloride in Waste Pit 4 from 1980 to 1983. The Detection Monitoring Program consisted of sampling 41 monitoring wells six times each between August 1985 and November 1987. In November 1987, based upon statistical comparisons completed as part of the program, the EPA and the OEPA were notified that Waste Pit 4 could be affecting groundwater quality in the waste pit area. At that time, the RCRA Detection Monitoring Program was changed to a RCRA Assessment Monitoring Program.

The Groundwater Quality Assessment Program Plan was the guiding document for the RCRA Assessment Monitoring of Waste Pit 4. This plan was revised several times to address regulator comments and programmatic findings. By the end of 1991, the number of wells sampled for the program had increased from 41 to 54.

The RCRA Assessment Monitoring Program was altered when a revised Part A Permit Application was submitted in June 1991. Prior to June 1991, Waste Pit 4 was the only regulated unit requiring groundwater monitoring under RCRA. The Part A Permit identified eight additional units requiring groundwater monitoring. In order to maintain RCRA compliance, the Groundwater Monitoring Plan was written which provided for a monitoring network with three "lines" of wells. By the beginning of 1993, the number of wells sampled for the program had increased to 84.

During 1993, it was determined that it would be both difficult and impractical to meet RCRA requirements under the current monitoring program. In order to integrate RCRA and CERCLA monitoring activities, an Alternate Monitoring Program was proposed and accepted by OEPA. This program identified 33 downgradient on-property wells to be monitored for RCRA to assess off-property releases from the FEMP.

Figure 2-4 shows all wells which have been sampled as part of the FEMP RCRA Groundwater Monitoring Program. Wells were sampled for various analytes consisting of general water quality, drinking water suitability, as well as chemical and radiological indicator parameters.

Results from the RCRA Detection Monitoring Program are summarized in the RCRA Groundwater Reports (ASI/TT 1988; Dames & Moore 1986a, 1986b, 1987a, 1987b, and 1987c). Results from the RCRA Assessment Monitoring Program are furnished in the RCRA Annual Groundwater Reports (DOE 1990b, 1991, 1992a, 1993b, and 1994).

3.0 DEVELOPMENT OF THE RI/FS BACKGROUND DATA SET

The RI/FS program was designed to determine the effects of FEMP operations on all environmental media, ecology, and human health. During this ongoing program, a substantial amount of surface water and groundwater data and interpretations have been generated. Preliminary data and data interpretations for background water quality have already been presented in the draft "Groundwater Report" (DOE 1990a) and the "Site-Wide Characterization Report" (DOE 1993c). This chapter concentrates on the aspects of the RI/FS program that pertain to background water quality and development of the comprehensive data set used in succeeding chapters to characterize background.

3.1 SAMPLING LOCATIONS

3.1.1 Surface Water

Sampling point W-1 on the Great Miami River was selected as a location to monitor water quality upstream of the FEMP. Station W-1 is located two miles directly east of the FEMP property boundary and about 1.5 miles upstream from the FEMP effluent line (Figure 1-4). Sampling occurred where State Route 126 crosses the river near Ross, Ohio.

Total uranium values for surface soil outside the FEMP property sampled in 1984 and 1986 indicate that some airborne dispersion of total uranium occurred from the production area toward the northeast, the direction of prevailing wind for the area. However, concentrations of total uranium in surface soil decrease rapidly in a northeast direction down to about 7 to 13 pCi/g (picocuries per gram) near the northeast corner of the FEMP property. Concentrations were even lower off-property in a north and northeast direction. Near Ross, Ohio (where W-1 is located), total uranium activity levels typically ranged from 1 to 3 pCi/g, which is similar to background concentrations of total uranium in surface soils. The watershed area upstream of sampling point W-1 is large and the flow rate at W-1 is substantial. Therefore, it is not expected that airborne transport of radionuclides will have a measurable effect on background water quality readings at sampling point W-1.

When the bridge at Ross was rebuilt in 1990, water samples were collected about nine miles upriver near Hamilton, Ohio. As described in Chapter 7, the total uranium concentrations at Hamilton were essentially the same as the concentrations measured at Ross before and after construction (Figure 7-1). Thus, the available evidence indicates that sampling point W-1 is an appropriate location for collection of background data for the Great Miami River.

Sampling point W-5 was identified in the RI/FS Work Plan as the background monitoring location for Paddys Run (Figure 1-4). However, the Work Plan specified that the data for W-5 would be provided through routine sampling conducted under the EM Program, so no RI/FS samples were collected at sampling point W-5 prior to 1993. EM data from sampling point W-5 were originally

intended to be the background data for the RI/FS program; however, these data were not complete (i.e., no Hazardous Substance List [HSL] organics or metals were analyzed) and could not be validated according to currently existing criteria. Therefore, two RI/FS water samples were collected from sampling point W-5 in 1993 and were analyzed for the full suite of organic, inorganic, and radiological analytes.

The RI/FS W-5 sampling location in 1993 was several hundred feet downstream of the original W-5 location used by EM. The RI/FS W-5 location is at the intersection of Paddys Run and State Route 126, whereas the EM W-5 location is at the intersection of Paddys Run and Paddys Run Road. After reviewing the data, it was determined that total uranium concentrations from the two locations are essentially the same (refer to Appendix C and Figure 8-1).

3.1.2 Groundwater

Presently, there are approximately 376 Type 1 wells, 216 Type 2 wells, 121 Type 3 wells, and 33 Type 4 wells in and around the FEMP property. These numbers do not include private wells that have been incorporated into the RI/FS program.

The next sections describe how wells were selected which could potentially represent background groundwater quality and how these wells were screened to eliminate wells that might not be representative of ambient groundwater. Several criteria were used in the screening process to develop the final inventory of wells. Water quality data from these wells were then used to characterize background conditions.

3.1.2.1 Identification of Potential Background Monitoring Wells

A current map of RI/FS well locations was visually scanned, and all wells that appeared to be potentially usable for background characterization were tabulated (Table 3-1). These included all RI/FS wells and private water-supply wells sampled during the RI/FS program that were:

- Northeast of the FEMP toward Ross, Ohio
- North and northwest of the FEMP toward Shandon, Ohio
- West of Paddys Run
- South of the FEMP (Type 1 wells)
- Within the FEMP but away from site activities and wastes

The list includes those wells that were originally identified as background monitoring wells for the "Site-Wide Characterization Report" (DOE 1993c), as well as several more wells that have been added for consideration. A number of wells located within the FEMP property were retained as potential sources of background data because they were close to the northern or western edges of the property and away from FEMP activities and wastes.

Table 3-1
Wells Considered for Use in Characterizing
Background Water Quality

General Area	FEMP Wells	Private Wells
Northeast of the FEMP	2098, ^a 3098 ^a	2026, ^a 2121, ^a 2122, ^a 3063, ^a 3099, ^a 3100 ^a

West of Paddys Run	2044, ^e 2096, ^a 2383, ^e 2384, ^e 3044, ^e 3096, ^a 4096, ^a AW-1 ^d	2036, ^a 2057, ^a 2104, ^a 2123 ^a
Within the FEMP property	1009, ^d 1011, ^g 1012, ^c 1015, ^d 1024, ^a 1052, ^g 1065, ^a 1679, ^d 1728, ^g 1733, ^g 1754, ^d 2024, ^g 2728, ^a 2754, ^c 3024, ^a 4011, ^a 4424 ^f	1124 ^b
South of the FEMP	-	1060 ^a
Total	33	18
Usable background wells	13	16

^aWells used in the background study.

^bWells excluded due to lack of driller's logs or unknown total depth.

^cWells excluded due to well being installed in geologic formations not of interest.

^dWells excluded due to lack of validated RI/FS data.

^eWells excluded due to location next to Paddys Run

^fWells downgradient of the waste pit area and former production area.

^gWells excluded due to unusual water chemistry.

NOTE: Type 1 wells have been completed in the glacial overburden. Type 2, 3, and 4 wells are completed in the Great Miami Aquifer.

In addition, four Type 1 wells located toward the southern edge of the property were evaluated as potential background monitoring wells. These wells are located some distance away from any potential contaminant source. Also, Paddys Run and the SSOD have completely eroded through the glacial overburden in this area, precluding lateral transport beyond these features; therefore, the wells were retained for consideration. However, as discussed later in this chapter, the chemical data from these wells were carefully evaluated before any were chosen to be background representatives.

As shown in Table 3-1, there are a total of 51 wells that have been considered. Most of these are monitoring wells constructed for the FEMP (33 out of 51), while 18 of the wells are privately owned. The locations of these potential background wells are shown in Figures 3-1 through 3-4. The majority of the wells are Type 1 and Type 2 wells. Fewer Type 3 and Type 4 wells are available for consideration. Most of the wells are located to the north and west of the FEMP. Figures 3-1 and 3-2 also show groundwater elevation contours for Type 1 and Type 2 wells, respectively. Groundwater elevation contours for Type 3 and Type 4 wells are essentially the same as shown in Figure 3-2 for the Type 2 wells.

3.1.2.2 Screening of Background Locations

The 51 wells identified as candidate background wells were then evaluated to determine whether they are representative of background groundwater quality conditions. These 51 wells were screened based on the following criteria:

- A driller's log, well completion log, or other document was required in order to establish the total depth of a well and the formation from which water samples were collected.
- The chemistry of samples should not contain "unusual" concentrations of chemical or radiological constituents. In particular, total uranium was one constituent that was used as a screening tool. The definition of "unusual" was based on subjective professional judgment. The "unusual" data were visually compared against the bulk of the data from other wells, and if the data appeared to have much higher values than the other data, the well was excluded from further consideration.
- The general chemistry of the well samples should group together when plotted on a trilinear diagram. If a well has general chemistry that is significantly different from other wells, then it would plot differently on the trilinear diagram. If so, the well would be excluded from further consideration as representative of background groundwater quality.

Many of the wells considered as potential background wells are privately owned. The installation procedures used to construct these wells do not conform to those normally required for RI/FS monitoring wells (e.g., a geologic log and well construction information are available for each of the monitoring wells constructed for the FEMP). An effort was made to collect geologic and well construction information for each of the private wells. Drillers' logs and well completion records

FIGURE 3-4. LOCATIONS OF TYPE 4 WELLS CONSIDERED FOR BACKGROUND

were located for 12 of the candidate private wells. These logs show the total depth of the well, geologic materials encountered during drilling, well construction information, and well-yield tests in some cases.

A driller's log was not available for four other private wells; however, other records that specified total well depth were located. Based on well location and depth, two of the four wells (2121 and 2122) are completed in the Great Miami Aquifer and the two others (1059 and 1060) are completed in glacial overburden. Thus, total depth is known for 16 of the 18 candidate private wells. Wells without information on total depth or without a driller's log (1058 and 1124) were removed from the list of candidate wells. Drilling, geologic, and well construction information collected for the 16 private wells retained for background evaluation are presented in Appendix B and summarized in Table 3-2.

For two residential wells (2121 and 2122) located northeast of the FEMP (Figure 3-2), the total depths of the wells are known but the screened intervals are unknown. There is no glacial overburden present in this area, so there is no question that these two wells are screened in the Great Miami Aquifer. Total depths are known for two other wells (1059 and 1060, Figure 3-1), but again screen intervals are unknown. These wells are much shallower, so it is known that the formation in which the wells are completed is the glacial overburden. The screened intervals of all other wells used to characterize background groundwater quality are known, and are shown on well completion logs included in Appendix B.

Two wells considered were determined not to be representative of the geologic formations of interest. One FEMP well (1012) was drilled and screened into bedrock and another FEMP well (2754) has been screened in a clay and silty clay layer above the normally saturated portion of the Great Miami Aquifer. Since samples from these wells are not representative of the two geologic formations of interest, the wells have been deleted from consideration as background wells.

Wells for which no RI/FS water sample analytic data were available were deleted from the list of potential background candidates. These include wells 1009, 1015, 1679, 1754, and AW-1 (five wells total). Thus, a total of nine wells were excluded because the wells lack any analytical results or for physical reasons (i.e., lack of well log or constructed in geological materials not being evaluated). Four other wells were excluded that are located along Paddys Run Road on the western edge of the FEMP property (wells 2044, 2383, 2384, and 3044). These wells are west of Paddys Run, but are sufficiently close that they may be influenced by surface water that has recharged the Great Miami Aquifer. Additionally, well 4424, located toward the northeast corner of the FEMP property, is downgradient of the waste pit area and the former production area.

A total of eight other wells were excluded because of unusual water chemistry or questionable results of sample analyses. Table 3-3 shows examples of the "suspect" data. The first group of excluded wells (1011, 1052, and 2024) is located along the north edge of the waste pit and former production areas. These wells contain elevated levels of total uranium, sulfate, and occasionally iron. Presumably the contaminants originate from the waste pit area and are migrating in a east-northeast direction. The second group of excluded wells (2679, 3066, and 3679) is located in the northwest corner and along the north edge of the FEMP property. These wells contain elevated levels of sodium, chloride, iron, and ammonia. Since groundwater in the Great Miami Aquifer in this area is flowing in an east-southeast direction, these elevated concentrations must come from an off-site source to the northwest of the FEMP property. Other excluded wells (1728 and 1733) are relatively new wells completed in the glacial overburden which apparently were not adequately developed and purged prior to sampling. Data from sample analyses are therefore suspect.

The eight wells discussed in the preceding paragraph were deleted because water samples from these wells differed substantially from the rest of the wells being considered. The total number of remaining wells considered to represent background groundwater quality conditions is 29, 5 completed in the glacial overburden and 24 in the Great Miami Aquifer.

3.1.2.3 General Water Chemistry and Charge Balance

The next step for well selection involved a graphical display of water quality for the remaining wells. Trilinear diagrams were used for this purpose. The graphical displays of data were useful to judge the relative homogeneity of water chemistry within the various geological regimes of interest (e.g., glacial overburden and various tributaries of the Great Miami Aquifer).

The values of major cations (calcium, magnesium, sodium, potassium, and ammonium) and major anions (bicarbonate, sulfate, chloride, and nitrate) were tabulated for each of the remaining wells. When a sample had an analysis performed for each of the major ions (i.e., there were no missing values), then the ion concentrations were converted from milligrams per liter (mg/L) to milliequivalents per liter (meq/L) and a cation-anion balance was performed to check for electrical neutrality. In other words, the sum of the cation charges should be approximately equal to the sum of anion charges for an individual water sample. If any sample values were nondetects, these were assigned a value equal to one-half the detection limit. Charge balance error (Freeze and Cherry 1979) was computed as:

$$\text{Percent Error} = \frac{\sum \text{cations} - \sum \text{anions}}{\sum \text{cations} + \sum \text{anions}} \times 100$$

^aF = filtered sample; U = unfiltered sample

Tables in Appendix D list samples with the concentrations of major cations and anions in mg/L, meq/L, percent of totals, and the computed charge balance error. If the charge balance error for a sample was less than five percent, the sample point was plotted on a trilinear diagram, often referred to as a Piper plot (Piper 1944).

Data from 12 samples for the five glacial overburden wells (i.e., Type 1 wells) are plotted on Figure 3-5. As shown, the groundwater in the glacial overburden is dominated by the calcium and magnesium cations and the bicarbonate anion. Calcium usually constitutes 50 percent or more of the cations (based on equivalent values) and sodium plus potassium usually make up no more than 20 percent of the cation charge. Anions were dominated by bicarbonate ions (usually 80 percent or more of the anion charge). Chloride and sulfate ions were each usually less than 20 percent of the total anion charge for each sample. The clustering of the samples is relatively tight and implies that the water chemistry in the five wells is similar.

A trilinear diagram of general water chemistry in the Great Miami Aquifer (Figure 3-6) shows a pattern similar to the plot of water chemistry for the glacial overburden. The cation charge is dominated by calcium (45 to 75 percent) and magnesium (20 to 30 percent). Sodium plus potassium values are usually less than 30 percent of the total cation charge. Bicarbonate is the largest component of the anions, generally ranging from 45 to 70 percent. Sulfate and chloride each range from 20 to 30 percent of the total anions. As with the glacial overburden background data, the clustering of the data for the Great Miami Aquifer is relatively tight. This implies that the water chemistry in the 24 wells is similar.

3.1.2.4 Summary

Through the screening process described in this section, two wells were excluded because no driller's log or well depth record could be located, two wells were excluded because they were not representative of the geologic formations of interest, five wells were excluded because RI/FS sample data are not available, four wells were excluded because of proximity to Paddys Run and the possibility of influence by surface water infiltration, one well was excluded because it is downgradient of FEMP waste pit and former production areas, and eight wells were excluded either because of inadequate well development, unusual water chemistry, or relatively high total uranium concentrations were present in samples from the wells.

Of the 51 wells initially considered, a total of 29 wells have been retained to characterize background groundwater quality. Five of the wells are completed in the glacial overburden and 24 are completed in the Great Miami Aquifer (Table 3-4). The five wells used to represent the glacial overburden (1024, 1040, 1059, 1060, and 1065) are the same five wells that were used for the draft report. For the Great Miami Aquifer, three wells (2383, 2384, and 3044) used during preparation of the draft report were eliminated because they might be affected by surface water recharge from Paddys Run.

Table 3-4
Wells Used to Characterize Background Groundwater Quality

General Area	FEMP Wells	Private Wells
Glacial overburden	1024, 1065	1040, 1059, 1060
Northeast of the FEMP (Ross section, Great Miami Aquifer)	2098, 3098	2026, 2121, 2122, 3063, 3099, 3100
North and northwest of the FEMP (Shandon section, Great Miami Aquifer)	2043, 2066, 2728, 3024, 3043, 4011	2050, 2056, 2105
West of Paddys Run (Dry Fork Section, Great Miami Aquifer)	2096, 3096, 4096	2036, 2057, 2104, 2123
Usable background wells	13	16

NOTE: Type 1 wells are completed in the glacial overburden; Type 2, 3, and 4 wells are completed in the Great Miami Aquifer.

However, well 2728 was added because new data became available (no data existed for the well prior to 1993). Well 2105 was excluded during preparation of the draft report because of one questionable sample. However, the data for other samples from well 2105 indicate that it has chemical characteristics similar to other wells completed in the Great Miami Aquifer. Therefore, this well has now been included in the group of background wells. Altogether, there is a net decrease of one well representing the Great Miami Aquifer.

3.2 SAMPLE COLLECTION

Methods for purging wells and sampling groundwater are specified in the Quality Assurance Project Plan (QAPP) of the RI/FS Work Plan (DOE 1988b) and Appendix K of the Site-wide CERCLA Quality Assurance Project Plan (SCQ) (DOE 1992b). RI/FS monitoring wells were purged by removing three well volumes from each well, if possible, before sampling occurred. Samples were collected with bailers or pumps. For private wells, direct access to the well was not possible. Hence, a spigot or tap in the distribution line closest to the well was generally opened and allowed to flow for a few minutes before a sample was collected.

Surface water samples were collected in large grab bottles from slightly below the water surface; aliquots of the sample were then transferred to the necessary sample bottles.

When samples were collected for filtered metals or filtered radionuclide analyses, the samples were passed through a 0.45- μ m membrane filter before being placed in sample bottles. Most metal samples were filtered in the field, and the majority of metals data represent dissolved concentrations. In addition to the filtered metal samples, a portion of the samples were not filtered. These data were primarily collected during 1993 so that total metal concentrations could be quantified. For radionuclide analyses, the majority of samples collected prior to 1993 were not filtered. A portion of samples were filtered yielding dissolved concentrations; this occurred primarily in the 1993 field programs. For both metals and radionuclide data, the dissolved and totals data have been kept separated and statistical evaluation of each group has been performed independently.

For a water quality sample, it is expected that dissolved concentrations will be less than or approximately equal to the total concentration for each corresponding constituent. As mentioned previously, there are much more filtered than unfiltered metals data. In addition, the data are not representative of the same time period; filtered metals data were collected from 1988 to 1993, whereas most of the unfiltered metals data were from 1993. The opposite is true for the radiological data; i.e., much more unfiltered radiological data exists than filtered data, and the filtered radiological data were collected primarily in 1993. For these reasons, the statistics (e.g., mean, median, UCL) calculated for filtered parameters may in some cases exceed the corresponding statistics of the unfiltered parameter.

3.3 ANALYTICAL PROCEDURES

Measurements of pH, specific conductance, and dissolved oxygen were performed in the field immediately before a sample was collected. In a field study conducted from 1988 through 1989, alkalinity titrations were performed on a sample aliquot within 24 hours of sample collection. Alkalinity was also analyzed at off-site laboratories.

Water samples were analyzed for chemical and radiological constituents using procedures specified in Tables 4-1, 4-2, and 4-3 of the QAPP and Appendix G of the SCQ. Most of the metals were analyzed using an inductively coupled argon plasma (ICAP) emission spectrometer. The method detection limits for several metals (antimony, arsenic, lead, molybdenum, selenium, and thallium) for ICAP are relatively high. Therefore, these metals were also analyzed by atomic absorption spectrometry with graphite furnace (AAS/GF) methods. In many cases these metals were analyzed using both methods. The cold vapor hydride method was used for mercury analyses.

Radiological analyses were performed by using contract laboratory standard operating procedures. Performance-based criteria were specified to the laboratories and acceptance windows were specified for detection limits, percent overall tracer/chemical recovery, method blank concentration, and laboratory-control sample values. The data validation process involved reviewing the reported data and comparing it to the performance-based requirements.

3.4 DATA VALIDATION PROCEDURES

All data used to calculate background water quality values in this report have been validated. Data validation is an after-the-fact, independent, systematic process of: evaluating data, comparing it to preestablished criteria, providing confirmation that the data are of the technical quality necessary to meet its intended use, and assuring that a defensible "road map" can be established to trace each sample from the time it is collected in the field to its ultimate end use. Data quality objectives (DQOs) address five principal parameters: precision, accuracy, completeness, comparability, and representativeness. To verify that these objectives are met and to determine compliance with appropriate and applicable procedures, the validation process examines: field measurements and quality control, sampling and handling procedures, laboratory analysis and reporting, and any nonconformances and discrepancies in the data. Data qualifiers are assigned to the analytical data to alert the user to any limitations placed on the data due to the quality assurance/quality control (QA/QC) requirements.

For the chemical data, the guidelines and protocol used to validate the data are consistent with U.S. National Functional Guidelines for Organic and Inorganic Data Review, and with the FEMP RI/FS data validation criteria. The radiological data were validated by project-specific criteria developed to review the data, since neither EPA, DOE, nor the Nuclear Regulatory Commission have issued

guidelines for radiological data validation. The criteria have been through an extensive peer review and are consistent with the procedures used to validate the chemical data for the RI/FS.

In general, the data were evaluated based on the following parameters:

- Sample holding times
- Instrument tuning
- Initial instrument calibration
- Continuing instrument calibrations
- Surrogate recoveries
- Matrix spike recoveries
- Blank contamination
- Internal standard response
- Linearity
- Retention time shift
- Detection limits
- Accuracy of calculations
- Internal calibration standards
- Method of standard addition
- Continuing calibration standards
- Laboratory control sample
- Serial dilutions

Definitions of qualifier codes which were assigned by the laboratories or through validation for radiologic, inorganic, and organic data are presented in Appendices C, D, and E, respectively.

3.5 VALIDATED AND DELETED DATA

All RI/FS data available for the 29 background wells, sample point W-1 on the Great Miami River, and sample point W-5 on Paddys Run have been through the data validation process. The data were downloaded from the primary database at the FEMP and were separated into numerous categories. The validated radiologic, inorganic, and organic analytical data are presented in Appendices C, D, and E, respectively. All data that failed validation or for which validation was not completed have been listed in separate tables in Appendices C, D, and E. These data were not used for any of the statistical analyses. Field measurements, including dissolved oxygen, pH, and specific conductivity were retained for this study, although the data were not formally validated. These data are found in Appendix D.

The validated data set served as the basis for the characterization of background water quality presented in this report. Besides removing nonvalidated data, several additional steps were taken to modify the validated data set prior to the calculation of background statistics:

- Removal of high nondetect data
- Removal of outliers
- Averaging of replicate samples

These three steps are described in Sections 4.2.2, 4.2.3, and 4.2.4.

4.0 DATA SET MODIFICATIONS AND STATISTICAL ANALYSIS PROCEDURES

4.1 OVERVIEW

Background characteristics of water quality in four different hydrological entities are being evaluated, including two streams (Great Miami River and Paddys Run) and two hydrostratigraphic units (Great Miami Aquifer and glacial overburden). Each of these may have its own individual characteristics. The development and statistical evaluation of the background water quality data set occurred in three general steps.

Step 1 involved development of the initial background data set. This step included: selecting potentially usable sampling locations (surface water and groundwater); compiling all available data from the primary database of the FEMP that pertain to the selected locations; deleting nonvalidated data from the data set; and using available chemical data and physical information to choose the most appropriate sampling locations. The approach and procedures used in selecting the representative sampling sites have been discussed in Chapter 3. The outcome of Step 1 was a large data file containing all validated analytical data for the sampling sites chosen.

Step 2 involved further evaluation of the data set and removal of data that could potentially cause bias in the statistical results. This included removing high nondetect values and data outliers and averaging replicate sample results. The procedures used to identify and delete these data are discussed in succeeding sections of this chapter. The outcome of Step 2 was a modified data set that contained only data that were usable and appropriate for background water quality characterization.

Step 3, statistical evaluation of the final background water quality data set, involved the selection and performance of statistical procedures appropriate for background characterization. These included tests for normal and lognormal distribution of data groups, parametric descriptive statistics, nonparametric descriptive statistics, and comparisons of populations. The rationale for the statistical design and the overall evaluation approach is described in the latter part of this chapter.

Step 1 (development of the background data set) was described in Chapter 3. Chapter 4 is devoted to describing how the initial data set was modified (Step 2) and how it was statistically analyzed (Step 3). EPA guidance regarding statistical procedures for data analysis has been followed to the fullest extent possible.

4.2 MODIFICATIONS OF THE BACKGROUND DATA SET

The initially compiled background data set was modified in five different ways:

- All nonvalidated data were removed.

- High nondetect data were identified and deleted.
- Values for remaining nondetect samples were set equal to one-half the detection limit.
- Outlier data were identified and deleted.
- Data from multiple samples collected during the same sampling event were averaged together.

Each of these modifications was essential in order to create a background data set that contained only usable, representative data.

4.2.1 Treatment of Rejected/Nonvalidated Data

All rejected/nonvalidated data were removed from the background data set; these data are listed in Appendices C, D, and E for radiological, inorganic, and organic parameters, respectively. Rejected data are data that have been identified through validation as being either unreliable or unusable. Nonvalidated data are data that have not been through the validation process described in Section 3.4. The validated data were then divided into the following data groups for each of the four hydrologic entities:

- Unfiltered radiological data
- Filtered radiological data
- Filtered inorganic data
- Unfiltered inorganic data
- Unfiltered organic data

Field measurements, including dissolved oxygen, pH, and specific conductivity, were retained for this study, although the data were not formally validated. These data are included in Appendix D along with the inorganic data.

4.2.2 Treatment of Nondetect Data

Nondetect data that had unusually high detection limits were removed from the background data set. High nondetect data were data with detection limits unusually high relative to detected values or other nondetect data in the same data group. As an example, results of lead analyses using ICAP emission spectrometry typically yielded detection limits of 50 to 200 $\mu\text{g/L}$. However, analyses using AAS/GF typically yielded detection limits of 5 $\mu\text{g/L}$ or less. Detected values were almost always less than 50 $\mu\text{g/L}$ (lowest detection limit of ICAP) and usually less than 15 $\mu\text{g/L}$ (maximum contaminant level) specified by EPA drinking water regulations).

Hence, the nondetect lead data with a detection limit of 50 $\mu\text{g/L}$ or higher do not provide useful information concerning lead concentrations in the background water. The high lead nondetect data would actually bias the statistical characteristics of background water quality upward toward higher

lead concentrations. Thus, these data needed to be removed in order to more accurately estimate the distribution of lead concentrations in background water. The same situation existed for arsenic, barium, selenium, and thallium. Other inorganic, organic, and radiological parameters also had detection limits that, on occasion, were unusually high relative to the other data in the same group.

The procedure that was followed in order to identify and delete high nondetect data was to:

- Sort the data in each group from high detect to low detect values, and high nondetect to low nondetect values.
- The nondetect "values" were all set equal to one-half the detection limit.
- If the high nondetect "values" (i.e., one-half the detection limit) exceeded the median of the detect values, then the high nondetects were generally removed from the background data set; a few exceptions occurred based on subjective professional judgment (e.g., too few values would remain in the data group).
- If there were no detect values in a data group but one or more high nondetect "values" greatly exceeded the remainder of the nondetect data, then these high nondetect data were removed from the background data set.

The data that have been excluded as high nondetects are listed in Appendices C, D, and E for radiological, inorganic, and organic data, respectively. There were no nondetect data for field measurements. For all nondetect data which remained in the background data set, the sample was assigned a "value" equal to one-half the detection limit for the purpose of performing statistical analyses.

4.2.3 Identification and Treatment of Outliers and Other "Suspect" Data

As discussed above, each group of data (e.g., filtered calcium data, glacial overburden data set) was sorted according to value — high detects to low detects and then high nondetects to low nondetects. Unusually high or low detect values were identified and these selected values were then checked against the original data package to ensure that the data had been properly entered into the database. Data that were not properly entered into the database were corrected. There were very few such data that required corrections. The remainder of the "suspect" data were considered to be potential outliers. These potential outliers were handled using "Rosner's Test for Many Outliers" (Gilbert 1987) or subjective professional judgment.

"Rosner's Test for Many Outliers" (maximum of 10 outliers) is a statistical test to determine if data fall outside the range of values expected for a normally distributed sample population. Those data that fall outside the expected distribution are likely the result of sampling error, analytical error, or unusual conditions that existed at the location or time that the sample was collected. Thus, such data are probably not representative of background conditions. If the data are lognormally distributed,

000060

computations are performed on the log-transformed data. The method is a two-tailed test and identifies both high and low outliers.

When a group of data had 25 or more data points and was normally or lognormally distributed, Rosner's Test was used to determine if the identified potential outliers were true outliers. All detect data positively identified as outliers from the Rosner's test were discarded from the background data set. However, only a few potential outliers could be evaluated using Rosner's test, either because the "outliers" were in groups that were not normally or lognormally distributed or because the data groups did not contain 25 or more data values. Rosner's test is described in more detail in Appendix F.

Potential outliers from groups of data that could not be evaluated using Rosner's test were evaluated using subjective professional judgment. A group of Fernald Environmental Management Corporation (FERMCO) staff and consultants reviewed the potential outliers and the corresponding data groups. The potential outliers were either retained or deleted from the background data set based on the group's collective professional judgment. In general, if a potential outlier was more than twice the next highest value, then it was discarded. However, consideration was also given to the distribution of all data within the data group being evaluated.

The preceding discussion focused on the evaluation of individual potential outliers. However, in a few cases, there were several outliers that came from the same well on the same date. Sample 3782 from well 2105 had nondetect calcium, nondetect magnesium, and high concentrations of sodium and chloride. These results were extreme outliers. As a consequence, the entire sample was considered suspect and all the inorganic and organic data from this sample were discarded. Two additional samples with high total uranium and uranium isotope values were sample 3096 from well 3024 and sample 30929U1060-3 from well 1060. All other samples from these two wells had total uranium concentrations and isotopic activities that were far below the levels found in the two questionable samples. Therefore, it was determined that the uranium levels in these two samples were not representative of background conditions. All radiological data that originated from these two samples were deleted from the background data set.

Another evaluation was conducted to determine whether total uranium values corresponded to isotopic values and whether isotopic values were in equilibrium. Assuming isotopic equilibrium conditions, the activity levels of uranium-234 and uranium-238 should be approximately equal in each sample. In addition, the total uranium value (in $\mu\text{g/L}$) should be approximately three times greater than the uranium-234 or uranium-238 activity level (in pCi/L [picocuries per liter]). There were a few cases where high total uranium concentrations did not have the corresponding high values of isotopic activities, and vice versa. There were also a few cases where the isotopic values (uranium-234 and

uranium-238) did not agree with one another. These data were evaluated by the FERMCO staff and consultants and data judged to be unacceptable were withdrawn from the background data set.

All radiological, inorganic, and organic data that were discarded as outliers (either using Rosner's test or subjective professional judgment) are listed in Appendices C, D, and E, respectively.

4.2.4 Data Averaging

On several occasions, two or more samples were collected at the same sampling location during the same sampling event (i.e., duplicates, triplicates, etc.). This was particularly true for surface water sampling locations W-1 and W-5 in 1993, when multiple samples were commonly collected. In order to avoid statistical bias, results from the multiple samples were averaged together (arithmetic mean) for each site and date whenever multiple sample data existed. Nondetect values were assigned a value of one-half the detection limit for computing the averages. If all the values being averaged were nondetects, then the average value was also a nondetect value. If one or more of the values being averaged were detect values, then the resulting average was also considered to be a detect value. Example computations are provided in Appendix F. The overall effect of this procedure was to condense the statistical data set so that only one "sample" result exists for any given sampling location and date.

4.3 STATISTICAL ANALYSIS

4.3.1 Testing of Data Distribution

The groups of data analyzed by parametric statistical procedures were data sets that had a sufficient number of detects and a sufficient frequency of detection such that the data could be tested to determine if they were normally or lognormally distributed. If a data set could be shown to follow a normal or lognormal distribution, conventional parametric statistical procedures were employed to evaluate the data.

There is no formal consensus within the scientific community as to a clear-cut separation between the use of parametric and nonparametric statistics. Ideally, parametric statistical analysis of data should be performed on data sets with few or no nondetect values. However, when evaluating concentrations of contaminants in environmental media, one must often cope with a variable proportion of nondetect data (Gilbert 1987). EPA (1989b) guidance suggests that a 50 percent frequency of detection be used as a criterion for separating parametric from nonparametric analyses, but also states: "These values are not hard and fast rules but are based on judgment." The guidance further states: "There are a variety of ways to deal with data that include values below detection. There is no general procedure that is applicable in all cases... The meaning of small, moderate, and large (amounts of nondetect data) is subject to judgment."

Normality testing and calculation of parametric descriptive statistics were performed on data having at least 40 percent detections and at least six detected values. A 40 percent cut-off point was selected instead of a 50 percent cut-off point because some of the important contaminants of concern at the FEMP were often present at 40 to 50 percent frequency of detection.

Whenever there was at least a 40 percent frequency of detection in a data set with at least six detections, a statistical test was performed to determine if the data were normally or lognormally distributed. The Shapiro-Wilk or Shapiro-Francia test was used to test for normality. The procedures for these tests are described in EPA (1992) guidance and are summarized in Appendix F. The "Shapiro-Wilk Test of Normality" was used when the number of data values was less than or equal to 50; the Shapiro-Francia test was used when the number of data values was greater than 50. Each of these tests for normality calculates a statistic (W or W'), which is then compared against a critical value (W_{crit}) to determine whether the data are normally or lognormally distributed. If the calculated statistic exceeded the W_{crit} value, then the data group was assigned one of the first four distributions listed below (i.e., N , L , N^* , or L^*).

In many cases, the results showed that a data set was neither normally nor lognormally distributed. However, the test statistic was often close to the critical value for either the normal or lognormal distribution. If a data population did not rigorously qualify as having a normal or lognormal distribution, it was classified as having a "qualified" normal (NQ) or lognormal (LQ) distribution if the calculated statistic (W or W') was less than W_{crit} but greater than $0.95 W_{crit}$. If the calculated statistic was less than $0.95 W_{crit}$, then the data group was labeled as having an undefined distribution (U). Examples of the Shapiro-Wilk and Shapiro-Francia testing and the critical values for accepting normality or lognormality are included in Appendix F.

An additional test was implemented to check whether a data group was lognormally distributed. If a data group passed the Shapiro-Wilk or Shapiro-Francia test for lognormal distribution and had a log variance value less than 2.0, then lognormal distribution was assigned to the data group. However, for a few data groups, the log variance was greater than 2.0. For this situation, the data distribution was considered to be undefined (U) irrespective of the results of the Shapiro-Wilk or Shapiro-Francia test.

As statistical results are presented in succeeding chapters, the following abbreviations are used to show the results of the distribution tests:

- N = Normal distribution accepted
- L = Lognormal distribution accepted

- N^* = Both normal and lognormal distributions tested positive, but normal distribution was a better fit
- L^* = Both normal and lognormal distributions tested positive, but lognormal distribution was a better fit
- NQ = Normal distribution, approximately
- LQ = Lognormal distribution, approximately
- U = Distribution undefined

Parametric statistics were computed for all data groups that fully or approximately satisfied normal or lognormal distribution criteria (i.e., data groups labeled N , L , N^* , L^* , NQ , and LQ). The data groups that fell into the undefined distribution (U) category include all those that had less than 40 percent detection frequency or less than six detections. The U category also includes a few data groups that were tested for normal or lognormal distribution, but failed to satisfy the specified distribution criteria. Nonparametric statistics were computed for data groups with undefined distributions.

4.3.2 Parametric Descriptive Statistics

A set of descriptive statistics was calculated for each parameter in each appropriate data group. For data groups with normal distribution (i.e., N , N^* , and NQ), these statistics included minimum values (detect and nondetect), maximum values (detect and nondetect), arithmetic mean, standard deviation, coefficient of variation, one-sided 95 percent UCL, and 95th percentile. For data groups with lognormal distribution (i.e., L , L^* , and LQ), a slightly different set of statistics was calculated. These statistics included minimum values (detect and nondetect), maximum values (detect and nondetect), estimated mean of a lognormal distribution, estimated standard deviation of a lognormal distribution, one-sided 95 percent UCL, and 95th percentile. The formulas used to calculate each of these statistics are included in Appendix F. An additional check was performed on the calculated UCLs. If the calculated UCL exceeded the maximum detected value for a data group, then the UCL was changed to the maximum detected value.

4.3.3 Nonparametric Descriptive Statistics

If the number of detect values in a data group was less than six or the frequency of detection was less than 40 percent, then testing of data distribution or computation of parametric statistics was not possible or appropriate and the data group was determined to be undefined. As discussed earlier, the distributions for some additional data groups were also found to be undefined. For the data groups with undefined distribution, only nonparametric descriptive statistics were computed. These statistics included minimum values (detect and nondetect), maximum values (detect and nondetect), median,

one-sided 95 percent UCL, and 95th percentile. The formulas used to calculate each of these statistics are included in Appendix F.

4.3.4 Comparison of Populations

Comparisons of populations were conducted to determine whether data subgroups that could potentially be combined have similar variances or means. When conducting comparisons of two data subgroups with defined distributions (normal or lognormal), the F-test and t-test were used. The F-test compares the variances of the two subgroups while the t-test compares the means. For comparing two data subgroups with nonparametric distributions, the Wilcoxin Rank Sum test was utilized. The Kruskal-Wallis test was utilized when comparing three data subgroups.

F-Test and t-Test

The F-test and t-test are common statistical procedures used to determine whether two sample populations have similar variance and means, respectively. If so, the two groups could be considered part of one population. These tests were applied (with $\alpha = 0.05$) to several parameters in FEMP and private glacial overburden wells to determine if the data were part of the same population (i.e., statistically not different). Examples from these procedures are presented in Appendix F.

Wilcoxin Rank Sum Test

The Wilcoxin Rank Sum test is a procedure which can be used to determine whether two sample groups with undefined distributions have equivalent means. This test assumes that the distributions of the two populations are identical in shape (variance), but the distributions need not be symmetric. In general, the Wilcoxin Rank Sum test was employed whenever the proportion of nondetects was greater than 15 percent, but less than 90 percent. This test was used for comparing FEMP and private wells in the glacial overburden. Example calculations are presented in Appendix F.

Kruskal-Wallis Test

The purpose of the Kruskal-Wallis test is to determine whether three or more sample groups have equivalent means. The Kruskal-Wallis test does not require that the sample groups have normal or lognormal distributions or even be symmetric. Therefore, the Kruskal-Wallis test can be used to evaluate the equivalency of means from three or more sample groups with undefined data distributions. This test was used for comparing total uranium data subgroups from the Ross, Shandon, and Dry Fork sections of the Great Miami Aquifer. Example calculations are presented in Appendix F.

4.4 SUMMARY OF REVISIONS TO CHAPTER 4 OF THE DRAFT REPORT

This chapter describes the procedures used to modify and statistically evaluate the background data set. These procedures have changed somewhat from the draft "Background Water Quality" report. The changes are summarized here and are described in more detail in Appendix G.

In general, data that did not pass through the validation process (i.e., nonvalidated data) were removed from the background data set, as was done previously. High nondetect data were also identified and removed, as was done previously. For this report, additional data were removed from the background data set if they were determined to be data outliers, using either Rosner's test or subjective professional judgment as a basis. The outliers constituted only a small percentage of the total background data set, albeit greater than previously. By removing the outlier data, it is believed that the remaining data (i.e., the background sample population) more accurately represent true background conditions.

Another way in which the initial background data set was manipulated prior to statistical analysis was data averaging. This occurred when more than one sample was collected and analyzed for the same location and sampling event (i.e., duplicates, triplicates, etc.). These data values were averaged so that only one set of values represented a given location and date. This procedure was not applied previously.

Once the background data set was finalized, some changes were made to the way in which data groups were evaluated. Four types of data groups were evaluated in the draft report: Pathway 1 - normal distribution; Pathway 1 - lognormal distribution; Pathway 2 - undefined distribution; and Pathway 3 - undefined distribution. In this report, only three types of data groups are evaluated: normal distributions, lognormal distributions, and undefined distributions. A standard set of descriptors for data groups is presented in Section 4.3.1.

In this revised report, the number of descriptive statistics calculated and reported for each data group has been reduced. Only those statistics that are appropriate for a given data distribution and needed for the purposes of the ongoing RIs have been included. For normally distributed data, only arithmetic mean, standard deviation, coefficient of variation, one-sided 95 percent UCL, and 95th percentile have been presented in this report. For lognormal distributions, only estimated mean, standard deviation, one-sided 95 percent UCL, and 95th percentile have been presented. For undefined distributions, only median, one-sided 95 percent UCL, and 95th percentile have been reported. These statistics for background water quality have the most utilitarian value for the purpose of RI report preparation.

000066

5.0 GLACIAL OVERBURDEN

This chapter presents the results of radiological and chemical analyses of groundwater samples collected from background water quality wells in the glacial overburden. As described in Chapter 3, the process by which the five glacial overburden background wells (two FEMP, three private) were selected involved a careful review of all available data, including development of trilinear diagrams. The relatively tight clustering of data evident in Figure 3-5 indicates that the water chemistry in the background wells is similar. This view is supported by population comparison tests of data from FEMP and private wells for several parameters.

However, as was true for the data utilized in the previous draft report (May 1993), there do seem to be differences in the FEMP and private well data "population" for the important parameter total uranium (unfiltered). Table 5-1 shows a comparison of statistics computed for total uranium using FEMP, private, and combined glacial overburden background well data. Based on these results, and in keeping with the approach used previously, only data from private wells are used to calculate statistics to characterize background for total uranium in the glacial overburden. Additionally, because total uranium is the summation of isotopic uranium activity, background statistics for these parameters are also calculated using only data from the private wells. In contrast to total and isotopic uranium, other radiological (or chemical) values for the FEMP wells in the background data set do not appear to be anomalous and there is no apparent reason to exclude them from calculating glacial overburden background water quality statistics.

5.1 RADIOLOGICAL CONSTITUENTS

The background wells were sampled and analyzed for 17 different unfiltered and 10 different filtered radiological parameters. The number of validated analytical values in the background data set for unfiltered parameters ranged from 10 to 26; for filtered parameters, the number of validated values ranged from 1 to 4. Total uranium, uranium-234, and uranium-238 had the highest detection frequencies among the unfiltered parameters, ranging from 50 to 70 percent frequency of detection.

The descriptive statistics calculated for the 17 unfiltered radiological constituents in the glacial overburden are presented in Table 5-2. The maximum detected value for total uranium was 1.5 $\mu\text{g/L}$. The average total uranium value was 0.54 $\mu\text{g/L}$. After total uranium, uranium-234, and uranium-238, the other unfiltered radiological parameters that have the highest detection frequencies were radium-226 (41 percent), thorium-228 (46 percent), and thorium-230 (44 percent). Several of the unfiltered radiological parameters had two or less detected values (cesium-137, plutonium-238, plutonium-239/240, ruthenium-106, strontium-90, total thorium, and uranium-235/236).

Statistics for the filtered parameters are presented in Table 5-3. The amount of validated filtered radiological data for the glacial overburden is much less than the quantity of unfiltered data. This is

because filtered radiological data were not routinely collected for the glacial overburden background wells prior to 1993. No validated data were available for the following filtered radiological parameters: cesium-137, neptunium-237, plutonium-238, plutonium-239/240, ruthenium-106, strontium-90, total thorium, and uranium-235/236. A maximum of four data values were available for the filtered radiological constituents analyzed.

No data for filtered total thorium were present in the FEMP database. However, total thorium is not an analyzed value but a calculated value equal to 9.17 times thorium-232 activity. Thorium-232 constitutes the primary percentage (by mass) of all thorium in nature. The total thorium statistics in Table 5-3 have been derived by multiplying the thorium-232 statistics by the 9.17 conversion factor.

5.2 INORGANIC CONSTITUENTS

Table 5-4 presents summary statistics for filtered inorganic constituents in the glacial overburden background wells. As discussed in Chapter 3, calcium is the dominant cation in the groundwater, followed by magnesium and sodium. According to the Shapiro-Wilk test, the population distributions of these three constituents are lognormal or near lognormal. Two other filtered constituents (manganese and potassium) also had lognormal distributions. The remaining 22 filtered constituents had undefined distributions, because they either did not pass the Shapiro-Wilk test or because they had too few detect values to allow normality testing. Only nonparametric descriptive statistics are presented for the parameters with undefined distributions.

Table 5-5 presents summary statistics for unfiltered inorganic constituents in the glacial overburden background wells. The unfiltered parameters list includes the constituents shown in Table 5-4, plus additional parameters (alkalinity, ammonia, chloride, nitrate, nitrate/nitrite, phosphorus, sulfate, sulfide, total kjeldahl nitrogen (TKN), and total solids) which are primarily anions and nutrients.

Two unfiltered parameters (nitrate and sulfate) were found to have normal distributions. Two other parameters (fluoride and phosphorus) had lognormal distributions. All the other unfiltered parameters, including the unfiltered metals data, had undefined distributions. A maximum of five values exist for each of the unfiltered metals (all collected during the 1993 field programs), which is the reason no normality testing could be performed on these data groups.

Three parameters were measured in the field for the glacial overburden, dissolved oxygen, pH, and specific conductivity. The number of measurements for these parameters ranged from 22 to 30 and they are each lognormally distributed. Descriptive statistics for these parameters are listed in Table 5-6.

5.3 ORGANIC CONSTITUENTS

Three samples collected from the glacial overburden background wells in 1988 and 1989 were analyzed for volatile organic compounds (VOCs); five additional samples were collected and analyzed in 1993 (one sample and one duplicate for each of the five wells). No VOCs were detected in any of the samples or duplicates. One sample from well 1065 has been analyzed for semivolatile organic compounds (SVOCs), organophosphorus pesticides, pesticides, and polychlorinated biphenyls (PCBs). No detects were found for these analyses.

The five glacial overburden background wells have been sampled and analyzed a number of times for phenols, total organic carbon (TOC), total organic halides (TOX), and total organic nitrogen (TON). Summary statistics for validated data for these parameters are given in Table 5-7. Of the 21 values for phenols, the maximum detected value was 0.03 mg/L. Seven samples were analyzed for TOC. The maximum TOC concentration found was 9 mg/L. Of the 16 validated analyses of TOX, only 3 were detections. The maximum detected value was 0.126 mg/L. Twenty validated analyses were available for TON, with a maximum detected value of 1.35 mg/L.

Table 5-1
Summary Statistics of Unfiltered Total Uranium for Background
Monitoring Wells in the Glacial Overburden

Statistics	Private wells	FEMP Wells	Combined Wells
No. of analyses	15	10	25
No. of detections	8	9	17
Detection frequency (%)	53	90	68
Minimum Detection	0.48	0.5	0.48
Maximum Detection	1.5	3.9	3.9
Minimum Nondetect	< 0.1	N/A	< 0.1
Maximum Nondetect	< 0.55	< 0.1	< 0.55
Distribution	NQ	N	U
Normal			
Mean	0.54	1.4	N/A
Standard deviation	0.47	1.1	N/A
Coefficient of variation	0.87	0.75	N/A
95% UCL	0.75	2.0	N/A
95th Percentile	1.3	3.2	N/A
Lognormal			
Mean	N/A	N/A	N/A
Standard deviation	N/A	N/A	N/A
95% UCL	N/A	N/A	N/A
95th Percentile	N/A	N/A	N/A
Nonparametric			
Median	N/A	N/A	0.76
95% UCL	N/A	N/A	1
95th Percentile	N/A	N/A	2

Note:

- (1) Concentrations are reported in ug/L
- (2) N/A = Not applicable.
- (3) Distribution types: N = Normal, L = Lognormal, N* = Normal (but also passed Lognormal test), L* = Lognormal (but also passed Normal test), NQ = Qualified Normal, LQ = Qualified Lognormal, U = Undefined.
- (4) Mean types: Normal = arithmetic mean, Lognormal = estimated mean of a lognormal distribution.
- (5) Standard deviation types: Normal = arithmetic standard deviation, Lognormal = estimated standard deviation of a lognormal distribution.

Summary Statistics of Unfiltered Radiological Constituents for
Background Monitoring Wells in the Glacial Overburden

Statistics	Thorium-232	Total Uranium	Uranium-234	Uranium-235/236	Uranium-238
No. of analyses	14	15	13	13	13
No. of detections	3	8	9	0	9
Detection frequency (%)	21	53	69	0	69
Minimum Detection	0.2	0.48	0.25	N/A	0.23
Maximum Detection	0.34	1.5	1.1	N/A	0.99
Minimum Nondetect	< 0.1	< 0.1	< 0.1	< 0.1	< 0.1
Maximum Nondetect	< 0.32	< 0.55	< 1	< 0.27	< 1
Distribution	U	NQ	N	U	N*
Normal					
Mean	N/A	0.54	0.44	N/A	0.39
Standard deviation	N/A	0.47	0.28	N/A	0.25
Coefficient of variation	N/A	0.87	0.64	N/A	0.66
95% UCL	N/A	0.75	0.58	N/A	0.51
95th Percentile	N/A	1.3	0.90	N/A	0.80
Lognormal					
Mean	N/A	N/A	N/A	N/A	N/A
Standard deviation	N/A	N/A	N/A	N/A	N/A
95% UCL	N/A	N/A	N/A	N/A	N/A
95th Percentile	N/A	N/A	N/A	N/A	N/A
Nonparametric					
Median	< 0.20	N/A	N/A	< 0.18	N/A
95% UCL	< 0.32	N/A	N/A	< 0.22	N/A
95th Percentile	0.34	N/A	N/A	< 0.27	N/A

Note:
 (1) Concentrations are reported in pCi/L except Total Thorium and Total Uranium, which are in ug/L.
 (2) N/A = Not applicable.
 (3) Distribution types: N = Normal, L = Lognormal, N* = Normal (but also passed Lognormal test), L* = Lognormal (but also passed Normal test), NQ = Qualified Normal, LQ = Qualified Lognormal, U = Undefined.
 (4) Mean types: Normal = arithmetic mean, Lognormal = estimated mean of a lognormal distribution.
 (5) Standard deviation types: Normal = arithmetic standard deviation, Lognormal = estimated standard deviation of a lognormal distribution.

6.0 GREAT MIAMI AQUIFER

This chapter presents the results of radiological and chemical analyses of groundwater samples collected from wells selected as representative of background water quality in the Great Miami Aquifer. As described in Chapter 3, the process by which the 24 Great Miami Aquifer background wells (8 Ross, 9 Shandon, 7 Dry Fork) were selected involved a careful review of all available data, including development of trilinear diagrams. The relatively tight clustering of data evident in Figure 3-6 indicates that the water chemistry in the background wells is similar.

Therefore, it is reasonable to calculate one set of background water quality statistics for the Great Miami Aquifer by combining data from the three sections (Ross, Shandon, Dry Fork) that contribute to groundwater flow in the vicinity of the FEMP. Statistics computed utilizing these combined data are provided in this chapter. For comparative purposes, similar statistics for each of the tributaries are included in Appendix H.

As noted previously, a significant amount of data was collected in 1993 field programs. After review of new Great Miami Aquifer radiological data, it appears that the radiological water chemistry of well 2098 is being affected by runoff from the FEMP. Of the wells chosen to represent Great Miami Aquifer background water quality, well 2098 had the highest unfiltered and filtered total uranium results, 5.1 and 4.6 ug/L, respectively. Surface water samples were also collected in 1993 from a drainage ditch directly north of well 2098. Replicate samples were taken, with the highest unfiltered and filtered total uranium results being 13.9 and 13.6 ug/L, respectively, thus indicating the possibility of the FEMP affecting the values measured for radiological parameters for samples collected from well 2098. Therefore, in order not to bias statistical computations, radiological constituents from well 2098 have been removed from the background data set.

Table 6-1 shows a comparison of descriptive statistics for the important parameter unfiltered total uranium after the removal of data from well 2098. The statistical results for the tributaries of the Great Miami Aquifer are very similar.

6.1 RADIOLOGICAL CONSTITUENTS

The Great Miami Aquifer background wells were sampled and analyzed for 17 unfiltered and filtered radiological constituents. Summary statistics for the unfiltered constituents are presented in Table 6-2. The number of validated data available for unfiltered constituents ranged from 50 to 115.

The detection frequency varied for Great Miami Aquifer radiological constituents. Ruthenium-106 was not detected in any sample and many other unfiltered constituents (cesium-137, neptunium-237,

plutonium-238, plutonium-239/240, strontium-90, technetium-99, total thorium, thorium-232, and uranium-235/236) had very low detection frequencies (less than 11 percent). Radium-226, radium-228, thorium-228, and thorium-230 had a moderate number of detects; the frequency of detection for these four parameters ranged from 22 to 53 percent. Maximum detected values of these four unfiltered constituents were 2, 5.2, 2.9, and 2.5 pCi/L, respectively.

Total uranium was detected in 60 percent of the unfiltered samples analyzed. The total uranium data were evaluated for normality using the Shapiro-Francia method and were found to have an undefined distribution. The median value for total uranium was 0.26 $\mu\text{g/L}$; the maximum value detected was 3.1 $\mu\text{g/L}$.

Summary statistics for the 17 filtered radiological constituents are presented in Table 6-3. The amount of validated filtered radiological data for the Great Miami Aquifer is much less than the quantity of unfiltered data. This is because filtered radiological data were not routinely collected for the Great Miami Aquifer background wells prior to 1993. Seven of the 17 filtered parameters have only one data value each. Nine parameters have between 10 and 13 data values each. Statistics for total thorium were calculated based on thorium-232 statistics as described in Section 5.1. Radium-226, total uranium, uranium-234, and uranium-238 data have normal distributions. All of the other parameters have undefined distributions. Total uranium was detected in 83 percent of the filtered samples analyzed. The mean value was 0.4 $\mu\text{g/L}$ and the maximum value detected was 0.8 $\mu\text{g/L}$.

6.2 INORGANIC CONSTITUENTS

Filtered and unfiltered inorganic statistics for the Great Miami Aquifer are found in Tables 6-4 and 6-5, respectively. Inorganic analyses have been performed on a large number of samples collected from Great Miami Aquifer background wells. Descriptive statistics for 27 filtered inorganic parameters are presented in Table 6-4. Fifteen of the 27 inorganic constituents have approximately 90 to 120 sample results. However, as few as 4 to 30 filtered samples exist for 10 other parameters. Five of the filtered parameters (aluminum, calcium, magnesium, potassium, and sodium) displayed lognormal data distributions. Total dissolved solids (TDS) had a normal data distribution. Data distributions for the other 21 filtered inorganic parameters were undefined.

Descriptive statistics for 37 unfiltered inorganic parameters are presented in Table 6-5. Table 6-5 includes additional nutrient and anion parameters not in Table 6-4. Over 100 validated values exist for most of the anions (chloride, fluoride, and sulfate) and a few of the nutrients (ammonia and phosphorus). Nitrate has 64 values and TKN has 53 values. For the other 30 unfiltered inorganic parameters, less than 22 values were present in the background water quality data set. Nearly all of the unfiltered metals data were collected in 1993, thus explaining the lesser quantity of these data.

Descriptive statistics of three field parameters are presented in Table 6-6. The number of values for dissolved oxygen, pH, and specific conductance ranges from 93 to 131. The mean values of these three parameters were 2.35 mg/L, 7.2 SU, and 635 μ mhos/cm, respectively.

6.3 ORGANIC CONSTITUENTS

Four general organic parameters were analyzed in samples from the Great Miami Aquifer. Descriptive statistics of phenols, TOC, TOX, and TON are presented in Table 6-7. Maximum detections for these four parameters were 0.091, 4.25, 0.12, and 2.75 mg/L, respectively.

Twenty-four samples have been collected from the background wells in the Great Miami Aquifer and analyzed for organics. The organic detections are listed in Table 6-8. Very low estimated detections of organics were found in the Great Miami Aquifer background wells, some of which are common laboratory contaminants. The only three nonestimated detections were also low and are also common laboratory contaminants.

Four samples were collected from Great Miami Aquifer background wells and analyzed for herbicides, pesticides, organophosphorus pesticides, and PCBs. No detections were reported for the four samples.

7.0 GREAT MIAMI RIVER

This chapter presents the results of radiological and chemical analyses of surface water collected from background sampling point W-1 in the Great Miami River. Figure 7-1 shows unfiltered total uranium data (nonvalidated) collected by the EM Program at W-1 for a seven-year period. For a portion of this period the location of W-1 was moved approximately nine miles upriver while the State Route 126 bridge at Ross was rebuilt (the usual W-1 location). As seen from Figure 7-1, the total uranium concentrations measured at W-1 were undistinguishable before, during, and after the temporary relocation of W-1.

RI/FS samples were collected from sampling point W-1 on three occasions in 1988 and 1989. Sampling was conducted on two more occasions in 1993 for inorganic and organic constituents. EM Program data (nonvalidated) from W-1 for 1991 are shown in Table 7-1 for several parameters. The results of statistical computations to characterize Great Miami River background water quality are shown in Tables 7-2 through 7-7. Only validated RI/FS data were used to calculate these statistics.

7.1 RADIOLOGICAL CONSTITUENTS

Descriptive statistics for W-1 unfiltered radiological data are presented in Table 7-2. A total of 17 radiological parameters were evaluated. Of these, there were no detects for eight of the unfiltered parameters and only one detect for three other parameters. Only thorium-228, thorium-230, total uranium, uranium-234, and uranium-238 had three or more detections out of five sampling events. The median total uranium value (undefined distribution) is 1 $\mu\text{g/L}$. Figure 7-1 shows that unfiltered total uranium values at sampling point W-1 for the period 1986 through 1993 typically ranged between 1 and 2 $\mu\text{g/L}$.

Table 7-3 presents the descriptive statistics of filtered radiological data for the Great Miami River. Filtered samples were collected on three different dates from W-1 and evaluated for the same 17 unfiltered radiological parameters. Ten of the filtered parameters had no detections. In general, the median values of the filtered radiological parameters are nearly the same as the corresponding unfiltered radiological parameters for W-1.

7.2 INORGANIC CONSTITUENTS

Descriptive statistics calculated for filtered and unfiltered inorganic data are presented in Tables 7-4 and 7-5, respectively. Because of the relatively limited number of RI/FS samples, all data distributions are undefined.

For the filtered inorganics, 26 different parameters were analyzed (Table 7-4). For the unfiltered inorganics, 35 different parameters were analyzed (Table 7-5). Of the 26 parameters common to both

groups, the median filtered and unfiltered data were similar, except for aluminum, iron, manganese, silicon, and zinc. For these five parameters, the unfiltered medians were considerably higher than the filtered median values. This should be expected, since these five elements are common to silt and clay particles, which are contained in the unfiltered samples.

Only one value of pH and specific conductivity field parameters has been measured. These values are 8.3 SU and 666 $\mu\text{mhos/cm}$, respectively.

7.3 ORGANIC CONSTITUENTS

Table 7-6 presents descriptive statistics for the four general organic parameters: phenols, TOC, TOX, and TON. These data indicate that low levels of organic compounds are present in the Great Miami River, which is to be expected because towns, sewage treatment plants, and industries are located upstream of the FEMP. The identity of the sources of these compounds cannot be determined based on these indicator tests. The TOX values suggest low levels of halogenated compounds are present in the stream.

Sampling point W-1 has been sampled and analyzed for VOCs, SVOCs, pesticides, PCBs, and organophosphorus pesticides on two different occasions in 1993. Only very low estimated values for acetone, methylene chloride, and bis (2-Ethelhexyl)phthalate were detected. Each of these constituents is a common laboratory contaminant and the results are likely caused by cross-contamination.

W-1	20-May-93	120075-2	Methylene chloride *	10	J
Semivolatile Organic Compound					
W-1	23-Jun-93	120414	bis(2-Ethylhexyl)phthalate *	1	J

* These organic constituents are common laboratory contaminants.

8.0 PADDYS RUN

This chapter presents the results of radiological and chemical analyses of surface water samples collected from sampling point W-5 in Paddys Run. Figure 8-1 shows unfiltered total uranium data (nonvalidated) collected by the EM Program at W-5 for a seven-year period. Table 8-1 shows 1991 EM Program data from W-5 for several parameters.

No validated background samples for Paddys Run were available prior to 1993. Since then, RI/FS samples have been collected from W-5 on two occasions. Data results from these samples used to characterize background in Paddys Run are provided in Tables 8-2 through 8-6. Sampling point W-5 for the RI/FS samples is in Paddys Run, just upstream of where it crosses under State Route 126.

8.1 RADIOLOGICAL CONSTITUENTS

Descriptive statistics for 16 unfiltered radiological parameters are presented in Table 8-2. Each parameter has data for either one or two sampling events. Half of the 16 parameters had no detected values. The two detections for unfiltered total uranium were 0.90 $\mu\text{g/L}$ and 1.1 $\mu\text{g/L}$. This compares closely to the long-term average of unfiltered total uranium displayed in Figures 8-1, which is about 1.2 $\mu\text{g/L}$. The median values for total uranium, uranium-234, and uranium-238 shown in Table 8-2 are about the same as those measured in the Great Miami River.

Descriptive statistics for 17 filtered radiological parameters are presented in Table 8-3. Data exist for either one or two RI/FS sampling events for each of these parameters. The maximum value detected for filtered total uranium at W-5 was 1.1 $\mu\text{g/L}$, which is essentially the same as the maximum value detected for unfiltered total uranium.

8.2 INORGANIC CONSTITUENTS

Sampling point W-5 was sampled on two different dates in 1993 and analyzed for 26 filtered inorganic parameters. However, not all parameters were analyzed for both sampling dates. The descriptive statistics for filtered inorganic data are presented in Table 8-4.

The same 26 parameters were analyzed for the unfiltered inorganic samples. In addition, another nine anion and nutrient parameters were analyzed in the unfiltered samples. The descriptive statistics of the unfiltered inorganic parameters are presented in Table 8-5. For the parameters common to both Tables 8-4 and 8-5, the median values of each are very similar, except the aluminum and iron medians, which are higher in the unfiltered sample data. Fine silt and clay in the stream most likely cause the somewhat higher concentrations of aluminum and iron in the unfiltered samples.

There were no field measurements available for dissolved oxygen, pH, or specific conductivity from this sampling location in 1993. The average pH value for the 1991 EM data from W-5 was 7.8 SU (Table 8-1).

8.3 ORGANIC CONSTITUENTS

Sampling point W-5 was sampled and analyzed twice in 1993 for general organic parameters: phenols, TOC, TOX, and TON. Descriptive statistics for these four parameters are presented in Table 8-6.

Sampling point W-5 was also sampled and analyzed twice in 1993 for VOCs, SVOCs, pesticides, PCBs, and organophosphorus pesticides. No organic compounds were detected among these samples.

Figure 8-1. Total Uranium Background Concentrations
Measured for Paddys Run at Sampling Point W-5

Table 8-1
Summary of Background Surface Water Quality Data
Collected by EM at Sampling Point W-5 on Paddys Run

Parameter		Number of Samples	Minimum	Maximum	Average
pH	(SU)	47	7.5	8.2	7.8
Fluoride	(mg/L)	14	0.2	0.5	0.29
Nitrate-Nitrogen	(mg/L)	13	<1.0	5.0	3.2
Total Uranium	(μ g/L)	47	0.41	1.6	0.78
Radium - 226 ^a	(pCi/L)	6	<0.1	<0.1	<0.1
Radium - 228 ^a	(pCi/L)	6	<0.1	0.1	<0.1

^aTwo-month composites of weekly samples.

Note: Data are from unfiltered samples; data source (WEMCO 1992).

9.0 CONCLUSIONS

This report presents and evaluates background water quality data for surface water (Paddys Run and the Great Miami River) and groundwater (glacial overburden and the Great Miami Aquifer) near the FEMP. Tables 9-1 and 9-2 present statistical summaries of unfiltered and filtered radiological constituents, respectively, in glacial overburden groundwater, the Great Miami Aquifer, the Great Miami River, and Paddys Run.

Tables 9-3 and 9-4 present statistical summaries of filtered and unfiltered inorganic data, respectively, for the same four hydrologic entities. Statistical summaries of four general organic parameters (phenols, TOC, TOX, and TON) are presented in Table 9-5.

Following are the major conclusions of this report:

- There are sufficient wells (i.e., FEMP wells and private wells) to characterize background groundwater quality in both the glacial overburden and the Great Miami Aquifer. Data from 29 groundwater wells have been validated and evaluated in order to characterize water quality in the glacial overburden and the Great Miami Aquifer. These 29 wells were carefully selected from among a potential list of 51 wells located upgradient from the FEMP or located sufficiently distant that they were not affected by FEMP activities or wastes. Sixteen of the 29 wells used to characterize background groundwater quality are private wells. The other 13 are FEMP wells specifically constructed for monitoring purposes. Five wells are completed in the glacial overburden and 24 wells are completed in the Great Miami Aquifer.
- The data set associated with the 29 background wells is sufficient to characterize background groundwater quality in both the glacial overburden and the Great Miami Aquifer for radiological, inorganic, and organic parameters. All data used to compute background water quality statistics in this report were validated according to procedures outlined in Section 3.4.
- A trilinear plot of the major cation and anion data from the five glacial overburden background wells shows a tight clustering of the data, implying that the water chemistry in these wells is similar. Additionally, several comparison tests were performed for the glacial overburden FEMP wells versus private wells. In general, the FEMP wells and private wells appeared to be from the same population except for total uranium results; therefore, the FEMP wells were excluded from the statistics for this parameter as they were in the draft report. In this revised report, isotopic uranium results from the FEMP wells were eliminated as well because total uranium is the summation of isotopic uranium activity.
- Major cation and anion data for the three sections of the Great Miami Aquifer that contribute background flow in the vicinity of the FEMP were plotted on a trilinear diagram. The tight clustering of the data implies that the water chemistry in the three sections is similar. Therefore, it is reasonable to calculate one set of background water quality statistics for the Great Miami Aquifer by combining data from the three sections.

The radiological water chemistry of well 2098 appears to be affected by the FEMP. Consequently, these data were removed from the background data set.

- The trilinear plots for the Great Miami Aquifer and the glacial overburden were compared, and they exhibit the same clustering pattern. This implies that the glacial overburden and Great Miami Aquifer background water chemistry is similar.
- Summary statistics for unfiltered total uranium in the glacial overburden background wells are as follows:

- Mean	0.54 µg/L
- 95 percent UCL	0.75 µg/L
- 95 th percentile	1.3 µg/L
- Summary statistics for unfiltered total uranium in the Great Miami Aquifer background wells are as follows:

- Median	0.26 µg/L
- 95 percent UCL	0.36 µg/L
- 95 th percentile	1.2 µg/L
- There were no detections of organics in the glacial overburden background wells. Very low estimated detections of organics were found in the Great Miami Aquifer background wells, some of which are common laboratory contaminants. The only three nonestimated detections were also low and are also common laboratory contaminants.
- When the draft "Background Water Quality" report was prepared, only limited RI/FS data were available for sampling points W-1 and W-5 in the Great Miami River (three sampling events) and Paddys Run (no validated data), respectively. Since that time, both W-1 and W-5 have been sampled on two different occasions, with analyses conducted for a comprehensive array of radiological and chemical parameters. Results from these analyses for the important parameter total uranium (unfiltered) compare closely with long-term EM data from these locations.
- Data from sampling point W-1 are sufficient to characterize background concentrations of radiological, inorganic, and organic parameters in the Great Miami River. Summary statistics for unfiltered total uranium background in the Great Miami River are as follows:

- Median	1 µg/L
- 95 percent UCL	1.4 µg/L
- 95 th percentile	1.4 µg/L

Organic analyses available for sampling point W-1 showed no detectable concentrations of pesticides, PCBs, or organophosphorus pesticides. The two VOCs (acetone, methylene chloride) and one SVOC (bis(2-Ethylhexyl) phthalate) detected were very low estimated results and are also common laboratory contaminants.

- Data from sampling point W-5 are sufficient to characterize background concentrations for Paddys Run. Summary statistics for unfiltered total uranium background in Paddys Run are as follows:

- Median	0.98 $\mu\text{g/L}$
- 95 percent UCL	1.1 $\mu\text{g/L}$
- 95 th percentile	1.1 $\mu\text{g/L}$

Organic analyses for two sampling dates showed no detectable concentrations of VOCs, SVOCs, pesticides, PCBs, or organophosphorus pesticides.

- Primarily because of extensive field programs conducted in the spring and summer of 1993, the amount of data available for background water quality characterization has increased significantly since the draft version of this report was prepared (May 1993). Additionally, in the 1993 field programs, both unfiltered and filtered samples were collected for radionuclide and inorganic chemical analyses. Previously, mainly unfiltered radionuclides and filtered metals analyses were performed.

Note:

(1) Concentrations are reported in mg/L.

(2) N/A = Not applicable.

(3) Distribution types: N = Normal, L = Lognormal, N* = Normal (but also passed Lognormal test), L* = Lognormal (but also passed Normal test), NQ = Qualified Normal.

LQ = Qualified Lognormal, U = Undefined.

(4) This table solely presents the results of statistical computations. Further interpretation may be required to determine numbers to be used in risk assessment and nature and extent comparisons.

^aSource of data: "Site-Wide Characterization Report" (DOE 1993a).

^bDistribution: N = Normal; L = Lognormal; U = Undefined if sample size ≤ 2 .

If the number of detects ≥ 7 and the frequency of detection $\geq 50\%$, a probability plot that handles censored data was used in determining the distribution. Otherwise, the distribution was estimated by visual inspection of the raw data, a histogram, and a standard probability plot.

^cIf the distribution is normal, the number of detects ≥ 7 , and the frequency of detection $\geq 50\%$, an arithmetic mean is given. If the distribution is lognormal, the number of detects < 7 , or the frequency of detection is $< 50\%$, a geometric mean is given.

^dIf the distribution is normal, the number of detects ≥ 7 , and the frequency of detection $\geq 50\%$, a 95% upper confidence limit (UCL) on the arithmetic mean is given. If the distribution is lognormal, the number of detects < 7 , or the frequency of detection is $< 50\%$, a 95% UCL on the geometric mean is given.

^eUpper 95% tolerance level (UTL) for background data with a 95% level of confidence.

^fWhen background sample size is one, the actual concentration is given instead of a UTL.

^gReported in mg/L.

Table A-12
(Continued)

^bDistribution: N = Normal; L = Lognormal; U = Undefined if sample size ≤ 2 .
 If the number of detects ≥ 7 and the frequency of detection $\geq 50\%$, a probability plot that handles censored data was used in determining the distribution. Otherwise, the distribution was estimated by visual inspection of the raw data, a histogram, and a standard probability plot. If the distribution is normal, the number of detects ≥ 7 , and the frequency of detection $\geq 50\%$, an arithmetic mean is given. If the distribution is lognormal, the number of detects < 7 , or the frequency of detection is $< 50\%$, a geometric mean is given.
^dIf the distribution is normal, the number of detects ≥ 7 , and the frequency of detection $\geq 50\%$, a 95% upper confidence limit (UCL) on the arithmetic mean is given. If the distribution is lognormal, the number of detects < 7 , or the frequency of detection is $< 50\%$, a 95% UCL on the geometric mean is given.
^eUpper 95% tolerance level (UTL) for background data with a 95% level of confidence.
^fDistribution could not be determined from available data; therefore, a normal distribution was assumed.
^gIf the 95% UCL on the mean exceeds the maximum detected concentration, or if the sample size ≤ 2 , the maximum detected concentration is substituted.
^hWhen background sample size contains only one detect, this concentration is given instead of a UTL.
ⁱNot applicable if sample size ≤ 2 .

^bDistribution: N = Normal; L = Lognormal; U = Undefined if sample size ≤ 2 .

If the number of detects ≥ 7 and the frequency of detection $\geq 50\%$, a probability plot that handles censored data was used in determining the distribution. Otherwise, the distribution was estimated by visual inspection of the raw data, a histogram, and a standard probability plot.

^cIf the distribution is normal, the number of detects ≥ 7 , and the frequency of detection $\geq 50\%$, an arithmetic mean is given. If the distribution is lognormal, the number of detects < 7 , or the frequency of detection is $< 50\%$, a geometric mean is given.

^dIf the distribution is normal, the number of detects ≥ 7 , and the frequency of detection $\geq 50\%$, a 95% upper confidence limit (UCL) on the arithmetic mean is given. If the distribution is lognormal, the number of detects < 7 , or the frequency of detection is $< 50\%$, a 95% UCL on the geometric mean is given.

^eUpper 95% tolerance level (UTL) for background data with a 95% level of confidence.

^fWhen background sample size contains only one detect, this concentration is given instead of a UTL.

^gUnits are reported in mg/L.

^hIf the 95% UCL exceeds the maximum detected concentration, or if the sample size ≤ 2 , the maximum detected concentration is substituted. Distribution could not be determined from available data, therefore, a normal distribution was assumed.

OUS/G:BACKGRD/TABLE A-14/05-94

Table A-14
(Continued)

^aUpper 95 % tolerance level for background data with a 95 % level of confidence.

^bDistribution: N = Normal; L = Lognormal. If the number of detects ≥ 7 and the frequency of detection $\geq 50\%$, a probability plot that handles censored data is used in determining the distribution. Otherwise, the distribution is estimated by visual inspection of the raw data, a histogram, and a standard probability plot.

^cIf the distribution is normal or if the distribution is lognormal, the number of detects ≥ 7 , and frequency of detection $\geq 50\%$, an arithmetic mean is given. If the distribution is lognormal and either the number of detects < 7 or the frequency of detection is $< 50\%$, a geometric mean is given.

^dIf the distribution is normal or if the distribution is lognormal, the number of detects ≥ 7 , and the frequency of detection $\geq 50\%$, an arithmetic upper 95 % confidence interval (CI) on the mean is given. If the distribution is lognormal and either the number of detects < 7 or the frequency of detection is $< 50\%$, a geometric upper 95 % CI on the mean is given.

^eDistribution could not be determined from available data; therefore, a normal distribution was assumed.

^fIf the upper 95 % CI on the mean exceeds the maximum detected concentration or if the sample size ≤ 2 , the maximum detected concentration is substituted.

^gWhen background sample size is one, this concentration is given instead of a UTL. The mean site-related value will be compared with the single background value.

^hNot applicable if sample size ≤ 2 .

REMARKS Hole was drilled to 155' to clearly define stratigraphy. Casing was pulled up to 125' and sand-hole was allowed to collapse in. The well was then plugged from 125' to 110' with bentonite to insure that no communication through "Blue Clay" was present. Well was then set from 110'.

REMARKS

This well was drilled to a total depth of 126.5' penetrating into the Blue Clay. It was allowed to collapse to 120' and the well was completed from that depth.

FOOTNOTES FOR APPENDIX C TABLES

(1) Units:

Picocuries per liter (pCi/L) was the primary unit used to quantify all radionuclides. Total uranium and total thorium are presented in units of $\mu\text{g/L}$.

(2) Radiological Validation Qualifiers:

- These data meet all requirements of the indicated analytical support level (ASL).
- J These data should be considered an estimate on the basis of laboratory quality control results.
- R These data are considered unreliable/unusable for any quantitative purpose.
- N These data had problems noted with standards or tracers that cause some doubt as to the quality of the data for specific isotopes.
- NV These data were not validated.
- U These data were not detected at levels up to the corresponding limit of detection.

Note: Laboratory qualifiers are not presented in this appendix. Laboratory qualifiers are addressed during the validation process and are reflected in the validation qualifiers.

(3) QA Type:

QA Type refers to the number of replicate samples taken from a location during the sampling event.

- N One sample set was obtained.
- D Duplicate sample sets were obtained.
- T Triplicate sample sets were obtained.

(4) Analytical Support Levels (ASLs):

The validation of analytical data is correlated to ASLs A through E defined in the SCQ; these FEMP-specific ASLs are analogous to the EPA's Analytical Levels 1 through 5. The ASLs are assigned depending on the intended use of the data and the quality control methods required. The ASL for most of the radionuclides was EPA Level 5.

(5) Area:

Area refers to the tributary section of the Great Miami Aquifer.

- D Dry Fork section of the Great Miami Aquifer
- R Ross section of the Great Miami Aquifer
- S Shandon section of the Great Miami Aquifer

FOOTNOTES FOR APPENDIX C TABLES
(continued)(6) Data Types:Validated Data:

Data that have been through the validation process and are of known quality based on the ASL specified.

High Nondetect Data:

Nondetect data that have unusually high detection limits. Refer to Section 4.2.2.

Result Outlier:

A result that has been deemed "suspect". Refer to Section 4.2.3.

Sample Outlier:

A sample that has several result outliers. Refer to Section 4.2.3.

Suspect Well Data:

Data from a well that is "suspect"; e.g. uranium data from the FEMP glacial overburden wells; radiological data from well 2098.

Rejected Data:

Data that have been identified through validation as being either unreliable or unusable.

Nonvalidated Data:

Data that have not been through the validation process.

(7) Statistics were not calculated for gross alpha and gross beta. There was one unfiltered result for each of these constituents in the glacial overburden. The Great Miami Aquifer, Great Miami River, and Paddys Run samples were not analyzed for gross alpha or gross beta.

(8) All nondetect data (data with a U qualifier) listed in these tables are the actual results reported by the laboratories. For statistical computations, nondetect data were set equal to one-half of the detection limit. Nondetect data can also be referred to by using a < symbol.

FOOTNOTES FOR APPENDIX D TABLES

- (1) Units:
All results within the tables are reported in mg/L (milligrams per liter) except where noted.
- (2) Lab Qualifiers:
- * Duplicate analysis was not within control limits. These data should be considered estimated.
 - + The correlation coefficient for the method of standard additions was less than 0.995. These data should be considered estimated.
 - B The reported value was obtained from a reading that was less than the contract required detection limit (CRDL) but greater than or equal to the instrument detection limit.
 - E The reported value was estimated because of the presence of interference.
 - N Spiked sample recovery was not within control limits. These data should be considered estimated.
 - S The reported value was determined by the method of standard additions.
 - U The analyte was analyzed for but was not detected.
 - W The reported value was generated from graphite furnace atomic absorption analysis, and post-digestion spike recovery was outside of the allowable range. These data should be considered estimated.
- (3) Validation Qualifiers:
- These data meet all requirements of the indicated analytical support level (ASL).
 - J These data should be considered an estimate on the basis of laboratory quality control results.
 - NV These data were not validated.
 - R These data are considered unreliable/unusable for any quantitative purpose.
 - U These data were not detected at levels up to the corresponding limit of detection. This qualifier was also used to denote a value that was adjusted by the use of the 5X/10X rule for evaluation for blank data.
 - Z These data indicate that a more representative result exists within the corresponding sample.
- (4) QA Type:
QA Type refers to the number of replicate samples taken from a location during the sampling event.
- N One sample set was obtained.
 - D Duplicate sample sets were obtained.
 - T Triplicate sample sets were obtained.
- (5) Analytical Support Levels (ASLs):
The validation of analytical data is correlated to ASLs A through E defined in the SCQ; these FEMP-specific ASLs are analogous to the EPA's Analytical Levels 1 through 5. The ASLs are assigned depending on the intended use of the data and the quality control methods required. The ASL for inorganic data was generally EPA Level 3 or 4 and the ASL for field data was EPA Level 2.

FOOTNOTES FOR APPENDIX D TABLES (continued)

(6) Area:

Area refers to the tributary section of the Great Miami Aquifer.

D Dry Fork section of the Great Miami Aquifer
R Ross section of the Great Miami Aquifer
S Shandon section of the Great Miami Aquifer

(7) Data Types:

Validated Data:

Data that have been through the validation process and are of a known quality based on the ASL specified.

High Nondetect Data:

Nondetect data that have unusually high detection limits. Refer to Section 4.2.2.

Low Nondetect Data:

Nondetect data that have unusually low detection limits.

Result Outlier:

A result that has been deemed "suspect". Refer to Section 4.2.3.

Sample Outlier:

A sample that has several result outliers. Refer to Section 4.2.3.

Rejected Data:

Data that have been identified through validation as being either unreliable or unusable.

Nonvalidated Data:

Data that have not been through the validation process.

(8) Due to the limited analytical results available, statistics were not calculated for phosphate, osmium, nitrite as nitrogen, or tin.

(9) All nondetect data (data with a U qualifier) listed in these tables are the actual results reported by the laboratories. For statistical computations, nondetect data were set equal to one-half of the detection limit. Nondetect data can also be referred to by using a < symbol.

FOOTNOTES FOR APPENDIX E TABLES

(1) Units:

Phenols, total organic carbon (TOC), total organic halides (TOX), and total organic nitrogen (TON) are reported in mg/L (milligrams per liter). Dioxins are reported in ng/L (nanograms per liter). All the other results within the tables are reported in $\mu\text{g/L}$ (micrograms per liter).

(2) Lab Qualifiers:

- * Duplicate analysis was not within control limits. These data should be considered estimated.
- B Analyte also detected in associated field or lab blank(s).
- J Analyte present; reported value may not be accurate or precise.
- P Result for pesticide/PCB exhibits significant imprecision between two chromatographic columns; lab reports lower value.
- U The analyte was analyzed for but was not detected.
- X Definition limit is higher than normal due to sample matrix interferences.

(3) Validation Qualifiers:

- These data meet all requirements of the indicated analytical support level (ASL).
- J These data should be considered an estimate on the basis of laboratory quality control results.
- NV These data were not validated.
- R These data are considered unreliable/unusable for any quantitative purpose.
- U These data were not detected at levels up to the corresponding limit of detection. This qualifier was also used to denote a value that was adjusted by the use of the 5X/10X rule for evaluation for blank data.
- Z These data indicate that a more representative result exists within the corresponding sample.

(4) QA Type:

QA Type refers to the number of replicate samples taken from a location during the sampling event.

- N One sample set was obtained.
- D Duplicate sample sets were obtained.
- T Triplicate sample sets were obtained.

(5) Analytical Support Levels (ASLs):

The validation of analytical data is correlated to ASLs A through E defined in the SCQ; these FEMP-specific ASLs are analogous to the EPA's Analytical Levels 1 through 5. The ASLs are assigned depending on the intended use of the data and the quality control methods required. The ASL for organic data was generally EPA Level 3 or 4.

(6) Area:

Area refers to the tributary section of the Great Miami Aquifer.

- D Dry Fork section of the Great Miami Aquifer
- R Ross section of the Great Miami Aquifer
- S Shandon section of the Great Miami Aquifer

FOOTNOTES FOR APPENDIX E TABLES
(continued)(7) Data Types:

Validated Data:

Data that have been through the validation process and are of known quality based on the ASL specified.

High Nondetect Data:

Nondetect data that have unusually high detection limits. Refer to Section 4.2.2.

Result Outlier:

A result that has been deemed "suspect". Refer to Section 4.2.3.

Sample Outlier:

A sample that has several result outliers. Refer to Section 4.2.3.

Rejected Data:

Data that have been identified through validation as being either unreliable or unusable.

Nonvalidated Data:

Data that have not been through the validation process.

- (8) All nondetect data (data with a U qualifier) listed in these tables are the actual results reported by the laboratories. For statistical computations, nondetect data were set equal to one-half of the detection limit. Nondetect data can also be referred to by using a < symbol.

Table F-1
Formulas for Summary Statistics

Statistic	Formula
Shapiro-Wilk Test (Gilbert 1987, Equations 12.3 and 12.4)	$W = \frac{1}{d} \left[\sum_{i=1}^k a_i (x_{[n-i+1]} - x_{[i]}) \right]^2$ <p>where:</p> $d = \sum_{i=1}^n x_i^2 - \frac{1}{n} \left(\sum_{i=1}^n x_i \right)^2$ $k = \frac{n}{2} \text{ if } n \text{ is even}$ $= \frac{n-1}{2} \text{ if } n \text{ is odd}$ $a_i = \text{Shapiro-Wilk coefficient}$ $x_i = i^{\text{th}} \text{ data value in the ordered data set}$ $x_i^2 = \text{square of the } i^{\text{th}} \text{ data value in the ordered data set}$ $n = \text{number of data points}$ $W = \text{Shapiro-Wilk test statistic}$
Shapiro-Francia Test (Shapiro-Francia, 1972)	$W' = \frac{\left[\sum_{i=1}^n m_i x_i \right]^2}{(n-1)s^2 \sum_{i=1}^n m_i^2}$ <p>where:</p> $m_i = \Phi^{-1} \text{ at } \left(\frac{1}{n+1} \right)$ $m_i = \text{normal quantile}$ $\Phi^{-1} = \text{inverse of standard normal distribution}$ $x_i = i^{\text{th}} \text{ data value in the ordered data set}$ $s^2 = \text{sample arithmetic variance}$ $W' = \text{Shapiro-Francia test statistic}$
Rosner's Test for Many Outliers (Gilbert 1987, Equations 15.1 to 15.3)	See page F-23.
Sample Arithmetic Mean (Gilbert 1987, Equation 4.3)	$\bar{x} = \frac{1}{n} \sum_{i=1}^n x_i$ <p>where:</p> $n = \text{number of data points}$ $x_i = i^{\text{th}} \text{ data value in the ordered data set}$ $\bar{x} = \text{arithmetic mean}$

TABLE F-1
(Continued)

Statistic	Formula
Sample Arithmetic Standard Deviation (Gilbert 1987, Equation 4.4)	$s^2 = \frac{1}{n-1} \sum_{i=1}^n (x_i - \bar{x})^2$ $s = \sqrt{s^2}$ <p>where: n = number of data points x_i = data set value \bar{x} = arithmetic mean s^2 = arithmetic variance s = arithmetic standard deviation</p>
Estimated Coefficient of Variation (Gilbert 1987, Page 34)	$CV = s/\bar{x}$ <p>where: \bar{x} = sample arithmetic mean s = sample arithmetic standard deviation CV = estimated coefficient of variation</p>
Estimated Mean of a Lognormal Distribution (Gilbert 1987, Equation 13.7)	$\hat{\mu} = \exp \left[\bar{y} + \frac{s_y^2}{2} \right]$ <p>where: \bar{y} = arithmetic mean of the ln transformed data s_y = arithmetic standard deviation of the ln transformed data $\hat{\mu}$ = estimated mean of a lognormal distribution</p>
Estimated Standard Deviation of a Lognormal Distribution (Gilbert 1987, Equation 13.8)	$\hat{\sigma} = \sqrt{\hat{\mu}^2 [\exp s_y^2 - 1]}$ <p>where: $\hat{\mu}$ = estimated mean of a lognormal distribution s_y = arithmetic standard deviation of the ln transformed data $\hat{\sigma}$ = estimated standard deviation of the lognormal distribution</p>

000927

TABLE F-1
(Continued)

Statistic	Formula
Sample Median - Nonparametric Technique (Gilbert 1987, Equation 13.15 and 13.16)	<p>If n is odd: sample median = $x_{[(n+1)/2]}$</p> <p>If n is even: sample median = $\frac{1}{2} (x_{[n/2]} + x_{[(n+2)/2]})$</p> <p>where: $x_{[i]}$ = ith data value in the ordered data set n = number of data points</p>
Upper 95% Confidence Limit on the Mean - Normal Distribution (Gilbert 1987, Equation 11.6)	<p>95% $UCL_N = \bar{x} + t_{0.95, n-1} \frac{s}{\sqrt{n}}$</p> <p>where: \bar{x} = arithmetic mean $t_{0.95, n-1}$ = student t distribution value n = number of data points s = arithmetic standard deviation 95% UCL_N = one-sided upper 95% confidence limit for a normal distribution</p>
Upper 95% Confidence Limit on the Arithmetic Mean for Lognormal Distribution (Gilbert 1987, Equation 13.13)	<p>95% $UCL_L = \exp \left(\bar{y} + 0.5 s_y^2 + \frac{s_y H_{0.95}}{\sqrt{n-1}} \right)$</p> <p>where: \bar{y} = arithmetic mean of the ln transformed data s_y^2 = arithmetic variance of the ln transformed data s_y = arithmetic standard deviation of the ln transformed data $H_{0.95}$ = value used to compute one-sided 95% confidence limit on a lognormal mean n = number of data points 95% UCL_L = one-sided upper 95% confidence limit for a lognormal distribution</p>

TABLE F-1
(Continued)

Statistic	Formula
Upper 95% Confidence Limit on the Median - Nonparametric Technique (Gilbert 1987, Equation 13.22)	$U = \frac{n + 1 + Z_{0.95} \sqrt{n}}{2}$ $95\% \text{ UCL}_{NP} = x_{(U)}$ <p>where: n = number of data points $Z_{0.95}$ = upper 95% limit from a standard normal curve for a Z distribution U = rank in an ascending order data set that corresponds to the one-sided upper 95% confidence limit for nonparametric distribution $f(U) = U$ rounded up to an integer (e.g., 24.2 \rightarrow 25) $95\% \text{ UCL}_{NP}$ = data point in the ascending ordered data set at rank $f(U)$</p>
0.95 Quantile - Normal Distribution (Gilbert 1987, Equation 11.1)	$95^{\text{th}} \text{ Percentile}_N = \bar{x} + s Z_{0.95}$ <p>where: \bar{x} = arithmetic mean s = arithmetic standard deviation $Z_{0.95}$ = 0.95 limit from a standard normal curve for a Z distribution $95^{\text{th}} \text{ Percentile}_N$ = 95^{th} percentile for normal distribution</p>
0.95 Quantile - Lognormal Distribution (Gilbert 1987, Equation 13.24)	$95^{\text{th}} \text{ Percentile}_L = \exp(\bar{y} + s_y Z_{0.95})$ <p>where: \bar{y} = arithmetic mean of the ln transformed data s_y = arithmetic standard deviation of the ln transformed data $Z_{0.95}$ = upper 95% limit from a standard normal curve for a distribution $95^{\text{th}} \text{ Percentile}_L$ = 95^{th} percentile for lognormal distribution</p>
0.95 Quantile - Nonparametric Technique	$Q = 0.95 n$ $95^{\text{th}} \text{ Percentile}_{NP} = x_{(f(Q))}$ <p>where: n = number of data points Q = rank in an ascending order data set that corresponds to the 95^{th} percentile based on a nonparametric technique $f(Q) = Q$ rounded up to an integer (e.g., 14.1 \rightarrow 15) $95^{\text{th}} \text{ Percentile}_{NP}$ = data point in the ascending order data set at rank $f(Q)$</p>

Shapiro-Wilk Test for Normality

The W test developed by Shapiro and Wilk (Gilbert 1987, Equations 12.3 and 12.4) was used to determine whether or not a data set has been drawn from a population which is normally distributed for sample size of 50 or less. By conducting this test on the natural logarithm of each data value, the W test was used to determine whether or not the sample was drawn from an underlying lognormal distribution. The null hypothesis to be tested is:

H_0 : The population has a normal (lognormal when the data is transformed) distribution.

versus

H_A : The population does not have a normal (lognormal when the data is transformed) distribution.

If H_0 is rejected, then H_A is accepted.

The following presents a step-by-step procedure for conducting the W test. The equation for calculating W is:

$$W = \frac{1}{d} \left[\sum_{i=1}^k a_i (x_{[n-i+1]} - x_{(i)}) \right]^2$$

1. Compute the denominator (d) of the W test statistic

$$d = \sum_{i=1}^n x_i^2 - \frac{1}{n} \left(\sum_{i=1}^n x_i \right)^2$$

where:

$$\sum_{i=1}^n x_i = x_1 + x_2 + \dots + x_n$$

$$\sum_{i=1}^n x_i^2 = x_1^2 + x_2^2 + \dots + x_n^2$$

2. Order the n data points in ascending order (smallest to largest) such that $x_1 \leq x_2 \leq x_3 \leq \dots \leq x_n$

3. Compute k , where:

$$k = \frac{n}{2} \text{ if } n \text{ is even}$$

$$k = \frac{n-1}{2} \text{ if } n \text{ is odd}$$

4. Find the coefficients $a_1, a_2, a_3, \dots, a_k$ for the sample size n from Table F-2.
5. Compute W

$$W = \frac{1}{d} \left[\sum_{i=1}^k a_i (x_{n-i+1} - x_i) \right]^2$$

6. Reject H_0 at the α significance level if W is less than the quantile given in Table F-3.

To test the null hypothesis that the population has a lognormal distribution, transform the observed data to y_1, y_2, \dots, y_n where $y_i = \ln x_i$. Repeat steps 1 through 6 as described above.

Source: Table A-7, Gilbert 1987

Example:

To illustrate the application of the Shapiro-Wilk test, the data in Table F-4 is used.

1. Compute d , the denominator of the W test.

$$\begin{aligned}
 d &= \sum_{i=1}^n x_i^2 - \frac{1}{n} \left(\sum_{i=1}^n x_i \right)^2 \\
 &= 0.0808 - \frac{1}{36} (1.634)^2 \\
 &= 0.0066
 \end{aligned}$$

2. Order data points from low to high.

3. Compute k for $n = 36$

$$k = \frac{n}{2}$$

$$k = \frac{36}{2} = 18$$

4. Find coefficients a_1, a_2, \dots, a_{15} for $n = 36$ from Table F-2.

$a_1 = 0.4068$	$a_6 = 0.1678$	$a_{11} = 0.0900$	$a_{16} = 0.0287$
$a_2 = 0.2813$	$a_7 = 0.1496$	$a_{12} = 0.0770$	$a_{17} = 0.0172$
$a_3 = 0.2415$	$a_8 = 0.1331$	$a_{13} = 0.0645$	$a_{18} = 0.0057$
$a_4 = 0.2121$	$a_9 = 0.1179$	$a_{14} = 0.0523$	
$a_5 = 0.1883$	$a_{10} = 0.1036$	$a_{15} = 0.0404$

(a) When the validation qualifier contains a "U", then one-half of the concentration is used in the statistical calculations.

5. Compute W.

$$W = \frac{1}{d} \sum_{i=1}^k a_i (x_{n-i+1} - x_i) \quad \left[\begin{array}{c} k \\ 2 \end{array} \right]$$

$$= \frac{1}{d} [a_1 (x_{36-1+1} - x_1) + a_2 (x_{36-2+1} - x_2) + \dots + a_{18} (x_{36-18+1} - x_{18})]^2$$

$$= \frac{1}{d} [a_1 (x_{36} - x_1) + a_2 (x_{35} - x_2) + \dots + a_{18} (x_{19} - x_{18})]^2$$

$$\begin{aligned} &= \frac{1}{d} [0.4068 (0.073 - 0.017) + 0.2813 (0.066 - 0.0245) + 0.2415 (0.064 - 0.025) \\ &\quad + 0.2121 (0.062 - 0.025) + 0.1883 (0.061 - 0.025) + 0.1678 (0.061 - 0.025) \\ &\quad + 0.1496 (0.060 - 0.032) + 0.1331 (0.06 - 0.035) + 0.1179 (0.057 - 0.035) \\ &\quad + 0.1036 (0.055 - 0.039) + 0.0900 (0.054 - 0.04) + 0.0770 (0.052 - 0.04) \\ &\quad + 0.0645 (0.0514 - 0.040) + 0.0523 (0.050 - 0.040) + 0.0404 (0.049 - 0.043) \\ &\quad + 0.0287 (0.048 - 0.044) + 0.0172 (0.047 - 0.044) + 0.0057 (0.045 - 0.045)]^2 \\ &= \frac{(0.080)^2}{0.0066} \\ &= 0.971 \end{aligned}$$

6. Fail to reject H_0 at the 0.05 significance level because $W_{\text{test}} = 0.971$ is greater than W_{critical} of 0.935, the quantile given in Table F-3, and conclude that the data were drawn from a population with an underlying normal distribution.

The W test was repeated after the transformation of $y_i = \ln x_i$ resulted in $W_{\text{test}} = 0.928$. Because the calculated value is less than the critical value ($W_{\text{critical}} = 0.935$), there is sufficient evidence to reject the null hypothesis. The conclusion is that the data set was not drawn from a population having an underlying lognormal distribution.

When the W test fails to reject the null hypotheses for both the normal and lognormal distributions, the W_{test} value which exceeds the W_{critical} value the most is selected as the distribution for the data set. When the W test rejects the null hypotheses for both the

normal and lognormal distribution but one is close ($W_{\text{test}} > 0.95 W_{\text{critical}}$) to the test value, then this distribution (normal or lognormal) is selected. If both the normal and lognormal W_{test} values are not close to W_{critical} , then the distribution is considered to be undefined and nonparametric statistical analyses will be used to described the data set.

Shapiro-Francia Test for Normality

The W test developed by Shapiro and Wilk was used to determine whether or not a data set has been drawn from a population which is normally distributed for sample size of 50 or less while the Shapiro-Francia test (Shapiro and Francia, 1972) was used when the sample size was greater than 50.

Like the Shapiro-Wilk test, the Shapiro-Francia test statistic (W') can be calculated using the natural logarithm of each data value. This is used to determine whether or not the sample was drawn from an underlying lognormal distribution. The null hypothesis to be tested is:

H_0 : The population has normal (lognormal when data is transformed) distribution.

versus

H_A : The population does not have a normal (lognormal when data is transformed) distribution.

If H_0 is rejected, then H_A is accepted.

To calculate the test statistic one can use the following formula:

$$W' = \frac{\left[\sum_{i=1}^n m_i x_i \right]^2}{(n-1) s^2 \sum_{i=1}^n m_i^2}$$

where x_i represents the i^{th} ordered value of the sample and where m_i denotes the approximate expected value of the i^{th} ordered normal quantile. The value for m_i can be approximately computed as:

$$m_i = \Phi^{-1} \alpha \left(\frac{i}{n+1} \right)$$

where Φ^{-1} denotes the inverse of the standard normal distribution with zero mean and unit variance. These values can be computed by hand using a normal probability table (Table F-5) or via simple commands in many statistical computer packages.

1. Order the n data points in ascending order (smallest to largest) such that $x_1 \leq x_2 \leq x_3 \leq \dots \leq x_n$.
2. Compute $[i/(n+1)]$ when n is the total number of samples and i is the i^{th} data point.
3. Compute the normal quantile (m_i).
4. Compute the square of the normal quantile.
5. Compute the multiplication of the normal quantile times the corresponding data value.
6. Compute the arithmetic standard deviation.

$$s = \sqrt{\frac{\sum_{i=1}^n (x_i - \bar{x})^2}{n-1}}$$

where:

$$\bar{x} = \frac{\sum_{i=1}^n x_i}{n}$$

7. Compute the denominator of Shapiro-Francia Test.
8. Compute the numerator of the Shapiro-Francia Test.
9. Compute W' .
10. Reject H_0 at the α significance level is W' is less than the quantile given in Table F-6.

To test the null hypothesis that the population has a lognormal distribution, transform the observed data to y_i , $y_2 \dots y_n$ where $y_i = \ln x_i$. Repeat steps 1 through 10 as described above.

Example:

To illustrate the application of the Shapiro-Francia test, the data in Table F-7 is used.

1. Order the n data points in ascending order (smallest to largest) as in Column 2.
 2. Compute $(i/(n+1))$ where n is the total number of samples ($n = 83$) which is presented in Column 3.
 3. Compute the normal quantile (m_i) corresponding to Column 3 probabilities. The normal quantiles are presented in Column 4.
 4. Compute the square of the normal quantiles which are presented in Column 5.
 5. Compute the multiplication of the normal quantiles (Column 4) times the corresponding data point (Column 2). These results are presented in Column 6.
 6. Compute the arithmetic standard deviation.
- $s = 0.019$ (See arithmetic standard deviation example for the procedure for calculation of this value; note that the data sets are not the same.)
7. Compute the denominator of the Shapiro-Francia Test.

$$(n-1) s^2 \sum_{i=1}^n m_i^2 = 82 (0.019)^2 (75.611) \\ = 2.238$$

8. Compute the numerator of the Shapiro-Francia Test.

$$\left[\sum_{i=1}^n m \bar{x}_{(i)} \right]^2 = [0.742]^2 = 0.551$$

9. Compute W' .

$$W' = \frac{0.551}{2.238}$$

$$= 0.246$$

10. Reject H_0 at the 0.05 significance level because $W'_{\text{test}} = 0.246$ is less than W'_{critical} of 0.985, the quantile given in Table F-6, and concluded that the data were not drawn from a population with an underlying normal distribution.

The Shapiro-Francia Test was repeated after the transformation of $y_i = \ln x_i$ resulted in $W'_{\text{test}} = 0.659$. Because the calculated value is less than the critical value ($W'_{\text{critical}} = 0.985$), it is concluded that the data set was not drawn from a population having an underlying lognormal distribution.

When the W' test fails to reject the null hypotheses for both the normal and lognormal distributions, the W'_{test} value which exceeds the W'_{critical} value the most is selected as the distribution for the data set. When the W' test rejects the null hypotheses for both the normal and lognormal distribution but one is close ($W'_{\text{test}} > 0.95 W'_{\text{critical}}$) to the test value, then this distribution is (normal or lognormal) selected. If both the normal and lognormal W'_{test} are not close to W'_{critical} , then the distribution is considered to be undefined and nonparametric statistical analyses will be used to describe the data set.

Rosner's Test for Many Outliers

To use Rosner's Test (Gilbert 1987, Equations 15.1 to 15.3) it is necessary to specify an upper limit of the number of potential outliers present. This analysis was performed for up to ten outliers. Rosner's Test requires the calculation of a test statistic R_{i+1} using the following equation:

$$R_{i+1} = \frac{|x^{(i)} - \bar{x}^{(i)}|}{s^{(i)}}$$

where:

R_{i+1} = test statistic for deciding whether the $i + 1$ most extreme values in the complete data set are statistical outliers

$i = 0$ for the first suspected outlier

$i = 1$ for the second suspected outlier

.

$i = 9$ for the tenth suspected outlier

$$\bar{x}^{(i)} = \frac{1}{n-i} \sum_{j=1}^{n-i} x_j$$

$\bar{x}^{(i)}$ = sample arithmetic mean of the remaining data set after the i most extreme observations have been deleted

$$s^{(i)} = \left[\frac{1}{n-i} \sum_{j=i}^{n-i} (x_j - \bar{x}^{(i)})^2 \right]^{1/2}$$

$s^{(i)}$ = sample standard deviation of the remaining data set after the i most extreme observations have been deleted

and

x_j = j^{th} observation in the data set

n = total number of observations in the data set

A suspected extreme value is determined to be an outlier if the calculated value of R_{i+1} exceeds the critical value λ_{i+1} for a sample of size n (Table F-8).

In applying Rosner's Test when there is only one suspected outlier, $i = 0$ and

$$R_{i+1} = R_1 = \frac{|x^{(0)} - \bar{x}^{(0)}|}{s^{(0)}}$$

and

$x^{(0)}$ = suspected outlier

$\bar{x}^{(0)}$ = sample arithmetic mean of the n observations including the suspected outlier

$s^{(0)}$ = sample arithmetic standard deviation of the n observations including the suspected outlier

Source: Table A-16, Gilbert 1987.

When Rosner's Test is applied in a situation where there are two suspected outliers, $i=1$ and

$$R_{i+1} = R_2 = \frac{|x^{(1)} - \bar{x}^{(1)}|}{s^{(1)}}$$

and

$x^{(1)}$ = the second suspected outlier

$\bar{x}^{(1)}$ = the sample arithmetic mean after the first suspected outlier $x^{(0)}$ has been deleted from the data set

$s^{(1)}$ = the sample arithmetic standard deviation after the first suspected outlier $x^{(0)}$ has been deleted from the data set

Example:

Table F-9 presents example data set number 3 which is used for this example. The highest and lowest posted concentrations of 4850 $\mu\text{g/L}$ and 189 $\mu\text{g/L}$, respectively, are considered to be potential outliers. To begin with, Rosner's Test is applied to determine whether or not the value of 4850 $\mu\text{g/L}$ is a statistical outlier. In this case, $i = 0$ and

$$R_1 = \frac{|x^{(0)} - \bar{x}^{(0)}|}{s^{(0)}}$$

The data are best described by a lognormal distribution and as such

$$R_1 = \frac{|y^{(0)} - \bar{y}^{(0)}|}{s^{(0)}}$$

where:

$$y^{(0)} = \ln x^{(0)}$$

$$= \ln (4850)$$

$$= 8.487$$

Table F-9
 Example Data Set Number 3

Chemical	Validated result, ug/L	Validation qualifier	Concentration used in statistics (a)	
			Normal	Lognormal
Manganese	189	-	189	5.242
Manganese	301	-	301	5.707
Manganese	351	-	351	5.861
Manganese	370	-	370	5.914
Manganese	386	-	386	5.956
Manganese	422	-	422	6.045
Manganese	437	-	437	6.080
Manganese	451	-	451	6.111
Manganese	456	-	456	6.122
Manganese	481	-	481	6.176
Manganese	488	J	488	6.190
Manganese	521	-	521	6.256
Manganese	534	-	534	6.280
Manganese	535	-	535	6.282
Manganese	543	-	543	6.297
Manganese	581	-	581	6.365
Manganese	615	-	615	6.422
Manganese	619	J	619	6.428
Manganese	747	J	747	6.616
Manganese	766	-	766	6.641
Manganese	785	-	785	6.666
Manganese	840	-	840	6.733
Manganese	941	-	941	6.847
Manganese	1050	-	1050	6.957
Manganese	1070	J	1070	6.975
Manganese	1090	-	1090	6.994
Manganese	1150	-	1150	7.048
Manganese	1460	-	1460	7.286
Manganese	1500	J	1500	7.313
Manganese	4850	-	4850	8.487

(a) When the validation qualifier contains a "U", then one-half of the concentration is used in the statistical calculations.

$\bar{y}^{(0)}$ = sample arithmetic mean of $\ln x$ using all 30 observations in the data set

$$= 6.477$$

$s^{(0)}$ = sample arithmetic standard deviation of $\ln x$ using all 30 observations in the data set

$$= 0.6098$$

Thus

$$R_1 = \frac{|8.487 - 6.477|}{0.6098} = 3.296$$

Because $R_1 = 3.296$ is greater than the critical value of $\lambda_{1,1} = 2.91$ (Table F-8) for a significance level of 0.05, Rosner's Test indicates that the observed value of 4850 $\mu\text{g/L}$ is a statistical outlier.

Next Rosner's Test is used to determine whether or not there is sufficient evidence to conclude that the minimum value of 189 $\mu\text{g/L}$ is a statistical outlier.

After deleting the maximum value of 4850 $\mu\text{g/L}$ from the data set, calculate

$$R_2 = \frac{|y^{(1)} - \bar{y}^{(1)}|}{s^{(1)}}$$

where:

$$y^{(1)} = \ln (189)$$

$$= 5.242$$

$$\bar{y}^{(1)} = 6.407$$

$$s^{(1)} = 0.4889$$

Then

$$R_2 = \frac{|5.242 - 6.407|}{0.489} \\ = 2.38$$

Because $R_2 = 2.38$ is less than the critical value of $\lambda_2 = 2.89$ (Table F-8) for a significance level of 0.05, Rosner's Test indicates that there is insufficient evidence to reject the observed value of $189 \mu\text{g/L}$. The value is not a statistical outlier. This test is repeated on the high and low ends until there is insufficient evidence to reject the null hypothesis or 10 outliers are identified. This test identifies outliers but professional judgment was used to determine whether the value should be removed from the data set.

Data Averaging

Data averaging was conducted when two or more samples were collected at the same sampling location on the same day (i.e., duplicates, triplicates, etc.). Multiple samples collected on a particular day and location were averaged to obtain one sample per day at the sampling location. Data averaging was conducted to avoid statistical bias which would have resulted from favoring one day's multiple sampling over one sample on a particular day. The data was separated into data groups by the following: media (i.e., Glacial Overburden, Great Miami Aquifer, Great Miami River, and Paddys Run), constituent type (i.e., radiological, inorganic, and organic constituents), and filter type (i.e., filtered and unfiltered). The following steps were repeated for each of the above data groups:

1. Nondetect values were assigned a value of one-half the detection limit.
2. The data were sorted by three key parameters: 1) chemical name, 2) sample location, and 3) sampling date.
3. A record-by-record comparison was performed to identify records for which all three sort parameters were the same. This step identified multiple samples collected on a particular day for a specific constituent.
4. A sample arithmetic mean was calculated on the records with matching key parameters.
5. If all of the values being averaged were nondetects, the average was also a nondetect. If one or more of the values being averaged were detect values, then the resulting average was also considered to be a detect value.
6. A new line was added to the database for the averages of the matching records.
7. The individual records that were combined to create the average line were removed from the statistical data set.

Example:

The example data set is presented in Table F-10. To simplify this example, only one constituent was selected. Seven ammonia samples were collected from 1988 to 1993. The following steps were performed to calculate the averaged values that were used in the statistical analysis:

1. Nondetect values were assigned a value of one-half the detection limit. This occurred for five of the seven values (i.e., <1 equals 0.05).

FEMP Background Study
May 1994

2. The data were sorted by three key parameters: 1) chemical name (ammonia), 2) sample location (W-1), and 3) sampling date. There only was one sampling location for W-1 and W-5; however, multiple sampling locations (wells) were sampled for the glacial overburden and Great Miami Aquifer (5 and 24, respectively).
3. A record-by-record comparison identified the following matches: three samples collected on May 20, 1993 and two samples collected on June 23, 1993. Individual records were identified on August 29, 1988 and April 3, 1989.
4. All samples collected on May 20 and June 23, 1993, had nondetect values of <0.1 (0.05 for statistics); therefore, the averaged value for these two days was a nondetect value of <0.1 .
5. The averaged values are both nondetects, since all of the data used to calculate the average value were nondetects.
6. New lines were added to the database for these two averaged records from the matching key parameters.
7. The five lines that were combined to create the averaged records were removed from the statistical database.

Sample Arithmetic Mean - Normal Distribution

The sample arithmetic mean for a normal distribution is given by:

$$\bar{x} = \frac{\sum_{i=1}^n x_i}{n}$$

Example:

Using example data set number 1 presented in Table F-4, the sample arithmetic mean is calculated as follows:

$$\begin{aligned}\bar{x} &= [0.017 + 0.0245 + \dots + 0.066 + 0.073]/36 \\ &= 0.045\end{aligned}$$

Sample Arithmetic Standard Deviation - Normal Distribution

The sample arithmetic standard deviation for a population based on a sample is given by:

$$s = \sqrt{\frac{\sum_{i=1}^n (x_i - \bar{x})^2}{n-1}} = \sqrt{\frac{\sum_{i=1}^n x_i^2 - \left[\sum_{i=1}^n x_i \right]^2 / n}{n-1}}$$

Example:

Using example data set number 1 presented in Table F-4, the sample arithmetic standard deviation for a normal distribution is calculated as follows where $n = 36$ and:

$$\sum_{i=1}^n x_i^2 = (0.017)^2 + (0.0245)^2 + \dots + (0.066)^2 + (0.073)^2$$

$$= 0.081$$

$$\left[\sum_{i=1}^n x_i \right]^2 = [0.017 + 0.0245 + \dots + 0.066 + 0.073]^2$$

$$= 2.670$$

$$s = \sqrt{\frac{0.081 - 2.670/36}{36 - 1}}$$

$$= 0.014$$

Estimated Coefficient of Variation - Normal Distribution

The estimated coefficient of variation for a normal distribution is calculated by the following:

$$CV = s/\bar{x}$$

where:

\bar{x} = arithmetic mean

s = sample standard deviation

CV = estimated coefficient of variation

Example:

Using example data set number 1 presented in Table F-4, the estimated coefficient of variation for a normal distribution is calculated as follows:

$$\begin{aligned}\bar{x} &= 0.045 \\ s &= 0.014\end{aligned}$$

$$\begin{aligned}CV &= 0.014/0.045 \\ &= 0.31\end{aligned}$$

Estimated Mean of a Lognormal Distribution

The estimated mean of a lognormal distribution (Gilbert 1987, Equation 13.7) can be calculated by using the sample mean (\bar{y}) and the sample standard deviation (s_y) of the log-transformed data. The formula is as follows:

$$\mu = \exp \left(\bar{y} + \frac{s_y^2}{2} \right)$$

Example:

Using the data in Table F-4, the estimated mean of a lognormal distribution is calculated as follows where $n = 36$ and:

$$\begin{aligned} \bar{y} &= \frac{\sum_{i=1}^n \ln(x_i)}{n} = \left[\frac{[\ln(0.017) + \ln(0.0245) + \dots + \ln(0.066) + \ln(0.0073)]}{36} \right] \\ &= \frac{-113.201}{36} \\ &= -3.144 \end{aligned}$$

$$s_y = \sqrt{\frac{\sum_{i=1}^n (\ln(x_i) - \bar{y})^2}{n - 1}} = \sqrt{\frac{\sum_{i=1}^n [\ln(x_i)]^2 - \left(\sum_{i=1}^n \ln(x_i) \right)^2 / n}{n - 1}}$$

FEMP Background Study
May 1994

$$\sum_{i=1}^n [\ln(x_i)]^2 = \ln(0.017)^2 + \ln(0.0245)^2 + \dots + \ln(0.066)^2 + \ln(0.073)^2$$

$$= 360.063$$

$$\sum_{i=1}^n [\ln(x_i)] = \ln(0.017) + \ln(0.0245) + \dots + \ln(0.066) + \ln(0.073)$$

$$= -113.201$$

$$s_y = \sqrt{\frac{360.063 - (-113.201)^2/36}{36-1}}$$

$$= 0.342$$

$$\hat{\mu} = \exp \left[-3.144 + \frac{(0.342)^2}{2} \right]$$

$$= 0.046$$

Estimated Standard Deviation of a Lognormal Distribution

The estimated standard deviation of a lognormal distribution (Gilbert 1987, Equation 13.8) can be calculated by using the estimate for the mean of the lognormal distribution ($\hat{\mu}$) and the sample standard deviation (s_y) of the log-transformed data. The formula is as follows:

$$\hat{\sigma} = \sqrt{\hat{\mu}^2 [\exp (s_y^2) - 1]}$$

Example:

Data in Table F-4 were used to calculate the estimated standard deviation of a lognormal distribution. The parameters used in this example were presented in the example for estimating the mean of a lognormal distribution where $\hat{\mu} = 0.046$ and $s_y = 0.342$. Therefore, the estimated standard deviation of a lognormal distribution is calculated as follows:

$$\begin{aligned}\hat{\sigma} &= \sqrt{(0.046)^2 [\exp (0.342)^2 - 1]} \\ &= 0.0162\end{aligned}$$

Sample Median - Nonparametric Technique

The true median of an underlying distribution (Gilbert 1989, Equations 13.15 and 13.16) is that value above which and below which half of the distribution lies. The median of any distribution, no matter what its shape, can be estimated by the following:

$$\begin{aligned} \text{Sample median} &= x_{[(n+1)/2]} \text{ if } n \text{ is odd} \\ &= \frac{x_{[n/2]} + x_{[(n+2)/2]}}{2} \text{ if } n \text{ is even} \end{aligned}$$

where:

$x_{[i]}$ = i^{th} data value in the ordered data set

Example:

Using example data set number 1 presented in Table F-4, the sample median is calculated as follows where $n = 36$ and:

$$\begin{aligned} \text{Median} &= \frac{x_{[36/2]} + x_{[(36+2)/2]}}{2} \\ &= \frac{x_{18} + x_{19}}{2} \\ &= (0.045 + 0.045)/2 \\ &= 0.045 \end{aligned}$$

If n were 35 rather than 36, then the median would be at $x_{18} = 0.045$.

Upper One-sided 95% Confidence Limit - Normal Distribution

The mean (\bar{x}_1) for a sample of size n is referred to as a point estimate of the true but unknown population mean (μ). If a second sample of size n is drawn from the sample population, the sample mean (\bar{x}_2) will most likely not be equal to \bar{x}_1 . In fact if the sampling process is replicated many times, the sample means themselves will have a distribution. Further, the distribution of means of samples of size n will tend toward a normal distribution, if n is sufficiently large.

The $100 (1-\alpha)$ Upper Confidence Limit (Gilbert 1987, Equation 11.6) of the population mean (μ) can also be calculated. When $\alpha = 0.05$, the upper one-sided 95 percent confidence limit is:

$$95\% \text{ } UCL_N = \bar{x} + t_{0.95, n-1} \frac{s}{\sqrt{n}}$$

where:

$$\bar{x} = \frac{1}{n} \sum_{i=1}^n x_i$$

$$s = \left[\frac{1}{n-1} \sum_{i=1}^n (x_i - \bar{x})^2 \right]^{1/2}$$

$t_{0.95, n-1}$ = value from the "t" distribution in Table F-11.

It should be noted that the 95 percent confidence limit for a second sample of size n drawn from the same population will most likely not be the same as that for the first sample. In theory if a limit estimate is calculated for the means of a very large set of samples of size n , the true population mean will be less than the limit 95 percent of these limits. If the number of degrees of freedom is not listed in Table F-11, then linear interpolation was performed to obtain the t-value.

Table F-11
Quantiles of the t Distribution (Values of t Such that 100p%
of the Distribution Is Less Than tp)

Degrees of freedom	t at 0.60	t at 0.70	t at 0.80	t at 0.90	t at 0.95	t at 0.975	t at 0.990	t at 0.995

Source: Table A-2, Gilbert 1987.

Example:

Using example data set number 1 in Table F-4, the upper one-sided 95 percent confidence limit for a normal distribution was calculated as follows:

$$n = 36$$

$$\bar{x} = 0.045$$

$$s = 0.014$$

$$t_{0.95,35} = 1.6905$$

$$95\% UCL_N = 0.045 + (1.6905) \frac{0.014}{\sqrt{36}}$$

$$= 0.049$$

Upper One-Sided 95% Confidence Limit - Lognormal Distribution

The procedure for calculating the upper 95% confidence limit for the lognormal distribution (Gilbert 1987, Equation 13.13) is given by:

$$95\% \text{ } UCL_L = \exp \left[\bar{y} + 0.5 s_y^2 + \frac{s_y H_{0.95}}{\sqrt{n-1}} \right]$$

where:

y = $\ln x$

\bar{y} = arithmetic mean of y

s_y = standard deviation of y

n = number of data points

$H_{0.95}$ = value from Table F-12 for sample of size n

Example:

The data presented in Table F-4 were used for this example. The mean of the log transformed data (\bar{y}) equals -3.144 and the standard deviation of the log transformed data equals 0.342. These were previously calculated in the section on calculating the estimated mean of a lognormal distribution. Tables for determining H values are presented individually by number of data points for various significance levels. A summary of these tables for a 0.05 significance level ($H_{0.95}$) is presented in Table F-12. When the number of data points was not listed in this Table F-12 then linear interpolation between columns was performed. In addition, if s_y did not match the s_y in the first column of Table F-12, then linear interpolation between column values was performed. The upper 95% one-sided confidence limit for the lognormal distribution is calculated as follows:

where:

$n = 36$

$y = -3.144$ (see estimated mean of lognormal distribution example)

$s_y = 0.342$

$H_{0.95} = 1.807$ (linear interpolation between s_y values)

Table F-12 (Continued)

Number of data points

Source: Land, C.E., "Tables of Confidence Limits for Linear Functions of the Normal Mean and Variance," Selected Tables in Mathematical

5644
4403

$$\begin{aligned} 95\% \text{ } UCL_L &= \exp \left[-3.144 + 0.5(0.342)^2 + \frac{(0.342)(1.807)}{\sqrt{36-1}} \right] \\ &= \exp (-2.981) \\ &= 0.051 \end{aligned}$$

Thus the upper one-sided 95% confidence limit for the lognormal distribution is 0.051.

Upper One-Sided 95% Confidence Limit - Nonparametric Technique

The upper 95% one-sided confidence limit for an undefined distribution is based on a nonparametric technique (Gilbert 1987, Equation 13.2). It is simply the upper 95% confidence limit on the median of the data set. The following equations are used to calculate the upper one-sided 95% confidence limit for an undefined distribution:

$$U = \frac{n+1 + Z_{0.95} \sqrt{n}}{2}$$

$$95\% \text{ } UCL_{NP} = x_{[f(U)]}$$

where:

n = number of data points

$Z_{0.95}$ = upper 95% limit from a standard normal curve for a Z distribution
[Table F-5 at 0.95 ($Z_{0.95}$) = 1.645]

U = rank in an ascending order data set that corresponds to the one-sided 95% confidence limit on the median

$f(U)$ = U rounded up to an integer (e.g., 24.2 \rightarrow 25)

Example:

Using the data presented in Table F-4, the upper one-sided 95% confidence limit on the median is calculated by the following steps.

1. Order the data in ascending order
2. Determine the number of data points (36)
3. Obtain the $Z_{0.95}$ from Table F-5 (1.645)

4. Calculate U

$$U = \frac{36+1 + 1.645 \sqrt{36}}{2}$$
$$= 23.435$$

5. Round up to an integer (24)
6. Determine the "U"th value in the ascending order data set value at the 24th rank = (0.514)

The 95% UCL_{NP} for this data set is 0.514.

95th Percentile - Normal Distribution

The 95th Percentile (or Quantile) for a normal distribution are used to determine maximum background concentrations from data sets that are normally distributed. The 95th percentile for a normal distribution (Gilber 1987, Equation 11.1) is calculated based on the following equation:

$$95^{\text{th}} \text{ Percentile}_N = \bar{x} + Z_{0.95} s$$

where:

\bar{x} = sample arithmetic mean

s = sample arithmetic standard deviation

$Z_{0.95}$ = upper 95% limit from a standard normal curve for a Z distribution
[Table F-5 at 0.95 ($Z_{0.95}$) = 1.645]

Example:

Using example data set number 1 in Table F-4, the 95th percentile for a normal distribution was calculated by the following:

$$\bar{x} = 0.045$$

$$s = 0.014$$

$$Z_{0.95} = 1.645$$

$$\begin{aligned} 95^{\text{th}} \text{ Percentile}_N &= 0.045 + (1.645) (0.014) \\ &= 0.068 \end{aligned}$$

95th Percentile - Lognormal Distribution

The 95th Percentile (or Quantile) for a lognormal distribution (Gilbert 1987, Equation 13.24) is calculated based on the following equation.

$$95^{\text{th}} \text{ Percentile}_L = \exp (\bar{y} + Z_{0.95} s_y) = \exp (\bar{y}) \exp (Z_{0.95} s_y)$$

where:

\bar{y} = sample arithmetic mean of y

s_y = sample arithmetic standard deviation of y

$Z_{0.95}$ = upper 95% limit from a standard normal curve for a Z distribution
[Table F-5 at 0.95 ($Z_{0.95}$) = 1.645]

Example:

Using example data set number 1 in Table F-4, the 95th Percentile for a lognormal distribution was calculated by the following:

$$\bar{y} = -3.144$$

$$s_y = 0.342$$

$$Z_{0.95} = 1.645$$

$$\begin{aligned} 95^{\text{th}} \text{ Percentile}_L &= \exp [-3.144 + (1.645) (0.342)] \\ &= \exp (-2.581) \\ &= 0.0757 \end{aligned}$$

95th Percentile - Nonparametric Technique

The 95th for an undefined distribution is based on a nonparametric technique. It is calculated by the following equations:

$$Q = 0.95 \ n$$

$$95^{\text{th}} \text{ Percentile}_{\text{NP}} = X_{[f(Q)]}$$

where:

n = number of data points

Q = rank in an ascending order data set that corresponds to the one-sided 0.95 quantile based on a nonparametric technique

$f(Q)$ = Q rounded up to an integer (e.g., $14.1 \rightarrow 15$)

Example:

Using the example data set presented in Table F-4, the 95th percentile based on a nonparametric technique is calculated by the following steps:

1. Order the data in ascending order
2. Determine the number of data point (36)
3. Calculate Q

$$Q = (0.95) (36)$$

$$= 34.2$$
4. Round Q up to an integer (35)
5. Determine the "Q"th value in the ascending order data set (value at 35th rank = 0.066)

The 95th Percentile_{NP} for this data set is 0.066.

F-Test

The F-test is conducted to test whether there is no difference between two population variances from a combined data set that is normally distributed. By conducting this test on the natural logarithms of each data value, the F-test was used to determine whether there is no difference between population variances from a combined data set that is lognormally distributed. An alpha of 0.05 was selected for this test. The null hypothesis to be tested is:

$$H_0: \text{The populations have equivalent variances } (\sigma_1^2 = \sigma_2^2)$$

versus

The alternative hypothesis Rejection Region for a Level 0.05 Test

$$H_A: \sigma_1^2 > \sigma_2^2$$

$$F_{\text{test}} \geq F_{0.05, n_1 - 1, n_2 - 1}$$

$$H_A: \sigma_1^2 < \sigma_2^2$$

$$F_{\text{test}} \leq F_{0.95, n_1 - 1, n_2 - 1}$$

$$H_A: \sigma_1^2 \neq \sigma_2^2$$

either

$$F_{\text{test}} \geq F_{0.025, n_1 - 1, n_2 - 1} \text{ Or}$$

$$F_{\text{test}} \leq F_{0.975, n_1 - 1, n_2 - 1}$$

The following is the procedure to determine whether the two groups have variances which are statistically significantly different.

1. Calculate the sample variances of the two groups (s_1^2 and s_2^2).
2. Calculate the test statistic.

$$F_{\text{test}} = s_1^2/s_2^2$$

3. Determine the two F_{critical} values. These critical values are $F_{0.025, n_1 - 1, n_2 - 1}$, which is obtained from Table F-13, while $F_{0.975, n_1 - 1, n_2 - 1}$ is obtained from $1/F_{0.025, n_2 - 1, n_1 - 1}$.

4. Compare F_{test} versus the F_{critical} values.

Based on the rejection table listed above, when F_{test} is between the two F_{critical} values, there is insufficient information to conclude that the sample variances are from two different populations. Some statistical packages provide p-values (significance levels) based on the F-test statistic (F_{test}). When using these statistical packages, a p-value (significance level) of 0.05 was used. When the p-value was greater than or equal to 0.05, then the null hypothesis (H_0) was not rejected. When the p-value was less than 0.05, then the null hypothesis was rejected or the alternative hypothesis was accepted.

Example:

The log transformed data column from Table F-14 was used to conduct the F-test. The procedure for determining whether the two populations have the same sample variances was calculated as follows:

1. Calculate the sample variances.

$$s^2 = \frac{1}{n-1} \sum_{i=1}^n (x_i - \bar{x})^2$$

$$s_1^2 = 1.415$$

$$s_2^2 = 1.853$$

2. Calculate the test statistic.

$$\begin{aligned} F_{\text{test}} &= s_1^2/s_2^2 \\ &= 1.415/1.853 \\ &= 0.764 \end{aligned}$$

3. Determine the two F_{critical} values.

$$\begin{aligned} F_{0.025,9,14} &= 3.21 \\ F_{0.975,9,14} &= 1/F_{0.025,14,9} \\ &= 1/3.80 \\ &= 0.263 \end{aligned}$$

Table F-14
Example Data Set Number 5

No. of data points	FEMP			Private			
	Total Uranium, ug/L	Validation qualifier	Conc. used in statistics (a)		Validation qualifier	Conc. used in statistics (a)	
			Normal	Log-normal		Normal	Log-normal
1	0.1	UJ	0.05	-2.996	UJ	0.05	-2.996
2	0.5	J	0.5	-0.693	UJ	0.05	-2.996
3	0.7	J	0.7	-0.357	UJ	0.05	-2.996
4	1	-	1	0.000	UJ	0.05	-2.996
5	1.1	-	1.1	0.095	U	0.05	-2.996
6	1.2325	-	1.2325	0.209	U*	0.275	-1.291
7	1.791	-	1.791	0.583	U*	0.275	-1.291
8	2	J	2	0.693	J	0.476	-0.742
9	2	-	2	0.693	J	0.735	-0.308
10	3.852	-	3.852	1.349	J	0.756	-0.280
11					J	0.851	-0.161
12					J	1	0.000
13					J	1	0.000
14					-	1	0.000
15					-	1.5	0.405
Average			1.423	-0.042		0.541	-1.243

(a) When the validation qualifier contains a "U", then one-half of the concentration is used in the statistical calculations.

4. Compare F_{test} versus the F_{critical} values.

$$F_{0.975, 9, 14} < F_{\text{test}} \text{ and } F_{0.025, 9, 14} > F_{\text{test}}$$

$$0.263 < 0.764 \text{ and } 3.21 > 0.764$$

Since F_{test} is between the two F_{critical} values, the null hypothesis (H_0) is not rejected. If F_{test} were not between the F_{critical} values, the null hypothesis would be rejected. Based on these results, there is insufficient evidence to conclude that the sample variances are from two different populations (lognormally distributed).

T-Test

The T-test is conducted to test whether there is no difference between two population means with equal variances from a combined data set that is normally distributed. By conducting this test on the natural logarithms at each data value, the T-test was used to determine whether there is no difference between two population means with equal variances from a combined data set that is lognormally distributed. An alpha of 0.05 was selected for this test. The null hypothesis to be tested is:

H_0 : The populations have equal means

versus

The alternative hypothesis Rejection Region for a Level 0.05 Test

H_A : $\mu_1 > \mu_2$

H_A : $\mu_1 < \mu_2$

H_A : $\mu_1 \neq \mu_2$

either

$$T_{\text{test}} \geq T_{0.95, n_1 + n_2 - 2}$$

$$T_{\text{test}} \leq -T_{0.95, n_1 + n_2 - 2}$$

$$T_{\text{test}} \geq T_{0.975, n_1 + n_2 - 2} \text{ OR}$$

$$T_{\text{test}} \leq -T_{0.975, n_1 + n_2 - 2}$$

The following is the procedure to determine whether the two groups have means which are statistically significantly different.

1. Calculate the sample means of the two groups (\bar{x}_1 and \bar{x}_2).
2. Calculate the sample variances of the two groups (s_1^2 and s_2^2).
3. Calculate the estimated pooled standard deviation.

$$s = \left[\frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2}{n_1 + n_2 - 2} \right]^{0.5}$$

4. Calculate the test statistic.

$$T_{\text{test}} = \frac{\bar{x}_1 - \bar{x}_2}{s \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}}$$

5. Determine the critical values (T_{critical}) from Table F-11.

6. Compare T_{test} versus the T_{critical} values.

Based on the rejection table listed above, when the T_{test} statistic is between the two critical values, there is insufficient information to conclude that the means are from two different populations. Some statistical packages provide p-values (significance levels) based on the T_{test} statistics. When using these statistical packages, a p-value (significance level) of less than 0.05 was used. When the p-value was greater than or equal to 0.05, then the null hypothesis (H_0) was not rejected. When the p-value was less than 0.05, then the null hypothesis was rejected or the alternative hypothesis was accepted.

Example:

The log transformed data column from Table F-14 was used to conduct the T-test. The procedure for determining whether the two populations have the same means is as follows:

1. Calculate the sample means.

$$\bar{x}_1 = -0.042 \text{ (from Table F-14)}$$

$$\bar{x}_2 = -1.243 \text{ (from Table F-14)}$$

2. Calculate the sample variances.

$$s_1^2 = 1.415 \text{ (from F-test example)}$$

$$s_2^2 = 1.853 \text{ (from F-test example)}$$

3. Calculate the estimated pooled standard deviation.

$$s = \left[\frac{(10 - 1)(1.415) + (15 - 1)(1.853)}{10 + 15 - 2} \right]^{0.5}$$

$$= 1.297$$

4. Calculate the test statistic.

$$T_{\text{test}} = \frac{((-0.042) - (-1.243))}{1.297 \sqrt{\frac{1}{10} + \frac{1}{15}}} = 2.268$$

5. Determine the critical values from Table F-11.

$$T_{0.975, 23} = 2.069$$

6. Compare T_{test} versus the critical values.

$$T_{\text{test}} \geq T_{0.975, 23} \quad \text{and} \quad T_{\text{test}} \geq -T_{0.975, 23}$$

$$2.268 \geq 2.069 \quad \text{and} \quad 2.268 \geq -2.069$$

Since T_{test} is greater than $T_{0.975, 23}$, the null hypothesis is rejected. Based on these results, there is a statistically significant difference between these two means. Furthermore, these data sets are not from the same lognormal distribution.

The Wilcoxon Rank Sum Test

The Wilcoxon Rank Sum test is a procedure which can be used to determine whether two sample groups have equivalent means. This test assumes that the distributions of the two populations are identical in shape (variance), but the distributions need not be symmetric. The Wilcoxon Rank Sum test was used when comparing two populations (i.e., FEMP vs. private wells in the glacial overburden), while the Kruskal-Wallis test was used when comparing three or more populations (i.e., Dry Fork, Ross, and Shandon tributaries of the Great Miami Aquifer). In general, the Wilcoxon Rank Sum test should be employed whenever the proportion of nondetects is greater than 15 percent but less than 90 percent. However, in order to provide valid results, the Wilcoxon Rank Sum test should not be used unless both data sets contain at least four samples. The following equations present a step-by-step procedure for conducting the Wilcoxon Rank Sum test.

1. Combine the Group 1 with the Group 2 data and rank the ordered values from 1 to N. Assume there are n Group 1 samples and m Group 2 samples so that $N = m + n$.

2. Compute the Wilcoxon statistic W:

$$W = \sum_{i=1}^n E_i - \frac{1}{2} n (n + 1)$$

where E_i are the ranks of the Group 1 samples. (Large values of the statistic W give evidence that the groups are not from the same populations.)

3. Compute an approximate Z_{test} . To find the critical value of W, a normal approximation to its distribution is used. The expected value and standard deviation of W under the null hypothesis (i.e., the groups are from the same population) are given by the formulas

$$E(W) = \frac{1}{2} mn;$$

$$SD(W) = \sqrt{\frac{1}{12} mn (N + 1)}$$

An approximate Z_{test} for the Wilcoxon Rank Sum test may be calculated by the following equations:

$$Z_{\text{test}} = \frac{W - E(W) - \frac{1}{2}}{SD(W)}$$

The factor of $\frac{1}{2}$ in the numerator serves as a continuity correction since the discrete distribution of the statistic W is being approximated by the continuous normal distribution. If $n, m > 10$ and ties are present, an adjustment to the approximate Z_{test} must be made:

$$Z_{\text{RS}} = \frac{W - E(W) - \frac{1}{2}}{SD'(W)} \quad \text{where } SD' = \left[\frac{mm}{12} N + 1 - \frac{\sum_{j=1}^g t_j (t_j^2 - 1)}{N(N-1)} \right]^{\frac{1}{2}}$$

and g is the number of tied groups and t_j is the number of tied data in the j^{th} group.

4. For a one-tailed 0.05 significance level test for H_0 versus the H_A (i.e., the measurements from population 1 tend to exceed those from population 2), reject H_0 and accept H_A if $Z_m \geq Z_{(1-\alpha)}$. For a one-tailed α significance level test for H_0 versus the H_A that the measurements from population 2 tend to exceed those from population 1, reject H_0 and accept H_A if $Z_m \leq Z_{(1-\alpha)}$.

Example:

The data for this example are presented in Table F-15.

1. Combine the FEMP and private Total Uranium data and rank the ordered values from 1 to 25 as shown in Table F-15.
2. Compute the Wilcoxon statistic W :

$$W = \sum_{i=1}^n E_i - \frac{1}{2}n(n+1) = 178 - \frac{1}{2}(10)(11) = 123$$

3. Compute an approximate Z_{test} . The expected value and standard deviation of W under the null hypothesis are given by the formulas

$$E(W) = \frac{1}{2}(15)(10) = 75; \quad SD(W) = \sqrt{\frac{1}{12}(15)(10)(25+1)} = 18.0$$

Table F-15
Example Data Set Number 6

Overall ranks	Total Uranium values used in calculations (a)	Type of well	Ranks	
			Private	FEMP
1	0.05	Private	1	N/A
2	0.05	Private	2	N/A
3	0.05	Private	3	N/A
4	0.05	Private	4	N/A
5	0.05	Private	5	N/A
6	0.05	FEMP	N/A	6
7	0.275	Private	7	N/A
8	0.275	Private	8	N/A
9	0.476	Private	9	N/A
10	0.5	FEMP	N/A	10
11	0.7	FEMP	N/A	11
12	0.735	Private	12	N/A
13	0.756	Private	13	N/A
14	0.851	Private	14	N/A
15	1	Private	15	N/A
16	1	Private	16	N/A
17	1	Private	17	N/A
18	1	FEMP	N/A	18
19	1.1	FEMP	N/A	19
20	1.2325	FEMP	N/A	20
21	1.5	Private	21	N/A
22	1.791	FEMP	N/A	22
23	2	FEMP	N/A	23
24	2	FEMP	N/A	24
25	3.852	FEMP	N/A	25
Sum			147	178

(a) These values are from Table F-14.

An approximate Z_{test} for the Wilcoxon Rank-Sum test then follows as:

$$Z_{\text{test}} = \frac{W - E(W) - \frac{1}{2}}{SD(W)} = \frac{123 - 75 - 0.5}{18.0} = 2.639$$

4. Compare the approximate Z_{test} to the upper 95th percentile of the standard normal distribution $Z_{0.05} = 1.645$. Since the approximate Z_{test} is greater than 1.645, the null hypothesis may be rejected at the 5 percent significance level, suggesting that there is statistically significant evidence that the populations have different means. The FEMP and private wells for Total Uranium in the Glacial Overburden are not from the same populations and not be combined.

Kruskal-Wallis Test for Comparing Populations

The Kruskal-Wallis test (Gilbert 1987) for comparing populations does not require that data sets be drawn from underlying distributions that are normal or even symmetric, but the K distributions are assumed to be identical in shape. The null hypothesis is

H_0 : The populations from which the data sets have been drawn have the same means.

The alternative hypothesis is

H_A : At least one population has a mean larger or smaller than at least one other population.

The data can be illustrated as follows:

Population				
1	2	3	...	k
x_{11}	x_{21}	x_{31}	...	x_{k1}
x_{12}	x_{22}	x_{32}	...	x_{k2}
.
.
.
x_{1n_1}	x_{2n_2}	x_{3n_3}	...	x_{kn_k}

The total number of data points is $m = n_1 + n_2 + \dots + n_k$; the n_i need not be equal.

Theses steps must be followed:

1. Rank the m data points from smallest to largest in which the smallest value has rank 1 and the largest value has rank m . If data points are equal ("ties") assign the midrank (e.g., data points 10 and 11 are the same; therefore, 10.5 is used for the rank of both points). If less-than-minimum detectable values occur, treat them as tied values that are less than the smallest detected value that is greater than the minimum detection limit. Suppose the m ranked values are as follows:

Data Value	Actual Rank	Assigned Rank
<0.05	1	2
<0.05	2	2
<0.05	3	2
0.08	4	4
0.09	5	5
0.12	6	6.5
0.12	7	6.5
0.20	8	8
0.21	9	10
0.21	10	10
0.21	11	10

2. Compute R_j the sum of the ranks for each data set.
3. If there are no tied or less-than-minimum detectable values, compute.

$$K_w = \left[\frac{12}{m(m+1)} \sum_{j=1}^k \frac{R_j^2}{n_j} \right] - 3(m+1)$$

where:

- m = total number of data values over all data sets
 R_j = sum of ranks of the j^{th} data set
 n_j = number of values in the j^{th} data set
 k = number of data sets

4. If there are ties or less-than-detectable values, compute:

$$K'_w = \frac{K_w}{1 - \frac{1}{m(m^2 - 1)} \sum_{j=1}^g t_j(t_j^2 - 1)}$$

where:

g = number of groups with ties
 t_j = the number of tied data in the j th group

5. Reject H_0 at α level and accept H_a if $K_w (K'_w)$ is equal to or greater than $\chi_{1-\alpha, k-1}$ using a probability level of $1-\alpha$ and $k-1$ degrees of freedom taken from Table F-16.

Example:

To illustrate the application of the Kruskal-Wallis K_w test consider the example data set presented in Table F-16. For these data, $m = 30 + 30 + 21 = 81$.

1. Rank all 81 observations (Table F-17).
2. The sum of the ranks for each group are as follows (Table F-18).

$$\begin{aligned} R_1 &= 1454 \\ R_2 &= 1209.5 \\ R_3 &= 657.5 \end{aligned}$$

3. Compute:

$$\begin{aligned} K_w &= \left[\frac{12}{m(m+1)} \sum_{j=1}^k \frac{R_j^2}{n_j} \right] - 3(m+1) \\ &= \left[\frac{12}{81(82)} \left(\frac{(1454)^2}{30} + \frac{(1209.5)^2}{30} + \frac{(657.5)^2}{21} \right) \right] - 3(82) \end{aligned}$$

$$= 0.001807 (70,471 + 48,763 + 20,586) - 246$$

$$= 252.61 - 246$$

$$= 6.61$$

4. Because there are ties, calculate a modified K'_w :

$$K'_w = \frac{K_w}{1 - \frac{1}{m(m^2 - 1)} \sum_{j=1}^g t_j(t_j^2 - 1)}$$

where:

- g = 6 = number of groups with ties
- t_1 = 2 = number of data points in the first tied group (Rank 4.5)
- t_2 = 2 = number of data points in the second tied group (Rank 17.5)
- t_3 = 2 = number of data points in the third tied group (Rank 26.5)
- t_4 = 2 = number of data points in the fourth tied group (Rank 46.5)
- t_5 = 2 = number of data points in the fifth tied group (Rank 44.5)
- t_6 = 2 = number of data points in the sixth tied group (Rank 55.5)

$$K'_w = \frac{6.61}{1 - \frac{1}{81[(81)^2 - 1]} [2(3) + 2(3) + 2(3) + 2(3) + 2(3) + 2(3)]}$$

$$= \frac{6.61}{0.99993}$$

$$= 6.61$$

5. Because $K'_w = 6.61$ is greater than $\chi^2_{0.95,2} = 5.99$, the null hypothesis H_0 is rejected at the $\alpha = 0.05$ level. The conclusion is that at least one population being compared has a mean different from the other populations.

APPENDIX G

SUMMARY OF REVISIONS TO THE
"CHARACTERIZATION OF BACKGROUND WATER
QUALITY FOR STREAMS AND GROUNDWATER"
DRAFT REPORT (MAY 1993)

SUMMARY OF REVISIONS TO THE
"CHARACTERIZATION OF BACKGROUND WATER
QUALITY FOR STREAMS AND GROUNDWATER"
DRAFT REPORT (MAY 1993)

In May 1993, a draft version of the "Background Water Quality" report was submitted to the U.S. Environmental Protection Agency (EPA) and the Ohio Environmental Protection Agency (OEPA). The report was approved by these agencies in October/November 1993, pending incorporation of comment responses and inclusion of new data collected during the field programs conducted in the spring and summer of 1993. In the initial draft, the data evaluated were those that were available and validated as of March 31, 1993. Since that date, the quantity of validated data in the Fernald Environmental Management Project (FEMP) database has increased substantially because: many new surface water and groundwater samples were collected and analyzed for the 1993 field program; some pre-1993 data have been located, validated, and entered into the FEMP database as part of the ongoing remediation investigation (RI) effort; and some pre-1993 nonvalidated data in the FEMP database last year have since gone through the validation process and are now validated.

As a result, there is a greater quantity of validated data available, which improves the ability to accurately characterize background conditions. Additionally, for the 1993 field programs, both filtered and unfiltered radiological and inorganic samples were collected and analyzed. Prior to 1993, the majority of metals analyzed were for filtered samples, while nearly all the radiological analyses were for unfiltered samples. In the draft document, only dissolved metals and total radiological background statistics were computed and reported. For this revised document, separate statistics are computed for filtered and unfiltered inorganic data, as well as filtered and unfiltered radiological data.

At the time that the draft report was prepared, no validated Remedial Investigation/Feasibility Study (RI/FS) data were available for sampling point W-5 on Paddys Run. Since then, the location has been sampled on two different dates. Sampling point W-1 on the Great Miami River was sampled on three different occasions in 1988 and 1989 for the RI/FS program. In 1993, sampling point W-1 was sampled on two more occasions. The quantity of background data for groundwater in the glacial overburden and the Great Miami Aquifer has also increased. Table G-1 shows the number of data records evaluated in the draft report (May 1993) and the number of data records evaluated for this revised document. In addition to the radiological, inorganic, and organic data evaluated, field measurements are also included in this revised document.

In the draft report, 51 wells were evaluated as potential candidates for background wells. From those wells, 30 were considered to be representative of background conditions (five wells in the glacial overburden and 25 wells in the Great Miami Aquifer). For this report, the same 51 wells were

re-evaluated for their adequacy to represent background conditions. During the re-evaluation, three wells (2383, 2384, and 3044) that were initially used to characterize background water quality in the Great Miami Aquifer have now been eliminated because they are located close to Paddys Run and may be influenced by surface water that has infiltrated from the stream. Conversely, two wells (2105 and 2728) have now been added to the list of background wells.

No data existed for well 2728 as of March 31, 1993; the 1993 data indicate that the well is representative of background conditions. Well 2105 was discarded for the draft report because of one unusual sample that had nondetect concentrations of calcium and magnesium, but high concentrations of sodium and chloride (sample 3782). The other samples from this well exhibit normal concentrations of major cations and anions. Based on professional judgment, it was decided that sample 3782 should be deleted, and well 2105 has been included as one of the usable wells for background characterization. Overall, the number of background wells representing the Great Miami Aquifer decreased by one to 24. The number of wells representing the glacial overburden did not change; the same five wells used for the draft report are still used in this document.

Based on a review of data collected in 1993, it was decided that radiological data from well 2098 should be removed from the background water quality data set. It appears that the radiological water chemistry of well 2098 is being affected by runoff from the FEMP. Of the wells chosen to represent Great Miami Aquifer background water quality, well 2098 had the highest unfiltered and filtered total uranium results, 5.1 and 4.6 ug/L, respectively. Surface water samples were also collected in 1993 from a drainage ditch directly north of well 2098. Replicate samples were taken, with the highest unfiltered and filtered total uranium results being 13.9 and 13.6 ug/L, respectively, thus indicating the possibility of the FEMP affecting the values measured for radiological parameters for samples collected from well 2098. Therefore, in order not to bias statistical computations, radiological constituents from well 2098 have been removed from the background data set. However, inorganic, organic, and field parameter data remain because well 2098 results were similar to those from other Great Miami Aquifer background wells.

During evaluation of RI/FS background data for the draft report, nonvalidated data and high nondetect data were removed from the data set before statistical analyses proceeded. (A description of high nondetect data and the protocol for disposition of these data are included in Section 4.2 of this report.) The same two types of data were removed from the current background data set evaluated for this report.

For the draft report, potential outlier data were identified but not discarded from the data set. According to EPA guidance (1989b, 1992), each potential outlier should be checked against the original data package and validation records to determine if an error occurred during the analysis, the validation process, or any transcriptions of the datum. If no evidence of error can be clearly

identified, then the datum should be assumed to be a real value and retained for evaluation. However, this approach was intended for "on-site" data or areas that could potentially be contaminated; it was not intended for strict application to background characterization.

It can be important to delete outliers during background characterization, because one or two unusually high values in a small data set could distort some of the statistics that are being generated. For the revised document, a few examples of outlier data have been rejected from the data set used to represent background conditions. In most cases, the identification of outliers was accomplished using professional judgment because a statistical test to identify outliers is not available for cases where the data distribution type is undefined. Where the data distribution could be shown to be normal or lognormal, "Rosner's Test of Many Outliers" (Gilbert 1987) was used to statistically evaluate whether a potential outlier was in fact an outlier.

A description of the process used to identify and delete outliers is found in Section 4.2, and a description of Rosner's test is found in Appendix F of this document. The outlier data that were removed from the background data set are listed in Appendices C, D, and E for radiological inorganic, and organic data, respectively.

Another step performed during this effort that was not performed during preparation of the draft report is "data averaging." This occurred whenever more than one sample was collected for one location on a single date. In other words, data from duplicate or triplicate samples were averaged into a single value for each analyte for specific dates. The averaged values were then used in the data pool to calculate statistics. This procedure was done in order to reduce the bias that would occur if duplicate or triplicate sample data were each treated as individual samples. The averaging was particularly needed for 1993 data for the surface water sampling sites (W-1, W-5) at which multiple single-day samples were collected to ensure that at least one "valid" RI/FS sample was available.

During preparation of the draft report, each group of data was assigned to one of these three categories:

- Pathway 1: ≥ 6 detect values and ≥ 40 percent detection frequency
- Pathway 2: 3 to 5 detect values, or 10 to 40 percent frequency of detection
- Pathway 3: < 3 detect values, or < 10 percent frequency of detection

The data groups assigned to Pathway 1 were then tested to determine whether the data were normally or lognormally distributed using the Shapiro-Wilk or Shapiro-Francia test (see Appendix F). Based on the results of these tests, all data groups in the "Pathway 1" category were assigned one of the following distribution classifications:

- N = Normal distribution accepted
- L = Lognormal distribution accepted
- N* = Both normal and lognormal distributions tested positive, but normal distribution was a better fit
- L* = Both normal and lognormal distributions tested positive, but lognormal distribution was a better fit
- NQ = Normal distribution, approximately
- LQ = Lognormal distribution, approximately

Any data group in the "Pathway 1" category that did not pass for either normal or lognormal distribution was assigned the distribution of "NQ" or "LQ"; i.e., whichever distribution the data most closely fit.

For the revised report, the data groups were first evaluated to determine if they belonged to the "Pathway 1" category. If so, they were tested for normal and lognormal distributions using the Shapiro-Wilk or Shapiro-Francia test, as was done previously. If the calculated statistic (W or W') exceeded a critical value (W_{crit}), then the data group was assigned one of the first four distributions listed above (i.e., N, L, N*, or L*). If the calculated statistic was less than W_{crit} but greater than $0.95 W_{crit}$, then the data group was assigned a distribution classification of NQ or LQ. If the calculated statistic was less than the $0.95 W_{crit}$ value, then the data group was labeled as having an undefined distribution. In other words, a few of the "Pathway 1" data groups have now been assigned to the undefined distribution (U) category. This did not occur in the draft report. In the draft report, every "Pathway 1" data group was placed in either a normal (N, N*, and NQ) or lognormal (L, L*, LQ) category.

For the revised report, a second test was implemented to check whether a data group was lognormally distributed. If a data group passed the Shapiro-Wilk or Shapiro-Francia test for lognormal distribution and had a log variance value less than 2.0, then lognormal distribution was assumed for the data group. However, for a few data groups, the log variance value was greater than 2.0. For this situation, the data distribution was considered to be undefined (U), irrespective of the results of the Shapiro-Wilk or Shapiro-Francia test.

In the current report, there are no longer any "Pathway 2" and "Pathway 3" categories. Any data group that did not meet the criteria for "Pathway 1" (i.e., ≥ 6 detects and ≥ 40 percent detection frequency), or met the "Pathway 1" criteria but could not be classified as having a normal or lognormal distribution, was assigned an undefined "U" classification. In summary, there are now three categories of data groups evaluated in this report — normal, lognormal, and undefined

distributions. The Pathway 1, 2, and 3 terminology used in the draft report is not utilized in this revised document. This revision was implemented in order to limit the statistics reported to those most appropriate and useful for the particular data distribution.

The following information is presented in this report for each data group evaluated:

- 1) number of analyses
- 2) number of detections
- 3) frequency of detection
- 4) minimum detect value
- 5) maximum detect value
- 6) minimum nondetect value
- 7) maximum nondetect value

Items 6 and 7 were not provided in the draft report. Median values, which were listed for all data groups in the draft report, are now presented only for the undefined data groups.

For data groups with normal distribution, statistics provided in the revised report (in addition to the common statistical parameters listed above) are arithmetic mean, standard deviation, coefficient of variation, one-sided 95 percent upper confidence level (UCL), and 95th percentile. These are the same as in the draft report, except 95 percent upper tolerance level (UTL) has been replaced with 95th percentile and two-sided 95 percent UCL has been replaced with one-sided 95 percent UCL. The basis for the change from UTLs to 95th percentile was from EPA Region V comments on recent FEMP RI reports. The two-sided 95 percent UCL was used for the draft report, but is now replaced by the more appropriate one-sided 95 percent UCL. An additional change is that any statistics relating to a lognormal distribution were eliminated from the "normal" portion of the summary statistics tables since this information does not apply to a data set that is normally distributed.

For data groups with lognormal distribution, statistics provided in the revised report (in addition to the common statistical parameters listed above) include an estimated mean of a lognormal distribution, estimated standard deviation of a lognormal distribution, one-sided 95 percent UCL, and 95th percentile. The change to the one-sided 95 percent UCL and the 95th percentile is based on the same reasoning as for data groups having normal distributions. Statistics relating to normal distributions were eliminated because they do not apply to a data set that is lognormally distributed. The geometric mean and geometric standard deviation have been replaced by the estimated mean of a lognormal distribution and estimated standard deviation of a lognormal distribution, respectively, based on EPA Region V comments on recent FEMP RI reports.

For an undefined distribution, statistics provided in the revised report (in addition to the common statistical parameters listed above) include the median, one-sided 95 percent UCL, and 95th percentile.

The median was reported in the draft report. The equations used to calculate the one-sided 95 percent UCL and 95th percentile for an undefined distribution are presented in Appendix F.

Additional changes to the draft "Background Water Quality" report involve incorporating comment responses as discussed in correspondence from the Department of Energy to EPA and OEPA, dated August 31, 1993. The primary "response to comments" revisions include: adding groundwater elevation contours to figures showing background well locations; justifying that sampling point W-1 is an appropriate background water quality location on the Great Miami River; expanding the discussion of the screening process used to select appropriate background wells; providing clarifications suggested by reviewers; and correcting errors noted by reviewers.

Some minor changes were also made to the draft document to promote consistency with the Operable Unit 5 RI Report. These changes primarily involved descriptions of site setting, sample and analysis programs, data validation, and updating the numbers and types of FEMP monitoring wells. A description of the RCRA groundwater monitoring program was also added to Chapter 2.

Table H-2 (Continued)
Summary Statistics of Unfiltered Radiological Constituents for Background
Monitoring Wells in the Shandon Section, Great Miami Aquifer

Statistics	Normal			Lognormal			Nonparametric		
	Distribution	Mean	Standard deviation	Coefficient of variation	95% UCL	95th Percentile	Mean	95% UCL	95th Percentile
No. of analyses	23	23	23	23	23	23	< 0.24	< 0.32	0.1
No. of detections	2	2	2	2	2	2	< 0.1	< 0.1	1.2
Detection frequency (%)	9	9	9	9	9	9	< 0.30	< 0.30	1.3
Minimum Detection	0.1	0.1	0.1	0.1	0.1	0.1	< 0.23	< 0.23	0.24
Maximum Detection	0.2	0.2	0.2	0.2	0.2	0.2	< 0.39	< 0.39	0.5
Minimum Nondetect	< 0.1	< 0.1	< 0.1	< 0.1	< 0.1	< 0.1	N/A	N/A	N/A
Maximum Nondetect	< 0.42	< 0.42	< 0.42	< 0.42	< 0.42	< 0.42	N/A	N/A	N/A
Thorium-232									
Total Uranium									
Uranium-234									
Uranium-235/236									
Uranium-238									

Note: (1) Concentrations are reported in pCi/L except Total Thorium and Total Uranium, which are in ug/L.
 (2) N/A = Not applicable.
 (3) Distribution types: N = Normal, L = Lognormal, N* = Normal (but also passed Lognormal test), L* = Lognormal (but also passed Normal test), NQ = Qualified Normal, LQ = Qualified Lognormal, U = Undefined.
 (4) Mean types: Normal = arithmetic mean, Lognormal = estimated mean of a lognormal distribution.
 (5) Standard deviation types: Normal = arithmetic standard deviation, Lognormal = estimated standard deviation of a lognormal distribution.

Note:

(1) Concentrations are reported in mg/L.

(2) N/A = Not applicable.

(3) Distribution types: N = Normal, L = Lognormal, N* = Normal (but also passed Lognormal test), L* = Lognormal (but also passed Normal test), NQ = Qualified Normal, LQ = Qualified Lognormal, U = Undefined.

(4) Mean types: Normal = arithmetic mean, Lognormal = estimated mean of a lognormal distribution. Standard deviation types: Normal = arithmetic standard deviation, Lognormal = estimated standard deviation of a lognormal distribution.

Lognormal = estimated standard deviation of a lognormal distribution.

Note: (1) Concentrations are reported in mg/L.
(2) N/A = Not applicable.
(3) Distribution types: N = Normal, L = Lognormal, N* = Normal (but also passed Lognormal test), L* = Lognormal (but also passed Normal test), NQ = Qualified Normal, U = Undefined.
(4) Mean types: Normal = arithmetic mean, Lognormal = estimated mean of a lognormal distribution.
(5) Standard deviation types: Normal = arithmetic standard deviation, Lognormal = estimated standard deviation of a lognormal distribution.

Table H-12 (Continued)
Summary Statistics of Unfiltered Inorganic Constituents for Background Monitoring Wells in the Dry Fork Section, Great Miami Aquifer

[illegible]

Note:

(1) Concentrations are reported in mg/L.

(2) N/A = Not applicable.

(3) Distribution types: $N = \text{Normal}$, $L = \text{Lognormal}$, $N^* = \text{Normal}$ (but also passed Lognormal test),

L* = Lognormal (but also passed Normal test), NQ = Qualified Normal.

LO = Qualified Lognormal, U = Undefined.

(4) Mean types: Normal = arithmetic mean, Lognormal = estimated mean of a lognormal distribution.

(5) Standard deviation types: Normal = arithmetic standard deviation,

Lognormal = estimated standard deviation of a lognormal distribution.
