Watts Bar Nuclear Plant, Unit 2
Facility Construction Permit No. CPPR-92
NRC Docket No. 50-391

**Subject: WATTS BAR NUCLEAR PLANT (WBN) UNIT 2 - TRANSMITTAL OF
UNIT 1/UNIT 2 AS-CONSTRUCTED FIRE PROTECTION REPORT
(TAC NO. ME3091)**

- References:
1. TVA letter to NRC dated June 30, 2014, "Watts Bar Nuclear Plant (WBN) Unit 2 - Transmittal of Unit 1/Unit 2 As-Constructed Fire Protection Report (TAC No. ME3091)"
 2. TVA letter to NRC dated March 13, 2013, "Watts Bar Nuclear Plant (WBN) Unit 2 - Transmittal of Revised Unit 1/Unit 2 As-Designed Fire Protection Report (TAC No. ME3091)"
 3. TVA letter to NRC dated February 7, 2013, "Watts Bar Nuclear Plant (WBN) Unit 2 – Fire Protection Program (TAC No. ME0853) – Commitment to Provide Additional Information on Multiple Spurious Operation (MSO) Scenarios"
 4. TVA letter to NRC dated April 26, 2012, "Watts Bar Nuclear Plant (WBN) Unit 2 – Transmittal of Revised Unit 1/Unit 2 As-Designed Fire Protection Report (TAC No. ME3091)"

By letter dated March 13, 2013 (Reference 2) the Tennessee Valley Authority (TVA) submitted the Revised Unit 1/Unit 2 As-Designed Fire Protection Report (FPR). This submittal contained a complete updated version of the Unit 1/Unit 2 As-Designed FPR submitted in Reference 4.

By letter dated June 30, 2014 (Reference 1), TVA submitted the following parts of the as-constructed version of the Unit 1/Unit 2 FPR:

- II, "Fire Protection Plan"
- III, "Safe Shutdown Capabilities"
- IV, "Alternate Shutdown Capability"
- VIII, "Conformance to Appendix A to BTP 9.5-1 Guidelines"
- IX, "Appendix R Compliance Matrix"
- X, "NFPA Code Evaluation"

On July 16, 2014, TVA met with the Nuclear Regulatory Commission (NRC) to discuss the parts of the as-constructed FPR that were submitted via Reference 1. From this meeting, it was agreed that certain changes would be made to Parts II, III and V and that all parts of the FPR would be resubmitted. Enclosure 1 contains the entire as-constructed FPR, superseding in its entirety the report that was provided in Reference 1.

Enclosure 2 provides a table that lists the sections of the FPR that were updated since the Reference 2 submittal. This table identifies the changes that modify the intent of previously submitted information and therefore, may require additional review by NRC. Please note that the tables in Part VI provided for each analysis volume (AV) were completely replaced. This means that both the format and some of the content of the AV tables has changed. To aid in the review of the other sections of Part VI and the other updated parts of the FPR, revision bars associated with previous updates were removed so that the revision bars in this version highlight only the intent changes made since the FPR version submitted via Reference 2. In addition, Parts V and VI have been updated to validate the Unit 2 and common Operator Manual Action (OMA) performance times using the data acquired by the completion of the timing walkdowns.

Changes were made in the As-Designed FPR submitted on March 13, 2013 (Reference 2) that were reflected in the As-Constructed parts submitted on June 30, 2014 (Reference 1) and are identified in Enclosure 2. Some additional changes have been made in the parts submitted on June 30, 2014. These additional changes are annotated in Enclosure 2 by an asterisk at the beginning of the change description.

A red-lined version of the updated FPR parts, annotating both the intent and non-intent (editorial) changes was placed on a Compact Disc (CD) and is being provided to Mr. Justin Poole, Nuclear Reactor Regulation (NRR) Senior Project Manager.

In Reference 1, TVA committed to update the list of commitments discussed in Enclosure 3 of Reference 3. The commitment update is provided in Enclosure 3 of this letter. Also in Reference 3, TVA committed to provide as-constructed information on the Multiple Spurious Operation (MSO) scenarios at the time the as-constructed FPR was submitted. To address this commitment, Enclosure 4 provides Revision 3 of Report R1976-20-01, "WBN Unit 2 Multiple Spurious Operation Evaluation."

The NRC's review of the as-designed Unit 1/Unit 2 FPR was documented in Supplemental Safety Evaluation Report (SSER) 26. The results of TVA's review of SSER 26 are provided in Enclosure 5.

Although the fire safe shutdown analyses (FPR Part VI) and the Unit 2 and common feasibility and reliability evaluations (FPR Part VII, Section 8.0) are based on verified input, information and analyses, the final supporting documents (calculations) have not yet been issued. These supporting calculations will be issued before TVA requests an operating license for WBN Unit 2. Additionally, for the as-constructed version of the dual unit FPR submitted by this letter, some construction work remains to be implemented. Standard TVA work control processes along with special measures such as the freezing of field changes for Appendix R work, are adequate to ensure the completion of the outstanding work. Once the calculations are issued and the construction is substantially complete, TVA will verify whether completion of these calculations and construction required any further changes to the FPR or resolution in TVA's corrective action program. After the completion of hot functional testing, TVA will notify the NRC that the supporting construction is substantially complete and whether the completion of the construction of Unit 2 impacted the enclosed version of the FPR.

NUREG-0847, SSER 26, Appendix HH, provides a status of required action items associated with open items, confirmatory issues, and proposed license conditions that the NRC staff has identified. In this submittal, TVA is confirming the completion of the Unit 2 OMA feasibility walkdowns (SSER 26, Appendix HH, Open Item 140), the multiple spurious operation scenario resolution actions for scenarios which only affect Unit 2 (SSER 26, Appendix HH, Open Item 141), the electrical coordination modifications (SSER 26, Appendix HH, Open Item 142), and the as-built FPR aligns with as-designed FPR with gaps submitted to the NRC for approval (SSER 26, Appendix HH, Open Item 143). Therefore, TVA has completed Appendix HH items 140, 141, 142, and 143 and these items can be closed.

The new commitments made in this letter are listed in Enclosure 6. If you should have any questions, please contact Gordon Arent at (423) 365-2004.

I declare under penalty of perjury that the foregoing is true and correct. Executed on this 18th day of September 2014.

Respectfully

J. W. Shea
Vice President, Nuclear Licensing

Enclosure 1
Unit 1/Unit 2 As-Constructed Fire Protection Report (FPR)

PART I – INTRODUCTION

1.0 BACKGROUND

On April 18, 1977, Watts Bar Nuclear Plant (WBN) submitted a Fire Protection Program (FPP) to the Nuclear Regulatory Commission (NRC) detailing the fire hazards analysis and a comparison to the guidelines of Appendix A to Branch Technical Position APCSB 9.5-1. On September 9, 1980, WBN submitted the Fire Protection Analysis describing the safe shutdown capabilities. On November 19, 1980, the NRC published 10CFR50.48, "Fire Protection," and a new Appendix R to 10CFR50 that established fire protection requirements for operating nuclear power plants. This rule became effective on February 17, 1981; it specified certain fire protection features for operating nuclear power plants licensed before January 1979.

2.0 PURPOSE

The purpose of the Fire Protection Report (FPR) is to consolidate a sufficiently detailed summary of the WBN regulatory-required FPP into a single document and to reflect the design of both units. The Final Safety Analysis Report (FSAR) references this report as detailing WBN's Fire Protection Program. Updates to this report are made on a schedule consistent with updates to the FSAR.

The FPR has been developed in accordance with the guidelines of NRC Generic Letter 86-10, "Implementation of Fire Protection Requirements" and NRC Generic Letter 88-12, "Removal of Fire Protection Requirements from Technical Specifications." The FPR brings WBN into compliance with NRC recommendations for documenting the FPP and commitments. The FPR documents WBN's Appendix R evaluation that ensures that safe shutdown capability can be maintained during and after a fire in accordance with Sections III.G, III.J, III.L and III.O of 10CFR50, Appendix R.

3.0 SCOPE

This report includes the following documentation:

1. Introduction (Part I)

Part I provides the introduction and a table that summarizes the plant design. The table is also a guide to the manner used to demonstrate compliance with 10CFR50 Appendix R.

2. Fire Protection Plan (Part II)

Part II describes the organizations supporting the WBN Fire Protection Program, the plant fire protection systems and features, fire loss prevention procedures and administrative controls, the plant emergency response organization, the Fire Protection Systems and Features Operating Requirements (OR), and Testing and Inspection Requirements (TIR).

3. Safe Shutdown Capabilities (Part III)

Part III identifies the analysis methodology used to demonstrate compliance with Sections III.G and III.L of 10CFR50, Appendix R. It describes the specific safe shutdown functions required to satisfy Appendix R and identifies the major systems used to satisfy the safe shutdown performance goals. The processes used to identify required components and required circuits are identified. Tabular lists of required mechanical and electrical equipment and components are also included in this part.

PART I – INTRODUCTION

4. Alternate Shutdown Capability (Part IV)

Part IV identifies and describes the methodology used to demonstrate compliance with Appendix R Section III.G.3 and III.L for alternative shutdown given a fire in the Control Building. The general design criteria for electric and physical independence of the alternative shutdown system from the Control Building are addressed.

5. Operator Actions, Repairs, and Emergency Lighting (Part V)

Part V describes the process used to determine manual action requirements. The ability of plant staff to perform the manual actions is evaluated based on minimum staffing levels and the location of the fire. Cold shutdown repairs incorporated into the compliance strategies are identified. The adequacy of emergency lighting for access to, and performance of actions at, manual action locations is also assessed.

6. Fire Hazards Analysis (Part VI)

Part VI summarizes the engineering evaluations performed to determine the adequacy of fire protection features for the fire areas and rooms identified for WBN. This part summarizes the physical characteristics of required fire barriers (including fire doors and fire dampers), combustible loading and fire severity, suppression and detection capabilities, deviations and evaluations, and fire safe shutdown capability for each area and room. The paths and systems available for safe shutdown are identified. Safe shutdown equipment, components, and cables that could be damaged by the fire are identified, along with the mitigating features to ensure availability.

7. Deviations and Evaluations (Part VII)

Part VII contains the deviations identified to the applicable sections of 10CFR50 Appendix R and Appendix A to Branch Technical Position (BTP) APCS 9.5-1. Engineering evaluations developed in accordance with the guidance of Generic Letters 83-33 and 86-10 are presented. National Fire Protection Association (NFPA) code deviations that impact the operational capabilities of fire protection features protecting safe shutdown or alternate shutdown equipment are also identified. Part VII also contains evaluations of the Unit 2 operator manual actions.

8. Conformance to BTP 9.5-1, Appendix A (Part VIII)

Part VIII contains a line-by-line comparison of WBN against the guidelines of Appendix A to BTP 9.5-1. The status of conformance with the guidelines is summarized. Alternatives to strict compliance are identified where applicable. The details that support Part VIII are contained in other parts of the FPR and in referenced plant documentation.

9. Conformance to 10CFR50, Appendix R (Part IX)

Part IX contains a line-by-line comparison of WBN against the guidelines of Appendix R to 10CFR50. The status of conformance with the requirements of Sections III.G, III.J, III.L and III.O is summarized. Alternatives to strict compliance are identified where applicable. The details that support Part IX are contained in other parts of the FPR and in referenced plant documentation.

PART I – INTRODUCTION

10. NFPA Code Conformance Evaluation (Part X)

Part X contains a review of the NFPA codes referenced in Appendix A to BTP 9.5-1 and addresses the applicability of the NFPA codes to the WBN regulatory compliance fire protection program.

4.0 SUMMARY COMPLIANCE TABLE

Table I-1 summarizes the classical fire protection features at WBN on a fire area and room basis. Not all of the fire protection features documented in Table I-1 are required to demonstrate compliance with the guidance of Appendix A to BTP 9.5-1 or the requirements of Appendix R to 10CFR50. Part II of the FPR identifies those detection and suppression systems that are required, along with the associated Operability and Testing and Inspection Requirements for the systems. Table I-1 also presents basic information on the fire safe shutdown significance of each room in the plant.

Table I-1 contains ten columns, which capture the following information:

Column 1: (Room Number and Name)	Fire area number and identification of rooms in the fire area
Column 2: (Safe Shutdown Equipment or Cables Y/N)	Presence of safe shutdown cables or components in each room
Column 3: (Automatic Detection Y/N, Full/Partial)	The presence and extent of automatic fire detection provided in each room
Column 4: (Automatic Suppression Y/N, Full/Partial)	The presence and extent of automatic fire suppression provided in each room
Column 5: (Fire Rated Wraps)	Use of fire rated fire barriers and rating on trays or conduits in each room for which it is credited
Column 6: (Combustible Load, Fire Severity)	The equivalent fire severity of in situ combustible materials in each room (see note below)
Column 7: (Deviation Number in Part VII)	Reference to deviations from 10CFR50 Appendix R, Appendix A to BTP 9.5-1, and NFPA codes documented in Part VII that are applicable to the room
Column 8: (Evaluation Number in Part VII)	Reference to engineering evaluations prepared in accordance with the guidance of Generic Letters 83-33 and 86-10 documented in Part VII that are applicable to the room
Column 9: (CSD Repairs required in any room due to fire in room)	Cold shutdown (CSD) repairs which may be required due to a fire in the specific room (with the repair potentially required due to a fire in any room in the analysis volume in which the specific room is located)

PART I – INTRODUCTION

<p>Column 10: (III.G compliance for HSD)</p>	<p>Notations in this column indicate the method of compliance with 10CFR50 Appendix R Section III.G for achieving hot shutdown (HSD):</p> <ul style="list-style-type: none"> • III.G.1 is not noted in the table, but is credited for some function in all rooms except the control building which is a III.G.3 area. • III.G.2.a is credited for some function in each room indicated by “2a” in this column. • III.G.2.b is credited for some function in each room indicated by “2b” in this column. • III.G.2.c is credited for some function in each room indicated by “2c” in this column. • III.G.2.d, e and f are credited for some functions in each room in containment indicated by “2def” in this column. • Operator Manual Actions credited in lieu of physical separation or to mitigate spurious equipment actuation is indicated by the following: <ul style="list-style-type: none"> ○ 2-G indicates a unit 2 OMA performed on equipment in the safe shutdown path (NEI 00-01 Green). The Feasibility and Reliability evaluations for actions required in less than 2 hours are included in Part VII, Section 8. ○ 2-O indicates a unit 2 OMA performed on equipment that is important to safe shutdown, but not in the safe shutdown path (NEI 00-01 Orange) ○ 1-G indicates a unit 1 OMA performed on equipment in the safe shutdown path (NEI 00-01 Green). As discussed in Part VII, Section 7, these OMAs were addressed in Section 3.5, “Manual Operator Actions,” of SSER 18 . ○ 1-O indicates a unit 1 OMA performed on equipment that is important to safe shutdown but not in the safe shutdown path (NEI 00-01 Orange). As discussed in Part VII, Section 7, these OMAs were addressed in Section 3.5 of SSER 18. ○ 0-G indicates an OMA applicable to both units performed on equipment in the safe shutdown path (NEI 00-01 Green). These OMAs were addressed in Section 3.5 of SSER 18 for Unit 1 and Part VII, Section 8 if required in less than 2 hours for Unit 2. These OMAs were addressed in SSER 26 ○ 0-O indicates an OMA applicable to both units performed on equipment that is important to safe shutdown but not in the safe shutdown path (NEI 00-01 Orange). These OMAs were addressed in SSER 26.
---	---

PART I – INTRODUCTION

Note: The equivalent fire severity values are defined in Section 2.1 of Part VI based on fire severity indices. The fire severity indices have five categories. The five categories are:

<u>CLASSIFICATION</u>	<u>COMBUSTIBLE LOAD</u>	<u>FIRE SEVERITY</u>
Insignificant	<6,500 Btu/ft ²	<5 minutes
Low	<80,000 Btu/ft ²	<60 minutes
Moderate	<160,000 Btu/ft ²	<120 minutes
Moderately Severe	<240,000 Btu/ft ²	<180 minutes
Severe	>240,000 Btu/ft ²	>180 minutes

PART I – INTRODUCTION

TABLE I-1 SUMMARY COMPLIANCE FIRE PROTECTION

Room Number and Name	Safe Shutdown Equipment or Cables Y/N	Automatic Detection Y/N, Full/Partial	Automatic Suppression Y/N, Full/Partial	Fire Rated Wraps	Combustible Load, Fire Severity	Deviation Number in Part VII	Evaluation Number in Part VII	CSD Repairs req'd in any room due to fire in room	III.G Compliance for HSD
729.0-A9 - Unit 2 Post Accident Sampling Room	Yes	Yes, Room Full, Corridor None	Yes, Room Full, Corridor None	1-hour	Insignificant	2.6			2c
757.0-A13 - Refueling Room (includes 741.5 – New Fuel Storage Vault)	Yes	No	No	No	Insignificant	2.6, 2.9, 4.1, 4.5			
772.0-A9 - HEPA Filter Plenum Room	Yes	Yes, Full	Yes, Full	No	Low	2.4	8.3.42, 63 & 64		0-G, 1-G, 2-G
776.0-A1 - Elevator Machine Room	No	No	No	No	Severe				
786.0-A1 - Fan Room	No	No	No	No	Insignificant				
814.75-ACS - Roof Access Room	No	No	No	No	Insignificant				
Stair No. 4 - Stairwell	No	Yes, Full	No	No	Insignificant				
FIRE AREA 11:									
729.0-A3 - Waste Package Area	No	Yes, Full	Yes, Full	No	Low				
729.0-A4 - Waste Package Area	No	Yes, Full	Yes, Full	No	Moderate				
FIRE AREA 12:									
729.0-A1 - Main Steam Valve Rm (Unit 1 South)	Yes	No	No	No	Insignificant	2.9	3.1		
737.0-A6 - Air Lock	No	No	No	No	Insignificant	2.9	3.1		
FIRE AREA 13:									
729.0-A2 - Main Steam Valve Rm (Unit 1 North)	Yes	No	No	No	Insignificant	2.9	3.1		
729.5-A16 – Unit 1 Shield Building Vent Radiation Monitoring Room	Yes	No	No	No	Insignificant				
U1 Additional Equip. Building (AEB) - (737.0-A13, 775.25-A1, 786.5-A1)	No	Yes (Partial & A13 none)	No	No	Moderate				
729.0-A14 U1-AEB	Yes	Yes (Partial)	No	No	Moderate				1-G
763.5-A1 U1-AEB	Yes	Yes (Partial)	No	No	Moderate				1-G
729.0-A12 – Unit 1 Steam Valve Instrument Room A	Yes	No	No	No	Low	2.9	3.1		
FIRE AREA 14:									
737.0-A1 - Auxiliary Building (Subdivided into 737.0-A1A, A1AN, A1BN, A1B, A1CN and A1C)	Yes	Yes, Full	Yes, Full	1 hour	Moderately Severe	2.4, 2.6, 4.1	3.1, 3.4, 3.6, 8.3.8, 9, 10 & 11	Yes	2b, 2c, 0-G, 0-O, 1-G, 1-O, 2-G, 2-O
737.0-A2 - Hot Instrument Shop	No	Yes, Full	No	No	Low		3.1		
737.0-A4 - Air Lock	No	No	No	No	Insignificant		3.1		
737.0-A7 - Unit 1 Letdown Heat Exchanger	Yes	No	No	No	Low		3.1		
737.0-A8 - Unit 2 Letdown Heat Exchanger	Yes	No	No	No	Insignificant		3.1		
737.0-A11 - Air Lock	No	No	No	No	Insignificant		3.1		
FIRE AREA 15-1:									
737.0-A3 – Unit 1 Heat and Vent Equipment Room	Yes	Yes, Full	Yes, Full	1 hour	Low	2.4	3.4	Yes	2c, 0-O, 1-O

Unit 2 Reactor Building Primary Containment (Subdivided into 2RO-1, 2RO-2, 2RO-3, 2RO-4, 2RI-1, 2RI-2, 2RI-3, 2RI-4, 2RIR, 2RA1, 2RA2, 2RA3, 2RA4, 2RF1, 2RF2, 2RU)	Yes	Yes, Partial	Yes, Partial	No	Moderate	2.7, 2.8, 2.9			

Note 1: 737.0-A15 is a small room within room 737.0-A5 and contains an insignificant amount of in-situ combustibles. The suppression system in Room 737.0-A5 extends into this room, but the detection system does not (no detectors in Room 737.0-A15). Actuation of detection system in 737.0-A5 is required to release the deluge valve and charge system head in 737.0-A15. See Part VI Section 3.22.1.

Note 2: Entire control building is an alternative shutdown area (III.G.3). Cable location by room not routed; therefore, assumed to be in any room.

PART I – INTRODUCTION

TABLE I-1 SUMMARY COMPLIANCE FIRE PROTECTION

Note 3: 737.0-A16 is a small room within room 737.0-A9 and contains an insignificant amount of in-situ combustibles. The suppression system in Room 737.0-A9 extends into this room, but the detection system does not (no detectors in Room 737.0-A16). Actuation of detection system in 737.0-A9 is required to release the deluge valve and charge system head in 737.0-A16. See Part VI Section 3.81.1.

Note 4: Conduit 1VC4024B (in 772.0-A2A1) is wrapped with 3-hour Thermo-Lag from the R-line south to where the conduit exits the room.

Note 5: The 125V Vital Battery and Battery Board Rooms (I, II, III & IV) are provided with a total area suppression system; however, it is manually actuated.

PART II – FIRE PROTECTION PLAN

1.0 PURPOSE AND SCOPE

Part II of the Watts Bar Nuclear Plant (WBN) Fire Protection Report describes the Fire Protection Plan (Plan) developed for WBN to ensure compliance with the requirements of 10 CFR 50.48, 10 CFR 50, Appendix R, Sections III.G, J, L, and O and the guidelines of Appendix A to Branch Technical Position (BTP) APCS 9.5-1.

2.0 OBJECTIVES OF THE FIRE PROTECTION PLAN

The Plan describes the controls associated with the WBN Fire Protection Program (FPP); identifies the organizations and positions that are responsible for the FPP; describes the authority of positions responsible for implementing the FPP; and outlines the plans for fire protection, fire detection and suppression capability, and limitation of fire damage. The Plan describes the features necessary to implement the FPP such as: administrative controls; personnel requirements for fire prevention and manual fire suppression activities; automatic and manually operated fire detection and suppression systems; and the means to limit fire damage to structures, systems, and components important to safety so that the capability to safely shutdown the plant is ensured.

The Plan describes the measures that are established at WBN to extend the concept of defense-in-depth to fire protection in areas important to safety. These measures are established:

- to prevent fires from starting,
- to rapidly detect, control, and promptly extinguish those fires that do occur, and
- to provide protection for systems important to safety, so that a fire that is not promptly extinguished by the fire suppression activities, will not prevent the safe shutdown of the plant.

3.0 BASIS OF THE FIRE PROTECTION PLAN

The Plan at WBN has been developed to comply with and is based upon the requirements of General Design Criterion 3 in Appendix A to 10 CFR 50, 10 CFR 50.48, paragraph (a) and TVA's commitment to implement Sections III.G, III.J, and III.O to 10 CFR 50, Appendix R and Appendix A to Branch Technical Position APCS 9.5-1, "Guidelines for Fire Protection for Nuclear Power Plants Docketed Prior to July 1, 1976" (August 23, 1976). The requirements contained in Section III.L of Appendix R to 10 CFR 50 are also applicable to areas where alternate shutdown capability is selected. This Plan establishes the policy for and describes the manner in which TVA conforms to these requirements and the guidelines which have been promulgated to describe acceptable implementation methods. The applicable guidelines used as the basis for the Plan are listed in Section 4.1, Regulatory Documents.

4.4 NFPA Codes and Standards

NOTE: Part X of this Fire Protection Report (FPR) documents the level of compliance with the NFPA codes and standards identified in Section 4.4. Major modifications and/or new

PART II – FIRE PROTECTION PLAN

installations of Fire Protection Systems shall be installed in accordance with the most recent edition of that code at the time the system is designed/installed. For expansions of existing features or installations, the below listed codes of record shall be used. Other codes and standards referenced in Appendix A to BTP 9.5-1 are also addressed in Part X. Deviations from code criteria that impact operational capability of the systems are documented in Part VII of the FPR. Code deviations that do not impact operational capability of the systems are documented in the applicable system descriptions.

- 4.4.1 NFPA 10-1975, "Portable Fire Extinguishers"
- 4.4.2 NFPA 11B-1977, "Foam-Water Sprinkler Systems"
- 4.4.3 NFPA 12-1973, "Carbon Dioxide Extinguishing Systems"
- 4.4.4 NFPA 12A-1973, "Halon 1301 Extinguishing Systems"
- 4.4.5 NFPA 12B-1973, "Halon 1211 Extinguishing Systems"
- 4.4.6 NFPA 13-1975, "Installation of Sprinkler Systems"
- 4.4.7 NFPA 14-1974, "Standpipe and Hose Systems"
- 4.4.8 NFPA 15-1973, "Water Spray Fixed Systems for Fire Protection"
- 4.4.9 NFPA 20-1973, "Centrifugal Fire Pumps" for electric driven pumps, NFPA 20-1993 for diesel driven fire pumps.
- 4.4.10 NFPA 24-1973, "Outside Protection"
- 4.4.11 NFPA 25-1992, "Inspection, Testing, and Maintenance of Water-Based Fire Suppression Systems"
- 4.4.12 NFPA 26-1958, "Valve Supervision"
- 4.4.13 NFPA 30-1973, "Flammable and Combustible Liquids"
- 4.4.14 NFPA 49-1975, "Hazardous Chemical Reactions"
- 4.4.15 NFPA 50A-1973, "Gaseous Hydrogen Systems"
- 4.4.16 NFPA 51-1975, "Oxygen Fuel Gas Systems for Welding and Cutting"
- 4.4.17 NFPA 51B-1976, "Cutting and Welding Processes"
- 4.4.18 NFPA 69-1973, "Explosion Prevention Systems"
- 4.4.19 NFPA 72D-1975, "Proprietary Protective Signaling Systems"
- 4.4.20 NFPA 72E-1974, "Automatic Fire Detectors"
- 4.4.21 NFPA 80-1975, "Fire Doors and Windows"

PART II – FIRE PROTECTION PLAN

- 4.4.22 NFPA 90A-1975, "Air Conditioning and Ventilating Systems"
- 4.4.23 NFPA 194-1974, "Fire Hose Connectors"
- 4.4.24 NFPA 196-1974, "Fire Hose"
- 4.4.25 NFPA 220-1985, "Types of Building Construction"
- 4.4.26 NFPA 251-1985, "Fire Tests of Building Materials"

5.0 **DEFINITIONS**

Analysis Volume – That portion of a fire area subjected to a detailed Appendix R safe shutdown analysis to ensure one train of Fire Safe Shutdown (FSSD) capabilities is always available. The analysis volume can consist of the entire fire area or a portion of the fire area. When the analysis volume is a portion of the fire area, it can consist of multiple rooms, a single room, portions of a room (as defined by column line locations), or any combination of the above. Analysis volumes involving only a portion of a room include a 20 foot wide (minimum) overlap with adjacent analysis volumes. Refer to Part III, Section 10.3 and Part VI, Section 2.2 for additional detail. (FPR Preparer)

Approved – Tested and accepted for a specific purpose or application by a nationally recognized testing laboratory (TVA General Engineering Specification G-73) or acceptable to the authority having jurisdiction. (FPR Preparer)

Aqueous Film Forming Foam (AFFF) – Synthetic foam concentrates based on fluorinated surfactants plus foam stabilizers, usually diluted with water to a 3-percent or 6-percent solution. The foam formed acts both as a barrier to exclude air or oxygen and to develop an aqueous film on the fuel surface capable of suppressing the evolution of fuel vapors. The foam produced with AFFF concentrate is dry chemical compatible; therefore, AFFF is suitable for combined use with dry chemicals. (G-73)

Authority Having Jurisdiction (AHJ) – The organization, office, or individual responsible for "approving" equipment, an installation, or a procedure. (Official NFPA Definitions) For TVA nuclear power facilities, the Vice President Nuclear Engineering is the AHJ per the Site Fire Protection Reports and serves as the central point of contact with other organizations, [NRC, Insurance Carrier] (G-73). For changes to the Fire Protection program that must be submitted to NRC for approval in accordance with the Fire Protection license condition, the AHJ is the NRC Director of Nuclear Reactor Regulation (NRR) (Regulatory Guide 1.189, Revision 2).

Automatic – Self-acting, operated by its own mechanism when actuated by some impersonal influence such as a change in current, pressure, temperature or mechanical configuration. (G-73)

Barrier – A feature of construction provided to separate or enclose various occupancies to create a boundary limit based on functional requirements, or a flexible material designed to withstand the penetration of water, vapor, grease, or harmful gases. (G-96)

Combustible Control Zone (CCZ) – Designated locations (such as spaces, areas, elevations) where transient combustibles storage is prohibited unless adequate evaluation and/or compensatory actions are implemented. These zones are subdivisions of fire areas and serve as a form of fire barrier, providing fire separation of redundant fire safe shutdown (FSSD)

PART II – FIRE PROTECTION PLAN

equipment. Combustible material stored in these areas is controlled by site instructions. (FPR Preparer)

Combustible Material – Material which does not meet the definition of noncombustible. Any material which in the form in which it is used and under the conditions anticipated will ignite and burn (e.g., cable insulation, lube oil, plastic sheeting, charcoal, paper, etc.) (G-73)

Combustible Liquid - A liquid having a flash point at or above 100°F (37.8°C) (G-73)

Electrical Raceway Fire Barrier System (ERFBS) – A special type of Fire Barrier System designed to protect electrical raceways (e.g., conduits, cable trays, junction boxes, etc.) containing FSSD circuits required for 10 CFR 50, Appendix R safe shutdown. (DS-M17.2.2)

Engineering – The organization responsible for the design basis of the plant. (G-73)

Fire Area – That portion of a building or plant that is separated from other areas by boundary fire barriers. (G-73)

Fire Barrier – Those components of construction; walls, floors, ceilings, and their supports including beams, joists, columns, penetration seals or closures, fire doors, and fire dampers that are rated by approving laboratories in hours of resistance to fire and are used to prevent the spread of fire. (G-73) An ERFBS and radiant energy shields are also considered as fire barriers. (FPR Preparer)

Fire Break (Fire Stop) – A passive fire protection feature of construction intended to limit flame propagation along vertical or horizontal cable tray runs.

NOTE: Functionally identical to "Fire Stop". (G-73)

Fire Damper – A device, installed in the air distribution system, designed to close automatically upon detection of heat or release as the result of a signal from a sensing device such as a CO₂ discharge signal or a smoke detector, to interrupt migratory air flow, and to restrict the passage of flame. A combination fire and smoke damper shall meet the requirements of both. (G-73)

Fire Detector – A device designed to automatically detect the presence of fire and initiate an alarm system and other appropriate action (see NFPA 72E, "Automatic Fire Detectors"). (G-73)

Fire Door – The door component of a fire door assembly. (G-73)

Fire Door Assembly – Any combination of a fire door, frame, hardware, and other accessories, that together provide a specific degree of fire protection to the opening. (G-73)

Fire Hazards Analysis (FHA) – An analysis performed by fire protection and systems engineers to consider potential in situ and transient fire hazards; determine the consequences of fire in any location in the plant on the ability to safely shutdown the reactor or on the ability to minimize and control the release of radioactivity to the environment and specify measures for fire prevention, fire detection, fire suppression and fire containment and alternative shutdown capabilities as required for each fire area containing structures, systems and components important to safety that are in conformance with NRC guidelines and regulations. The FHA demonstrates that the plant will maintain the ability to perform safe shutdown functions and minimize radioactive release to the environment in the event of a fire, and should verify that NRC FPP guidelines or equivalent level of protection have been met. (G-73)

PART II – FIRE PROTECTION PLAN

Fire Loading – The amount of combustibles present in a given situation, expressed in BTU per square foot. (G-73)

Fire Rated Assembly – A passive fire protection feature that is used to separate redundant fire safe shutdown capabilities. A fire rated assembly includes fire rated walls, floors, ceilings, ERFBSs, equipment hatches, stairwells, doors, dampers, and penetration seals. (FPR Preparer)

Fire Rated Penetration Seal – An opening in a fire barrier for the passage of pipe, cable, etc., which has been sealed to the same fire resistive rating of the fire barrier. (DS-M17.2.2)

Fire Resistance Rating – The time that materials or assemblies have withstood a fire exposure in accordance with the test procedures of "Standard Methods of Fire Tests of Building Construction and Materials," NFPA 251. (G-73)

Fire Safe Shutdown (FSSD) Equipment – Structures, systems, or components required to shutdown the reactor and maintain it in a safe shutdown condition in the event of a fire. Structures, systems, and components used to satisfy fire safe shutdown requirement commitments do not have to be safety-related. (FPR Preparer)

Fire Severity – A unit of measure, in terms of time (hours or minutes) that is used to quantify the hazards associated with the fire loading in a given plant area. It is based on an approximate relationship between fire loading and exposure to a fire severity equivalent to the ASTM E119 standard time-temperature curve. The fire loading of ordinary combustibles such as wood, paper, and similar materials with a heat of combustion of 7000 to 8000 Btu per lb. is related to hourly fire severity. It should not be used with combustibles having a high heat-release rate. (FPR Preparer)

Fire Suppression – Control and extinguishing of fires. Manual fire suppression is the use of hoses, portable extinguishers, or manually-actuated fixed systems by plant personnel. Automatic fire suppression is the use of automatically actuated fixed systems such as water, Halon, or carbon dioxide systems. (G-73)

Fire Wall – A wall having adequate fire resistance and structural stability under fire conditions to accomplish the purpose of subdividing buildings to restrict the spread of fire. (DS-M17.2.2)

Fire Watch – A fire watch is a compensatory action used when fire protection systems or features are inoperable or impaired as required by Operating Requirements (ORs). Additionally, fire watches may be utilized for compensatory actions when limits are exceeded in administrative controls for areas (e.g., excessive transient fire loads). (FPR Preparer)

Fire Watch-Roving – Roving fire watch requires that a trained individual be in the specified fire area(s) within specified intervals. A margin of 25 percent is allowed for unforeseen emergencies and to identify, report, and/or minimize unacceptable fire hazards in the area(s). (FPR Preparer)

Fire Watch-Continuous – Continuous fire watch requires that a trained individual be in the fire area at all times, that the fire area contain no impediment to restrict the movements of the continuous fire watch, and that each compartment within the fire area is patrolled at least once every 15 minutes with a margin of 5 minutes. A fire area designated for a continuous fire watch consists of one or more rooms which are easily accessible to each other and can be patrolled within 15 minutes with a margin of 5 minutes. Exceptions are provided in Section 13.0.A where

PART II – FIRE PROTECTION PLAN

more than one fire area may be covered by one continuous fire watch. The location(s) that a single continuous fire watch can patrol are based on time studies and require approval of the Fire Protection Supervisor or designee. (FPR Preparer)

Fire (Protection) Water Distribution System – The piping and appurtenances on TVA property between a source of fire protection water and the base of the riser (flange or flange and spigot piece or base tee) for automatic sprinkler systems, fixed water spray systems, standpipe systems, and other water based fire suppression systems. (G-73)

Flammable Liquid – A liquid having a flash point below 100°F and having a vapor pressure not exceeding 40 lbs./in² (absolute) at 100°F shall be known as a Class I Liquid. (G-73)

Foam-Water Sprinkler System – An extinguishing system: pipe connected to a source of air-foam concentrate, and a water supply, and appropriate sprinklers, which distributes foam and water over the protected area. (G-73)

Frequency – Each Testing and Inspection Requirement (TIR) has a specified Frequency in which the TIR must be met in order to meet the associated Operating Requirement (OR). The "specified frequency" is discussed in Section 14.0. (FPR-Preparer)

Functional Test – Use of a simulated signal to the sensor or device to verify the operability, including alarm and/or activation functions. (FPR-Preparer)

Inaccessible Area – Those areas defined in FSAR Chapter 12.3 as a Zone IV, IVa, or IVb (High Radiation Area) or a Zone V (Very High Radiation Area). Areas may be designated as inaccessible by the Fire Protection Supervisor because operating conditions that pose immediate danger to life and health from environmental or operational conditions or require the shutdown of essential operating equipment to perform the testing/inspection. Inaccessible areas are as follows:

Inaccessible Areas

Building	Elevation	Area/Room
Auxiliary Bldg	674.0	Waste Hold-Up Tank Room, 674.0-A1**
	676.0	Hold-Up Tank Room A, 676.0-A2**
	676.0	Hold-up Tank Room B, 676.0-A3**
	676.0	Floor Drain Collector Tank Room, 676.0-A4a
	676.0	Unit 1 Pipe Chase. 676.0-A16*
	676.0	Unit 2 Pipe Chase. 676.0-A17*
	692.0	Spent Resin Tank Room, 692.0-A15**
	692.0	Valve Gallery, 692.0-A16
	692.0	Unit 1 Pipe Gallery and Chase. 692.0-A8*
	692.0	Unit 2 Pipe Gallery and Chase. 692.0-A24*
	692.0	Spare , 692.0-A31*
	692.0	Gas Decay Tank Room, 692.0-A3**
	692.0	Gas Decay Tank Room, 692.0-A5**
	713.0	Unit 1 Volume Control Tank Room, 713.0-A7
	713.0	Unit 2 Volume Control Tank Room, 713.0-A20
	713.0	Unit 1 Pipe Gallery and Chase. 713.0-A28*
	713.0	Unit 2 Pipe Gallery and Chase. 713.0-A29*
	713.0	Unit 1 Mixed Bed and Cation Valve Gallery, 713.0-A9*

PART II – FIRE PROTECTION PLAN

Building	Elevation	Area/Room
	713.0	Mixed Bed Valve Gallery, 713.0-A18*
	713.0	CVCS Valve Gallery, 713.0-A23*
	729.0	Cask Loading Area, 729.0-A5*
	729.0	Unit 1 North Main Steam Valve Room (all elev.)
	729.0	Unit 1 South Main Steam Valve Room (all elev.)
	729.0	Unit 2 North Main Steam Valve Room (all elev.)
	729.0	Unit 2 South Main Steam Valve Room (all elev.)
	737.0	Unit 1 Letdown Heat Exchanger, 737.0-A7
	737.0	Unit 2 Letdown Heat Exchanger, 737.0-A8
	757.0	Unit 1 Reactor Building Equip. Hatch, 757.0-A11
	757.0	Unit 2 Reactor Building Equip. Hatch, 757.0-A15
U1 Reactor Bldg	All	All
U2 Reactor Bldg	All	All

* Inaccessible only during resin transfer.

**Refer to Part VII for engineering evaluation.

Internal Conduit Seals

- (1) Smoke and Hot Gas Seals - Seals installed inside conduit openings to prevent the passage of smoke and hot gasses through fire barriers. These seals may be located at the fire barrier or at the nearest conduit entry on both sides of the fire barrier. Smoke and hot gas seals are not required to have a fire resistance rating equal to the fire barrier in which they are installed. (G-96)
- (2) Heat and Fire Seals - Fire rated seals installed inside conduits at or in close proximity to the fire barrier. Heat and fire seals have the same or greater fire resistance rating as the fire barrier they are installed in. (G-96)

Labeled - Equipment or materials to which has been attached a label, symbol or other identifying mark of an organization acceptable to the authorities having jurisdiction and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner. (G-73)

Limited Combustible Material - As applied to a building construction material, a material not complying with the definition of noncombustible material, which, in the form in which it is used, has a potential heat value not exceeding 3500 Btu per lb. (8141 Kj/Kg), and complies with one of the following paragraphs (a) or (b). Materials subject to increase in combustibility or flame spread rating beyond the limits herein established through the effects of age, moisture, or other atmospheric condition shall be considered combustible.

- (1) Materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 1/8 in. (3.2mm) which has a flame spread rating not greater than 50.
- (2) Materials, in the form and thickness used, other than as described in (a), having neither a flame spread rating greater than 25 nor evidence of continued progressive combustion

PART II – FIRE PROTECTION PLAN

and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread rating greater than 25 nor evidence of continued progressive combustion. (NFPA 220).

Listed – Equipment or materials included in a list published by an organization acceptable to the authority having jurisdiction and concerned with product evaluation, that maintains periodic inspection of production of listed equipment or materials and whose listing states either that the equipment or material meets appropriate standards or has been tested and found suitable for use in a specified manner. (G-73)

Mode – The term Mode is used with the numbers 1 through 6 to associate the plant's status with specific plant physical parameters. For the definition of these parameters see the Technical Specifications. (FPR Preparer)

Noncombustible Material –

- (1) A material which in the form in which it is used and under the conditions anticipated, will not ignite, burn, support combustion, or release flammable vapors when subjected to fire or heat; having a structural base of noncombustible material, as defined above, with a surfacing not over 1/8-inch thick that has a flame spread rating not higher than 50 when measured using ASTM E84 Test, "Surface Burning Characteristics of Building Materials". (G-73)

-OR-

- (2) A material which, in the form in which it is used and under the conditions anticipated, will not ignite, burn, support combustion, or release flammable vapors, when subjected to fire or heat. Materials which are reported as passing ASTM E136, Standard Test Method for Behavior of Materials in a Vertical Tube Furnace at 750°C, shall be considered noncombustible materials. (NFPA 220)

Operable-Operability – A fire protection feature (i.e., system, subsystem, train, component, or device) is Operable when it is capable of performing its specified function(s) and when all necessary attendant instrumentation, controls, normal or emergency electrical power, cooling and seal water, lubrication, and other auxiliary equipment that are required by the systems, subsystems, train, component, or device to perform its specified function(s) are also capable of performing their related support function(s). Equipment being tested does not need to be declared inoperable provided appropriate manual actions by the test performer, stationed at the test location, are addressed under written procedures. The written procedures must provide the ability to recognize input signals for action, ready recognition of setpoints, design nuances that may complicate subsequent manual operation such as auto-reset, or other functions which are inherent to the fire protection system. For the Fire Detection System central processor unit (CPU), operability is defined in the Bases for OR 14.1.4. (FPR Preparer)

Operating Requirement (OR) – The lowest level functional capabilities or performance levels of equipment required to ensure adequate fire protection capability is established and maintained to protect safety-related and FSSD equipment from the effects of fire. When an OR is not met, action statements are provided to describe remedial action until the OR can be met. (FPR Preparer)

PART II – FIRE PROTECTION PLAN

Operator Actions - Operator Actions (OAs) are actions taken by an Operator while in the Main Control Room (MCR). Additionally, actions performed at auxiliary control system stations (e.g., Auxiliary Control Room) in response to a main control room abandonment event are considered OAs but are evaluated against the guidance provided in NUREG 1852.

Operator Manual Actions - Operator Manual Actions (OMAs) are those actions performed by operators to manipulate components and equipment from outside the main control room to achieve and maintain post fire hot shutdown, but do not include “repairs”. OMAs comprise an integrated set of actions needed to help ensure that hot shutdown can be accomplished, given that a fire has occurred in a particular plant area. Actions performed inside the main control room are not included in the definition of operator manual actions. OMAs are identified in calculation EDQ00099920090016, “Appendix R – Units 1 & 2 Manual Action Requirements,” (Reference 4.2.59) which also establishes the allowable time to complete each action. Operator actions performed inside the main control room are also identified in a separate appendix within this calculation.

Penetration – An opening through structural members or barriers such as walls, floors, or ceilings for passage of penetrating components. (G-96)

Penetration Seal – Materials, devices, or assemblies installed in communicating spaces across barriers, which provide effective sealing against defined environmental exposure criteria to achieve the same functional requirement as that originally intended by the structural member or the barrier. (G-96)

Portable Fire Extinguisher – A portable device containing powder, liquid, or gases which can be expelled under pressure for the purpose of suppressing or extinguishing a fire. (FPR Preparer)

Preaction Sprinkler System – A system employing automatic sprinklers attached to a piping system connected to a water supply containing air that may or may not be under pressure, with a supplemental fire detection system installed in the same area as the sprinklers. Actuation of the fire detection system (as from a fire) opens a valve that permits water to flow into the sprinkler piping system and to be discharged from any sprinklers that may be open. (G-73)

Primary Containment – A structure that contains the reactor vessel that acts as a barrier to the release of radioactive fission products or other radioactive substances. Primary containment is a gas-tight shell that receives and contains the water, steam, and fission products that flow from any break in the reactor coolant pressure boundary located within the structure. (FPR Preparer)

Safety-Related – Items that meet the following criteria:

Those functions necessary to ensure:

- (1) The integrity of the reactor coolant pressure boundary.
- (2) The capability to shut down the reactor and maintain it in a safe condition.
- (3) The capability to prevent or mitigate the consequences of an incident which could result in potential offsite exposures comparable to those specified in 10CFR100. (G-73)

Safety-Related Area – Any area containing safety-related equipment. Safety-related areas include: Unit 1 and 2 Reactor Buildings, Auxiliary Building, Control Building, Intake Pumping

PART II – FIRE PROTECTION PLAN

Station, Diesel Generator Building, duct banks, and portions of the Yard containing safety-related equipment. (FPR Preparer)

Secondary Containment – The structure that provides a plenum for the temporary, low pressure retention of gaseous leakage from primary containment. (FPR Preparer)

Smoke Detector – A device which detects the visible or invisible particles of incomplete combustion. (G-73)

Sprinkler System – A network of piping connected to a reliable water supply that will distribute the water throughout the area protected and will discharge the water through sprinklers in sufficient quantity either to extinguish the fire entirely or to prevent its spread. The system, usually activated by heat, includes a controlling valve and a device for actuating an alarm when the system is in operation. (G-73) Manually actuated systems do not contain a device for actuating an alarm when the system is in operation. (FPR Preparer).

Standpipe and Hose System – An arrangement of piping, valves, hose connections, and allied equipment installed in a building with the hose connections located in a manner that the water can be discharged in streams or spray patterns through attached hose and nozzles, for the purpose of extinguishing a fire and so protecting a building and its contents in addition to protecting its occupants. This is accomplished by connections to water supply systems or by pumps, tanks and other equipment necessary to provide an adequate supply of water to the hose connections (G-73).

Testable Valves – Refers to valves such as Outside Stem and Yoke (OS&Y), butterfly, and gate, (with or without automatic operators) that are designed to be cycled or exercised to ensure operation and prevent binding. This does not refer to valves such as check valves, solenoid valves, alarm test valves, or suppression system water flow alarm valves. (FPR Preparer)

Testing and Inspection Requirement (TIR) – Physical attributes to be reviewed and re-verified to ensure the equipment specified can perform its intended function(s) of the protection of safety-related or fire safe shutdown systems. The frequency of this review and re-verification is also provided. (FPR Preparer)

Thermal Detector – A device that detects abnormally high temperature or rate of temperature rise. (FPR Preparer)

Transient Fire Loads – Any combustible material that is not permanently present in a given area, and may be introduced during maintenance, repair, rework, or may be transported to a final destination for permanent installation or maintenance, repair, rework of equipment systems and components present there. (G-73)

Water Spray Nozzle – A normally open water discharge device which, when supplied with water under pressure, will distribute the water in a special, directional pattern peculiar to the particular device. (G-73)

Water Spray System – A special fixed piping system connected to a reliable source of fire protection water supply and, equipped with water spray nozzles for specific water discharge and distribution connected to the water supply through an automatically or manually actuated valve which initiates the flow of water. An automatic valve is actuated by operation of automatic detection equipment installed in the same areas as the water spray nozzles. (In special cases the automatic detection equipment may also be located in another area.) (G-73)

PART II – FIRE PROTECTION PLAN

Water Supply – An arrangement of pumps, piping, valves, and associated equipment necessary to provide an adequate, reliable supply of water for the extinguishment of fires. (FPR Preparer)

6.0 FIRE PROTECTION QUALITY ASSURANCE

TVA procedure NPG-SPP-18.4.5, "Fire Protection Quality Assurance (Q07)," (Reference 4.2.28) defines the augmented Quality Assurance (QA) Program for fire protection. This procedure satisfies the guidelines for QA for Fire Protection established by Appendix A to Branch Technical Position BTPAPCSB 9.5.1 and "Nuclear Plant Fire Protection Functional Responsibilities, Administrative Controls and Quality Assurance" (dated August 29, 1977) for fire protection features that provide protection for safety-related structures, systems or components and fire safe shutdown systems. Refer to Part VIII of the FPR for a comparison of the WBN Fire Protection Program with Appendix A guidelines. The QA program for fire protection uses the applicable parts of the TVA Nuclear Quality Assurance Plan (TVA-NQA-PLN89-A). More stringent QA requirements may apply to fire protection features that also perform nuclear safety-related functions such as secondary containment isolation. This QA program is described in corporate Standards and implemented in WBN procedures.

7.0 FIRE PROTECTION ORGANIZATION/PROGRAMS

The following is a summary of the TVA procedures such as the Topical Report TVA-NPOD89, "Nuclear Power Group Organization Description" and FPDP-1, "Conduct of Fire Protection".

7.1 TVA Corporate Management

The Executive Vice President and Chief Nuclear Officer (CNO) has the overall responsibility for establishing policies and programs related to fire protection. The CNO assumes or delegates the responsibility for "Authority Having Jurisdiction" (AHJ) for Operational fire protection matters.

The Vice President Nuclear Engineering has the overall responsibility for establishing the design basis of the plant systems and features related to fire protection. The Vice President Nuclear Engineering assumes or delegates the responsibility as the "Authority Having Jurisdiction" (AHJ) for the design basis fire protection matters. A corporate level fire protection group will provide oversight and governance of the fire protection and fire safe shutdown programs of the site fire protection programs.

NPG has on staff or as a consultant, off-site or on-site, an individual(s) who meet the eligibility requirements as a Member Grade in the Society of Fire Protection Engineers.

7.2 Site Vice President (VP)

The Site VP is responsible for the development, implementation, and administration of the Fire Protection Program. Authority and accountability for overview and implementation of the program have been further delegated to the Plant Manager. Specific requirements and responsibilities related to tasks such as administrative control of fire hazards, manual fire suppression, and maintenance of fire protection equipment have been delegated to various site organizations. The Site VP also provides design, engineering, and construction resources for fire protection systems and features.

PART II – FIRE PROTECTION PLAN

7.3 Plant Manager

The Plant Manager is responsible for management oversight of the development and implementation of the WBN Fire Protection Program.

7.4 Operations Manager

The Operations Manager is responsible for the development, implementation, and control of the WBN Fire Protection Program. The Operations Manager provides senior management assistance and departmental interface for the resolution of fire protection-related issues referred by the Fire Protection Supervisory personnel.

7.5 Fire Protection Supervisory Personnel

The WBN Fire Protection Supervisory personnel have responsibility for the following:

- a. Maintain knowledge of industry trends and issues.
- b. Continue to challenge the program to achieve high performance.
- c. Ensure necessary resource needs are provided to support an effective fire protection program are elevated to appropriate management.
- d. Interface with other site organizations to ensure cost effective responses to fire protection issues.
- e. Provide off-site agency (e.g., NRC/INPO/NEIL) inspection/evaluation fire protection interface.
- f. Ensures the fire brigade is properly equipped and trained and reviews fire brigade training and drills.
- g. Oversight to fire investigations.
- h. Minimize the threat of fire to the plant by appropriate control of ignition source work, transient combustibles, and impairments to fire protection equipment.
- i. Directs or oversees fire protection equipment inspection, testing and maintenance including ensuring the performing personnel understand the fire protection equipment design and requirements.
- j. Ensure fire protection related procedure and guidelines (e.g., Fire Protection Report, fire safe shutdown procedures, test instructions and pre-fire plans) are maintained.
- k. Ensures the training provided on fire protection program functions meet NPS standards or better including training such as for general employee population, personnel performing testing and inspections or fire protection equipment, and for fire response.
- l. The Fire Protection Supervisor has available an individual who meets the eligibility requirements as a "member grade" in the Society of Fire Protection Engineers to oversee the fire protection administrative program.

PART II – FIRE PROTECTION PLAN

7.6 Fire Protection Support Personnel

Personnel assigned to the fire protection organization or other site organization, perform specific work activities as required to support the fire protection supervisory personnel. These personnel may be under the direct supervision of the fire protection supervisory personnel or other supervisors but provide support functions to fire protection. This would include situations such as planning for work instructions or training of fire watch personnel.

7.7 Site Engineering

The Site Engineering Director is responsible for fire protection related design activities at the site.

- a. Maintains fire protection systems oversight through the use of system monitoring via system health reports, Maintenance Rule (10CFR50.65), apparent and root cause analyses, etc. as appropriate.
- b. Performs periodic walk downs of the fire protection systems and components to maintain a current awareness of the system and component conditions.
- c. Ensures fire protection systems are designed in accordance with licensing requirements and industry standards and deviations are documented.
- d. Ensures changes to plant configuration and designs are analyzed and controlled so that no adverse impacts result to the fire protection program.

7.8 Quality Assurance

Quality Assurance ensures that audits are performed in accordance with the NQAP which includes the periodic assessments for the fire protection program including fire drill and training conducted by the fire brigade and plant personnel.

7.9 Site Personnel

The WBN Fire Protection Report applies to all TVA employees and contractors performing activities at WBN.

Site personnel who have duties or perform work activities at WBN are responsible for being familiar with procedures applicable to them during a fire emergency and conducting day-to-day work activities in accordance with plant fire protection administrative procedures.

Unescorted accesses authorized general employee's fire protection-related responsibilities and requirements are provided in annual general employee training.

8.0 **FIRE PROTECTION PROGRAM ADMINISTRATIVE AND TECHNICAL CONTROLS**

This section of the WBN Plan provides the administrative process and controls for implementation of the Fire Protection Program.

PART II – FIRE PROTECTION PLAN

8.1 Program Changes and Associated Review and Approval

- a. The Nuclear Safety Review Board (NSRB) provides independent review, oversight, and technical reviews.
- b. The Fire Protection Supervisor reviews proposed changes to the Fire Protection Report to ensure adequacy and compliance with established regulatory commitments in accordance with site specific procedures.
- c. WBN may make changes to the approved Fire Protection Report without prior approval of the NRC in accordance with the Appendix R License Condition in each unit's Operating License.
- d. The Fire Protection Report is updated on a schedule consistent with 10CFR50.71.

8.2 Modification Control

A fire protection evaluation is performed (when required) for plant modifications in accordance with established procedures. This evaluation is performed to ensure that adequate fire protection measures are maintained, combustible loading considerations are addressed, the overall Fire Protection Program is not degraded, and requirements and guidelines of regulatory agencies have been considered. The evaluation also addresses specific commitments to the applicable sections of 10CFR50, Appendix R.

8.3 Audits/Inspections of the Fire Protection Program

Generic Letter No. 82-21, "Technical Specifications for Fire Protection Audits" provides for a system of audits to be conducted to assess the WBN fire protection equipment and FPP implementation to verify continued compliance with NRC requirements and TVA commitments. The audit program is provided in the NQAP. The frequency of audits is different from GL 82-21 per industry guidance as documented in the NQAP.

8.4 Assessment of Information Notices, Generic Letters, Bulletins, etc.

The Watts Bar Nuclear Experience Review (NER) Program ensures that NRC Information Notices, Generic Letters, Bulletins, and other relevant documents that provide information on generic or specific fire protection and/or fire safe shutdown issues are assessed for applicability to WBN. The responsible organizations (i.e., Licensing, Engineering, Operations, etc.) for addressing the applicable issues are determined upon assessment of the issues identified in the documents.

8.5 Violation and Reportability

Non-compliance with an Operating Requirement (OR) or a Testing and Inspecting Requirement (TIR) described in Section 14.0 shall be evaluated for reportability in accordance with 10 CFR 50.72 and 10 CFR 50.73. Non-compliances occur when the limits of the TIR (including allowable extensions) are exceeded or conditions of the OR and its associated action statement are not met. The required reportability evaluations will be performed in accordance with TVA's Corrective Action Program.

PART II – FIRE PROTECTION PLAN

9.0 EMERGENCY RESPONSE

9.1 Fire Brigade Staffing

Effective handling of fire emergencies is an important aspect of the WBN Fire Protection Program. This is accomplished by trained and qualified emergency response personnel. The fire response organization is staffed and equipped for firefighting activities. Each shift fire brigade is comprised of a fire brigade leader and four fire brigade members. Additionally an Incident Commander is available to direct each shift's fire brigade. The Incident Commander meets the requirements of a Unit Supervisor or Shift Technical Advisor and has sufficient training in or knowledge of plant safety-related systems to understand the effects of fire and fire suppressants on safe shutdown capability. The Incident Commander position is separate from the Shift Manager, Unit Supervisor and Shift Technical Advisor positions. The fire brigade shall not include the Shift Manager or the other members of the minimum shift crew necessary for safe shutdown of the unit, nor any personnel required for other essential functions during a fire emergency. Additional firefighting support is available when needed through an agreement with a local fire department.

The fire brigade composition may be less than the minimum requirements for a period of time not to exceed two hours, in order to accommodate unexpected absence, provided immediate action is taken to fill the required positions. The following are examples of emergencies that may prevent the full fire brigade from being available onsite:

- a. a life-threatening medical emergency, requiring the plant ambulance and appropriately trained medical personnel to leave the site for transport of the patient, and
- b. the fire brigade may respond to fires outside the site area, but still on the TVA Reservation, that has the potential to or is affecting the ability for WBN to maintain the ability to safely shut down. This includes areas such as the Watts Bar Hydro and former Fossil Plant switchyards. A response of this type is at the direction of the Shift Manager based on a concern for plant safety due to the fire or fire's threat. These are expected to be rare occurrences.

9.2 Fire Brigade Support Personnel

- a. Site Nuclear Security provides access to the security controlled area for the fire brigade and offsite fire response personnel during fire emergencies. This includes traffic and crowd control, when necessary.
- b. Site Radiation Protection (RP) personnel provide radiological support for the fire brigade to advise them on radiological hazards and assist in radiological decontamination efforts if necessary. RP personnel also provide radiological support for offsite fire response personnel.
- c. Additional support is provided as required, by Operations, Maintenance, Chemistry, etc.

9.3 Training and Qualifications

WBN fire brigade training ensures that each fire brigade's capability to combat fires is established and maintained. In addition each fire brigade member and leader annually receives:

PART II – FIRE PROTECTION PLAN

1. Training on the use of special respiratory equipment
2. Training to maintain qualification for unescorted access to the plant
3. A medical evaluation to ensure ability to perform strenuous physical activity

The training program consists of initial (classroom and practical) training and recurrent training which includes periodic instruction, fire drills and annual fire brigade training.

a. Initial Training

Initial training consists of classroom instruction and practical exercises to include actual fire extinguishment and use of firefighting and related equipment under strenuous firefighting conditions. Training includes:

- 1) Identification of the fire hazards and associated types of fires that may occur in the plant and an identification of the location of such hazards.
- 2) Identification of the location of firefighting equipment for each fire area, and familiarization with layout of the plant including access and egress routes to each area.
- 3) The proper use of available firefighting equipment, and the correct method of fighting each type of fire. The types of fires covered include electrical fires, fires in cables and cable trays, hydrogen fires, flammable liquid fires, waste/debris fires, and record file fires.
- 4) Indoctrination on the plant firefighting plan with specific coverage of each individual's responsibilities.
- 5) The proper use of communication, lighting, ventilation, and emergency breathing apparatus.
- 6) The toxic characteristics of expected products of combustion.
- 7) The proper methods for fighting fires inside buildings and tunnels.
- 8) Detailed review of firefighting procedures and procedure changes.
- 9) Review of latest plant modifications and changes in firefighting plans.
- 10) The direction and coordination of the firefighting activities (fire brigade leaders only).

In addition, fire brigade leaders receive additional training that provides the fire brigade leader with the knowledge and skills necessary to supervise and direct the activities of the fire brigade during an incident.

b. Recurrent Training

Training and qualification are scheduled with a maximum allowed extension of 25 percent of the listed frequency interval. Performance deficiencies of the fire brigade or individual brigade members are remedied by scheduling additional training. Any individual who misses or fails to complete recurrent training is placed in an ineligible

PART II – FIRE PROTECTION PLAN

status when the current training expires until the training is completed in accordance with site procedure (Ref. 4.2.80).

1) Periodic Classroom Instruction (PCI)

Regular planned training sessions are held every three months. These planned training sessions repeat the initial training subject matter over a two-year period. These sessions are normally held on-site. If the appropriate quarterly session's subject matter is covered during the Annual Fire Brigade Training, credit may be given for the quarterly PCI.

2) Fire Drills

Drills are preplanned to establish the objectives and are conducted by the fire training instructor or designated representative. Drills are conducted as follows:

- a) A minimum of one on-site drill per shift every 92 days.
- b) A minimum of one unannounced drill per shift per year.
- c) At least one drill per shift per year on a "backshift" for each fire brigade.
- d) At three-year intervals, a randomly selected, unannounced drill critiqued by qualified individuals performing a triennial audit of the fire protection plan.
- e) An annual fire drill, which includes participation by the offsite fire departments that have an active agreement to provide firefighting and equipment response to the plant.
- f) Fire brigade members including leaders shall participate in at least two on-site drills per year.
- g) When assigned as the shift Incident Commander, the Incident Commander attends the fire drills that occur during that shift.

3) Annual Fire Brigade Training

Annual Fire Brigade Training is held for the fire brigade on the proper method of fighting various types of fires similar in magnitude, complexity, and difficulty as those that may occur. These types of fires include Class A (ordinary combustible material such as wood, cloth, paper, rubber, plastics, etc.) and/or Class B (flammable liquids, combustible liquids, petroleum greases, oils, flammable gasses, etc.). In addition, some fires may address Class C (energized electrical) fires in combination with a Class A and/or B. This training includes actual fire extinguishment of a live fire similar to that which may occur in the plant of sufficient magnitude to exceed the capacity of a single hand held fire extinguisher and require the use of emergency breathing apparatus under strenuous conditions.

Annual briefings are provided to the local fire departments to assure their continued understanding of their role in the event of a fire emergency at the

PART II – FIRE PROTECTION PLAN

plant. The annual briefings are required for only those local fire departments that have aid agreements with the plant.

9.4 Firefighting Equipment

Firefighting equipment is provided throughout the plant. The availability of firefighting equipment is such that delays in obtaining equipment by the fire brigade for fire emergencies are minimized.

Firefighting equipment may, alternatively, be staged adjacent to or at the access to areas/locations to facilitate equipment availability. This may be necessary to address equipment surveillance test concerns relative to life safety and ALARA practices.

Examples of the types of firefighting equipment available are as follows:

- motorized apparatus
- portable ventilation equipment
- fire extinguishers
- self-contained breathing apparatus and reserve air bottles
- fire hose
- nozzles, gated wyes, fittings, and foam applicators
- personal protective equipment such as turn-out coats, boots, gloves, and helmets
- communication equipment
- portable lights
- ladders for firefighting use

9.5 Fire Emergency Procedures and Prefire Plans

Fire emergency procedures and prefire plans specify actions taken by the individual discovering a fire and actions considered by the emergency response organization. Included in these procedures are operational instructions for response to the fire detection system annunciation. These procedures provide different levels of response based on whether there is an actual fire or an annunciation (e.g., a single zone annunciation in a cross zoned area will not carry the same level of response as a cross zone annunciation in the same area). An annunciation may or may not carry the same level of response as the report of a fire by site personnel. Prefire plans are not intended to establish a procedure or step-by-step process but to provide guidance, depending upon the particular circumstances, to aid in firefighting efforts. It is recognized that many different firefighting techniques or strategies exist which are acceptable for fire suppression efforts.

Prefire plans are developed to support firefighting activities in safety-related areas, in fire safe shutdown system areas, and areas which may present a hazard to safety-related or FSSD

PART II – FIRE PROTECTION PLAN

equipment inside the boundaries of the Site Perimeter. The prefire plans include the following information, as appropriate:

- Identification of plant equipment
- Access and egress routes for fire areas
- Firefighting strategy and tactics
- Location of fire protection features
- Identification of special fire, toxic material, and radiological hazards
- Special consideration of hazards
- Ventilation methodology

Safe shutdown procedures are available in the event a fire occurs in safety-related or FSSD equipment areas of the plant.

10.0 CONTROL OF COMBUSTIBLES

Combustibles are controlled to reduce the severity of a fire which might occur in a given area and to minimize the amount and type of material available for combustion.

The use and application of combustible materials at WBN are controlled utilizing the following methods:

- Instructions/guidelines provided during general employee training/orientation programs
- The chemical traffic control program
- Periodic plant housekeeping inspections/tours by management and/or the plant fire protection organization
- Design/modification and installation process review
- Administrative procedures (e.g., NPG-SPP-18.4.7 (Ref. 4.2.73) Control of Transient Combustibles)

The fire protection organization performs a periodic fire safety inspection of the safety-related areas of the plant to identify and minimize potential fire hazards.

The use and handling of combustible materials such as fire retardant-treated lumber, paper, plastic, and flammable/combustible gases and liquids are controlled in safety-related areas. The use of untreated lumber in safety related and selected power production structures requires specific approval of the fire protection organization.

Combustible materials generated as a result of work activities are removed/cleaned up from the work area at the end of the shift or at the conclusion of the work activity, whichever is sooner.

PART II – FIRE PROTECTION PLAN

The storage of combustible materials within safety-related areas is controlled by the fire protection organization.

The control of hazardous waste and hazardous materials is conducted in accordance with the chemical control and hazardous material processes.

Design considerations in the control of combustibles are utilized when appropriate. These considerations include the application of noncombustible or limited combustible construction materials or components, use of noncombustible fluids in operating equipment, provision of dikes or containments for equipment containing combustible liquids, etc.

Combustible Control Zones (CCZs) are established at WBN to strictly control or prohibit the placement of transient combustibles. Transient combustibles brought into CCZs require an evaluation in accordance with site administrative procedures. The strict control or prohibition of combustibles by site procedures within the combustible control zone provides reasonable assurance that a fire will not propagate and jeopardize redundant FSSD equipment. CCZs are shown on the compartmentation drawings (Figures II-27A through II-46A excluding 37A).

11.0 CONTROL OF IGNITION SOURCES

The use of ignition sources such as welding, flame cutting, thermite welding, brazing, grinding, arc gouging, torch applied roofing, and open flame soldering within safety-related areas is controlled through the approval and issuance of an ignition source permit. Permits are reviewed and approved by appropriate plant personnel. The ignition source permit is valid for one job. Job area inspections shall be performed and documented at the start of each shift that ignition source activities are being performed. If no ignition source activities are performed, then re-inspection is not required.

Designated ignition source activity areas are reviewed and approved by the fire protection organization. A fire watch system shall be established for all ignition source work activities that are performed in safety-related areas of the plant except for specific non-risk ignition source activities of underwater welding, outside areas (fences, light poles, etc), and electric soldering. These fire watches remain with the work activity in accordance with the requirements stated in NPG-SPP-18.4.8 (Ref. 4.2.65).

Smoking is not allowed in any safety-related or power production area.

12.0 DESCRIPTION OF FIRE PROTECTION SYSTEMS AND FEATURES

Fire protection systems and related features consist of the following subsystems:

- water supply
- standpipes, hoses, and hydrants
- automatic and manual fire suppression
- fire detection
- lightning protection, emergency lighting, and communications

PART II – FIRE PROTECTION PLAN

- reactor coolant pump lube oil collection, and
- fire-rated assemblies.

The following subsections are summary discussions of these fire protection systems and related features.

Those portions of the fire protection systems and features within Seismic Category I structures, whose failure during a seismic event may result in damage to safety-related equipment, have been designed and installed to Seismic Category I(L) requirements. Those portions that satisfy safety-related functions have been designed and installed to Seismic Category I requirements if needed due to the design basis. Piping in the Annulus is Seismic I(L)A, pressure retention. This has been analyzed to ensure the primary safety function of maintaining secondary containment isolation boundary.

12.1 Water Supply

The High Pressure Fire Protection (HPFP) system water supply is common to both units and consists of four, ASME Section III, seismic Category I, high pressure, vertical turbine motor-driven pumps and one horizontal, centrifugal diesel fire pump. Each electric pump is rated at 1590 gpm at 300-foot head (130 psig). The diesel pump is rated at 2500 gpm at 288-foot head (125 psig). Electric fire pump capabilities are evaluated by testing at the rated head and at two diverse points, one above and one below the rated head. The diesel fire pump capability is evaluated by testing at three points on the fire pump curve. They are: 1) not to exceed 140% of rated pressure (175 psig/404-foot head) at shutoff capacity 2) develop a minimum 100% capacity (2500 gpm) at rated pressure (125 psig/288-foot head), and 3) develop a minimum 150% capacity (3750 gpm) at not less than 65% rated pressure (81 psig/187-foot head). The electric pumps are located in the seismic Category I Intake Pumping Station (IPS). A three-hour fire-rated barrier is provided to separate two electric fire pumps from the other two. The diesel fire pump is remotely located in the Yard adjacent to the Unit 1 cooling tower.

The WBN fire protection system has four electric driven pumps and one diesel driven pump. As defined in Section 14.2.a below, fire protection Operability is based on only two of the four electric pumps and the diesel driven pump. The other two electric driven pumps are considered spares for fire protection purposes. The four electric pumps and associated main piping headers are ASME Section III, seismic class I available for supplying auxiliary feedwater during a design basis event (i.e., Flood Mode). During Flood Mode two electric pumps are aligned to each train header. Details of the Flood Mode are documented in several places in the FSAR such as Section 2.4.14.2, "Plant Operation During Floods Above Grade". The ASME and seismic requirements are beyond the requirements of the NFPA Code and are not required for fire protection purposes.

The electric pumps are automatically started by activation of the fire detection systems associated with the automatic water-based suppression systems. The electric pumps can be started manually from either the main control room or the respective 480V shutdown board. The diesel pump is auto-started on low system pressure or manually from the Main Control Room.

Each electric fire pump motor is powered from a separate 480V shutdown board. In the event of loss of offsite power, each shutdown board is powered by an emergency diesel generator. Indications of fire pump motor running and loss of line power on the line side of the switchgear

PART II – FIRE PROTECTION PLAN

are provided in the Main Control Room (MCR). Required annunciation signals for the diesel fire pump and its controller are automatically transmitted to the MCR.

Inspection of the strainers for the electric pumps is included in the WBN Preventative Maintenance Program. A single, automatic, motor-driven, self-cleaning strainer is provided for each power train to filter the discharge flow of the two electric pumps on that train. Each strainer is capable of straining 100 percent of the rated flow of two pumps. The strainers are located in the IPS. The strainers conform to the requirements of ASME Section III, Seismic Category I components. Mechanical screens are provided in the suction of the diesel fire pump and a strainer on the discharge.

Water supply for the electric fire pumps is taken from the Tennessee River and is considered unlimited for fire protection purposes. The diesel fire pump takes suction from the Unit 1 cooling tower basin, which has sufficient capacity for the diesel fire pump to run at 150% capacity for two hours. A fire protection water distribution system is provided to serve both units. Sectional isolation valves are provided so that maintenance may be performed on portions of the loop while maintaining firefighting capability. The sectional isolation valves in the underground and building loops are locked or sealed in position and surveillance is performed to ensure proper system alignment. The fire protection water distribution system is crosstied between units. The HPFP system is normally pressurized by the raw cooling water (RCW) system when the fire pumps are not running. The RCW system is automatically isolated when a fire pump starts.

The high pressure fire protection system is shared with the raw service water (RSW) system. Automatic isolation valves are provided to isolate selected large raw service water loads from the HPFP system when any fire pump is started. Specific RSW loads are automatically isolated from the fire protection water system when the fire pump(s) start due to a fire in safety-related areas to reduce the RSW load on the fire protection system to ensure adequate flow and pressure is available.

The electric fire pumps are also used for supplying auxiliary feedwater during a design basis event (i.e. Flood Mode) at which time two pumps are aligned to each train. Details of the Flood Mode operations are documented in the FSAR.

Measures were taken to account and compensate for the effects of corrosion on piping due to biological growth, such as microbiologically induced corrosion (MIC) nodules by designing normally raw water wetted, unlined carbon steel pipe using calculations that:

1. reduced the pipe diameter to account for diameter reducing inclusions, and
2. lowered the C-factor to C=55 in the Hazen-Williams formula to account for the added roughness.

The water used in both the HPFP and RCW system is chemically treated to address concerns resulting from the use of raw water. WBN has a comprehensive chemical treatment program for treating raw water systems. This treatment is a major part of WBN Raw Water Corrosion Program as specified by site procedures. The chemical treatment is used to control corrosion to control organic fouling, including slime, to minimize the effect of MIC and inhibit growth of Asiatic clams in carbon steel. Buried piping portions of the HPFP system are monitored by the buried piping program in accordance with NEI 09-14, "Guideline for the Management of Underground Piping and Tank Integrity," which provides for the risk ranking of buried piping relative to installed conditions (e.g., design and construction practices, as well as soil) and consequences of a failure and testing of the piping.

PART II – FIRE PROTECTION PLAN

Silt from river water is addressed for fire protection in two methods. One method is the design of the IPS. For the fire pumps, water has to travel up two elevations, traverse the basin area that is just under one half the size of the IPS between elevation changes, and there is a weir at the entrance to the fire pumps wet wells. This relative movement of water to reach the fire pump wet wells allows for the majority of the silt to drop out. The other method is the design of the Raw Cooling Water (RCW) system, which provides normal makeup for the HPFP system. The RCW system pumps draw water remotely from the water's entrance to the IPS allowing for silt settlement. The cross tie of the RCW and HPFP is in the Turbine Building close to the service water load on the HPFP system. Thus, silt drawn into the HPFP system is in the paths of these service water loads.

The water used in both the HPFP and RCW system is chemically treated to address concerns resulting from the use of raw water. In 1995 (at licensing of Unit 1), a three year evaluation program was implemented to monitor the performance of the HPFP system by yearly testing of the HPFP distribution system. The results of this evaluation determined that testing on a three year basis (instead of yearly) was adequate (see Reference 4.2.60). Actions taken to improve the program include the addition of the buried pipe program with the associated risk ranking and testing using advanced technology, such as guided wave testing.

The chemical treatment for raw water systems, including HPFP, is consistent with other nuclear facilities and includes oxidizing biocide, non-oxidizing biocide, phosphate, and zinc. On the existing HPFP piping, the phosphate is used to sequester iron from existing corrosion products, the zinc is used to passivate the carbon steel surfaces, and the oxidizing and non-oxidizing biocide controls slime, which helps prevent MIC growth. This provides the most effective treatment that a nuclear plant may use to prevent corrosion in raw water systems.

12.2 Standpipes, Hose Stations, and Hydrants

Hydrants are located around the yard loop and provide coverage for exterior portions of significant structures. Normally open key operated curb valves or post indicating valves are provided for isolation of each hydrant off the yard loop. Motorized apparatus at WBN is provided with sufficient equipment to effectively fight fires in the yard area.

Interior manual hose installations are provided throughout the plant typically as back up for the automatic suppression systems and, in some cases, as the primary suppression system. Selected hazards in the Reactor Buildings have automatic suppression systems as primary protection. These hazards include closed head water spray systems installed for each reactor coolant pump (RCP) and preaction sprinklers in the annulus that serve as water spray on select cable concentrations and prevent specific cable interactions. These automatic suppression systems are the primary suppression for these hazards with standpipes as the backup. For other general areas in the Reactor Buildings the primary suppression system is the Reactor Buildings' standpipes with the Auxiliary Building standpipes serving as the backup system. Selected areas in the Intake Pumping Station have automatic preaction sprinkler systems as primary protection with the standpipe system serving as the backup system in these areas. In areas of the IPS without automatic preaction sprinklers the standpipe system serves as the primary system, with yard hydrants providing the backup system.

Selected areas in the Diesel Generator Building (DGB) have automatic CO₂ and preaction sprinkler systems as primary protection with the standpipe system serving as the backup system in these areas. In areas of the DGB without automatic suppression, the standpipe system serves as the primary system, with yard hydrants providing the backup system. The primary and backup for the Diesel Generator Building's Conduit Interface Room is from yard

PART II – FIRE PROTECTION PLAN

hydrants. The design of manual hose stations were hydraulically verified per the guidelines of NFPA 14. The Diesel Generator Building (DGB) has two feeds from the fire protection water distribution system. One line feeds the fire suppression system and the other line feeds the standpipe and hose system.

Hose stations in safety-related areas of the plant are supplied from risers separate from those for the preaction sprinkler systems serving the same area. One exception is the Reactor Buildings in which both the hose station flow control valves and the automatic suppression system flow control valves are supplied from a single header for the systems in the respective Reactor Building.

Class II and III Hose stations are equipped with nozzles rated for the hazards present and with a sufficient amount of hose to support firefighting needs in that area. Hose station equipment may, alternatively, be staged adjacent to or at the access to areas/locations to facilitate equipment availability. This may be necessary to address equipment concerns relative to life safety and ALARA practices.

Most of the buildings are provided with a wet standpipe system. These systems have supply valves open and water pressure to the hose rack isolation valve. The Reactor Buildings (including the Annulus) is provided with a dry standpipe system. The standpipe systems within the Reactor Buildings are normally dry and are arranged to admit water into the systems through manual operation of push buttons located at each hose station. The systems are controlled by electrically or manually operated deluge valves which are located in the Auxiliary Building. The systems for each Reactor Building' RCP preaction sprinkler and dry standpipe are provided with automatic containment isolation capabilities for primary containment to address nuclear safety concerns. In case a fire in primary containment causes a spurious containment isolation signal, administrative controls have been established to address reestablishing flow to these systems.

12.3 Automatic Fire Suppression

The automatic fire suppression systems are designed to extinguish a fire or control and minimize the effects of a fire until the fire brigade can respond and extinguish it. The automatic suppression systems consist of water based systems and total flooding CO₂ systems. In addition, manually actuated fixed water suppression systems are also addressed in this section. There are typically three types of automatic suppression systems provided in safety-related areas at WBN:

- a. automatic preaction sprinkler systems
- b. automatic fire suppression systems with closed water spray heads
- c. automatic total flooding CO₂ systems

The annulus area of the Reactor Building has automatic preaction sprinklers that serve as water spray on select cable concentrations and prevent specific cable interactions.

Transformers in the Yard and specific hazards in the Turbine Building are protected with automatic fixed open head water spray systems.

PART II – FIRE PROTECTION PLAN

12.3.1 Preaction Sprinkler Systems

Automatic preaction sprinkler systems generally are provided in areas where it is important to prevent accidental discharge of water. In a preaction sprinkler system, the piping network is maintained dry until water is needed for fire suppression. A deluge valve (sometimes referred to as a preaction valve when used in a preaction system) is used to control when the water is introduced into the piping network.

Operation of the preaction sprinkler system is initiated by a signal from a detection system in the protected area. This signal starts two electric fire pumps and causes the preaction valve to open to fill the piping network. Actuation can also be initiated manually by mechanical operation at the preaction valve. Manual initiation does not automatically start the electric fire pumps. In accordance with 0-AOI-30.1, "Plant Fires" (Reference 4.2.89), the Operations staff ensures the fire pumps are running when notified of a fire. Selected preaction sprinkler systems have manual actuation stations at strategic locations remote from the preaction valve.

Water is then applied to the fire when the heat from the fire melts the fusible element in the sprinkler head. Water flow is stopped by manually closing the associated isolation valve.

12.3.2 Fire Suppression Systems with Closed Water Spray Heads

Automatic fire suppression systems with closed water spray heads are provided for charcoal type filter units, the reactor coolant pumps, and cable tray interactions in both Annulus areas. The actuation of the deluge valves is the same as that described for the preaction sprinkler systems section.

Operation of the fire suppression system is initiated by a signal from a detection system in the protected area. This signal starts two electric fire pumps and opens the deluge valve, filling the piping network with water. Actuation can also be initiated manually by mechanical operation at the deluge valve. Manual initiation does not automatically start the electric fire pumps.

Water is applied when the heat from the fire melts the fusible element in the closed water spray head. Water flow is stopped by manually closing the associated isolation valve.

12.3.3 Carbon Dioxide Suppression Systems

Automatic total flooding CO₂ suppression systems have been provided for the Auxiliary Instrument Rooms and Computer Room in the Control Building; and the Lube Oil Storage Room, each Diesel Engine Room (4), Fuel Oil Transfer Room, and each 480-V Board Room (4) in the Diesel Generator Building. The design basis for the areas protected by CO₂ are as follows:

- Auxiliary Instrument Rooms - Deep seated fires. Must achieve 30% concentration within 2 minutes, 50% concentration within 7 minutes, and maintain at least 45% concentration for at least 15 minutes.
- Computer Room - Deep seated fire. Must achieve 30% concentration within 2 minutes and 50% concentration within 7 minutes.
- Diesel Generator Engine Rooms - Surface fire (diesel fuel) and rotating electrical equipment. Must achieve 34% concentration within 1 minute and maintain at least 30% concentration for at least 20 minutes.

PART II – FIRE PROTECTION PLAN

- Diesel Generator Electrical Board Rooms - Deep seated fires. Must achieve 30% concentration within 2 minutes and 50% concentration within 7 minutes.
- Lube Oil Storage and Fuel Oil Transfer Rooms - Surface fire. Must achieve 34% concentration within 1 minute.

A signal from either the fire detection system or a push button station activates the area alarms, CO₂ discharge timer which actuates the master control valve and the area selector valve permitting the CO₂ to be discharged into the selected area. In addition, the system can be manually operated, even with a loss of power to the system, via the electro-manual pilot valve for each hazard protected

Personnel safety is considered by providing the pre-discharge alarm to notify anyone in the area that CO₂ is going to be discharged and by the addition of an odorizer to the CO₂ to warn personnel that CO₂ has been discharged.

Actuation of the CO₂ system causes selective closure of dampers and doors to the area protected and shut down HVAC air flows to the protected area. This prevents spread of the fire and ensures that the minimum concentration of CO₂ is maintained. Full discharge tests for representative rooms in conjunction with door fan pressurization tests have been conducted to validate CO₂ concentration and soak times. The duration of the discharge is determined by the area requirements and is controlled by the discharge timer.

The carbon dioxide system providing protection for the diesel generator building is stored in a tank at the diesel generator building. The diesel generator units are protected from the effects of a postulated failure of this storage tank by an 18-in thick reinforced concrete wall. Therefore, any missiles or pressure buildup generated by a rupture of the carbon dioxide storage tank does not damage safety-related equipment. The vent path for the storage tank compartment is through one set of double doors into a stairwell then, if needed, through another set of double doors which open to the atmosphere from the stairwell.

Carbon dioxide for the powerhouse areas is supplied from another storage tank in an underground vault in the yard; therefore, rupture or explosion of the tank cannot pose a threat to any safety-related structure. This part of the carbon dioxide suppression system has a non-seismic portion. The rupture of the non-seismic portion of the carbon dioxide system cannot result in the total depletion of the carbon dioxide supply to areas protecting safety-related and FSSD equipment. A pneumatic timer is located in the carbon dioxide supply line to hazards in non-seismic areas. This timer allows only the discharge equivalent to that required for the greatest hazard in a non-seismic area to be discharged from the system. After this specified length of time, the timer causes closure of the master control valve on the supply line to non-seismic hazards.

12.4 Manual Suppression Systems and Features

12.4.1 Portable Extinguishers

Portable fire extinguishers of a size and type compatible with specific hazards are located throughout the plant.

PART II – FIRE PROTECTION PLAN

12.4.2 Manual Sprinkler Systems

Manually activated sprinkler systems are provided for the 125-volt vital battery and battery board rooms I, II, III, and IV. The piping network isolation valve is maintained in the closed position. Personnel are alerted to a problem in these areas by the fire detection system. After confirming there is a fire, personnel then open the appropriate isolation valve to allow water to the system. Water is applied to the fire when the heat from the fire melts the fusible element in the sprinkler head.

12.5 Fire Detection Systems

Fire detection is installed to provide for prompt detection of a fire in its incipient stage and provide early warning capability. Prompt detection of a fire reduces the potential for damage to structures, systems and equipment and is an important part of the overall fire protection program at WBN. The fire detection systems at WBN are designed to be operable with or without offsite power.

The fire detection systems consist of initiating devices, proprietary protective signaling devices, local control panels, remote transmitter/receiver units which provide remote multiplex (MUX) functions, and computerized multiplex central control equipment.

The system processes the following signal types:

1. Alarm - A signal indicating the actuation of smoke or heat detectors or the sensing of flow through fire suppression systems. Also, some suppression supervision monitoring devices transmit an alarm signal.
2. Trouble - A signal indicating the occurrence of a fault condition in the proprietary protective signaling system. Normally suppression supervision monitoring devices transmit a trouble signal.

A central processor unit (CPU) of the computerized multiplex central control equipment communicates with the local control panels via the remote transmitter/receiver units over looped circuits. The transmitting equipment allows the processor to interrogate each local control panel in turn and to receive data from the panels. When an initiating device changes from normal to a trouble or alarm status, it is detected at the local control panel and, when next interrogated, the remote transmitter/receiver transmits this status change. The status change is evaluated by the CPU and visual and audible indications are provided. The computerized multiplex central control equipment is located in a constantly attended location.

Where detection is provided for the protection of safety-related or FSSD equipment, Class A, four wire, supervised circuits link the fire detectors to the local control panels. These circuits are used to annunciate status change to a constantly attended location.

A status change generally results in the following system responses:

1. Audible and visual annunciation by the computerized multiplex central control equipment. This annunciation includes identification of the location and the time of receipt of the status change on a monitor and a printer.
2. Illumination of indicating lamps on the local control panel indicating the status change.

PART II – FIRE PROTECTION PLAN

3. Actuation of local control panel circuits for the control of automatic suppression systems, fire pumps, fire dampers, or ventilation equipment as appropriate for selected alarm status changes.
4. An alarm status change can be reset at the local control panel. Local control panel reset, in safety-related areas, can also be achieved through the computerized multiplex central control equipment.

A second CPU is provided in a constantly attended location as an alternate for the primary processor.

The fire detection system for safety-related areas is comprised of different types of devices, components, or parts that provide the system functions of detection, annunciation, and/or activation of automatic suppression systems. The devices used are:

1. Smoke Detectors
 - a. Ionization
 - b. Photoelectric
2. Thermal Detectors

The thermal detectors are the rate compensation/fixed temperature type and are self restoring. They have temperature ratings appropriate for the area environment.

3. Air Duct Detectors

The smoke-type air duct detectors are specifically designed to sense the presence of smoke or combustion products in HVAC ducts.

4. Monitoring Devices

The fire detection system utilizes the following devices to monitor the fire suppression systems status.

- a. Pressure Switch - piping integrity
 - b. Pressure Switch - for water flow
 - c. Pressure Switch – CO₂ discharge
 - d. Status Switch - diesel fire pump running
5. Manual Pull Stations
6. Power Supply

Two sources of 120V AC power are provided to the portion of the fire detection system protecting the safety-related equipment. The primary power supply is from Class 1E power sources with a high degree of reliability and adequate capacity for the intended service. The standby power is from a diesel generator. An interim power supply is provided when the transfer

PART II – FIRE PROTECTION PLAN

from the main power supply to the standby power source takes longer than 30 seconds. The interim power supply consists of batteries that provide power to the remote transmitter/receiver modules only. Electrical isolation is provided between the fire detection system and the Class 1E power source from which it is supplied.

12.6 Lightning Protection

The basic principle to protecting life and property from damage or loss due to lightning is to provide a direct low impedance path for the lightning to travel to ground rather than through structures and/or equipment.

The lightning protection system consists of three basic parts which provide the low impedance path:

1. The air terminals on roofs and other elevated locations.
2. The ground grid.
3. The conductors connecting the air terminals to the ground grid.

Overhead shield wires and lightning arrestor protection is provided for the transmission lines, the switchyard, and the transformers.

12.7 Emergency Lighting

The plant design includes three lighting systems classifications:

1. Normal - powered only from offsite power,
2. Standby - powered from offsite or onsite power, and
3. Emergency - powered from 125V vital batteries or individual battery packs.

Normal and standby lighting are energized during normal plant operation. 125V emergency lighting comes on automatically during the transition from offsite to onsite power. The individual emergency battery pack lights come on automatically upon loss of voltage to the normal lighting circuit serving the area.

Standby and emergency lighting is designed to provide essential lighting to accomplish safe shutdown and for personnel access/egress. However, since fire damage may disable portions of the standby and 125V DC emergency lighting systems, and in accordance with the requirements of 10 CFR 50 Appendix R, Section III.J, eight-hour emergency battery pack lighting is provided in areas required for manual operation of safe shutdown equipment and in the access/egress routes thereto in all areas except the Turbine Building, Yard Area, and Containment.

Emergency Diesel Generator backed standby lighting is available and maintained for the Turbine Building. Diesel generator backed security lighting is provided and maintained for the Yard. Additionally, portable hand-held lighting is provided and maintained to provide task-lighting capability (e.g., breaker tripping) in these areas. Portable hand-held battery lights are provided and maintained for the Containment. Deviation 2.7 in Part VII, "Deviations and Evaluations," provides TVA's justification for the lighting available for these areas.

PART II – FIRE PROTECTION PLAN

The illumination provided by emergency lighting in access routes to and in areas where shutdown functions must be performed is sufficient to enable a qualified operator to perform the shutdown functions. Illumination levels are adequate for personnel to perform their intended task(s).

Portable, hand-held lighting is available for predetermined locations for use by Operations personnel in those areas where emergency lighting is temporarily out of service for maintenance or repair.

12.8 Communications

There are several means of communication available to the Operations staff such as telephones, code alarm and paging, sound powered phones, and two-way radios. The in-plant radio signal will be the primary means of communication for performing manual actions and for the fire brigade use.

The trunked in-plant radio system consists of multiple base radios, portable radios (including tri-band), and redundant in-plant distributed antenna systems. To ensure communication availability, one of the radios and associated power cabling is located in a separate fire zone or is separated by minimum of 20 feet. The base radios are located at floor elevation 772.0 of the Auxiliary Building within the 480V Board Room 2A and the 480V Transformer Room 2A. The radios (multiple frequencies) are available for use by the fire brigade and for operations personnel for performing safe shutdown manual actions. The radio equipment features redundant diesel and battery backed power supplies. Antennas for the radios are located on the Aux Building exhaust stack (above elevation 814.75) to transmit and receive the radio signal. In addition to the antennas on the exhaust stack, the internal distributed antenna systems (Radiax) are located in the control and turbine buildings and two widely separated trunk lines feed the radio signal to redundant distributed antenna systems located throughout the auxiliary building.

Adequate radio communications are provided for areas of the plant that contain equipment that must be manually operated in the event of a fire. In some rooms such as the RHR heat exchanger room, two-way radio communications may not be adequate in the room; however, adequate communications are available immediately outside this room. The action to be performed does not require that communication be established at the device (e.g., for example open/close valve or breaker).

A sound powered phone system connects the auxiliary control room and various local control stations to supplement the radios during alternative shutdown. Control of communication equipment outages are via the normal work control program. Fire protection impairment permits are not used to control this type of outage.

12.9 Reactor Coolant Lube Pump Oil Collection

The major fire hazard within the containment is the reactor coolant pump (RCP) lube oil system. To prevent a fire as a result of oil leakage WBN has provided an oil collection system for each RCP. The oil collection system includes enclosing the RCP oil lift pump and providing an oil collection basin at the access platform elevation of each pump to collect and drain away any combustible liquid and/or suppression system discharge. Any discharge is drained from the collection basin into the containment floor and equipment drain sump located inside primary containment. See Part VII for the deviation associated with the RCP oil collection system.

PART II – FIRE PROTECTION PLAN

Each RCP is provided with a heat collection hood to reduce the response time of the thermal detectors and the thermal-actuated closed head water spray nozzles installed below the heat collector hood.

12.10 Fire-Rated Assemblies

Fire rated assemblies at WBN are part of the passive fire protection features which ensure that the function of one set of redundant fire safe shutdown components necessary to achieve and maintain FSSD remains free of fire damage. Fire rated assemblies consist of fire barriers, raceway protection, equipment hatches and stairwells, fire doors, fire dampers, and penetration seals. Fire barriers and fire doors are identified on the compartmentation drawings in Part II of the FPR.

In general, the fire barriers are of either reinforced concrete or reinforced concrete block construction. The concrete barriers are normally a minimum of 12-inch thick (some are 8-inch thick) and the block barriers are normally 8-inch thick. National Fire Protection Association Handbook, 17th Edition Section 6, Chapter 5, Figure 6-5G (Reference 4.3.2) provides a correlation between the thickness of reinforced concrete and its fire resistance. Figure 6-5G shows that six inches of reinforced concrete has a fire resistance of approximately four-hours. Based on this, the 8-inch thick concrete barriers far exceed the maximum three-hour rating assigned to these barriers at WBN. The UL Fire Resistance Directory identifies similar concrete block barriers (designs U904, U905, U906, and U907) as two-hour to four-hour fire-rated barriers. The 8-inch thick concrete block barriers are only used when barriers are required to have a fire rating of 2-hours or less.

12.10.1 Walls, Floors, and Ceilings

Fire areas are separated by 2- or 3-hour equivalent fire barriers that are bounded by UL rated designs. Rooms within each fire area may be separated from other rooms in the same area by regulatory or nonregulatory fire barriers. (Only regulatory fire barriers are relied on for the fire safe shutdown separation analysis.) Where fire barriers are used to separate rooms in the same area, the barriers have equivalent 2-hour fire ratings, except for portions of the main control room elevation complex which is 1-hour rated. If the separation between rooms in the same fire area is less than 3-hour, then automatic suppression and detection systems are provided or deviations justified (see Part VII for the discussion of deviations).

12.10.2 Raceway Protection

Cable raceways that require separation by Electrical Raceway Fire Barrier Systems (ERFBS) are provided with one-hour rated ERFBS and automatic suppression and detection in the area, or three-hour rated ERFBS. Inside the reactor building, which includes primary containment (Unit 1 only) and secondary containment (i.e., annulus), radiant energy shields or automatic detection and suppression are used to obtain separation where a fire may damage redundant safe shutdown components. Note that radiant energy shields are not installed on Unit 2 inside primary containment.

The radiant energy shields used in Unit 1 are constructed primarily of 3M M20A or M20C (see Part VII, section 2.2). During the 2012 refueling outage, radiant shields were added to the Unit 1 Annulus and were constructed of 3M E54C (M20 is no longer available and E54C is a replacement). The radiant energy shields used in the Unit 2 Annulus are constructed of 3M E54C (no radiant energy shields are used in Unit 2 Primary containment). The E54C material is

PART II – FIRE PROTECTION PLAN

non-combustible and has a minimum 30-minute fire resistive rating (Ref. 4.2.82). This is in compliance with Appendix R, section III.G.2.f.

The ERFBS for WBN was tested to the guidance provided in GL86-10, Supplement 1 (Ref. 4.1.10) and GL92-08 (Ref. 4.1.13) and the associated Information Notices (Ref. 4.1.15 thru 4.1.24) which have established the industry standards for acceptable ERFBS. Mechanical Design Standard DS-M17.2.2 (Ref. 4.2.23) and General Engineering Specification G-98 (Ref. 4.2.24) document the testing, design, installation, quality control and maintenance requirements of the ERFBS. The design standard also provided the guidelines for evaluating unique ERFBS configurations to ensure that a unique design is within the important parameters that keep it bounded by tested configurations. NRC previously reviewed and approved this program (Ref. 4.3.9 and 4.3.11).

From 1992 through 1995 TVA performed numerous fire tests on a large variety of ERFBS configurations (cable trays, conduits, junction boxes, air drops, etc.) to ensure the fire resistive rating assigned to the ERFBS was in accordance with the established industry/NRC standards. These tests also provided sufficient information to establish the bounding parameters (thickness of material, attachment methods, etc.) and thereby develop the design standards for the ERFBS at TVA. In addition to the fire testing, TVA also tested the ERFBS to ensure it may withstand a seismic event; ampacity derating requirements for the various ERFBS applications; and quality assurance standards for the acceptance of the ERFBS material from the vendor, material handling, and installation of the ERFBS.

Standard drawings (Ref. 4.2.23 and 4.2.26) document the ERFBS configurations used at WBN. These drawings identify such critical attributes as material thickness, pre-buttering with trowel grade Thermo-Lag, scoring and folding requirements, tie wire/banding spacing, raceway support protection, interfering item protection, attachment of ERFBS to concrete barriers, etc.

The installation of ERFBS is by a modification package (design change notice). If during the installation of an ERFBS, it cannot be installed as per the DCN, a field change request is generated to document the unique configuration. Each unique ERFBS configuration is evaluated per DS-M17.2.2 (Ref. 4.2.23), Appendix H, "Guidelines for Evaluation Unique Thermo-Lag 330-1 ERFBS Configurations", by personnel cognizant of the important parameters. These people must be knowledgeable of the impact these important parameters have on the overall performance of the ERFBS assemblies. The evaluator judges the synergistic effects that may be experienced when one or more important parameter(s) is (are) different and ensures compensating design measures are incorporated into the unique ERFBS to overcome these differences. This evaluation ensures that the unique configuration is designed and installed within the list of important parameters that were communicated to utilities through a 50.54(f) letter to Generic Letter 92-08. The installed configuration is therefore ensured of being bounded by the acceptable parameters of a rated fire barrier.

The ERFBS are designed, procured and installed in accordance with the requirements of NPG-SPP-18.4.5, Fire Protection Quality Assurance (Q07), (Reference 4.2.28). TVA inspects the Thermo-Lag at the manufacturer to ensure chemical composition, material thickness and appearance, etc. are in accordance with TVA requirements. The installation of the ERFBS is monitored by TVA Quality Control personnel for adherence to the issued design. This overall program ensures that the design, procurement, installation and maintenance of the ERFBS meets the requirements for adequate separation as stated in Appendix R, Section III.G.2.

PART II – FIRE PROTECTION PLAN

12.10.3 Equipment Hatches and Stairwell

Equipment hatches in floor or ceiling fire barriers fall into three categories:

- a) Precast concrete plugs which overlap mating surfaces for support--These plugs are usually associated with radiation shielding and provide a fire barrier equivalent to the floor or ceiling in which they are located.
- b) Steel covers that overlap mating surfaces for support--These covers are of substantial construction and provide an effective barrier to prevent fire from propagating from one side of the barrier to the other. However, since they are not fire rated, they are either provided with a draft stop and water curtain around them or redundant safe shutdown components on either side have been separated from each other by a cumulative horizontal distance of 20 or more feet. In either case, automatic fire suppression and detection are provided on both sides of the equipment hatch cover, if appropriate, or an engineering evaluation has been performed. See Part VII for justifications for deviations and/or evaluations.
- c) Open hatches and stairwells - Redundant safe shutdown components located on each side of the opening have been identified. If separated by less than a cumulative distance of 20 feet horizontally, either the hatch/stairwell has been provided with a water curtain to separate elevations, or a one hour fire barrier has been provided on the cables for one of the redundant paths. In either case, automatic fire suppression and detection has been provided on both sides of the opening, except for the refueling area and the 676 ft elevation of the Auxiliary Building. See Part VII for justifications for deviations and/or evaluations.

12.10.4 Fire Doors

Fire door assemblies (doors, frames, and hardware) are generally provided for door openings in required fire barriers. These assemblies are UL listed as either "A" label (3-hour rated) or "B" label (1-1/2 hour rated). "A" label doors are provided in 3-hour or less rated fire barriers and "B" label doors are provided in some barriers that require a 2-hour or less fire rating.

Sliding fire doors are provided in selected locations. These sliding fire doors are closed by heat melting a fusible link, and in CO₂ protected areas, when a CO₂ system pressure-activated release occurs.

In some cases, such as air lock doors, equipment doors, submarine type doors, etc., the doors cannot be purchased as labeled fire doors. These doors have been evaluated by a Fire Protection Engineer for their ability to prevent the propagation of a fire. These evaluations are either kept on file for review or are documented in Part VII, Deviations.

Repairs on fire door assemblies require the approval of a Fire Protection Engineer except when replacing a like item for a like item as specified on design output.

12.10.5 Fire Dampers

Fire dampers are provided in HVAC ducts that penetrate required fire barriers to prevent the propagation of a fire through the duct. Some duct penetrations do not have fire rated dampers and are shown on the compartmentation drawings as unprotected openings. In some cases, the fire damper is also used to isolate an area prior to CO₂ discharge. Fire dampers are

PART II – FIRE PROTECTION PLAN

provided with appropriately rated fusible links based on the ambient temperatures in the location. The fire dampers provided with CO₂ suppression system isolation capability are actuated by CO₂ system pressure activated release mechanism and/or by thermal link. Fire dampers in safety-related HVAC systems may have double fusible links installed if required by a single failure analysis.

12.10.6 Penetration Seals

When plant commodities (i.e., pipe, cable trays, conduits, etc.) must pass through required fire barriers, the openings are provided with seals that meet or exceed the fire protection requirements of the barrier. The mechanical and electrical penetration seals used at Watts Bar have been bounded by fire tests conducted at independent testing laboratories that are experienced in fire testing (e.g., Underwriters Laboratories, Omega Point Laboratories, Construction Technologies Laboratories, etc.). The testing labs were required to conduct the test using the standard temperature-time curve as described in ASTM E-119. The critical attributes of an acceptable mechanical and electrical seal are defined below. The most important attribute is that the penetration seal has withstood the fire endurance test without passage of flame or gases hot enough to ignite cable or other fire stop material on the unexposed side for a period equal to the required fire rating. In addition, these seals may be required to meet other plant design bases requirements such as radiation shielding, HVAC pressure differential, and/or flood. Engineering report for Penetration Seal Program Assessment (Ref. 4.2.50) documents the testing acceptance parameters and design standards for fire rated penetration seals at WBN. This document along with General Engineering Specifications G-96 (Ref. 4.2.61) and drawing series 45A883 (Ref. 4.2.62), 45W883 (Ref. 4.2.63) and 47W472 (Ref. 4.2.64) control the penetration seal program at WBN. NRC performed an “audit type review of mechanical and electrical penetration seals” and stated, “The staff concludes from its audit of the applicant’s penetration seal program that this program adequately demonstrates the fire resistive ratings of these typical penetration seal designs and, therefore, they conform to the guidelines of Positions D.1.j and D.3.d of Appendix A to BTP (APCSB) 9.5-1 and are acceptable” (Ref. 4.3.10). In addition the NRC stated in NUREG-1552 (Ref. 4.1.25), Section 5.5.6, “The staff had documented its review and evaluation of the WBN fire penetrations seal program in Section 9.5.1, “Fire Protection Section,” of NUREG-0847 “Safety Evaluation Report Related to the Operation of Watts Bar Nuclear Plant, Unit 1 and 2.” On the basis of its comprehensive safety evaluation of the WBN penetration seal program, the staff had concluded that the program satisfied applicable NRC requirements and guidelines.”

(A) Mechanical Pipe Penetrations

A 1-hour, 2-hour, or 3-hour Fire rating in accordance with ASTM E-814-83, section 10.1, and 1-hour, 2-hour, or 3-hour T rating in accordance with ASTM E-814-83, section 10.2 is established for mechanical penetration seals. The T rating acceptance criteria is limited to a temperature rise of 325° F above ambient for cold side seal surface temperatures. Cold side surface temperatures are defined by thermocouples required to be on the fire stop surface (field) per section 10.2 of ASTM E-814-83. A T rating is not required on the penetrant(s). In addition to the above listed criteria of fire rating, differential pressure, etc., the seal must be able to accommodate the service temperature and any thermal or mechanical movement of the pipe.

(B) Electrical Penetrations

A 1-hour, 2-hour, or 3-hour rating in accordance with IEEE 634-1978, section 6.1 was established for electrical penetration seals. Transmission of heat through the penetration seal

PART II – FIRE PROTECTION PLAN

was limited to 700° F or the lowest auto-ignition temperature of cable in the penetration, whichever is lower.

Conduit penetrations typically require only internal seals since most conduit penetrations were poured-in-place during plant construction. Internal seal materials, design, and locations in walls and floor/ceiling assemblies have been evaluated as equivalent to tested configurations. If a conduit requires an external seal (e.g., the conduit passed through a sleeve larger than the conduit), the external seal meets the same criteria as stated in the above paragraph. The criteria for internal conduit seals that were reviewed and approved by the NRC are based on the information presented in an RAI response from July 1, 1994 (ML073230669). The following information is from that submittal. The internal conduit seal criteria is documented on drawing series 45W883 and is as follows.

Smoke and gas seals shall have a (min) 3 inch RTV silicone foam and 1 inch ceramic fiber damming at the bottom/back side of the foam. The fiber damming may or may not exist in the front/top side of the foam. The silicone foam shall be installed at the first available opening. Conduits that terminate in junction boxes or other non-combustible enclosures need no additional sealing except for Auxiliary Building secondary containment envelope boundaries. See table below for sealing instructions. A closed electrical cubical similar to a motor control center or switchgear cabinet is not considered a non-combustible enclosure.

CONDUIT	TOTAL LENGTH OF CONDUIT FROM BARRIER					
SIZE	CONTINUOUS THRU AREA	<1'	≥1' - <3'	≥3' - <5'	≥5' - <22'	≥22'
<1"	NSR	F	NSR	NSR	NSR	NSR
1"	NSR	F	S	S	NSR	NSR
>1" - <2"	NSR	F	S	S	NSR	NSR
2"	NSR	F	F	S ⁴	NSR	NSR
>2" - ≤4"	NSR	F	F	F ⁴	S ⁴	NSR
>4"	NSR	F	F	F	S	NSR

Notes:

1. NSR – No Seal Required
2. S – Smoke and Hot Gas Seal Required
3. F – Fire Seal Required
4. NSR if cable fill exceeds 40%

C. Hose Stream Test for Penetrations

Hose stream test requirements are in accordance with IEEE 634-1978 or ASTM E-814-83. The penetration seal configurations at Watts Bar have withstood a hose stream test without the hose stream causing an opening through the penetration seal that permits a projection of water beyond the unexposed side.

PART II – FIRE PROTECTION PLAN

13.0 FIRE PROTECTION SYSTEM IMPAIRMENTS AND COMPENSATORY ACTIONS

Fire protection impairments are controlled to maximize the availability of the active and passive fire protection systems and features.

Fire protection systems and features are intended to remain fully operational to the maximum extent possible. However, it is expected for outages or impairments to occur to support plant or fire protection-related modifications or maintenance. As a minimum, fire protection systems and features are to remain operable whenever the equipment they protect is required to be operable, or appropriate compensatory actions are established as prescribed in the associated ORs.

WBN "Regulatory Required" (REG) fire protection systems and features, although not classified as safety related, provide fire protection capabilities in those areas where protection of safety-related or FSSD equipment is deemed necessary. In the event a REG fire protection system or feature becomes inoperable, compensatory actions have been developed to minimize the effects of the impaired equipment on safe plant operations and safe shutdown. To ensure the maximized availability of REG fire protection systems and features, processes are in place, through administrative procedures, to keep fire protection system and feature inoperability as short in duration as possible.

13.1 Compensatory Actions

Compensatory actions for impaired REG fire protection systems or features generally consist of fire watches as defined in the applicable sections of this plan. Alternate compensatory actions such as additional/alternative fire protection equipment, temporary/portable detection systems, temporary alternate feeds to suppression systems, or closed circuit television may be utilized on a case by case basis. These alternative actions are considered when they provide equal or better protection and/or when the primary methods are too restrictive, create further hazards, or represent personnel safety concerns.

A summary of each of the primary and alternate actions are as follows:

A. Fire Watch - Continuous (Primary)

The locations that a continuous fire watch is required are based on plant conditions existing at the time the fire watch is in place and modified as needed. Continuous fire watches are restricted to patrolling one fire area except as noted below.

Continuous fire watches are only required when the affected unit is in Modes 1 (Power Operation) to 4 (Hot Shutdown), inclusive. A "roving" fire watch covers the designated areas on an hourly basis in areas where only the unit in Modes 5, 6, or core empty may be affected by a fire. If a fire in an area may affect both units, then a Continuous fire watch is required.

Specific patrol locations are selected to accommodate plant features such as locked doors, security card readers, contaminated areas, etc., so that patrol access is not unduly impeded under existing conditions. The patrol routes are specified such that the fire watch can routinely accomplish the route within 15 minutes with a thorough review of the route, with a margin of 5 minutes to accommodate and handle unforeseen circumstances and to report and/or resolve potential fire hazards in a location.

PART II – FIRE PROTECTION PLAN

There are locations where one or more rooms are in different fire areas but their proximity and limited size warrant allowing them to be combined for one continuous fire watch to address. Time study information is used to identify the rooms, in different fire areas, that can be covered in 15 minutes without putting undue exertion on the person. The below listed rooms have been identified as an exception to the definition of a continuous fire watch. The specific patrol locations requires approval of the Fire Protection Supervisor or his designee to ensure the conditions that formed a basis for the time study have not changed such as to invalidate the time study. The routes with more than one fire area that are exceptions to a continuous fire watch staying in one fire area are:

1. Diesel Generator Building, Elev. 742
2. Diesel Generator Building, Elev. 760
3. Auxiliary Building Rooms (0-FCV-26-143 and 0-FCV-26-322 out of service):

757.0-A15	782.0-A4

Situations may arise in which the system or equipment cannot be restored within the time specified by the Fire Protection Systems and Features Operating Requirements (Section 14.0). In such cases, an augmented compensatory action is taken to ensure that a continuous fire watch does not go to different fire areas. The 15 minute requirement still applies, but the continuous fire watch must remain within the same fire area. This augmented compensatory action is not required for fire locations that only affect the unit that is in Mode 5, 6 or core empty.

B. Fire Watch - Roving (Primary)

A roving fire watch consists of a trained individual in an affected location at 60 minute intervals with a 15 minute margin to accommodate and handle unforeseen circumstances and to report and/or resolve potential fire hazards in a location. Roving fire watches are required as a compensatory action in all modes of plant operation (i.e., Modes 1 through 6 or core empty).

With a unit in Modes 5, 6, or core empty, locations where a continuous fire watch are required may be combined and patrolled by a roving fire watch when approved by the Fire Protection Supervisor (or designee) if the location only affects the unit in Modes 5, 6, or core empty.

PART II – FIRE PROTECTION PLAN

C. Additional/Alternative Fire Protection Equipment (Alternative)

Additional/alternative fire protection equipment consists of firefighting features such as fire hose and wheeled fire extinguishers, or mobile apparatus. Normal compensatory actions for inoperable fire protection features such as hose stations consist of physical routing and/or staging of backup fire hose capable of supplying water from the nearest operable fire hose station to the area left unprotected by the inoperable hose station. Additionally, the use of wheeled fire extinguishers or mobile apparatus may be considered when physical constraints such as fire barrier integrity preclude breaching the barrier to stage compensatory fire protection equipment. In the event an alternative compensatory action is considered, an evaluation is performed by the plant fire protection staff and documented with the impairment permit or work initiation document to demonstrate technical equivalency to standard compensatory actions identified in Section 14, "Fire Protection Systems and Features Operating Requirements (OR)."

D. Temporary/Portable Detection Systems (Alternative)

A temporary/portable detection system consists of one or more listed or approved detectors, a power supply and monitor unit, connecting cable, and a method of transmitting an alarm to a constantly attended location. Fire detectors may be placed in more than one room or more than one elevation of the plant. The use of a temporary/portable fire detection system is similar to the industry precedent established by Toledo Edison Company's Davis-Besse Nuclear Plant, and other utilities, and approved for use by the NRC. An evaluation is performed by the plant fire protection staff and documented with the impairment permit or work initiation document for each type of temporary/portable detection system to demonstrate technical equivalency to standard compensatory actions identified in Section 14, "Fire Protection Systems and Features Operating Requirements (OR)." The area with impaired fire protection equipment of Section 14 as well as the associated temporary/portable detection system monitor unit(s) is observed by an hourly roving fire watch. Portable detection systems are used where plant configuration and conditions are acceptable for its use.

E. Closed Circuit Television -CCTV (Alternative)

CCTV equipment consists of CCTV cameras and monitors. Cameras may be placed in more than one room or more than one elevation of the plant. CCTV systems are similar to the ones used by other utilities for monitoring of inoperable fire barriers as well as CCTVs previously utilized at Browns Ferry Nuclear Plant in inaccessible tunnels. An evaluation is performed by the plant fire protection staff and documented with the impairment permit or work initiation document for use of CCTV equipment (cameras and monitors) to demonstrate technical equivalency to standard compensatory actions identified in Section 14, "Fire Protection Systems and Features Operating Requirements (OR)." CCTV monitors are monitored by fire watch personnel at a frequency consistent with standard compensatory actions identified in Section 14, "Fire Protection Systems and Features Operating Requirements (OR)." CCTV may be used in instances where personal safety exceeds OSHA thresholds based on detailed evaluation, operational conditions in high heat areas such as the main steam vault, or ALARA concerns in high radiation areas preclude using a human fire watch in the area.

F. Constantly Manned Location (Alternative)

In plant areas that are continuously manned, credit may be taken for the constant manning in lieu of establishing either continuous or roving compensatory fire watches when the responsible individual(s) are informed and accept this responsibility. All employees receive training annually on proper reporting of fires. Documentation for the fire watch position is not required provided

PART II – FIRE PROTECTION PLAN

the manned position is documented (e.g., Main Control Room logs or documented security post).

13.2 Exceeding Return to Service Times

Impaired fire protection systems or features are returned to operable condition in the time frame specified in the OR sections. If this restoration is not done, a 10 CFR 50.72 and 10 CFR 50.73 review is performed and documented in accordance with site administrative procedures.

The fire protection organization performs a periodic walkdown to ensure fire protection and compensatory actions are established for those fire protection system impairments or features that are out-of-service.

14.0 FIRE PROTECTION SYSTEMS AND FEATURES OPERATING REQUIREMENTS (ORs)

The ORs established in this section have been developed to ensure adequate fire protection capability is available and maintained, to detect, control, and extinguish fires occurring in any portion of the plant where safety-related or FSSD equipment are located.

Fire protection systems and features at WBN are not assumed to be operable to mitigate the consequences of a Design Basis Accident (DBA) or plant transient. The bases for this assumption are contained in Section I of Appendix R which states that the need to limit fire damage to systems required to achieve and maintain FSSD conditions is greater than the need to limit fire damage to those systems required to mitigate the consequences of DBAs. As a result, Section I identifies that fire protection features must be capable of limiting fire damage so that:

1. One train of systems necessary to achieve and maintain hot shutdown conditions from either the control room, auxiliary control room, or emergency control stations is free of fire damage; and
2. Systems necessary to achieve and maintain cold shutdown from either the control room, auxiliary control room, or emergency control stations can be repaired within 72 hours.
3. Alternate shutdown capability is provided at WBN, when needed, to achieve and maintain cold shutdown within 72 hours.

Operability of the fire protection systems and features are required whenever safety-related equipment and fire safe shutdown systems protected by the fire protection systems and features are required to be Operable.

The Fire Protection Report provides applicable action statements and thus does not have a requirement similar to Technical Specification 3.0.3 except for equipment listed in Section 14.10. When a piece of equipment in section 14.10 is out of service, there are mode reduction requirements similar to Technical Specification 3.0.3. However, equivalent methods (documented in an engineering evaluation in accordance with site procedures) that ensure fire safe shutdown can be achieved per the requirements of 10CFR50, Appendix R may be used to delay or remove the mode reduction requirements. These equivalent methods once documented by engineering evaluation provide alternatives to the applicable actions statements when equipment listed in this part, Section 14.10 must be declared inoperable.

PART II – FIRE PROTECTION PLAN

The Fire Protection Report does not have a requirement similar to Technical Specifications 3.0.4 preventing mode changes while in an action statement.

The Testing and Inspection Requirements (TIRs) for the WBN fire protection systems and features have been developed taking into consideration industry practice (e.g., similar methods approved for use by other licensed nuclear power facilities), NFPA consensus standards, and insurance carrier loss prevention recommendations.

Engineering judgment has also been utilized in the development of testing and inspection frequencies and criteria for the WBN FPP. The following factors or influences are considered when developing the testing and inspection frequencies and criteria:

1. Personal safety is of paramount concern when developing and implementing the fire protection testing and inspection requirements at WBN. Therefore, alternative frequencies and/or criteria may be necessary when operational considerations, equipment accessibility, or other conditions warrant such changes.
2. Good ALARA practices in concert with equipment/component failure histories are considered to ensure "value add" is achieved without undue challenge to system components and/or personnel.
3. Nuclear facilities by nature and design are controlled and structured environments. The importance of fire protection systems and features and the established administrative controls at WBN are reinforced to plant personnel through training, sign posting, procedures, and processes.

The performance of the WBN fire protection testing and inspection plan is driven by a trending philosophy which is used to evaluate the success and/or target the testing and inspection activities needing improvement. This philosophy provides an added level of flexibility to increase or decrease as necessary, the testing and inspecting activities based on empirical data.

Refer to the TIR matrix for operational testing requirements. The specified frequency for each TIR is met if the test/inspection is performed within 1.25 times the interval specified in the frequency, as measured from the last scheduled performance date. This extension facilitates TIR scheduling and considers plant operating conditions that may not be suitable for conducting the TIR (e.g., transient conditions or other ongoing TIR or maintenance activities). The provisions for such extensions are not intended to be used repeatedly merely as an operational convenience to extend the TIR testing interval or periodic completion time intervals beyond those specified. The same scheduling policy used for the Technical Specifications is used for each TIR.

Testing of the fire protection systems involve manually disabling portions of them to prevent unwanted responses. These responses can be in the form of excessive starting of deep draft pumps, discharging water in a radiological controlled area, etc. The equipment, generally in the area of the testing, still functions normally once the temporary, intentional impairment is removed. When test personnel are actively performing the test, the compensatory fire watches are not required. This allows for the test personnel to serve as the fire watch for the area in question.

PART II – FIRE PROTECTION PLAN

14.1 Fire Detection (Early Warning Fire Detection and Notification Only) (OR)

The minimum number of fire detectors are identified on Table 14.1 and shall be Operable when the safety-related or FSSD equipment in that area is required to be Operable.

NOTE 1: The action statements below apply to only the Function A fire detectors as defined in Table 14.1. The action statements of Section 14.3 and 14.4 apply to the Function B fire detectors that are associated with automatic suppression systems.

NOTE 2: Inoperable fire detectors may cause alarms or troubles on the associated local control panels that cause a masking condition addressed in Section 14.5.

NOTE 3: The central processing unit (CPU) for the fire detection system shall be operable when the fire detection system identified in Operating Requirement 14.1 is required to be operable.

NOTE 4: With a unit in Modes 5, 6, or core empty, locations where a continuous fire watch is required may be combined and patrolled by a roving fire watch when approved by the Fire Protection Supervisor (or designee) if the location only affects the unit in Modes 5, 6, or core empty.

14.1.1 With any of the required Function A fire detectors in a fire detection zone identified on Table 14.1 inoperable in any accessible area, within one hour restore the inoperable equipment

-OR-

establish a roving fire watch once per hour.

14.1.2.a With any of the required Function A fire detectors in a fire detection zone identified on Table 14.1 inoperable inside containment, within eight hours, restore the inoperable equipment

-OR-

either establish a roving fire watch once per 8-hours

-OR-

monitor the air temperature for the area affected once per hour using the following:

<u>AREA</u>	<u>INSTRUMENT(S)</u>
Upper Containment	U-9019 on Unit 1 Plant Computer
Lower Containment	U-9020 on Unit 1 Plant Computer
Upper Containment	U-9019 on Unit 2 Plant Computer
Lower Containment	U-9020 on Unit 2 Plant Computer

14.1.2.b With any of the required Function A fire detectors in a fire detection zone identified on Table 14.1 inoperable in an inaccessible area outside containment, within eight hours, restore the inoperable equipment

PART II – FIRE PROTECTION PLAN

-OR-

establish a roving fire watch once per 8-hours.

- 14.1.3** Restore the inoperable detector(s) to Operable status within 14 days. If not restored within 14 days, continue the compensatory actions AND perform 10CFR50.72 and/or 10CFR50.73 reviews per site administrative procedures. Also, determine if any continuous fire watch routes are to be augmented as specified in Section 13.0.A.
- 14.1.4** With the CPU inoperable, within one hour establish the following compensatory action:
- a. Fire detection zones containing Function A detectors in accessible areas shall be continuously monitored at the local fire detection panel. Exempted from this action are zones inside the Main Control Room and zones associated with supervisory functions (i.e., pressure switches, valve position, fire door position, etc.).
 - b. For fire detection zones containing Function A detectors in inaccessible areas, the air temperature shall be monitored once per hour

-OR-

the local fire detection panel shall be monitored once per hour.

- c. For fire detection zones containing function B detectors or for zones providing a supervisory function in accessible or inaccessible areas, the local fire detection panel shall be monitored hourly.
- 14.1.5** Restore the inoperable CPU to operable status within 14 days. If not restored within 14 days, continue the compensatory actions AND perform 10CFR50.72 and/or 10CFR50.73 reviews per site administrative procedures.

14.2 **Water Supply**

The Fire Suppression Water Supply System shall be Operable at all times as follows:

NOTE 1: With a unit in Modes 5, 6, or core empty, locations where a continuous fire watch is required may be combined and patrolled by a roving fire watch when approved by the Fire Protection Supervisor (or designee) if the location only affects the unit in Modes 5, 6, or core empty.

NOTE 2: Alarms or troubles on the associated local fire detection system control panel (e.g., 0-PNL-13-L631) for the diesel driven pump that may cause a masking condition is addressed in Section 14.5. Section 14.5 is not applicable to the diesel driven pump control panel (e.g., 0-PNL-26-3150A).

- a. Three fire suppression pumps consisting of the diesel driven pump (2500 gpm at 125 psig (288 feet of head)) AND two electric driven pumps, each with a minimum capacity

PART II – FIRE PROTECTION PLAN

of 1590 gpm at 300 feet of head (130 psig), with their discharge aligned to the fire suppression system header,

AND

- b. An Operable flow path from the suction supplies, through distribution piping, sectionalizing, control or isolation valves up to but not including the first valve off the headers, leading to the yard hydrant (Section 14.7), the fire hose station/standpipes (Section 14.6), and each water based suppression system (Section 14.3).

14.2.1 With at least two electric pumps operable and the diesel driven fire pump inoperable:

- a. Restore the diesel driven fire pump to operable status within 7 days AND within one hour a fire watch is established as follows:

- 1(a). hourly roving fire watch is established In the Auxiliary Building Elevation 713 feet (coordinates Q-U / A10-A15) if the fire detection equipment for the area is operable

-OR-

- 1(b). continuous fire watches are established In the Auxiliary Building Elevation 713 feet (coordinates Q-U / A10-A15) if the fire detection equipment for the area is inoperable.

-AND-

- 2(a). hourly roving fire watch is established In the Auxiliary Building Elevation 737 feet (coordinates Q-U / A8-A13, Q-S / A13-A15) if the fire detection equipment for the area is operable

-OR-

- 2(b). continuous fire watches are established In the Auxiliary Building Elevation 737 feet (coordinates Q-U / A8-A13, Q-S / A13-A15) if the fire detection equipment for the area is inoperable.

-OR-

- b. Ensure at least three electric driven pumps operable AND within one hour a fire watch is established as follows:

- 1(a). hourly roving fire watch is established In the Auxiliary Building Elevation 713 feet (coordinates Q-U / A10-A15) if the fire detection equipment for the area is operable

-OR-

PART II – FIRE PROTECTION PLAN

- 1(b). continuous fire watches are established In the Auxiliary Building Elevation 713 feet (coordinates Q-U / A10-A15) if the fire detection equipment for the area is inoperable.

-AND-

- 2(a). hourly roving fire watch is established In the Auxiliary Building Elevation 737 feet (coordinates Q-U / A8-A13, Q-S / A13-A15) if the fire detection equipment for the area is operable

-OR-

- 2(b). continuous fire watches are established In the Auxiliary Building Elevation 737 feet (coordinates Q-U / A8-A13, Q-S / A13-A15) if the fire detection equipment for the area is inoperable.

-OR-

- c. Provide a backup pump with at least the same capacity as an electric fire pump

- AND-

establish hourly roving fire watch coverage for the areas with common power supplies. Within 7 days after entry from either 14.2.1.a or 14.2.1.b;

1. either enter 14.2.1.b

-OR-

2. restore the diesel driven fire pump to operable status.

14.2.2 With only one electric driven fire pump operable

- AND-

the diesel driven fire pump operable:

- a. Restore an additional electric driven fire pump to operable status within 30 days.

14.2.3 With no electric driven pumps operable

- AND-

the diesel driven fire pump operable, within 7 days:

- a. Restore one electric driven pump to operable status

- AND-

enter 14.2.2.

PART II – FIRE PROTECTION PLAN

14.2.4 With only one electric driven pump operable

- AND-

the diesel driven fire pump inoperable, within 24 hours:

- a. Restore an additional electric driven pump to operable,

- AND-

enter 14.2.1,

-OR-

- b. Restore the diesel driven fire pump to operable

- AND-

enter 14.2.2.

14.2.5 With no water supply system pumps operable:

- a. Establish a backup water supply system within 24 hours,

- AND-

restore one electric driven pump to operable within 48 hours

- AND-

a second electric driven pump to operable with 72 hours,

- AND-

restore the diesel fire pump to operable within 7 days,

-OR-

- b. Establish a backup water supply system within 24 hours,

- AND-

restore the diesel driven fire pump within 48 hours

- AND-

enter 14.2.3.

- c. Perform 10CFR50.72 and/or 10CFR50.73 reviews in accordance with site administrative procedures

14.2.6 With the Fire Suppression Water supply system inoperable for reasons other than loss of a fire pump:

PART II – FIRE PROTECTION PLAN

- a. Within one (1) hour enter the applicable Operating Requirements of Section 14.3 AND/OR 14.6 AND/OR 14.7 for those devices with no flow path available. No other action is necessary.
- b. If the condition involves powering up a normally de-energized valve operator to cycle the valve, then within one (1) hour establish a constant attendant at the breaker.
- c. Restore the system to normal alignment within 30 days. If not restored within 30 days, continue the compensatory actions AND perform 10CFR50.72 and/or 10CFR50.73 reviews per site administrative procedures.

14.2.7 With High Pressure Fire Protection (HPFP) or raw service water (RSW) usage's that are not as-designed loads or as-designed loads that have inhibited automatic isolation capability:

- a. Provide isolation capability

- AND-

within one (1) hour establish a constant attendant in communication with the Operations for HPFP/RSW usage's that are not as-designed.

- b. Ensure the inhibited automatic isolation is controlled by procedure.
- c. Remove the non-as-designed HPFP/RSW usage

-OR-

restore the automatic isolation capability within 30 days. If not restored within 30 days, continue the compensatory actions AND perform 10CFR50.72 and/or 10CFR50.73 reviews per site administrative procedures.

14.2.8 With three of the electric driven pumps capable of manual starting from the Main Control Room (MCR) or their associated 480V shutdown board but the automatic start circuitry inoperable.

- a. Ensure the inhibited automatic start circuitry is controlled by an approved configuration control method.
- b. Restore the system to normal alignment within 30 days. If not restored within 30 days perform 10 CFR 50.72 and/or 10 CFR 50.73 reviews per site administrative procedures.

14.3 **Water Based Fire Suppression**

The water based fire suppression systems in the following areas (See Table 14.3 for specific systems) and their associated fire detectors shall be Operable whenever the protected safety-related or FSSD equipment is required to be Operable:

PART II – FIRE PROTECTION PLAN

- a. Unit 1 Reactor building - RC pump area, Annulus.
- b. Unit 2 Reactor building – RC pump area, Annulus
- c. Auxiliary building - Elev. 692, 713, 729, 737, 757, 772, and 782.
- d. Auxiliary building - ABGTS filters, EGTS filters, Containment Purge Air Exhaust Filters, 125V battery and battery board rooms.
- e. Control building - Elev. 692, cable spreading room, operator living area.
- f. Control building - MCR air filters.
- g. Diesel building - Corridor area.
- h. Intake Pumping Station
- i. Turbine Building - Control Building Wall

Note 1: The action statements of this section apply to the Function B fire detectors that are associated with an automatic suppression system. Refer to Table 14.1 for the specific number of fire detectors associated with the water based fire suppression systems in the areas noted below.

Note 2: Inoperable fire detectors may cause alarm or trouble conditions on the associated local control panels that may cause a masking condition addressed in Section 14.5.

Note 3: With a unit in Modes 5, 6, or core empty, locations where a continuous fire watch is required may be combined and patrolled by a roving fire watch when approved by the Fire Protection Supervisor (or designee) if the location only affects the unit in Modes 5, 6, or core empty.

14.3.1 . With either suppression and/or associated Function B fire detectors inoperable in any of the locations noted above (a-i) in which redundant fire safe shutdown systems or components may be damaged by a single fire, within one hour, restore the inoperable equipment:

-OR-

- a. For accessible areas, within one hour establish the following:
 - 1. A continuous fire watch AND backup suppression equipment for those areas, if detection or both suppression and detection are inoperable,

-OR-

- 2. A roving fire watch and backup suppression equipment for those areas, except for 737' elevation of the Auxiliary Building, if only the suppression is inoperable.

PART II – FIRE PROTECTION PLAN

-OR-

3. A continuous fire watch and backup suppression equipment for the 737' elevation of the Auxiliary Building if suppression or detection or both are inoperable. This watch shall be limited to the 737' elevation of the Auxiliary Building.

-OR-

- b. For inaccessible areas, as noted below, establish the following within one hour:
 1. For either Reactor Building, Lower Containment, establish a continuous fire watch using the alternatives defined in Sub-section D or E of Section 13.1.

-OR-

monitor the air temperature in the area once per hour using U-9020 on Plant Computer.

2. For other inaccessible areas with detection inoperable OR both suppression and detection inoperable, within one hour establish backup suppression equipment:

-AND-

- a. A continuous fire watch using the alternatives defined in Sub-section D and E of Section 13.1.

-OR-

- b. Provide alternate compensatory actions in accordance with an engineering evaluation.
3. For other inaccessible areas with inoperable suppression only, within one hour establish backup fire suppression equipment:

-AND-

- a. An hourly roving fire watch using the alternatives defined in Sub-section D and E of Section 13.1.

-OR-

- b. Provide alternate compensatory actions in accordance with an engineering evaluation.

14.3.2

With either inoperable suppression or associated Function B fire detectors in any of the locations noted above (a-i) in which redundant fire safe shutdown systems or components are NOT exposed to the damage of a single fire, within one hour

PART II – FIRE PROTECTION PLAN

establish a roving fire watch AND backup suppression equipment for those areas.

- 14.3.3** Restore the inoperable suppression and/or associated detection to Operable status within 14 days. If not restored within 14 days, continue the compensatory actions AND perform 10CFR50.72 and/or 10CFR50.73 reviews per site administrative procedures. Also, determine if any continuous fire watch routes are to be augmented as specified in Section 13.0.A.

14.4 Carbon Dioxide (CO₂) Suppression Systems

The CO₂ suppression systems in the following areas and their associated fire detectors shall be operable whenever the protected safety-related or FSSD equipment is required to be operable:

NOTE 1: The action statements of this section apply to the Function B fire detectors that are associated with an automatic suppression system. Refer to Table 14.1 for the specific number of fire detectors associated with the CO₂ based fire suppression systems in the locations noted below.

NOTE 2: Inoperable fire detectors may cause alarms or troubles on the associated local control panels that may cause a masking condition addressed in Section 14.5.

NOTE 3: With a unit in Modes 5, 6, or core empty, the locations where a continuous fire watch is required may be combined and patrolled by a roving fire watch when approved by the Fire Protection Supervisor (or designee) if the location only affects the unit in Modes 5, 6, or core empty.

- a. Auxiliary instrument room (Units 1 and 2).
- b. Computer room.
- c. Diesel generator rooms.
- d. Diesel generator fuel oil pump room.
- e. Diesel generator electrical board rooms.
- f. Diesel generator lube oil storage room.

- 14.4.1** With either suppression or associated Function B fire detectors inoperable in any of the locations noted above (a-f) in which redundant fire safe shutdown systems or components may be damaged, within one hour establish a continuous fire watch AND backup suppression equipment for those areas.

- 14.4.2** With either inoperable suppression or associated Function B fire detectors in any of the locations noted above (a-f) in which redundant fire safe shutdown systems or components are NOT exposed to the damage of a single fire, within one hour establish a roving fire watch AND backup suppression equipment for those areas.

- 14.4.3** Restore both the inoperable CO₂ suppression and associated detection to operable status within 14 days. If not restored within 14 days, continue the

PART II – FIRE PROTECTION PLAN

compensatory actions AND perform 10CFR50.72 and/or 10CFR50.73 reviews per site administrative procedures. Also determine if any continuous fire watch routes are to be augmented as specified in Section 13.0.A.

14.5 **Fire Detection Supervision**

The supervision capabilities of the local control panels identified on Table 14.5 shall be Operable when the associated fire detectors identified on Table 14.1 are required to be operable.

NOTE: These action statements apply to both Function A and Function B detectors and the actuation circuits for automatic valves in the flow path.

14.5.1 With the supervisory function of a panel listed in Table 14.5 masked by a panel alarm or trouble, within eight hours:

a. restore the inoperable equipment,

-OR-

b. jumper out the zone(s) providing the masking condition (alarm or trouble)

-AND-

implement the compensatory actions and time limits of Section 14.1, 14.2, 14.3, or 14.4 as appropriate.

14.5.2 If the masking condition cannot be cleared by jumpering out a zone(s), within 8 hours evaluate the condition for affects on the equipment operation and implement the compensatory actions and time limits of Section 14.1, 14.2, 14.3, and 14.4 as appropriate

-AND-

restore the panel to Operable status within 14 days. If not restored within 14 days, continue the established compensatory actions AND perform 10CFR50.72 and/or 10CFR50.73 reviews per site administrative procedures.

14.5.3 If conditions exist that warrant returning a masked circuit to a functional status prior to the circuit's return to normal, with the supervisory function of a panel listed in Table 14.5 masked by a panel alarm or trouble, defeat the alarm or trouble masking condition while maintaining the circuit's functional capability, verify the circuit's functional capability,

-AND-

establish the controls to monitor the circuit's functional capability periodically. Restore the panel to Operable status within 30 days. If not restored within 30 days, continue the established compensatory actions -AND- perform 10CFR50.72 and/or 10CFR50.73 reviews per site administrative procedures.

PART II – FIRE PROTECTION PLAN

14.6 Fire Hose Stations/Standpipes

The fire hose stations listed in Table 14.6 have been provided to support manual firefighting efforts in safety-related or FSSD buildings, areas, and/or rooms at WBN. The fire hose stations also provide backup suppression when the automatic suppression systems are inoperable. The fire hose stations listed in Table 14.6 shall be Operable whenever the safety-related or FSSD equipment in the areas protected by the fire hose stations is required to be Operable.

14.6.1 With one or more of the fire hose stations listed in Table 14.6 inoperable, within eight hours:

a. restore the inoperable equipment

-OR-

b. provide alternate protection for the area served by the inoperable hose stations(s).

14.6.2 Restore the fire hose station(s) to Operable status within 14 days. If not restored within 14 days, continue the compensatory actions AND perform 10CFR50.72 and/or 10CFR50.73 reviews per site administrative procedures.

14.7 Fire Hydrants

Two fire hydrants listed in Table 14.7 have been provided to support manual firefighting efforts in the Diesel Generator Building's Conduit Interface Room. One fire hydrant listed in Table 14.7 is also provided as backup for hose stations in the Intake Pumping Station. The fire hydrants listed in Table 14.7 shall be Operable whenever the safety-related or FSSD equipment in the areas protected by the fire hydrants is required to be operable. An additional fire hydrant is included in Table 14.7 as an alternate for a situation in which one of the other hydrants becomes inoperable. The relevant fire hydrants are specified in the table.

14.7.1 With any of the fire hydrants identified on Table 14.7 inoperable, within eight hours:

a. restore the inoperable equipment

-OR-

b. provide alternate suppression capabilities for the area served by the inoperable fire hydrant(s).

14.7.2 Restore the fire hydrant to Operable status within 28 days. If not restored within 28 days, continue the compensatory actions AND perform 10CFR50.72 and/or 10CFR50.73 reviews per site administrative procedures.

14.8 Fire-Rated Assemblies

Fire-rated assemblies shall be Operable whenever the safety-related and FSSD equipment on either side of the barrier/assembly is required to be Operable. Fire doors are listed in Table 14.8.1 and fire dampers are listed in Table 14.8.2. Fire barriers are depicted on Fire Compartmentation drawings, Figures II-27A through II-46A excluding 37A.

PART II – FIRE PROTECTION PLAN

NOTE: With either a unit in Modes 5, 6, or core empty, locations where a continuous fire watch is required may be combined and patrolled by a roving fire watch when approved by the Fire Protection Supervisor (or designee) if the location only affects the unit in Modes 5, 6, or core empty.

14.8.1 With one or more of the required fire-rated assemblies/fire barriers, electrical raceway fire barrier systems, or electrical raceway radiant energy shields inoperable within one hour, restore the inoperable equipment:

-OR-

Within one hour:

- a. If no fire detection (as listed in Table 14.1) is designed to protect both sides of the inoperable barrier then, post a continuous fire watch.

-OR-

- b. If fire detection (as listed in Table 14.1) is designed to protect only one side of the inoperable barrier, then post a roving fire watch once per hour for the side without detection.

-OR-

- c. If suppression (as listed in Section 14.3 and 14.4) and fire detection (as listed in Table 14.1) is designed to protect both sides of the inoperable barrier, then no compensatory actions are required (not applicable to ERFBS or radiant energy shield raceway protection).

14.8.2 Restore the inoperable fire-rated assembly/fire barrier to Operable status within 30 days. If not restored within 30 days, continue the compensatory actions AND perform 10CFR50.72 and/or 10CFR50.73 reviews per site administrative procedures. Also determine if any continuous fire watch routes are to be augmented as specified in Section 13.0.A.

14.9 Emergency Battery Lighting Units

Emergency battery lighting units provided for FSSD (required in Modes 1, 2 or 3) shall be Operable whenever the illuminated associated fire safe shutdown equipment is required.

14.9.1 With any of the emergency battery lighting units provided for FSSD inoperable, within 24 hours:

- a. restore the inoperable units to Operable status

-OR-

- b. ensure alternate lighting is available .

14.9.2 Restore the inoperable emergency battery lighting unit to Operable status within 14 days. If not restored within 14 days, continue the compensatory actions AND

PART II – FIRE PROTECTION PLAN

perform 10CFR50.72 and/or 10CFR50.73 reviews per site administrative procedures. Also determine if any continuous fire watch routes are to be augmented as specified in Section 13.0.A.

14.10 Fire Safe Shutdown Equipment

The equipment listed on Table 14.10 is required for Fire Safe Shutdown (FSSD) and shall be Operable (or in its FSSD condition) when it supports FSSD for a unit in modes 1, 2, and 3. The non-System 26 valves noted on the plants mechanical flow diagrams as being administratively locked in the open, closed, or throttled position (with breaker open) for Appendix R shall be maintained in that condition when the applicable unit is in Modes 1, 2 and 3.

- 14.10.1** With one or more required equipment in Table 14.10 inoperable (or not in its FSSD condition), restore to operable status (or its FSSD condition) within 30 days.
- 14.10.2** With one or more of the breakers and/or valves specified in design output documents not in the noted position or condition, return the breakers and/or valve to the required position within 30 days.
- 14.10.3** If required action and associated completion time cannot be met,
- a. place the equipment in the condition required for FSSD,
 - OR-
 - b. provide a back-up means of instrumentation monitoring for the equipment in Table 14.10,
 - OR-
 - c. perform an evaluation to justify using alternate means to provide FSSD,
 - OR-
 - d. be in Mode 3 within 6-hours and Mode 4 within the following 12-hours.
- 14.10.4** With any of the below listed Pressurizer Block valve closed in Modes 1, 2 or 3:

Block Valve Closed	Fire Watch in Room
1-FCV-68-332-B	757-A1
	757-A10
2-FCV-68-332-B	757-A16
2-FCV-68-333-A	737-A1B
	757-A21

- a. Restore the Pressurizer Block valve to OPEN status as soon as possible, but not longer than the next refueling outage:
- AND-
- b. Establish a fire watch within one hour as follows:

PART II – FIRE PROTECTION PLAN

1. If the fire detection equipment for the above affected area is operable, an hourly roving fire watch is established in the Auxiliary Building according to the above table:

-OR-

2. If the fire detection equipment for the above affected area is inoperable, a continuous fire watch is established in the Auxiliary Building according to the above table:

PART II – FIRE PROTECTION PLAN

TESTING AND INSPECTION REQUIREMENTS (TIR)

PAGE 1 OF 16

ITEM NO.	TYPE OF SYSTEM/COMPONENT	FREQUENCY	TESTING/INSPECTION REQUIREMENT (TIR)	NOTES
14.1.a	NOTE: The TIRs specified by Section 14.1 apply to all input devices listed in Table 14.1. Fire Detection Instrumentation (refer to Table 14.1)	6 months	Perform a functional test on at least one detector and a minimum of 10% of the detectors on each signal initiating circuit of the restorable heat detectors in any accessible area with all detectors tested within five years.	
14.1.b		6 months	Perform a functional test on each of the required smoke detection instruments in any accessible area.	
14.1.c		18 months	For the unit in a refueling outage, perform a functional test on each of the required smoke detection and restorable heat detection instruments which are in any inaccessible area.	

PART II – FIRE PROTECTION PLAN

TESTING AND INSPECTION REQUIREMENTS (TIR)

PAGE 2 OF 16

ITEM NO.	TYPE OF SYSTEM/COMPONENT	FREQUENCY	TESTING/INSPECTION REQUIREMENT (TIR)	NOTES
14.2.a	Water Supply	31 days	Operate each electric motor driven pump for a minimum of 15 minutes on recirculation flow.	
14.2.b		92 days	Visually inspect each testable valve in any accessible area in the flow path to ensure it is in its correct position.	
14.2.c		Twice per year	Perform system flush in conjunction with biocide injection.	
14.2.d		12 months	Cycle each testable valve located in any accessible area in the flow path through at least one cycle.	
14.2.e		18 months	Perform a system functional test with simulated automatic actuation, and: <ul style="list-style-type: none"> a. Verify electric motor driven pump starting logic ability for timing design requirements. b. Verify electric motor driven pumps develop flow ≥ 1590 gpm at a head of ≥ 300 feet (130 psig). c. Verify automatic valves in the flow path actuate to the correct position. 	
		Refueling Outage	d. For the unit in a refueling outage, cycle testable valves in any inaccessible area in the flow path through one cycle

Verify each APP R N ₂ manual, power operated, and automatic valve in the flow path that is not locked, sealed, or otherwise secured in position, that is in an accessible area, from the liquid nitrogen skid to AFW LCVs and PCVs is in the correct position.	
		18 months	c. Verify that the AFW LCVs/PCVs can be operated properly with nitrogen by a functional test.	

PART II – FIRE PROTECTION PLAN

BASES – OPERATING REQUIREMENTS (OR) FIRE DETECTION

B.14.1 Fire detectors are provided within various locations at WBN to ensure adequate warning of fires, detect and locate fires in their early stages to facilitate suppression efforts, and to meet regulatory requirements. Prompt detection of fires reduces the potential for damage to plant equipment and is an integral element in the overall plant FPP. The specific number of required detectors in each room to ensure adequate spatial coverage and the desired level of detector redundancy are specified on Table 14.1. Instrumentation designed to detect smoke as a part of other systems (e.g., smoke detectors in HVAC ducts for main control room habitability) are excluded from Table 14.1 since they were designed for purposes other than fire protection.

This requirement is provided to ensure, as a minimum, the Fire Detection Instrumentation for each Fire Detection Zone shown in Table 14.1 is Operable. The operability of the Fire Detection Instrumentation ensures that adequate warning capability to a constantly attended location is available for prompt detection of fires and that Fire Suppression Systems that are actuated by fire detectors discharge extinguishing agents in a timely manner. Prompt detection and suppression of fires reduces the potential for damage to safety-related equipment and is an integral element in the overall facility fire protection program.

When detectors are inoperable, an acceptable alternative in lieu of fire watches is the use of a portable fire detection system designed specifically for fire protection use. Placement of the detectors for the portable system is at the approximate location of the inoperable permanent detector on a one-to-one basis. The cables from the detectors to the portable system panel are not installed in conduits or cable trays but are routed and secured so as not to interfere with routine plant operations. The system would not interface with any existing fire detection systems.

When a unit is in Modes 5 (Cold Shutdown), 6 (Refueling), or core empty, the locations where a continuous fire watch is required may be combined and patrolled by one or more roving fire watch(es) provided the area only affects the unit in Modes 5, 6, or core empty. While a unit is in cold shutdown or refueling, there are fewer systems needed for maintaining cold shutdown and more people present that could detect and report a fire (General Employee Training includes how to report a fire). Roving fire watches provide an adequate level of coverage for these systems by ensuring that potential fire hazards are detected and corrected in a timely manner to prevent fires from occurring, or if a fire were to occur, ensuring that timely action is taken.

Outputs from the Fire Detection system also provide for the automatic shutdown of selected plant fans/air movers and dampers. This output is beyond the scope of this Fire Detection OR for Function A detectors since this automatic shutdown does not affect the operation of the system as exhibited by the annunciation of the affected Fire Detection equipment. Manual actions can be used to compensate for this automatic shutdown.

The testing of the fire detection system is based on the codes in place when the system was designed and purchased. As such, the testing of internal circuit supervisory functions (e.g., trouble due to an open circuit or ground on a detection circuit) of the equipment on a periodic basis is not required. The confirmation of the Operability of such supervisory functions is confirmed as applicable upon a component's initial installation.

PART II – FIRE PROTECTION PLAN

B.14.1.1 With any Function A Fire Detection Instrumentation shown in Table 14.1 inoperable in an accessible area, the inoperable instrument(s) must be restored within 1 hour. The Completion Time of 1 hour to establish a fire watch is reasonable considering that it is consistent with standard Technical Specifications. If the inoperable instrument(s) cannot be restored within 1 hour, a fire watch patrol must be established to inspect the zone(s) with inoperable instrument(s), and thereafter, inspect the zone(s) once per hour. The establishment of frequent fire watch patrols in the affected areas is required to provide detection capability until the inoperable instrumentation is restored to Operability. The Completion Time of one hour to perform a roving fire watch is reasonable and based upon the typical time necessary to establish a fire watch patrol and perform an inspection.

B.14.1.2a With any Function A Fire Detection Instrumentation shown in Table 14.1 inoperable in any inaccessible area in either containment, the inoperable instrument(s) must be restored within 8 hours. The Completion Time of 8 hours is based on containment access considerations. If the inoperable instrument(s) cannot be restored within 8 hours, the zone(s) with inoperable instrument(s) must be inspected once per 8 hours, or the air temperature must be monitored in the affected area once per hour. The Completion Times of once per 8 hours required for a roving fire watch and once per hour required for monitoring of the air temperature are reasonable.

Furthermore, the 1-hour frequency for air temperature monitoring is considered adequate in view of other indications available in the control room, including alarms, to alert the operator to abnormal containment temperature conditions.

Fire detection instrumentation is not assumed to be operable to mitigate the consequences of a design accident or transient. In designing the accident sequence for theoretical hazard evaluation, fires are not assumed to take place simultaneously with the design basis event (DBE) or transient. Therefore, observing the same instruments that are used by SRs 3.6.5.1 and 3.6.5.2 once per hour along with the other indications available in the Main Control Room, including alarms to alert the operator of abnormal containment temperature conditions, provides an equivalent level of fire safety without exposing personnel to unnecessary radiation exposure. Additionally, this method of compensatory actions for inoperable detection systems in the RB is consistent with industry standard technical specification requirements. If the Technical Specification instrumentation is not available to support this monitoring, then other appropriately maintained and tested instrumentation are used after evaluation.

B.14.1.2.b With any function A Fire Detection Instrumentation shown in Table 14.1 inoperable in any inaccessible area outside of either containment, the inoperable instrument(s) must be restored within 8 hours. The Completion Time of 8 hours is based on access considerations to these hazardous areas to ensure personnel safety. If the inoperable instrument(s) cannot be restored within 8 hours, the zone(s) with inoperable instrument(s) must be inspected once per 8 hours. The completion Times of once per 8 hours required for a roving fire watch is reasonable to ensure protection of personnel and the confined areas (relatively small rooms with heavy concrete wall bounding the areas and limited combustibles) that are involved for areas outside of containment.

B.14.1.3 The restoration of equipment to Operable in 14 days is reasonable based on the type of equipment that is out of service. The time frame is consistent with standard Technical Specifications.

PART II – FIRE PROTECTION PLAN

- B.14.1.4.a** The CPU is considered Operable when it is capable of notifying the constantly attended location personnel of fire alarms for Operating Requirement (OR) detection zones. With the CPU inoperable, for zones containing Function A Fire Detection Instrumentation shown in Table 14.1 in an accessible area, the local detection panel shall be monitored within 1 hour. If the inoperable CPU cannot be restored within 1 hour, a continuous monitor patrol must be established. The establishment of a continuous monitor patrol for the affected panels is required to provide detection capability and notification to a constantly attended location until the inoperable CPU is restored to Operability. The Completion Time of one hour to establish a continuous roving monitor is reasonable and based upon the typical time necessary to establish a monitor patrol and to perform an inspection. These actions are consistent with the standard Technical Specifications requirements if the detectors are declared inoperable. The Main Control Room (MCR) is exempted from this action since the MCR is the constantly attended location that is normally notified.
- B.14.1.4.b** With the CPU inoperable, for zones containing Function A Fire Detection Instrumentation shown in Table 14.1 in an inaccessible area, the monitoring of the air temperature for the affected area once per hour or the monitoring of the local detection panel once per hour is established within one hour. The time frame of one hour to establish one of the compensatory actions is reasonable considering that it is consistent with standard Technical Specifications. The establishment of temperature monitoring or monitor patrols for the affected panels is required to provide detection capability to a constantly attended location until the inoperable CPU is restored to Operability. The time frame and actions are reasonable and based upon the necessary times and actions that are required if these devices are declared inoperable.
- B.14.1.4.c** With the CPU inoperable, for zones containing Function B Fire Detection Instrumentation shown in Table 14.1 in an inaccessible or accessible area, the local detection panel shall be monitored hourly within one hour. The establishment of a monitor patrol once per hour for the affected panels is required to provide detection notification to a constantly attended location until the inoperable CPU is restored to Operability. The automatic actuations are still operable so the more restrictive compensatory action of a continuous fire watch is not needed. The completion time of one hour to establish an hourly roving monitor is reasonable and is consistent with the standard Technical Specifications when annunciation to a constantly attended location is inoperable such as in OR-14.1.1.
- B.14.1.5** The restoration of equipment to Operable in 14 days is reasonable based on the type of equipment that is out of service. The time frame is consistent with standard Technical Specifications.

PART II – FIRE PROTECTION PLAN

BASES – TESTING AND INSPECTION REQUIREMENTS (TIR)

FIRE DETECTION

- B.14.1.a** TIR 14.1.a is the performance of a functional test (excluding confirmation of setpoint accuracy) on one or more of the required accessible thermal detection instruments in each signal circuit which are accessible during plant operation. At least one detector and a minimum of 10% on each signal initiating circuit shall be tested semi-annually such that all are tested within five years. The frequency of six months is based on NFPA consensus standard 72E (code of record) and has been shown acceptable through industry operating experience.
- B.14.1.b** TIR 14.1.b requires a functional test be performed on each of the required accessible smoke detection instruments. The associated frequency for this surveillance is 6 months which is based on NFPA consensus standard 72E criteria and is consistent with standard Technical Specification requirements.
- B.14.1.c** TIR 14.1.c is the performance of a functional test on each of the required smoke detection and restorable heat detection instruments which are in any inaccessible area. This test is performed for the unit in a refueling outage. The expected frequency for this testing is each unit's Refueling Outage and is based on operating experience.

PART II – FIRE PROTECTION PLAN

BASES – OPERATING REQUIREMENTS (ORs) WATER SUPPLY

B.14.2 This requirement is provided to ensure, as a minimum, the water supply is Operable. The water for firefighting is supplied by four vertical turbine, high pressure, motor driven pumps, and one centrifugal diesel driven fire pump. The pumps are required to provide the flow for the most hydraulically demanding area in a safety-related structure.

The water suppression system is a prime element of the overall plant fire suppression capability and is not mode dependent; therefore, its availability is maximized.

Three fire suppression pumps (the diesel and two electric driven pumps) are required to be Operable. With one of the three required pumps inoperable, 100 percent of the required flow can still be provided by the two remaining Operable pumps. The flow path through the distribution piping and valves to each supply terminal are also required to be Operable. In the section of standard Technical Specifications for water supplies, two 100% pumps are addressed. WBN has taken the option allowed by BTP 9.5-1 to provide three pumps; however in place of being three 50% capacity pumps as addressed in the BTP, WBN has a 100% capacity diesel fire pump and two 50% capacity electric motor driven pumps. Since standard Technical Specifications provide action statements when one pump is inoperable and does not cover the three pump installation, the capacity of operable pumps was taken into account in determining the action statements and associated times for action statement completion in Section 14.2.

The Water Supply consists of a flow path from the water source to the using devices (i.e., water based fire suppression systems, the fire hose station/standpipes, and the fire hydrants). The normal configuration is such that the Water Supply piping is looped, meaning it is fed from two directions. Alternately, the pipe that goes to the using devices is only fed from the point of attachment to the Water Supply piping. WBN identifies piping, valves, fittings, and other appropriate items associated with the Water Supply in Section 14.2 as follows:

- 1) The piping, valves, fittings, and other appropriate items, starting at the water supply, through the fire pumps and up to the first valve on the pipe going to the using devices are included in Section 14.2. The piping, valves, fittings and other appropriate items downstream of this first valve are included under Section 14.3 and 14.6 as appropriate.
- 2) The isolation of a single valve on the supply/looped piping, covered by Section 14.2, does not preclude water from getting to the using devices.
- 3) The isolation of a single valve on the using device piping, covered by Section 14.3 and 14.6, does prevent water from getting to the using devices. Separating the water supply piping/features from the using device piping/features eliminates the confusion presented when comparing WBN's design to the standard Technical Specifications which may lead to entering two action statements.

PART II – FIRE PROTECTION PLAN

B.14.2.1 With two electric pumps operable and the diesel driven fire pump inoperable, compensatory actions must be taken. These actions consist of:

(a) Restoring the diesel fire pump within 7 days, (b) ensuring that three of the electric motor driven pumps are operable or (c) ensuring two electric fire pumps are operable and a backup pump, either electric or diesel driven, of at least equal capacity to an electric driven fire pump. For action (b), the three electric motor driven pump option, a fire watch, continuous or hourly roving based on fire detection equipment status in the areas, is established in the Auxiliary Building elevations listed in the table below. For cases involving a continuous fire watch, one continuous fire watch is assigned in the Auxiliary Building elevations listed in the table below. The areas are as noted below:

Building/Elevation	Room Number (Analysis Volume)	Column Line
Auxiliary Building Elevation 713	713.0-A1 (AV-026)	Q to U and A8 to A15
Auxiliary Building Elevation 737	737.0-A1 (AV-038)	Q to U and A8 to A13, plus Q to S and A13 to A15

For action (c), the two electric fire pumps and a backup fire pump, either a hourly roving or continuous fire watch is established in areas containing common power supplies. The determination of the fire watch(es) frequency and area of coverage are based on information provided in action (b) (e.g. Hourly fire watch(es) in areas with operable detection).

Either Action (a) or (b) is taken within 7 days so that three pumps are available. This provides 150% pump capacity to safety-related areas. The completion time of 7 days is reasonable considering that 100% of the required pumping capacity to safety-related areas is still provided, and the time required to identify the problem and to take the corrective actions. This is consistent with the standard Technical Specifications.

The Auxiliary Building areas requiring either an hourly roving or continuous fire watch are areas where the Diesel Fire Pump (DFP) is the only fire pump credited in Fire Protection Report (FPR) Part VI, "Fire Hazards Analysis." In these areas, the Electric Driven Fire Pumps (EDFP) are not credited as a possible source of water to the fire protection suppression systems and enhancement measures must be taken to assist in detecting a general fire at its incipient stage to prevent the fire from becoming an Appendix R fire. Additionally, all areas where the DFP and one EDFP are credited In FPR Part VI were evaluated In Reference 4.2.83 and it was demonstrated one EDFP in these areas can supply the required flow and pressure to the fire protection suppression systems. Therefore these areas where one EDFP remains available do not require the enhancement action.

Action (c) is anticipated for planned outage activities where normally an entry is made into (a) or (b) and then enter (c) for 7 days before re-entry into (a) or (b). While in cases of unplanned outages, it is anticipated an entry is made into (a), (b), or OR 14.2.2, 14.2.3, 14.2.4 or 14.2.5 as appropriate. The backup pump for Action (c) also provides a measure of diversity by the general nature of how the existing electric pumps are installed. The backup pump would be located on another water source, with another energy source and a diverse location to provide a tie-in for supplying the fire protection system. Compliance with Action (c) requires the two electric fire pumps, a backup fire pump, and an hourly roving fire watch is established in areas containing common

PART II – FIRE PROTECTION PLAN

power supplies. The determination of the fire watches' area of coverage is based on information provided in Action (b) and additional areas where the power supplies for the backup pump are not separated by at least a one hour fire barrier from the cables associated with the Operable electric fire pumps. The provision of fire watches in areas of power supply interaction between the available electric fire pumps as well as the backup pump is consistent with other actions of OR-14.2.1.b. The completion time of 7 days to restore the 150% pump capacity (i.e., entering OR-14.2.1.b or restoration of the diesel fire pump) is reasonable and is consistent with other existing actions to ensure there is 150% pump capacity.

A backup pump is available which meets the following criteria to ensure that the pump is operated within the HPFP design limits.

1. The pump driver is a diesel engine capable and with fuel oil capacity for two hours of continuous operation.
2. The pump provides a minimum 1590 gpm at 300 ft. head as demonstrated by a flow test.
3. Suction supply for the pump is from the Tennessee River, a cooling tower basin, the 35 acre pond, the lined pond or other pond with a minimum of two hour supply at 1590 gpm.
4. A maximum pressure capability of 135 psig at elevation 729 feet. This maximum can be controlled manually provided the pump is constantly attended.
5. The pump is connected to the High Pressure Fire Protection system via a non-OR fire hydrant using one 5 inch and two nominal 2½ inch hoses that are in current hydrostatic test requirements.
6. Manual start and control of the pump is acceptable provided the pump is constantly attended when required to be available.

When a unit is in Modes 5, 6, or core empty, the locations where a continuous fire watch is required may be combined and patrolled by one or more roving fire watch(es) provided the area only affects the unit in Modes 5, 6, or core empty. While the plant is in cold shutdown or refueling, there are fewer systems needed for maintaining cold shutdown and more people present that could detect and report a fire (General Employee Training includes how to report a fire). Roving fire watches provide an adequate level of coverage for these systems by ensuring that potential fire hazards are detected and corrected in a timely manner to prevent fires, or if a fire were to occur, ensuring that timely action is taken.

B.14.2.2 With only one electric driven fire pump operable and the diesel driven fire pump operable, compensatory actions must be taken. These actions consist of:

Restore an additional electric motor driven pump (to ensure a total of three operable pumps) within 30 days. The condition with the diesel fire pump and only one electric motor driven pump operable provides 150% pump capacity to safety-related areas. The action of restoring an additional electric motor driven pump in 30 days is reasonable given that 150% of the required fire pump capacity is operable.

PART II – FIRE PROTECTION PLAN

- B.14.2.3** With no electric driven pumps operable and the diesel driven fire pump operable, compensatory actions must be taken. These actions consist of:

Restoring one electric motor driven pump to operable within 7 days. This provides 150% pump capacity to safety-related areas. The diesel fire pump alone connected to the fire protection system provides 100% pump capacity to safety-related areas. This is consistent with the requirements of 14.2.2 and of standard Technical Specifications.

- B.14.2.4** With only one electric driven pump operable and the diesel driven fire pump inoperable, compensatory actions must be taken. These actions consist of:

Restore an additional pump to operable within 24 hours. This provides a minimum 100% pump capacity to safety-related areas. Restore the third required pump to operable in accordance with either 14.2.1 or 14.2.2, as applicable. The time frames are consistent with standard Technical Specification time allowance for related equipment out of service conditions.

- B.14.2.5** With no water supply pumps operable, compensatory actions must be taken. These actions consist of:

- a.
 1. Establish a backup water supply within 24 hours, and
 2. Restore one electric driven pump within 48 hours, and
 3. Restore a second electric driven pump within 72 hours. This provides a 100% pump capacity to safety-related areas, and
 4. Restore the diesel fire pump to operable within 7 days. With a backup pump available and two electric driven pumps Operable, fire watches are not required.
- b. An alternative to the above is to establish a backup water supply within 24 hours and restore the diesel fire pump within 48 hours. Once the diesel is operable, it provides a 100% capacity to safety-related areas and the backup water supply can be secured. Restore one of the two required electric driven pumps within 7 days, and the second required electric drive pumps within 30 days.

This provides a backup supply within 24 hours as required by standard Technical Specifications. This also returns WBN to 100% pump capacity within 72 hours or less. Either method provides a 100% pump capacity to safety-related areas within 72 hours and the time (72 hours) is reasonable considering the seriousness of the situation.

- B.14.2.6** The closing of multiple sectional valves in the water supply piping of Section 14.2 can isolate the flow path to the using devices of Section 14.3, 14.6 and 14.7.

- a. In such a situation, the more restrictive requirements of Section 14.3, 14.6 or 14.7 apply. The requirements of 14.3, .6 or .7 although more restrictive, address the specifically affected area(s). The entering of compensatory actions for the isolated using devices is reasonable.

PART II – FIRE PROTECTION PLAN

- b. Specific valve operators that have had power removed due to Appendix R concerns require re-energizing to perform periodic testing such as cycling of valves to meet other regulatory requirements. The establishment of an attendant at the breaker allows prompt action to be taken if a fire condition occurs during this time period.
- c. The restoration time of thirty (30) days is reasonable based on the equipment involved and the limited impairment to the Fire Suppression System.

B.14.2.7

Specific usages are supplied by the HPFP/RSW system and are required to be operable during normal plant operation. A calculation determined the limits for the total HPFP/RSW usage and is as follows:

- a. Selected as-designed RSW loads to remain unisolated during a fire condition (e.g., chiller packages and plant processes required during plant operation).
- b. Manual RSW isolation valves to be locked closed to preclude non-as designed RSW loads being added.
- c. Selected as designed RSW loads to automatically isolate during a fire condition.

This provides control of HPFP/RSW usage to ensure an adequate water supply is available for fire protection when needed.

RSW was originally designed to be used for multiple usages (e.g., supply various chiller units and plant processes, cleaning of plant areas and other miscellaneous uses). Therefore when HPFP/RSW is needed outside the bounds of the established calculation, it is acceptable to establish compensatory actions employing isolation capability that allows for prompt isolation of additional usage without requiring a Temporary Alteration Control Form (TACF).

- a. For HPFP/RSW usage that automatically isolates, it is not necessary to have the isolation point constantly attended with the attendant in communication with the Main Control Room (MCR), 0-M-29 Operator. In the case where non-as designed HPFP/RSW loads are needed, a manual isolation capability is required and an attendant established in the area within one (1) hour. The attendant is in communication (e.g., radio, telephone, PA, etc.) with the 0-M-29 Operator in the MCR.
- b. For those as designed RSW usage's that are designed to automatically isolate on a fire pump start, there are times when this automatic isolation capability will need to be inhibited (e.g., during fire pump testing). During hot weather, there are chillers that are needed for plant operations and since the inhibiting of the automatic isolation is procedurally controlled, this allows the plant to continue to operate normally during testing and still provide adequate compensatory actions to ensure an adequate supply of water for firefighting if needed.
- c. Thirty (30) days is reasonable based on the actions required by Operating Requirement (OR) 14.10, which requires restoration of equipment required for 10CFR50, Appendix R within that time limit.

PART II – FIRE PROTECTION PLAN

B14.2.8

The electric driven pump start circuitry, including the buffer relays, may be temporarily inhibited during maintenance/testing to prevent the fire pumps from starting automatically. The excessive starting of the deep draft electric motor driven fire pumps is an industry concern, therefore, limiting the starting of the electric driven fire pumps is a good practice. This action does not require additional compensatory measures for the following reasons:

- a. Taking the circuitry out of service and returning it to service is administratively controlled by the testing documentation.
- b. The manual starting of the electric motor driven fire pumps from the Main Control Room (MCR) or their associated 480V shutdown board is not impaired. Additional administrative controls and abnormal operating instructions exist that ensure fire pumps are started upon the discovery of a fire.
- c. The system is normally pressurized without the operation of the fire pumps.

PART II – FIRE PROTECTION PLAN

BASES – TESTING AND INSPECTION REQUIREMENTS (TIRs) WATER SUPPLY

- B.14.2.a** TIR 14.2.a verifies that the electric driven pumps operate as designed. Every 31 days, the pumps are tested by starting each pump and letting it operate for a minimum of 15 minutes on recirculation flow. A test frequency of 31 days is reasonable for pumps which are not normally in operation and is consistent with standard Technical Specification requirements.
- B.14.2.b** TIR 14.2.b verifies every 92 days that each testable valve in any accessible area is visually inspected to be in its correct position. This applies to testable valves that are manual, power-operated, and automatic valves in the flow path. Verification of valve position is not required for valves that are not part of the main flow path which feed branch headers to form a train separation boundary, or which have capped or blind flanges downstream of the valves, or if inadvertently opened/left open leads to a visible, noticeable discharge which may be corrected. Valves which are not part of the main flow path which are normally closed and feed to branch headers to closed station drains are included in the verification of position, since if left mispositioned could lead to undetected leakage. Verification of valve position is not required for the pressure control valve which has a designed orifice plate downstream to limit the effect, to within design parameters, of the valve failing. Valves that are locked, sealed or otherwise secured in position need only be verified to be locked, sealed, etc., since these were verified to be in the correct position before locking, sealing, or securing. A frequency of 92 days has been established and is more conservative than the inspection criteria established for primary system valves that are locked, sealed, etc.
- B.14.2.c** TIR B.14.2.c requires the fire protection water distribution system be flushed twice per year in conjunction with biocide injection. The frequency of twice per year is needed to support chemical treatment requirements for biocide injection and meets the intent of standard Technical Specification requirements.
- B.14.2.d** TIR 14.2.d requires that valves in any accessible area, which are testable, are cycled every 12 months. This verifies that each valve operates properly. Verification of the position of valves every 12 months is based on industry operating experience, and is consistent with standard Technical Specification requirements and NFPA consensus standard 25 criteria.
- B.14.2.e** TIR 14.2.e consists of a fire suppression water system functional test every 18 months, which includes the electric motor driven pumps and major valves. The electric motor driven pumps start circuitry uses a time delay to ensure the associated emergency diesel generator is not overloaded and/or a combination of the time delay and pressure demand to start additional pumps if system pressure falls below predetermined setpoints.

Only two of the four pumps are needed to satisfy the requirements of OR 14.2. Normally, the first two pumps start based on time delay and the remaining pumps start on pressure demand and time delay. However, there are possible pump alignments where one of the two pumps needed for the OR requirement will have a start logic based on time and pressure delay. The electric motor driven pumps start logic is verified for proper normal operation by verifying pump time delay starts. TVA does not test the time and pressure delay aspects of the start circuitry because:

PART II – FIRE PROTECTION PLAN

1. Testing this circuitry involves extensive plant configuration changes in order to minimize the number of pump starts.
2. The pressure switches are periodically maintained and calibrated in accordance with the WBN preventive maintenance program.
3. Plant instructions for responding to fires include verification measures to ensure that at least two electric motor driven pumps are operating.
4. Minimize the number of starts on deep draft pumps.

There are numerous sets of contacts that are associated with the physical fire pump start circuit. These points do not affect the logic beyond providing a start signal for the logic. When there is a set of contacts that provides an automatic start for the logic, it is tested with the associated equipment (e.g. preaction sprinkler system).

Devices that are manual in nature such as hose stations, except as noted in 14.6, do not need the automatic start input because plant personnel are trained to report all fires before trying to fight them. Additional administrative controls are in place to ensure that a fire pump(s) is running after a fire is reported. Testable valves in any inaccessible area are cycled during the refueling outage for the applicable unit. Automatic valves are checked for correct position and operation each 18-months. The functional test frequency of 18 months/refueling outage is based on industry operating experience, gives acceptable assurance that the system is Operable at all times, and is consistent with standard Technical Specification requirements.

B.14.2.f TIR 14.2.f specifies a flow test every three years of the system in accordance with Reference 4.3.2. Underground and exposed piping is flow tested to determine the internal condition of the piping at minimum three-year intervals. Flow tests are made at flows representative of those expected during a fire, for the purpose of comparing friction loss characteristics of the pipe with that expected for the particular type of pipe involved, with due consideration given to the age of the pipe and to the results of previous flow tests. Any flow test results that indicate unacceptable deterioration of available water flow and pressure shall be fully investigated. The test frequency of three years is based on industry experience and NFPA consensus standard 25 and is considered acceptable.

B.14.2.g TIR 14.2.g verifies that the diesel engine driven fire pump operates as designed and has an adequate fuel supply to provide fuel for the running time (i.e. min. 2 hours). Every 31 days, the pump is tested by starting the pump and letting it operate for a minimum of 30 minutes on recirculation flow. A test frequency of 31 days is reasonable for pumps which are not normally in operation and is consistent with standard Technical Specification requirements.

B.14.2.h TIR 14.2.h verifies that the quality of the diesel fuel is within the acceptable limits of Table 1 of ASTM-D975-1990. This either uses the documentation from the fuel in the main diesel fuel storage tanks, when filled from the source, or testing performed on the fuel in the diesel fire pump storage tank. Testing on the fuel in the diesel fire pump fuel oil tank is performed on a bottom sample as defined by ASTM-D40507-1990. Additional samples from the midpoint or top of the fuel tank per ASTM-D-40507 are not needed since the main concern is water and sediment in the tank. A bottom sample is sufficient for detecting water and sediment. The test frequency of 92 days is

PART II – FIRE PROTECTION PLAN

reasonable based on the limited consumption during the 31 day runs and is consistent with standard Technical Specification requirements.

- B.14.2.i** TIR 14.2.i subjects the diesel engine driver to an inspection as specified by the manufacturer for the class of service. The extent of the inspection is based on performance factors of the engine and pump.
- B.14.2.j** TIR 14.2.j verifies that the diesel engine driven fire pump performs in accordance with the proper normal operation start logic based on plant design of pump. The pump is tested to verify that it starts from a drop in system pressure \leq the design specified set point and that the performance of the pump meets the following criteria:
- $\geq 150\%$ of rated flow at 65% of rated head,
- $\geq 100\%$ of rated flow at rated head, and
- Shutoff flow $\leq 140\%$ of rated head
- The frequency of 18 months is consistent with standard Technical Specifications.
- B.14.2.k** TIR 14.2.k verifies (1) the electrolyte level of each battery in the 24 volt battery bank; and (2) the charger is operable by measuring the voltage at the battery to ensure that it is ≥ 24 volts. The test frequency of 7 days is consistent with standard Technical Specifications.
- B.14.2.l** TIR 14.2.l verifies that the specific gravity of each battery is within tolerance to ensure continued service of the battery. The frequency of 92 days is consistent with standard Technical Specifications.
- B.14.2.m** TIR 14.2.m verifies that there is no visible physical damage to the batteries, cell plates and battery racks and that the battery to battery connections are clean, tight, free of corrosion and coated with anti corrosion material. The frequency of 18 months is consistent with standard Technical Specifications.

PART II – FIRE PROTECTION PLAN

BASES – OPERATING REQUIREMENTS (OR) WATER BASED FIRE SUPPRESSION

B.14.3 Water based fire suppression systems and their associated fire detectors are required to be Operable whenever safety-related or FSSD equipment protected by the suppression/detection system is required to be Operable. This is necessary to minimize the adverse effects of fires on structures, systems, and components important to safety.

This water based suppression equipment and associated fire detection equipment is provided as a means to directly detect and annunciate to a constantly attended location, and automatically actuate systems to suppress or control fires with particular emphasis on preserving the ability to achieve and maintain safe plant shutdown by protecting the fire safe shutdown equipment.

The main emphasis is on early detection to a constantly attended location and automatic actuation of the system for the suppression of a fire while the fire is easily controlled and quickly suppressed before it is capable of damaging fire safe shutdown systems. Two levels of actions are provided in recognition of the varying fire safe shutdown impact depending on the location of the fire. The determination whether a single fire can affect redundant FSSD systems or components is based on whether both FSSD paths are in the same fire area with less than a 3-hour fire barrier separating them. This is consistent with Appendix R in that when 3-hour separation is provided within the same fire area, then suppression and detection are not required. Backup suppression equipment is normally the installed hose stations as discussed in Part II, Section 12.2.

When a unit is in Modes 5, 6, or core empty, the locations where a continuous fire watch is required may be combined and patrolled by one or more roving fire watch(es) provided the area only affects the unit in Modes 5, 6, or core empty. While the plant is in cold shutdown or refueling there are fewer systems needed for maintaining cold shutdown and more people present that could detect and report a fire (General Employee Training includes how to report a fire). Roving fire watches provide an adequate level of coverage for these systems by ensuring that potential fire hazards are detected and corrected in a timely manner to prevent fires, or if a fire were to occur, ensuring that timely action is taken.

Outputs from the associated fire detection equipment also provide for the automatic shutdown of selected plant fans/air movers and dampers. This output is beyond the scope of this OR for Function B detectors since this automatic shutdown does not affect the operation of the system as exhibited by the annunciation of the associated fire detection equipment. Manual actions can be used to compensate for this automatic shutdown.

B.14.3.1 More restrictive compensatory actions are appropriate where water based suppression equipment or associated fire detection equipment are provided to protect redundant fire safe shutdown systems or components that may be damaged if a fire occurred. With any fire suppression shown in Table 14.3 inoperable in any accessible or inaccessible area, the inoperable equipment must be restored within one hour. If both the suppression and associated detection are inoperable in an area containing both trains of fire safe shutdown equipment, then it is appropriate to provide continuous fire watch

PART II – FIRE PROTECTION PLAN

coverage except as modified below. The completion time of one hour is based on the standard Technical Specifications.

- a. When detection or both suppression and the associated detection are inoperable in an area, then the more stringent compensatory actions are needed. If only the water based suppression is inoperable, then the early warning detection system provides more extensive coverage of the area and faster notification than can be provided by a fire watch. Therefore, it is appropriate to provide a lesser degree of fire watch coverage (i.e., Hourly roving fire watch). When the detection is inoperable and the associated suppression is still operable then the more restrictive compensatory action is required. In this situation, not only is the early warning capability lost, but so is the automatic actuation capability of the suppression system.
- b. The inoperable suppression is restored within one hour. If the area is in the Reactor Buildings' Lower Containment, then special consideration is needed due to the radiological conditions, building construction, and hazards present. In this case the area with inoperable suppression and/or detection must have a continuous fire watch established using the alternatives defined in Sub-section D or E of Section 13.1, or the air temperature must be monitored in the affected area once per hour. The completion time of one hour to establish continuous fire watch or hourly monitoring of the air temperature is reasonable. Either of these compensatory actions and associated time frequency is acceptable based on the air supervision for the Reactor Coolant Pump (RCP) sprinkler systems, the RCP oil collection system and the capability to monitor RCP bearings temperatures in the MCR. Furthermore, the one hour frequency for air temperature monitoring is considered adequate in view of other indications available in the MCR, including alarms to alert the operator to abnormal containment temperature conditions. This is also consistent with the standard Technical Specification on the loss of detection in an inaccessible area such as Lower Containment.

Fire suppression is not assumed to be operable to mitigate the consequences of a design accident or transient. In designing the accident sequence for theoretical hazard evaluation, fires are not assumed to take place simultaneously with the design basis event (DBE) or transient. Therefore, observing the same instruments that are used by SRs 3.6.5.1 and 3.6.5.2 once per hour along with the other indications available in the main Control Room, including alarms to alert the operator of abnormal Containment temperature conditions provides an equivalent level of fire safety without exposing personnel to unnecessary radiation exposure. Additionally, this method of compensatory actions for inoperable suppression systems in Lower Containment was approved by NRC for Sequoyah Nuclear Plant's TS 3.3.3.8 that was current at the time Watts Bar Nuclear Plant's FPR was written. This approval was also contained in Sequoyah Nuclear Plant's FPR when Sequoyah's fire protection was removed from TS and placed in the FPR.

If this Technical Specification instrumentation is not available to support this monitoring, then other appropriate maintained and tested instrumentation is used after evaluation.

PART II – FIRE PROTECTION PLAN

The 737' elevation of the Auxiliary Building is to have a dedicated continuous fire watch when the water based suppression system equipment or associated fire detection equipment is out of service. In such a situation, the continuous fire watch is limited to the 737' elevation due to the FSSD sensitivity of the area. The continuous fire watch is not allowed to cover areas in other elevations that this sprinkler system protects.

Alternate compensatory actions are generally defined in Section 13.1. In selected cases the established compensatory measures may be inadequate or present a concern such as in the areas of personnel safety or radiological safety. In such situations engineering evaluations will be used to define and accomplish adequate compensatory measures. Guidance for these engineering evaluations are provided in regulatory guidance as issued by the NRC in Regulatory Issue Summary (RIS) 2005-07 regarding compensatory measures applicable to Fire Protection Program (FPP) requirements. The purpose of the RIS was to allow licensees with the standard fire protection license condition to make changes to the approved FPP (i.e., WBN FPR) to use alternate compensatory measures. It was specified that if a licensee were to choose to implement alternate compensatory measures as otherwise required by the approved FPP, the licensee must document an evaluation to determine the impact of the alternate measures and the adequacy of those measures relative to those specified by the FPP. Examples of acceptable alternate compensatory measures include operator briefings, additional administrative controls, interim shutdown strategies, temporary procedural requirements, temporary fire protection features, etc. The evaluation must demonstrate that the implementation of alternate actions does not adversely affect the ability to achieve and maintain safe shutdown in the event of a fire, and should incorporate aspects of risks due to fire hazards, presence of ignition sources, installed fire protection features (manual and automatic), and human error probabilities where applicable.

In addition to the actions in Section 13.1 is the alternate compensatory action for the two Reactor Building Equipment Hatch Rooms (757.0-A11 & A15). The Reactor Building Equipment Hatch Rooms (757.0-A11 & A15) are inaccessible by the placement of the Reactor Building hatch and the shield blocks during plant operation. Due to the construction and thus inaccessibility, an evaluation (see Part VII, section 6.1) has been performed to determine the applicability of the compensatory actions of OR 14.3.1. The results show that this room has such limited fire hazards that the compensatory actions can be omitted without reducing nuclear safety or the fire safe shutdown capability of the plant.

- B.14.3.2** Where redundant FSSD systems or components are not damaged by a single fire, the least restrictive compensatory actions are required for inoperable water based suppression equipment or associated fire detection equipment would necessitate.
- B.14.3.3** The restoration of the equipment to Operable in 14 days is reasonable based on the type of equipment that is out of service. The time frame is consistent with the standard Technical Specifications.

PART II – FIRE PROTECTION PLAN

BASES – TESTING AND INSPECTION REQUIREMENTS (TIR) WATER BASED FIRE SUPPRESSION

- B.14.3.a** TIR 14.3.a verifies the correct alignment for testable valves that are manual, power-operated, and automatic valves in any accessible area in the spray/sprinkler systems flow paths and provides assurance that the proper flow paths exists for spray/sprinkler system operation. Valves that are locked, sealed, or otherwise secured in position need only be verified to still be locked, sealed, etc., since these were verified to be in the correct position prior to locking, sealing, or securing. This inspection does not require any testing or valve manipulation. Rather, it involves verification that those valves capable of being mispositioned and preventing or inhibiting fire suppression activities are in the correct position. A frequency of 92 days has been established and is more conservative than the inspection criteria established for primary system valves that are locked, sealed, etc.
- B.14.3.b** TIR 14.3.b ensures that testable valves in the flow path in any accessible area travel through at least one cycle. This is necessary to ensure valves are Operable in the event of a fire. A frequency of 12 months has been shown to be acceptable through operating experience and is consistent with NFPA consensus standard 25 criteria.
- B.14.3.c** TIR 14.3.c ensures that each automatic spray/sprinkler system valve actuates to its correct position. These deluge valves for preaction systems have limited means to ensure a cycle of travel is achieved. Industry practice on cycling these valves by closing the isolation valve all but a few turns until the deluge valve opens and then completing the closing of the isolation valve is used. This TIR also ensures that each testable valve in any inaccessible area travels through at least one cycle. Any pushbuttons provided at deluge valves for manual start of the fire pumps are not tested as a part of this TIR. These pushbuttons are provided for when the deluge valve is manually activated. Upon discovery of a fire, plant personnel are trained to report all fires before trying to fight them. Additional administrative controls are in place to ensure that a fire pump(s) is running when a fire is reported. A unit's Refueling Outage frequency was developed considering that many surveillances can only be performed during an outage. Standard Technical Specification requirements and operating experience has shown these components routinely pass the TIR when performed on the 18 months/Refueling Outage frequency. Therefore, the frequency was concluded to be acceptable from a reliability standpoint.
- B.14.3.d** TIR 14.3.d performs a general, floor level visual inspection of each spray or sprinkler system once every 18 months for accessible areas and for the unit in a Refueling Outage for inaccessible areas. This general inspection identifies any abnormal conditions and/or physical damage to the riser, sprinkler piping network, and hangers. This inspection includes assurance that spray/sprinkler head discharge patterns are not obstructed from providing protection from the hazards present. This inspection is not intended to perform a field verification of the design of the installed spray/sprinkler system. The 18 months/Refueling Outage frequencies have been established and are consistent with standard Technical Specification requirements. Design and modification controls exist to prevent improper fire protection system installation or permanent impairment of operation through improper installation of plant equipment.

PART II – FIRE PROTECTION PLAN

- B.14.3.e** TIR 14.3.e verifies during outages that each testable valve in any inaccessible area is visually inspected to be in its correct position. The test is performed during each cold shutdown exceeding 24 hours unless the TIR was performed in the previous 92 days. The verification is performed each 92 days during extended outages. The frequency for the TIR is based on the assumption that the required valves cannot be tested until the plant is in cold shutdown for more than 24 hours. Valves that are locked, sealed, or otherwise secured in position need only be verified to be locked, sealed, etc. since these were verified to be in the correct position before locking, sealing, or securing. A frequency of 92 days during outages has been established and is more conservative than the inspection criteria established for primary system valves that are locked, sealed, etc. The expected frequency for this testing is each unit's Refueling Outage and is based on operating experience.

PART II – FIRE PROTECTION PLAN

BASES – OPERATING REQUIREMENTS (OR) CARBON DIOXIDE (CO₂) SUPPRESSION SYSTEMS

B.14.4 Carbon Dioxide based fire suppression systems and their associated fire detectors are required to be Operable whenever safety related or FSSD equipment is required to be Operable. The low pressure CO₂ equipment and associated fire detection equipment is provided as a means to directly detect and suppress fires with particular emphasis on preserving the ability to achieve and maintain safe plant shutdown by protecting the fire safe shutdown equipment.

The main emphasis is on early detection to a constantly attended location and automatic actuation of the system for the suppression of a fire while the fire is easily controlled and quickly suppressed before it is capable of damaging fire safe shutdown systems. Two levels of actions are provided in recognition of the varying FSSD impact depending on the location of the fire. The determination whether a single fire can affect redundant FSSD systems or components is based on whether both FSSD paths are in an area with less than a 3-hour fire barrier separating them. This is consistent with Appendix R in that when 3-hour separation is provided, then suppression and detection are not required. Backup suppression equipment is normally the installed hose stations as discussed in Part II, Section 12.2.

The Operability of the total flooding CO₂ systems is dependent on the discharge areas' compartment integrity provided by the enclosing civil structure. This structure may or may not be a fire-rated assembly. A penetration of such a non-fire-rated or fire-rated assembly invokes compensatory actions for an inoperative CO₂ system only.

Outputs from the associated fire detection equipment also provide for the automatic shutdown of selected plant fans/air movers and dampers. This output is within the scope of this OR for Function B detectors. This automatic shutdown can directly affect the operation of the total flooding CO₂ system since the original testing was performed with this automatic shutdown. Manual actions may be used to compensate for this automatic shutdown but the delay is unacceptable.

When a unit is in Modes 5, 6, or core empty, the locations where a continuous fire watch is required may be combined and patrolled by one or more roving fire watch(es) provided the area only affects the unit in Modes 5, 6, or core empty. While the plant is in cold shutdown or refueling there are fewer systems needed for maintaining cold shutdown and more people present that could detect and report a fire (General Employee Training includes how to report a fire). Roving fire watches provide an adequate level of coverage for these systems by ensuring that potential fire hazards are detected and corrected in a timely manner to prevent fires, or if a fire were to occur, ensuring that timely action is taken.

B.14.4.1 More restrictive compensatory actions are appropriate where the total flooding CO₂ system equipment or associated fire detection equipment are provided to protect redundant fire safe shutdown systems or components that may be damaged if a fire occurred.

PART II – FIRE PROTECTION PLAN

- B.14.4.2** Where redundant fire safe shutdown components are not damaged if a fire occurs, the least restrictive compensatory actions are required for inoperable total flooding CO₂ system equipment or associated fire detection equipment.
- B.14.4.3** The restoration of the equipment to Operable in 14 days is reasonable based on the type of equipment that is out of service. The time frame is consistent with the standard Technical Specifications.

PART II – FIRE PROTECTION PLAN

BASES – TESTING AND INSPECTION REQUIREMENTS (TIR) CARBON DIOXIDE (CO₂) SUPPRESSION SYSTEMS

- B.14.4.a** TIR 14.4.a verifies that each of the carbon dioxide storage tank level is greater than the capacity needed to provide two normal timed discharges to the single largest hazard, and that each tank pressure is greater than 270 psig. This surveillance ensures that the quantity of carbon dioxide and the pressure in the tanks are adequate for fire suppression. The frequency of seven days has been established based on consensus standard NFPA 12, and has been shown to be acceptable through operating experience and is consistent with standard Technical Specification requirements.
- B.14.4.b** TIR 14.4.b requires that each valve is visually verified to be in its correct position. This applies to each system's tank shutoff valve and vapor pilot valve. Valves that are locked, sealed, or otherwise secured in position need only be verified to be in the correct position prior to locking, sealing, or securing. No further testing to confirm the valve's position is required to be performed due to the associated hazard of a CO₂ discharge. This surveillance does not require any testing or valve manipulation. Rather, it involves verification that those valves capable of being mispositioned are in the correct position. No NFPA consensus standard requires CO₂ valve position verification on a routine basis. A frequency of 92 days has been established and is more conservative than the inspection criteria established for primary system valves that are locked, sealed, etc.
- B.14.4.c** TIR 14.4.c requires that the system be demonstrated Operable by verifying that the system's valves, timers, associated ventilation system actions (e.g., fans shutdown and damper closure), fire dampers, and fire door release mechanisms actuate automatically upon receipt of a simulated actuation signal. Manual manipulation of this equipment does not need to be tested since the associated actions are demonstrated during the automatic actuation (e.g., opening of an HVAC fan breaker to stop a fan and shut down a damper is accomplished when the fan is shut down by the automatic actuation). A "puff test" is performed to ensure that flow from each nozzle can be achieved. Pneumatic actions/responses are demonstrated by the "puff test" as opposed to the automatic actuation discussed above to provide a more representative test. A pneumatic full flow "puff test" is accomplished using nitrogen or other suitable gas. The 18 month frequency has been shown to be acceptable through operating experience and is consistent with standard Technical Specification requirements.
- B.14.4.d** TIR 14.4.d requires that a visual inspection be performed to verify that discharge nozzles are not physically damaged and that the nozzle orifice openings are not externally obstructed. No actual discharge of carbon dioxide (pneumatic full-flow) is required unless inspection results indicate its advisability. The 18 month frequency is based upon the need to keep CO₂ equipment operable during unit operation, and is consistent with standard Technical Specification requirements.

PART II – FIRE PROTECTION PLAN

BASES – OPERATING REQUIREMENTS (OR) FIRE DETECTION SUPERVISION

B.14.5 The supervisory function of a zone is masked in one of two ways:

1. An Alarm condition on a local panel causes any existing Trouble conditions to clear locally and at the central alarm location. It also prevents any additional Trouble conditions from being annunciated locally and at the constantly attended location.
2. A Trouble condition on a local panel prevents additional Trouble conditions from being annunciated at the constantly attended location. Additional Trouble conditions on other zones or circuits are, however, annunciated on the local panel.

With the supervisory function of a zone listed in Table 14.1 masked by a panel Alarm or Trouble, the supervision must be restored within 8 hours. The 8 hours is reasonable considering: 1) The probability of a zone going into Trouble is minimal; 2) If a zone goes into Trouble, the probability of it being the type of problem that disables the Alarm function of a Class A circuit is minimal; 3) If a zone did have the type of problem that disables the Alarm function, the probability of a fire in that zone is minimal.

If the supervisory function is masked by an annunciation and cannot be unmasked within 8 hours, the zone(s) causing the masking is jumpered out using appropriate plant procedures and compensatory actions and time limits of Section 14.1, 14.2, 14.3, or 14.4, as appropriate, are established. A zone(s) jumpered out, that is addressed by Section 14.1, 14.2, 14.3, or 14.4 will have time limitations to establish compensatory measures, defined compensatory measures, time limitations to address the cause of the masking condition, and reporting requirements to address failure to meet the final repair of the zone(s) of 14.1, 14.2, 14.3, and 14.4. Thus additional time limitations and reporting requirements are not needed in OR 14.5 when an OR related zone(s) is jumpered out. A zone(s) not addressed by Section 14.1, 14.2, 14.3, or 14.4 has controls addressed by the plant's loss prevention program and are outside the scope of this OR.

Masking conditions can be caused by equipment defects that cannot be cleared/ removed by jumpering out a zone(s). In such a case, an evaluation must be made to determine the affect the masking condition has on the OR related equipment. Based on this evaluation, then compensatory measures and time limits of Section 14.1, 14.2, 14.3, or 14.4 are established as appropriate. If the masking condition can not be cleared by jumpering but did not cause an entry into an OR for Section 14.1, 14.2, 14.3, or 14.4, then it is appropriate to ensure a panel listed in Table 14.5 is returned to normal within 14 days.

Normally a circuit that causes an alarm or trouble condition that results in a masking condition is repaired within 8 hours or taken out of service. Due to special situations, it may be desired to clear this masking condition while maintaining the circuit's functional capability to actuate (i.e., alarm) and to detect grounds and to monitor for internal module failures (i.e., trouble) but not the Class A supervision to detect conductor failure. In such special conditions, the resulting temporary alteration control form (TACF) provides the advantage of the circuit remaining alarm functional which is preferable to the lifting of the field wiring, jumpering the monitoring module out of

PART II – FIRE PROTECTION PLAN

service, and thus completely removing any capability of the circuit. An example of this situation is a problem such as a cable between two devices on a circuit must be removed for operational purposes and this causes a trouble but due to the Class A design of the system the devices remain functional. If the circuit field wiring is lifted at the controlling module and the devices taken completely out of service then the resulting compensatory measures is an hourly or continuous fire watch. There is an advantage of having the equipment functional for normal automatic operation in lieu of the manual actions of a fire watch and the subsequent fire brigade. The module providing the supervision continues to monitor itself and report trouble conditions of the module and grounds on the circuit. The propose of OR-14.5.3 is to address the masking concern by applying jumpers to the controlling module to clear the trouble and cause the loss of supervision of the field wiring for a break in the conductors but the circuit actuation capability remains functional to provide actuation as well as the circuits ability to detect grounds and internal failures of the monitoring module. The device(s) on either side of this lifted cable are functionally tested for actuation capability at the time the TACF is first installed to ensure the functional actuation capability then periodically tested to ensure the continued integrity of the remainder of the circuit. When the portion of the circuit taken out of service includes an initiating device, then the appropriate OR-14.1, -14.3, or -14.4 is entered for the device taken out of service and OR-14.5.3 is entered for the balance of the circuit that is actuation functional. Periodic testing of the circuit is expected every 7 days for detection circuits and every 6 months for suppression system actuation circuits for automatic valves in the flow path. These frequencies are reasonable due to the configuration and work control processes provided at WBN along with the problem reporting process (e.g., corrective action program) which investigates any condition that might have endangered a circuit. In addition, the 6 month testing frequency for the suppression system actuation circuits for automatic valves in the flow path, is reasonable since the associated detection circuits are still available to alert plant personnel of any fire. The frequency of 6 months is the same frequency SQN tests similar suppression system actuation circuits for automatic valves in the flow path. The 30 days to correct this condition is reasonable since the problem is of such a nature that the desire for the continued function of the circuit is of sufficient importance that a TACF was generated in lieu of using the 14 day limits of the other ORs referenced. This includes the advantage of maintaining equipment in an automatic mode instead of the reliance on manual actions coupled with the reliability of the administrative controls to prevent damage to the equipment. The need for the extra time may be caused by such factors as inaccessibility due to radiological or personnel safety reasons. The physical action, lifting the field cable in the above example, is a TACF and is addressed by appropriate site procedures which are prepared to establish the requirements to address this condition in advance of its implementation.

The temporary, unique configuration addressed in OR-14.5.3 is not applicable to the zones that report the diesel fire pump (DFP) annunciations to the Main Control Room since these DFP zones are Class B and not Class A in accordance with NFPA-72D.

PART II – FIRE PROTECTION PLAN

BASES – OPERATING REQUIREMENTS (OR) FIRE HOSE STATIONS/STANDPIPES

B.14.6 Fire hose stations listed in Table 14.6, as part of the water suppression system, ensure that adequate manual fire suppression capability is available to confine and extinguish fires occurring in any portion of the facility where safety-related or FSSD equipment is located and to provide backup to primary suppression systems.

B.14.6.1 With one or more of the fire hose stations inoperable, the degree of fire protection provided to safety related equipment and fire safe shutdown equipment is degraded. Consequently, a backup source of fire hose protection must be supplied from the nearest operable fire hose station. This can be accomplished by routing additional fire hose from an Operable water source (hydrant, hose station, etc.) to the affected area; by staging fire hose immediately outside the affected area; or by providing alternate fire suppression equipment commensurable with the fire hazards present. Normally the method to do this is by providing a gated wye(s) and additional fire hose at the nearest operable fire hose station. In some instances, the physical routing of fire hoses from the Operable hose station to the inoperable hose station may result in a recognizable hazard to operating technicians, plant equipment (e.g., breaching a fire barrier), or the hose itself. In such cases, the hose is appropriately stored at the operable hose station. The completion time of eight hours is reasonable since normally the responding fire brigade brings additional fire hose. In addition, this hose is not for occupant use but restricted for use by trained firefighting personnel.

The hose stations in the Reactor Buildings' Lower Containment require special consideration. To provide protection during outages (during Modes 5, 6, or core empty), appropriate lengths of hose and nozzles are provided at the fire protection Siamese connection located at the entrance to Lower Containment. In Modes 1 through 4 these hoses are not required since occupancy and access is limited, thus personnel are normally not available locally to use this manual means of firefighting. The hose station valves and water supply are maintained operable. Extra hose and nozzles are available in the Fire Equipment Cages in the plant in case of an emergency.

B.14.6.2 Restoration of the equipment to Operable status within 14 days is reasonable considering the equipment involved. The time frame is consistent with the standard Technical Specifications.

PART II – FIRE PROTECTION PLAN

BASES – TESTING AND INSPECTION REQUIREMENTS (TIR) FIRE HOSE STATIONS/STANDPIPES

- B.14.6.a** TIR 14.6.a requires performance of a visual inspection of the fire hose stations in any accessible area to assure all required equipment is at the station and the station is not blocked or obstructed. The frequency of 92 days is considered reasonable in view of the infrequent problems found with hoses and is based on operating experience.
- B.14.6.b** TIR 14.6.b verifies the correct alignment for testable valves (except hose valves) in any accessible area in the fire hose station/standpipe system flow paths and provides assurance that the proper flow paths exists for hose station operation. Valves that are locked, sealed, or otherwise secured in position need only be verified to still be locked, sealed, etc., since these were verified to be in the correct position prior to locking, sealing, or securing. This inspection does not require any testing or valve manipulation. Rather, it involves verification that those valves capable of being mispositioned and preventing or inhibiting fire suppression activities are in the correct position. A frequency of 92 days has been established and is more conservative than the inspection criteria established for primary systems valves that are locked, sealed, etc.
- B.14.6.c** TIR 14.6.c ensures that each testable valve (except hose valves) in any accessible area travels through at least one cycle. This TIR is necessary to ensure the valves are Operable in the event of an actuation for fire suppression needs. A frequency of 12 months has been established based on operating experience, and is consistent with standard Technical Specification requirements and NFPA consensus standard 25 criteria.
- B.14.6.d** TIR 14.6.d requires that fire hose, associated with fire hose stations identified in Table 14.6 and stored in unheated areas, undergo a hydrostatic test once every 12 months. This hydrostatic test ensures that the hose is reliable and can withstand the working fire main pressure. Appropriate manufacturers' markings or initials and date by test personnel are sufficient to document this hydrostatic test. The manufacturers' markings are done in accordance with industry consensus standards. Initials and date by test personnel are sufficient to ensure proper controls are maintained. The frequency of 12 months is based upon regulatory guidelines, has been shown to be acceptable through operating experience, and is consistent with standard Technical Specification requirements.
- B.14.6.e** TIR 14.6.e ensures that each dry standpipe water flow device actuates to its correct position upon an initiation signal. The dry standpipe control valve is a deluge valve for which there is limited means to ensure a complete cycle of travel is achieved. For cycling these valves, the industry practice of closing the isolation valve all but a few turns until the deluge valve opens and then completing the closing of the isolation valve. Also, each testable valve in any inaccessible area travels through at least one cycle. The pushbuttons associated with these hose stations in the Reactor Buildings not only provide a means to open the deluge valve that allows water into the normally dry standpipe system as discussed in Section 12.2 but also start the fire pumps. Although these Reactor Building hose stations are manual and plant personnel are trained to report a fire before fighting it, there are no administrative controls to ensure the deluge valve is activated as there are for the start of the electric motor driven fire pump(s). Therefore, these push buttons are tested. Any other pushbuttons provided at hose stations other than the Reactor Buildings for manual start of the fire pumps are

PART II – FIRE PROTECTION PLAN

not tested as part of this TIR. The 18 month frequency for accessible areas and each unit's Refueling Outage frequency for inaccessible areas was developed considering the scope and requirements of some tests and inspections can only be performed during a unit outage. Operating experience has shown these components routinely pass the TIR when performed on the 18 month/Refueling Outage frequency. Therefore, the frequency was concluded to be acceptable from a reliability standpoint, and is consistent with standard Technical Specification requirements.

- B.14.6.f** TIR 14.6.f requires performance of a visual inspection of the fire hose stations that are in any inaccessible area to assure all required equipment is at the station and the station is not blocked or obstructed. The Refueling Outage frequency was developed considering that many tests and inspections can only be performed during a unit outage. Operating experience has shown these components routinely pass the TIR when performed on each unit's Refueling Outage frequency. Therefore, the frequency was concluded to be acceptable from a reliability standpoint, and is consistent with standard Technical Specification requirements.
- B.14.6.g** TIR 14.6.g requires removal of each fire hose for inspection of the hose condition and gaskets in the hose couplings. Degraded gaskets and/or hoses require replacement. Following inspection and gasket and/or hose replacement, the fire hose must be reracked, preferably at different folds. The 18 month or Refueling Outage frequency was developed considering that some areas can only be accessed during a unit outage, and is consistent with standard Technical Specification requirements.
- B.14.6.h** TIR 14.6.h requires that fire hose, associated with fire hose stations identified in Table 14.6 and stored in a heated area, undergo a hydrostatic test once every three years. This hydrostatic test ensures that the hose is reliable and can withstand the working fire main pressure. Appropriate manufacturers' markings or initials and date by test personnel are sufficient to document this hydrostatic test. The manufacturers' markings are done in accordance with industry consensus standards. Initials and date by test personnel are sufficient to ensure proper controls are maintained. The frequency of three years is based upon regulatory guidelines, has been shown to be acceptable through operating experience, and is consistent with standard Technical Specification requirements.
- B.14.6.i** TIR 14.6.i verifies the Operability of each fire hose station valve by partially opening the hose station valve with limited water flow. In the case of selected areas such as the Reactor Building, this flow test can use air in order to address the ALARA concerns. The period of three years between tests is reasonable because the infrequent use of the fire hoses provides for little opportunity for physical degradation or buildup of silt or other obstructions. This surveillance frequency and criteria is consistent with standard Technical Specifications.
- B.14.6.j** TIR 14.6.j verifies correct alignment during outages for each testable valve (except hose valves) in any inaccessible area in the fire hose station/standpipe system flow path and provides assurance that the proper flow paths exist for hose station operation. The test is performed during each cold shutdown exceeding 24 hours unless the TIR was performed in the previous 92 days. The verification is performed each 92 days during extended outages. The frequency for the TIR is based on the assumption that the required valves cannot be tested until the plant is in cold shutdown for more than 24 hours. Valves that are locked, sealed, or otherwise secured in position need only be verified to be locked, sealed, etc. since these were verified to be in the correct position before locking, sealing, or securing. A frequency of 92 days

PART II – FIRE PROTECTION PLAN

during outages has been established and is more conservative than the inspection criteria established for primary system valves that are locked, sealed, etc. The expected frequency for this testing is each refueling outage and is based on operating experience.

PART II – FIRE PROTECTION PLAN

BASES – OPERATING REQUIREMENTS (OR) FIRE HYDRANTS

- B.14.7** Fire hydrants listed in Table 14.7, as part of the water suppression system, ensure that adequate fire suppression capability is available to provide coverage for selected portions of safety-related structures.

The Intake Pumping Station uses fire hydrants as a backup water source for fire hoses used in manual firefighting. For the Diesel Generator Building's Conduit Interface Room, the fire hydrants are the primary and backup water source for fire hoses used in manual firefighting.

Although the specific fire hydrants in Table 14.7 are to remain operable while the safety related or FSSD equipment in the areas is required to be operable, one hydrant (specified in the table) may be inoperable as long as the alternate hydrant remains operable in its place. In the case that the specified hydrant becomes inoperable, it is acceptable for this hydrant to remain such for as long as necessary, since adequate fire suppression capability is provided by the alternate hydrant.

- B.14.7.1** With one or more of the fire hydrants inoperable, the degree of fire protection provided to safety-related equipment and fire safe shutdown systems is degraded. Consequently, a backup source of water must be supplied from the nearest Operable water supply whether it is another Operable fire hydrant or a hose station. This is done by providing a gated wye(s) at the nearest Operable water source. In some instances, the physical routing of fire hoses from the Operable water source to the inoperable fire hydrant may result in a recognizable hazard to operating personnel, plant equipment (e.g., breaching fire barriers), or the hose itself. In such cases, the hose is appropriately stored at the Operable water source with the hose dedicated for hydrant use. The completion time of eight hours is reasonable since normally the responding fire brigade brings additional fire hose. In addition, this hose is not for occupant use, but restricted for use by trained firefighting personnel.
- B.14.7.2** Restoration of the equipment to Operable status within 28 days is reasonable considering the restraints to getting to (i.e., digging up) and restoring (i.e., cure time for concrete thrust blocks) the equipment involved.

PART II – FIRE PROTECTION PLAN

BASES – TESTING AND INSPECTION REQUIREMENTS (TIR) FIRE HYDRANTS

- B.14.7.a** TIR 14.7.a requires performance of a visual inspection of the fire hose equipment dedicated to support the use of fire hydrants for manual firefighting. This assures all required equipment is at the assigned location and is available for use. The frequency of 92 days is considered reasonable in view of the infrequent use of the hose, and is consistent with operating experience.
- B.14.7.b** TIR 14.7.b verifies the correct alignment for testable valves in any accessible area in the fire hydrant flow path and provides assurance that the proper flow paths exists for fire hydrant operation. Valves that are locked, sealed, or otherwise secured in position need only be verified to still be locked, sealed, etc., since these were verified to be in the correct position prior to locking, sealing, or securing. This inspection does not require any testing or valve manipulation. Rather, it involves verification that those valves, capable of being mispositioned and preventing or inhibiting fire suppression activities, are in the correct position. A frequency of 92 days has been established and is more conservative than the inspection criteria in standard Technical Specifications for safety system valves that are locked, sealed, etc.
- B.14.7.c** TIR 14.7.c this visual inspection ensures accessibility and condition of the fire hydrants. Fire hydrants are more likely subject to mechanical damage due to their normal locations. The six-month frequency is needed to ensure continued Operability. The frequency of six months is based on industry operating experience and is consistent with standard Technical Specification requirements.
- B.14.7.d** TIR 14.7.d requires that fire hose dedicated to support fire hydrant use undergo a hydrostatic test once every 12 months. This hose is normally located on a motorized apparatus and is periodically exposed to uncontrolled environmental conditions, mainly atmospheric temperature extremes. This hydrostatic test ensures that the hose is reliable and can withstand the working fire main pressure. Appropriate manufacturers' markings or initials and date by test personnel are sufficient to document this hydrostatic test. The manufacturers' markings are done in accordance with industry consensus standards. Initials and date by test personnel are sufficient to ensure proper controls are maintained. The frequency of 12 months is based upon regulatory guidelines, has been shown to be acceptable through operating experience, and is consistent with standard Technical Specification requirements and NFPA consensus standard 25 criteria.
- B.14.7.e** TIR 14.7.e requires that fire hydrants be inspected and operated once every 12 months to ensure proper function and to flow water from the hydrant until perceptible foreign material has cleared. The frequency of 12 months is consistent with standard Technical Specification requirements and NFPA consensus standard 25 criteria.

PART II – FIRE PROTECTION PLAN

BASES – OPERATING REQUIREMENTS (OR) FIRE-RATED ASSEMBLIES

B.14.8 Fire-rated assemblies/fire barriers (including walls, floors, ceilings, penetration seals, fire doors, electrical raceway fire barrier systems [ERFBS] and radiant energy shields, and fire dampers that comprise the fire boundaries separating redundant safe shutdown components) or separating systems important to safe shutdown within a fire area ensure that fires are confined or adequately retarded from spreading to adjacent portions of the facility prior to detection and extinguishment. Fire-rated assemblies/fire barriers are used in conjunction with other fire protection features such as fire detection and fire suppression systems. Thus, the completion times and compensatory action requirements vary based on the Operability of the other fire protection features. With the exception of electrical raceway fire barrier systems and radiant energy shields, fire-rated assemblies/fire barriers are depicted on drawings in Part II of the FPR. Cables that require protection are routed in raceways enclosed with fire barriers or radiant energy shields and are identified in Part VI of the FPR.

When a unit is in Modes 5, 6, or core empty, the locations where a continuous fire watch is required may be combined and patrolled by one or more roving fire watch(es) provided the area only affects the unit in Modes 5, 6, or core empty. While the plant is in cold shutdown or refueling there are fewer systems needed for maintaining cold shutdown and more people present that could detect and report a fire (General Employee Training includes how to report a fire). Roving fire watches provide an adequate level of coverage for these systems by ensuring that potential fire hazards are detected and corrected in a timely manner to prevent fires, or if a fire were to occur, ensuring that timely action is taken.

Additionally, during Modes 5, 6, or core empty, it is necessary to breach some fire barriers for longer than 30 days. These breaches are excluded from the 10CFR50.72 and 10CFR50.73 reviews. The fire barrier components that are breached are as follows:

Reactor Building Equipment Hatch Shield Blocks for the unit in outage.

Doors: A65, A78, A156, 157, A164, A165, A166 and A167

The exemption of the 10CFR50.72 and 10CFR50.73 reviews for those identified components that are breached to facilitate the outage for longer than 30 days is consistent with other nuclear station practices. Roving fire watches are used until the breaches are restored.

Other than that specified above, the time requirements for correcting equipment problems of OR 14.8 remains the same.

In addition, those fire rated assemblies/fire barriers that are not accessible due to being in long-term high radiation areas are evaluated in Part VII.

PART II – FIRE PROTECTION PLAN

B.14.8.1 The fire-rated assemblies/fire barriers are provided as a part of the defense-in-depth concept of fire protection. The degradation of an assembly/barrier is reviewed in concert with the other fire protection features available. Thus, this review produces the following:

- a. When the assembly/barrier is degraded and there is no fire detection designed to protect both sides of the assembly/barrier, the continuous fire watch is reasonable.
- b. When the assembly/barrier is degraded and there is fire detection designed to protect one side of the assembly/barrier, then a roving fire watch is reasonable.
- c. When the assembly/barrier is degraded and there is suppression and fire detection designed to protect both sides of the assembly/barrier, then no compensatory action is reasonable.

The Operability or inoperability of the suppression or fire detection does not need to be addressed in the cases of degraded assemblies/barriers. This is because of the fact that an inoperable suppression or fire detection system/feature that protects Operable safety-related and FSSD equipment has its own compensatory actions.

B.14.8.2 The completion time of 30 days is reasonable based on the curing time of common fire barrier materials.

PART II – FIRE PROTECTION PLAN

BASES – TESTING AND INSPECTION REQUIREMENTS (TIR) FIRE-RATED ASSEMBLIES

- B.14.8.a** TIR 14.8.a ensures that fire doors are in the correct position, free to close, and the door is not damaged. NFPA consensus standards do not delineate specific frequencies for visual inspections of fire doors. Plant personnel are provided training in General Employee Training of the importance of maintaining fire doors closed and Operable. Plant fire doors are conspicuously identified as fire doors. Therefore, the 31 day frequency is considered acceptable.
- B.14.8.b** TIR 14.8.b requires a functional test of all associated release and closing mechanisms and latches on fire door assemblies to ensure fire door Operability. The frequency of 12 months is consistent with the guidance found in NFPA 80.
- B.14.8.c** TIR 14.8.c requires visual inspections of the surface areas of fire-rated barriers to verify Operability. Approximately twenty percent of the barriers are inspected every 12 months to ensure that all barriers are inspected at least once every five years. Inspection of bellows, metal plates, ERFBS, or insulation covering a penetration seal, provides verification of the fire-rated assembly/fire barrier integrity, provided there is no apparent change in appearance or abnormal degradation. Inspections validate their functional integrity and ensure that fires are confined or adequately retarded from spreading to adjacent portions of the facility.

The exposed surfaces of the fire-rated assembly/fire barrier are visually inspected to ensure the integrity of the assembly. Fire dampers are part of the fire-rated assembly/fire barrier. Damper inspections are performed in accordance with Fire Operating Requirement instruction 0-FOR-304-3, "Fire Damper (Internal) Visual Inspection-Auxiliary, Control and Diesel Generator Building." There is no disassembly of equipment (e.g., removal of damming material, junction box covers, or conduit fitting covers) to perform this visual inspection. Documentation of these inspections is based on the acceptability of the barrier or barrier portion (i.e., individual sign-offs for each penetration are not required). The barrier acceptability is used since a failed assembly leads to the barrier being declared inoperable not just the assembly. The surveillance frequency and criteria are considered to be adequate since they are consistent with current industry practice of ensuring all barriers are inspected within 5 years. Although the Standard Technical Specifications call for the inspection of the exposed surfaces of each fire rated assemblies every 18 months, it only required 10% of the penetration seals to be inspected. This results in a delay of 15 years to review all penetration seals. These penetration seals are more susceptible to damage than concrete walls and thus fire safety is increased with the additional inspections.

- B.14.8.d** TIR 14.8.d requires each unit's Refueling Outage frequency visual inspection of approximately 33-1/3 percent of the surface area of fire rated assemblies/fire barriers to determine Operability. Inspection of bellows, metal plates, ERFBSs, radiant energy shields, or insulation covering a penetration seal, provides verification of the fire rated assembly/fire barrier integrity, provided there is no apparent change in appearance or abnormal degradation. Inspections validate their functional integrity and ensure that fires are confined or adequately retarded from spreading to adjacent portions of the facility.

PART II – FIRE PROTECTION PLAN

The exposed surfaces of the fire-rated assembly/fire barrier is visually inspected to ensure the integrity of the assembly. There is no disassembly of equipment (e.g., removal of damming material, junction box covers, or conduit fitting covers) to perform this visual inspection. Documentation of these inspections is based on the acceptability of the barrier or barrier portion (i.e., individual sign-offs for each penetration are not required). The barrier acceptability is used since a failed assembly leads to the barrier being declared inoperable not just the assembly. The surveillance frequency and criteria are considered conservative since they exceed current industry practice of ensuring all barriers are inspected within 5 years. The frequency for inaccessible areas follows the criteria set out for inspections in accessible areas but adapted to the special circumstances associated with inaccessible areas.

PART II – FIRE PROTECTION PLAN

BASES – OPERATING REQUIREMENTS (OR) EMERGENCY BATTERY LIGHTING UNITS

B.14.9 Emergency battery lighting units are required to support a unit shutdown in the event of a fire and coincident loss of offsite power.

An ability to access and operate fire safe shutdown systems is required as well as the protection of such systems. This ability must be capable of being performed in conjunction with the loss of offsite power. To achieve this, emergency battery lighting units with 8 hour lighting capacity are provided.

B.14.9.1 Section 14.9.1 uses the term "alternate battery lighting" for a temporary substitute for installed emergency battery lighting units. This "alternate battery lighting" generally refers to portable, hand-held lighting as addressed in Section 12.7, "Emergency Lighting" of this report.

B.14.9.2 The restoration of the equipment to Operable in 14 days is reasonable based on the type of equipment that is out of service.

PART II – FIRE PROTECTION PLAN

BASES – TESTING AND INSPECTION REQUIREMENTS (TIR) EMERGENCY BATTERY LIGHTING UNITS

- B.14.9.a** TIR 14.9.a verifies proper operation of Emergency Battery Lighting (EBL) units by simulating a loss of power. When manually actuated, normal AC power is interrupted to the EBL at the primary or secondary side of the step-down transformer. Thus, the EBL's ability to go from the float charge mode to the discharge mode is fully exercised. This functional test also demonstrates:
- 1) The EBL is configured for automatic operation and is not in the standby mode
 - 2) The load transfer circuitry is functional
 - 3) The lamps are functional
 - 4) Continuity exists between the battery and all lamps
 - 5) The battery is functional
 - 6) The charging circuit is functional
 - 7) The status indicators are functional

A visual inspection to assess the general condition of the EBL, to detect obvious signs of degradation, and to detect any damage to the unit that may affect Operability is included. The visual inspection can identify degradation mechanisms at an early stage, and in many cases, can warn personnel of an impending failure. Included is a visual inspection to identify electrolyte leakage, and for vented cells, to determine whether water addition is needed. Early detection of battery leakage allows battery replacement before the leakage results in complete battery failure or in severe damage to other EBL components.

The frequency of 92 days for accessible EBLs is based upon vendor recommendations and industry practice. Over time, the optimal inspection frequency is driven by trending data.

The turbine building standby lighting is not tested as a part of the TIR.

- B.14.9.b** TIR 14.9.b requires that a battery is replaced periodically as a function of its service life, the environmental conditions the battery experiences, and a safety factor. The service life and the environmental factors are based on information from the manufacturer. This manufacturer's information plus the safety factor results in the frequencies as shown in chart.
- B.14.9.c** TIR 14.9.c requires that the EBL in inaccessible areas inside the Unit 1 and 2 Annulus be replaced each refueling outage for that unit and that the tests and inspection described under bases 14.9.a be performed to ensure EBL operability. This is being done due to the ALARA considerations in the Reactor Building and the limited accessibility during plant operation. The surveillance frequency and battery replacement are considered conservative and reasonable based on the fact that these are 15 year service life batteries that are being replaced on a refueling outage frequency.

PART II – FIRE PROTECTION PLAN

BASES – TESTING AND INSPECTION REQUIREMENTS (TIR) EMERGENCY BATTERY LIGHTING UNITS

Type of Battery	Environmental Conditions* (ambient temperature)	Service Life (Years)	Replacement Frequency (Years)
Sealed lead acid and calcium alloy	constantly below 95°F	5	3
		15	8
		20	11
Sealed lead acid and calcium alloy	constantly above 95°F	5	1.5
		15	6
		20	8
Sealed lead acid and calcium alloy	Unit 1 and 2 Annulus	15**	Refueling Outage
Solid gel	constantly below 95°F	4	3
Solid gel	constantly above 95°F	4	2

* Based on site environmental drawings for average temperature during normal operation.

**The 15 year service life is for the existing Exide LEC-36. Replacement battery (Sentry PM 6420) has a service life of 5 years. Replacement EBL (Lightguard F-100 w/LC-361 battery) has a service life of 20 years. Regardless of the battery/EBL combination used, the replacement frequency is every refueling outage for batteries in that unit's Annulus.

Type of Battery	Environmental Conditions* (ambient temperature)	Service Life (Years)	Replacement Frequency (Years)
UB 6420	below 84°F	3-5	3
UB6420	above 84°F and below 95°F	<3	1.5
UB 6420	above 95°F	<2	1

* Based on site environmental drawings for average temperature during normal operation.

The replacement method is preferred for the accessible EBL since a periodic, deep discharge (8 hour) test is not recommended by the manufacturer. The refueling outage replacement for inaccessible EBLs is preferred due to ALARA considerations and very limited access to the Reactor Building during operations which means that inspection and testing is only practical during outages. The frequency and criteria is based on vendor recommendations. The turbine building standby lighting is not tested as a part of the TIR.

PART II – FIRE PROTECTION PLAN

BASES – OPERATING REQUIREMENTS (OR) FIRE SAFE SHUTDOWN EQUIPMENT

B.14.10 A minimum set of plant systems and components has been identified at WBN to ensure that the plant can achieve and maintain safe shutdown in the event of plant fires (see Part III, Safe Shutdown Capabilities). In the majority of cases the identified plant systems and components are addressed by WBN Technical Specifications and Technical Requirements Manual which list surveillance requirements for verifying the Operability of the systems and components. This OR lists the systems and components which are not included as part of a Technical Specification or Technical Requirement.

Thermal overloads that are by-passed during accident conditions must remain operable during normal plant operation. This ensures that valves that are required for a Control Building fire are not damaged due to a hot short that may by-pass the torque switch. In addition, the thermal overloads are required for limiting current flow in the event of fire induced multiple high impedance faults and documented in the Multiple High Impedance Fault Analysis. The Technical Requirements Manual, Table 3.8.3-1, "Motor-Operated Valves Thermal Overload Devices Which Are Bypassed Under Accident Conditions" provides the list of thermal overloads this statement addresses.

This OR is provided to ensure that systems and components which are required for safe shutdown are maintained operable and tested to ensure operability. The intent of this OR is to ensure the equipment listed in Table 14.10 is capable of performing its FSSD function for the specific unit or both units. To ensure this, equipment listed in Table 14.10 shall satisfy the FSSD Condition listed by being Operable, capable of achieving its FSSD Condition, or in its FSSD Condition. The equipment listed in Table 14.10 is considered inoperable when it is not in or cannot achieve its listed FSSD Condition. The actions are based on Technical Specifications 3.3.4, Remote Shutdown System.

B.14.10.1 With a safe shutdown component shown in Table 14.10 inoperable, the inoperable component must be restored within 30 days when the unit is in modes 1, 2, or 3.

Table 14.10 defines the Fire Safe Shutdown (FSSD) condition as "OPERABLE" for the Temperature Control Valves (TCVs) supplying for the Lower Compartment Coolers (LCCs) and Control Rod Drive Mechanism (CRDM) coolers. In Modes 1, 2, or 3, these valves are required to modulate to control temperature to their respective cooler. "OPERABLE" for these TCVs is a position to ensure that their respective cooler has sufficient cooling flow to maintain the Reactor Building Lower Compartment temperature. Functional Evaluations (FEs) have been performed on a single TCV, and determined that with the TCV in the open position it meets the requirement for FSSD condition.

B.14.10.2 With a breaker and/or valve specified in design output documents as being administratively controlled for Appendix R out of its required position (as noted on the drawing), the breaker and/or valve must be returned to the required position within 30 days when the unit is in Modes 1, 2, or 3. These breakers and/or valves are administratively controlled to prevent inadvertent operation during an Appendix R fire event. There is no TIR associated with the OR since the valves and/or breaker positions are controlled by the applicable System Operating Instruction and the plant's configuration control program.

PART II – FIRE PROTECTION PLAN

B.14.10.3 If the required action and associated completion time are not met, the plant must be placed in a condition where the OR does not apply. If possible, the inoperable or misconfigured component can be placed in the condition required for safe shutdown (i.e., close a valve, shutdown a pump, lock open a breaker), or a backup instrument can be provided for monitoring temperature, flow, or pressure. If this cannot be accomplished, an evaluation can be performed to justify using an alternate means to achieve compliance with Appendix R FSSD requirements. The evaluation is performed using the plant's standard review process. The plant's Temporary Control and Alteration process (TACF) along with a 10CFR50.59 review can also be used to provide the alternate means of FSSD compliance. If none of the above actions can be accomplished, the unit must be brought to at least Mode 3 within 6-hours and to Mode 4 within the following 12-hours.

B.14.10.4 With a Pressurizer Block Valve is closed in Modes 1, 2, or 3, the Pressurizer Block valve must be restored to OPEN status as soon as possible but not longer than the next refueling outage and an hourly roving or continuous fire watch (see OR 14.10.4) is established within one hour in Auxiliary Building (AB) rooms according to the following table:

Block Valve Closed	Fire Watch in Room
1-FCV-68-332-B	757-A1
	757-A10
2-FCV-68-332-B	757-A16
2-FCV-68-333-A	737-A1B
	757-A21

For a fire in these rooms, the Reactor Head Vent valves are not available and the Pressurizer PORV credited for RCS pressure control is the same Train as the CLOSED block valve, and opening of the block valve may not be possible due to the loss of its electrical power source due to cable fire damage. If the block valve is in a CLOSED position, the fire damage may prevent the valve from being opened from the MCR or its auxiliary control switch on its Motor Control Center (MCC) to enable operation of the credited Pressurizer PORV.

WBN procedural guidance (SOI-68.01) directs the operator to close the block valve in the event of a Pressurizer PORV "simmering" excessive leakage to the Pressurizer Relief Tank. Closure of the block valve with power maintained is required under the provisions of Technical Specification 3.4.11 and operation is permitted until the next refueling outage so that maintenance can be performed on the Pressurizer PORV. An Appendix R fire in the rooms listed in the above table damages the power cable or power supply to the block valve, which negates the provision of Technical specification 3.4.11 to maintain power to the block valve. It also negates the Fire Safe shutdown (FSSD) analysis assumption that the block valve is OPEN or can be opened with a credited Operator Manual Action. In these areas, enhanced measures must be taken to assist in detecting a general fire at its incipient stage to prevent fire growth leading to entry into the Appendix R post fire safe shutdown procedures (0-AOI-30.2 - Reference 4.2.90).

PART II – FIRE PROTECTION PLAN

For example, justification for not having a Fire Watch or an additional Main Control Room (MCR) Operator Action (OA) for an Appendix R fire in the AB and Fire Room 757-A24 (6.9 kV and 480 V Shutdown Board Room B). The block valve 1-FCV-68-333-A is credited when there is an Appendix R fire in the AB and Fire Room 757-A24, and power is lost to the block valve 1-FCV-68-332-B. If block valve 1-FCV-68-333-A is closed since the associated PORV was "simmering" excessive leakage to the Pressurizer Relief Tank, the block valve 1-FCV-68-333-A is flagged in the MCR denoting that the valve is closed. MCR Operator Action (OA) is relied upon (that is, intuitively obvious to the Operator) to open the block valve if the associated PORV is required for control of Reactor Coolant System (RCS) pressure.

PART II – FIRE PROTECTION PLAN

BASES – TESTING AND INSPECTION REQUIREMENTS (TIR) FIRE SAFE SHUTDOWN EQUIPMENT

- B.14.10.a** TIR 14.10.a is performance of a terminal voltage check and an alignment check of the plant's 250 VDC Batteries 1 and 2. This provides assurance that the batteries are operable and aligned to the appropriate DC bus. This check is performed at least once every 31 days when the plant is in modes 1, 2, or 3.
- B.14.10.b** TIR 14.10.b is performance of a breaker alignment check for the 250 VDC Battery Boards 1 and 2 and Distribution Panels 1 and 2. This check provides assurance that breakers which supply control power to steam load trip circuits and RCP breaker trip circuits are aligned properly. This check is performed at least once every 31 days when the plant is in modes 1, 2, or 3.
- B.14.10.c** TIR 14.10.c verifies every 18 months that main steam system valves are capable of being closed via Main Control Room switch. This verifies that each valve operates properly to ensure the isolation of main steam loads when main steam isolation valves become inoperable in the event of fire damage. The valves are tested every 18 months when the unit is shutdown since operation of the valve via the hand switch during operation can cause a reactor trip.
- B.14.10.d** TIR 14.10.d is performance of a channel calibration on instruments required for safe shutdown. Many of these instruments are required for local operation of plant systems and components during a fire event. The performance of the calibration ensures the accuracy of these instruments if use is required. This calibration is performed once per 18 months.
- B.14.10.e** TIR 14.10.e is performance of in-service testing for the Thermal Barrier Booster Pumps under the augmented in-service testing program. These pumps are needed to support fire safe shutdown requirements. The augmented in-service testing program requires flow verification at least once per 92 days to ensure that the pump is operable.
- B.14.10.f** TIR 14.10.f verifies every 92 days that RCS Pressurizer Spray Valves are capable of being closed from the Main Control Room controller. The valves are tested every 92 days (quarterly) in accordance with the augmented in-service testing program.
- B.14.10.g** TIR 14.10.g verifies every 18 months that the Control Rod Drive Cooler Motors and associated dampers operate properly from MCR controls. The CRDM Coolers and dampers are tested every 18 months when the unit is shutdown since these coolers are normally in operation during unit operation. Also, cycling these coolers on and off during plant operation may have an adverse effect on the Rod Position Indication System.
- B.14.10.h** TIR 14.10.h verifies every 18 months that the Generator Control System Solenoid can be operated from its associated hand switch in the MCR. This test is performed every 18 months when the unit is shutdown since operation of this solenoid causes a unit trip. The solenoid is tested every 18 months as part of the Technical Requirements Surveillance Program.
- B.14.10.i** TIR 14.10.i verifies every 18 months that the Lower Compartment Cooler System Temperature Control Valves (TCVs) operate properly from MCR controls. The TCVs are tested every 18 months when the unit is shutdown since these coolers are required for Containment cooling during unit operation.

PART II – FIRE PROTECTION PLAN

- B.14.10.j** TIR 14.10.j.a verifies every 31 days that the nitrogen tanks have the quantity and pressure of nitrogen required for operation of the valves. This check is performed at least once every 31 days when the plant is in modes 1, 2 or 3.
- TIR 14.10.j.b verifies every 18 months that the SG PORVs and AFW LCVs can be operated properly from backup control stations using the compressed nitrogen. The PORVs and LCVs are tested every 18 months when the unit is shutdown since these valves are required to be operable per plant Technical Specifications when the plant is in operating modes 1 through 4 and testing these valves utilizing the nitrogen system makes the valves inoperable.
- B.14.10.k** TIR 14.10.k verifies every 92 days that the Auxiliary Control Air Compressors are capable of starting automatically if the air receiver pressure drops below a pre-established setpoint. Re-establishing and maintaining system pressure ensure adequate capacity to meet the needs of the small set of components credited for remote pneumatic operation during Fire Safe Shutdown.
- B.14.10.l** TIR-14.10.l relies on testing requirements defined for Technical Surveillance Requirement 3.8.3.1 of the Technical Requirements Manual to test the thermal overload bypass devices. The concern for the FPR is to identify faulty bypass circuitry which may lead to the bypassing of the overloads during normal operation and thus defeating their protection features as addressed in the bases to OR-14.10. Compliance with TIR-14.10.l provides a method for the surveillance program to ensure OR-14.10 is entered if the associated test fails to restore the thermal overload circuit back to normal operation.
- B.14.10.m** TIR 14.10.m verifies every 18 months that the CREATCS Appendix R transfer switches (0-XS-31-12-A and 0-XS-31-11-B) function as intended by the performance of a continuity check. This ensures that CREATCS is available for local control during an Appendix R fire that takes out the normal control circuit. The continuity test is consistent with the surveillance requirements for other safety-related transfer switches (reference Technical Specification Bases SR3.3.4.2).
- B.14.10.n** TIR 14.10.n verifies every 18 months the remote switches for P-Auto operate correctly when the associated transfer switch is in AUX. This testing is consistent with the surveillance requirements for these switches (reference Technical Specification SR3.3.2, 3.3.3, 3.3.4 and 3.7.5).
- B.14.10.o** TIR 14.10.o verifies every 7 days there is adequate pressure, volume and flow of liquid nitrogen for sustaining the Appendix R event requirements. Pressure leaving the skid is verified to be ≥ 120 psig (dual unit operation) or ≥ 100 psig (single unit operation) by reading 0-PI-77-2785. Volume is verified to be ≥ 60 -inches (236,960 scf - dual unit operation) or ≥ 49 -inches (190,904 scf - single unit operation) by reading 0-LI-77-2701. Flow is verified to be ≤ 69.5 scfm (dual unit operation) or ≤ 66.5 scfm (single unit operation) by taking the difference of the tank volume from one inspection to the next and dividing by the elapsed time to yield the average flow from the tank for that time period. Flow rates above these values are indication of a possible leak. These parameters will conservatively supply the operation of the AFW LCVs and PCVs for 38 hours as determined by Calculation MDQ0000772012000033 (volume and flow) and Calculation MDQ00103220120188 (pressure). This is reasonable time for Operations to refill the tank or connect an alternate high pressure supply such as a nitrogen gas tube trailer. The required alternate nitrogen gas volume is $\geq 78,500$ scf (dual unit

PART II – FIRE PROTECTION PLAN

operation) or $\geq 39,284$ scf (single unit operation) when only the Appendix R required portion of the nitrogen system required for operation of the AFW LCVs and PCVs is being served with a minimum pressure of 70 psig at the valves and the rest of the system is isolated from the alternate source of nitrogen.

- B.14.10.p** TIR 14.10.p verifies every 18 months RCP Thermal Barrier Booster Pump trip and Thermal Barrier isolation function can be blocked from MCR controls by the performance of a functional test or continuity check. This test is performed every 18 months when the unit is shutdown since the flow transmitters are required to operate during normal plant operation. This ensures RCP Seal Cooling is maintained in the event CVCS Seal Injection Flow becomes unavailable during an Appendix R fire condition.
- B.14.10.q** TIR 14.10.q verifies every 18 months that the RCP Seal Leakoff valves will fail open on loss of air with the Non-essential Control Air header isolated and vented inside Containment. Non-Essential Air solenoids (1-XSV-32-112A1, -112A2, -112B1 & -112B2 and 2-XSV-32-112A1, -112A2, -112B1, -112B2) vent Non-Essential Air solenoids inside Containment with the use of a single handswitch (1-HS-32-112 or 2-HS-32-112A) in the MCR. Power to 1-HS-32-112 is supplied from 1-XS-32-112, which supplies trained power from "A" Train and "B" Train. The function is to vent non-essential air and fail open the RCP Seal Leakoff Valves in a fire safe shutdown condition. This will ensure the ability to maintain RCP Seal Cooling if an Appendix R fire causes one or more RCP Seal Leakoff valves to spuriously close. This surveillance can be performed as a functional test for each of the solenoid vent valves only, since the RCP Seal Leakoff valves fail safe position (open) are tested under the Augmented In-service Testing Program at a similar frequency of once per Refueling Outage (normally 18 months). Each solenoid vent valve must be tested in conjunction with the close interlock contact with 1-FCV-32-110-A and 2-FCV-32-111-B (Non-Essential Air to Containment).
- B.14.10.r** TIR 14.10.r.a verifies every 18 months that the isolation solenoid valves for nitrogen to the MDAFW LCVs and PCVs and isolation of nitrogen to the TDAFW LCVs can be operated from its associated hand switch in the MCR. Nitrogen is a secondary motive force for the MDAFW level and pressure valves and the TDAFW level valves since control air is not credited during a postulated Appendix R event. The solenoid valves isolate the nitrogen sub-header to prevent blowdown of the nitrogen tank in case of a failure of valve actuator diaphragm(s) or positioner(s). TIR 14.10.r.a also verifies that 1-XS-77-2561 disables hand switch 1-HS-77-2561A and 2-XS-3-2561 disables hand switch 2-HS-3-164A contacts used to actuate nitrogen sub-header valves for MDAFW LCVs/PCVs with a continuity check. This is necessary to mitigate the consequences of a postulated Appendix R fire resulting in the assumed short circuit of the hand switch contacts which could inadvertently energize (close) the solenoid valve. This test is performed every 18 months when System 77 is inspected as part of the leak check program (Ref. WBN-SDD-N3-77A-4001, section 6.0).
- TIR 14.10.r.b verifies every 92 days that each testable valve, in an accessible area, from the liquid nitrogen skid to the AFW LCVs and PCVs are inspected to be in its correct position. Valves that are locked, sealed or otherwise secured in position need only be verified to be locked, sealed, etc, since these were verified to be in the correct position before being locked, sealed or secured.

PART II – FIRE PROTECTION PLAN

TIR 14.10.r.c verifies every 18 months functional valve operation with nitrogen for AFW LCVs and PCVs. This functional check verifies proper control of the AFW LCV or PCV when only nitrogen supplies the valve positioner. The valves are tested every 18 months when the unit is shutdown since they are required to be operable per plant Technical Specifications and testing these valves using the nitrogen system would make the valves inoperable for normal plant operation and LCO 3.7.5, since the Essential Air supply is the normal mode of operation for these AFW valves.

The fire detection instruments located within the containment are not required to be OPERABLE during the performance of Type A containment leakage rate tests.

TABLE NOTATION

**** A/B:** A is a number of Function A (early warning fire detection and notification only) instruments.

B is a number of Function B (actuation of fire suppression systems and early warning notification) instruments.

- (1) See Part VII, Deviation and Evaluations for deviation of door gap criteria.
- (2) Door has been permanently closed by DCN D-51255-A as part of the Site Security Plan. Operation of this door is not required as part of the Testing and Inspection Requirements (TIR). Visual inspection requirements still apply.

TABLE 14.8.1 NOTES:

1. These doors are not UL listed doors, but have been evaluated as being equivalent (EQ) to fire rated doors or are personnel air lock assemblies that are not 3-hour listed door assemblies, but have been evaluated as acceptable (AC).

PART III – SAFE SHUTDOWN CAPABILITIES

1.0 INTRODUCTION

Part III describes the methodology used to identify, select, and analyze the systems, components, and cables needed to demonstrate compliance with Appendix R to 10CFR50, and the applicable Nuclear Regulatory Commission (NRC) generic letters. The safe shutdown analysis methodology as applied at Watts Bar Nuclear Plant (WBN) is also described.

Paragraph 50.48 of 10CFR50 became effective on February 17, 1981 and requires all nuclear plants licensed to operate prior to January 1, 1979 to comply with the requirements of 10CFR50 Appendix R Sections III.G, III.J, and III.O regardless of any previous approvals by the NRC of other design features. Section III.G.1 requires that fire protection features be provided for those systems, structures, and components important to safe shutdown. These features shall be capable of limiting fire damage so that:

- (1) One train of systems necessary to achieve and maintain hot shutdown conditions from either the control room or the emergency control station(s) is free of fire damage; and
- (2) Systems necessary to achieve and maintain cold shutdown from either the control room or the emergency control station(s) can be repaired within 72 hours.

Where alternative shutdown capability is required (i.e., for control building fires that require shutdown from outside of the Main Control Room), cold shutdown must be achieved within 72 hours. Alternate shutdown capability is evaluated per Appendix R Sections III.G.3 and III.L. Plant locations that do not require alternative shutdown capability are evaluated per Section III.G.2 of Appendix R. Generic Letter 81-12 (February 20, 1981) Enclosure 1 "Staff Position", provides additional guidance on the NRC's requirements for safe shutdown capability.

1.1 Design Basis Evaluation

The purpose of this evaluation is to demonstrate fire safe shutdown capability for postulated fires involving in situ and/or transient combustibles that could impact systems, structures, or components located in or adjacent to that area. For purposes of this evaluation, it is assumed that these fires may adversely affect those systems, structures or components essential to safe shutdown. The availability of offsite power for specific systems and/or fire scenarios has been evaluated for non-alternative shutdown locations. Cases for only on-site power available and for off-site power available are evaluated for control building fires, for which alternative shutdown is provided. No concurrent or sequential design basis accidents or transients are assumed to occur. Failures that are a consequence of the fire are evaluated.

1.2 Limiting Safety Consequences

The limiting safety consequences used in the evaluation of fire safe shutdown are: (1) no fuel failure due to calculated cladding temperature increases; (2) no rupture of any primary coolant boundary; (3) no rupture of the containment boundary; (4) following the event, the reactor coolant system process variables shall be within those predicted for a loss of normal AC power; and (5) shutdown capability shall be able to achieve and maintain subcritical conditions in the reactor, maintain reactor coolant inventory, achieve and maintain hot standby conditions for an extended period of time, achieve cold shutdown conditions within 72 hours with equipment

PART III – SAFE SHUTDOWN CAPABILITIES

powered by onsite power sources if using alternative shutdown methods, and maintain cold shutdown conditions thereafter.

Generic Letter 81-12, Enclosure 1, specifies the performance goals and associated safe shutdown functions necessary to ensure the limiting safety consequences of the fire safe shutdown analysis. Other sub-functions may exist under each of these broad headings. Examples of such sub-functions are steam generator level control and steam generator pressure control which exists as part of reactor heat removal. Steam generator level and pressure control are required during hot standby. However, during certain portions of hot shutdown and all of cold shutdown, the residual heat removal system is operable and these sub-functions are not required. Other sub-functions such as emergency power, process cooling, etc., are included as support functions.

In addition to the performance goals and safe shutdown functions identified in Generic Letter 81-12, the reactor coolant pressure control function has been included. Although this function could be placed within the reactor coolant makeup function and reactor heat removal function, the specific goals achieved by the performance of this function are unique enough to warrant a separate safe shutdown function classification. Multiple spurious operation of components due to fire damage on cables has also been considered.

The performance goals and safe shutdown functions identified in the generic letter adequately ensure that the containment pressure boundary is not threatened. Uncontrolled mass and energy releases to the containment from the primary systems are limited by the achievement of these safe shutdown functions and ensures that no rupture of the reactor coolant or containment pressure boundaries occurs.

Figures III-1 through III-4 present the Appendix R safe shutdown/interaction analysis flow chart. The figures include:

- (1) Identification of performance goals and functions
- (2) Identification of safe shutdown systems
- (3) Identification of safe shutdown equipment
- (4) Identification of safe shutdown cables
- (5) Performance of separation/interaction analysis
- (6) Documentation of compliance strategies

These topics are described below.

2.0 SAFE SHUTDOWN FUNCTIONS

This section provides a brief overview of the WBN safe shutdown functions. The specific safe shutdown functions necessary to satisfy the performance goals and safe shutdown functions of Appendix R as identified in Enclosure 1 to Generic Letter 81-12 are:

PART III – SAFE SHUTDOWN CAPABILITIES

- (1) the reactivity control function
- (2) the reactor coolant makeup function
- (3) the reactor coolant pressure control function
- (4) the reactor/residual heat removal function
- (5) the process monitoring function
- (6) the support function

2.1 Reactivity Control

After a reactor trip, the reactivity control systems must be capable of achieving and maintaining adequate reactivity shutdown margin from zero power hot standby to cold shutdown. The function must be capable of compensating for any reactivity changes associated with xenon decay and reactor coolant temperature decrease which occur during cooldown to cold shutdown conditions.

2.2 Reactor Coolant Makeup

The reactor coolant makeup systems shall be capable of assuring that sufficient makeup inventory is provided to compensate for reactor coolant system (RCS) fluid losses due to identified leakage from the reactor coolant pressure boundary and shrinkage of the RCS water volume during cooldown from hot standby to cold shutdown conditions. Adequate performance of this function is demonstrated by the maintenance of reactor coolant level within the pressurizer.

2.3 Reactor Coolant Pressure Control

Reactor coolant pressure control is required to assure that the RCS is operated:

- (1) Within the Technical Specifications for RCS pressure-temperature requirements;
- (2) To prevent peak RCS pressure from exceeding 110% of system design pressure;
and
- (3) With a sufficient subcooling margin to minimize void formation within the reactor vessel.

2.4 Residual Heat Removal

The residual heat removal (RHR) systems shall be capable of transferring fission product decay heat from the reactor core at a rate such that specified acceptable fuel design limits and design conditions of the reactor coolant pressure boundary are not exceeded. The function shall be capable of achieving (for alternative shutdown) cold shutdown within a 72-hour period and maintaining cold shutdown conditions thereafter.

PART III – SAFE SHUTDOWN CAPABILITIES

2.5 Process Monitoring

When information on process variables is required by operators to modify safe shutdown system alignments or control safe shutdown equipment, such monitoring information must be available. The process monitoring function shall be capable of providing, if possible, direct readings of those plant process variables necessary for plant operators to perform and/or control the previously identified functions.

2.6 Support

The systems and equipment used to perform the Fire Safe Shutdown (FSSD) functions may require miscellaneous support functions such as process cooling, lubrication and AC/DC power. These supporting functions shall be available and capable of providing the support necessary to assure acceptable performance of the FSSD functions.

3.0 ANALYSIS OF SAFE SHUTDOWN SYSTEMS

3.1 Introduction

Various analytical approaches ensure that sufficient plant systems are available to perform the FSSD functions. Numerous plant systems are available, alone and in combination with other systems, to provide these required functions. A minimum set of plant systems and components are identified to demonstrate that the plant can achieve and maintain safe shutdown per TVA's commitments to Appendix R at WBN. In addition, for control building fires that require shutdown from outside of the Main Control Room (MCR), the concurrent loss of off-site power is also assumed. Providing adequate protection of this minimum system, component, and cable set from the effects of postulated fires constitutes an adequate and conservative demonstration of the ability to achieve and maintain safe shutdown for the purpose of fire protection.

The safe shutdown systems selected for WBN are capable of:

- (1) achieving and maintaining subcritical conditions in the reactor,
- (2) maintaining reactor coolant inventory,
- (3) achieving and maintaining hot shutdown conditions for an extended period of time,
- (4) within 72 hours, performing cold shutdown repairs needed to achieve and maintain cold shutdown (or, for control building fires that require shutdown from outside of the MCR, achieving cold shutdown conditions within 72 hours), and
- (5) maintaining cold shutdown conditions thereafter.

Common Unit 1 and Unit 2 support systems and process monitoring equipment (such as Component Cooling System (CCS), Essential Raw Cooling Water (ERCW), electrical power distribution, and common area HVAC) are required for the safe shutdown analysis. In the electrical power distribution discussions, reference is made to "per unit" equipment. "Per unit", as used in the discussions, designates the Unit 1 and Unit 2 common support equipment that are required for safe shutdown of the plant.

PART III – SAFE SHUTDOWN CAPABILITIES

3.2 Initial Assumptions

- (1) Each unit is operating at 100% power upon the occurrence of a fire.
- (2) For alternative shutdown locations (control building fires that require shutdown from outside of the MCR), the post fire safe shutdown analysis is conducted for both the case with offsite power available as well as the case with only onsite power available for 72 hours.
- (3) The reactor(s) are tripped either manually or automatically. The Appendix R fire response procedures direct the operators to manually trip the reactor. There is also the possibility of an automatic reactor trip initiated by fire damage such as damage to the reactor protection system input cables. The Appendix R safe shutdown analysis begins ($t=0$) with reactor trip; either manual or automatic, whichever occurs first.
- (4) No failures are considered other than those directly attributable to the fire.
- (5) Equipment required for safe shutdown is assumed to be operable (i.e., not out of service).

3.3 Definitions

Hot Standby (Mode 3)	The initial safe shutdown state with the reactor at zero power, K_{eff} less than 0.99 and average RCS temperature T_{avg} greater than or equal to 350°F.
Hot Shutdown (Mode 4)	Reactor at zero power, K_{eff} less than 0.99 and average RCS temperature T_{avg} between 350°F and 200°F.
Cold Shutdown (Mode 5)	Reactor at zero power, K_{eff} less than 0.99 and average RCS temperature T_{avg} below or equal to 200°F.
Subcooling Margin	The difference between the saturation temperature at the RCS pressure, and the maximum temperature in the hot legs or Reactor Pressure Vessel (RPV).

3.4 Safe Shutdown Functions

The following is a comparison of the Generic Letter 81-12 safe shutdown functions and the corresponding safety functions used in the Appendix R FSSD analysis for WBN:

Process Cooling

Each plant system or subsystem function relied on to accomplish the above safe shutdown functions is identified. A separate designator is assigned to each plant system or subsystem function to ensure consistency between analysis documents and calculations. Each designator is identified as a safe shutdown "Key". Figure III-5 depicts the safe shutdown system and/or system function, associated Key number, and logical relationships between systems and Keys used to demonstrate compliance with Appendix R criteria. Table 3-1 identifies the plant systems and subsystems sorted by Key. The correlation between Keys and safe shutdown systems is provided in Section 4. The following sections provide a general description of the methods and systems used to satisfy the safe shutdown performance goals and functions as delineated in Generic Letter 81-12.

3.4.1 Reactivity Control

Initial reactivity control results from an automatic reactor protection system (RPS) trip or from operator initiation of a manual trip upon notification of a major fire. This action de-energizes the normally energized control rod drive mechanism (CRDM) to actuate a reactor trip. The RPS has a diversity of inputs, each of which "fails safe" and actuates on an open circuit or a loss of power. As such, fire damage to the RPS does not preclude the initiation of an automatic trip or control rod insertion.

Following rod insertion, hot standby (subcritical, Mode 3) conditions may be maintained for over eight hours with no addition of boron, assuming all rods are inserted into the core (even if the highest worth rod is not inserted) and the reactor trip occurs at end of fuel life and at 100% power, with xenon at steady-state level. (Note that for the Appendix R analysis, the stuck-rod assumption is not required.) As xenon decays it adds positive reactivity, requiring the addition of borated water from the refueling water storage tank (RWST) to maintain the required shutdown reactivity margin. The cooldown transition from hot standby to hot shutdown, and ultimately to cold shutdown, requires additional boration to compensate for the moderator's negative temperature coefficient. The chemical and volume control system (CVCS) draws minimum 2000 ppm boron water from the RWST and injects it into the RCS to achieve and maintain the required shutdown reactivity level.

PART III – SAFE SHUTDOWN CAPABILITIES

3.4.2 Reactor Coolant Makeup Control

For the assumed fire scenario, reactor coolant makeup control can be achieved by isolating normal makeup and boron injection tank (BIT) injection path, isolation of the normal and excess letdown CVCS paths, and operation of the charging portion of the CVCS through the reactor coolant pump (RCP) seal injection path. Reactor coolant makeup is available post-reactor trip.

Successful maintenance of RCS integrity is also necessary to achieve adequate inventory control. Inadvertent opening of boundary isolation valves such as the reactor head vent valves and RHR suction isolation valves has been precluded. Adequate reactor coolant pump seal integrity is maintained to assure safe shutdown.

Control of pressurizer water level is achieved manually by controlling CVCS charging flow based on charging flow or pressurizer level information. The total quantity of water from the RWST which must be injected into the RCS to achieve the required cold shutdown margin is less than the quantity of borated water required to maintain a constant pressurizer level during cooldown (RCS volume shrinkage compensation).

3.4.3 Reactor Coolant Pressure Control

Establishing and maintaining a sufficient subcooling margin within the RCS is required to minimize void formation in the core and to ensure the ability to maintain natural circulation (if the RCPs are not operable) through the steam generators (SGs). This is essential to achieving and maintaining safe shutdown.

Overpressure protection of the RCS prior to a controlled cooldown and depressurization is provided by the pressurizer safety valves. During cooldown from Mode 3 hot standby (above 350°F) to Mode 4 hot shutdown (below 350°F), pressure control may be by pressurizer heaters or by varying pressurizer level in combination with control of SG pressure and RCS temperature using SG power operated relief valves (PORVs). Pressure is reduced by discharging to the pressurizer relief tank (PRT) using either the reactor coolant (pressurizer) PORVs or reactor head vent valves. To ensure adequate RCS pressure and adequate subcooling margin, the operator isolates pressurizer spray valves, or trips the RCPs to limit depressurization, and isolate the pressurizer auxiliary spray. Entering Mode 4 permits aligning the RHR system to the RCS for decay heat removal. While on RHR, the maximum pressures in both the RHR and RCS systems are limited by the RHR system safety valves.

The specific combinations of systems used are identified in Part VI under the safe shutdown analysis discussion for each plant location.

3.4.4 Reactor Heat Removal

Following a reactor trip with loss of off-site power (either assumed or caused by the fire), decay heat is initially removed by natural circulation within the RCS, heat transfer to the main steam system via the steam generators, and operation of the steam generator PORVs or lift of the main steam system code safety valves.

For decay heat removal via natural circulation a minimum of two steam generators are available. Decay heat removal requires the ability to supply sufficient auxiliary feedwater to the steam generators to make up for the inventory discharged as steam by the safety valves or steam generator PORVs. For maintenance of initial hot standby conditions, the required

PART III – SAFE SHUTDOWN CAPABILITIES

feedwater flow to the steam generators is supplied by the auxiliary feedwater (AFW) system. AFW sources are available from the condensate storage tanks, and alternatively, from the ERCW system. AFW may be supplied to the steam generators by the motor-driven AFW pumps or by the turbine-driven AFW pump. Continued heat removal is achieved by the controlled operation of the PORVs and continued operation of the AFW system. After reduction of RCS temperature to 350°F, the RHR system is used to establish long-term core cooling by the removal of decay heat from the RCS to the environment via the RHR, CCS, and ERCW systems.

3.4.5 Process Monitoring Instrumentation

The operator requires knowledge of various plant parameters to perform required system transitions and essential operator actions. A discussion by safe shutdown function of the necessary instrumentation is provided below.

For the fire scenarios assumed in this analysis, inventory makeup to the RCS is from the RWST through the RCP seal injection lines. As previously discussed, sufficient negative reactivity exists in the RCS (after rod insertion) for over eight hours without the need for additional boron. Furthermore, the negative reactivity inserted by the control rods and borated water injected by the CVCS (to compensate for the RCS volume decrease) maintains the core subcritical while cooling down from hot full power to a cold shutdown condition, even assuming no letdown is available. Sufficient boron is added to the primary system in a timely manner via charging of borated water through the seals to achieve the necessary cold shutdown reactivity margin. With boron concentration in the Volume Control Tank (VCT) and RWST under procedural control, no operator actions are required based on direct-reading neutron monitoring to ensure an adequate safe shutdown negative reactivity margin. However, core source range detectors are available for core reactivity monitoring in the MCR or local station. An additional source range channel indicator is available in the Auxiliary Control Room (ACR) to provide this information for fires in control building areas requiring alternative shutdown.

Various process monitoring functions must be available to adequately achieve and maintain the reactor coolant makeup, pressure control and decay heat removal functions. For the assumed fire scenario, maintenance of hot standby requires that pressurizer level and RCS pressure instrumentation are available. RCS temperature is maintained during hot standby by proper decay heat removal via steam generators using the steam generator PORVs. When the reactor coolant pumps are tripped and cooling is required in the natural circulation mode of operation, the difference between the hot-leg and cold-leg wide range temperatures ($T_h - T_c$) provide indication of the existence of a natural circulation condition.

RCS hot and cold leg temperature instrumentation is available for use given a fire that does not require MCR abandonment. For alternative shutdown, SG pressure instrumentation is required in order to provide a means of determining RCS cold-leg temperature from the ACR. (Refer to Part VII for the deviation request associated with T_{sat} in lieu of direct indication of T_c in the ACR.) During RCS cooldown, SG pressure is controlled to maintain desired RCS temperature by manual control of the SG PORV if control from the MCR is unavailable.

Operating personnel maintain RCS pressure to assure that appropriate subcooling margin is achieved by monitoring of RCS pressure and hot leg temperature (T_h) instrumentation. Manual control of the pressurizer heaters may be used if available, but is not required for safe shutdown. Pressurizer level control is maintained by monitoring pressurizer level instrumentation and manual control of CVCS charging flow through the RCP seals.

PART III – SAFE SHUTDOWN CAPABILITIES

The above methods of controlling primary system parameters by means of the secondary system require monitoring secondary system parameters. Steam generator level and pressure indicators are available to assure adequate and controlled decay heat removal. Steam generator level is controlled by operator manipulation (either from the MCR or locally) of AFW system flow based on steam generator wide range level indication or AFW system flow and steam generator narrow range level indications. Use of AFW flow indication and narrow range level indication for monitoring SG inventory is consistent with analyses for FSAR Chapter 15 design basis events. Secondary system pressure is monitored by steam generator pressure indication.

The plant operators utilize the instrumentation discussed above for monitoring natural circulation conditions, subcooling margin, heat removal and compliance with the RCS low temperature pressure/temperature limits (minimum cold leg temperature for a given RCS pressure).

3.5 Support Functions

The support functions for various safe shutdown equipment or systems are provided by the following systems:

- (1) Emergency Power Distribution System
- (2) Offsite Power System
- (3) Essential Raw Cooling Water System
- (4) Component Cooling Water System
- (5) Ventilation to areas containing essential fire safe shutdown equipment
- (6) Main Control Room chillers and ventilation

The following sections discuss the required safe shutdown systems and support systems.

4.0 SAFE SHUTDOWN SYSTEMS

4.1 Chemical and Volume Control System (CVCS) - Keys 1A, 2, 4, 5, 9

The charging portion of the CVCS accomplishes the following safe shutdown functions:

- (1) Reactivity control by injection of boron into the RCS
- (2) Reactor coolant makeup control by maintaining seal water injection to the RCS
- (3) Maintenance of reactor coolant pump seal integrity

Reactivity control for safe shutdown is provided by the control rods, with boron injection used to compensate for the xenon decay and positive reactivity insertion due to cooldown. Insertion of the control and shutdown rod groups make the reactor adequately subcritical following trip from any credible operation condition to the hot zero power condition, even assuming the most reactive rod remains in the fully withdrawn position.

PART III – SAFE SHUTDOWN CAPABILITIES

For the assumed post-fire scenario, makeup water to the RCS is provided by the CVCS from the RWST. When the unit is at power, the concentration of boron in the RWST exceeds that quantity required to bring the reactor from an initial hot standby condition to hot shutdown and then to cold shutdown, assuming that the only volume injected is that required to make up for reactor water volume decrease due to cooling. Letdown, which permits adding more borated water, is not necessary to achieve adequate boron concentration for cold shutdown reactivity margin.

Numerous CVCS paths are normally available for charging to the RCS. The flow path that is used to provide reactor coolant makeup and boration is the charging line to the reactor coolant pump seals. This path is available by ensuring that at least one of the charging pumps is operable and charging flow control valve remains open.

For the assumed event, charging and boration is accomplished by operating a minimum of one centrifugal charging pump taking suction from the RWST and injecting borated water through the RCP seal injection line to the RCS. Suction to the charging pump can be delivered from the RWST by opening either one of two normally closed motor-operated valves.

Controlled leakage (letdown) from the RCS normally occurs via the seal leak-off return path and the normal and excess letdown paths. For the post-fire operational scenario, the normal and excess letdown paths are isolated. Isolation of the normal and excess letdown lines may occur as a result of loss of instrument air or is achieved by operator action to assure adequate inventory control. Procedural controls for isolation of all potentially spurious RCS letdown paths, including pressurizer PORVs and reactor head vents, provide assurance that isolation of normal and excess letdown paths is achieved.

The injection path from the charging pumps to the reactor coolant pump seals contains the charging flow control valve (normally open) which is provided with a minimum-flow pneumatic stop. Thus, operation of one charging pump ensures availability of minimum RCS charging flow. In the event of failure of the pneumatic stop and complete cutoff of injection path flow, thermal barrier cooling (Key 9) is credited to assure seal integrity until charging is reestablished. Thermal barrier cooling ensures that the RCP seal integrity is maintained. No boron injection is required during this period.

Isolation of the VCT by closure of either one of two motor-operated valves during emergency makeup from the RWST can be performed either remotely or by local manual operation. The VCT is isolated to prevent introduction of H₂ cover gas into the centrifugal charging pump (CCP) suction in the event of VCT drainage.

Pressurizer water level is maintained by operation of one centrifugal charging pump using pressurizer level instrumentation information.

4.1.1 Centrifugal Charging Pumps - Key 1A

The two high-head centrifugal charging pumps (per unit) are normally aligned for the CVCS charging function. During design basis accidents, they are part of the Emergency Core Cooling System (ECCS). The centrifugal charging pumps are of the horizontal multistage type with a design flow rate of 150 gpm at 5800 feet total dynamic head. Each pump is designed to provide rated flow against a pressure equal to the sum of the RCS normal maximum pressure (existing when the pressurizer PORV is operating) and the piping, valve and equipment pressure losses

PART III – SAFE SHUTDOWN CAPABILITIES

at the design charging flows. Each of the centrifugal charging pumps has a motor-operated minimum re-circulation flow valve to prevent damage to the pump when it is operating at shut-off pressure. The pumps require cooling water from the CCS to their mechanical-seal heat exchangers, gear oil coolers, bearing oil coolers and seal housings.

4.1.2 Refueling Water Storage Tank - Key 5

In addition to its normal duty to supply borated water to the refueling cavity for refueling operations, the RWST provides borated water to ECCS pumps for cooling and to provide shutdown margin.

The capacity of the refueling water storage tank (one per unit) is based on the requirement for filling the refueling cavity. This quantity is in excess of that required for safe shutdown. The Technical Specification requirement for the volume of the RWST is 370,000 gallons of borated water at a minimum concentration of 2000 ppm boron.

4.2 Reactor Coolant System - Keys 7, 8, 28, 48

The RCS consists of four similar heat transfer loops (per unit) connected in parallel to the reactor vessel. Each loop contains a reactor coolant pump and a steam generator. In addition, the system includes a pressurizer with associated code safety and power-operated relief valves (PORVs). RCS instrumentation includes cold-leg and hot-leg temperatures (wide range), pressure (wide range), and pressurizer water level.

The natural circulation capability of the plant provides a means of decay heat removal when the reactor coolant pumps are unavailable. Natural circulation flow rates are governed by the amount of decay heat, relative component elevations, primary to secondary heat transfer, loop flow resistance, steam generator and RCS inventories, and any RCS voiding. These conditions determine whether adequate primary to secondary heat transfer and subcooling during natural circulation can be maintained.

For this analysis of safe shutdown capability, two of the four RCS loops (for which steam generator level and pressure are controlled) are available to ensure that natural circulation is established and maintained.

While in natural circulation, adequate heat transfer and coolant flow are dependent on adequate inventory in both the primary and secondary systems. Maintaining water level above the "U" tubes on the secondary side of the steam generators and adequate level within the pressurizer are required for natural circulation. RCS loop temperatures confirm flow and heat transfer while in natural circulation. Cold-leg temperature (T_c) should drop to a few degrees higher than the saturation temperature of the secondary inventory. Hot-leg temperature (T_h) should reach a value which is less than at full power but higher than T_c .

RCS inventory control is based on the operation of CVCS charging paths. High pressure seal water from the CVCS system is injected into the reactor coolant pumps lower radial bearing chamber to prevent leakage of high temperature reactor coolant along the pump shaft. The injection flow splits in the bearing chamber with a portion flowing up through the radial bearing and into the shaft seal chamber. The remaining portion flows down the shaft, through the RCP thermal barrier and into the RCS. For added operational flexibility in certain post-fire scenarios, RCP thermal barrier cooling provided by CCS is available for safe shutdown. Maintenance of either seal injection or thermal barrier cooling provides adequate protection of the RCP seals.

PART III – SAFE SHUTDOWN CAPABILITIES

4.2.1 Pressurizer Heaters

The pressurizer heaters are not required to operate for safe shutdown. Alternate means of controlling RCS pressure are credited in the WBN Appendix R analysis. (Refer to Calculation WBN-OSG4-031 for details.) However, should the pressurizer heaters be available, subcooling within the RCS can be maintained by controlled operation of the pressurizer heaters. The availability of pressurizer heaters has been analyzed to enhance the capability of controlling RCS pressure and subcooling margin. The locations where pressurizer heaters are available are documented in Part VI of the FPR. The heat from one pressurizer heater conservatively covers heat losses from the pressurizer at or below normal operating temperature and pressure.

4.3 Main Steam Systems - Keys 20, 21, 22, 24, 25, 26

For the post-fire scenario, maintenance of the steam generator inventory and control of steam generator pressure are required for both hot standby and subsequent primary system cooldown to support the decay and sensible heat removal function, within the applicable operational limits, until initiation of RHR to bring the affected unit to cold shutdown.

The main steam (MS) system for each unit consists of four parallel flow paths, one from each steam generator to the main turbine of the unit. The MS system is isolated either by operation of the turbine stop and control, dump, reheat, feed turbine stop and control, and gland steam valves; or by the main steam isolation valves.

In accordance with supporting analyses, inventory control of two steam generators provides the reactor heat removal function during natural circulation conditions. Maintenance of the steam generator water level during the period of AFW operation (hot standby) involves either MCR operator or local manual positioning of the AFW level control valves and operation of the motor-driven or turbine-driven AFW pumps based on steam generator level information. Steam generator water level and pressure indication are available in the MCR and in the ACR.

The MS system also delivers motive steam to the turbine-driven AFW pump. Steam to the turbine is supplied by branch connections upstream of the main steam isolation valves on two steam lines (corresponding to steam generators No. 1 and 4). Either line is sufficient to supply steam for the AFW pump turbine, however, credit is only taken for steam supply from steam generator No. 1.

4.3.1 Steam Generator Power - Operated Relief Valves

A power-operated relief valve (PORV) provided on each steam line is capable of releasing the sensible and decay heat to the atmosphere. The PORVs are used for plant cooldown by steam discharge to the atmosphere since the steam dump system is assumed to be unavailable. The PORVs have a total combined capacity of approximately 10% of the maximum steam flow. For the assumed fire scenario, a minimum of two PORVs are available to support controlled cooldown of the RCS.

Controls for the steam generator PORVs are provided in the MCR and locally at the shutdown stations. During hot standby conditions, the steam generator PORVs are used in MCR modular mode or manual steam pressure control mode. In this mode, the RCS temperature is controlled by maintaining the steam generator at the corresponding saturation pressure.

PART III – SAFE SHUTDOWN CAPABILITIES

4.4 Auxiliary Feedwater System - Keys 11, 12, 14, 16, 17, 19

The AFW system is required during hot standby to support RCS decay heat removal. For hot standby, secondary system (steam generator) inventory control is provided by the AFW system. Two motor-driven pumps and one turbine-driven pump are provided to each unit. Each motor-driven pump is rated at 450 gpm at a nominal 3270 feet total dynamic head. The turbine-driven pump is rated at 790 gpm at 3350 feet total dynamic head. The pumps have the design capability to provide the rated flow, less bypass, against the lowest steam generator safety valve setpoint plus 3% accumulation and 3% set error.

The AFW system is designed to deliver enough water to maintain sufficient heat transfer in the steam generators in order to prevent loss of primary water through the RCS pressurizer safety or relief valves.

4.4.1 Turbine-Driven Auxiliary Feedwater Pump

The turbine-driven AFW pump (one per unit) is designed to deliver a sufficient flow to all four steam generators and maintain steam generator water levels at the lower limit of the wide range level indicator. The pump is a horizontal, six-stage, centrifugal pump driven by a single-stage atmospheric exhaust turbine. During automatic operation the turbine speed, and therefore capacity, are governed by pump flow. The turbine is provided with automatic speed control that ensures a minimum of 720 gpm. Manual speed control is also provided to enable the operator to control speed from 2076 rpm to 3950 rpm. Use of the speed control in combination with manual operation of the level control valves (LCVs) allows the operator to control the flow from 0 to 720 gpm. Two overspeed trip devices are provided. The electrical overspeed trip resets automatically. The higher mechanical overspeed trip device must be reset manually.

The AFW pump turbine lube oil system uses a pump driven from the turbine shaft. Water for the turbine oil cooler and pump bearing cooler is supplied from the AFW pump discharge line. Lube and control oil and lube oil cooling are therefore available whenever the AFW pump turbine is operating.

Steam generators No. 1 and/or 4 provide motive steam to the turbine-driven AFW pump. However, only the steam supply from steam generator No. 1 is credited for safe shutdown. The turbine-driven AFW pump is capable of operating down to a steam pressure of 115 psia, which is below the pressure at which the RHR system must be placed in service.

4.4.2 Motor-Driven Auxiliary Feedwater Pumps

WBN is supplied with two motor-driven AFW pumps per unit with only one per unit required for safe shutdown. Pump A supplies SGs 1 and 2 and Pump B supplies SGs 3 and 4. Each pump is a horizontal, nine-stage centrifugal pump. Bearings are cooled by water from the first stage. A separate motor-driven oil pump is provided for motor bearings. Pump bearings use ring oilers. The pumps require no external lube oil cooling or other support services other than AC power.

4.4.3 Condensate Storage Tank

Each unit is provided a Condensate Storage Tank (CST). At hot standby, the minimum volume of water required by the WBN Technical Specification for each CST is 200,000 gallons. The CST is normally aligned to the supply for the AFW pumps. As a backup, cross-ties to the AFW

PART III – SAFE SHUTDOWN CAPABILITIES

supply from the ERCW system are provided. Ample time is available post-fire for a local manual realignment of the supply to the AFW pumps from CST to ERCW.

4.5 Residual Heat Removal System - Keys 30, 31

The RHR system is designed to remove residual and sensible heat from the core by reducing the temperature of the RCS during the hot and cold shutdown phases of safe shutdown. The following discussion is applicable for each unit.

The RHR system for each unit consists of two RHR heat exchangers, two RHR pumps and associated piping, valving and instrumentation necessary for operational control. The design residual heat load is based on the residual heat fraction of the full core MW (thermal) power level that exists 20 hours following reactor shutdown from an extended power run near full power.

During cold shutdown operations, reactor coolant flows from the RCS to the RHR pumps through the tube side of the RHR heat exchangers and back to the RCS. The heat load is transferred to CCS on the shell side.

Four motor-operated valves isolate the inlet line to the RHR system from the RCS. The four valves are arranged in an "H" Configuration, with pairs of parallel valves in series. To avoid potential RCS boundary leakage at this high/low pressure interface, all four of the motor-operated valves in the RHR suction line are kept closed (pre-fire condition) with the corresponding motor control center breaker in the open position. The return lines are isolated by two series check valves in each line and a common motor-operated valve.

A minimum-flow return line from the downstream side of each RHR heat exchanger to the corresponding pump's suction line is provided to assure that the RHR pumps do not overheat under low flow conditions. A motor-operated valve located in each minimum flow line is opened if RHR pump flow falls below 250 gpm and is closed when the flow increases above 1100 gpm.

The cooldown rate of the reactor coolant is controlled by regulating the flow through the tube side of the RHR heat exchangers. A bypass line, which serves both residual heat exchangers, is used to regulate the temperature of the return flow to the RCS as well as to maintain a constant flow through the RHR system.

The RHR system can be placed in operation when the pressure and temperature of the RCS are about 400 psig and 350°F, respectively. If one of the pumps and/or one of the heat exchangers is not operable, safe operation of the plant is not affected; however, the time for cooldown is extended.

4.5.1 Residual Heat Removal Pumps

Two identical pumps per unit are installed in the RHR system. Each pump is sized to deliver sufficient reactor coolant flow through the residual heat exchangers to meet the unit's cooldown requirements. A seal heat exchanger for each pump is supported by operation of the CCS.

PART III – SAFE SHUTDOWN CAPABILITIES

4.5.2 RHR Safety Valves

The RHR system safety valves provide RCS cold overpressure protection whenever the RHR system is in operation. The valves are located inside containment, one each on the RHR system suction and discharge path, and discharge to the pressurizer relief tank. The valves are set at 450 psig and 600 psig, respectively.

4.6 Safety Injection System Accumulators - Key 36

During normal plant operating conditions, the safety injection system accumulators are pressurized by nitrogen gas in order to inject borated water in the RCS when RCS pressure falls below 600 psi unintentionally. During a controlled depressurization, the accumulators are isolated to prevent injection of safety injection system accumulator borated water. However, if the isolation valves remain open, the borated water is injected and nitrogen pressure decreases due to the increased empty volume of the accumulators. Injection of nitrogen into the RCS occurs when RCS pressure is less than 150 psi.

The manual isolation of the accumulators is assumed as a post-fire activity. The isolation valve at each accumulator is closed only when the RCS is intentionally depressurized below 1000 psig. If the cables associated with these valves were damaged by fire, isolation is performed locally per appropriate plant procedures (post-fire). In the event the valves are inaccessible, RCS pressure is maintained greater than 150 psi to preclude nitrogen injection into the RCS via the accumulators.

4.7 Component Cooling System (CCS) - Key 1B

CCS is a supporting system to other safe shutdown systems. Two redundant trains per unit are available. For each unit, Train A consists of two available pumps (pumps 1A-A and 1B-B for Unit 1 and pumps 2A-A and 2B-B for Unit 2) and the associated valves, piping, instrumentation and heat exchanger (Heat Exchanger A for Unit 1 and Heat Exchanger B for Unit 2). Train B is common for both units and consists of one pump (pump C-S) and the associated valves, piping, instrumentation and heat exchanger (Heat Exchanger C). Each unit has a Train A pump (1A-A for Unit 1 and 2A-A for Unit 2) which receives electrical power from Train A. Each unit also has a Train A pump (1B-B for Unit 1 and 2B-B for Unit 2) which receives electrical power from Train B. These pumps are normally aligned to the Train A piping system for that unit but can be aligned to the common Train B piping system. The C-S pump, which normally receives Train B electrical power while serving as the common Train B CCS pump, is capable of being powered from a Train A power source.

The CCS system serves as an intermediate heat transfer loop between the various safe shutdown components and the ERCW system (ultimate heat sink).

The CCS system provides cooling for the following safe shutdown equipment per unit:

- (1) Residual heat removal exchangers
- (2) Centrifugal charging pumps
 - (a) Mechanical-seal heat exchangers
 - (b) Gear oil coolers
 - (c) Bearing oil coolers
 - (d) Seal housing

PART III – SAFE SHUTDOWN CAPABILITIES

- (3) Residual heat removal pumps mechanical-seal heat exchangers
- (4) Reactor coolant pump thermal barrier heat exchanger (Train A only)
- (5) Spent fuel pool cooling system heat exchanger (Train A only)
- (6) Chemical volume control system seal water heat exchanger (Train A only)

One CCS pump and its associated CCS heat exchanger fulfill the heat removal function of a unit during normal full-load operation for various components located in the auxiliary and reactor buildings. During normal unit cooldown in RHR mode, two CCS trains (i.e., that unit's Train A and the common Train B) are utilized to remove the residual heat. If only one train is used, cooldown is at a lower rate. Both units are not typically cooled from hot standby to cold shutdown at the same time.

Other than the RHR heat exchangers, the essential loads are normally valved open to the supply header and discharge to the suction of the CCS pump with which they are normally associated, so that component cooling water is circulated continuously through the essential loads during normal operation.

The CCS outlet lines from each unit's Train A RHR heat exchangers (one per unit) have a normally closed motor-operated valve which must be opened during RHR cooldown. The CCS outlet lines (one per unit) from the Train B RHR heat exchanger have throttleable motor-operated valves. The valve for the unit undergoing cooldown must be open during RHR cooldown and the other unit's valve must be closed. The motor-operated valves that isolate the RCP thermal barrier coolers (Train A only) are included as safe shutdown components for operational flexibility in a post-fire scenario, since the thermal barriers may be required to perform a redundant function to RCP seal injection cooling.

4.8 Essential Raw Cooling Water System - Key 1C

The ERCW system provides cooling for the following safe shutdown heat transfer equipment:

- (1) Component cooling heat exchangers
- (2) Emergency diesel generator heat exchangers
- (3) Essential ventilation coolers and water chillers
- (4) Auxiliary control air compressors

The system also provides a back-up supply of water to the AFW system in the event that the condensate storage tank is depleted.

This system consists of four traveling water screens and their wash pumps, eight pumps, four discharge strainers, and four main headers (1A, 1B, 2A, and 2B). These components, together with the associated heat exchangers, valves, piping and local instrumentation, complete the ERCW system.

The ERCW system can remove the heat transferred to CCS, plus the heat loads of the emergency diesel generator engine (EDG) coolers (i.e., the air aftercoolers, lubricating oil cooler, and jacket water cooler), auxiliary control air compressors and essential ventilation coolers and water chillers, and provide makeup flow to the turbine and motor-driven AFW pumps.

PART III – SAFE SHUTDOWN CAPABILITIES

The four Train A ERCW pumps are installed in a portion of the intake pumping station separate from the Train B pumps. The Train A pumps supply ERCW to two Train A ERCW headers (i.e., 1A and 2A). Interlocks exist to preclude starting more than one ERCW pump on a single diesel generator. One ERCW pump is sufficient to carry the heat load of one unit during normal operation or hot standby conditions. Normal ERCW alignment is for Train A ERCW header 2A to provide cooling to both unit's Train A CCS heat exchangers which utilize two Train A ERCW pumps. Three pumps (two Train A and one Train B) are normally used to carry the dual unit heat removal duties of the system during RHR cooldown of a unit. Local manual operation of motor-operated valves and strainers is credited post-fire. Train B pumps and headers are arranged similar to the Train A configuration.

4.9 Essential HVAC - Keys 37A, 37C, 37J, 37K, and 37O

Essential HVAC is provided for the control, auxiliary, diesel generator, and reactor buildings. Portions of the systems in each building that service safe shutdown equipment required for compliance with Appendix R have been analyzed to ensure that at least one path of the required systems is available for an Appendix R fire. The systems consist of filters, fans, ductwork, dampers, heating/cooling coils, instrumentation, and controls for general building ventilation, along with separate systems for individual rooms. The required systems, components, and cables for those subsystems relied on to protect equipment for safe shutdown have been incorporated into the Appendix R analysis as required equipment and cables. The location of equipment and routing of cables has been identified and evaluated as described in Sections 5 and 6 of this Part. These systems are discussed below.

The primary safety-related portions of the control building are cooled by two independent trains of HVAC. The two trains are separated by fire barriers and/or separation distance in accordance with Appendix R requirements to ensure that the control building HVAC system remains functional during a fire. The entire control building HVAC system is separate from the HVAC system servicing the ACR.

The auxiliary building HVAC system is required to achieve and maintain hot standby. Specifically, HVAC is required for the 480V transformer rooms and for the general floor area on the 713' elevation to support the use of the motor-driven auxiliary feedwater (MDAFW) and CCS pumps. Individual room coolers are also required for the CCP and RHR pumps and are addressed in the equipment logics for their respective systems (Keys 1A and 31).

The turbine-driven auxiliary feedwater (TDAFW) pump room is provided with a DC operated exhaust fan sized (1200 CFM +/-10%) to provide required air flow in the room for the volume method of cooling. The fan is a roof ventilator type with intake and venting to the general area of the auxiliary building. The fan automatically starts upon the start of the TDAFW pump. The fan is addressed in the TDAFW pump equipment logic (Key 14).

The diesel generator HVAC systems serve each combination of diesel generator and associated batteries and electrical boards. The diesel generator building HVAC system consists of various subsystems. The subsystems for each combination include diesel generator room HVAC subsystems, generator and electrical panel subsystems, battery hood exhaust subsystems, electric board room exhaust and heating subsystems, and muffler room exhaust systems. A fire in any combination of diesel generator and associated batteries and electrical boards, which are separate fire areas, will not affect the HVAC systems servicing the adjacent combinations of diesel generator and associated batteries and electrical boards.

PART III – SAFE SHUTDOWN CAPABILITIES

The containment air cooling systems are designed to maintain acceptable temperatures within the upper and lower compartments, CRDM shroud, and instrument room for the protection of controls. Each unit's lower compartment cooling (LCC) system consists of (4) 33-1/3% fan coil assemblies. Each unit's CRDM cooling system consists of (4) 50% fan coil assemblies combined into two subsystems, with one fan coil assembly in each subsystem normally operating. Each unit's containment air cooling is evaluated to ensure either 3 out of 4 LCC fan coil assemblies, or 2 out of 4 LCC/CRDM pairs of fan coil assemblies, are available for Appendix R fire scenarios.

All other areas of the plant which contain equipment required for safe shutdown per Appendix R have been evaluated and determined that acceptable temperatures are maintained for the required equipment to perform its intended function if HVAC is lost.

4.10 Onsite Power System - Key 38

The plant Emergency Power System (EPS) includes on-site, independent, automatically-starting emergency power sources that supply power to essential safe shutdown equipment if the normal off-site power sources are unavailable.

The emergency power sources consist of four 6.9kV diesel generators. Each consists of a single generator driven by two engines on a common shaft. Each diesel engine is equipped with its own auxiliaries. These include starting air, fuel oil, lube oil, cooling water, intake and exhaust system, speed regulator (governor) and controls. Cooling water is provided from the ERCW system while electric power for each engine's auxiliaries is provided by its own generator. The governors for each pair of engines are electrically linked.

4.10.1 6.9KV Shutdown Power System

Each of the four 6.9kV shutdown boards is normally fed from 161kV/6.9kV Common Station Service Transformers (CSSTs) that receive power from offsite sources. In addition, upon loss of the normal CSST, the 6.9kV boards transfer the power source to another CSST.

Each of four 6.9kV shutdown boards can also be fed from the corresponding 6.9kV diesel generator. Loss of offsite power to the 6.9kV boards is sensed by undervoltage relays. Upon sensing an undervoltage, the master relay(s) automatically start the emergency diesel generators, trip the normal feed switchgear breakers and trip all motor feeder breakers on the boards. The emergency diesel generators can also be manually started locally, from the MCR, or from the ACR. For shutdown scenarios that do not require MCR abandonment, a switchgear breaker on each board is automatically closed when its diesel generator is at rated speed and rated voltage and re-energizes the bus. The essential loads are sequentially connected to the bus. For shutdown scenarios from the ACR, breaker closure and diesel generator loading is done manually. The emergency diesel generators then supply all equipment which must operate under emergency conditions for the respective safeguard train.

4.10.2 480V AC Shutdown Power System

The 480V power system distributes power for low voltage station service demands. The normal source of power is the 6.9kV shutdown boards via the 6.9kV/480V transformers.

PART III – SAFE SHUTDOWN CAPABILITIES

The 480V power system consists of eight boards, two per unit per train. Each 480V board is fed from the associated unit/train 6.9kV board through the normal or spare 6.9kV/480V transformers. There are a total of eight normal and four spare transformers, with each spare transformer able to feed either of the two boards of the same train/unit. The 480V shutdown boards feed 480V loads and various motor control centers (MCCs). The MCCs in turn feed various motor operated valves and other loads required for safe shutdown. Each MCC has a normal and alternate power source that can be utilized when needed for equipment maintenance.

4.10.3 120V AC Vital Instrument Power System

The 120V AC Vital Instrument Power System consists of four separate vital boards per unit. Each 120V AC Vital Bus is supplied by an independent inverter. Each station battery supplies two inverters (one per unit) of the same channel. Each channel also includes a normally de-energized spare inverter that can be energized and manually aligned to be an alternate supply to either Unit 1 or Unit 2 associated 120V AC vital bus. Each inverter is normally supplied by the 480V AC power system of the associated train (A for D or F and B for E or G) and can be supplied from the opposite trains via a manual transfer switch. In addition, the uninterrupted supply to each inverter is its respective 125V DC battery board via a static transfer switch scheme.

The output of each inverter is connected to its 120V AC vital instrument power board through a normally closed circuit breaker. The vital instrument power boards supply all of the required normal safe shutdown instrumentation per channel.

4.10.4 125V DC Power System

The 125V DC power system consists of four batteries, four normal chargers, two spare chargers, and four main DC battery boards. The 125V dc power system supplies power for control of 6.9kV/480V shutdown boards, operation of vital inverters, pneumatic-operated, solenoid controlled valves, and MCR emergency lights. The battery system consists of four separately located sets of batteries powering four channels of DC boards. Each normal vital battery has its own normal charger. Each vital battery board can also be supplied from one of two spare chargers. The battery chargers are energized from normal or alternate MCCs via a manual transfer switch. A fifth vital battery may be used as an installed spare and can be placed into service in place of any of the four normal vital batteries. The fifth vital battery is maintained by its own charger until connected to one of the normal vital battery boards.

During normal operation, the 125V DC loads are fed from the battery chargers, with the batteries being supplied a "trickle" charge floating on the system. Upon loss of ac power, the entire DC load is drawn from the batteries. The batteries are credited for two hours of operation after a loss of charging, predicated upon the continued operation of DC emergency equipment. However, the battery chargers can be manually aligned to alternate power sources to take over the load and recharge their associated battery.

All direct current loads associated with engineered safeguards equipment are fully redundant. These loads are arranged so that each battery supplies its associated redundant channel.

PART III – SAFE SHUTDOWN CAPABILITIES

4.10.5 250V DC Power System

The 250V DC power system consists of two batteries, two normal chargers, two spare chargers, and two 250V DC battery boards. Control power for start board power circuit breakers and associated protective relays is distributed from the 250V DC supply via circuit breakers on the turbine building DC distribution boards. The 250V DC power system provides power for non-safety-related loads and, for Appendix R fire scenarios, is used to operate steam load trip circuits and to provide capabilities to trip the RCPs.

4.11 Offsite Power System - Key 38A

The offsite power system evaluated for safe shutdown consists of CSSTs and common station service boards that provide power from the 161kV offsite power sources to the 6.9kV shutdown boards. Two CSSTs provide normal and alternate power to four 6.9kV shutdown boards. One CSST is the normal source for Train A shutdown boards and also supplies the alternate power to the Train B shutdown boards. The other CSST is the normal source for Train B shutdown boards and the alternate source to the Train A shutdown boards.

4.12 Containment Isolation - Key 10

In order to maintain the integrity of the containment boundary, it is necessary to ensure the capability to isolate all containment penetrations. The normal containment isolation requirements have been relaxed to be consistent with fire safe shutdown requirements and assumptions. Only one isolation boundary is necessary for each penetration and can consist of a check valve or a closed system on either side of the boundary regardless of the piping class. When penetrations are isolated only by electrically isolated valves, the valves were included as required FSSD components.

4.13 Reactor Trip - Key 29

A fire inside or outside of the control building may require the reactor trip to bring the plant to hot standby. Manual trip circuits for manual shutdown from the MCR are available for any fire except one that damages the reactor trip breakers. The RPS is not specifically protected from fire damage given the fail safe design of the RPS. Diversity of input signals could initiate a reactor trip, if required, before the trip is manually initiated. The reactor trip provides sufficient initial reactivity control. Long term reactivity control is accomplished by preventing boron dilution and assuring that injected makeup water is at least the boron concentration of the RWST.

4.14 Auxiliary Control Air System (ACAS) - Key 13

The ACAS provides essential air to the following fire safe shutdown equipment if the normal air supply system cannot maintain minimum system pressure:

- (1) Turbine/Motor-driven auxiliary feedwater level control valves (LCVs)
- (2) Motor-driven auxiliary feedwater pressure control valves (PCVs)
- (3) Steam generator power operated relief valves (SG PORVs)

PART III – SAFE SHUTDOWN CAPABILITIES

The ACAS is separated into two independent trains, one supplied from Train A power and the other supplied from Train B power. Each train consists of a compressor, receiver, dryer and filter. The system is supplied from two motor-driven, non-lubricated, compressors that are integral skid mounted assemblies. Relief valves are in place on the compressors and air receivers for overpressure protection. The ACAS automatically isolates from the non-essential control air system (CAS) on low pressure.

The ACAS air dryers normal operation is with one of the dual towers in the regeneration (purge) state and the other tower supplying the air loads. With the local hand switch in the automatic mode, the dryer is interlocked with the ACAS compressor such that when the compressor is running the ACAS dryer will operate continuously. The dryer cycle will continue to run after the associated compressor has stopped until the local hand switch is placed in the "stop" position. The dual air dryer towers are alternately regenerated (purged) and fully pressurized for service via cam-operated cycling valves controlled by adjustable timers in automatic mode. The dryer regeneration and pressurization cycle can be manually started with the local hand switch allowing operations periodically to change which dryer tower is "in-service" to preclude moisture saturation. This will be at significantly reduced periodicity than the cycle timer cycling. The dryer is designed such that in the event of electrical failure to the equipment, it will continue to dry air for 4 to 8 hours. The electrical circuit is designed with interlocks that prevents a purge exhaust valve and an inlet switching valve on the same side of the dryer to be open at the same time. This precludes loss of air from the system through the purge valve.

The ERCW system provides the source of cooling to the ACAS compressors, inter-coolers and after coolers.

5.0 IDENTIFICATION OF SAFE SHUTDOWN SYSTEM COMPONENTS

Section 4 described the specific systems which are used to achieve safe shutdown. This subsection discusses the WBN method of selection of safe shutdown components.

For each system, plant flow diagrams (P&IDs), system descriptions and one-line diagrams were used to identify the precise primary flow paths and operational characteristics that must be established to accomplish the desired safe shutdown function. From this information, a list was compiled of the components which participate in the system's performance of its safe shutdown function. These components are:

- (1) Active components that need to be powered to establish, or assist in establishing, the primary flow path and/or the system's operation;
- (2) Active components in the primary flow path that normally are in the proper position whose power loss will not result in a change of position, but may be affected by open, short, or ground faults in control or power cabling;
- (3) Power-operated components that need to change position to establish or assist in establishing the primary flow path, whose loss of electrical or air supplies result in the component adopting the required safe shutdown position but which may be affected by open, short or ground faults in control or power cabling; and
- (4) Major mechanical components that support safe shutdown.

PART III – SAFE SHUTDOWN CAPABILITIES

From the analysis of the safe shutdown system flow paths, those components whose spurious operation threatens safe shutdown system operability were also identified. This identification included those branch flow paths that must be isolated and remain isolated to assure that flow is not substantially diverted from the primary flow path. See Section 7 for the detailed discussion of spurious operations.

A list was generated for safe shutdown devices including device identification and operating requirements for the various shutdown Keys. The shutdown Keys were previously identified in Section 4 and Table 3-1.

The safe shutdown equipment list (SSEL) for WBN is the equipment necessary to safely shut down the affected unit or units. For reasons of operational flexibility, equipment such as pressurizer heater availability for RCS pressure control was identified in Sections 3 and 4. Optional components are not required for safe shutdown; however, they are included in the safe shutdown equipment list and in the safe shutdown interaction calculation.

The safe shutdown equipment list developed for WBN includes the components required to protect the safe shutdown capability from the exposure fire damage postulated in Appendix R. The safe shutdown equipment list is provided as Table 3-2.

6.0 IDENTIFICATION OF SAFE SHUTDOWN CIRCUITS AND CABLES

The equipment list developed during the WBN safe shutdown system analysis was the basic input for the identification of electrical circuits essential to ensure adequate equipment performance. Essential safe shutdown electrical circuits were identified for all the electrically-dependent devices in Table 3-2. However, for some equipment, either a subset of cables or no cables were identified. For example, cables were not selected for valves where local manual operation is required during cooldown and nitrogen bottle control stations are used for AFW flow control. The circuits identified included power, control, and instrumentation. Type II associated circuits as addressed in Section 7 were also treated as required circuits.

The identification and analysis of these essential electrical circuits was based on one-line diagrams, schematics, and wiring diagrams from which the necessary circuit cables were selected for the subsequent cable routing and separation analysis. Circuit evaluation and identification considers equipment operability requirements. Circuits are identified for active and passive equipment. Circuit identification for high/low pressure boundary components considered the possibility of more conservative cable faults (e.g., 3 phase to 3 phase faults).

For each electrical component, circuits and cables were identified (1) which are required for safe shutdown to ensure operability or (2) failure of which is detrimental. The circuits not included per the above criteria included annunciator, computer, motor stator heaters and external monitoring circuits. Those circuits which are electrically isolated from the electrical circuits of concern, or whose failure does not affect operability, were not included in the separation analysis.

WBN utilizes Distributed Control Systems (DCS) for Non Safety Related Control Systems. Each unit's DCS is interconnected via fiber optic networks but is isolated from the other unit. Unit 1 has one DCS network which is located totally in the control building Auxiliary Instrument Room (AIR). The Unit 2 DCS is segmented into two Virtual Local Area Networks (VLANs) with one segment in the Auxiliary Control Room (ACR) and one in the control building Auxiliary Instrument Room. The network in the ACR is for monitoring and maintenance purposes only

PART III – SAFE SHUTDOWN CAPABILITIES

and the controls function independent of the network. In order to allow monitoring by the DCS Work Station, the ACR and AIR network segments are interconnected via a network switch which is configured to inhibit data transfer between each segment. This prevents a failure of one network segment (i.e., ACR network) from affecting the other segment (i.e., AIR network) and vice versa. Data packet rate from the ACR network is also limited to provide redundant assurance that data transmission cannot impede communications in the AIR segment. This isolation between the ACR and AIR, ensures that no event arising from equipment failures, such as caused by a fire, can inhibit DCS equipment outside that fire zone.

For each safe shutdown Key, cable block diagrams were developed for each safe shutdown component to identify cables required to ensure that the component can perform its safe shutdown function.

7.0 ASSOCIATED CIRCUITS OF CONCERN

7.1 Introduction

The separation and protection requirements of 10 CFR 50, Appendix R apply not only to safe shutdown circuits but also to "associated" circuits which could prevent operation or cause maloperation of shutdown systems and equipment. The identification of these associated circuits of concern was performed for WBN in accordance with NRC Generic Letter 81-12, the Staff's clarification to Generic Letter 81-12, and Generic Letter 86-10. The generic letters defined associated circuits of concern as those which have a physical separation less than that required by Section III.G of Appendix R, and have one of the following:

- | | |
|----------|--|
| Type I | A common power source with the shutdown equipment and the power source is not electrically protected from the circuit of concern by coordinated breakers, fuses, or similar devices; |
| Type II | A connection to circuits of equipment whose spurious operation would adversely affect the shutdown capability; |
| Type III | A common enclosure with the shutdown cables, and,
(1) are not electrically protected by circuit breakers, fuses or similar devices,
or
(2) will allow propagation of the fire into the common enclosure |

7.2 Associated Circuits by Common Power Supply and Common Enclosures

The electrical distribution system was reviewed to assure that Type I associated circuits by common power supply are addressed by providing selective protective trip coordination for all FSSD power supplies. Type III associated circuits by common enclosures were addressed by ensuring that all existing circuits in Category 1 buildings are electrically protected with a fuse or breaker that actuates prior to the jacket of existing faulted cables reaching their auto-ignition temperature. For new circuits, Type III associated circuit electrical fault protection is provided to ensure that the fuse or breaker operates prior to the temperature of the insulation reaching its insulation damage temperature.

Electrical circuit fault protection was originally designed to provide protection for plant electric circuits via protective relaying, circuit breakers and fuses. Protective equipment was designed and applied to ensure adequate protection of electrical distribution equipment, including cables, from electric faults and overload conditions in the circuits. The selection and application of these

PART III – SAFE SHUTDOWN CAPABILITIES

devices was in accordance with TVA design practices and is documented in engineering calculations. The protective equipment ensures that electrical faults and overloads do not result in any more cable degradation than is expected when operating conditions are below the set point of the protective equipment. This also limits cable damage and prevents cable faults from resulting in internal cable temperatures which could cause ignition of cable insulation.

An integral part of the original electric system protection was the proper coordination of these electrical protective devices. Such coordination assures that the protective device nearest (in an electrical sense) to the fault operates prior to the operation of any "upstream" protective devices, and provides interruption of electrical service to a minimum amount of equipment. The original electrical protection design at WBN required coordination of such electrical protective devices and is documented in engineering calculations. Electrical design practices ensures that no associated circuits of concern by common power supply (Type I) or by common enclosure (Type III) exist

7.3 Associated Circuits by Spurious Operation

Cables that are not part of safe shutdown circuits may be damaged by the effects of postulated fires. This cable damage may consequently prevent the correct operation of safe shutdown components, or result in the maloperation of equipment which directly prevents the proper performance of the safe shutdown systems. The effects of spurious operations may be conceptually divided into two subclasses as follows:

- (1) Maloperation of safe shutdown equipment due to control circuit electrical interlocks between safe shutdown circuits and other circuits; for example, the numerous safe shutdown equipment automatic operation interlocks from process control and instrument circuits.
- (2) Maloperation of equipment that is not defined as part of the safe shutdown systems, but that could prevent the accomplishment of a safe shutdown function; for example, inadvertent depressurization of the RCS or the MS system by spurious opening of boundary valves.

The evaluation of Appendix R events ensures that any failure of associated circuits of concern by spurious operation (Type II) does not prevent safe shutdown. Credible electrical faults considered in the analysis included open circuit, short circuit (conductor-to-conductor), short to ground, and cable-to-cable (hot-short) including 3-phase hot-shorts for high/low pressure interface valves. The analysis also considers that the normally ungrounded 125V DC power distribution system is grounded due to fire damage.

In order for cable faults that generate spurious operation to occur, the following conditions must exist synergistically at the cable fault location:

- (1) Sufficient energy must exist due to the fire to create failure of the cable jacket and insulating material;
- (2) The failure of the jacket and insulating material must occur in a way that directly exposes the cable conductors;
- (3) For each short circuit, two or more specific conductors must come into direct contact causing low impedance conductor-to-conductor connections;

PART III – SAFE SHUTDOWN CAPABILITIES

- (4) For certain types of spurious operation, multiple electrically independent shorts must occur;
- (5) No additional conductors that would cause circuit fault currents and operation of circuit protective devices may participate in the short condition; and
- (6) No ground faults that would cause operation of circuit protective devices must occur.

The spurious operation analysis performed for WBN recognized the extremely low probability of certain types of these faulted conditions. The following cable short conditions causing spurious operation were considered of sufficiently low likelihood that they were assumed not to require additional analysis or modification (unless it involves high-low pressure boundary interfaces):

CASE:

- (1) Three phase-AC power circuit cable-to-cable faults (6.9kV and 480V)
- (2) Two wire ungrounded-DC power circuit cable-to-cable faults (125V)
- (3) Two wire ungrounded-AC control circuit cable-to-cable faults (120V)

With respect to Cases (1), (2), and (3), no conductor-to-conductor faults within the same power cable can cause spurious powering of the associated device. Only power cable-to-cable connections between one de-energized and one energized power circuit could permit operation. For the case of the three-phase-AC circuit, three electrically independent cable-to-cable shorts must occur without grounds in order to power the associated device. Similarly, for the two-wire ungrounded DC power circuit, two electrically independent cable-to-cable shorts without grounds must occur. The likelihood of such occurrences has been acknowledged by the NRC Staff to be sufficiently low to permit excluding such faulted conditions from consideration except for high/low pressure boundary components. Therefore, for the above identified spurious operations caused by cable faults, only 3-phase hot-shorts for high/low pressure boundary interface valves have been incorporated into the analysis.

The fundamental basis of excluding the remaining shorts from consideration is based on the need for multiple cable-to-cable electrically independent faults in order for spurious operation to occur.

Concerning Case (2), all DC control circuits at WBN are ungrounded. In order for spurious operation to occur due to circuit-to-circuit faults between DC circuits supplied from different sources, at a minimum, two electrically independent cable-to-cable shorts without grounds must occur.

For the ungrounded AC control circuits in Case (3), the identical consideration exists. Most MCC transformer secondary 120V AC control circuits are ungrounded. Therefore, at a minimum, two cable-to-cable shorts must simultaneously occur in order for spurious operation to result for circuits supplied from different sources.

PART III – SAFE SHUTDOWN CAPABILITIES

7.4 Multiple High Impedance Faults

Multiple High Impedance Faults (MHIFs) are considered in accordance with Appendix B.1 to NEI-00-01 (Part II, reference 4.3.12) as endorsed by RG 1.189 revision 2 (Part II, reference 4.1.26) which establishes a base case analysis demonstrating that the probability of MHIFs is sufficiently low such that they do not pose a credible risk to post-fire safe shutdown when certain criteria are met. Those criteria are requirements which establish applicability of the base case to individual plant designs. The Watts Bar electrical power supplies relied upon for motive and control power for safe shutdown equipment that must operate for FSSD comply with those requirements is described in the following table:

NEI-00-01 Rev. 2 Appendix B.1 MHIF Base Case Applicability and Compliance	
Base Case Condition	WBN Compliance
The power supply in question must operate at a nominal AC or DC voltage greater than 110 V. Specifically, this analysis does not apply to AC and DC control power systems operating at 12 V, 24 V, or 48 V. Nor is the analysis applicable to instrument loops regardless of operating voltage.	The applicable WBN FSSD power supplies all operate at greater than 110V (120V AC, 125V DC, 250V DC, 480V AC, and 6900V AC)
For the power supply in question, electrical coordination must exist between the supply-side overcurrent protective device(s) and load-side overcurrent protective devices of concern. Achievement of proper selective tripping shall be based on the guidance of IEEE 242, or other acceptable criteria	For FSSD power sources, electrical coordination exists between the supply side overcurrent protective device(s) and load-side overcurrent protective devices of concern. Proper selective tripping is based on the guidance of IEEE 242. (Note 1)
For 120 V AC and 125 V DC power supplies, in addition to adequate coordination, a minimum size ratio of 2:1 shall exist between the supply-side protective device(s) and load-side devices of concern (for example, a distribution panel with a 50 A main circuit breaker cannot have any load-side breakers larger than 25 A). This stipulation adds additional margin to account for slower protective device clearing times of low-energy circuits.	For 120 V AC and 125 V DC FSSD power supplies the WBN design meets the minimum size ratio of 2:1 between the supply-side protective device(s) and load-side devices of concern.
The electrical system must be capable of supplying the necessary fault current for sufficient time to ensure predictable operation of the overcurrent protective devices in accordance with their time-current characteristics.	The WBN FSSD electrical power systems are capable of supplying the necessary fault current for sufficient time to ensure predictable operation of the overcurrent protective devices in accordance with their time-current characteristics. These features are demonstrated in the WBN electrical power system coordination and protection calculations.

PART III – SAFE SHUTDOWN CAPABILITIES

NEI-00-01 Rev. 2 Appendix B.1 MHIF Base Case Applicability and Compliance	
Base Case Condition	WBN Compliance
Each overcurrent protective device credited for interrupting fault current shall: <ul style="list-style-type: none"> Be applied within its ratings, including voltage, continuous current, and interrupting capacity Be listed or approved by a nationally recognized test laboratory (e.g., UL, ETL, CSA, etc.) to the applicable product safety standard (fuses, molded case circuit breakers, circuit protectors, GFI devices) or be designed and constructed in accordance with applicable ANSI and NEMA standards (protective relays, low and medium voltage switchgear). 	The WBN FSSD power supply overcurrent protective devices credited for interrupting fault current are: <ul style="list-style-type: none"> Applied within their ratings, including voltage, continuous current, and interrupting capacity Listed or approved by UL to the applicable product safety standard or are designed and constructed in accordance with applicable ANSI and NEMA standards. (Note 1)
Proper operation of the overcurrent devices shall be ensured by appropriate testing, inspection, maintenance, and configuration control.	The overcurrent protective devices associated with FSSD electrical power sources are included in the WBN electrical inspection, testing, and maintenance program and are under the WBN configuration control program. (Note 1)
The electrical system associated with the power supply in question shall conform to a recognized grounding scheme. Recognized schemes include solidly grounded, high impedance or resistance grounded, or ungrounded.	WBN electrical power systems associated with the FSSD power sources conform to recognized grounding schemes. The 480 VAC and DC systems are ungrounded. The 120 VAC systems are grounded. The 6900 VAC system is high impedance grounded.

Note 1 – Power supplies whose load cables are not located in fire zones where the supply is credited do not pose a MHIF concern (e.g. Offsite power sources and their breaker control power sources are not safety-related nor Class 1E. But, they are not an MHIF concern because they are not credited where their load cables could be exposed to potential high impedance faults).

7.5 Current Transformer Secondaries

When a secondary circuit of a current transformer (CT) opens due to a fire at a remote location, ionized gases and/or additional fires in other locations could be generated, resulting in fire propagation to additional fire areas. Fire hazards due to a fire-induced open circuit in the secondary of CTs installed in high energy panels (i.e., 6.9kV switchgear) of the required and non-required power systems have been evaluated. Three types of CT circuits used in the auxiliary power system have been evaluated: ground fault, differential relaying, and protective relaying.

For Appendix R required and non-required 480V switchgear panels, the CT circuits are contained in the panels. For the CT secondary circuit to be opened by the fire, the fire has to be

PART III – SAFE SHUTDOWN CAPABILITIES

localized inside the switchgear assembly. The same is true for the 6.9kV switchgear panel ground fault circuit. Since it is contained within the 6.9kV panels, the fire has to be localized in the switchgear assembly for the CT secondary circuit to be opened by a fire. Ground fault circuits do not, therefore, result in fire propagation to other fire areas.

The 6.9kV CT circuit that is connected to protective relaying and a current transducer is also contained within the switchgear panel. The output of the current transducer is connected to a remote indicator, and the current transducer is an electrical isolator. Additionally, the output-to-input of the current transducer has been tested for 1500V AC differential. Electrical isolation also exists for the Watt & VAR transducers used on the 6.9kV switchgear at WBN.

With three exceptions, the board differential relaying circuits are totally internal to the switchgear panels. The three exceptions are: (1) between the 6.9kV switchgear emergency supply feeders and the diesel generators which are included in the interaction analysis as required circuits; (2) between the 6.9kV Start and Unit Boards which are not required circuits; and (3) the CSST differential relaying circuits which are required offsite power circuits. Current imbalance created by an open CT circuit causes the protective differential relay to open the supply circuit breaker. This removes primary power to the CT within the time required for protective relay and breaker operation. Since the EDG or CSST differential relay circuit can cause loss of the power train, it is evaluated as a required circuit. Likewise, current imbalance in the protective differential relay of the non-required circuits also opens the supply circuit breaker.

8.0 HIGH/LOW PRESSURE BOUNDARY INTERFACES

Special considerations for high/low pressure interfaces to meet the requirements of 10CFR50 Appendix R are described in Generic Letters 81-12 and 86-10 and Information Notice 87-50. Per Generic Letter 81-12, the following information is required for high/low pressure boundary interfaces in order to ensure that they are adequately protected for the effects of a single fire:

- (1) Identify each high/low pressure interface that uses redundant electrically controlled devices (such as two series motor operated valves) to isolate or preclude rupture of any primary coolant boundary.
- (2) Identify the essential cabling for each device.
- (3) Identify each location where the identified cables are separated by a barrier having less than a 3-hour fire rating.
- (4) For the areas identified in (3) above (if any), provide the bases and justification.

Per Generic Letter 86-10, the possibility of getting a hot short on all three phases of three phase AC circuits in the proper sequence to cause spurious operation of a motor is only required to be evaluated for cases involving high/low pressure interfaces. The same applies to ungrounded DC circuits regarding two hot shorts of proper polarity without grounding resulting in spurious operation of high/low pressure interfaces.

Per Information Notice 87-50, for those low pressure systems that connect to the reactor coolant system (a high pressure system) at least one isolation valve must remain closed despite any damage that may be caused by fire, because the high pressure from the reactor coolant system could result in failure of the low pressure piping.

PART III – SAFE SHUTDOWN CAPABILITIES

Based on the above, a review of the systems credited for safe shutdown at WBN was conducted to identify potential high/low pressure interfaces. These interfaces were evaluated to identify valves that, if spuriously opened, expose low pressure piping to high pressure resulting in failure of the low pressure system.

The control system for RHR valves has been designed to prohibit opening unless the reactor coolant pressure is low enough to prevent RHR piping failure. However, if these valves opened spuriously, exposure of RHR piping to high pressure may cause failure of the RHR system piping and render the system inoperable. Therefore, the RHR/RCS isolation valves (1/2-FCV-74-1, 2, 8, and 9) are considered high/low pressure interface valves.

Excess letdown is not required for safe shutdown. However, spurious opening of these valves could expose downstream piping to excess pressure that may cause failure resulting in the rupture of the primary coolant boundary. Therefore, the excess letdown isolation valves (1/2-FCV-62-55, and 56) are considered high/low pressure interface valves.

Normal letdown is not required for safe shutdown. However, spurious opening of these valves may cause failure to maintain RCS inventory control. Therefore, the normal letdown isolation valves (1/2-FCV-62-69 and 70) are considered high/low pressure interface valves.

The safety injection system (SIS)/RHR interface valve with the RCS is located in piping that connects the SIS with the RHR system at a point between the RCS/RHR isolation valves. SIS is not required for safe shutdown. However, spurious opening of valve 1/2-FCV-63-186 along with either 1/2-FCV-74-1-A or -9-B could expose SIS piping to damaging pressure. Therefore, this valve is considered a high/low pressure interface.

The pressurizer PORV and reactor head vent isolation valves are designed to function at high RCS operating pressure. They provide two safe shutdown functions: 1) to initially remain closed for RCS inventory control purposes, and; 2) to provide a means of depressurizing the RCS to the point that the RHR system can be initiated to bring the plant to a cold shutdown condition. Discharge from the RCS through these valves is directed to the inlet of the pressurizer relief tank (PRT). The inlet lines are sized to accommodate vent/relief discharge flow without piping or component failure. Continuous letdown to the PRT may eventually cause spillage of excess coolant to containment through the PRT rupture disks. Therefore, the pressurizer PORVs and block valve combinations, and reactor head vent isolation valves, are required for RCS inventory control (and RCS letdown) and are considered high/low interface valves.

9.0 LOCATION OF SAFE SHUTDOWN EQUIPMENT, CABLES AND RACEWAYS

The safe shutdown equipment list (Table 3-2) identifies the equipment, components, and sub-components relied on for fire safe shutdown.

The routing (conduits and tray nodes) of each safe shutdown cable was obtained from the Integrated Cable and Raceway Design System (ICRDS). This information was entered into a database concurrently with the corresponding room location of each conduit and cable tray node. The route of each safe shutdown cable by room and by fire area has been identified and later used as part of the separation analysis. For large rooms containing redundant paths of safe shutdown equipment and cables, equipment locations and cable routes were further refined by subdividing the room based on column lines. Walkdowns were conducted to verify the locations of the equipment and conduits.

PART III – SAFE SHUTDOWN CAPABILITIES

10.0 SAFE SHUTDOWN SYSTEM SEPARATION EVALUATION METHODOLOGY

10.1 Overview of Evaluation Methodology

The safe shutdown analysis first established the systems, components, and cables required for fire safe shutdown purposes. The locations of equipment and routing of cables were determined as described in previous sections. The separation criteria of Appendix R were evaluated on a fire area basis to meet the safe shutdown performance goals as identified in NRC generic letters and guidance documents.

The Appendix R analysis evaluated fire areas that contain systems, components, and cables required for fire safe shutdown. The turbine building, condensate demineralized waste evaporator (CDWE) building, and Yard specific plant locations that directly abut fire areas containing FSSD capabilities, were also included in the separation analysis. Plant structures that do not contain systems, components, or cables associated with FSSD capabilities, or which do not directly abut fire areas containing FSSD capabilities (e.g., service building, modification building, etc.) were not included in the separation analysis. The adequacy of barriers separating safe shutdown-related and non-safe shutdown-related buildings (such as between the control and turbine buildings) was evaluated.

The fire safe shutdown analysis was based on the evaluation of separation in the auxiliary, control, diesel generator, and reactor building, along with the intake pumping station. The auxiliary and diesel generator buildings, and the intake pumping station, were evaluated against the requirements of Appendix R Sections III.G.1, III.G.2a, III.G.2b, and III.G.2c. Detailed procedures have been developed to ensure fire safe shutdown capability in case of an Appendix R fire in the identified locations where applicable.

For purposes of this analysis, the entire control building was evaluated as a single alternative shutdown location under the criteria of Appendix R Section III.G.3 and III.L. Fire safe shutdown activities take place outside of the control building at the ACR and other manual action locations. Detailed procedures have been developed to ensure fire safe shutdown capability in case of an Appendix R fire in the control building.

The reactor buildings were analyzed in accordance with the criteria of Appendix R Sections III.G.2d, III.G.2e, and III.G.2f. Interactions were identified where less than 20 feet, free of intervening combustibles, exist between redundant safe shutdown paths or trains of components. Such interactions are resolved by some combination of protecting one redundant path or train of safe shutdown components with noncombustible radiant energy shields or by fire detectors and automatic suppression in the area. Detailed procedures have been developed to ensure fire safe shutdown capability in case of an Appendix R fire in either reactor building.

Interactions between redundant safe shutdown paths were identified based on the location of the components and cables of redundant safe shutdown trains. Interactions are defined as locations where components of redundant shutdown paths do not meet Appendix R separation criteria. Interactions which require resolution were identified when redundant capabilities did not meet the above criteria. These interactions were evaluated for their impact on the safe shutdown capability of the plant and their resolutions have been documented. The resolutions may consist of modifications, use of alternate equipment, manual operator actions, fire barrier and radiant energy shield installation, post-fire repairs, engineering evaluations prepared in accordance with the guidance of Generic Letter 86-10, or deviation requests.

PART III – SAFE SHUTDOWN CAPABILITIES

10.2 Fire Area Evaluation Methodology

Separation analyses were initially evaluated for viability on a fire area basis. The fire area separation analysis was effective where only a single room constituted a fire area, and where redundant capability existed outside of the fire area. Large rooms and specific fire areas containing redundant trains of safe shutdown systems, components, or cables have been further subdivided for purposes of the analysis. Where multiple rooms exist in the fire area, regulatory barriers (walls and floor/ceiling assemblies) with a 2-hour fire rating have been credited under Appendix R Section III.G.2c criteria. The 2-hour fire rating exceeds the requirements of Section III.G.2c. The 2-hour rating (as opposed to a minimum 1-hour rating) has been chosen because of the positive effect on fire protection IPEEE and PRA analyses. Where the 2-hour fire rated barriers have been credited, they are identified as regulatory fire barriers, and automatic detection and suppression capabilities on both sides of the barriers have been evaluated per Section III.G.2c criteria. The fire rated non-regulatory fire barriers (maintained for property protection, but not required for Appendix R separation) have not been credited in the analysis.

Credit has been taken for a minimum of 20 feet of separation under Appendix R Section III.G.2b criteria in those fire areas that contain multiple rooms not separated by regulatory fire barriers. Section III.G.2b criteria have also been utilized in large rooms that contain redundant trains of safe shutdown capability. Section III.G.2c criteria have been applied where 20 feet of separation was not available. Section III.G.2b criteria have been used in the large open areas of the auxiliary building and adjacent rooms which are not enclosed by regulatory fire barriers. It also applies to the B train 480V reactor MOV board rooms on 772' elevation, above the part-height 1-hour barrier separating redundant CCS pumps and cables, and in the electrical equipment room in the intake pumping station (IPS).

10.3 Analysis Volume Evaluation Methodology

An analysis volume (AV) is a defined area subjected to a detailed Appendix R safe shutdown analysis to ensure that one train of FSSD capability is always available. The analysis volume can consist of an entire fire area or a portion of a larger fire area. When the analysis volume is a portion of the fire area, it can consist of multiple rooms, a single room, portions of a room (normally defined by column line locations), or any combination of the above. Each analysis volume that involves only a portion of a room includes a 20 foot wide (minimum) "buffer zone" between it and the adjacent analysis volume. The buffer zones are analyzed as part of the larger analysis volume and as a separate analysis volume.

In performing safe shutdown analyses, safe shutdown components and cables are assigned to the analysis volume containing the component. Additionally, components located in the buffer zones are assigned to an analysis volume for the buffer zone.

The safe shutdown analysis is performed assuming that all components and cables in the analysis volume are damaged. A set of safe shutdown equipment is then selected and corrective actions designated to ensure safe shutdown functions can be maintained with the selected equipment. Corrective actions consist of cable relocation, cable protection by electrical raceway fire barrier system (ERFBS), manual operator actions, application of Appendix R, Section III.G.2 separation criteria as described in Sections 10.1, 10.2 and 10.3.

PART III – SAFE SHUTDOWN CAPABILITIES

10.3.1 Analysis Volume Types and Appendix R Compliance

The following types of analysis volumes were identified and used for evaluating Appendix R compliance.

- a. *Fire Area* - The fire area is separated from other adjacent areas by rated fire barriers (walls, floors, & ceilings) that are sufficient to withstand the hazards associated with the area and, as necessary, to protect equipment in the area from a fire outside the area. The fire area may be a single room or several individual rooms. If redundant safe shutdown cables are located in the analysis volume, they are protected by an ERFBS throughout the analysis volume (i.e., from rated fire barrier to rated fire barrier). For example an analysis volume consisting of an entire fire area (FA-19) is shown in Figure 1.

Figure 1

This analysis volume is bounded on all sides by 3-hour rated fire barriers. The 3-hour fire barriers provide for protection of safe shutdown components in accordance with Appendix R Section III.G. Redundant safe shutdown cables in the analysis volume are protected by an ERFBS throughout the analysis volume (i.e., from 3-hour rated fire barrier to 3-hour rated fire barrier).

- b. *Single Room within a Fire Area* - The room is separated from other adjacent rooms in a fire area by regulatory fire barriers (walls, floors, & ceilings) that have a 1-hour or greater fire rating. The fire barriers are provided in accordance with Appendix R Section III.G.2.a or III.G.2.c. If redundant safe shutdown cables are located in the analysis volume, they are protected by an ERFBS throughout the analysis volume (i.e., from regulatory fire barrier to regulatory fire barrier). An example of an analysis volume consisting of a single room within a fire area (FA-1) is shown in figure 2.

Figure 2

This analysis volume is bounded on all sides by rated fire barriers. Fire propagation does not occur beyond the physical barriers of the room. This type of analysis volume configuration provides for protection of safe shutdown equipment in accordance with Appendix R Section III.G.2.c. Redundant cables requiring protection are protected with an ERFBS from the rated fire barrier to rated fire barrier.

PART III – SAFE SHUTDOWN CAPABILITIES

- c. *Combination of Rooms within a Fire Area* - The combination of rooms in the analysis volume are separated from other analysis volumes within the same fire area by regulatory fire barriers that are rated for at least 1-hour. The regulatory fire barriers that separate the analysis volume from other analysis volumes in the fire area provide for protection of safe shutdown equipment in accordance with Appendix R Section III.G.2. Except as discussed in Section 10.2 above and in Part VII, Section 2.5, "Partial Fire Wall Between CCS Pumps," if redundant safe shutdown cables are located in the analysis volume, they are protected by an ERFBS throughout the analysis volume (i.e., from regulatory fire barrier to regulatory fire barrier that establishes the analysis volume boundary). An example of this type analysis volume configuration is shown in Figure 3.

(713-A2)	(713-A3)	AV-27 (713-A4)	(713-A5)	(713-A30)
----------	----------	--------------------------	----------	-----------

Figure 3
Combination of rooms within a Fire Area
(single lines denote non-regulatory barrier room divisions)

In this example, rooms 713-A2 through A5 and 713-A30 were combined and evaluated as a single analysis volume (AV-27). Fire is unlikely to spread from one room to the next but, in any event, does not propagate beyond the regulatory barriers establishing the boundary of the analysis volume. ERFBS installed to protect redundant cables are applied from regulatory barrier to regulatory barrier and do not stop at the intermediate walls.

- d. *Sections of Large General Areas* - Analysis volumes consisting of sections of large general areas are separated from each other by "buffer zones." The buffer zones are greater than 20 feet in width. In large general areas where buffer zones are used that include intervening combustibles, enhanced automatic suppression and detection systems are installed in the large general area. Refer to FPR Part VII, Section 2.4, "Intervening Combustibles," for additional information. If redundant safe shutdown cables are located in the analysis volume, one train is selected for protection by an ERFBS. The ERFBS is applied throughout the analysis volume (i.e., from analysis boundary to analysis volume boundary); exceptions are noted and justified for the applicable analysis volumes in FPR Part VI. An example of this type of analysis volume is shown in Figures 4.1 and 4.2.

A15	A10	A8	A6	A1
AV-38 (737-A1B)	(737-A1BN)	(737-A1AN)	AV-36 (737-A1A)	

Figure 4.1

PART III – SAFE SHUTDOWN CAPABILITIES

Figure 4.2
Sections of large general areas (Aux. Bldg. El. 737)

In this example, the 737' elevation of the auxiliary building was subdivided into smaller sections to facilitate analysis. First as shown in Figure 4.1, the 737' elevation was split into two main analysis volumes at column line A8 (AV-36 and AV-38). AV-36 covers the area between column lines A1 to A8. AV-38 covers the area between column lines A8 to A15. Each analysis volume includes a >20' buffer zone (737-A1BN and 737-A1AN) which forms the interface between the analysis volume subdivisions. Next as shown in Figure 4.2, a third analysis volume (AV-37) was formed that consisted of the AV-36 and AV-38 buffer zones. AV-37 consists of the area between column lines A6 to A10 and is approximately 42 feet in width.

TVA first evaluated the main analysis volumes (AV-36 and AV-38). In each of these analysis volumes, TVA performed an evaluation to ensure compliance with Appendix R Section III.G.2. Where cables of redundant safe shutdown equipment are located in an AV, one train is selected for protection with an ERFBS. The selected cables are protected from AV boundary to AV boundary. In this example, Train B cables are protected in the AV-36 area and Train A cables are protected in the AV-38 area. If a Train B cable were to transition AV-36, it would be protected from the rated fire barrier at A1 to the end of the analysis volume at A8.

TVA next evaluated the analysis volume created by combining the AV-36 and AV-38 buffer zones (AV-37). This evaluation addresses potential fires that may occur at the AV-36/AV-38 interface as well as address the potential for a fire to propagate across the interface. In performing the AV-37 analysis, TVA credited components and cables outside AV-37 to the maximum extent practical to ensure that separation between redundant trains was greater than 20 feet. Where cables of redundant safe shutdown equipment were located in AV-37, one train was selected for protection with an ERFBS. Any ERFBS needed are installed on the selected safe shutdown equipment cables throughout the boundaries of AV-37.

Theoretically, this evaluation process results in an overlap area of greater than 20 feet where both trains of safe shutdown equipment cables are protected. For example, if Train A cables were selected to be protected throughout AV-37, both trains of safe shutdown equipment cables would be protected in AV-36's buffer zone (column lines A-6 to A-8) because Train B cables are protected throughout AV-36. In actual practice, the only cables that require protection in AV-37 are:

PART III – SAFE SHUTDOWN CAPABILITIES

- (1) A conduit containing Channel D instrumentation cables (to ensure adequate instrumentation is available)
- (2) A conduit containing PORV and reactor head vent cables (for prevention of hot spurious shorts)

In each of the above cases, the conduits are wrapped throughout AV-36 and AV-37. For other components, TVA credited cables located outside AV-37 to achieve separation much greater than 20 feet.

- e. *Sections of Large Rooms* - Analysis volumes that consist of large room sections separated by an overlap region that is greater than 20 ft. The overlap region is considered part of both analysis volumes. If the overlap region contains intervening combustibles, enhanced automatic suppression and detection systems are installed in the large room. Refer to Section 2.4, "Intervening Combustibles," in Part VII for additional information. If redundant safe shutdown cables are located in the analysis volume, they are protected by an ERFBS throughout the analysis volume (i.e., from analysis volume boundary to analysis volume boundary). An example of this type of analysis volume is shown in Figures 5.1 and 5.2.

Figure 5.1

Figure 5.2

Sections of large rooms (Aux. Bldg. El. 772)

Room 772-A2 is a large room subdivided into two analysis volumes to facilitate analysis (AV-59 and AV-60). As showing in Figure 5.1, AV-59 consists of sections A2A1, A2A2, and A2A3. As showing in Figure 5.2, AV-60 consists of sections A2A3 and A2A4. Section A2A3 is the overlap area that is part of both analysis volumes. This overlap area was selected to provide a separation distance greater than 20 feet between the joining analysis volumes.

PART III – SAFE SHUTDOWN CAPABILITIES

In each of these analysis volumes, TVA performed an evaluation to ensure compliance with Appendix R Section III.G.2. Where cables of redundant safe shutdown equipment are located in an AV, one train is selected for protection with an ERFBS. The selected cables are protected from AV boundary to AV boundary. In this example the only cables requiring ERFBS protection in AV-59 and AV-60 were located and protected in both AVs.

Table 3-3 identifies by analysis volume the rooms and portions of rooms included in the Appendix R separation analysis for each analysis volume. The compartmentation drawings, Figures II-27A through II-40A contained in Part II of the FPR, locate the fire areas and rooms at WBN.

Intervening combustibles consisting of exposed cable insulation in trays, ERFBS cable protection, or floor-based fixed and transient combustibles have been mitigated by:

- (1) Enhanced suppression consisting of automatic preaction sprinklers located at ceiling level and below obstructions to provide coverage of floor based fires.
- (2) Documented electrical cable protective device sizing to preclude electrical initiation of cable fire.
- (3) Limited flame spread of cable insulation/jacket material - New cables are required to meet IEEE-383 vertical tray test if available; flame retardant coating is applied to all cables in a tray if it contains more than nine non-IEEE-383 qualified cables; and most old cables are covered with flame retardant coating.
- (4) Very low flame spread of Thermo-Lag 330-1.
- (5) Dedicated onsite fire brigade.

Refer to the intervening combustible deviation request in Part VII of the FPR for additional justification.

Where redundant cables or components could be damaged by fire in an analysis volume, that function was ensured primarily by either 1-hour raceway fire barriers (radiant energy shields or automatic suppression and detection inside containment) or manual operator actions. Three hour raceway fire barriers are used where automatic suppression and detection are not provided.

11.0 Multiple Spurious Operation (MSO) Evaluation

Regulatory Guide 1.189, Fire Protection for Nuclear Power Plants, Revision 2, formalized the requirements for addressing multiple fire induced circuit failures, or MSOs and multiple concurrent hot shorts. RG 1.189 (Part II, Reference 4.1.26) endorsed the methodology in NEI 00-01 Revision 2 (Part II, Reference 4.3.12) for addressing those issues. In accordance with the NEI 00-01 Rev. 2 guidance an expert panel was used to identify plant specific scenarios that might be caused by MSOs (Part II, Reference 4.3.14). Subsequent evaluation of the identified scenarios for Unit 1 resulted in a number of deficiencies which were entered into the plant corrective action tracking system. Results of the scenario evaluation for Unit 2 are documented in report number R1976-20-01, Multiple Spurious Operation Evaluation (Part II, Reference 4.3.13).

PART III – SAFE SHUTDOWN CAPABILITIES

TABLE 3-3 - ANALYSIS VOLUME BY FIRE AREA LIST

NOTES:

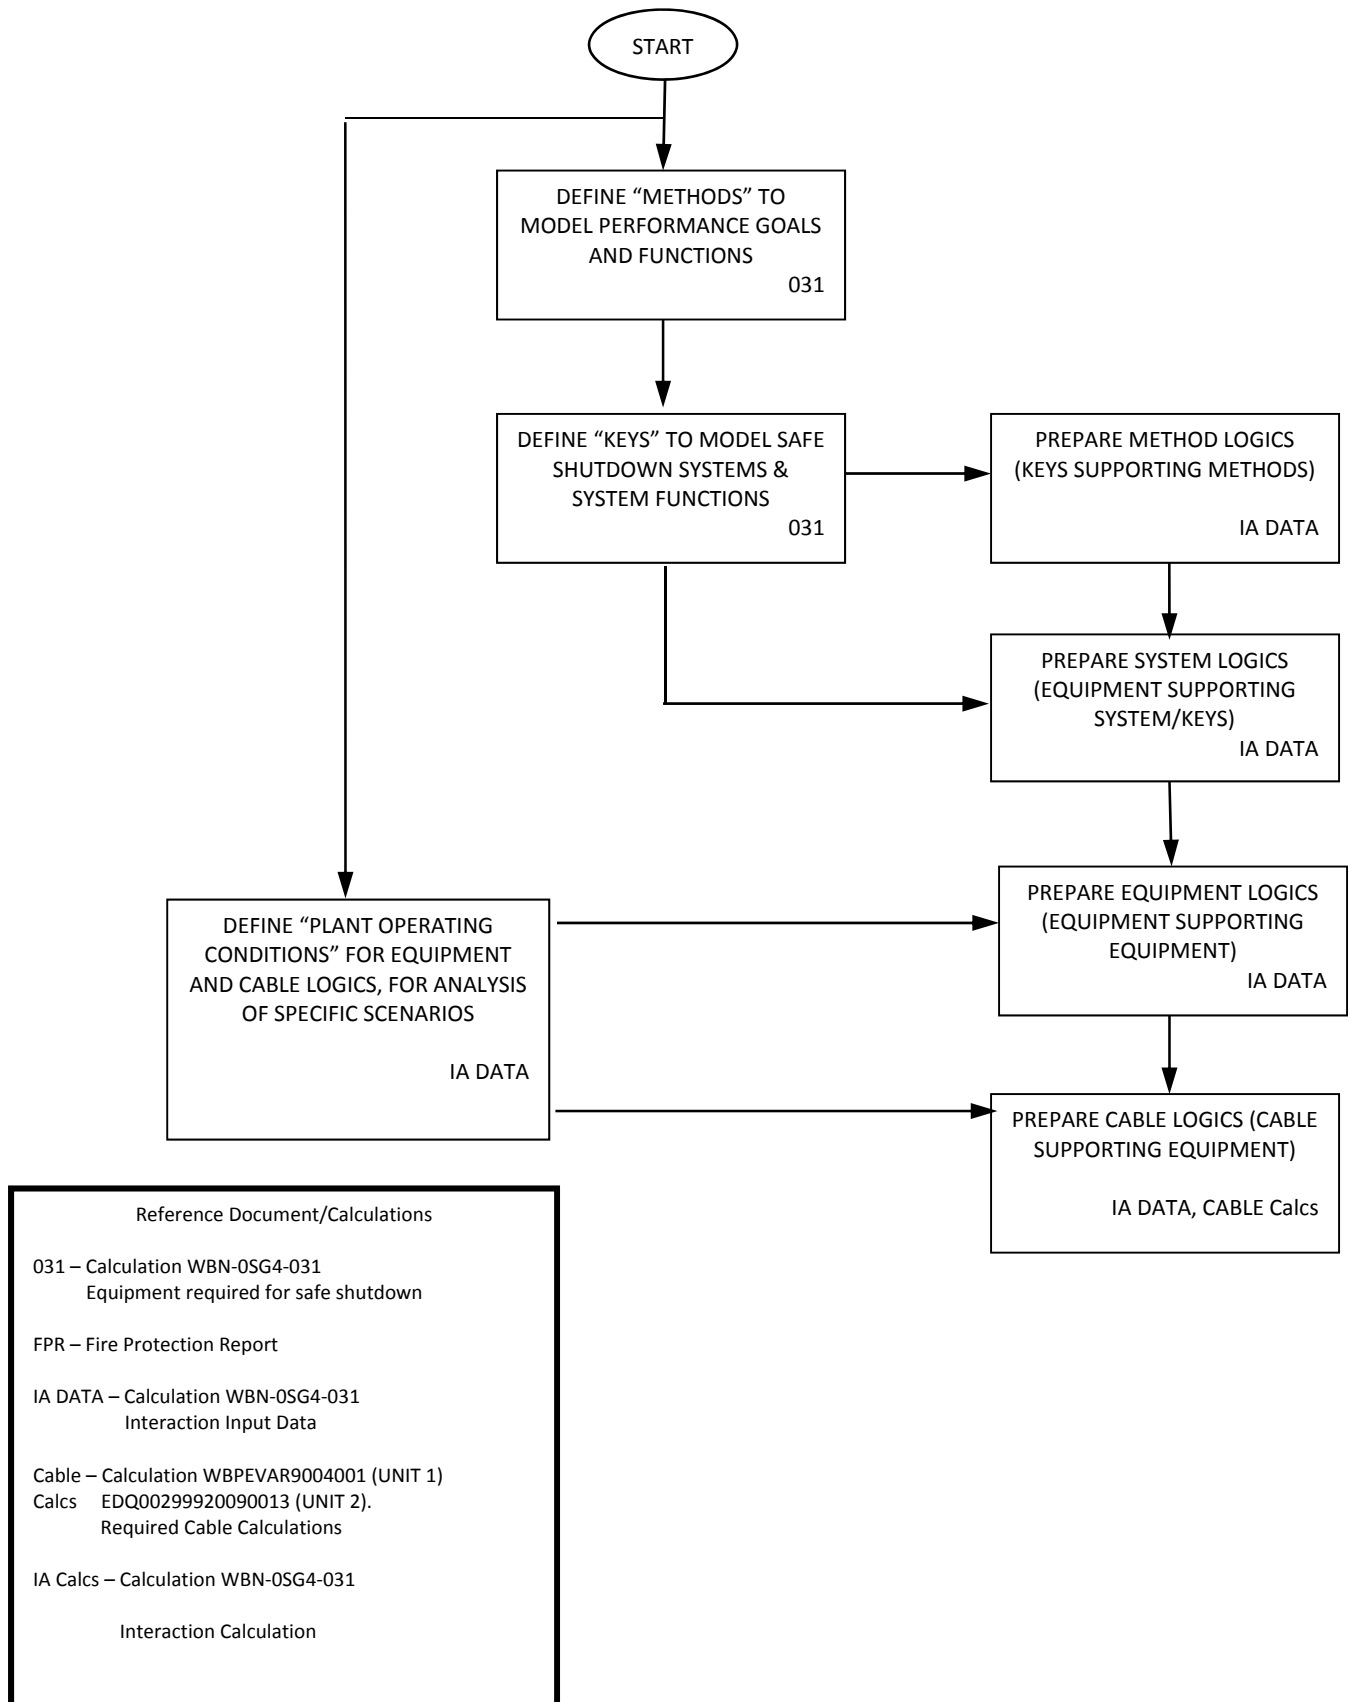

The following notes are applicable to the entire AV or AVs under which they are listed. The lining up of a note with a particular room is only coincidental.

1. This AV contains both RHR power feeds (692.0-A1AN - Train A; 692.0-A1BN - Train B. Therefore, two separate analyses (AV-004A and AV-004B) are performed to address the use of either path depending on the location of the fire within this volume.
2. This AV is analyzed to address the "soft" interface between 692.0-A1C and 692.0-A1AN and 692.0-A1BN (i.e., to obtain 20 feet of separation on either side of Column Line U).
3. This AV is analyzed to address the "soft" interface between 713.0-A1C and 713.0-A1AN and 713.0-A1BN (i.e., to obtain 20 feet of separation on either side of Column Line U).
4. This AV is analyzed to address the "soft" interface between 737.0-A1CN and 737.0-A1AN and 737.0-A1BN (i.e., to obtain 20 feet of separation on either side of Column Line U).
5. This AV contains cables and/or equipment associated with the fifth vital battery. The fifth vital battery is credited as an "installed spare" that can be used during normal plant operation if one of the existing batteries is down for maintenance. There were an additional four analyses performed for this AV to address the various combinations where the fifth vital battery can be used. These AVs have been analyzed to address the effects of a fire on the 125V DC system if the fifth vital battery is in service in replacement of any one of the other four normally credited batteries.

SAFE SHUTDOWN LOGIC DIAGRAM

PART IV – ALTERNATE SHUTDOWN CAPABILITY

1.0 INTRODUCTION

Part IV provides a description of the alternative shutdown capabilities used to achieve compliance with the requirements of Sections III.G.3 and III.L of Appendix R. For purposes of evaluating conformance to Appendix R, the control building at Watts Bar Nuclear Plant (WBN) is treated as a single fire area comprised of all rooms within the building. Regulatory and non-regulatory fire barriers are used to separate specific rooms within the building. The Appendix R compliance strategy for the control building is based on ensuring alternative shutdown capability for those fires in the building that could result in abandonment of the Main Control Room (MCR). An overview of required manual operator actions associated with MCR abandonment and alternative shutdown capabilities is provided in Part V of the FPR.

2.0 DISCUSSION

WBN's original design provided for an auxiliary control system to address situations requiring MCR abandonment. This system is located outside of the control building and is physically independent of the control building (control room, auxiliary instrument rooms, cable spreading room, etc.). The design provides appropriate means to isolate the necessary safe shutdown equipment and control features from the control building. The system is provided to satisfy General Design Criteria (GDC) 19 in Appendix A to 10CFR50 and 10CFR50 Appendix R Section III.G.3 and III.L criteria.

In order to meet GDC 19 requirements, the auxiliary control system instrumentation and controls are physically remote from, and their circuits are electrically separated from, their counterparts in the MCR. In order to meet Appendix R requirements, the auxiliary control system is both physically and electrically independent of the control building. Neither GDC 19 nor Appendix R requires redundant auxiliary control systems (e.g., a Train A and Train B auxiliary control systems).

3.0 ALTERNATE CONTROL ROOM CAPABILITIES

The principle feature of alternative shutdown capability at WBN is the Auxiliary Control Room (ACR) complex. It is divided into five independent, dedicated rooms. Each room is separated from the others and from the auxiliary building by 2- or 3-hour rated fire barriers and from the control building by 3-hour rated fire barriers. The five independent rooms consist of a Train A and a Train B transfer switch room for each unit and a common ACR containing multiple instrumentation and control panels for both units.

The ACR is designed to be the central control point when operating in the auxiliary control mode. Systems requiring frequent manipulations have the necessary controls located in the ACR along with their associated transfer switches located in the adjacent transfer switch rooms. Adequate instrumentation is provided for monitoring conditions of the plant. (Refer to the deviation request in Part VII of the FPR.).

The instruments and controls located in the ACR are separated from, or can be electrically isolated from, the corresponding instrumentation and controls located in the MCR. Operators are periodically trained in shutdown procedures from the ACR. The instrumentation and controls are adequate and sufficiently similar to those available in the MCR to permit a safe and orderly shutdown. The post fire alternate safe shutdown analysis is conducted for both the case with offsite power available as well as the case with only onsite power available for 72 hours.

PART IV – ALTERNATE SHUTDOWN CAPABILITY

The safe shutdown analysis (Part II, Reference 4.2.8) for a fire in the control building demonstrates that the auxiliary control system (ACS) components and electrical circuits necessary to achieve and maintain hot shutdown are free of fire damage and capable of performing the necessary safe shutdown functions or are prevented from causing actions that prevent safe shutdown. The analysis was performed in accordance with the guidance provided in Appendix D to NEI-00-01 revision 2, "Guidance for Post Fire Safe Shutdown" (Part II, Reference 4.3.12) as endorsed by Regulatory Guide 1.189, revision 2, "Fire Protection for Nuclear Power Plants" (Part II, Reference 4.1.26). The analysis considers that offsite power may be available or may not be available for 72 hours. Prior to transfer from the main control room to the ACS the analysis considers one spurious actuation or signal to occur. Based on potential adverse effects of each spurious actuation or signal the available time for transfer was established and the worst case (shortest time) applied to transfer completion of each control location. After control of the plant is transferred to the ACS, consideration is given to the possibility of multiple spurious actuations that could occur due to fire damage in the control building.

WBN utilizes Distributed Control Systems (DCS) for Non Safety Related Control Systems. Each unit's DCS is interconnected via fiber optic networks but is isolated from the other unit. Unit 1 has one DCS network which is located totally in the control building Auxiliary Instrument Room (AIR). The Unit 2 DCS is segmented into two Virtual Local Area Networks (VLANs) with one segment in the Auxiliary Control Room (ACR) and one in the Aux Instrument Room. The network in the ACR is for monitoring and maintenance purposes only and the controls function independent of the network. In order to allow monitoring by the DCS Work Station, the ACR and AIR network segments are interconnected via a network switch which is configured to inhibit data transfer between each segment. This prevents a failure of one network segment (i.e., ACR network) from affecting the other segment (i.e., AIR network) and vice versa. Data packet rate from the ACR network is also limited to provide redundant assurance that data transmission cannot impede communications in the AIR segment. This isolation between the ACR and AIR, ensures that no event arising from equipment failures, such as caused by a fire, can inhibit DCS equipment outside that fire zone.

3.1 Instruments Required for Alternative Shutdown in the ACR

The instruments and controls found in the ACR that are required for MCR abandonment are as follows:

1/2-LI-68-325C	Pressurizer Level
1/2-LI-68-326C	Pressurizer Level
1/2-PI-68-342C	Pressurizer Pressure
1/2-TI-68-1C	Loop 1 RCS Hot Leg Temperature (T-hot)
1/2-TI-68-24C	Loop 2 RCS Hot Leg Temperature (T-hot)
1/2-TI-68-43C	Loop 3 RCS Hot Leg Temperature (T-hot)
1/2-TI-68-65C	Loop 4 RCS Hot Leg Temperature (T-hot)
1/2-PI-1-1C	Loop 1 SG Pressure w/ corresponding T-sat scale
1/2-PI-1-8C	Loop 2 SG Pressure w/ corresponding T-sat scale
1/2-PI-1-19C	Loop 3 SG Pressure w/ corresponding T-sat scale
1/2-PI-1-26C	Loop 4 SG Pressure w/ corresponding T-sat scale
1/2-LI-3-164C	Loop 1 SG Level
1/2-LI-3-156C	Loop 2 SG Level
1/2-LI-3-148C	Loop 3 SG Level
1/2-LI-3-171C	Loop 4 SG Level

PART IV – ALTERNATE SHUTDOWN CAPABILITY

1/2-NI-92-138	Source Range Flux Monitor
1/2-LI-62-129C	Volume Control Tank Level
1/2-FI-3-163C	Loop 1 Auxiliary Feed Water (AFW)Flow
1/2-FI-3-155C	Loop 2 Auxiliary Feed Water (AFW)Flow
1/2-FI-3-147C	Loop 3 Auxiliary Feed Water (AFW)Flow
1/2-FI-3-170C	Loop 4 Auxiliary Feed Water (AFW)Flow
1/2-FI-62-93C	Charging Flow
1/2-FI-67-61C	ERCW Supply Header A Flow
1/2-FI-67-62C	ERCW Supply Header B Flow
1/2-TI-74-38C	RHR Supply A Outlet Temperature
1/2-TI-74-40C	RHR Supply B Outlet Temperature
1/2-PDIC-3-122C	AFW Pump 1A-A/2A_A Discharge Pressure
1/2-PDIC-3-132C	AFW Pump 1B-B/2B-B Discharge Pressure

3.2 Controls Required for Alternative Shutdown in the ACR

The following controls are located in the ACR and are required for MCR abandonment:

1/2-HS-30-82C	CRDM Cooler Unit D-B Room Division Damper
1/2-HS-30-85C	CRDM Cooler Unit A-A Room Division Damper
1/2-HS-30-90C	CRDM Cooler Unit C-A Room Division Damper
1/2-HS-30-94C	CRDM Cooler Unit B-B Room Division Damper
1/2-HS-62-55C	Excess Letdown Isolation Valve
1/2-HIC-62-56C	Excess Letdown Flow Control
1/2-HS-62-69C	RCS Isolation Valve
1/2-HS-62-70C	RCS Isolation Valve
1/2-HS-62-84C	Charging Flow to RCS Spray
1/2-HS-67-84C	Lower Containment Vent Cooler A Supply Control Valve
1/2-HS-67-85C	CRD Vent Cooler A Supply Control Valve
1/2-HS-67-92C	Lower Containment Vent Cooler C Supply Control Valve
1/2-HS-67-93C	CRD Vent Cooler C Supply Control Valve
1/2-HS-67-100C	Lower Containment Vent Cooler B Supply Control Valve
1/2-HS-67-101C	CRD Vent Cooler B Supply Control Valve
1/2-HS-67-108C	Lower Containment Vent Cooler D Supply Control Valve
1/2-HS-67-109C	CRD Vent Cooler D Supply Control Valve
1/2-HS-68-334C	RCS Pressurizer Pressure PORV
1/2-HS-68-340C	RCS Pressurizer Pressure PORV
1-HS-82-16C	DG 1A-A Emergency Start
1-HS-82-17C	DG 1A-A Emergency Stop
1-HS-82-46C	DG 1B-B Emergency Start
1-HS-82-47C	DG 1B-B Emergency Stop
2-HS-82-76C	DG 2A-A Emergency Start
2-HS-82-77C	DG 2A-A Emergency Stop
2-HS-82-106C	DG 2B-B Emergency Start
2-HS-82-107C	DG 2B-B Emergency Stop
1/2-XS-1-4A	Main Steam Isolation Valve
1/2-XS-1-4B	Main Steam Isolation Valve
1/2-XS-1-11A	Main Steam Isolation Valve
1/2-XS-1-11B	Main Steam Isolation Valve

PART IV – ALTERNATE SHUTDOWN CAPABILITY

3.2 Controls Required for Alternative Shutdown in the ACR (continued)

1/2-XS-1-22A	Main Steam Isolation Valve
1/2-XS-1-22B	Main Steam Isolation Valve
1/2-XS-1-29A	Main Steam Isolation Valve
1/2-XS-1-29B	Main Steam Isolation Valve
1/2-XS-1-6A	Steam Generator PORV
1/2-XS-1-6B	Steam Generator PORV
1/2-XS-1-13A	Steam Generator PORV
1/2-XS-1-13B	Steam Generator PORV
1/2-XS-1-23A	Steam Generator PORV
1/2-XS-1-23B	Steam Generator PORV
1/2-XS-1-31A	Steam Generator PORV
1/2-XS-1-31B	Steam Generator PORV
1/2-XS-1-7	Steam Generator Blowdown Control Valve Loop 1
1/2-XS-1-14	Steam Generator Blowdown Control Valve Loop 2
1/2-XS-1-25	Steam Generator Blowdown Control Valve Loop 3
1/2-XS-1-32	Steam Generator Blowdown Control Valve Loop 4
1/2-XS-1-181	Steam Generator Blowdown Isolation Valve Loop 1
1/2-XS-1-182	Steam Generator Blowdown Isolation Valve Loop 2
1/2-XS-1-183	Steam Generator Blowdown Isolation Valve Loop 3
1/2-XS-1-184	Steam Generator Blowdown Isolation Valve Loop 4

3.3 Instruments and Controls Required for Alternative Shutdown Not in the ACR

The controls for the following are located just outside the ACR in the 6.9kV Shutdown Board Rooms. The number in parentheses is the number available for shutdown.

- ERCW pumps (8)
- Motor-driven AFW pumps (2 per unit)
- RHR pumps (2 per unit)
- Centrifugal charging pumps (2 per unit)
- Pressurizer heaters (4 groups per unit)
- SI pumps (trip) (2 per unit)

The controls for the following are located in the 480V Shutdown Board Rooms which are located adjacent to the 6.9kV Shutdown Board Rooms.

- CRDM cooler fans (4 per unit)
- Lower compartment cooler fans (4 per unit)
- CCS pumps (5)
- Electric fire pumps (4)
- Containment Spray pumps (trip) (2 per unit)

Controls for the valves powered from the 480V boards are located in the 480V MOV board rooms which are one elevation above the ACR.

PART IV – ALTERNATE SHUTDOWN CAPABILITY

The following controls are located in the 125V Vital Battery Board Rooms:

1-HS-3-945A-A	Unit 1 Main Feedwater Bypass Valves	Bd Rm I
1-HS-30-1080A-A	Unit 1 RB Ventilation Isolation Dampers	Bd Rm I
2-HS-3-945A-A	Unit 2 Main Feedwater Bypass Valves	Bd Rm III
2-HS-30-1080A-B	Unit 2 RB Ventilation Isolation Dampers	Bd Rm III
2-HS-3-945B-B	Unit 2 Main Feedwater Bypass Valves	Bd Rm IV

The above instrumentation and controls are well in excess of that detailed in Information Notice 84-09 (Part II, Reference 4.1.14). There are also numerous local indications and controls available to the operators outside the ACR which provide additional information and control which were not included in the above listing.

PART V – MANUAL ACTIONS, REPAIRS, AND EMERGENCY LIGHTING

1.0 INTRODUCTION

Part V documents the methodology used to satisfy Appendix R Section III.G, III.J, and III.L requirements for actions as a result of fire events that occur in any plant location. This includes the criteria and assumptions used to evaluate feasibility and reliability of operator manual actions (OMAs) credited in achieving and maintaining hot shutdown conditions. Part V describes the process for determining the need for, and adequacy of, emergency lighting in the access routes to operator manual action locations, and at the specific locations where the operator manual action is required to take place. Part V also identifies the repairs that are required in order to achieve and maintain cold shutdown conditions. The following sections describe these topics in more detail.

2.0 OPERATOR MANUAL ACTIONS

Operator Manual Actions (OMAs) are those actions performed by operators to manipulate components and equipment from outside the main control room to achieve and maintain post fire hot shutdown, but do not include “repairs”. OMAs comprise an integrated set of actions needed to help ensure that hot shutdown can be accomplished, given that a fire has occurred in a particular plant area. Operator Actions (OAs) are actions taken by an Operator while in the Main Control Room (MCR). Actions performed inside the main control room are not included in the definition of operator manual actions. Additionally, actions performed at auxiliary control system stations (e.g., Auxiliary Control Room) in response to a main control room abandonment event are considered OAs but are evaluated against the guidance for OMAs. OMAs are identified in calculation EDQ00099920090016, “Appendix R – Units 1 & 2 Manual Action Requirements,” (Part II, Reference 4.2.59) which also establishes the allowable time to complete each action. Operator actions performed inside the main control room are also identified in a separate appendix within this calculation.

OMAs have been identified that are required to ensure the proper operation of specific equipment that is relied on for safe shutdown as a result of an Appendix R fire at WBN Units 1 and 2. These actions are based on an analysis of:

1. The location of the fire,
2. The components and cables in the location that may be affected by the fire,
3. The location of the specific component manually operated,
4. The time requirements for completion of the operator manual action following reactor trip as a result of the Appendix R fire, including the time it takes to get to the operator manual action location and the time it takes to perform the operator manual action; and
5. The minimum operator staffing level available to perform the operator manual actions.

For each combination of rooms analyzed for Appendix R compliance, Part VI of the FPR summarizes which major component(s) may be damaged by the fire and assumed unavailable. Part VI of the FPR also identifies the OMAs necessary to mitigate the postulated impact of fire damage to the component(s).

In accordance with Regulatory Guide 1.189 (Part II, Reference, 4.1.26), OMAs provide an acceptable protection method for Structures, Systems, and Components (SSC) including

PART V – MANUAL ACTIONS, REPAIRS, AND EMERGENCY LIGHTING

circuits that are important to safe shutdown. OMAs for SSC in the safe-shutdown success path require prior NRC approval. The OMAs relied upon for post fire safe shutdown as identified for each analysis volume in Part VI of this FPR fall into three categories as follows:

1. OMAs required for Unit 1 only operation and approved by the NRC in SSER 18 (Part II, Reference, 4.3.9). Feasibility and reliability has been evaluated in the Re-verification and Revalidation of Appendix R Manual Operator Actions walkdowns.
2. OMAs added for Unit 1 after issuance of SSER 18. The added OMAs are for SSC important to safe shutdown; prior NRC approval is not required. Feasibility and reliability has been evaluated and documented in the Re-verification and Revalidation of Appendix R Manual Operator Actions walkdowns; or
3. OMAs required for Unit 2 operation (including common equipment). Feasibility and reliability of these OMAs are evaluated as described below. Those requiring prior NRC approval are documented as engineering evaluations in Part VII, Section 8 of this FPR.

2.1 OMA Feasibility and Reliability

OMAs are evaluated to ensure they are feasible (can be performed) and that they are reliable (can be performed reliably under a wide range of plant conditions that an operator might encounter during a fire). Feasibility and reliability of WBN Unit 2 and common OMAs (including OMAs for Control Room abandonment) are evaluated to the criteria below which are based on the criteria and technical bases provided in NUREG 1852; “Demonstrating the Feasibility and Reliability of Operator Manual Actions in Response to Fire” (Part II, Reference 4.1.27). Watts Bar Unit 1 is not committed to NUREG 1852 for the evaluation of OMAs but instead uses it as a goal as discussed below. The timing for Unit 1 OMAs is judged against the criteria of WCAP-16755-NP, “Operator Time Critical Action Program Standard” (Part II, Reference 4.1.29)

A robust defense-in-depth fire prevention/protection program provides additional assurance that OMAs are both feasible and reliable. This defense-in-depth at WBN consists of a transient control program, Hot Work Permit procedure, fire rated barriers (including fire doors, fire dampers, and penetration seals), detection and automatic suppression, standpipe and hose station system, and a well trained, dedicated fire brigade. The fire prevention/protection program serves to minimize the possibility and severity of a fire in an area where an OMA is relied upon. Any area crediting OMAs with a required time less than 2 hours and lacking robust defense-in-depth, is given additional consideration in the feasibility and reliability evaluation.

2.1.1 Feasibility and reliability analysis criteria:

1. Adequate time exists for the operator to perform the action considering:
 - a. Differences between analyzed and actual conditions that may be present during a fire; and
 - b. Human performance uncertainties that may be encountered.
2. Appropriate allowances have been made for environmental factors that negatively impact the ability to perform the operator manual action. Environmental factors considered include;
 - a. Smoke and hot gases;
 - b. Water from firefighting activities;

PART V – MANUAL ACTIONS, REPAIRS, AND EMERGENCY LIGHTING

- c. Radiation;
 - d. Temperature and humidity;
 - e. Noise; and
 - f. Lighting.
3. Equipment to be operated is available and accessible
- a. Equipment is functional and accessible;
 - b. Support equipment (if needed) is available and functional;
 - c. Diagnostic instrumentation (if needed) to identify the need for the action and to confirm action results. Diagnostic instrumentation is not required for preventive actions;
 - d. Necessary communications;
 - e. Necessary personnel protective equipment; and
 - f. Necessary portable equipment.
4. Plant procedures directing performance of the OMA exist and procedure training has been conducted. (see Section 2.2)
5. Adequate personnel (staffing) are available to perform the OMAs exclusive of the fire brigade.

2.1.2 Acceptance Criteria

Unit 2 and common Operator Manual Actions that meet the following criteria of NUREG 1852 are considered feasible and reliable. Unit 1 OMAs utilize NUREG 1852 as a goal, but are judged against the specific Unit 1 timing criteria below. As provided in NUREG 1852, specific evaluations can be performed for situations not meeting the acceptance criteria.

1. Adequate time (≥ 10 minutes) available to perform actions ($t=0$ is defined in Section 2.2.2) and either:
- a. Use of self-contained breathing apparatus (SCBA) and entry to Radiological Control Area (RCA) are not required and:
 - i. demonstrated performance time is less than 50% of the allowable time (100% margin) (Unit 2 and common)
 - ii. demonstrated performance time is less than 80% of the allowable time (20% margin) (Unit 1)
 - b. Alternatively the following uncertainty allowances, as applicable, should be added to the demonstrated performance time before comparing to the total allowable time:
 - i. A two (2) minute delay to gain access to a RCA; and/or
 - ii. A three (3) minute delay for human centered uncertainties such as size, physical strength, cognitive differences and experience level; and/or
 - iii. If SCBA is needed and not carried during the performance demonstration, a 15 percent penalty for each applicable OMA (which thus affects the time for all subsequent actions) will be added to the performance demonstration times.

PART V – MANUAL ACTIONS, REPAIRS, AND EMERGENCY LIGHTING

The 15 percent penalty is similar in magnitude to the requirement defined in Regulatory Guide 8.15 (Reference 4.1.28) for ALARA purposes and has been shown to be conservative based on plant walkdowns using SCBA for Appendix R purposes.

- c. Unit 1 and Unit 2 action(s) taken in the MCR associated with abandoning the MCR in the case of a fire are excluded from NUREG 1852. Additionally, Unit 1 and Unit 2 actions performed at auxiliary control system stations (e.g., Auxiliary Control Room) in response to a main control room abandonment event are considered OAs but are evaluated against the guidance provided in NUREG 1852.
- 2. Environmental factors
 - a. Availability of a path for the operator to travel to the control location along the 8-hour battery pack emergency light illuminated paths defined in calculation EDQ00099920090017 (Part II, Reference, 4.2.58) without traversing the fire affected room ensures adequate lighting and minimal impact from fire suppression effects;
 - b. The 100% time margin or performance time plus uncertainty allowances from paragraph 1.a and 1.b above ensures adequate time to reach the control location and perform the action. Additional time margin must be included for OMAs required for a fire in an area lacking robust defense-in-depth fire prevention/protection;
 - c. Communications: Part II section 12.8 and calculation WBPEVAR9205004, Appendix R Analysis for Intraplant Communication System (Part II, Reference 4.2.76), describe the design adequacy of the communication systems for operator manual actions. This is validated by as-constructed walkdown of OMAs; and
 - d. OMAs to be performed in the fire affected room in about an hour are specifically evaluated and documented in FPR Part VII.
 - 3. Equipment functionality and accessibility
 - a. Equipment and associated cables (if required) are unaffected by the fire;
 - b. Support equipment (if needed) is unaffected by the fire;
 - c. Diagnostic instrumentation (not needed for preventive actions) is not affected by the fire; and
 - d. Personal protective equipment and tools (portable equipment) are staged and readily available.
 - 4. Plant procedures are available for the affected room (see Section 2.2 below)
 - 5. Adequate personnel (staffing) are available to perform all of the credited OMAs for the affected fire (including sequential actions performed by the same operator).

The OMA feasibility and reliability analyses for OMAs added after issuance of SSER 18 are documented in calculation EDQ00299920110381 (Part II, Reference 4.2.59A). Additionally a summary of the analysis for Unit 2 and common OMAs and the OMAs added for Unit 1 after issuance of SSER 18 of the following types are included in Part VII, Section 8 of the FPR:

PART V – MANUAL ACTIONS, REPAIRS, AND EMERGENCY LIGHTING

1. OMAs involving FSSD success path components with a required time (allowable) less than 120 minutes;
2. OMAs requiring reentry into the fire zone in about 1 hour.

The following assumptions may be applied (if appropriate) in the feasibility and reliability analysis:

1. A bounding analysis can be used for OMA's with similar characteristics; and
2. Operator Manual Actions with a required completion time (allowable time) of 120 minutes or greater have adequate time for feasible and reliable performance and can be excluded from performance validation demonstrations.

2.2 Safe Shutdown Procedures

Abnormal Operating Instruction 0-AOI-30.1, "Plant Fires" (Part II, Reference 4.2.89) provides operator actions to respond to and mitigate the consequences of a plant fire including:

1. Initiate fire alarm;
2. Ensure Fire Operations (fire brigade) is notified;
3. Announce fire location and the location of the incident command post, over the public address system;
4. Ensure the diesel fire pump or two electric fire pumps are running; and
5. For fire located in the Control Building, Auxiliary Building, or Reactor Building, notify the Appendix R AUOs to report to the control room, and to obtain SCBA, radio, and other equipment as required.

The decision to declare an Appendix R fire and to trip the unit(s) is left to the judgment of the Unit SRO/Shift Manager and must be based on the magnitude of the fire and its potential effect on the System Structures and Components necessary to achieve and maintain safe shutdown.

Abnormal Operating Instruction 0-AOI-30.2, "Fire Safe Shutdown" (Part II, Reference 4.2.90) has been developed to specify the actions which may be required for fires that damage equipment necessary to achieve and maintain safe shutdown. The fire safe shutdown procedures contained in 0-AOI-30.2 are developed based on calculations WBN-0SG4-031, "Equipment Required for Safe Shutdown per 10CFR50 Appendix R" (Part II, Reference 4.2.8) and EDQ00099920090016, "Manual Actions Required for Safe Shutdown Following a Fire" (Part II, Reference 4.2.59). The procedure documents the required operator actions and operator manual action(s) that must take place given an Appendix R fire in any room of the plant. The procedure also documents, on an operator-by-operator basis, the locations and sequence in which the operator manual actions must be performed.

For unit(s) in Modes 1, 2 or 3, the minimum staffing level required to perform the actions for the worst case Appendix R fire is as follows:

POSITION	NUMBER
Shift Manager-Licensed SRO (SM)	1 for one or two units
Unit Supervisor-Licensed SRO (US)	1 per unit
Licensed Unit Operator (UO)	2 per unit

PART V – MANUAL ACTIONS, REPAIRS, AND EMERGENCY LIGHTING

POSITION	NUMBER
Non-licensed Assistant Unit Operator (AUO)	8 for one or two units
Shift Technical Advisor (STA)	1 for one or two units
Incident Commander (IC)	1 for one or two units

The Shift Technical Advisor and Incident Commander positions require SRO level knowledge and shall be separate from the Shift Manager and Unit Supervisor(s).

2.2.1 Plant Walk Downs

Plant walk downs were conducted to: (i) sequence actions, (ii) verify the amount of time required to accomplish the operator actions and operator manual actions, and (iii) verify the minimum number of operators required to support operator manual actions given a fire in any plant location. The plant walk downs address those actions required within the first 2-hours following a reactor trip as a result of the Appendix R fire. The 2-hour time frame corresponds to predicted minimal operator staffing prior to availability of additional personnel for operator manual actions as a result of the plant callback procedure.

2.2.2 Operator Locations Prior to Initiating Operator Manual Actions and t=0 Definition

For the purposes of developing the post fire safe shutdown procedures, assistant unit operators (AUOs) performing operator manual actions assemble at and are dispatched from the Main Control Room (MCR) for fires in most plant locations, or the Auxiliary Control Room for control building fires. The basis for dispatch locations is that the AUOs must obtain the operator-specific safe shutdown procedures from these locations. Upon detection of a fire either automatically or via observation, the MCR recalls AUOs to the assembly location from their normal duties in various plant locations. Based on AUO recall exercises (Part II, Reference 4.2.92), AUOs working near the MCR are available within about three minutes and any AUOs at the most remote location (intake pumping station) are available within about eight minutes. The other AUO availability times would be expected to be between these two times. It is expected that in most cases the AUOs will be assembled with their proper gear before the plant declares an Appendix R event.

The time requirements for completion of operator manual actions are based on defining the initial time ($t = 0$) as the time when the reactor is tripped. This definition of $t = 0$ is appropriate because the operator manual actions are not required to maintain the operating status of plant equipment prior to tripping the reactor because the reactor is considered to be in a stable operating condition prior to reactor trip. After the reactor is tripped, either automatically or manually, the OMAs are preventive (not reactive) and are performed to prevent spurious equipment operation and to ensure safe shutdown can be accomplished.

The following reactor trip scenarios are postulated and evaluated:

1. Manual trip by the MCR operator after evaluating fire significance and potential effects on plant operability.
2. Automatic reactor trip resulting from fire damage to multiple channels of reactor protection system (RPS) concurrent logic inputs.
3. Spurious reactor trip initiated by fire damage to the manual reactor trip circuit.

PART V – MANUAL ACTIONS, REPAIRS, AND EMERGENCY LIGHTING

MCR operators are alerted in the early stage of fire development by the NFPA Code compliant smoke detection provided in the plant as described in Part II, Section 12.5 and Part X. The fire (smoke) detection system is installed to provide for prompt detection of a fire in its incipient stage and provide early warning capability. The MCR will be alerted to the fire (even small fires that might slowly degrade devices) before the fire can affect the safe shutdown capability. With this early notification, the decision to trip the reactor manually is expected to be reached prior to or about the same time as needed for fire damage to develop sufficiently to cause an automatic reactor trip. Multiple concurrent RPS logic inputs are necessary to initiate an automatic reactor trip and these input circuits are physically separated in accordance with Watts Bar Design Criteria WBN-DC-30-4, Separation/Isolation (Part II, Reference 4.2.20) which follows the guidance of Regulatory Guide 1.75, "Physical Independence of Electrical Systems". Since the circuits are in physically separated raceways and there is early warning provided by the smoke detection system, reactor trip is not expected to be the first observed indication of a fire or first observed circuit failure resulting from the fire. Defense in depth provided by early detection, automatic fire suppression, and physical separation will delay fire development and automatic reactor trip thereby allowing time for the MCR to recall the AUOs, evaluate the fire, and manually initiate reactor trip if necessary in accordance with Part II, References 4.2.89 and 4.2.90.

A spurious reactor trip due to fire damage to the manual trip circuits does not adversely affect OMA performance time because for the rooms where the reactor trip circuit is located the allowable time for the first OMA is 60 minutes (except as noted below). Even considering a fire induced reactor trip prior to recalling the AUOs to the MCR there is more than adequate time for the AUOs to perform the needed local actions within the allowable time. The spurious manual reactor trip circuit is evaluated in calculation WBN-OSG4-031 (Part II, Reference 4.28). The worst Unit 2 case is a fire in 772.0-A16 (480VAC Reactor MOV Board Room 2A). There are two 15-minute OMAs (operate switches on C&A Vent boards just outside the MCR) for a fire in this room. However, the basis for the 15 minute allowable time is not reactor trip, but rather two separate unrelated, but concurrent, spurious motor operated valve operations. Defense in depth provided by early detection, automatic fire suppression, and physical separation will delay fire development and multiple spurious valve operations thereby allowing time for the MCR to recall the AUOs to perform these OMAs. Plant AUO recall exercises show that the first two AUOs will be available in about 5 minutes and can reliably complete the actions within the allowable time.

Once reactor trip is initiated, either automatically or manually, the preventive OMAs are performed to prevent spurious equipment operation and to ensure safe shutdown can be accomplished. Since the OMAs are preventive rather than reactive, they are performed per procedure without diagnostic delays.

There are very few situations where action must be taken based upon fire damage to equipment or cables before reactor trip. In these situations, the plant Emergency Operating Instructions (EOIs) (Part II, Reference 4.2.91) provides the immediate response (before reactor trip) while the FSSD procedure is preventive (action taken after reactor trip but before fire damage causes a need for the action). For example:

1. Electrical power distribution board fire – The EOI response and the safe shutdown action are the same; de-energize the board prior to extinguishing the fire.

PART V – MANUAL ACTIONS, REPAIRS, AND EMERGENCY LIGHTING

2. Spurious start of a containment air return fan. The fan must be stopped. Existing system operating procedures require securing the fan (opening the breaker) which is the same action required for fire safe shutdown.

For rooms without automatic fire detection it is theoretically possible for a fire to develop slowly and affect cables and equipment before the MCR operators are aware of the fire. Each room without automatic fire detection was evaluated for potential adverse effects on OMA timing due to delayed notification of the fire. The evaluation is documented in calculation WBN-OSG4-031 (Part II, Reference 4.2.8). The evaluation determined that there are no OMAs needed to achieve and maintain hot shutdown for rooms without automatic fire detection. Therefore, normal and emergency operating instructions are used to address equipment failures.

2.3 Actions Prior to Main Control Room Abandonment

A fire in the Control Building is the only postulated fire event that may require abandonment of the MCR to ensure fire safe shutdown capabilities. Upon reactor trip as a result of the Appendix R fire that requires abandonment of the MCR, two actions are taken in addition to tripping the reactor(s). One is to close the two pressurizer power operated relief (PORV) block valves for both units to prevent loss of RCS pressure/inventory due to possible spurious PORV opening prior to transferring plant control to the ACS. The other is to trip the reactor coolant pumps (RCPs). In the event of a fire in the Control Building, an immediate trip of the RCPs for both units is necessary to prevent reactor coolant system (RCS) depressurization caused by a spurious actuation of pressurizer spray valves, since the pressurizer spray valve circuits are not isolated from the Control Building. The following discussion provides justification for also taking credit for closing the pressurizer PORV block valves and tripping the RCPs.

While the fire safe shutdown analysis typically assumes instantaneous burnout of the entire location of fire influence, it is reasonable to predict that a fire requiring MCR abandonment is a slow growth fire, especially one that occurs in the MCR or a MCR panel. Such a fire is detected in its early stages by either an operator or an installed fire detector. Other Control Building locations that may result in MCR abandonment (e.g., the cable spreading room or auxiliary instrument room) are provided with automatic detection and suppression systems, which also results in detection of the fire in its early stages. The RCP Start Bus breaker controls in the MCR are separated by greater than 20 feet from the pressurizer spray valve controller cables; therefore, a fire involving one does not affect the other simultaneously. Upon MCR abandonment, sufficient time is available to isolate the Pressurizer PORV and block valve circuits for each unit from the control building and to locally open the RCP breakers for each unit from outside the Control Building to prevent reclosure and ensure the RCPs remain tripped.

2.4 Access Routes to Operator Manual Action Locations

For fire events that require operator manual actions be taken, TVA has evaluated the availability of access routes to reach the operator manual action location. In recognition that certain operator manual actions are required in one portion of a large fire area that is separated at least 20 feet from a different portion of the same fire area in which the fire occurs, an additional access route has been evaluated. The additional route was considered to provide flexibility regarding access through these large areas due to the potential for heat and smoke spread. Fire suppression activities, either automatic by installed suppression systems or manual by the fire brigade, were also considered. Plant walk downs verify the viability of the operator manual actions.

PART V – MANUAL ACTIONS, REPAIRS, AND EMERGENCY LIGHTING

3.0 COLD SHUTDOWN REPAIRS

Appendix R Section III.G.1.b requires that systems necessary to achieve and maintain cold shutdown from either the MCR or emergency control station(s) can be repaired within 72 hours. There are two generic repairs that are required to ensure cold shutdown capabilities. Repair procedures have been developed and the required materials are available onsite to accomplish the repairs. The two repairs are described below.

3.1 RHR Room Cooler Repair

There are a number of plant locations where fire damage disables the control and/or power cable for the room cooler to an RHR pump that is relied on for cold shutdown capabilities. For Unit 1, the repair requires the installation of a jumper on 1-MCC-214-A1/9A-A in Room 757.0-A2 when the control cable for the RHR Pump A cooler 1-MTR-30-175-A is lost, or on 1-MCC-214-B1/9A-B in room 757.0-A5 when the control cable for the RHR Pump B cooler 1-MTR-30-176-B is lost. With the jumper in place, the appropriate room cooler automatically starts when the associated RHR pump starts. Should the fire damage the power cable for the cooler, the repair consists of replacement of the power cable from the MCC to the room cooler.

A fire in the following plant locations results in the need to implement this repair procedure:

1. Room 676.0-A1, -A16
2. Room 692.0-A1A, -A1B, -A1C, -A8
3. Room 713.0-A1A, -A27, -A28
4. Room 737.0-A1A, -A3
5. Room 757.0-A2, -A9

For Unit 2, the repair requires the installation of a jumper, on 2-MCC-214-A1/9A-A in Room 757.0-A21 when the control cable for the RHR Pump A cooler 2-MTR-30-175-A is lost, or on 2-MCC-214-B1/9A-B in room 757.0-A24 when the control cable for the RHR Pump B cooler 2-MTR-30-176-B is lost. With the jumper in place, the appropriate room cooler automatically starts when the associated RHR pump starts. Should the fire damage the power cable for the cooler, the repair consists of replacement of the power cable from the MCC to the room cooler.

A fire in the following plant locations results in the need to implement this repair procedure:

1. Room 676.0-A1, -A16
2. Room 692.0-A1A, -A1B, -A1C, -A8
3. Room 713.0-A1A, -A1B, -A1C, -A27, -A28
4. Room 737.0-A1B, -A1CN, -A1N

3.2 RHR/RCS High-Low Pressure Boundary Valve Repair

There are a number of locations where fire damage disables the Unit 1 control and/or power cable for RHR/RCS high-low pressure boundary valves 1-FCV-74-1-A, -2-B, -8-A and/or -9-B. The repair requires the installation of a jumper on 1-MCC-213-A1-A and/or on 1-MCC-213-A2-A (both of which are in Room 772.0-A1) when the control cable for 1-FCV-74-1-A and/or 1-FCV-74-8-A are lost. When the control cables for valves 1-FCV-74-2-B and/or 1-FCV-74-9-B are lost, the jumper is installed on 1-MCC-213-B1-B in Room 772.0-A2. The jumper allows the boundary valves to be opened for cold shutdown capability. Should the fire damage the power

PART V – MANUAL ACTIONS, REPAIRS, AND EMERGENCY LIGHTING

and limit switch cables for the valve(s), the repair consists of replacement of the power and limit switch cables from the respective MCC to junction boxes located in Room 757.0-A10.

A fire in the following plant locations results in the need to implement this repair procedure:

1. Room 737.0-A1A,
2. Room 757.0-A2, -A9, -A10
3. Room 772.0-A6 (power and limit switch cable replacement)
4. Unit 1 Reactor Building includes Annulus

There are a number of locations where fire damage disables the Unit 2 control and/or power cable for RHR/RCS high-low pressure boundary valves 2-FCV-74-1-A, -2-B, -8-A and/or -9-B. The repair requires the installation of a jumper on 2-MCC-213-A1-A and/or on 2-MCC-213-A2-A (both of which are in Room 772.0-A16) when the control cable for 2-FCV-74-1-A and/or 2-FCV-74-8-A are lost. When the control cables for valves 2-FCV-74-2-B and/or 2-FCV-74-9-B are lost, the jumper is installed on 2-MCC-213-B1-B in Room 772.0-A15. The jumper allows the boundary valves to be opened for cold shutdown capability. A fire in the following plant locations results in the need to implement this repair procedure:

1. Room 713.0-A1B
2. Room 737.0-A1A, -A1B
3. Room 757.0-A1, A2, -A9, -A21, -A23, -A27
4. Room 772.0-A12, -A15(EAST), -A15(WEST)

4.0 EMERGENCY LIGHTING

Emergency lighting units with at least an 8-hour battery power supply are provided in areas needed for operation of safe shutdown equipment and in access and egress routes. Offsite power is assumed lost for Control Building fires that require MCR abandonment. While offsite power is not assumed lost for non-alternative shutdown fire locations (i.e., fires outside of the Control Building), cables for normal plant lighting have not been included in the Appendix R separation analysis. Therefore, emergency lighting is provided for Appendix R fire scenarios that result in operator manual actions in order to ensure safe shutdown capability. The operators carry a portable lantern when required to perform an operator manual action in an area that has experienced a fire (time to perform the action is after the fire has been extinguished). Refer to Sections 12.7, "Emergency Lighting," and 14.9, "Emergency Battery Lighting Units," of Part II, "Fire Protection Plan," for additional requirements.

4.1 Adequacy of Emergency Lighting Locations and Illumination Levels

Plant walkdowns were conducted during the licensing of WBN Unit 1 using "blackout" conditions to assess the adequacy of emergency lighting in access routes to operator manual action locations in the plant. In addition, the adequacy of emergency lighting has been assessed at the operator manual action locations. The adequacy of emergency lighting was evaluated by plant operators who are responsible for performing the operator manual actions during an Appendix R event. Operator sign-offs for the emergency lighting provided for access/egress routes and at operator manual action locations document the adequacy of lighting levels per Appendix R Section III.J requirements.

PART VI – FIRE HAZARDS ANALYSIS

1.0 INTRODUCTION

Part VI documents the results of the fire hazards and safe shutdown analyses performed for fire areas and rooms at Watts Bar (WBN). The results are documented on a fire area basis, broken down into separate discussions of classical fire protection features and safe shutdown analyses for each area. This section includes the following:

- (1) A summary of the evaluation performed to document the adequacy of the fire protection capabilities for each fire area.
- (2) A summary of the fire safe shutdown analysis performed to document the ability to achieve safe shutdown in case of a fire in each fire area.

The information in this section describes how each fire area meets the requirements of 10 CFR 50 Appendix R, Sections III.G, III.L and/or III.O. The fire hazards and safe shutdown evaluations were performed by qualified nuclear, mechanical, electrical, and fire protection engineers. The deviation requests and evaluations applicable to each fire area have also been identified in this section.

2.0 FIRE HAZARDS ANALYSIS STRUCTURE

The information for each fire area is presented in two distinct formats, subdivided into a summary of the classical fire protection features, and a summary of the safe shutdown analyses for the fire area. Figures II-27A through II-40A identify each plant location by fire area, room number, and room subdivision number referenced in the following sections.

2.1 SUMMARY OF CLASSICAL FIRE PROTECTION FEATURES

Each fire area consists of a single room or a group of rooms. For this discussion the word “area” can be either a single room or a group of rooms. The Classical Fire Protection Features discussed in this section of the Fire Protection Report document the following for each area evaluated.

- (1) Area evaluated (room number[s])
- (2) Description of the area (e.g., Waste Decay Tank Room, RHR Pump 1A-A Room, etc.).
- (3) Fire loading, including the main combustible materials, and severity rating of the combustible loading in the area. The following Fire Severity Index was developed from the Fire Protection Handbook (ref. 4.3.2).

<u>FIRE SEVERITY INDEX</u>	<u>COMBUSTIBLE LOADING</u>	<u>EQUIVALENT FIRE SEVERITY</u>
Insignificant	< 6,500 Btu/ft ²	< 5 minutes
Low	< 80,000 Btu/ft ²	< 60 minutes
Moderate	< 160,000 Btu/ft ²	< 120 minutes
Moderately Severe	< 240,000 Btu/ft ²	< 180 minutes
Severe	> 240,000 Btu/ft ²	> 180 minutes

- (4) For each area, the following compartmentation information is documented in tabular form:
 - (a) Room number,
 - (b) Barrier description (e.g., North Wall, Ceiling, etc.),

PART VI – FIRE HAZARDS ANALYSIS

- (c) Adjacent Fire Area/Room,
 - (d) Compartmentation drawing showing the barrier,
 - (e) Fire resistive rating of the barrier if it is a regulatory required fire barrier
- (5) The next table documents any required fire rated doors in the barriers, including the door number and its fire resistive rating.
 - (6) Required fire dampers are identified in the next table, which includes information on the damper number, fire resistive rating, etc.
 - (7) Fire detection within the area.
 - (8) Fire suppression within the area.
 - (9) Identifies if any deviation or engineering evaluation is applicable to the area

(Part VII of the Fire Protection Report documents the deviations for TVAN's commitments against applicable NRC regulatory criteria and guidance documents and engineering evaluations of the adequacy of specific fire protection features)

2.2 SUMMARY OF SAFE SHUTDOWN ANALYSES FOR THE FIRE AREA

The summaries of safe shutdown capability for each fire area are presented on an Analysis Volume (AV) basis. An AV can consist of a single room, multiple rooms, or sub-divisions of a large volume for the Appendix R separation analysis; generally all required safe shutdown cables and components in the AV are conservatively assumed damaged by the fire. This assumption is extremely conservative, especially for large AVs composed of many rooms which often have an insignificant fire severity index. Refer to Part III, Section 10, for a more complete description of the application of AVs to the analysis of the safe shutdown separation criteria of Appendix R.

The following information on the safe shutdown analysis is presented for each AV in the fire area:

- (1) Identification of the specific AV for which the summary of safe shutdown information is provided, such as AV-001,
- (2) Identification of the area that is included in the AV,
- (3) Descriptive text of the fire safe shutdown compliance strategy for the AV,
- (4) Tabular listings of the following information:
 - (a) Identification of the power systems and major equipment affected and credited for a fire in the AV. Listed power systems include 6.9kv shutdown boards powered from offsite and onsite sources, 480vac shutdown boards, 125vdc boards and 125vac vital instrument boards. The 480vac motor control centers are included in the analysis, but not listed as they are generally available when their associated 480vac shutdown board is available. The affected and credited equipment listed in the analysis summary are only the large process pumps which identify the train or path of safe shutdown equipment that is credited. Valves and instrumentation associated with the listed equipment are included in the analysis but not listed because they must be available for the train or path to be credited.
 - (b) Mitigating actions taken to return the potentially damaged equipment and/or cables to an operable status for fire safe shutdown. The mitigating actions include local manual operator actions and repairs, main control room operator

PART VI – FIRE HAZARDS ANALYSIS

actions, and/or electrical raceway fire barrier systems (ERFBS) or radiant energy shields to protect the cable(s). The cables listed in the "Cable Protection" tables are protected by 1-hour rated ERFBS except for those noted which are protected by 3-hour rated ERFBS. The cables in the "Cable Protection" tables in the Reactor Buildings are protected by radiant energy shields.

In addition to the local and main control room operator actions summarized for each specific AV, Table 6-1 summarizes local manual operator actions and main control room operator actions which may be needed for a fire in any Analysis Volume. These generic actions are for pneumatic controlled valves (control air may not be available) or MCR initiation of Fire Safe Shutdown (FSSD) functions specifically listed to properly align MCR hand switches to prevent spurious actuation from fire damaged automatic process interlocks. Additionally, generic actions may be listed to address the ability to achieve a given FSSD function from the MCR. Each operator action includes a "When Required" time (minutes) in which the action is to be performed. These times are relative with respect to event initiation. Several actions have 0 for "When Required" time which only serves to indicate that they are the initial actions.

The details associated with fire safe shutdown separation analysis for each AV within the WBN fire areas are contained in the references identified in Part II of the FPR.

3.0 FIRE AREA HAZARDS ANALYSIS

3.1 FIRE AREA 1

Fire Area 1 consists of the following rooms on the lower four elevations of the Auxiliary Building as depicted on Figures II-27A, II-28A, II-29A, and II-30A.

Room No.	Description
674.0-A1	WASTE HOLDUP TANK ROOM
674.0-A2	WASTE EVAPORATOR FEED PUMP ROOM
676.0-A1	CORRIDOR
676.0-A2	HOLDUP TANK ROOM A
676.0-A3	HOLDUP TANK ROOM B
676.0-A4	FLOOR DRAIN COLLECTION PUMP AND FILTER ROOM
676.0-A4a	FLOOR DRAIN COLLECTION TANK ROOM
676.0-A5	GAS STRIPPER FEED PUMP ROOM
676.0-A6	SPARE
676.0-A7	SPARE
676.0-A8	CONTAINMENT SPRAY PUMP ROOM 1B-B
676.0-A9	CONTAINMENT SPRAY PUMP ROOM 1A-A
676.0-A14	CONTAINMENT SPRAY PUMP ROOM 2A-A
676.0-A15	CONTAINMENT SPRAY PUMP ROOM 2B-B
676.0-A16	UNIT 1 PIPE GALLERY AND CHASE
692.0-A8	UNIT 1 PIPE GALLERY AND CHASE
692.0-A1	CORRIDOR (SUBDIVIDED INTO 692.0-A1A (692-A1A1, -A1A2, -A1A3, -A1AN), 692-A1B (A1B1, A1B2, A1B3, -A1BN) AND 692-A1C
692.0-A2	VALVE GALLERY
692.0-A3	GAS DECAY TANK ROOM

PART VI – FIRE HAZARDS ANALYSIS

Room No.	Description
692.0-A4	CHEMICAL DRAIN TANK ROOM
692.0-A5	GAS DECAY TANK ROOM
692.0-A9	CHARGING PUMP 1A-A
692.0-A12	SAFETY INJECTION PUMP 1B-B
692.0-A13	SAFETY INJECTION PUMP 1A-A
692.0-A17	MAINTENANCE AND TESTING EQUIPMENT (M&TE) HOT TOOL ROOM
692.0-A18	HOT TOOL ROOM
692.0-A27	CONCENTRATE FILTER ROOM
692.0-A29	BORIC ACID EVAPORATOR PACKAGE ROOM B
692.0-A30	BORIC ACID EVAPORATOR PACKAGE ROOM A
692.0-A31	SPARE
713.0-A28	UNIT 1 PIPE GALLERY AND CHASE

3.1.1 Rooms 674.0-A1 and A2

Description: Waste Holdup Tank Room and Waste Evaporator Feed Pump Room

Fire Loading: Combustible materials consist of plastics and small amounts of lube oil associated with the Waste Evaporator Feed Pumps and anticipated amounts of radwaste trash and laundry. The fire severity is classified as insignificant.

Compartmentation: The only regulatory barriers are the south walls of both rooms to the RHR pump cubicles and the ceilings of both rooms.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
674.0-A1	South Wall	Area 3-1, Room 676.0-A11	II-27A	2 hours
	Ceiling	Area 1, Room 692.0-A1C	II-27A, II-28A	2 hours
		Area 1, Room 692.0-A17	II-27A, II-28A	2 hours
		Area 1, Room 692.0-A18	II-27A, II-28A	2 hours
674.0-A2	South Wall	Area 3-2, Room 676.0-A12	II-27A	2 hours
	Ceiling	Area 1, Room 692.0-A18	II-27A, II-28A	2 hours
		Area 1, Room 692.0-A1C	II-27A, II-28A	2 hours

Doors: None.

Dampers: None.

Detection: None.

Suppression: A fire hose station is available in adjacent room 676.0-A1.

Deviations: None

Evaluations: The lack of total area suppression and detection is documented in Part VII, Section 3.1. The relaxation of penetration seal surveillance requirements in high radiation areas is documented in Part VII, Section 6.4.

PART VI – FIRE HAZARDS ANALYSIS

3.1.2 Rooms 676.0-A1, A2, A3, A4, A4a, A5, A6, A7, A16, 692.0-A8, 713.0-A28

Room No.	Description
676.0-A1	Corridor
676.0-A2	Holdup Tank Room A
676.0-A3	Holdup Tank Room B
676.0-A4	Floor Drain Collector Pump and Filter Room
676.0-A4a	Floor Drain Collector Tank Room
676.0-A5	Gas Stripper Feed Pump Room
676.0-A6	Spare
676.0-A7	Spare
676.0-A16	Unit 1 Pipe Gallery and Chase
692.0-A8	Unit 1 Pipe Gallery and Chase
713.0-A28	Unit 1 Pipe Gallery and Chase

Fire Loading: Combustible loading consists of small amounts of lube oil in the pumps, motors, and valves in the area; plastics associated with the various electrical panels; small amounts of rubber, cloth, and paper in the Health Physics cabinet; anticipated amounts of radwaste trash and laundry; and miscellaneous other materials. The fire severity rating is classified as insignificant in all rooms except the Corridor (676.0-A1) and the Gas Stripper Feed Pump room (676.0-A5). The fire severity rating classification of these two rooms is low.

Compartmentation: The only regulatory barriers are 3-hour between the Control Building and Auxiliary Building and 2-hour rated barriers to the RHR and Containment Spray pump cubicles and between the Unit 2 pipe and valve gallery and the upper elevations. The walls of rooms 676.0-A2, -A3, -A4, -A4a, -A5, -A6, and -A7 are not required fire barriers except as noted in the table below (ref. Figure II-27A):

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
676.0-A1	North Wall	Area 1, Room 676.0-A15	II-27A	2 hours

Detection: Ionization smoke detectors are provided in rooms 676.0-A1, 676.0-A5, 676.0-A6, 676.0-A16, 692.0-A8, and 713.0-A28.

Suppression: A standpipe and hose station is located in room 676.0-A1, 692.0-A8, and 713.0-A13. No automatic suppression is provided.

Deviations: The unprotected stair and equipment hatch openings in the floor separating elevations 676.0 from 692.0 are documented in Part VII, Section 2.6.

PART VI – FIRE HAZARDS ANALYSIS

Evaluations: The lack of total area suppression and detection is documented in Part VII, Section 3.1. The relaxation of penetration seal surveillance requirements in high radiation areas is documented in Part VII, Section 6.4.

3.1.3 Rooms 692.0-A1, A2, A3, A4, A5, A17, A18, A27, A29, A30 and A31

Room No.	Description
692.0-A1	Corridor (Subdivided into 692.0-A1A (692-A1A1, -A1A2, -A1A3, -A1AN), 692-A1B (692-A1B1, -A1B2, A1B3, -A1BN) and 692-A1C
692.0-A2	Valve Gallery
692.0-A3	Gas Decay Tank Room
692.0-A4	Chemical Drain Tank Room
692.0-A5	Gas Decay Tank Room
692.0-A17	Maintenance and Testing Equipment (M&TE) Hot Tool Room
692.0-A18	Hot Tool Room
692.0-A27	Concentrate Filter Room
692.0-A29	Boric Acid Evaporator Package Room B
692.0-A30	Boric Acid Evaporator Package Room A
692.0-A31	Spare

Fire Loading: The combustibles consist of various amounts of lube oil associated with several pumps and valves, plastics associated with various electrical panels and boxes, transformer oil associated with two transformers, insulation on cables in the cable trays and anticipated amounts of radwaste trash and laundry. The fire severity loading for room 692.0-A1 is classified as moderate and room 692.0-A31 is classified as low. The other rooms contain insignificant amounts of combustibles.

Compartmentation: Room 692.0-A1 has been subdivided into 692.0-A1A (692-A1A1, -A1A2, -A1A3, -A1AN), 692-A1B (692-A1B1, -A1B2, -A1B3, -A1BN) and 692-A1C (see Figure II-28A). There is one rectangular heating, ventilation, and air conditioning (HVAC) duct penetration, one round Emergency Gas Treatment System (EGTS) duct penetration without fire dampers in the 692.0-A1 floor slab, and one round EGTS duct penetration without fire dampers in the ceiling of 692.0-A1. Stairwell No. 3, an equipment hatch, three HVAC duct penetrations, and the elevator shaft are also unprotected openings in the 692.0-A1 floor slab, as well as Stairwell No. 3, 5 and 6, an equipment hatch, and the elevator shaft in the 692.0-A1 ceiling. There is one unprotected steel hatch in 692.0-A27 floor slab. There are two rectangular unprotected openings in 692.0-A31 floor slab. The walls of rooms 692.0-A2, -A3, -A4, -A5, -A17, -A18, -A27, -A29, -A30 and -A31 are not required fire barriers except as indicated in the table below.

	1-ISD-31-5446 47A381-770	F-C	AREA 8, ROOM 713.0-A1C	47W866-2 47W920-2	3 Hours

Detection: Ionization smoke detectors are provided in Rooms 692.0-A1A, -A1B, -A1C (except in the tunnels to the RWSTs), 692.0-A17, -A18 and 692.0-A31. Room 692.0-A4 is a part-height enclosure with no ceiling; as a result, detection coverage in Room 692.0-A1A also provides coverage for this room.

Suppression: Automatic sprinkler systems are provided in Rooms 692.0-A1A, -A1B, and -A1C (except in the tunnels to the RWSTs and Room 692.0-A2 and the entrance labyrinths into Rooms 676.0-A2 and -A3, 692.0-A29, and -A30), and 692.0-A18 (except the entrance labyrinth). Room 692.0-A4 is a part-height enclosure with no ceiling; as a result, suppression coverage in Room 692.0-A1A also provides coverage for this room. Enhanced sprinkler coverage below obstructions is also provided in Rooms 692.0-A1A, -A1B, and -A1C.

PART VI – FIRE HAZARDS ANALYSIS

Standpipes and hose stations are also available in Room 692.0-A1A, -A1B, and -A1C for all the rooms in this area.

Deviations: Intervening combustibles in the form of insulation on cables in trays and Thermo-Lag on electrical raceways are identified and justified in Part VII, Section 2.4. There are two round spiral welded HVAC ducts that penetrate the floor of 692.0-A1B from 676.0-A1. These combine into one duct that continues through the ceiling of 692.0-A1B onto elevation 713. The penetrations are not provided with fire dampers. This duct work is part of the Emergency Gas Treatment System (EGTS). Spiral welded pipe is treated like a pipe and is provided with fire rated seals between the pipe and the sleeve. Justification is documented in Part VII, Section 2.6. A non-rated personnel hatch in room 692.0-A27 provides access into the Unit 2 Pipe Gallery 676.0-A17. Justification is documented in Part VII, Section 2.6. Compliance to III.G.1 with FHA for rooms 692.0-A29 and 692.0-A30 is justified and documented in Part VII, Section 2.9.

Evaluations: The lack of total area suppression and detection in the tunnels to the RWSTs (that connect with 692.0-A1) and rooms 692.0-A2, -A3, -A27, -A29, and -A30 and the lack of total area suppression in 692.0-A18 is documented in Part VII, Section 3.1. The relaxation of penetration seal surveillance requirements in high radiation areas is documented in Part VII, Section 6.4. The feasibility and reliability evaluation for Unit 2 Operator Manual Actions is documented in Part VII, Section 8.3.1.

3.1.4 Room 676.0-A8

Description: Containment Spray Pump Room 1B-B

Fire Loading: The combustibles in the pump room consist of approximately six gallons of lube oil associated with the pump and small amounts of plastics associated with three junction boxes and five light fixtures. The fire severity is classified as insignificant.

Compartmentation: The containment spray pump room is separated from other plant locations by regulatory fire barriers.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
676.0-A8	North Wall	Area 1, Room 676.0-A9	II-27A	2 hours
		Area 1, Room 676.0-A1	II-27A	2 hours
	South Wall	Area 1, Room 676.0-A5	II-27A	2 hours
		Area 1, Room 676.0-A7	II-27A	2 hours
	East Wall	Area 1, Room 676.0-A1	II-27A	2 hours
	West Wall	Area 1, Room 676.0-A16	II-27A	2 hours
	Ceiling	Area 7, Room 692.0-A11	II-27A, II-28A	2 hours
		Area 1, Room 692.0-A1A	II-27A, II-28A	2 hours

PART VI – FIRE HAZARDS ANALYSIS

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
676.0-A8	A3	North	Area 1, Room 676.0-A1	II-27A	3 hours

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
676.0-A8	1-ISD-31-3775	E-W	Area 1	47W866-2	1.5 hrs
	47A381-391		Room 676.0-A16	47W920-1	

Detection: Ionization smoke detectors are provided in the pump room (except in the entrance labyrinth). (See note below)

Suppression: A standpipe and hose station is provided in the adjacent room (Corridor 676.0-A1). (See Note below)

Deviations: None.

Evaluations: The lack of total area detection and suppression is documented in Part VII, Section 3.1.

Note: Although this room is not provided with suppression and full area detection, as suggested by Appendix A, Section F.11, fire barrier ratings are sufficient given the combustible loadings in the room. This room does not contain redundant safe shutdown equipment. Therefore, a fire in this room will not endanger other safety related equipment required for safe plant shutdown. Refer to Paragraph F.11 of Part VIII of the FPR for information on conformance to Appendix A regarding this issue.

3.1.5 Room 676.0-A9

Description: Containment Spray Pump Room 1A-A.

Fire Loading: The combustibles consist of approximately six gallons of lube oil associated with the pump and small amounts of plastics associated with three junction boxes and four light fixtures. The fire severity is classified as insignificant.

Compartmentation: The containment spray pump room is separated from other plant locations by regulatory fire barriers.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
676.0-A9	North Wall	AREA 2-1, ROOM 676.0-A10	II-27A	2 Hours
	South Wall	AREA 1, ROOM 676.0-A1	II-27A	2 Hours

Detection: Ionization smoke detectors are provided (except in the entrance labyrinth). (See note below)

Suppression: A standpipe and hose station is provided in the adjacent room (Corridor 676.0-A1). (See note below)

Deviations: None.

Evaluations: The lack of total area suppression and detection is documented in Part VII, Section 3.1.

Note: Although this room is not provided with suppression and full area detection, as suggested by Appendix A, Section F.11, fire barrier ratings are sufficient given the combustible loadings in the room. This room does not contain redundant safe shutdown equipment. Therefore, a fire in this room will not endanger other safety related equipment required for safe plant shutdown. Refer to Paragraph F.11 of Part VIII of the FPR for information on conformance to Appendix A regarding this issue.

3.1.6 Rooms 676.0-A2 and A3

Description: Holdup Tank Rooms A and B.

Fire Loading: The combustibles consist of anticipated amounts of radwaste trash and laundry. The fire severity is classified as insignificant.

Compartmentation: The only regulatory fire barriers for these two rooms are the south walls connecting the rooms with the Control Building at elevation 692.0 and up, and their ceilings.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
676.0-A2	South	Area 48, Room 692.0-C3	II-28A, II-33A	3 Hours
		Area 48, Room 692.0-C4	II-28A, II-33A	3 Hours

		Area 8, Room 713.0-A22	II-28A, II-29A	2 Hours
		Area 8, Room 713.0-A23	II-28A, II-29A	2 Hours

Doors: None.

Dampers: None.

Detection: None.

Suppression: A standpipe and hose station is provided in the adjacent room (Corridor 692.0-A1). No automatic suppression is provided.

Deviations: None

Evaluations: The lack of total area suppression and detection is documented in Part VII, Section 3.1. The relaxation of penetration seal surveillance requirements is documented in Part VII, Section 6.4.

3.1.7 Rooms 692.0-A3 and A5

Description: Gas Decay Tank Rooms

Fire Loading: There are no significant combustibles in these rooms. The fire severity is classified as insignificant.

Compartmentation: The only regulatory barriers are the south wall to the Control Building and Turbine Building and the ceiling.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
692.0-A3	South Wall	Area 48, Room 692.0-C2	II-28A, II-33A	3 Hours

		Area 48, Room 692.0-C2	II-28A, II-33A	3 Hours
		Area 48, Room 708.0-C1	II-28A, II-33A	3 Hours
		Area 63, Turbine Building	II-28A, II-33A	3 Hours
	Ceiling	Area 8, Room 713.0-A1A	II-28A, II-29A	2 Hours
		Area 8, Room 713.0-A27	II-28A, II-29A	2 Hours

Doors: None.

Dampers: None.

Detection: None.

Suppression: A standpipe and hose station is provided in the adjacent room (Corridor 692.0-A1). No automatic suppression is provided.

Deviations: None.

Evaluations: The lack of total area suppression and detection is documented in Part VII, Section 3.1.

3.1.8 Room 692.0-A9

Description: Charging Pump 1A-A

Fire Loading: The combustibles consists of approximately 53 gallons of lube oil in the charging pump, plastics associated with lights and a junction box and anticipated amounts of radwaste trash and laundry. The fire severity is classified as low.

Compartmentation: The charging pump room is bounded by regulatory fire barriers, except for the floor which is not adjacent to any other plant location.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
692.0-A9	North Wall	AREA 1, ROOM 692.0-A8	II-28A	2 Hours
		AREA 5, ROOM 692.0-A7	II-28A	2 Hours
	South Wall	AREA 1, ROOM 692.0-A1A	II-28A	2 Hours
	East Wall	AREA 6, ROOM 692.0-A10	II-28A	2 Hours
	West Wall	AREA 1, ROOM 692.0-A1A	II-28A	2 Hours

PART VI – FIRE HAZARDS ANALYSIS

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
	Ceiling	AREA 8, ROOM 713.0-A1A	II-28A, II-29A	2 Hours
		AREA 8, ROOM 713.0- A9	II-28A, II-29A	2 Hours

Doors:

	47A381-394F			47W920-2	

Detection: Ionization smoke detectors are provided in the room (except in the entrance labyrinth). (See note below)

Suppression: An automatic sprinkler system is provided in the room (except the entrance labyrinth). A standpipe and hose station is provided in the adjacent room (Corridor 692.0-A1). (See note below)

Deviations: None.

Evaluations: The lack of total area suppression and detection in the entrance labyrinth is documented in Part VII, Section 3.1.

Note: Although this room is not provided with full area suppression and detection, as suggested by Appendix A, Section F.11, fire barrier ratings are sufficient given the combustible loadings in the room. This room does not contain redundant safe shutdown equipment. Therefore, a fire in this room will not endanger other safety related equipment required for safe plant shutdown. Refer to Paragraph F.11 of Part VIII of the FPR for information on conformance to Appendix A regarding this issue.

3.1.9 Room 692.0-A12

Description: Safety Injection Pump 1B-B.

Fire Loading: The combustibles consist of the lube oil for the pump and two valves, plastics associated with lights and control and junction boxes and anticipated amounts of radwaste trash and laundry. The fire severity is classified as insignificant.

Compartmentation: The pump room is bounded by regulatory fire barriers.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided in the area. A standpipe and hose station is provided in the adjacent room (Corridor 692.0-A1).

Deviations: None.

Evaluations: None.

3.1.10 Room 692.0-A13

Description: Safety Injection Pump 1A-A

Fire Loading: The combustibles consist of the lube oil in the pump and two valves, plastics associated with lights and a control box and anticipated amounts of radwaste trash and laundry. The fire severity is classified as insignificant.

Compartmentation: The pump room is bounded by regulatory fire barriers.

Barriers:

PART VI – FIRE HAZARDS ANALYSIS

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
		AREA 8, ROOM 713.0-A15	II-28A, II-29A	2 Hours

Doors: None.

Dampers: None.

Detection: Ionization smoke detectors are provided for this room.

Suppression: An automatic preaction sprinkler system is provided in the room (except in the entrance labyrinth). A standpipe and hose station is provided in the adjacent room (Corridor 692.0-A1).

Deviations: None.

Evaluations: The lack of total area suppression in the entrance labyrinth is documented in Part VII, Section 3.1.

3.1.12 Room 692.0-A31

Description: Spare

Fire Loading: The combustibles consist of lube oil in a hoist, plastics associated with lights and anticipated amounts of radwaste trash and laundry. The fire severity is classified low.

Compartmentation: The south wall, floor, and ceiling are regulatory fire barriers.

BARRIERS:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
692.0-A31	SOUTH WALL	AREA 48, ROOM 693.0-C6	II-28A, II-33A	3 Hours
		AREA 48, ROOM 693.0-C7	II-28A, II-33A	3 Hours

PART VI – FIRE HAZARDS ANALYSIS

Detection: Ionization smoke detectors are provided for the room.

Suppression: A standpipe and hose station is provided in the adjacent room (Corridor 692.0-A1).

Deviations: There is an unprotected opening in the floor to a chase down to room 676.0-A4a, and a non-fire rated hatch cover in the ceiling to a monolithic enclosure on elevation 713. The non-fire rated hatch cover provides a sufficient level of protection due to the insignificant quantities of combustibles on both sides of the hatch. Justification is documented in Part VII, Section 2.6.

Evaluations: The lack of total area suppression is documented in Part VII, Section 3.1.

3.1.13 Room 676.0-A14

Description: Containment Spray Pump Room 2A-A

Fire Loading: The combustibles consist of approximately six gallons of lube oil associated with the pump and small amounts of plastics associated with three junction boxes and four light fixtures. The fire severity is classified as insignificant.

Compartmentation: The room is separated from other plant locations by regulatory fire barriers.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
676.0-A14	North Wall	Area 2-2, Room 676.0-A13	II-27A	2 Hours

PART VI – FIRE HAZARDS ANALYSIS

Detection: Ionization smoke detectors are provided (except in the entrance labyrinth). (See note below)

Suppression: A standpipe and hose station is provided in the adjacent room (Corridor 676.0-A1). (See note below)

Deviations: None.

Evaluations: The lack of total area suppression and detection is documented in Part VII, Section 3.1.

Note: Although this room is not provided with suppression and full area detection, as suggested by Appendix A, Section F.11, fire barrier ratings are sufficient given the combustible loadings in the room. This room does not contain redundant safe shutdown equipment. Therefore, a fire in this room will not endanger other safety related equipment required for safe plant shutdown. Refer to Paragraph F.11 of Part VIII of the FPR for information on conformance to Appendix A regarding this issue.

3.1.14 Room 676.0-A15

Description: Containment Spray Pump Room 2B-B

Fire Loading: The combustibles consist of approximately six gallons of lube oil associated with the pump and small amounts of plastics associated with three junction boxes and five light fixtures. The fire severity is classified as insignificant.

Compartmentation: The room is separated from other plant locations by regulatory fire barriers.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
676.0-A15	North Wall	Area 1, Room 676.0-A14	II-27A	2 Hours
		Area 1, Room 676.0-A1	II-27A	2 Hours

		Area 65, Room 676.0-A17	II-27A	2 Hours
	East Wall	Area 65, Room 676.0-A17	II-27A	2 Hours
	West Wall	Area 1, Room 676.0-A16	II-27A	2 Hours
	Ceiling	Area 7, Room 692.0-A21	II-27A, II-28A	2 Hours
		Area 1, Room 692.0-A1B	II-27A, II-28A	2 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
676.0-A15	A11	North	Area 1, Room 676.0-A1	II-27A	3 Hours

PART VI – FIRE HAZARDS ANALYSIS

Dampers					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
676.0-A15	2-ISD-31-3855 47A381-391	E-W	Area 65 Room 676.0-A17	47W866-11 47W920-1	1.5 Hours

Detection: Ionization smoke detectors are provided in the pump room (except in the entrance labyrinth). (See note below)

Suppression: A standpipe and hose station is provided in the adjacent room (Corridor 676.0-A1). (See Note below)

Deviations: None.

Evaluations: The lack of total area detection and suppression is documented in Part VII, Section 3.1.

Note: Although this room is not provided with suppression and full area detection, as suggested by Appendix A, Section F.11, fire barrier ratings are sufficient given the combustible loadings in the room. This room does not contain redundant safe shutdown equipment. Therefore, a fire in this room will not endanger other safety related equipment required for safe plant shutdown. Refer to Paragraph F.11 of Part VIII of the FPR for information on conformance to Appendix A regarding this issue.

PART VI – FIRE HAZARDS ANALYSIS

3.1.15 Fire Area 1 Safe Shutdown Analysis by Analysis Volume

3.1.15.1 AV-001

Room No.	Description
674.0-A1	Waste Holdup Tank Room
674.0-A2	Waste Evaporator Feed Pump Room
676.0-A1	Corridor
676.0-A2	Holdup Tank Room A
676.0-A3	Holdup Tank Room B
676.0-A4	Floor Drain Collection Pump and Filter Room
676.0-A4a	Floor Drain Collection Tank Room
676.0-A5	Gas Stripper Feed Pump Room
676.0-A6	Spare
676.0-A7	Spare
676.0-A16	Unit 1 Pipe Gallery and Chase
692.0-A1C	Corridor
692.0-A8	Unit 1 Pipe Gallery and Chase
692.0-A31	Spare
713.0-A28	Unit 1 Pipe Gallery and Chase

A fire in Analysis Volume 1 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 long term decay heat removal and steam generator inventory control functions and Unit 2 reactor coolant inventory control function. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include providing fire wrap (3-hour ERFBS) to selected cables to preclude damage to the Unit 1 and Unit 2 A RHR pump power cable in the event of a fire and manual operation of Unit 1 and Unit 2 equipment required for safe shutdown and post fire repairs. Operator Manual Actions (OMAs) are not required to mitigate fire in room 674.0-A1 per engineering evaluation in Part VII, section 3.1.1. These features and equipment affected and credited are identified below:

3.1.15.3 AV-003

Room No.	Description
692.0-A1A2	Corridor, Column Lines S-T/A4-A5
692.0-A1A3	Corridor, Column Lines S-T/A5-A6
692.0-A1AN	Corridor, Column Lines S-U/A6-A8
676.0-A2	Holdup Tank Room A
676.0-A3	Holdup Tank Room B

A fire in AV-003 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 long term decay heat removal, steam generator inventory control and reactor coolant inventory control functions and Unit 2 containment HVAC functions. Mitigating features are required to restore systems necessary for safe shut down. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include manual operation of Unit 1 and Unit 2 equipment required for safe shutdown and post fire repairs. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.1.15.4 AV-004A

Room No.	Description
692.0-A1AN	Corridor, Column Lines S-U/A6-A8
692.0-A1BN	Corridor, Column Lines S-U/A8-A10
676.0-A2	Holdup Tank Room A
676.0-A3	Holdup Tank Room B

AV-004 contains both RHR power feeds. Therefore, two separate analyses (AV-004A and AV-004B) are performed to address the use of either path depending upon on the location of the fire within this analysis volume. Only RHR Train A power feeds for both units are provided with a 1-hour fire barrier until a minimum of 20 feet of separation exists between trains. This is an exception to the general methodology of providing cable protection (ERFBS) from analysis volume boundary to analysis boundary as described in FPR Part III, Section 10.3.1. The Train A RHR pump power cable is protected such that there is greater than 20 feet of separation between the Train A and Train B RHR pump cables to ensure that a fire cannot damage the power cables for both pumps.

A fire in Analysis Volume 4A could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 long term decay heat removal, steam generator inventory control and reactor coolant inventory control functions and Unit 2 containment HVAC functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available.

The required mitigating features for Unit 1 and Unit 2 include providing fire wrap to preclude damage to the A RHR pump power cables in the event of a fire and manual operation of equipment required for safe shutdown and post fire repairs. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.1.15.6 AV-004AC

Room No.	Description
692.0-A1AN	Corridor, Column Lines S-U/A6-A8
692.0-A1BN	Corridor, Column Lines S-U/A8-A10
692.0-A1C	Corridor

This AV is analyzed to address the interface between 692.0-A1C and 692.0-A1AN and 692.0-A1BN (i.e., to obtain 20 feet of separation on either side of Column Line U).

A fire in Analysis Volume 4AC could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 long term decay heat removal, steam generator inventory control and reactor coolant inventory control functions and Unit 2 containment HVAC functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available.

The required mitigating features for Unit 1 and Unit 2 include providing fire wrap to selected cables to preclude damage to the A RHR pump power cables in the event of a fire and manual operation of equipment required for safe shutdown and post fire repairs. AV-004 contains both RHR power feeds. Therefore, two separate analyses (AV-004AC and AV-004BC) are performed to address the use of either path depending upon the location of the fire within this analysis volume. The Train A RHR pump power feeds for both units are provided with a 1-hour fire barrier until more than 20 feet of separation exists between trains. This is an exception to the general methodology of providing cable protection (ERFBS) from analysis volume boundary to analysis boundary as described in FPR Part III, Section 10.3.1. The Train A RHR pump power cable is protected such that there is greater than 20 feet of separation between the Train A and Train B RHR pump cables to ensure that a fire cannot damage the power cables for both pumps. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.1.15.7 AV-004BC

Room No.	Description
692.0-A1AN	Corridor, Column Lines S-U/A6-A8
692.0-A1BN	Corridor, Column Lines S-U/A8-A10
692.0-A1C	Corridor

This AV is analyzed to address the interface between 692.0-A1C and 692.0-A1AN and 692.0-A1BN (i.e., to obtain 20 feet of separation on either side of Column Line U).

A fire in Analysis Volume 4BC could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 long term decay heat removal, steam generator inventory control and reactor coolant inventory control functions and Unit 2 containment HVAC. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features for Unit 1 and Unit 2 include providing fire wrap to selected cables to preclude damage to the A RHR pump power cables in the event of a fire and manual operation of equipment required for safe shutdown and post fire repairs. AV-004 contains both RHR power feeds. Therefore, two separate analyses (AV-004AC and AV-004BC) are performed to address the use of either path depending upon the location of the fire within this analysis volume. The Train A RHR pump power feeds for both units are provided with a 1-hour fire barrier until more than 20 feet of separation exists between trains. This is an exception to the general methodology of providing cable protection (ERFBS) from analysis volume boundary to analysis boundary as described in FPR Part III, Section 10.3.1. The Train A RHR pump power cable is protected such that there is greater than 20 feet of separation between the Train A and Train B RHR pump cables to ensure that a fire cannot damage the power cables for both pumps. These features and equipment affected and credited are identified below:

692.0-A18	Hot Tool Room

A fire in Analysis Volume 6 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 long term decay heat removal and reactor coolant inventory control functions and Unit 2 steam generator inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features for Unit 1 and Unit 2 include manual operation of equipment required for safe shutdown and repair procedures. These features and equipment affected and credited are identified below:

A fire in Analysis Volume 8 could potentially affect systems and components necessary to maintain the Unit 1 long term decay heat removal functions however no mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Unit 2 major equipment required to maintain safe shutdown functions is not impacted such that shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Offsite power is available. Equipment affected and credited to achieve shutdown are identified below:

3.1.15.12 AV-009

Room No.	Description
692.0-A9	Charging Pump 1A-A

A fire in Analysis Volume 9 could potentially affect systems and components necessary to maintain the Unit 1 reactor coolant inventory control functions however no mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Unit 2 major equipment required to maintain safe shutdown functions is not impacted such that shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Offsite power is available. Equipment affected and credited to achieve shutdown are identified below:

3.1.15.14 AV-011

Room No.	Description
692.0-A13	Safety Injection Pump 1A-A

A fire in Analysis Volume 11 could potentially affect systems and components necessary to maintain the Unit 1 long term decay heat removal. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include manual operation of Unit 1 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

3.1.15.15 AV-100

Room No.	Description
676.0-A14	Containment Spray Pump 2A-A

A fire in Analysis Volume 100 could potentially affect systems and components necessary to maintain the Unit 2 long term decay heat removal functions however no mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Unit 1 major equipment required to maintain safe shutdown functions is not impacted such that shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Offsite power is available. Equipment credited to achieve shutdown is identified below:

3.1.15.16 AV-101

Room No.	Description
676.0-A15	Containment Spray Pump 2B-B

A fire in Analysis Volume 101 could potentially affect systems and components necessary to maintain the Unit 2; however, no mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below, as credited. Unit 1 major equipment required to maintain safe shutdown functions is not impacted such that shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Offsite power is available. Equipment credited to achieve shutdown is identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.2 FIRE AREA 1-1

3.2.1 Room 692.0-A20

Description: Safety Injection Pump 2B-B

Fire Loading: The combustibles consist of the lube oil in the pump and two valves and plastics associated with electrical boxes and lights. The fire severity is classified as insignificant.

Compartmentation: The pump room is bounded by regulatory fire barriers.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
692.0-A20	NORTH WALL	AREA 1-2, ROOM 692.0-A19	II-28A	2 HOURS
	EAST WALL	AREA 65, ROOM 692.0-A24	II-28A	2 HOURS
	SOUTH WALL	AREA 1, ROOM 692.0-A1B	II-28A	2 HOURS
		AREA 66, ROOM 692.0-A21	II-28A	2 HOURS
	WEST WALL	AREA 1, ROOM 692.0-A1C	II-28A	2 HOURS
	FLOOR	AREA 1, ROOM 676.0-A1	II-27A, II-28A	2 HOURS
		AREA 1, ROOM 676.0-A14	II-27A, II-28A	2 HOURS
		AREA 2-2, ROOM 676.0-A13	II-27A, II-28A	2 HOURS
	CEILING	AREA 8, ROOM 713.0-A16	II-28A, II-29A	2 HOURS
		AREA 8, ROOM 713.0-A17	II-28A, II-29A	2 HOURS
		AREA 65, ROOM 713.0-A29	II-28A, II-29A	2 HOURS

Doors:					
Room	Door Number	Dir	Adjacent Area/Room	FPR Figure Number	Door Rating
692.0-A20	A40	SOUTH	AREA 1, 692.0-A1B	II-28A	3 HOURS

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
692.0-A20	2-ISD-31-3857	E-W	Area 65, Room 692.0-A24	47W866-11	1.5
	47A381-394			47W920-2	HOURS

Detection: Ionization smoke detectors are provided in this room.

Suppression: An automatic preaction sprinkler system is provided in this room. A standpipe and hose station is provided in the adjacent room (Corridor 692.0-A1).

Deviations: None.

Evaluations: None

PART VI – FIRE HAZARDS ANALYSIS

3.2.2 Fire Area 1-1 Safe Shutdown Analysis by Analysis Volume

3.2.2.1 AV-102

Room No.	Description:
692.0-A20	Safety Injection Pump 2B-B

A fire in Analysis Volume 102 does not impact major equipment required to maintain safe shutdown functions. Shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Equipment credited to achieve shutdown is identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.3 FIRE AREA 1-2

3.3.1 Room 692.0-A19

Description: Safety Injection Pump 2A-A

Fire Loading: The combustibles consist of the lube oil in the pump and two valves and plastics associated with electrical boxes and lights. The fire severity is classified as insignificant.

Compartmentation: The pump room is bounded by regulatory fire barriers.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
692.0-A19	North Wall	Area 1, Room 692.0-A1C	II-28A	2 HOURS
	South Wall	Area 1-1, Room 692.0-A20	II-28A	2 HOURS
	East Wall	Area 65, Room 692.0-A24	II-28A	2 HOURS
	West Wall	Area 1, Room 692.0-A1C	II-28A	2 HOURS
	Ceiling	Area 8, Room 713.0-A16	II-28A, II-29A	2 HOURS
	Floor	Area 1, Room 676.0-A1	II-27A, II-28A	2 HOURS
		Area 3-2, Room 676.0-A12	II-27A, II-28A	2 HOURS
		Area 2-2, Room 676.0-A13	II-27A, II-28A	2 HOURS

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
692.0-A19	A39	North	Area 1, 692.0-A1C	II-28a	3 HOURS

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
692.0-A19	2-ISD-31-3856 47A381-394	E-W	Area 65, Room 692.0-A24	47W866-11 47W920-2	1.5 HOURS

Detection: Ionization smoke detectors are provided in this room.

Suppression: An automatic preaction sprinkler system is provided in this room. A standpipe and hose station is provided in the adjacent room (Corridor 692.0-A1).

Deviations: None.

Evaluations: None

PART VI – FIRE HAZARDS ANALYSIS

3.3.2 Fire Area 1-2 Safe Shutdown Analysis by Analysis Volume

3.3.2.1 AV-012

Room No.	Description:
692.0-A19	Safety Injection Pump 2A-A

A fire in Analysis Volume 12 could potentially affect Unit 2 systems and components necessary to maintain the long term decay heat removal function. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Unit 1 major equipment required to maintain safe shutdown functions is not impacted such that shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Offsite power is available. The required mitigating features include manual operation of Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.4 FIRE AREA 2-1

3.4.1 Room 676.0-A10

Description: RHR Pump Room 1B-B

Fire Loading: The combustibles consists of lube oil associated with the RHR pump and valve, small amounts of plastics associated with lights and a control panel and anticipated amounts of radwaste trash and laundry. The fire severity is classified as insignificant.

Compartmentation: The RHR pump room is bounded by regulatory fire barriers.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
676.0-A10	NORTH WALL	AREA 3-1, ROOM 676.0-A11	II-27A	2 HOURS
	SOUTH WALL	AREA 1, ROOM 676.0-A9	II-27A	2 HOURS
	EAST WALL	AREA 1, ROOM 676.0-A1	II-27A	2 HOURS
	WEST WALL	AREA 1, ROOM 676.0-A16	II-27A	2 HOURS
	CEILING	AREA 1, ROOM 692.0-A12 AREA 1, ROOM 692.0-A13	II-27A, II-28A II-27A, II-28A	2 HOURS 2 HOURS

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
676.0-A10	A5	EAST	AREA 1, ROOM 676.0-A1	II-27A	3 HOURS

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
676.0-A10	1-ISD-31-3777 47A381-391	E-W	AREA 1, ROOM 676.0-A16	47W866-2 47W920-1	1.5 HOURS

Detection: Ionization smoke detectors are provided (except in the entrance labyrinth). (See Note below)

Suppression: A standpipe and hose station is provided in the adjacent room (corridor 676.0-A1). (See Note below)

Deviations: None.

Evaluations: None

PART VI – FIRE HAZARDS ANALYSIS

Note: Although this area is not provided with suppression or full area detection, fire barrier ratings are sufficient given the combustible loadings in the area. This is a separate fire area which does not contain redundant safe shutdown equipment. Therefore, a fire in this area will not endanger other safety related equipment required for safe plant shutdown. Refer to Paragraph F.11 of Part VIII of the FPR for information on conformance to Appendix A guidelines regarding this issue.

PART VI – FIRE HAZARDS ANALYSIS

3.4.2 Fire Area 2-1 Safe Shutdown Analysis by Analysis Volume

3.4.2.1 AV-013

Room No.	Description:
676.0-A10	RHR Pump Room 1B-B

A fire in Analysis Volume 13 could potentially affect systems and components necessary to maintain the long term decay heat removal function. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Unit 2 major equipment required to maintain safe shutdown functions is not impacted such that shutdown can be achieved by utilizing both Train A and B systems and components without mitigating actions. Offsite power is available. The required mitigating features include manual operation of equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.5 FIRE AREA 2-2

3.5.1 Room 676.0-A13

Description: RHR Pump Room 2B-B

Fire Loading: The combustibles in this room consist of lube oil associated with the RHR pump and valve and small amounts of plastics associated with lights and a control panel. The fire severity is classified as insignificant.

Compartmentation: The pump room is bounded by regulatory fire barriers.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
676.0-A13	NORTH WALL	AREA 3-2, ROOM 676.0-A12	II-27A	2-HOURS
	SOUTH WALL	AREA 1, ROOM 676.0-A14	II-27A	2 HOURS
	EAST WALL	AREA 65, ROOM 676.0-A17	II-27A	2 HOURS
	WEST WALL	AREA 1, ROOM 676.0-A1	II-27a	2 HOURS
	CEILING	AREA 1-2, ROOM 692.0-A19	II-27A	2 HOURS
		AREA 1-1, ROOM 692.0-a20	II-27A	2 HOURS

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
676.0-A13	A9	West	Area 1, Room 676.0-A1	II-27A	3 Hours

Dampers					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
676.0-A13	2-ISD-31-3852	E-W	Area 65, Room 676.0-A17	47W866-11	1.5 Hours
	47A381-391			47W920-1	

Detection: The pump room is provided with ionization smoke detectors (except in the entrance labyrinth). (See note below)

Suppression: A standpipe and hose station is provided in the adjacent room (corridor 676.0-A1). (See note below)

Deviations: None.

Evaluations: None.

Note: Although this area is not provided with suppression and full area detection, as suggested by Appendix A, Section F.11, fire barrier ratings are sufficient given the combustible loadings in the area. This is a separate fire area which does not contain redundant safe shutdown equipment. Therefore, a fire in this area will not endanger other safety related equipment required for safe plant shutdown. Refer to Paragraph F.11 of Part VIII of the FPR for information on conformance to Appendix A regarding this issue.

PART VI – FIRE HAZARDS ANALYSIS

3.5.2 Fire Area 2-2 Safe Shutdown Analysis by Analysis Volume

3.5.2.1 AV-014

Room No.	Description:
676.0-A13	RHR Pump Room 2B-B

A fire in Analysis Volume 14 could potentially affect Unit 2 long term decay heat removal functions through loss of Unit 2 Train B RHR but does not otherwise impact major equipment required to maintain safe shutdown functions. Shutdown for Unit 1 and Unit 2 can be achieved by utilizing remaining Train A and B systems and components without mitigating actions. Equipment credited to achieve shutdown is identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.6 FIRE AREA 3-1

3.6.1 Room 676.0-A11

Description: RHR Pump Room 1A-A

Fire Loading: The combustibles consist of lube oil associated with the RHR pump and valve, small amounts of plastics associated with lights and a control panel and anticipated amounts of radwaste trash and laundry. The fire severity is classified as insignificant.

Compartmentation: The room is bounded by regulatory fire barriers.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
676.0-A11	North Wall	AREA 1, ROOM 674.0-A1	II-27A	2 Hours
	South Wall	AREA 2-1, ROOM 676.0-A10	II-27A	2 Hours
	East Wall	AREA 1, ROOM 676.0-A1	II-27A	2 Hours
	West Wall	AREA 1, ROOM 676.0-A16	II-27A	2 Hours
	Ceiling	AREA 1, ROOM 692.0-A13	II-27A, II-28A	2 Hours
		AREA 1, ROOM 692.0-A1C	II-27A, II-28A	2 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
676.0-A11	A6	East	Area 1, Room 676.0-A1	II-27A	3 HOURS

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
676.0-A11	1-ISD-31-3778	E-W	Area 1, Room 676.0-A16	47W866-2	1.5
	47A381-391			47W920-1	HOURS

Detection: Ionization smoke detectors are provided (except in the entrance labyrinth). (See Note below)

Suppression: A standpipe and hose station is provided in the adjacent room (corridor 676.0-A1). (See Note below)

Deviations: None.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

Note: Although this area is not provided with suppression or full area detection, fire barrier ratings are sufficient given the combustible loadings in the area. This is a separate fire area which does not contain redundant safe shutdown equipment. Therefore, a fire in this area will not endanger other safety related equipment required for safe plant shutdown. Refer to Paragraph F.11 of Part VIII of the FPR for information on conformance to Appendix A guidelines regarding this issue.

PART VI – FIRE HAZARDS ANALYSIS

3.6.2 Fire Area 3-1 Safe Shutdown Analysis by Analysis Volume

3.6.2.1 AV-015

Room No.	Description:
676.0-A11	RHR Pump Room 1A-A

A fire in Analysis Volume 15 could potentially affect Unit 1 long term heat decay removal functions through the loss of Unit 1 Train A RHR but does not otherwise impact major equipment required to maintain safe shutdown functions. Shutdown for Unit 1 and Unit 2 can be achieved by utilizing remaining Train A and B systems and components without mitigating actions. Equipment credited to achieve shutdown is identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.7 FIRE AREA 3-2

3.7.1 Room 676.0-A12

Description: RHR Pump Room 2A-A

Fire Loading: The combustibles in this room consist of lube oil associated with the RHR pump and valve and small amounts of plastics associated with lights. The fire severity is classified as insignificant.

Compartmentation: The pump room is constructed of reinforced concrete.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
676.0-A12	NORTH WALL	AREA 1, ROOM 674.0-A2	II-27A	2 HOURS
		AREA 1, ROOM 676.0-A1	II-27A	2 HOURS
	SOUTH WALL	AREA 2-2, ROOM 676.0-A13	II-27A	2 HOURS
	EAST WALL	AREA 65, ROOM 676.0-A17	II-27A	2 HOURS
	WEST WALL	AREA 1, ROOM 676.0-A1	II-27A	2 HOURS
	CEILING	AREA 1-2, ROOM 692.0-A19	II-27A, II-28A	2 HOURS
		AREA 1, ROOM 692.0-A1C	II-27A, II-28A	2 HOURS

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
676.0-A12	A8	WEST	AREA 1, ROOM 676.0-A1	II-27A	3 HOURS

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
676.0-A12	2-ISD-31-3853	E-W	AREA 65, ROOM 676.0-A17	47W866-11	1.5
	47A381-391			47W920-1	HOURS

Detection: The pump room is provided with ionization smoke detectors (except in the entrance labyrinth). (See note below)

Suppression: A standpipe and hose station is provided in the adjacent room (corridor 676.0-A1). (See note below)

Deviations: None.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

Note: Although this area is not provided with suppression and full area detection, as suggested by Appendix A, Section F.11, fire barrier ratings are sufficient given the combustible loadings in the area. This is a separate fire area which does not contain redundant safe shutdown equipment. Therefore, a fire in this area will not endanger other safety related equipment required for safe plant shutdown. Refer to Paragraph F.11 of Part VIII of the FPR for information on conformance to Appendix A regarding this issue.

PART VI – FIRE HAZARDS ANALYSIS

3.8 FIRE AREA 4

3.8.1 Room 692.0-A6

Description: Turbine Driven Auxiliary Feedwater Pump 1A-S

Fire Loading: The combustibles consists of lube oil associated with the feedwater pump, turbine, oil cooler, 2 sump pumps, and 5 valves and various amounts of plastics associated with electrical panels and lights. The fire severity is classified as Insignificant.

Compartmentation: The Auxiliary Feedwater Pump Room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
692.0-A6	North Wall	Area 5, Room 692.0-A7	II-28A	2 Hours
	South and East Walls and Ceiling	Area 1, Room 692.0-A1a	II-28A	2 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
692.0-A6	A25	EAST	AREA 1, ROOM 692.0-A1A	II-28A	3 HOURS

	1-ISD-31-3783	C	AREA 1, ROOM 692.0-A1A	47W866-2	3 HRS
				47W920-2	

Detection: Ionization smoke detectors are provided in the pump room.

Suppression: An automatic preaction sprinkler system is provided. A standpipe and hose station is provided in the adjacent room (Corridor 692.0-A1).

Deviations: None.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

3.8.2 Fire Area 4 Safe Shutdown Analysis by Analysis Volume

3.8.2.1 AV-017

Room No.	Description:
692.0-A6	Turbine Driven Auxiliary Feedwater Pump 1A-S

A fire in Analysis Volume 17 could potentially affect Unit 1 systems and components used to maintain steam generator inventory control functions by affecting the Unit 1 Turbine-Driven AFW pump. Safe shutdown for Unit 1 and Unit 2 can be achieved through the remaining train A and B systems and components without mitigating actions. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.9 FIRE AREA 5

3.9.1 Room 692.0-A7

Description: Unit 1 Pipe Gallery

Fire Loading: The combustibles located in the room consist of the lube oil and grease associated with the fans, pumps, and valves and the plastics associated with the electrical panels and boxes and lights. The fire severity is classified as insignificant.

Compartmentation: The room is of reinforced concrete construction.

Barriers:

Detection: Ionization smoke detection is provided in the room.

Suppression: An automatic preaction sprinkler system is provided for the room. A standpipe and hose station is provided in the adjacent room (Corridor 692.0-A1).

PART VI – FIRE HAZARDS ANALYSIS

Deviations: None.

Evaluations: The Unit 1 evaluation for performing a manual action in the room of fire origin is documented in Part VII, section 7.1.3.

PART VI – FIRE HAZARDS ANALYSIS

3.9.2 Fire Area 5 Safe Shutdown Analysis by Analysis Volume

3.9.2.1 AV-018

Room No.	Description:
692.0-A7	Unit 1 Pipe Gallery

A fire in Analysis Volume 18 could potentially affect Unit 1 systems and components necessary to maintain the long term decay heat removal, reactor coolant inventory control and containment HVAC functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Unit 2 major equipment required to maintain safe shutdown functions is not impacted such that shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Offsite power is available. The required mitigating features for Unit 1 include manual operation of equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.10 FIRE AREA 6

3.10.1 Room 692.0-A10

Description: Charging Pump Room 1B-B

Fire Loading: The combustibles consist of the lube oil in the charging pump and plastics associated with lights and a junction box and anticipated amounts of radwaste trash and laundry. The fire severity is classified as low.

Compartmentation: The pump room is bounded by regulatory fire barriers.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
692.0-A10	NORTH WALL	AREA 1, ROOM 692.0-A8	II-28A	2 HOURS
		AREA 7, ROOM 692.0-A11	II-28A	2 HOURS
	SOUTH WALL	AREA 1, ROOM 692.0-A1A	II-28A	2 HOURS
	EAST WALL	AREA 7, ROOM 692.0-A11	II-28A	2 HOURS
	WEST WALL	AREA 1, ROOM 692.0-A9	II-28A	2 HOURS
	CEILING	AREA 8, ROOM 713.0-A1A	II-28A, II-29A	2 HOURS
		AREA 8, ROOM 713.0-A9	II-28A, II-29A	2 HOURS
	FLOOR (partial)	AREA 1, ROOM 676.0-A16	II-27A, II-28A	2 HOURS

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
692.0-A10	A29	South	Area 1, Room 692.0-A1A	II-28A	3 HOURS

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
692.0-A10	1-ISD-31-3799	N-S	Area 1, Room 692.0-A8	47W866-2	1.5 HOURS
	47A381-394			47W920-2	

Detection: Ionization smoke detectors are provided in the room (except in the entrance labyrinth). (See Note below)

Suppression: An automatic preaction sprinkler system is provided in the room (except in the entrance labyrinth). A standpipe and hose station is provided in the adjacent room (Corridor 692.0-A1). (See Note below)

Deviations: None.

Evaluations: The lack of total area suppression and detection is addressed in Part VII, Section 3.1.

PART VI – FIRE HAZARDS ANALYSIS

Note: Although this area is not provided with full area detection and suppression, as suggested by Appendix a guideline, Section F.11, fire barrier ratings are sufficient given the combustible loadings in the area. This is a separate fire area which does not contain redundant safe shutdown equipment. Therefore, a fire in this area will not endanger other safety related equipment required for safe plant shutdown. Refer to Paragraph F.11 of Part VIII of the FPR for information on conformance to Appendix A regarding this issue.

PART VI – FIRE HAZARDS ANALYSIS

3.10.2 Fire Area 6 Safe Shutdown Analysis by Analysis Volume

3.10.2.1 AV-019

Room No.	Description:
692.0-A10	Charging Pump Room 1B-B

A fire in Analysis Volume 19 could potentially affect systems and components necessary to maintain the Unit 1 long term decay heat removal and reactor coolant inventory control functions through the loss of Unit 1 Train B RHR and Charging pumps. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Unit 2 major equipment required to maintain safe shutdown functions is not impacted such that shutdown can be achieved by utilizing both train A and B systems and components. The required mitigating features include manual operation of Unit 1 equipment. Equipment credited to achieve shutdown is identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.11 FIRE AREA 7

3.11.1 Room 692.0-A11

Description: Charging Pump Room 1C

Fire Loading: The combustibles consist of the lube oil in the charging pump and a valve; plastics associated with lights and a junction box and anticipated amounts of radwaste trash and laundry. The fire severity is classified as low.

Compartmentation: The pump room is bounded by regulatory fire barriers.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
692.0-A11	North Wall	Area 1, Room 692.0-A8	II-28A	2 hours
		Area 1, Room 692.0-A12	II-28A	2 hours
	South Wall	Area 1, Room 692.0-A1A	II-28A	2 hours
		Area 6, Room 692.0-A10	II-28A	2 hours
	East Wall	Area 1, Room 692.0-A1A	II-28A	2 hours
	West Wall	Area 6, Room 692.0-A10	II-28A	2 hours
	Ceiling	Area 1, Room 692.0-A1A*	II-28A, II-29A	2 hours
		Area 8, Room 713.0-A1A	II-28A, II-29A	2 hours
	Floor	Area 1, Room 676.0-A8	II-27A, II-28A	2 hours
		Area 1, Room 676.0-A9	II-27A, II-28A	2 hours
		Area 1, Room 676.0-A16	II-27A, II-28A	2 hours
		(*Entrance Labyrinth Ceiling)		

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
692.0-A11	A30	East	Area 1, Room 692.0-A1A	II-28A	3 hours

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
692.0-A11	1-ISD-31-3798	N-S	Area 1, Room 692.0-A8	47W866-2	1.5 hrs
	47A381-394			47W920-2	

Detection: Ionization smoke detectors are provided in the room (except in the entrance labyrinth). (See Note below)

Suppression: An automatic preaction sprinkler system is provided in the room (except in the entrance labyrinth). A standpipe and hose station is provided in the adjacent room (Corridor 692.0-A1). (See Note below)

Deviations: None.

PART VI – FIRE HAZARDS ANALYSIS

Evaluations: None.

Note: Although this area is not provided with full area detection and suppression, per the guidelines of Appendix A, Section F.11, fire barrier ratings are sufficient given the combustible loadings in the area. This is a separate fire area which does not contain redundant safe shutdown equipment. Therefore, a fire in this area will not endanger other safety related equipment required for safe plant shutdown. Refer to Section F.11 of Part VIII of the FPR for information on conformance to Appendix A regarding this issue.

PART VI – FIRE HAZARDS ANALYSIS

3.11.2 Fire Area 7 Safe Shutdown Analysis by Analysis Volume

3.11.2.1 AV-020

Room No.	Description:
692.0-A11	Charging Pump Room 1C

A fire in Analysis Volume 20 does not impact major equipment required to maintain safe shutdown functions. Shutdown for both units can be achieved by utilizing both train A and B systems and components without mitigating actions. Equipment credited to achieve shutdown is identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.12 FIRE AREA 8

Fire Area 8 consists of several rooms on Auxiliary Building Elevation 713.0.

3.12.1 Rooms 713.0-A1, A9, A10, A17, A18, A22, A23, A24, A25, A26 and A27

Room No.	Description:
713.0-A1	Auxiliary Building Subdivided into 713.0-A1A (713-A1A1, -A1A2, -A1A3, -A1A4, A1AN), -A1B (713-A1BN) and -A1C
713.0-A9	Unit 1 Mixed Bed and Cation Valve Gallery
713.0-A10	Seal Water Heat Exchanger 1A
713.0-A17	Seal Water Heat Exchanger 2A
713.0-A18	Unit 2 Mixed Bed and Cation Valve Gallery
713.0-A22	Holdup Tank Valve Gallery
713.0-A23	CVCS Valve Gallery
713.0-A24	Waste Gas Compressor Valve Gallery
713.0-A25	Waste Gas Compressor B
713.0-A26	Waste Gas Compressor A
713.0-A27	Decontamination Room

Fire Loading: The fire severity for rooms 713.0-A9, A17, A18, A23, and A24 is classified as insignificant. The combustibles in room 713.0-A1 consist of lube oil in the pumps, motors, and valves, plastics associated with the electrical panels, boxes and lights, insulation on cables routed in cable trays and anticipated amounts of radwaste trash and laundry. The fire severity for this room is classified as moderately severe. The combustibles in rooms 713.0-A10 and A22 consist of anticipated amounts of radwaste trash and laundry. Rooms 713.0-A25 and A26 have combustibles consisting of lube oil in compressors, plastics associated with electrical panels, equipment, light covers and radwaste/laundry. Room 713.0-A27 has combustibles consisting of plastics associated with electrical panels, equipment, light covers, trash, and temporary shielding blankets. The fire severity for all of these rooms is classified as low.

Compartmentation: Room 713.0-A1 has been subdivided into 713.0-A1A (column lines A1-A8/Q-U), 713.0-A1B (A8-A15/Q-U), and 713.0-A1C (A7-A9/U-W), each of which is identified in the tabular listing of regulatory barriers. All of these rooms are of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
713.0-A1A	North Wall	Area 1, Room 713.0-A28	II-29A	2 Hours
		Area 8, Room 713.0-A11	II-29A	2 Hours

	2-ISD-31-5447B 47A381-773	F-C	Area 14, Room 737.0-A1B	47W866-11 47W920-4	3 Hours
	2-ISD-31-5445 47A381-772	F-C	Area 1, Room 692.0-A1C	47W866-11 47W920-2	3 Hours
	1-ISD-31-5446 47A381-770	F-C	Area 1, Room 692.0-A1C	47W866-2 47W920-2	3 Hours

Detection: Rooms 713.0-A9, A10, A17, A18, A23, A24, A25, and A26 do not have detection. Room 713.0-A1 is provided with ionization smoke detectors. Room 713.0-A22 is enclosed by part-height walls with no ceiling; as a result, detection coverage in room 713.0-A1 also provides coverage for room 713.0-A22.

Room 713.0-A27 is provided with ionization smoke detection.

Suppression: Standpipe and hose stations are provided for all these rooms from 713.0-A1. Automatic sprinklers are provided for room 713.0-A1 and 713.0-A27 (Suppression in 713.0-A1 does not extend over Boric Acid equipment). Room 713.0-A22 is enclosed by part-height walls with no ceiling; as a result, suppression coverage in room 713.0-A1 also provides coverage for room 713.0-A22.

Deviations: Intervening combustibles in the form of insulation on cables routed in cable trays and ERFBS are present, but are compensated for by an enhanced automatic preaction sprinkler system. Justification is documented in Part VII, Section 2.4(713-A1). The CCS pumps are separated by a partial 1 hour fire barrier. Justification is documented in Part VII, Section 2.5(713-A1). The floor slabs at elevation 713.0 and 737.0 have stairwells that are protected with draft stops and water curtains in lieu of enclosed stairwells. Justification is documented in Part VII, Section 2.6. There is a 12 inch round spiral welded HVAC duct that penetrates the floor of 713.0-A1B. The duct continues through the ceiling of 713.0-A1B onto elevation 737. The penetrations are not provided with fire dampers. This duct is part of the Emergency Gas Treatment System (EGTS). Spiral welded pipe is treated like a pipe and is provided with fire rated seals between the pipe and the sleeve. Justification is documented in Part VII, Section 2.6.

Evaluations: The lack of total area suppression in 713.0-A1B over the boric acid transfer pumps, tanks and filters (column lines A11.5-A14/Q-R) is documented in Part VII, Section 3.1. The other portions of Fire Area 8 that are not provided with total area suppression and detection are documented in Part VII, Section 3.1. The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.4, 5, 63 and 64. The justification for the in situ combustible load in Room 713.0-A1 is provided in Part VII, Section 3.6.

PART VI – FIRE HAZARDS ANALYSIS

3.12.2 Rooms 713.0-A13, A14, and A31

Room No.	Description:
713.0-A13	Sample Room 1
713.0-A14	Sample Room 2
713.0-A31	Waste Gas Analyzer Room

Fire Loading: The combustibles in Sample Room 1 (713.0-A13) consist of lube oil in a chiller, valve and radiation monitor, plastic associated with electrical panels, boxes and lights, and anticipated amounts of radwaste trash and laundry. The fire severity is classified as low. The combustibles in the Waste Gas Analyzer Room (713.0-A31) consist of plastic associated with electrical panels. The fire severity is classified as insignificant. The combustibles in Sample Room 2 (713.0-A14) consist of lube oil in a chiller and valve, plastic associated with electrical panels, boxes and lights, and anticipated amounts of radwaste trash and laundry. The fire severity is classified as insignificant.

Compartmentation: The rooms are of reinforced concrete construction.

Barriers:

713.0-A14	A92	North	Area 65, Room 713.0-A29	II-29A	3 Hours

Dampers: None.

PART VI – FIRE HAZARDS ANALYSIS

Detection: Ionization smoke detectors are provided in the sample rooms. The Waste Gas Analyzer room is not provided with detection.

Suppression: Automatic preaction sprinkler systems are provided in the sample rooms. The Waste Gas Analyzer room is not provided with suppression. A standpipe and hose station is available from the room 713.0-A1.

Deviations: None.

Evaluations: The lack of total area suppression and detection in the Waste Gas Analyzer rooms is documented in Part VII, Section 3.1.

3.12.3 Rooms 713.0-A2, A3, A4, A5, and A30

Room No.	Description:
713.0-A2	Air Lock
713.0-A3	Titration Room
713.0-A4	Radio Chemical Lab
713.0-A5	Counting Room
713.0-A30	Air Lock

Fire Loading: The combustibles in the Air Lock (713.0-A2) consist of plastics associated with junction boxes and a lighting unit and anticipated amounts of radwaste trash and laundry. The combustibles in the Titration Room (713.0-A3) consist of lube oil in two pumps, plastic associated with electrical panels and other plastics, rubber and paper. The combustibles in the Radio Chemical Lab (713.0-A4) consist of lube oil in a pump, miscellaneous plastic, rubber, wood, and paper, and anticipated amounts of radwaste trash and laundry. The combustibles in the Counting Room (713.0-A5) consist of miscellaneous plastic, paper and wood. The fire severity for these rooms is classified as low. The fire severity in the Air Lock (713.0-A30) is classified as insignificant.

Compartmentation: These rooms are of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating

713.0-A30	A60	South	Area 8, Room 713.0-A1A	II-29A	3 Hours

Dampers: None.

Detection: Ionization smoke detectors are provided in all of these rooms except in the 713.0-A30 Airlock.

Suppression: Automatic sprinklers are provided in all of these rooms except in the 713.0-A30 Airlock. Standpipe and hose stations are provided from the adjacent room (713.0-A1).

Deviations: Intervening combustibles are present in Room 713.0-A4. The justification for intervening combustibles such as insulation on cables in trays and Thermo-Lag is documented in Part VII, Section 2.4.

Evaluations: The lack of total area suppression and detection in the Air Lock is documented in Part VII, Section 3.1.

3.12.4 Rooms 713.0-A24, A25, A26, and A27

Room No.	Description:
713.0-A24	Waste Gas Compressor Valve Gallery
713.0-A25	Waste Gas Compressor B
713.0-A26	Waste Gas Compressor A
713.0-A27	Decontamination Room

Fire Loading: The combustibles in the Waste Gas Compressor rooms consist of lube oil in the compressors, plastic associated with panels and lights, and anticipated amounts of radwaste trash and laundry. The fire severity in 713.0-A25 and -A26 are classified as low. The fire severity is insignificant in 713.0-A24. The fire severity in the Decontamination Room consists of plastic associated with electrical panels, equipment, lights and temporary shielding blankets is classified as low.

Compartmentation: The rooms are of reinforced concrete construction.

Barriers:

	Floor	Area 1, Room 692.0-A5	II-28A, II-29A	2 Hours

Doors: None.

Dampers: None.

Detection: The Decontamination Room is provided with ionization smoke detectors. The remaining rooms are not provided with detection systems.

Suppression: The Decontamination Room is provided with automatic sprinklers. The remaining rooms are not provided with suppression systems. Standpipe and hose stations are provided in the adjacent room (Corridor 713.0-A1).

Deviations: None.

Evaluations: The lack of total area suppression and detection is documented in Part VII, Section 3.1. The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.6, 63 and 64 for room 713.0-A27.

3.12.5 Room 713.0-A11

Description: Heat Exchanger 1B

Fire Loading: The combustibles consist of lube oil in four valves, plastic associated with lights, and anticipated amounts of radwaste trash and laundry. The fire severity is classified as insignificant.

Compartmentation: The room is of reinforced concrete construction.

713.0-A11	A68	East	Area 8, Room 713.0-A1C	II-29A	3 Hours

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
713.0-A11	1-ISD-31-3815 47A381-407F	E-W	Area 1, Room 713.0-A28	47W866-2 47W920-5	3 Hours

Detection: None.

Suppression: Standpipe and hose stations are provided from the adjacent room (corridor 713.0-A1).

Deviations: None.

Evaluations: The lack of total area suppression and detection is documented in Part VII, Section 3.1.

3.12.6 Room 713.0-A12

Description: Heat Exchanger 1A

Fire Loading: The combustibles consist of lube oil in three valves, plastic associated with lights, and anticipated amounts of radwaste trash and laundry. The fire severity is classified as insignificant.

Compartmentation: The room is of reinforced concrete construction.

PART VI – FIRE HAZARDS ANALYSIS

Detection: None.

Suppression: Standpipe and hose stations are provided from the adjacent room (corridor 713.0-A1).

Deviations: None.

Evaluations: The lack of total area suppression and detection is documented in Part VII, Section 3.1.

PART VI – FIRE HAZARDS ANALYSIS

3.12.9 Fire Area 8 Safe Shutdown Analysis by Analysis Volume

3.12.9.1 AV-021

Room No.	Description:
713.0-A1A1	Corridor, Col Lines S-U/A1-A4, ceiling level only S-CCS Wall/A1-A3
713.0-A9	Unit 1 Mixed Bed and Cation Valve Gallery

A fire in Analysis Volume 21 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 long term decay heat removal, steam generator inventory control and reactor coolant inventory control functions and Unit 1 containment HVAC functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features for Unit 1 and Unit 2 include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown and post fire repairs. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.12.9.2 AV-022

Room No.	Description:
713.0-A1A2	Corridor, Col Lines S-U/A1-A4, Ceiling level only CCS Wall-U/A1-A3
713.0-A9	Unit 1 Mixed Bed and Cation Valve Gallery

A fire in Analysis Volume 22 could potentially affect systems and components necessary to maintain the long term decay heat removal, steam generator inventory control, containment HVAC (Unit 1) and reactor coolant inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features for Unit 1 and Unit 2 include providing fire wrap to selected cables to preclude damage in the event of a fire, manual operation of equipment required for safe shutdown and post fire repairs. The following is an exception to the general methodology of providing cable protection (ERFBS) from analysis volume boundary to analysis boundary as described in FPR Part III, Section 10.3.1. The control cables for CCS Pumps 1-MTR-70-46-A and 1-MTR-70-38-B are protected such that there is greater than 20 feet separation between the two MTRs to ensure that 1-MTR-70-38-B is available. These features and equipment affected and credited are identified below:

713.0-A26	Waste Gas Compressor A
713.0-A27	Decontamination Room

A fire in Analysis Volume 23 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 long term decay heat removal, containment HVAC, steam generator inventory control and Unit 1 reactor coolant inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features for Unit 1 and 2 include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown and post fire repairs. These features and equipment affected and credited are identified below:

A fire in Analysis Volume 24 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 long term decay heat removal, containment HVAC, steam generator inventory control, and Unit 2 reactor coolant inventory control and functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include providing fire wrap to selected Unit 1 cables to preclude damage in the event of a fire and manual operation of Unit 1 and Unit 2 equipment required for safe shutdown and post fire repairs. These features and equipment affected and credited are identified below:

A fire in Analysis Volume 25 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 long term decay heat removal, steam generator inventory control, reactor coolant inventory control and Unit 1 containment HVAC functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include providing fire wrap to selected Unit 1 cables to preclude damage in the event of a fire and manual operation of Unit 1 and Unit 2 equipment required for safe shutdown and repair procedures. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.12.9.6 AV-025C

Room No.	Description:
713.0-A1AN	Corridor, Column Lines Q-U/A6-A8
713.0-A1BN	Corridor, Column Lines Q-U/A8-A10
713.0-A1C	Corridor, Column Lines U-W/A7-A9
713.0-A10	Seal Water Heat Exchanger 1A
713.0-A17	Seal Water Heat Exchanger 2A
713.0-A22	Holdup Tank Valve Gallery
713.0-A23	CVCS Valve Gallery

This AV is analyzed to address the interface between 713.0-A1C and 713.0-A1AN and 713.0-A1BN (i.e., to obtain 20 feet of separation on either side of Column Line U).

A fire in Analysis Volume 25C could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 long term decay heat removal, steam generator inventory control, reactor pressure control reactor coolant inventory control and Unit 1 containment HVAC functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include providing fire wrap to selected Unit 1 cables to preclude damage in the event of a fire and manual operation of Unit 1 and Unit 2 equipment required for safe shutdown and repair procedures. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.12.9.8 AV-026A

Room No.	Description:
713.0-A1C	Corridor, Column Lines U-W/A7-A9
713.0-A13	Sample Room 1
713.0-A14	Sample Room 2
713.0-A31	Waste Gas Analyzer Room

A fire in Analysis Volume 26A could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 long term decay heat removal and reactor inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.12.9.10 AV-028

Room No.	Description:
713.0-A11	Heat Exchanger 1B

A fire in Analysis Volume 28 could potentially affect Unit 1 systems and components necessary to maintain the long term decay heat removal and reactor coolant inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Unit 2 major equipment required to maintain safe shutdown functions is not impacted such that shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Offsite power is available. The required mitigating features include manual operation of Unit 1 equipment required for safe shutdown. These features and equipment credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.12.9.13 AV-109

Room No.	Description:
713.0-A16	Heat Exchanger 2B

A fire in Analysis Volume 109 could potentially affect systems and components necessary to maintain the long term decay heat removal function for Unit 2. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Unit 1 major equipment required to maintain safe shutdown functions is not impacted such that shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Offsite power is available. The required mitigating features include manual operation of Unit 2 equipment required for safe shutdown. These features and equipment credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.13 FIRE AREA 9

3.13.1 Room 713.0-A6

Description: Unit 1 Pipe Gallery

Fire Loading: The combustibles consist of lube oil and grease in a valve and air handling unit, charcoal in an air exhaust filter assembly, plastics associated with electrical panels, radiation monitors and lights, insulation on cables in cable trays, and anticipated amounts of radwaste trash and laundry. The fire severity is classified as moderate.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
713.0-A6	North Wall	Area 9-1, Room 713.0-A7	II-29A	2 Hours
		Area 61, Reactor Building	II-29A	3 Hours
	South Wall	Area 8, Room 713.0-A1A	II-29A	2 Hours

Detection: Ionization smoke detectors are provided in the room.

PART VI – FIRE HAZARDS ANALYSIS

Suppression: An automatic preaction sprinkler system is provided for the room. Standpipe and hose stations are provided from the adjacent room (corridor 713.0-A1).

Deviations: Intervening combustibles in the form of insulation on cables routed in cable trays are present, but are compensated for by an enhanced automatic preaction sprinkler system. Justification is documented in Part VII, Section 2.4.

Evaluations: Detection and suppression capability is discussed in Part VII, Section 3.1.3. Justification for the lack of fire dampers in the containment purge air system return and exhaust air duct openings to the annulus is documented in Part VII, Section 3.2. Justification of the fire door in this room is documented in Part VII, Section 3.5.

3.13.2 Room 713.0-A8

Description: Unit 1 Reactor Building Access Room

Fire Loading: The combustibles consist of plastic associated with electrical panels and boxes and lights. The fire severity is classified as insignificant.

Compartmentation: The Reactor Building Access Room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
713.0-A8	North Wall	Area 61, Reactor Building	II-29A	3 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
713.0-A8	A65	North	Area 61, Reactor Building	II-29A	EQ

Dampers: None.

Detection: None.

Suppression: A standpipe and hose station is provided in the room.

Deviations: None.

Evaluations: The lack of total area suppression and detection is documented in Part VII, Section 3.1.3. .

PART VI – FIRE HAZARDS ANALYSIS

3.13.3 Fire Area 9 Safe Shutdown Analysis by Analysis Volume

3.13.3.1 AV-030

Room No.	Description:
713.0-A6	Unit 1 Pipe Gallery
713.0-A8	Unit 1 Reactor Building Access Room

A fire in Analysis Volume 30 could potentially affect Unit 1 systems and components necessary to maintain the long term decay heat removal, containment HVAC, steam generator inventory control and reactor coolant inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Unit 2 major equipment required to maintain safe shutdown functions is not impacted such that shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Offsite power is available. The required mitigating features include providing fire protection for selected cables and manual operation of Unit 1 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.14 FIRE AREA 9-1

3.14.1 Room 713.0-A7

Description: Unit 1 Volume Control Tank (VCT) Room

Fire Loading: The combustibles consist of the hydrogen in the VCT, lube oil in two valves, plastic associated with electrical boxes and lights, and anticipated amounts of radwaste trash and laundry. The fire severity is classified as insignificant.

Compartmentation: The VCT room is of reinforced concrete construction.

Barriers:

	47A381-331			47W920-4	

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided in the room (except in the entrance labyrinth). Standpipe and hose stations are provided from the adjacent room (corridor 713.0-A1).

Deviations: None.

PART VI – FIRE HAZARDS ANALYSIS

Evaluations: Refer to Part VII, Section 3.1 for the evaluation of the lack of full suppression and Part VII, Section 3.5 for the evaluation of the fire damper in the VCT room door. The Unit 1 evaluation for performing a manual action in the room of fire origin is documented in Part VII, Section 7.1.3.

PART VI – FIRE HAZARDS ANALYSIS

3.14.2 Fire Area 9-1 Safe Shutdown Analysis by Analysis Volume

3.14.2.1 AV-031

Room No.	Description:
713.0-A7	Unit 1 Volume Control Tank (VCT) room

A fire in Analysis Volume 31 could potentially affect Unit 1 systems and components necessary to maintain the reactor coolant inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Unit 2 major equipment required to maintain safe shutdown functions is not impacted such that shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Offsite power is available. The required mitigating features include manual operation of Unit 1 equipment required for safe shutdown. These features and equipment credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.15 FIRE AREA 10

Fire Area 10 consists of several rooms in the Auxiliary Building on elevations 692.0, 729.0, 757.0, and 772.0, and connecting spaces.

3.15.1 Auxiliary Building Elevation 729.0

Description:

Room No.	Description:
728.0-A7	Cask Decontamination Room
729.0-A6	Nitrogen Storage Area
729.0-A8	Unit 1 Post Accident Sampling Room
729.0-A9	Unit 2 Post Accident Sampling Room
Stair No. 4	Stairwell

Fire Loading: The combustibles consist of lube oil in motors, charcoal in the filter units, and plastic associated with electrical panels and boxes and lights. The Fuel Transfer Valve Rooms contain small compressed gas cylinders of hydrogen at concentrations of less than 10 percent by volume. The fire severity, for each of the rooms, is classified as insignificant except 729.0-A8 which is classified as low.

Compartmentation: The rooms are of reinforced concrete construction. The barriers of the rooms in this fire area have been evaluated in accordance with the guidelines of Appendix A, Section D.1.j. The barrier ratings are adequate for the level of fire hazard (i.e., insignificant fire severity) in the area/rooms.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
728.0-A7	South Wall	Area 10, Spent Fuel Pit	II-38A	2 Hours
	Ceiling (hatch)	Area 10, Room 757.0-A13	II-31A, II-38A	See Part VII Section 2.6
729.0-A6	West Wall	Area 13, Room 729.0-A14	II-38A	3 Hours
		Area 16, Room 737.0-A5	II-30A	2 Hours
		Area 10, Spent Fuel Pit	II-38A	2 Hours
		Area 16, Room 729.0-A8	II-30A	
	South Wall	Area 10, Spent Fuel Pit	II-38A	2 Hours
		Area 10, Room 737.0-A1C	II-30A	2 Hours
	East Wall	Area 73, Room 729.0-A15	II-38A	3 Hours
		Area 10, Spent Fuel Pit	II-30A	2 Hours
		Area 10, Room 729.0-A9	II-30A	2 Hours
		Area 10, New Fuel Storage Vault	II-38A	2 Hours
		Area 74, Room 737.0-A9	II-30A	2 Hours
	Ceiling	Area 10, New Fuel Storage Vault	II-38A	2 Hours
		Area 10, Room 757.0-A13	II-38A	2 Hours

PART VI – FIRE HAZARDS ANALYSIS

729.0-A9	2-ISD-31-3984 47A381-508F	F-C	Area 10, Room 729.0-A6	47W866-10 47W920-6	3 Hours

Detection: Smoke detection is provided in the Nitrogen Storage room, the two Post Accident Sampling Rooms (except in the entrance corridors), the Nitrogen Storage Area, and Stair No. 4.

Suppression: Automatic sprinkler systems are provided for the two Post Accident Sampling Rooms (except in the entrance corridors). A standpipe and hose station is provided in the Nitrogen Storage Area.

Deviations: Justification for the HVAC ducts without fire dampers between rooms 729.0-A6,-A8 and -A9 and adjacent fire areas is documented in Part VII, Section 2.6. Compliance to III.G.1 with FHA for room 729.0-A6 (see Part VII, Section 2.9).

Evaluations: The corridors associated with 729.0-A8 and -A9 have been evaluated for conformance to the guidelines of Appendix A, Section D.1.j and for the lack of suppression and detection. Given the insignificant fire load in the corridors and the 2 and 3 hour ratings of the corridor walls, the design provides an adequate level of fire protection. The relaxation of fire damper surveillance due to location in high radiation area 15 documented in Part VII, Section 6.2. The relaxation of fire penetration seal surveillance, due to location in high radiation area 15 documented in Part VII, Section 6.4. The lack of total area suppression in room 729.0-A6 is documented in Part VII, Section 3.1. The feasibility and reliability evaluations for Unit 2 Operator Manual Actions in room 729.0-A8 are documented in Part VII, Sections 8.3.7, 63 and 64.

3.15.2 Room 729.0-A5

Description: Cask Unloading Area

PART VI – FIRE HAZARDS ANALYSIS

Fire Loading: The combustibles consist of plastic associated with storage tanks, electrical panels and boxes, and lights. The fire severity is classified as low.

Compartmentation: The area is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
729.0-A5	North Wall	Area 11, Room 729.0-A3	II-38A	2 Hours
		Area 11, Room 729.0-A4	II-38A	2 Hours

	West Wall	Area 13, Room 729.0-A14	II-38A	3 Hours
		Area 62, CDWE Building	II-38A	3 Hours
		Area 73, Room 729.0-A15	II-38A	3 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
729.0-A5	A111	North	Area 11, Room 729.0-A4	II-38A	3 Hours

Dampers: None.

Detection: Thermal smoke detectors are provided for the area.

Suppression: An automatic preaction sprinkler system is provided for the area.

Deviations: None.

Evaluations: None.

3.15.3 Room 757.0-A13

Description: Refueling Room (Includes 741.5 – New Fuel Storage Vault)

Fire Loading: The combustibles consist of InstaCote, (a plastic type Fuel Transfer Canal coating), lube oil in the compressors and cranes, plastics associated with the electrical equipment, panels and boxes, and anticipated amounts of radwaste trash and laundry. The fire severity is classified as insignificant.

Compartmentation: The Refueling Area is of reinforced concrete construction.

Detection: None.

Suppression: Standpipes and hose stations are provided in the room.

Deviations: The justification for heavy sheet metal ducts and fire doors is documented in Part VII, Sections 2.6.3.2.b and 4.1. The justification for compliance with III.G.1 using a FHA is in Part VII, Section 2.9. The justification for lack of detection is documented in Part VII, Section 4.5.

Evaluations: None.

3.15.4 Room 772.0-A9

Description: HEPA Filter Plenum Room

Fire Loading: The combustibles consist of plastic associated with the lights and insulation on cables in the trays. The fire severity is classified as low.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
772.0-A9	North Wall	Area 75, Room 757.0-A16	II-31A, II-32A	2 Hours
		Area 75, Room 782-A3	II-32A	2 Hours
	South Wall	Area 46, Room 772.0-A16	II-32A	2 Hours
	East Wall	Area 40, Room 772.0-A10	II-32A	2 Hours
	Floor	Area 31, Room 757.0-A17	II-31A, II-32A	2 Hours

PART VI – FIRE HAZARDS ANALYSIS

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
772.0-A9	A212	East	Area 40, Room 772.0-A10	II-32A	3 Hours
	A213	East	Area 40, Room 772.0-A10	II-32A	3 Hours

Dampers: None.

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided in the room. A standpipe and hose station is provided from the adjacent room (772.0-A10).

Deviations: The justification for intervening combustibles such as insulation on cables in trays and Thermo-Lag is documented in Part VII, Section 2.4.

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.42, 63 & 64.

3.15.5 Rooms 776.0-A1, 786.0-A1, and 814.75-ACS

Room No.	Description:
776.0-A1	Elevator Machine Room
786.0-A1	Fan Room
814.75-ACS	Roof Access Room

Fire Loading: The combustibles in the elevator machine room consist of oil and plastic associated with the hoisting machine and plastics associated with telephone and electrical equipment. The fire severity for this room is classified as severe. The combustibles in the fan room include plastic associated with the fans and other electrical equipment. The combustibles in the roof access room include plastics associated with lights and a telephone. The fire severity for these rooms is classified as insignificant.

Compartmentation: These rooms are of reinforced concrete or reinforced concrete block construction.

Barriers: None.

Doors: None.

Dampers: None.

Detection: None.

Suppression: Standpipe and hose stations are provided in adjoining spaces.

Deviations: None.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

3.15.6 Rooms 692.0-A14, A15 and A16

Room No.	Description:
692.0-A14	Cask Decontamination Collection Tank Room
692.0-A15	Spent Resin Tank Room
692.0-A16	Valve Gallery

Fire Loading: The combustibles consist of small amounts of plastics associated with electrical panels, a sampling station and lights, and anticipated amounts of radwaste trash and laundry. The fire severity is classified as insignificant.

Compartmentation: The only regulatory fire barriers are the east walls to the Unit 2 pipe gallery and chase and the walls separating 692.0-A14 from 692.0-A1C and the Spent Fuel Pit.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
692.0-A14	West Wall	Area 10, Spent Fuel Pit	II-28A	2 Hours
	East Wall	Area 65, Room 692.0-A24	II-28A	2 Hours

PART VI – FIRE HAZARDS ANALYSIS

Detection: Ionization smoke detectors are only provided in 692.0-A14 (except for a portion of the east corridor).

Suppression: Automatic sprinklers are provided in 692.0-A14 only. A standpipe and hose station is provided in room 692.0-A14.

Deviations: None.

Evaluations: The justification for relaxation of penetration seal surveillance requirements is documented in Part VII, Section 6.4.

PART VI – FIRE HAZARDS ANALYSIS

3.15.7 Fire Area 10 Safe Shutdown Analysis by Analysis Volume

3.15.7.1 AV-032

Room No.	Description:
Stair No. 4	Stairwell
692.0-A14	Cask Decontamination Collection Tank Room
692.0-A15	Spent Resin Tank Room
692.0-A16	Valve Gallery
728.0-A7	Cask Decontamination Room
729.0-A5	Cask Unloading Area
729.0-A6	Nitrogen Storage Area
729.0-A8	Unit 1 Post Accident Sampling Room
757.0-A13	Refueling Room
772.0-A9	HEPA Filter Plenum Room
776.0-A1	Elevator Machine Room
786.0-A1	Fan Room
814.75-ACS	Roof Access Room

A fire in Analysis Volume 32 could potentially affect systems and components necessary to maintain the long term decay heat removal (Unit 2), steam generator inventory control, reactor coolant inventory control, containment HVAC (Unit 2), fire pumps and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include providing fire protection for selected cables and manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. Operator Manual Actions (OMA's) are not required to mitigate fire in room 729.0-A6 or 757.0-A13 per deviation documented in Part VII, section 2.9.

These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.15.7.2 AV-119

Room No.	Description:
729.0-A9	Unit 2 Post Accident Sampling Room

A fire in Analysis Volume 119 could potentially affect systems and components necessary to maintain the Unit 2 steam generator inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Unit 1 major equipment required to maintain safe shutdown functions is not impacted such that shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Offsite power is available. The required mitigating features for Unit 2 include providing fire wrap to selected cables to preclude damage in the event of a fire. These features and equipment credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.16 FIRE AREA 11

3.16.1 Rooms 729.0-A3 and A4

Description: Waste Package Areas

Fire Loading: The combustibles in the rooms consist of oil and plastic associated with the crane and plastic associated with control and junction boxes and resin storage tanks. The fire severity for room 729.0-A3 is classified as low, and for room 729.0-A4 is classified as moderate.

Compartmentation: The rooms are of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
729.0-A3	South Wall	Area 10, Room 729.0-A5	II-38A	2 Hours
		Area 10, Room 757.0-A13	II-38A	2 Hours
	South Wall	Area 10, Room 729.0-A5	II-38A	2 Hours
		Area 10, Room 757.0-A13	II-38A	2 Hours
729.0-A4	East Wall	Area 62, CDWE Building	II-38A	3 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating

	DE2	East	Area 62, CDWE Building	II-38A	3 Hours

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
729.0-A3	0-ISD-31-3838 47A381-413F	N-S	Area 10, Room 757.0-A13	47W866-10 47W920-6, 7	3 Hours
729.0-A4	0-ISD-31-3837 47A381-621F	N-S	Area 10, Room 757.0-A13	47W866-10 47W920-6, 7	3 Hours
	0-ISD-31-2427 47A381-517	E-W	Area 62, CDWE Building	47W866-10 47W920-39	1.5 Hours
	0-ISD-31-2429 47A381-517	E-W	Area 62, CDWE Building	47W866-10 47W920-39	1.5 Hours

Detection: Ionization detectors are provided for both rooms.

Suppression: Automatic preaction sprinkler systems are provided for both rooms. A standpipe and hose station is provided from 729.0-A.5

PART VI – FIRE HAZARDS ANALYSIS

Deviations: None.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

3.16.2 Fire Area 11 Safe Shutdown Analysis by Analysis Volume

3.16.2.1 AV-033

Room No.	Description:
729.0-A3	Waste Package Area
729.0-A4	Waste Package Area

A fire in Analysis Volume 33 does not impact major equipment required to maintain safe shutdown functions for Unit 1 or Unit 2. Shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Equipment available to achieve shutdown is identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.17 FIRE AREA 12

3.17.1 Room 729.0-A1 and 737.0-A6

Room No.	Description:
729.0-A1	Main Steam Valve Room (Unit 1 South)
737.0-A6	Air Lock

Fire Loading: The combustibles in 729.0-A1 consist of lube oil in the valves and plastic associated with electrical panels and boxes and lights. The fire severity is classified as insignificant. The combustibles in 737.0-A6 consist of plastic associated with light covers. The fire severity is classified as insignificant.

Compartmentation: The walls of these rooms are of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
729.0-A1	North Wall	Area 61, Reactor Building	II-30A	3 Hours
	South Wall	Area 8, Room 713.0-A1A	II-29A, II-30A	2 Hours
		Area 15-1, Room 737.0-A3	II-30A	2 Hours
		Area 17, Room 757.0-A2	II-31A	2 Hours
		Area 37, Room 772.0-A6	II-32A	2 Hours
	East Wall	Area 16, Room 737.0-A5	II-30A	2 Hours
		Area 25, Room 757.0-A10	II-31A	2 Hours
		Area 25, Room 782.0-A1	II-32A	2 Hours
	Floor	Area 9, Room 713.0-A6	II-29A, II-30A	2 Hours
737.0-A6	North	Area 61, Reactor Building	II-30A	3 Hours
	South	Area 15-1, Room 737.0-A3	II-30A	2 Hours
		Area 14, Room 737.0-A4	II-30A	2 Hours
	East	Area 16, Room 737.0-A5	II-30A	2 Hours
	Floor	Area 9, Room 713.0-A6	II-29A, II-30A	2 Hours
	Ceiling	Area 16, Room 737.0-A5	II-30A	2 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
737.0-A6	A125	East	Area 16, Room 737.0-A5	II-30A	3 Hours

Dampers: None.

Detection: No detectors are provided in room 729.0-A1. No detection is provided in room 737.0-A6.

PART VI – FIRE HAZARDS ANALYSIS

Suppression: Standpipes and hose stations are provided from adjacent rooms.

Deviations: Compliance to III.G.1 with FHA (see Part VII, Section 2.9).

Evaluations: The lack of total area suppression and detection in specific rooms is documented in Part VII, Sections 3.1.

PART VI – FIRE HAZARDS ANALYSIS

3.17.2 Fire Area 12 Safe Shutdown Analysis by Analysis Volume

3.17.2.1 AV-034

Room No.	Description:
729.0-A1	Main Steam Valve Room (Unit 1 South)
737.0-A6	Air Lock

The in situ combustible loading for AV-034 consists of small quantities of lubricants in several valves and miscellaneous plastics associated with area radiation monitors, small electrical control panels and boxes, and lighting. The total combustible loading results in a fire severity classification of Insignificant (less than 1-minute). The area is designated a Combustible Control Zone which in conjunction with procedure NPG-SPP-18.4.7, Control of Transient Combustibles provides assurance that transient combustibles will not be introduced into the area without adequate compensatory measures. The valve motors are normally de-energized (power is only applied when an operator moves the valve from open to close (or close to open); therefore, the valve motors are not considered an ignition source. The area radiation monitors are not considered a significant ignition source because they contain insignificant quantities of combustible material and their power supply is adequately protected with properly sized breakers/fuses. Procedure NPG-SPP-18.4.8, Control of Ignition Sources (Hot Work) ensures that ignition sources (e.g. cutting, welding, grinding) will not be introduced into the area without adequate compensatory measures. Since there are no concentrations of in situ combustibles and no credible ignition sources, it is concluded that there will be no credible fire in the analysis volume that would result in the loss of required fire safe shutdown (FSSD) components or other components that could result in the necessity to shutdown either Unit 1 or Unit 2. Therefore, there is no impact to FSSD for this analysis volume. Operator Manual Actions (OMA's) are not required to mitigate a fire in rooms 729.0-A1 or 737.0-A6 per deviation documented in Part VII, section 2.9.

PART VI – FIRE HAZARDS ANALYSIS

3.18 FIRE AREA 13

Fire Area 13 consists of several rooms within the Auxiliary Building associated with the Main Steam Valve Room (Unit 1 North).

3.18.1 Room 729.0-A2

Description: Main Steam Valve Room (Unit 1 North)

Fire Loading: The combustibles consist of lube oil in the valves and plastic associated with electrical panels and boxes and lights. The fire severity is classified as insignificant.

Compartmentation: The valve room walls are of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
729.0-A2	South Wall	Area 61, Reactor Building	II-38A	3 Hours
	South and East Walls and Ceiling of 729.0-A12	Area 13, Room 729.0-A12	II-38A	3 Hours

Doors: None.

Dampers: None.

Detection: No detectors are provided in the room.

Suppression: A standpipe and hose station is provided from the Unit 1 Additional Equipment Building (729.0-A14).

Deviations: Compliance to III.G.1 with FHA (see Part VII, Section 2.9).

Evaluations: The lack of total area suppression and detection in room 729.0-A2 is documented in Part VII, Sections 3.1.

3.18.2 Room 729.5-A16

Description: Unit 1 Shield Building Vent Radiation Monitoring Room

Fire Loading: The combustibles consist of lube oil in pumps and plastic associated with electrical panels and boxes and lights. The fire severity is classified as insignificant.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
729.5-A16	South Wall	Area 61, Reactor Building	II-38A	3 Hours

PART VI – FIRE HAZARDS ANALYSIS

Doors: None.

Dampers: None.

Detection: None.

Suppression: A standpipe and hose station is provided from the adjacent room (729.0-A14).

Deviations: None.

Evaluations: None

3.18.3 Unit 1 Additional Equipment Building (U1-AEB)

Description: Unit 1 Additional Equipment Building (U1-AEB) (729.0-A14, 737.0-A13, 763.5-A1, 775.25-A1, 786.5-A1)

Fire Loading: The combustibles consist of lube oil and hydraulic fluid in valves, pumps and motors, plastics associated with electrical panels and boxes and lights and glycol in the chiller packages and barrels. The fire severity is classified as Moderate.

Compartmentation: The Unit 1 Additional Equipment Building is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
729.0-A14	South Wall	Area 10, Room 729.0-A8	II-29A	3 Hours
		Area 25, Room 757.0-A12	II-31A	3 Hours
		Area 16, Room 737.0-A5	II-30A	3 Hours
		Area 61, Reactor Building	II-38A	3 Hours
		Area 16, Room 737.0-A13	II-30A	3 Hours
	East Wall	Area 10, Room 729.0-A5	II-38A	3 Hours
		Area 10, Room 729.0-A6	II-38A	3 Hours
		Area 10, Room 757.0-A13	II-38A	3 Hours
		Area 10, Stair No. 4	II-38A	3 Hours
737.0-A13	South Wall	Area 16, Room 737.0-A5	II-30A	3 Hours
	West Wall	Area 61, Reactor Building	II-30A	3 Hours
	East Wall	Area 16, Room 737.0-A5	II-30A	3 Hours
	North Wall	Area 16, Room 729.0-A14	II-30A, II-38A	3 Hours
	Ceiling	Area 16, Room 737.0-A5	II-30A	3 Hours
	Floor	Area 10, Room 729.0-A8	II-29A, II-30A	3 Hours
763.5-A1	South Wall	Area 25, Room 757.0-A12	II-31A, II-38A	3 Hours
		Area 61, Reactor Building	II-38A	3 Hours

PART VI – FIRE HAZARDS ANALYSIS

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
775.25-A1	East Wall	Area 10, Room 757.0-A13 Area 10, Stair No. 4	II-31A, II-38A II-38A	3 Hours 3 Hours
	South Wall	Area 25, Room 757.0-A12 Area 25, Room 782.0-A2 Area 61, Reactor Building Area 10, Room 757.0-A13	II-31A II-32A II-32A II-32A	3 Hours 3 Hours 3 Hours 3 Hours
	East Wall	Area 25, Room 782.0-A2	II-32A	3 Hours
	South Wall	Area 61, Reactor Building	II-32A	3 Hours
	East Wall	Area 10, Room 757.0-A13	II-38A	3 Hours
	East Wall	Area 10, Room 757.0-A13	II-38A	3 Hours
	East Wall	Area 10, Room 757.0-A13	II-38A	3 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
737.0-A13	A183	East	Area 16, Room 737.0-A5	II-30A	3 Hours
763.5-A1	A162	South	Area 25, Room 757.0-A12	II-31A	3 Hours

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
763.5-A1	1-ISD-31-2987 47A381-528F	E-W	Area 10, Room 757.0-A13	47W866-8 47W920-7	3 Hours

Detection: Partial ionization smoke detector protection is provided in the AEB. No detection is provided in 737.0-A13 Air lock.

Suppression: Standpipe and hose stations are provided for each elevation in the AEB except for the 737 elevation.

Deviations: None.

Evaluations: None.

3.18.4 Room 729.0-A12

Description: Unit 1 Steam Valve Instrument Room A

Fire Loading: The combustibles consist of Thermo-Lag and plastic associated with electrical boxes, panels and lights. The fire severity is classified as low.

Compartmentation: The instrument room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
729.0-A12	North and West	Area 13, Room 729.0-A2	II-38A	3 Hours

PART VI – FIRE HAZARDS ANALYSIS

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
	Walls and Ceiling			
	South Wall	Area 61, Reactor Building	II-38A	3 Hours

Doors: None.

Dampers: None.

Detection: None.

Although the Unit 1 Steam Valve Instrument Room A contains remote safety related panels, it is not considered a "general area" as described in Section F.6 of Appendix A. It is a small isolated room containing only instrumentation and as such, Section F.6 of Appendix A is not considered applicable. Due to the lack of combustibles (i.e., low fire severity) and the availability of a standpipe hose station in the area, the fire protection available is considered adequate for the hazards involved.

Suppression: A standpipe and hose station is provided from the Unit 1 Additional Equipment Building (729.0-A14).

Deviations: Compliance to III.G.1 with FHA (see Part VII, Section 2.9).

Evaluations: The lack of total area suppression and detection and the limited fire damage in room 729.0-A12 is documented in Part VII, Sections 3.1.

PART VI – FIRE HAZARDS ANALYSIS

3.18.5 Fire Area 13 Safe Shutdown Analysis by Analysis Volume

3.18.5.1 AV-035

Room No.	Description:
729.0-A12	Unit 1 Steam Valve Instrument Room A
729.0-A14	Unit 1 Additional Equipment Building
729.5-A16	Unit 1 Shield Building Vent Radiation Monitoring Room
737.0-A13	Air Lock
763.5-A1	Unit 1 Additional Equipment Building
775.25-A1	Unit 1 Additional Equipment Building
786.5-A1	Unit 1 Additional Equipment Building

A fire in Analysis Volume 35 could potentially affect systems and components necessary to maintain the Unit 1 steam generator inventory control secondary side isolation functions. The Appendix R required circuits that route through room 729.5-A16 are all routed in conduits that are embedded in the floor and are not affected by a postulated fire in the room; therefore, a fire in this room does not affect any required FSSD function. Operator Manual Actions (OMA's) are not required to mitigate fire in room 729.5-A16. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Unit 2 major equipment required to maintain safe shutdown functions is not impacted such that shutdown can be achieved by utilizing both Train A and B system components without mitigating actions. Offsite power is available. The required mitigating features include manual operation of Unit 1 equipment required for safe shutdown. Operator Manual Actions (OMAs) are not required to mitigate fire in room 729.0-A12 per deviation documented in Part VII, section 2.9. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.18.5.2 AV-035A

Room No.	Description:
729.0-A2	Main Steam Valve Room (Unit 1 North)

The in situ combustible loading for AV-035A consists of small quantities of lubricants in several valves and miscellaneous plastics associated with area radiation monitors, small electrical control panels and boxes, and lighting. The total combustible loading results in a fire severity classification of Insignificant (less than 3-minutes). The area is designated a Combustible Control Zone which in conjunction with procedure NPG-SPP-18.4.7, Control of Transient Combustibles provides assurance that transient combustibles will not be introduced into the area without adequate compensatory measures. The valve motors are normally de-energized (power is only applied when an operator moves the valve from open to close (or close to open); therefore, the valve motors are not considered an ignition source. The area radiation monitors are not considered a significant ignition source because they contain insignificant quantities of combustible material and their power supply is adequately protected with properly sized breakers/fuses. Procedure NPG-SPP-18.4.8, Control of Ignition Sources (Hot Work) ensures that ignition sources (e.g. cutting, welding, grinding) will not be introduced into the area without adequate compensatory measures. Since there are no concentrations of in situ combustibles and no credible ignition sources, it is concluded that there will be no credible fire in the analysis volume that would result in the loss of required fire safe shutdown (FSSD) components or other components that could result in the necessity to shutdown either Unit 1 or Unit 2. Therefore, there is no impact to FSSD for this analysis volume. Operator Manual Actions (OMA's) are not required to mitigate fire in room 729.0-A2 per deviation documented in Part VII, section 2.9.

PART VI – FIRE HAZARDS ANALYSIS

3.19 FIRE AREA 14

Fire Area 14 consists of various rooms on Auxiliary Building Elevation 737.

3.19.1 Rooms 737.0-A1, A4, A11

Description:

Room No.	Description:
737.0-A1	Auxiliary Building (Subdivided into 737.0-A1A, -A1AN, -A1BN, -A1CN, -A1B, and -A1C)
737.0-A4	Air Lock
737.0-A11	Air Lock

Fire Loading: The combustibles in 737.0-A1 consist of lube oil in the pumps, motors, and valves, plastic associated with electrical panels and boxes and lights and insulation on cables in trays. The majority of the combustibles are the insulation on the cables. The fire severity is classified as moderately severe. The fire severity in the airlocks is classified as insignificant.

Compartmentation: Room 737.0-A1 has been subdivided into 737.0-A1A (column lines A1-A8/Q-U), 737.0-A1B (A8-A15/Q-U), and 737.0-A1C (remaining area of 737.0-A1 north of column line U), each of which is identified in the tabular listing of regulatory barriers. The rooms are of reinforced concrete construction.

Barriers:

Detection: Ionization smoke detectors are provided in room 737.0-A1.

Suppression: Automatic sprinklers are provided in room 737.0-A1. Standpipe and hose stations are provided for the rooms from room 737.0-A1.

Deviations: The presence of intervening combustibles (insulation on cables in trays) is justified and documented in Part VII, Section 2.4. The 737.0 floor slab has stairwell and hatch openings that are not provided with fire rated closures. The justification for these openings is documented in Part VII, Section 2.6. There is a 12 inch round spiral welded HVAC duct that penetrates the floor of 737.0-A1B. The penetration is not provided with a fire damper. This duct is part of the Emergency Gas Treatment system. Spiral welded pipe is treated like a pipe and is provided with fire rated seals between the pipe and the sleeve. Justification is documented in Part VII, Section 2.6. The acceptability of fire door A154 is justified in Part VII, Section 4.1.

PART VI – FIRE HAZARDS ANALYSIS

Evaluations: The lack of total area suppression and detection in the airlocks is documented in Part VII, Section 3.1 and large damper is documented in Part VII, Section 3.4. The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.8, 9, 10 and 11. The justification for the in situ combustible load in Room 737.0-A1 is provided in Part VII, Section 3.6.

3.19.2 Room 737.0-A2

Description: Hot Instrument Shop

Fire Loading: The combustibles consist of miscellaneous plastics, paper and furniture and anticipated amounts of radwaste trash and laundry. The fire severity is classified as low.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
737.0-A2	North Wall	Area 15-1, Room 737.0-A3	II-30A	2 Hours
	Floor	Area 8, Room 713.0-A1A	II-29A, II-30A	2 Hours

Doors: None.

Dampers: None.

Detection: Automatic detection is provided in the room.

Suppression: None. A standpipe and hose station is provided from the adjacent room (737.0-A1).

Deviations: None.

Evaluations: The lack of total area suppression is documented in Part VII, Section 3.1.

3.19.3 Room 737.0-A7

Description: Unit 1 Letdown Heat Exchanger

Fire Loading: The combustibles consist of plastic associated with the panel, junction box, and light covers and anticipated amounts of radwaste trash and laundry. The fire severity is classified as low.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
737.0-A7	North Wall	Area 8, Room 713.0-A11	II-30A	2 Hours

Detection: None.

Suppression: A standpipe and hose station is provided in the adjacent room (737.0-A1).

Deviations: None.

Evaluations: The lack of total area suppression and detection is documented in Part VII, Section 3.1.

3.19.4 Room 737.0-A8

Description: Unit 2 Letdown Heat Exchanger

Fire Loading: The combustibles in this room consist of plastic associated with light covers. The fire severity is classified as insignificant.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
737.0-A8	North Wall	Area 8, Room 713.0-A16	II-30A	2 Hours

Detection: None.

Suppression: A standpipe and hose station is provided in the adjacent room (737.0-A1).

Deviations: None.

Evaluations: The lack of total area suppression and detection is documented in Part VII, Section 3.1.

PART VI – FIRE HAZARDS ANALYSIS

3.19.5 Fire Area 14 Safe Shutdown Analysis by Analysis Volume

3.19.5.1 AV-036

Room No.	Description:
737.0-A1A	Auxiliary Building, Column Lines Q-U/A1-A6
737.0-A1AN	Auxiliary Building, Column Lines Q-U/A6-A8
737.0-A2	Hot Instrument Shop
737.0-A4	Air Lock

A fire in Analysis Volume 36 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control, long term decay heat removal, fire pumps, reactor coolant inventory control, reactor pressure control, containment HVAC, Unit 1 secondary side isolation functions and Unit 1 containment integrity functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power may not be available. The required mitigating features for Unit 1 and Unit 2 include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown and repair procedures. The following are exceptions to the general methodology of providing cable protection (ERFBS) from analysis volume boundary to analysis boundary as described in FPR Part III, Section 10.3.1. The control cables for 1-PSV-1-13B-B and 1-PSV-1-13C-A are protected such that there is greater than 20 feet horizontal separation between the two PSVs to ensure that 1-PCV-1-12 (Steam Generator 2 Power Relief Valve) will close. The control cables for 1-PSV-1-31B-B and 1-PSV-1-31C-A are protected such that there is greater than 20 feet horizontal separation between the two PSVs to ensure that 1-PCV-1-30 (Steam Generator 4 Power Relief Valve) will close. The features and equipment affected and credited are identified below:

Room No.	Description:
737.0-A1AN	Auxiliary Building, Column Lines Q-U/A6-A8
737.0-A1BN	Auxiliary Building, Column Lines Q-U/A8-A10

A fire in Analysis Volume 37 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control, long term decay heat removal, containment HVAC, fire pumps, reactor coolant inventory control, reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power may not be available. The required mitigating features for Unit 1 and Unit 2 include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown and repair procedures. The following are exceptions to the general methodology of providing cable protection (ERFBS) from analysis volume boundary to analysis volume boundary as described in FPR Part III, Section 10.3.1. The control cables for 1-PSV-1-13B-B and 1-PSV-1-13C-A are protected such that there is greater than 20 feet horizontal separation between the two PSVs to ensure that 1-PCV-1-12 (Steam Generator 2 Power Relief Valve) will close. The control cables for 1-PSV-1-31B-B and 1-PSV-1-31C-A are protected such that there is greater than 20 feet horizontal separation between the two PSVs to ensure that 1-PCV-1-30 (Steam Generator 4 Power Relief Valve) will close. The features are identified below:

737.0-A7	Unit 1 Letdown Heat Exchanger
737.0-A8	Unit 2 Letdown Heat Exchanger

A fire in Analysis Volume 37A could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control, reactor coolant inventory control and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features for Unit 1 and Unit 2 include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.19.5.4 AV-037C

Room No.	Description:
737.0-A1AN	Auxiliary Building, Column Lines Q-U/A6-A8
737.0-A1BN	Auxiliary Building, Column Lines Q-U/A8-A10
737.0-A1CN	Auxiliary Building, Column Lines U-RxCL/A5-A11
737.0-A7	Unit 1 Letdown Heat Exchanger
737.0-A8	Unit 2 Letdown Heat Exchanger

This AV is analyzed to address the interface between 737.0-A1C and 737.0-A1AN and 737.0-A1BN (i.e., to obtain 20 feet of separation on either side of Column Line U).

A fire in Analysis Volume 37C could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control, long term decay heat removal, containment HVAC, fire pumps, reactor coolant inventory control, reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is not available. The required mitigating features for Unit 1 and Unit 2 include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown and repair procedures. The following are exceptions to the general methodology of providing cable protection (ERFBS) from analysis volume boundary to analysis volume boundary as described in FPR Part III, Section 10.3.1. The control cables for 1-PSV-1-13B-B and 1-PSV-1-13C-A are protected such that there is greater than 20 feet horizontal separation between the two PSVs to ensure that 1-PCV-1-12 (Steam Generator 2 Power Relief Valve) will close. The control cables for 1-PSV-1-31B-B and 1-PSV-1-31C-A are protected such that there is greater than 20 feet horizontal separation between the two PSVs to ensure that 1-PCV-1-30 (Steam Generator 4 Power Relief Valve) will close. Greater than 20 feet horizontal separation is also credited to prevent possible CCP-2B overheating due to delayed letdown isolation concurrent with loss of letdown heat exchanger (HTX) cooling. The letdown isolation valve (2-FCV-62-70-A) cables are horizontally separated more than 20 feet from the HTX cooling water temperatures controls (2-TIS-62-79) such that a credible fire could not cause both failures. The features and equipment affected and credited are identified below:

737.0-A1BN	Auxiliary Building, Column Lines Q-U/A8-A10
737.0-A11	Air Lock

A fire in Analysis Volume 38 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control and long term decay heat removal, containment HVAC, fire pumps, reactor coolant inventory control, reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available for 6.9kV Shutdown Board 1A-A and onsite power is available for 6.9kV Shutdown Board 2A-A. The required mitigating features for Unit 1 and Unit 2 include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown and repair procedures. The following are exceptions to the general methodology of providing cable protection (ERFBS) from analysis volume boundary to analysis volume boundary as described in FPR Part III, Section 10.3.1. The control cables for 1-PSV-1-6B-A and 1-PSV-1-6C-B are protected such that there is greater than 20 feet horizontal separation between the two PSVs to ensure that 1-PCV-1-5 (Steam Generator 1 Power Relief Valve) will close. Greater than 20 feet horizontal separation is also credited to prevent possible CCP-2B overheating due to delayed letdown isolation concurrent with loss of letdown heat exchanger (HTX) cooling. The letdown isolation valve (2-FCV-62-70-A) cables are horizontally separated more than 20 feet from the HTX cooling water temperatures controls (2-TIS-62-79) such that a credible fire could not cause both failures. The features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.20 FIRE AREA 15-1

3.20.1 Room 737.0-A3

Description: Unit 1 Heat and Vent Equipment Room

Fire Loading: The combustibles consist of lubricant for the fans, plastic associated with electrical panels and boxes and lights and insulation on cables in trays and lube oil for the FLEX pump. The fire severity is classified as low.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
737.0-A3	North Wall	Area 12, Room 729.0-A1	II-30A	2 Hours
		Area 14, Room 737.0-A4	II-30A	2 Hours
		Area 12, Room 737.0-A6	II-30A	2 Hours
		Area 16, Room 737.0-A5	II-30A	2 Hours
	East Wall	Area 14, Room 737.0-A1A	II-30A	2 Hours
		Area 14, Room 737.0-A4	II-30A	2 Hours
	South Wall	Area 14, Room 737.0-A1A	II-30A	2 Hours
		Area 14, Room 737.0-A2	II-30A	2 Hours
	Floor	Area 8, Room 713.0-A1A	II-29A, II-30A	2 Hours
		Area 14, Room 737.0-A4*	II-30A	2 Hours
	Ceiling	Area 17, Room 757.0-A2	II-30A, II-31A	2 Hours
		Area 27, Room 757.0-A5	II-30A, II-31A	2 Hours
	(* Partial height room)			

Doors:					
Room	Door Number	Dir	Adjacent Area/Room	FPR Figure Reference	Door Rating
737.0-A3	A122	East	Area 14, Room 737.0-A4	II-30A	1.5 Hours

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
737.0-A3	1-ISD-31-3803 47A381-443F	F-C	Area 8, Room 713.0-A1A	47W866-2 47W920-18	3 Hours
	1-ISD-31-3806 47A381-404F	N-S	Area 14, Room 737.0-A1A	47W866-2 47W920-5	3 Hours
	1-ISD-31-3807 47A381-410F	E-W	Area 14, Room 737.0-A1A	47W866-2 47W920-5	3 Hours

Detection: Ionization smoke detectors are provided in the room.

PART VI – FIRE HAZARDS ANALYSIS

Suppression: An automatic preaction sprinkler system is provided in the room. Standpipe and hose stations are provided from the adjacent room (737.0-A1).

Deviations: The justification for intervening combustibles such as insulation on cables in trays and Thermo-Lag is documented in Part VII, Section 2.4.

Evaluations: The justification for large fire dampers is documented in Part VII, Section 3.4.

PART VI – FIRE HAZARDS ANALYSIS

3.20.2 Fire Area 15-1 Safe Shutdown Analysis by Analysis Volume

3.20.2.1 AV-039

Room No.	Description:
737.0-A3	Unit 1 Heat and Vent Equipment Room

A fire in Analysis Volume 39 could potentially affect systems and components necessary to maintain the Unit 1 long term decay heat removal, steam generator inventory control, fire pump, containment HVAC, reactor coolant inventory control and secondary side isolation functions and Unit 2 steam generator inventory control functions.. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features for Unit 1 and Unit 2 include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown and repair procedures. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.21 FIRE AREA 15-2

3.21.1 Room 737.0-A12

Description: Unit 2 Heat and Vent Equipment Room

Fire Loading: The combustibles consist of lubricant for fans, plastic associated with electrical panels, boxes and lights and lube oil for the FLEX pump. The fire severity is classified as low.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
737.0-A12	North Wall	Area 14, Room 737.0-A11	II-30A	2 Hours
		Area 72, Room 729.0-A11	II-30A	2 Hours
		Area 72, Room 737.0-A10	II-30A	2 Hours

		Area 31, Room 757.0-A24	I-30A, II-31A	2 Hours
	Ceiling	Area 28, Room 757.0-A21	II-30A, II-31A	2 Hours
(*PARTIAL HEIGHT ROOM)				

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
737.0-A12	A133	West	Area 14, Room 737.0-A11	II-30A	3 Hours

Dampers:					
Room	Damper/ Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
737.0-A12	2-ISD-31-3869 47A381-443F	F-C	Area 8, Room 713.0-A1B	47W866-11 47W920-18	3 Hours
	2-ISD-31-3882 47A381-410F	E-W	Area 14, Room 737.0-A1B	47W866-11 47W920-5	3 Hours
	2-ISD-31-3883 47A381-404F	N-S	Area 14, Room 737.0-A1B	47W866-11 47W920-5	3 Hours
	2-ISD-31-5452 47A381-775	N-S	Area 14, Room 737.0-A1B	47W866-11 47W920-5	3 Hours

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided in the room. Standpipe and hose stations are provided from the adjacent room (737.0-A1).

PART VI – FIRE HAZARDS ANALYSIS

Deviations: The justification for intervening combustibles such as insulation on cables in trays and Thermo-Lag is documented in Part VII, Section 2.4.

Evaluations: The justification for large fire dampers is documented in Part VII, Section 3.4. The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.18 and 65.

PART VI – FIRE HAZARDS ANALYSIS

3.21.2 Fire Area 15-2 Safe Shutdown Analysis by Analysis Volume

3.21.2.1 AV-040

Room No.	Description:
737.0-A12	Unit 2 Heat and Vent Equipment Room

A fire in Analysis Volume 40 could potentially affect systems and components necessary to maintain the long term decay heat removal, containment HVAC, fire pumps, steam generator inventory control and reactor coolant inventory control functions including loss of Unit 1 and Unit 2 Train B RHR, Charging and Auxiliary Feedwater pumps. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include providing fire protection for selected Unit 2 cables and manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.22 FIRE AREA 16

3.22.1 Rooms 737.0-A5 and A15

Room No.	Description:
737.0-A5	Ventilation and Purge Air Room (Subdivided into 737.0-A5S, -A5M, -A5N)
737.0-A15	Gross Failed Fuel Detector Room

Fire Loading: The combustibles in the Ventilation and Purge Air Room consist of lube oil in valves and plastic associated with electrical panels and lights. The fire severity is classified as low. The fire severity in the Gross Failed Fuel Detector room is classified as insignificant.

Compartmentation: The rooms are of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
737.0-A5	North Wall	Area 13, Room 729.0-A14	II-30, II-38A	3 Hours
		Area 13, Room 737.0-A13	II-30A	3 Hours
		Area 61, Reactor Building	II-30A	3 Hours
	South Wall	Area 1, Room 713.0-A28	II-29A, II-30A	2 Hours
		Area 14, Room 737.0-A1A	II-30A	2 Hours
		Area 14, Room 737.0-A3	II-30A	2 Hours
		Area 14, Room 737.0-A4	II-30A	2 Hours

	0-ISD-31-3847 47A381-421	E-W	Area 10, Room 729.0-A6	47W866-10 47W920-6, 7	1.5 Hours
	0-ISD-31-3848 47A381-420	E-W	Area 10, Room 729.0-A6	47W866-10 47W920-6, 7	1.5 Hours
	0-ISD-31-3849 47A381-419F	E-W	Area 10, Room 729.0-A6	47W866-10 47W920-6	3 Hours

Detection: Ionization smoke detectors are provided in room 737.0-A5. (See note below)

Suppression: Automatic preaction sprinkler systems are provided in both rooms. (See note below) Standpipe and hose stations are provided from the adjacent room (737.0-A1).

PART VI – FIRE HAZARDS ANALYSIS

Deviations: HVAC ducts penetrate two of the required fire barriers but are not provided with fire dampers. The justification is documented in Part VII, Section 2.6.

Evaluations: The justification for the relaxation of fire damper surveillance requirements is documented in Part VII, Section 6.2. The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.12, 13, 14, 63 and 64.

Note: Room 737.0-A15 is a partial height room and is contained within room 737.0-A5 (See FPR Figure II-30A). There are no detectors in room 737.0-A15. The walls and ceiling of the room are not rated. The suppression head in the room is considered an obstruction coverage head for the full area suppression of room 737.0-A5. Room 737.0-A15 contains no safe shutdown equipment or cables. Actuation of the preaction sprinkler system in room 737.0-A15 requires the actuation of the detection system in room 737.0-A5.

PART VI – FIRE HAZARDS ANALYSIS

3.22.2 Fire Area 16 Safe Shutdown Analysis by Analysis Volume

3.22.2.1 AV-041

Room No.	Description:
737.0-A5	Ventilation and Purge Air Room
737.0-A15	Gross Failed Fuel Detector Room

AV-041 contains redundant Steam Generator circuits/components and redundant source range circuits. Therefore, three separate analyses (AV-041M, AV-041N, and AV-041S) are performed to address the use of either path depending upon on the location of the fire within this volume.

3.22.2.2 AV-041M

Room No.	Description:
737.0-A5M	Middle portion of 737-A5 extending from 2' north of column line V to 2'-6" south of the RX Bldg centerline (includes 737-A15).

A fire in Analysis Volume 41M could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control functions, Unit 1 reactor coolant inventory control functions, and Unit 2 long term decay heat removal. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.22.2.4 AV-041S

Room No.	Description:
737.0-A5S	South portion of 737-A5 extending from column line U to column line W.

A fire in Analysis Volume 41S could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control and reactor inventory control, Unit 1 secondary side isolation functions, and containment HVAC functions and Unit 2 long term decay heat removal function. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.23 FIRE AREA 17

3.23.1 Rooms 757.0-A2 and A9

Room No.	Description:
757.0-A2	6.9kV and 480V Shutdown Board Room A
757.0-A9	Unit 1 Personnel and Equipment Access

Fire Loading: The combustibles in the 6.9kV and 480V Shutdown Board Room A consist of plastics associated with electrical boards, panels, and boxes and lights and insulation on cables in trays. The fire severity is classified as moderately severe. The combustibles in the Personnel and Equipment Access consist of plastics associated with the panel and junction boxes and insulation on cables in trays. The fire severity is classified as moderate.

Compartmentation: The rooms are of reinforced concrete construction. The equipment hatch opening is normally closed with a steel hatch cover that is non-rated, and the opening is protected with a water curtain.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating

PART VI – FIRE HAZARDS ANALYSIS

Detection: Ionization smoke detectors are provided in both rooms.

Suppression: Automatic preaction sprinkler systems are provided in both rooms. In addition, standpipes and hose stations are provided.

Deviations: The 772.0 floor slab has an equipment hatch with a non-rated cover that is protected by a water curtain. The justification for this opening is documented in Part VII, Section 2.6. The justification for intervening combustibles such as insulation on cables in trays and Thermo-Lag is documented in Part VII, Section 2.4. The justification for manual hose stations having hose lengths greater than 100 feet is documented in Part VII, Section 4.3.

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.20 and 24. The justification for the in situ combustible load in Room 757.0-A2 is provided in Part VII, Section 3.6.

PART VI – FIRE HAZARDS ANALYSIS

3.23.2 Fire Area 17 Safe Shutdown Analysis by Analysis Volume

3.23.2.1 AV-042

Room No.	Description:
757.0-A2	6.9kV and 480V Shutdown Board Room A
757.0-A9	Unit 1 Personnel and Equipment Access

This AV contains cables and/or equipment associated with the 5th Vital Battery. The 5th Vital Battery is credited as an "installed spare" that can be used during normal plant operation if one of the existing batteries is down for maintenance. This AV has been analyzed to address the effects of a fire on the 125V DC system if the 5th Vital Battery is in service in replacement of any one of the other four normally credited batteries. There has been an additional four analyses performed (AV-042D through G) for this AV to address the various combinations where the 5th Vital Battery can be used.

A fire in Analysis Volume 42 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control, long term decay heat removal, containment HVAC, fire pumps, reactor coolant inventory control, reactor pressure control and secondary side isolation functions and Unit 1 containment integrity functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is not available. The required mitigating features include providing fire wrap to selected Unit 1 cables to preclude damage in the event of a fire and manual operation of Unit 1 and Unit 2 equipment required for safe shutdown and repair procedures. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.23.2.2 AV-042D

Room No.	Description:
757.0-A2	6.9kV and 480V Shutdown Board Room A
757.0-A9	Unit 1 Personnel and Equipment Access

A fire in Analysis Volume 42D could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control, long term decay heat removal, containment HVAC, fire pumps, reactor coolant inventory control, reactor pressure control, and secondary side isolation functions and Unit 1 containment integrity functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is not available. The required mitigating features for Unit 1 and Unit 2 include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown and repair procedures. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.23.2.3 AV-042E

Room No.	Description:
757.0-A2	6.9kV and 480V Shutdown Board Room A
757.0-A9	Unit 1 Personnel and Equipment Access

A fire in Analysis Volume 42E could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control, long term decay heat removal, containment HVAC, fire pumps, reactor coolant inventory control, reactor pressure control, and secondary side isolation functions and Unit 1 containment integrity functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is not available. The required mitigating features for Unit 1 and Unit 2 include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown and repair procedures. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.23.2.4 AV-042F

Room No.	Description:
757.0-A2	6.9kV and 480V Shutdown Board Room A
757.0-A9	Unit 1 Personnel and Equipment Access

A fire in Analysis Volume 42F could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control, long term decay heat removal, containment HVAC, fire pumps, reactor coolant inventory control, reactor pressure control and secondary side isolation functions and Unit 1 containment integrity functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is not available. The required mitigating features for Unit 1 and Unit 2 include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown and repair procedures. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.23.2.5 AV-042G

Room No.	Description:
757.0-A2	6.9kV and 480V Shutdown Board Room A
757.0-A9	Unit 1 Personnel and Equipment Access

A fire in Analysis Volume 42G could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control, long term decay heat removal, containment HVAC, fire pumps, reactor coolant inventory control, reactor pressure control and secondary side isolation functions and Unit 1 containment integrity functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is not available. The required mitigating features for Unit 1 and Unit 2 include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown and repair procedures. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.24 FIRE AREA 18

3.24.1 Room 757.0-A3

Description: 125V Vital Battery Board Room II

Fire Loading: The combustibles consist of plastics associated with electrical panels and boxes and insulation on cables in trays. The fire severity is classified as low.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
757.0-A3	North Wall	Area 17, Room 757.0-A2	II-31A	3 Hours
	South Wall	Area 48, Room 755.0-C12	II-31A, II-34A	3 Hours
	East Wall	Area 21, Room 757.0-A25	II-31A	3 Hours
		Area 22, Room 757.0-A26	II-31A	3 Hours
	West Wall	Area 19, Room 757.0-A4	II-31A	3 Hours
	Floor	Area 14, Room 737.0-A1A	II-30A, II-31A	3 Hours
	Ceiling	Area 34, Room 772.0-A3	II-31A, II-32A	3 Hours
		Area 35, Room 772.0-A4	II-31A, II-32A	3 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
757.0-A3	A141	North	Area 17, Room 757.0-A2	II-31A	3 Hours

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
757.0-A3	0-ISD-31-2713 47A381-192F	N-S	Area 17, Room 757.0-A2	47W866-3 47W920-8	3 Hours
	0-ISD-31-2715 47A381-115F	N-S	Area 17, Room 757.0-A2	47W866-3 47W920-8	3 Hours

Detection: Ionization smoke detectors are provided in the room.

Suppression: A manually actuated sprinkler system is provided in the room. A standpipe and hose station is provided from room 757.0-A2.

Deviations: None.

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.21 and 65.

PART VI – FIRE HAZARDS ANALYSIS

3.24.2 Fire Area 18 Safe Shutdown Analysis by Analysis Volume

3.24.2.1 AV-043

Room No.	Description:
757.0-A3	125-V Vital Battery Board Room II

A fire in Analysis Volume 43 could potentially affect systems and components necessary to maintain the long term decay heat removal, reactor coolant inventory control, steam generator inventory control, containment HVAC, fire pumps and reactor pressure control functions for both units. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include manual operation Unit 1 and Unit 2 of equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.25 FIRE AREA 19

3.25.1 Room 757.0-A4

Description: 125V Vital Battery Board Room I

Fire Loading: The combustibles consist of plastics associated with electrical panels and boxes and insulation on cables in trays. The fire severity is classified as low.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
757.0-A4	North Wall	Area 17, Room 757.0-A2	II-31A	3 Hours
	South Wall	Area 48, Room 755.0-C12	II-31A, II-34A	3 Hours
		Area 48, Room 755.0-C3	II-31A, II-34A	3 Hours
	East Wall	Area 18, Room 757.0-A3	II-31A	3 Hours
	West Wall	Area 27, Room 757.0-A5	II-31A	3 Hours
	Floor	Area 14, Room 737.0-A1A	II-30A, II-31A	3 Hours
	Ceiling	Area 33, Room 772.0-A2	II-31A, II-32A	3 Hours
		Area 35, Room 772.0-A4	II-31A, II-32A	3 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
757.0-A4	A142	North	Area 17, Room 757.0-A2	II-31A	3 Hours

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
757.0-A4	0-ISD-31-4618 47A381-513G	N-S	Area 27, Room 757.0-A5	47W866-3 47W920-8	3 Hours
	0-ISD-31-2733 47A381-115G	N-S	Area 17, Room 757.0-A2	47W866-3 47W920-8	3 Hours

Detection: Ionization detectors are provided in the room.

Suppression: A manually actuated sprinkler system is provided in the room. A standpipe and hose station is provided from room 757.0-A2.

Deviations: None.

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.22, 63 and 64.

PART VI – FIRE HAZARDS ANALYSIS

3.25.2 Fire Area 19 Safe Shutdown Analysis by Analysis Volume

3.25.2.1 AV-044

Room No.	Description:
757.0-A4	125V Vital Battery Board Room I

A fire in Analysis Volume 44 could potentially affect systems and components necessary to maintain the long term decay heat removal, reactor coolant inventory control, steam generator inventory control, containment HVAC, fire pumps and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.26 FIRE AREA 20

3.26.1 Room 757.0-A1

Description: Auxiliary Control Room

Fire Loading: The combustibles consist of plastics associated with electrical panels and boxes and lights and insulation on cables in trays. The fire severity is classified as moderate.

Compartmentation: The room is reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
757.0-A1	North Wall	Area 17, Room 757.0-A2	II-31A	2 Hours
		Area 31, Room 757.0-A24	II-31A	2 Hours
	South Wall	Area 48, Room 755.0-C12	II-31A, II-34A	3 Hours
	East Wall	Area 23, Room 757.0-A27	II-31A	2 Hours
		Area 24, Room 757.0-A28	II-31A	2 Hours
	West Wall	Area 21, Room 757.0-A25	II-31A	2 Hours
		Area 22, Room 757.0-A26	II-31A	2 Hours

	0-ISD-31-2779 47A381-259F	E-W	Area 24, Room 757.0-A28	47W866-3 47W920-26	3 Hours

Detection: Ionization detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided in the room. Standpipe and hose stations are provided from rooms 757.0-A2 and A24.

Deviations: The following instrumentation has not been provided in the Auxiliary Control Room:

- a. Wide range steam generator level
- b. Tank level for the condensate storage tank (CST) and refueling water storage tank (RWST).
- c. RCS cold leg temperature (T_c).

The justifications are documented in Part VII, Section 2.1.

The justification for intervening combustibles such as insulation on cables in trays and Thermo-Lag is documented in Part VII, Section 2.4.

Evaluations: The feasibility and reliability evaluation for Unit 2 Operator Manual Action is documented in Part VII, Section 8.3.19.

PART VI – FIRE HAZARDS ANALYSIS

3.26.2 Fire Area 20 Safe Shutdown Analysis by Analysis Volume

3.26.2.1 AV-045

Room No.	Description:
757.0-A1	Auxiliary Control Room

A fire in Analysis Volume 45 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control, long term decay heat removal, containment HVAC, fire pumps, reactor coolant inventory control and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is not available. The required mitigating features for Unit 1 and Unit 2 include providing fire wrap to selected cables to preclude damage in the event of a fire, manual operation of equipment required for safe shutdown and repair procedures. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.27 FIRE AREA 21

3.27.1 Room 757.0-A25

Description: Auxiliary Control Instrument Room 1A

Fire Loading: The combustibles consist of plastics associated with electrical panels and boxes and lights, Thermo-Lag, and insulation on cables in trays. The fire severity is classified as moderately severe.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
757.0-A25	North Wall	Area 22, Room 757.0-A26	II-31A	2 Hours
	South Wall	Area 48, Room 755.0-C12	II-31A, II-34A	3 Hours
	East Wall	Area 20, Room 757.0-A1	II-31A	2 Hours
	West Wall	Area 18, Room 757.0-A3	II-31A	3 Hours
	Floor	Area 14, Room 737.0-A1A	II-30A, II-31A	2 Hours
	Ceiling	Area 33, Room 772.0-A2 Area 34, Room 772.0-A3	II-31A, II-32A II-31A, II-32A	2 Hours 3 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
757.0-A25	A138	East	Area 20, Room 757.0-A1	II-31A	3 Hours

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
757.0-A25	0-ISD-31-2723 47A381-258F	E-W	Area 20, Room 757.0-A1	47W866-3 47W920-26	3 Hours
	0-ISD-31-2725 47A381-257F	E-W	Area 20, Room 757.0-A1	47W866-3 47W920-26	3 Hours

Detection: Ionization detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided in the room. Standpipe and hose stations are provided from rooms 757.0-A2 and A24.

PART VI – FIRE HAZARDS ANALYSIS

Deviations: The justification for intervening combustibles such as insulation on cables in trays and Thermo-Lag is documented in Part VII, Section 2.4.

Evaluations: The justification for the in situ combustible load in Room 757.0-A25 is provided in Part VII, Section 3.6.

PART VI – FIRE HAZARDS ANALYSIS

3.27.2 Fire Area 21 Safe Shutdown Analysis by Analysis Volume

3.27.2.1 AV-046

Room No.	Description:
757.0-A25	Auxiliary Control Instrument Room 1A

A fire in Analysis Volume 46 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control, reactor coolant inventory control and long term decay heat removal functions and Unit 1 containment HVAC, and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.28 FIRE AREA 22

3.28.1 Room 757.0-A26

Description: Auxiliary Control Instrument Room 1B.

Fire Loading: The combustibles consist of plastics associated with electrical panels and boxes and lights, Thermo-Lag, and insulation on cables in trays. The fire severity is classified as moderately severe.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
757.0-A26	North Wall	Area 17, Room 757.0-A2	II-31A	2 Hours
	South Wall	Area 21, Room 757.0-A25	II-31A	2 Hours
	East Wall	Area 20, Room 757.0-A1	II-31A	2 Hours
	West Wall	Area 18, Room 757.0-A3	II-31A	3 Hours
	Floor	Area 14, Room 737.0-A1A	II-30A, II-31A	2 Hours
	Ceiling	Area 33, Room 772.0-A2	II-31A, II-32A	2 Hours
		Area 34, Room 772.0-A3	II-31A, II-32A	3 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
757.0-A26	A139	East	Area 20, Room 757.0-A1	II-31A	3 Hours

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
757.0-A26	0-ISD-31-2726 47A381-257F	E-W	Area 20, Room 757.0-A1	47W866-3 47W920-26	3 Hours
	0-ISD-31-2728 47A381-259F	E-W	Area 20, Room 757.0-A1	47W866-3 47W920-26	3 Hours

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided in the room. Standpipe and hose stations are provided from rooms 757.0-A2 and A24.

Deviations: The justification for intervening combustibles such as insulation on cables in trays and Thermo-Lag is documented in Part VII, Section 2.4.

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.32 and 65. The justification for the in situ combustible load in Room 757.0-A26 is provided in Part VII, Section 3.6.

PART VI – FIRE HAZARDS ANALYSIS

3.28.2 Fire Area 22 Safe Shutdown Analysis by Analysis Volume

3.28.2.1 AV-047

Room No.	Description:
757.0 A26	Auxiliary Control Instrument Room 1B

A fire in Analysis Volume 47 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control, long term decay heat removal and reactor coolant inventory control functions and Unit 1 reactor pressure control and containment HVAC functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features for Unit 1 and Unit 2 include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.30 FIRE AREA 24

3.30.1 Room 757.0-A28

Description: Auxiliary Control Instrument Room 2B

Fire Loading: The combustibles consist of plastics associated with electrical panels and boxes and lights and insulation on cables in trays. The fire severity is classified as moderately severe.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
757.0-A28	North Wall	Area 31, Room 757.0-A24	II-31A	2 Hour
	South Wall	Area 23, Room 757.0-A27	II-31A	2 Hours
	East Wall	Area 30, Room 757.0-A23	II-31A	3 Hours
	West Wall	Area 20, Room 757.0-A1	II-31A	2 Hours
	Floor	Area 14, Room 737.0-A1B	II-30A, II-31A	2 Hours
	Ceiling	Area 44, Room 772.0-A14 Area 45, Room 772.0-A15	II-31A, II-32A II-31A, II-32A	3 Hours 2 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
757.0-A28	A175	West	Area 20, Room 757.0-A1	II-31A	3 Hours

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
757.0-A28	0-ISD-31-2777 47A381-257F	E-W	Area 20, Room 757.0-A1	47W866-3 47W920-26	3 Hours
	0-ISD-31-2779 47A381-259F	E-W	Area 20, Room 757.0-A1	47W866-3 47W920-26	3 Hours

Detection: Ionization detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided for the room. Standpipe and hose stations are provided from rooms 757.0-A2 and A24.

Deviations: The justification for intervening combustibles such as insulation on cables in trays and Thermo-Lag is documented in Part VII, Section 2.4.

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.34, 62 and 65. The justification for the in situ combustible load in Room 757.0-A28 is provided in Part VII, Section 3.6.

PART VI – FIRE HAZARDS ANALYSIS

3.30.2 Fire Area 24 Safe Shutdown Analysis by Analysis Volume

3.30.2.1 AV-049

Room No.	Description:
757.0-A28	Auxiliary Control Instrument Room 2B

A fire in Analysis Volume 49 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 long term decay heat removal, containment HVAC, reactor coolant inventory control, steam generator inventory control and reactor pressure control functions and Unit 2 secondary side isolation functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.31 FIRE AREA 25

3.31.1 Rooms 782.0-A1 and A2, 757.0-A10

Room No.	Description:
782.0-A1	Unit 1 Control Rod Drive Equipment Room
782.0-A2	Pressurizer Heater Transformer Room 1
757.0-A10	Reverse Osmosis Equipment Room

Fire Loading: The combustibles consist of plastics associated with the electrical panels, transformers, and lights, oil in the transformers, and the insulation on the cables in the trays. The fire severity is classified as moderate.

Compartmentation: The rooms are of reinforced concrete construction. The floor slab in Room 782.0-A1 to 757.0-A10 has an equipment hatch that is covered with a nonfire rated steel cover, two HVAC ducts without fire dampers, and a stairway enclosed by 2 hour non-regulatory fire barriers. The floor slab in Room 782.0-A2 to Room 757.0-A12 has a stairway enclosed by 2 hour non-regulatory fire barriers.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
782.0-A1	North Wall	Area 61, Reactor Building	II-32A	3 Hours
	South Wall	Area 37, Room 772.0-A6	II-32A	2 Hours
		Area 38, Room 772.0-A7	II-32A	2 Hours
		Area 39, Room 772.0-A8	II-32A	2 Hours
	East Wall	Area 10, Room 757.0-A13	II-32A	2 Hours
	West Wall	Area 12, Room 729.0-A1	II-32A	2 Hours
		Area 61, Reactor Building	II-32A	3 Hours
782.0-A2	Floor	Area 25, Room 757.0-A10	II-31A, II-32A	2 Hours
		Area 26, Room 757.0-A11	II-31A, II-32A	3 Hours
	North Wall	Area 13, Room 775.25-A1	II-32A	3 Hours
		Area 13, Room 786.5-A1	II-32A	3 Hours
	East Wall	Area 10, Room 757.0-A13	II-32A	2 Hours
	West Wall	Area 61, Reactor Building	II-32A	3 Hours
	Floor	Area 25, Room 757.0-A12	II-31A, II-32A	2 Hours
		Area 26, Room 757.0-A11	II-31A, II-32A	3 Hours
757.0-A10	North Wall	Area 26, Room 757.0-A11	II-31A	3 Hours
		Area 61, Unit 1 Reactor Bldg	II-31A	3 Hours
	South Wall	Area 17, Room 757.0-A2	II-31A	2 Hours

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
782.0-A1	1-ISD-31-3119 47A381-256F	E-W	Area 10, Room 757.0-A13	47W866-2 47W920-9	3 Hours
	1-ISD-31-3117 47A381-253	E-W	Area 10, Room 757.0-A13	47W866-2 47W920-10	3 Hours
757.0-A10	1-ISD-31-3786 47A381-438	N-S	Area 17, Room 757.0-A9	47W866-2 47W920-8	1.5 Hours
	1-ISD-31-3788 47A381-440F	E-W	Area 10, Room 757.0-A13	47W866-2 47W920-8	3 Hours

Detection: Ionization smoke detectors are provided in the rooms.

Suppression: Automatic preaction sprinkler systems are provided in the rooms. A standpipe and hose station is provided in room 782.0-A1.

Deviations: The justification for intervening combustibles such as insulation on cables in trays and Thermo-Lag is documented in Part VII, Section 2.4. The justification for the heavy sheet metal ducts is documented in Part VII, Section 2.6.3.2.b. The justification for manual hose stations having hose lengths greater than 100 feet is documented in Part VII, Section 4.3.

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.25, 51, 52, 62 and 65.

3.31.2 Room 757.0-A12

Description: Reactor Building Access Room (Unit 1)

Fire Loading: The combustibles consist of plastics associated with electrical panels and boxes and lights, insulation on cables in trays, and anticipated amounts of radwaste trash and laundry. The fire severity is classified as moderate.

PART VI – FIRE HAZARDS ANALYSIS

Compartmentation: The room is of reinforced concrete construction. A stairway provides access to Room 757.0-A12 from Room 782.0-A2.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
757.0-A12	North Wall	Area 13, Room 763.5-A1	II-31A, II-38A	3 Hours

Detection: Ionization smoke detectors are provided in the room.

Suppression: Automatic sprinklers are provided in the room. Standpipe and hose stations are provided.

Deviations: The justification for intervening combustibles such as insulation on cables in trays and Thermo-Lag is documented in Part VII, Section 2.4.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

3.31.3 Fire Area 25 Safe Shutdown Analysis By Analysis Volume

3.31.3.1 AV-050

Room No.	Description:
757.0-A10	Reverse Osmosis Room
782.0-A1	Unit 1 Control Rod Drive Equipment Room
782.0-A2	Pressurizer Heater Transformer Room 1

A fire in Analysis Volume 50 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control and reactor pressure control functions and Unit 1 containment HVAC, reactor coolant inventory control, and secondary side isolation functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include providing fire wrap to selected Unit 1 cables to preclude damage in the event of a fire and manual operation of Unit 1 and Unit 2 equipment required for safe shutdown and repair procedures. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.31.3.2 AV-051

Room No.	Description:
757.0-A12	Reactor Building Access Room (Unit 1)

A fire in Analysis Volume 51 could potentially affect systems and components necessary to maintain the Unit 1 steam generator inventory control and secondary side isolation functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include manual operation of Unit 1 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.32 FIRE AREA 26

3.32.1 Room 757.0-A11

Description: Reactor Building Equipment Hatch (During power operations this room is considered as part of Unit 1 Reactor Building.)

Fire Loading: The combustibles consist of plastics associated with the lights and insulation on cables in trays and Thermo-Lag on conduits. The fire severity is classified as low.

Compartmentation: The room is of reinforced concrete construction. The concrete plugs that close the opening provide an equivalent 3-hour fire barrier.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
757.0-A11	North Wall	Area 10, Room 757.0-A13	II-31A	3 Hours
		Area 25, Room 757.0-A12	II-31A	3 Hours
	South Wall	Area 10, Room 757.0-A13	II-31A	3 Hours
		Area 25, Room 757.0-A10	II-31A	3 Hours
	East Wall	Area 10, Room 757.0-A13	II-31A	3 Hours
	Floor	Area 14, Room 737.0-A1C	II-30A, II-31A	3 Hours
		Area 16, Room 737.0-A5	II-30A, II-31A	3 Hours
	Ceiling	Area 25, Room 782.0-A1	II-31A, II-32A	3 Hours
		Area 10, Room 757.0-A13	II-31A, II-32A	3 Hours

Doors: None.

Dampers: None.

Detection: Ionization smoke detectors are provided in the room.

Suppression: Automatic sprinklers are provided in the room. Standpipe and hose stations are provided from the adjacent room (757.0-A13) when the equipment hatch concrete plugs are removed, e.g., during outages. This room is not accessible during power operations.

Deviations: The justification for intervening combustibles such as insulation on cables in trays and Thermo-Lag is documented in Part VII, Section 2.4.

Evaluations: The justification for the surveillance frequency for sprinklers, detectors, penetration seals and Thermo-lag in the room is documented in Part VII, Section 6.1 of the FPR.

PART VI – FIRE HAZARDS ANALYSIS

3.32.2 Fire Area 26 Safe Shutdown Analyses By Analysis Volume

3.32.2.1 AV-052

Room No.	Description:
757.0-A11	Reactor Building Equipment Hatch (During power, part of U1 Rx Bldg)

A fire in Analysis Volume 52 could potentially affect Unit 1 systems and components necessary to maintain the steam generator inventory control, containment HVAC, reactor pressure control and secondary side isolation functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features for Unit 1 include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.33 FIRE AREA 27

3.33.1 Room 757.0-A5

Description: 480V Shutdown Board Room 1B

Fire Loading: The combustibles consist of plastics associated with electrical panels and boxes and lights and insulation on cables in trays. The fire severity is classified as moderately severe.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
757.0-A5	North Wall	Area 17, Room 757.0-A2	II-31A	2 Hours
	South Wall	Area 48, Room 755.0-C1	II-31A, II-34A	3 Hours
		Area 48, Room 755.0-C6	II-31A, II-34A	3 Hours
		Area 48, Room 755.0-C8	II-31A, II-34A	3 Hours
		Area 48, Room 755.0-C9	II-31A, II-34A	3 Hours
		Area 48, Room 755.0-C12	II-31A, II-34A	3 Hours
		Area 48, Room 755.0-C3	II-31A, II-34A	3 Hours

	0-ISD-31-4621	N-S	Area 17, Room 757.0-A2	47W866-3	1.5 Hours

PART VI – FIRE HAZARDS ANALYSIS

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
	47A381-495F			47W920-8	

Detection: Ionization smoke detectors are provided in the room.

Suppression: Automatic sprinklers are provided in the room. Standpipe and hose stations are provided from the adjacent room (757.0-A2).

Deviations: The justification for intervening combustibles such as insulation on cables in trays and Thermo-Lag is documented in Part VII, Section 2.4. The justification for fire doors is documented in Part VII, Section 4.1.

Evaluations: The feasibility and reliability evaluation for Unit 2 Operator Manual Action is documented in Part VII, Section 8.3.23. The justification for the in situ combustible load in Room 757.0-A5 is provided in Part VII, Section 3.6.

PART VI – FIRE HAZARDS ANALYSIS

3.33.2 Fire Area 27 Safe Shutdown Analysis By Analysis Volume

3.33.2.1 AV-053

Room No.	Description:
757.0-A5	480V Shutdown Board Room 1B

A fire in Analysis Volume 53 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control, long term decay heat removal, containment HVAC, reactor coolant inventory control and Unit 2 reactor pressure control functions and Unit 1 fire pump function. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available but not credited for Train B since the associated 480V shutdown boards are affected. The required mitigating features for Unit 1 and Unit 2 include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.34 FIRE AREA 28

3.34.1 Room 757.0-A21

Description: 480V Shutdown Board Room 2A

Fire Loading: The combustibles consist of plastics associated with electrical panels and boxes and lights and insulation on cables in trays. The fire severity is classified as moderately severe.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
757.0-A21	North Wall	Area 31, Room 757.0-A24	II-31A	2 Hours
	South Wall	Area 48, Room 755.0-C12	II-31A, II-34A	3 Hours
		Area 48, Room 755.0-C13	II-31A, II-34A	3 Hours
		Area 48, Room 755.0-C18	II-31A, II-34A	3 Hours

	0-ISD-31-4624 47A381-495F	N-S	Area 31, Room 757.0-A24	47W866-3 47W920-8	1.5 Hours
	0-ISD-31-4625 47A381-495F	N-S	Area 31, Room 757.0-A24	47W866-3 47W920-8	1.5 Hours

Detection: Ionization smoke detectors are provided in the room.

PART VI – FIRE HAZARDS ANALYSIS

Suppression: Automatic sprinklers are provided in the room. Standpipe and hose stations are provided from the adjacent room (757.0-A24).

Deviations: Intervening combustibles (in the form of insulation on cables in trays and ERFBS) are present in the room. The justification is documented in Part VII, Section 2.4. The justification for fire doors is documented in Part VII, Section 4.1.

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.28 and 64. The justification for the in situ combustible load in Room 757.0-A21 is provided in Part VII, Section 3.6.

PART VI – FIRE HAZARDS ANALYSIS

3.34.2 Fire Area 28 Safe Shutdown Analysis By Analysis Volume

3.34.2.1 AV-054

Room No.	Description:
757.0-A21	480V Shutdown Board Room 2A

A fire in Analysis Volume 54 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control and long term decay heat removal functions and Unit 2 containment HVAC, fire pump, containment integrity, secondary side isolation and reactor coolant inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features for Unit 1 and Unit 2 include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown and repair procedures. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.35 FIRE AREA 29

3.35.1 Room 757.0-A22

Description: 125V Vital Battery Board Room IV

Fire Loading: The combustibles consist of plastics associated with electrical panels and boxes and insulation on cables in trays. The fire severity is classified as low.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
757.0-A22	North Wall	Area 31, Room 757.0-A24	II-31A	3 Hours
	South Wall	Area 48, Room 755.0-C12	II-31A, II-34A	3 Hours
	East Wall	Area 28, Room 757.0-A21	II-31A	3 Hours
	West Wall	Area 30, Room 757.0-A23	II-31A	3 Hours
	Floor	Area 14, Room 737.0-A1B	II-30A, II-31A	3 Hours
	Ceiling	Area 43, Room 772.0-A13	II-31A, II-32A	3 Hours
		Area 45, Room 772.0-A15	II-31A, II-32A	3 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
757.0-A22	A169	North	Area 31, Room 757.0-A24	II-31A	3 Hours

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
757.0-A22	0-ISD-31-2785 47A381-115G	N-S	Area 31, Room 757.0-A24	47W866-3 47W920-8	3 Hours
	0-ISD-31-4622 47A381-513G	E-W	Area 28, Room 757.0-A21	47W866-3 47W920-8	3 Hours

Detection: Ionization detection is provided in the room.

Suppression: A manually actuated preaction sprinkler system is provided in the room. A standpipe and hose station is provided from the adjacent room (757.0-A24).

Deviations: None.

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.29, 62 and 65.

PART VI – FIRE HAZARDS ANALYSIS

3.35.2 Fire Area 29 Safe Shutdown Analysis By Analysis Volume

3.35.2.1 AV-055

Room No.	Description:
757.0-A22	125V Vital Battery Board Room IV

A fire in Analysis Volume 55 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 long term decay heat removal, fire pumps, containment HVAC, reactor coolant inventory control, steam generator inventory control, secondary side isolation and reactor pressure control functions and Unit 2 containment integrity functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.36 FIRE AREA 30

3.36.1 Room 757.0-A23

Description: 125V Vital Battery Board Room III

Fire Loading: The combustibles consist of plastics associated with electrical panels and boxes and insulation on cables in trays. The fire severity is classified as low.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
757.0-A23	North Wall	Area 31, Room 757.0-A24	II-31A	3 Hours
	South Wall	Area 48, Room 755.0-C12	II-31A, II-34A	3 Hours
	East Wall	Area 29, Room 757.0-A22	II-31A	3 Hours
	West Wall	Area 23, Room 757.0-A27	II-31A	3 Hours
		Area 24, Room 757.0-A28	II-31A	3 Hours
	Floor	Area 14, Room 737.0-A1B	II-30A, II-31A	3 Hours
	Ceiling	Area 43, Room 772.0-A13	II-31A, II-32A	3 Hours
		Area 44, Room 772.0-A14	II-31A, II-32A	3 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
757.0-A23	A170	North	Area 31, Room 757.0-A24	II-31A	3 Hours

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
757.0-A23	0-ISD-31-2780 47A381-192F	N-S	Area 31, Room 757.0-A24	47W866-3 47W920-8	3 Hours
	0-ISD-31-2782 47A381-115G	N-S	Area 31, Room 757.0-A24	47W866-3 47W920-8	3 Hours

Detection: Ionization detectors are provided in the room.

Suppression: A manually actuated preaction sprinkler system is provided in the room. A standpipe and hose station is provided from the adjacent room (757.0-A24).

Deviations: None.

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.30, 63 and 64.

PART VI – FIRE HAZARDS ANALYSIS

3.36.2 Fire Area 30 Safe Shutdown Analysis By Analysis Volume

3.36.2.1 AV-056

Room No.	Description:
757.0-A23	125V Vital Battery Board Room III

A fire in Analysis Volume 56 could potentially affect systems and components necessary to maintain the long term decay heat removal, containment HVAC, fire pumps, steam generator inventory control, reactor coolant inventory control and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include manual operation of equipment required for safe shutdown and repair procedures. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.37 FIRE AREA 31

3.37.1 Rooms 757.0-A17 and A24

Room No.	Description:
757.0-A17	Unit 2 Personnel and Equipment Access Room
757.0-A24	6.9kV and 480V Shutdown Board Room B

Fire Loading: The combustibles in the Personnel and Equipment Access room consist of plastics associated with electrical panels and boxes and lights and insulation on cables in trays. The fire severity is classified as low. The combustibles in the 6.9kV and 480V Shutdown Board Room B consist of plastics associated with electrical panels and boxes and lights and insulation on cables in trays. The fire severity is classified as moderately severe.

Compartmentation: The room is of reinforced concrete construction. The equipment hatch is normally closed with a steel cover that is non-rated and the opening is protected with a water curtain.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
757.0-A24	North Wall	Area 10, Elevator Shaft	II-31A	2 Hours

PART VI – FIRE HAZARDS ANALYSIS

Dampers:					
Room	Damper/Mark Number	Dir.	Adjacent Area/Room	Drawing Reference	Damper Rating
	2-ISD-31-3957 47A381-438	E-W	Area 10, Room 757.0-A13	47W866-11 47W920-8	1.5 Hours

Detection: Ionization smoke detectors are provided in the rooms.

Suppression: Automatic sprinklers are provided in the rooms. In addition a water curtain is provided for the equipment hatch. A standpipe and hose station is provided in the room.

Deviations: Intervening combustibles (in the form of insulation on cables in trays and ERFBS) are present in rooms 757.0-A17 and 757.0-A24. The justification is documented in Part VII, Section 2.4. The 772.0 floor slab has an equipment hatch with a non-rated cover that is protected by a water curtain. The justification is documented in Part VII, Section 2.6. The justification for hose stations having more than 100 feet of hose is documented in Part VII, Section 4.3.

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.27, 31, 62 and 65. The justification for the in situ combustible load in Room 757.0-A24 is provided in Part VII, Section 3.6.

PART VI – FIRE HAZARDS ANALYSIS

3.37.2 Fire Area 31 Safe Shutdown Analysis By Analysis Volume

3.37.2.1 AV-057

Room No.	Description:
757.0-A17	Unit 2 Personnel and Equipment Access
757.0-A24	6.9kV and 480V Shutdown Room B

This AV contains cables and/or equipment associated with the 5th Vital Battery. The 5th Vital Battery is credited as an "installed spare" that can be used during normal plant operation if one of the existing batteries is down for maintenance. This AV is analyzed to address the effects of a fire on the 125V DC system if the 5th Vital Battery is in service in replacement of any one of the other four normally credited batteries. An additional four analyses are performed (AV-057D through G) for this AV to address the various combinations where the 5th Vital Battery can be used.

A fire in Analysis Volume 57 could potentially affect systems and components necessary to maintain the steam generator inventory control, long term decay heat removal, containment HVAC, fire pumps, secondary side isolation reactor coolant inventory control and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is not available. The required mitigating features include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.37.2.2 AV-057D

Room No.	Description:
757.0-A17	Unit 2 Personnel and Equipment Access Room
757.0-A24	6.9kV and 480V Shutdown Room B

A fire in Analysis Volume 57D could potentially affect systems and components necessary to maintain the steam generator inventory control, long term decay heat removal, containment HVAC, fire pumps, secondary side isolation, reactor coolant inventory control and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is not available. The required mitigating features for Unit 1 and Unit 2 include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.37.2.3 AV-057E

Room No.	Description:
757.0-A17	Unit 2 Personnel and Equipment Access Room
757.0-A24	6.9kV and 480V Shutdown Room B

A fire in Analysis Volume 57E could potentially affect systems and components necessary to maintain the steam generator inventory control, long term decay heat removal, containment HVAC, fire pumps, secondary side isolation, reactor coolant inventory control and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is not available. The required mitigating features for Unit 1 and Unit 2 include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.37.2.4 AV-057F

Room No.	Description:
757.0-A17	Unit 2 Personnel and Equipment Access Room
757.0-A24	6.9kV and 480V Shutdown Room B

A fire in Analysis Volume 57F could potentially affect systems and components necessary to maintain the steam generator inventory control, long term decay heat removal, containment HVAC, fire pumps, secondary side isolation, reactor coolant inventory control and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is not available. The required mitigating features for Unit 1 and Unit 2 include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.37.2.5 AV-057G

Room No.	Description:
757.0-A17	Unit 2 Personnel and Equipment Access Room
757.0-A24	6.9kV and 480V Shutdown Room B

A fire in Analysis Volume 57G could potentially affect systems and components necessary to maintain the steam generator inventory control, long term decay heat removal, containment HVAC, fire pumps, secondary side isolation, reactor coolant inventory control and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is not available. The required mitigating features for Unit 1 and Unit 2 include providing fire wrap to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.38 FIRE AREA 32

3.38.1 Room 772.0-A1

Description: 480V Board Room 1-A

Fire Loading: The combustibles in the 480V Board room consist of plastics associated with the electrical panels and boards and lights, oil in a hoist, and insulation on cables in trays. The fire severity is classified as moderately severe.

Compartmentation: The rooms are of reinforced concrete construction. The equipment hatch in the floor of the 480V Board room is provided with a non-fire rated steel cover, and the opening is protected with a water curtain.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating

Detection: Ionization smoke detectors are provided in the room.

Suppression: Automatic preaction sprinkler systems are provided in the room. A standpipe and hose station is provided from adjacent room (772.0-A7).

Deviations: The room contains intervening combustibles in the form of insulation on cables in trays and ERFBS. The justification for using an enhanced automatic preaction sprinkler system to compensate for these intervening combustibles is documented in Part VII, Section 2.4. The floor has an equipment hatch with a non-rated cover that is protected by a water curtain. The justification is documented in Part VII, 2.6.

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.35, 63, and 64. The justification for the in situ combustible load in Room 772.0-A1 is provided in Part VII, Section 3.6.

PART VI – FIRE HAZARDS ANALYSIS

3.38.2 Fire Area 32 Safe Shutdown Analyses By Analysis Volume

3.38.2.1 AV-058

Room No.	Description:
772.0-A1	480V Board Room 1-A

A fire in Analysis Volume 58 could potentially affect systems and components necessary to maintain the long term decay heat removal, steam generator inventory control, containment HVAC, fire pumps reactor pressure control and reactor coolant inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include providing fire wrap to selected Unit 1 cables to preclude damage in the event of a fire and manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below;

PART VI – FIRE HAZARDS ANALYSIS

3.39 FIRE AREA 33

3.39.1 Room 772.0-A2

Description: 480V Board Room 1-B (Subdivided into 772.0-A2A1, -A2A2, -A2A3, -A2A4)

Fire Loading: The combustibles consist of plastics associated with electrical boards, panels, and boxes, HVAC duct insulation, and insulation on cables in trays. The fire severity is classified as moderately severe.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided for the room, except between column lines A6-A8/Q-R. A standpipe and hose station is provided from room 772.0-A7.

Deviations: The room contains intervening combustibles in the form of insulation on cables in trays and ERFBS. The justification for using an enhanced suppression system to compensate for the intervening combustibles is documented in Part VII, Section 2.4.

Evaluations: The lack of suppression between column lines A6-A8/Q-R is documented in Part VII, Section 3.1. The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.36, 37, 62, 63, 64, and 65. The justification for the in situ combustible load in room 772.0-A2 is provided in Part VII, Section 3.6.

PART VI – FIRE HAZARDS ANALYSIS

3.39.2 Fire Area 33 Safe Shutdown Analysis By Analysis Volume

3.39.2.1 AV-059

Room No.	Description:
772.0-A2A1	480V Board Room 1-B, Column Lines A8-A6
772.0-A2A2	480V Board Room 1-B, Column Lines A6-A5
772.0-A2A3	480V Board Room 1-B, Column Lines A5-A4

A fire in Analysis Volume 59 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control, long term decay heat removal, containment HVAC, secondary side isolation, fire pumps, reactor coolant inventory control and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available for Trains 1A and 2A. The Unit 1 Train B 480VAC C&A Vent Boards are initially available, but may be lost after 3 hours due to transformer vent fan failures. Train 1B C&A Vent Board power is only needed to close two MOVs (seven minutes) to prevent RWST drawdown. The required mitigating features include providing fire wrap to selected Unit 1 cables to preclude damage in the event of a fire and manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.39.2.2 AV-060

Room No.	Description:
772.0-A2A3	480V Board Room 1-B, Column Lines A5-A4
772.0-A2A4	480V Board Room 1-B, Column Lines A4-A3

A fire in Analysis Volume 60 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control, long term decay heat removal, containment HVAC, reactor coolant inventory control and reactor pressure control functions and Unit 1 fire pump and secondary side isolation functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The Unit 1 Train B 480VAC C&A Vent Boards are initially available, but may be lost after 3 hours due to transformer vent fan failures. Train 1B C&A Vent Board power is only needed to close two MOVs (seven minutes) to prevent RWST drawdown. The required mitigating features include providing fire wrap to selected Unit 1 cables to preclude damage in the event of a fire and manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.40 FIRE AREA 34

3.40.1 Room 772.0-A3

Description: 125V Vital Battery Room II

Fire Loading: The combustibles consist of plastics associated with electrical panels and boxes and the battery cases. Adequate ventilation is provided to preclude explosive concentrations of hydrogen. The fire severity is classified as low.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
772.0-A3	North Wall	Area 33, Room 772.0-A2	II-32A	3 hours
	South Wall	Area 48, Room 755.0-C12	II-32A, II-34A	3 hours
	East Wall	Area 33, Room 772.0-A2	II-32A	3 hours
	West Wall	Area 35, Room 772.0-A4	II-32A	3 hours
	Floor	Area 18, Room 757.0-A3	II-31A, II-32A	3 hours
		Area 21, Room 757.0-A25	II-31A, II-32A	3 hours
		Area 22, Room 757.0-A26	II-31A, II-32A	3 hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
772.0-A3	A181	East	Area 33, Room 772.0-A2	II-32A	3 hours

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
772.0-A3	1-ISD-31-2523 47A381-312F	E-W	Area 33, Room 772.0-A2	47W866-3 47W920-9	3 hours
	1-ISD-31-2555 47A381-738	N-S	Area 33, Room 772.0-A2	47W866-3 47W920-9	3 hours
	1-ISD-31-2556 47A381-737	E-W	Area 35, Room 772.0-A4	47W866-3 47W920-9	3 hours

Detection: Ionization smoke detection is provided in the room.

Suppression: A manually actuated preaction sprinkler system is provided in the room. A standpipe and hose station is provided from room 772.0-A7.

Deviations: None.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

3.40.2 Fire Area 34 Safe Shutdown Analysis By Analysis Volume

3.40.2.1 AV-061

Room No.	Description:
772.0-A3	125V Vital Battery Room II

A fire in Analysis Volume 61 could potentially affect systems and components necessary to maintain the long term decay heat removal, reactor coolant inventory control, steam generator inventory control, fire pumps, containment HVAC and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

Detection: Ionization smoke detectors are provided in the room.

Suppression: A manually actuated preaction sprinkler system is provided in the room. Standpipe and hose stations are provided from room 772.0-A7.

Deviations: None.

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.38, 63, and 64.

PART VI – FIRE HAZARDS ANALYSIS

3.41.2 Fire Area 35 Safe Shutdown Analysis By Analysis Volume

3.41.2.1 AV-062

Room No.	Description:
772.0-A4	125V VITAL BATTERY ROOM I

A fire in Analysis Volume 62 could potentially affect systems and components necessary to maintain the long term decay heat removal, reactor coolant inventory control, steam generator inventory control, fire pumps, containment HVAC and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.42 FIRE AREA 36

3.42.1 Room 772.0-A5

Description: 480V Transformer Room 1-B

Fire Loading: The combustibles consist of plastics associated with electrical panels, oil in the transformers, and insulation on the cables in the trays. The fire severity is classified as moderate.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
772.0-A5	NORTH WALL	AREA 37, ROOM 772.0-A6	II-32A	2 Hours
	SOUTH WALL	AREA 48, ROOM 755.0-C1	II-32A, II-34A	3 Hours
		AREA 48, ROOM 755.0-C6	II-32A, II-34A	3 Hours
		AREA 48, ROOM 755.0-C8	II-32A, II-34A	3 Hours
		AREA 48, ROOM 755.0-C9	II-32A, II-34A	3 Hours

		AREA 32, ROOM 772.0-A1	II-32A	2 Hours
		AREA 33, ROOM 772.0-A2	II-32A	2 Hours
	FLOOR	AREA 27, ROOM 757.0-A5	II-31A, II-32A	2 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
772.0-A5	A185	NORTH	AREA 37, ROOM 772.0-A6	II-32A	3 Hours

Dampers: None.

Detection: Ionization detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided in the room. A standpipe and hose station is provided from room 772.0-A7.

Deviations: The room contains intervening combustibles in the form of insulation on the cables in trays and ERFBS. The justification for using an enhanced automatic preaction sprinkler system to compensate for these intervening combustibles is documented in Part VII, Section 2.4.

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.39 and 62.

PART VI – FIRE HAZARDS ANALYSIS

3.42.2 Fire Area 36 Safe Shutdown Analysis By Analysis Volume

3.42.2.1 AV-063

Room No.	Description:
772.0-A5	480V Transformer Room 1-B

A fire in Analysis Volume 63 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 long term decay heat removal, steam generator inventory control and reactor coolant inventory control functions and Unit 1 fire pumps, containment HVAC and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include providing fire wrap (1-hour ERFBS) to selected Unit 1 cables (1V1208B, 1V5490B and 1V5596B) to preclude damage in the event of a fire and manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.43 FIRE AREA 37

3.43.1 Room 772.0-A6

Description: 480V Transformer Room 1-A

Fire Loading: The combustibles consist of plastics associated with electrical panels, oil in the transformers, and insulation on the cables in the trays. The fire severity is classified as moderately severe.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
772.0-A6	NORTH WALL	AREA 12, ROOM 729.0-A1	II-32A	2 Hours
		AREA 25, ROOM 757.0-A10	II-31A, II-32A	2 Hours
		AREA 25, ROOM 782.0-A1	II-32A	2 Hours
	SOUTH WALL	AREA 36, ROOM 772.0-A5	II-32A	2 Hours
	EAST WALL	AREA 32, ROOM 772.0-A1	II-32A	2 Hours
		AREA 38, ROOM 772.0-A7	II-32A	2 Hours
	FLOOR	AREA 17, ROOM 757.0-A2	II-31A, II-32A	2 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
772.0-A6	A185	SOUTH	AREA 36, ROOM 772.0-A5	II-32A	3 Hours
	A186	EAST	AREA 32, ROOM 772.0-A1	II-32A	3 Hours

Dampers: None.

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided in the room. A standpipe and hose station is provided from the adjacent room (772.0-A7).

Deviations: The room contains intervening combustibles in the form of insulation on the cables in the trays and ERFBS. The justification for using an enhanced automatic preaction sprinkler system to compensate for these intervening combustibles is documented in Part VII, Section 2.4.

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.40 and 64. The justification for the in situ combustible load in Room 772.0-A6 is provided in Part VII, Section 3.6.

PART VI – FIRE HAZARDS ANALYSIS

3.43.2 Fire Area 37 Safe Shutdown Analysis By Analysis Volume

3.43.2.1 AV-064

Room No.	Description:
772.0-A6	480V Transformer Room 1-A

A fire in Analysis Volume 64 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 long term decay heat removal, steam generator inventory control and containment HVAC functions and Unit 1 fire pumps, secondary side isolation, reactor coolant inventory control and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include providing fire wrap to selected Unit 1 cables to preclude damage in the event of a fire and manual operation of Unit 1 and Unit 2 equipment required for safe shutdown and repair procedures. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.44 FIRE AREA 38

3.44.1 Room 772.0-A7

Description: Unit 1 Mechanical Equipment Room

Fire Loading: The combustibles consist of lube oil in motors and compressors, plastics associated with the electrical panels and boxes and lights, and insulation on piping and cables in trays. The fire severity is classified as severe.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
772.0-A7	North Wall	Area 25, Room 757.0-A10 Area 25, Room 782.0-A1	II-31A, II-32A II-32A	2 Hours 2 Hours
	South Wall	Area 32, Room 772.0-A1	II-32A	2 Hours
	East Wall	Area 39, Room 772.0-A8	II-32A	2 Hours
	West Wall	Area 37, Room 772.0-A6	II-32A	2 Hours
	Floor	Area 17, Room 757.0-A2 Area 17, Room 757.0-A9	II-31A, II-32A II-31A, II-32A	2 Hours 2 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
772.0-A7	A187	SOUTH	AREA 32, ROOM 772.0-A1	II-32A	3 Hours

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
772.0-A7	1-ISD-31-2500 47A381-326F	F-C	AREA 17, ROOM 757.0-A9	47W866-3 47W920-17	3 Hours

	1-ISD-31-2515 47A381-644G	N-S	AREA 32, ROOM 772.0-A1	47W866-3 47W920-9	1.5 Hours
	1-ISD-31-2516 47A381-301F	N-S	AREA 32, ROOM 772.0-A1	47W866-3 47W920-9	3 Hours

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided in the room. A standpipe and hose station is provided in the room.

PART VI – FIRE HAZARDS ANALYSIS

Deviations: The justification for intervening combustibles such as insulation on cables in trays and Thermo-Lag is documented in Part VII, Section 2.4. The justification for hose stations having more than 100 feet of hose is documented in Part VII, Section 4.3.

Evaluations: The justification for the in situ combustible load in Room 772.0-A7 is provided in Part VII, Section 3.6.

PART VI – FIRE HAZARDS ANALYSIS

3.44.2 Fire Area 38 Safe Shutdown Analysis By Analysis Volume

3.44.2.1 AV-065

Room No.	Description:
772.0-A7	Unit 1 Mechanical Equipment Room

A fire in Analysis Volume 65 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 reactor pressure control and containment HVAC functions and Unit 1 long term decay heat removal, reactor coolant inventory control and steam generator inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.45 FIRE AREA 39

3.45.1 Room 772.0-A8

Description: Fifth Vital Battery and Board Room

Fire Loading: The combustibles consist of lube oil in the fan motors and plastics associated with electrical panels, boxes and battery cases. The fire severity is classified as low.

Compartmentation: The rooms are of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
772.0-A8	NORTH WALL	AREA 25, ROOM 757.0-A10	II-31A, II-32A	2 Hours
		AREA 25, ROOM 782.0-A1	II-32A	2 Hours
	SOUTH WALL	AREA 32, ROOM 772.0-A1	II-32A	2 Hours
	EAST WALL	AREA 10, ROOM 757.0-A13	II-32A	2 Hours
	WEST WALL	AREA 38, ROOM 772.0-A7	II-32A	2 Hours
	FLOOR	AREA 17, ROOM 757.0-A9	II-31A, II-32A	2 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
772.0-A8	A210	SOUTH	AREA 32, ROOM 772.0-A1	II-32A	3 Hours

Dampers:					
Room	Damper/Mark Number	Direction	Adjacent Area/Room	Drawing Reference	Damper Rating
772.0-A8	0-ISD-31-5455	S-N	AREA 32, ROOM	47W866-3	3 Hours
	47A381-776		772.0-A1	47W920-16	

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided in the room. A standpipe and hose station is provided from the adjacent room (772.0-A7).

Deviations: None.

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.41, 62, 63, 64, and 65.

PART VI – FIRE HAZARDS ANALYSIS

3.45.2 Fire Area 39 Safe Shutdown Analysis By Analysis Volume

3.45.2.1 AV-066

Room No.	Description:
772.0-A8	Fifth Vital Battery and Board Room

This AV contains cables and/or equipment associated with the 5th Vital Battery. The 5th Vital Battery is credited as an "installed spare" that can be used during normal plant operation if one of the existing batteries is down for maintenance. This AV is analyzed to address the effects of a fire on the 125V DC system if the 5th Vital Battery is in service in replacement of any one of the other four normally credited batteries. An additional four analyses are performed (AV-066D through G) for this AV to address the various combinations where the 5th Vital Battery can be used.

A fire in Analysis Volume 66 could potentially affect only the 5th vital battery. A fire in Analysis Volume 66 would not impact major equipment required to maintain safe shutdown functions. Shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Equipment available to achieve shutdown are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.45.2.2 AV-066D

Room No.	Description:
772.0-A8	Fifth Vital Battery and Board Room

A fire in Analysis Volume 66D could potentially affect Unit 1 and Unit 2 systems and components necessary to maintain the long term decay heat removal, reactor coolant inventory control, steam generator inventory control, secondary side isolation, fire pumps, containment HVAC and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available to Train B. The required mitigating features include manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.45.2.3 AV-066E

Room No.	Description:
772.0-A8	Fifth Vital Battery and Board Room

A fire in Analysis Volume 66E could potentially affect Unit 1 and Unit 2 systems and components necessary to maintain the long term decay heat removal, reactor coolant inventory control, steam generator inventory control, secondary side isolation, fire pumps, containment HVAC and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available to Train A. The required mitigating features include manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

PART VI – FIRE HAZARDS ANALYSIS

3.46 FIRE AREA 40

3.46.1 Room 772.0-A10

Description: Unit 2 Mechanical Equipment Room

Fire Loading: The combustibles consist of lube oil in the air cooler equipment, plastic associated with lights, and insulation on pipes and cables in trays. The fire severity is classified as moderately severe.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
772.0-A10	NORTH WALL	AREA 75, ROOM 757.0-A16	II-31A, II-32A	2 Hours
		AREA 75, ROOM 782.0-A3	II-32A	2 Hours
	SOUTH WALL	AREA 46, ROOM 772.0-A16	II-32A	2 Hours
	EAST WALL	AREA 41, ROOM 772.0-A11	II-32A	2 Hours
	WEST WALL	AREA 10, ROOM 772.0-A9	II-32A	2 Hours
	FLOOR	AREA 31, ROOM 757.0-A24	II-31A, II-32A	2 Hours
		AREA 31, ROOM 757.0-A17	II-31A, II-32A	2 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
772.0-A10	A188	SOUTH	AREA 46, ROOM 772.0-A16	II-32A	3 Hours
	A212	WEST	AREA 10, ROOM 772.0-A9	II-32A	3 Hours
	A213	WEST	AREA 10, ROOM 772.0-A9	II-32A	3 Hours

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
772.0-A10	2-ISD-31-2500 47A381-326F	C-F	AREA 31, ROOM 757.0-A17	47W866-3 47W920-17	3 Hours
	2-ISD-31-2504 47A381-301F	N-S	AREA 46, ROOM 772.0-A16	47W866-3 47W920-9	3 Hours
	2-ISD-31-2515 47A381-644G	N-S	AREA 46, ROOM 772.0-A16	47W866-3 47W920-9	1.5 Hours
	2-ISD-31-2516 47A381-301F	N-S	AREA 46, ROOM 772.0-A16	47W866-3 47W920-9	3 Hours

Detection: Ionization smoke detectors are provided in the room.

PART VI – FIRE HAZARDS ANALYSIS

Suppression: An automatic preaction sprinkler system is provided in the room. A standpipe and hose station is provided in the room.

Deviations: The justification for intervening combustibles such as insulation on cables in trays and Thermo-Lag is documented in Part VII, Section 2.4. The justification for fire doors is documented in Part VII, Section 4.1. The justification for hose stations with more than 100 foot hose is documented in Part VII, Section 4.3.

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.43, 63, and 64. The justification for the in situ combustible load in room 772.0-A10 is provided in Part VII, Section 3.6.

PART VI – FIRE HAZARDS ANALYSIS

3.46.2 FIRE AREA 40 SAFE SHUTDOWN ANALYSIS BY ANALYSIS VOLUME

3.46.2.1 AV-067

Room No.	Description:
772.0-A10	Unit 2 Mechanical Equipment Room

A fire in Analysis Volume 67 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control and containment HVAC functions and Unit 2 long term decay heat removal, fire pumps, containment integrity, secondary side isolation, reactor coolant inventory control and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.47 FIRE AREA 41

3.47.1 Room 772.0-A11

Description: 480V Transformer Room 2-B

Fire Loading: The combustibles consist of the oil in the transformers, plastic associated with hand switches and insulation on the cables in the trays. The fire severity is classified as moderately severe.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
772.0-A11	NORTH WALL	AREA 75, ROOM 782.0-A3	II-32A	2 Hours
		AREA 72, ROOM 729.0-A11	II-32A	2 Hours
		AREA 75, ROOM 757.0-A16	II-31A, II-32A	2 Hours
	SOUTH WALL	AREA 42, ROOM 772.0-A12	II-32A	2 Hours
	WEST WALL	AREA 40, ROOM 772.0-A10	II-32A	2 Hours
		AREA 46, ROOM 772.0-A16	II-32A	2 Hours
	FLOOR	AREA 31, ROOM 757.0-A24	II-31A, II-32A	2 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
772.0-A11	A189	WEST	AREA 46, ROOM 772.0-A16	II-32A	3 Hours
	A190	SOUTH	AREA 42, ROOM 772.0-A12	II-32A	3 Hours

Dampers: None.

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided in the room. A standpipe and hose station is provided from the adjacent room (772.0-A10).

Deviations: The room contains intervening combustibles in the form of insulation on the cables in the trays and ERFBS. The justification for using an enhanced automatic preaction sprinkler system to compensate for these intervening combustibles is documented in Part VII, Section 2.4.

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.44 and 65. The justification for the in situ combustible load in Room 772.0-A11 is provided in Part VII, Section 3.6.

PART VI – FIRE HAZARDS ANALYSIS

3.47.2 Fire Area 41 Safe Shutdown Analysis By Analysis Volume

3.47.2.1 AV-068

Room No.	Description:
772.0-A11	480V Transformer Room 2-B

A fire in Analysis Volume 68 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control, long term decay heat removal, fire pumps, containment HVAC, reactor coolant inventory control functions, secondary side isolation and reactor coolant pressure control functions and Unit 2 containment integrity. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include providing fire wrap to selected Unit 2 cables to preclude damage in the event of a fire and manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.48 FIRE AREA 42

3.48.1 Room 772.0-A12

Description: 480V Transformer Room 2-A

Fire Loading: The combustibles consist of oil in the transformers and insulation on the cables in the trays. The fire severity is classified as moderately severe.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
772.0-A12	NORTH WALL	AREA 41, ROOM 772.0-A11	II-32A	2 Hours
	SOUTH WALL	AREA 48, ROOM 755.0-C13	II-32A, II-34A	3 Hours
	WEST WALL	AREA 31, ROOM 757.0-A24	II-31A, II-32A	2 Hours
		AREA 45, ROOM 772.0-A15	II-32A	2 Hours
		AREA 46, ROOM 772.0-A16	II-32A	2 Hours
	FLOOR	AREA 28, ROOM 757.0-A21	II-31A, II-32A	2 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
772.0-A12	A190	NORTH	AREA 41, ROOM 772.0-A11	II-32A	3 Hours

Dampers: None.

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided in the room. A standpipe and hose station is provided from room 772.0-A10.

Deviations: The room contains intervening combustibles in the form of insulation on cables in trays and ERFBS. The justification for using an enhanced automatic preaction sprinkler system to compensate for these intervening combustibles is documented in Part VII, Section 2.4.

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.45 and 64. The justification for the in situ combustible load in Room 772.0-A12 is provided in Part VII, Section 3.6.

PART VI – FIRE HAZARDS ANALYSIS

3.48.2 Fire Area 42 Safe Shutdown Analysis By Analysis Volume

3.48.2.1 AV-069

Room No.	Description:
772.0-A12	480V Transformer Room 2-A

A fire in Analysis Volume 69 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control, containment HVAC, fire pumps, and reactor coolant inventory control functions and Unit 2 long term decay heat removal secondary side isolation, containment integrity and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include manual operation of Unit 1 and Unit 2 equipment required for safe shutdown and repair procedures. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.49 FIRE AREA 43

3.49.1 Room 772.0-A13

Description: 125V Vital Battery Room IV

Fire Loading: The combustibles consist of plastics associated with electrical panels, boxes and battery cases. Adequate ventilation is provided to preclude explosive concentrations of hydrogen. The fire severity is classified as low.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
772.0-A13	NORTH AND EAST WALLS	AREA 45, ROOM 772.0-A15	II-32A	3 Hours
	SOUTH WALL	AREA 48, ROOM 755.0-C12	II-32A, II-34A	3 Hours
	WEST WALL	AREA 44, ROOM 772.0-A14	II-32A	3 Hours
	FLOOR	AREA 29, ROOM 757.0-A22 AREA 30, ROOM 757.0-A23	II-31A, II-32A II-31A, II-32A	3 Hours 3 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
772.0-A13	A194	EAST	AREA 45, ROOM 772.0-A15	II-32A	3 Hours

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
772.0-A13	2-ISD-31-2525 47A381-311F	E-W	AREA 45, ROOM 772.0-A15	47W866-3 47W920-9	3 Hours
	2-ISD-31-2558 47A381-690	E-W	AREA 44, ROOM 772.0-A14	47W866-3 47W920-9	3 Hours
	2-ISD-31-2564 47A381-736	E-W	AREA 44, ROOM 772.0-A14	47W866-3 47W920-9	3 Hours

Detection: Ionization smoke detectors are provided in the room.

Suppression: A manually actuated preaction sprinkler system is provided in the room. A standpipe and hose station is provided from room 772.0-A10.

Deviations: None.

Evaluations: The feasibility and reliability evaluation for Unit 2 Operator Manual Action is documented in Part VII, Section 8.3.46, 62 and 65.

PART VI – FIRE HAZARDS ANALYSIS

3.49.2 Fire Area 43 Safe Shutdown Analysis By Analysis Volume

3.49.2.1 AV-070

Room No.	Description:
772.0-A13	125V Vital Battery Room IV

A fire in Analysis Volume 70 could potentially affect Unit 1 and 2 systems and components necessary to maintain the long term decay heat removal, steam generator inventory control, containment HVAC, fire pumps, reactor coolant inventory control and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:
