PART VI – FIRE HAZARDS ANALYSIS

3.50 FIRE AREA 44

3.50.1 Room 772.0-A14

Description: 125V Vital Battery Room III

Fire Loading: The combustibles consist of plastics associated with electrical panels, boxes and battery cases. Adequate ventilation is provided to preclude explosive concentrations of hydrogen. The fire severity is classified as low.

Compartmentation: The room is of reinforced concrete construction.

Barriers

Detection: Ionization smoke detectors are provided in the room.

PART VI – FIRE HAZARDS ANALYSIS

Suppression: A manually actuated preaction sprinkler system is provided in the room. A standpipe and hose station is provided from room 772.0-A10.

Deviations: None.

Evaluations: The feasibility and reliability evaluation for Unit 2 Operator Manual Action is documented in Part VII, Section 8.3.47, 63 and 64.

PART VI – FIRE HAZARDS ANALYSIS

3.50.2 Fire Area 44 Safe Shutdown Analysis By Analysis Volume

3.50.2.1 AV-071

Room No.	Description:
772.0-A14	125V Vital Battery Room III

A fire in Analysis Volume 71 could potentially affect Unit 1 and 2 systems and components necessary to maintain the long term decay heat removal, steam generator inventory control, containment HVAC, fire pumps, reactor coolant inventory control and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

3.51 FIRE AREA 45

3.51.1 Room 772.0-A15

Description: 480V Board Room 2-B (Subdivided into 772.0-A15A1, -A15A2, -A15A3, -A15A4)

Fire Loading: The combustibles consist of plastics associated with the electrical boards, panels, boxes and lights and insulation on the HVAC ducts and on the cables in the trays. The fire severity is classified as severe.

Compartmentation: The room is of reinforced concrete construction.

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided for the room, except for the area between column lines A8-A10/Q-R. A standpipe and hose station is provided from room 772.0-A10.

Deviations: The room contains intervening combustibles in the form of insulation on cables in trays and ERFBS. The justification for using an enhanced automatic preaction sprinkler system to compensate for these intervening combustibles is documented in Part VII, Section 2.4.

Evaluations: The lack of suppression between column lines A8-A10/Q-R is documented in Part VII, Section 3.1. The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.48, 49, 62, and 65. The justification for the in situ combustible load in Room 772.0-A15 is provided in Part VII, Section 3.6.

PART VI – FIRE HAZARDS ANALYSIS

3.51.2 Fire Area 45 Safe Shutdown Analysis By Analysis Volume

3.51.2.1 AV-072

Room No.	Description:
772.0-A15A1	480V Board Room 2-B, Column Lines A13-A12
772.0-A15A2	480V Board Room 2-B, Column Lines A12-A11

A fire in Analysis Volume 72 could potentially affect Unit 1 and 2 systems and components necessary to maintain the long term decay heat removal, containment HVAC, fire pumps, reactor coolant inventory control, reactor pressure control, and steam generator inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include providing fire wrap to selected Unit 2 cables to preclude damage in the event of a fire and manual operation of Unit 1 and Unit 2 equipment required for safe shutdown and repair procedures. These features and equipment affected and credited are identified below:

772.0-A15A4	480V Board Room 2-B, Column Lines A10-A8

A fire in Analysis Volume 73 could potentially affect systems Unit 1 and 2 and components necessary to maintain the long term decay heat removal, containment HVAC, fire pumps, reactor coolant inventory control, reactor pressure control, and steam generator inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Onsite 1A and 2A power and offsite 1B and 2B power is available. The required mitigating features include manual operation of Unit 1 and Unit 2 equipment required for safe shutdown and repair procedures. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.52 FIRE AREA 46

3.52.1 Room 772.0-A16

Description: 480V Board Room 2-A

Fire Loading: The combustibles consist of plastics associated with the electrical boards, panels, boxes and lights and the insulation on the cables in the trays. The fire severity is classified as moderately severe.

Compartmentation: The room is of reinforced concrete construction. The equipment hatch opening in the floor slab is provided with a nonrated steel cover and is also protected by a water curtain.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating

PART VI – FIRE HAZARDS ANALYSIS

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
	47A381-311F			47W920-9	
	2-ISD-31-2554 47A381-693	N-S	AREA 45, ROOM 772.0-A15	47W866-3 47W920-9	3 Hours

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided in the room. A standpipe and hose station is provided from the adjacent room 772.0-A10.

Deviations: Intervening combustibles in the form of insulation on cables routed in cable trays and ERFBS are present, but are compensated for by an enhanced automatic preaction sprinkler system. Justification is documented in Part VII, Section 2.4. The justification for the hatch opening through the floor is documented in Part VII, Section 2.6. This hatch is protected with a water curtain. The justification for fire doors is documented in Part VII, Section 4.1.

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Section 8.3.50, 63, and 64. The justification for the in situ combustible load in Room 772.0-A6 is provided in Part VII, Section 3.6.

PART VI – FIRE HAZARDS ANALYSIS

3.52.2 Fire Area 46 Safe Shutdown Analysis By Analysis Volume

3.52.2.1 AV-074

Room No.	Description:
772.0-A16	480V Board Room 2-A

A fire in Analysis Volume 74 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 long term decay heat removal, steam generator inventory control, containment HVAC and reactor coolant inventory control functions and Unit 2 containment integrity, secondary side isolation, fire pumps and reactor coolant pressure control. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.53 FIRE AREA 47

3.53.1 Room 786.0-A2, A3, A4, AR, A5, A6

Description:

Room No.	Description:
786.0-A2	Roof Access Air Lock
786.0-A3	Mechanical Equipment Room 2B
786.0-A4	Mechanical Equipment Room 1B
786.0-A5	225 kVA DG Room B
786.0-A6	225 kVA DG Room A
786.0-AR	Roof

Fire Loading: The combustibles in rooms 786.0-A2, -A3, -A4, and -AR consists of plastics associated with electrical panels and lights and oil in chillers. The fire severity in these rooms is classified as insignificant. The combustibles in rooms 786.0-A5 and -A6 consists of fuel and lube oil contained in the DG skids and associated plastics in electrical components. The fire severity in these rooms is classified as moderate.

Compartmentation: Rooms 786.0-A2, -A3 and A4 are reinforced concrete construction. Rooms 786.0-A5 and -A6 are reinforced concrete (floor and north wall) and steel frame and plate (roof and east, west and south walls).

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
786.0-A3	Floor	Area 45, Room 772.0-A15	II-32A	2 Hours
786.0-A3	South Wall	Area 47, Room 786.0-A5	II-32A	3 Hours
786.0-A4	Floor	Area 33, Room 772.0-A2	II-32A	2 Hours
786.0-A4	South Wall	Area 47, Room 786.0-A6	II-32A	3 Hours
786.0-A5	Floor	Area 33, Room 772.0-A2	II-32A	3 Hours
786.0-A5	North Wall	Area 47, Room 786.0-A3	II-32A	3 Hours
786.0-A6	Floor	Area 45, Room 772.0-A15	II-32A	3 Hours
786.0-A6	North Wall	Area 47, Room 786.0-A4	II-32A	3 Hours

Doors: None. (Metal Doors In Rooms 786.0-A5 and 786.0-A6 are not Fire Rated)

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
786.0-A3	2-ISD-31-2517	F-C	AREA 45, ROOM 772.0-A15	47W866-3	3 Hours

Detection: Ionization detectors are provided for Rooms 786.0-A5 and 786.0-A6.

Suppression: Standpipe and hose stations are provided from the Auxiliary Building roof (786.0-AR). Automatic preaction suppression is provided for Rooms 786.0-A5 and 786.0-A6.

Deviations: None.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

3.53.2 Fire Area 47 Safe Shutdown Analysis By Analysis Volume

3.53.2.1 AV-075

Room No.	Description:
786.0-A2	Roof Access Air Lock
786.0-A3	Mechanical Equipment Room 2B
786.0-A4	Mechanical Equipment Room 1B
786.0-A5	225 kVA DG Room B
786.0-A6	225 kVA DG Room A
786.0-AR	Roof

A fire in Analysis Volume 75 does not impact major equipment required to maintain safe shutdown functions. However, offsite power may be lost. Shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Onsite power is available. Equipment credited to achieve shutdown is identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.54 FIRE AREA 48

Fire Area 48 consists of the entire Control Building.

3.54.1 Rooms 692.0-C1 and C2

Description: Mechanical Equipment Rooms

Fire Loading: The combustibles consist of plastics associated with electrical panels, boxes and lights and insulation on pipes. The fire severity is classified as insignificant.

Compartmentation: The rooms are of reinforced concrete construction. The walls separating the Control Building and Auxiliary Building are equivalent to three-hour fire rated barriers. The ceiling separating the Control Building from the Turbine Building is equivalent to a three-hour fire rated barrier, except for the equipment hatch. The equipment hatch is covered with non-fire rated steel plates.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
692.0-C1	NORTH WALL	AREA 1, ROOM 692.0-A1A	II-28A, II-33A	3 Hours
		AREA 1, ROOM 692.0-A5	II-28A, II-33A	3 Hours
	CEILING	AREA 63, TURBINE BUILDING	II-33A	3 Hours
692.0-C2	NORTH WALL	AREA 1, ROOM 692.0-A3	II-28A, II-33A	3 Hours
		AREA 1, ROOM 692.0-A5	II-28A, II-33A	3 Hours

Doors: None.

Dampers: None.

Detection: Ionization smoke detectors are provided in the rooms.

Suppression: Automatic preaction sprinkler systems are provided in the rooms. Standpipes and hose stations are provided in other rooms on this building elevation.

Deviations: The justification for the hatch opening through the ceiling of 692.0-C1 to the Turbine Building is documented in Part VII, Section 2.6.

Evaluations: None.

3.54.2 Room 692.0-C3

Description: 250V Battery Room 1

Fire Loading: The combustibles consist of plastics associated with electrical panels and boxes and lights and the battery cases. The fire severity is classified as low.

PART VI – FIRE HAZARDS ANALYSIS

Compartmentation: The room is of reinforced concrete block and reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
692.0-C3	NORTH WALL	AREA 1, ROOM 676.0-A2	II-28A, II-33A	3 Hours
		AREA 1, ROOM 692.0-A3	II-28A, II-33A	3 Hours

Doors: None.

Dampers: None.

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided in the room. A standpipe and hose station is provided from the stairwell.

Deviations: None.

Evaluations: None.

3.54.3 Rooms 692.0-C4, C5, C8, C11, and C12

Description:

Room No.	Description:
692.0-C4	250V Battery Board Room 1
692.0-C5	250V Battery Board Room 2
692.0-C8	24V and 48V Battery Board and Charger Room
692.0-C11	Corridor
692.0-C12	Secondary Alarm Station Room

Fire Loading: The combustibles consist of plastics associated with electrical panels, boards, chargers, TV monitors and lights, furniture, pipe insulation and insulation on cables in trays. The fire severity classification for each room is as follows:

Room No.	Description:	Fire Loading
692.0-C4	250V Battery Board Room 1	Low
692.0-C5	250V Battery Board Room 2	Low
692.0-C8	24V and 48V Battery Board and Charger Room	Low
692.0-C11	Corridor	Low
692.0-C12	Secondary Alarm Station Room	Moderate

Compartmentation: The rooms are of reinforced concrete block and reinforced concrete construction.

PART VI – FIRE HAZARDS ANALYSIS

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
692.0-C4	NORTH WALL	AREA 1, ROOM 676.0-A2	II-28A, II-33A	3 Hours
692.0-C5	NORTH WALL	AREA 1, ROOM 676.0-A2	II-28A, II-33A	3 Hours
		AREA 1, ROOM 676.0-A3	II-28A, II-33A	3 Hours
	CEILING (PARTIAL)	AREA 48, ROOM 708.0-C3	II-33A	2 Hours
692.0-C8	NORTH WALL	AREA 1, ROOM 692.0-A31	II-28A, II-33A	3 Hours
692.0-C11	CEILING (PARTIAL)	AREA 48, ROOM 708.0-C2	II-33A	2 Hours
692.0-C12	NORTH WALL	AREA 1, ROOM 692.0-A30	II-28A, II-33A	3 Hours
		AREA 1, ROOM 692.0-A31	II-28A, II-33A	3 Hours

Doors: None.

Dampers: None.

Detection: Ionization smoke detectors are provided for all the rooms.

Suppression: Automatic sprinklers are provided in rooms C11 and C12. Standpipe and hose stations are provided from the stairwells located at each end of the Corridor.

Deviations: The justification for not providing an automatic suppression system in rooms C4, C5, and C8 is documented in Part VII, Section 2.3. The justification for the gutter penetration in the walls separating the stairwells from corridor 692.0-C11 is documented in Part VII, Section 4.2.

Evaluations: None.

3.54.4 Room 692.0-C6

Description: 250V Battery Room 2

Fire Loading: The combustibles consist of plastic associated with the batteries. The fire severity is classified as low.

Compartmentation: The room is of reinforced concrete block and reinforced concrete construction.

PART VI – FIRE HAZARDS ANALYSIS

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
692.0-C6	NORTH	AREA 1, ROOM 676.0-A3	II-28A, II-33A	3 Hours
	WALL	AREA 1, ROOM 692.0-A31	II-28A, II-33A	3 Hours
	CEILING (PARTIAL)	AREA 48, ROOM 708.0-C3	II-33A	2 Hours

Doors: None.

Dampers: None.

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided in the room. Standpipe and hose stations are provided from the stairwells.

Deviations: None.

Evaluations: None.

3.54.5 Room 692.0-C7

Description: 24V and 48V Battery Room

Fire Loading: The combustibles consist of plastic associated with the batteries. The fire severity is classified as low.

Compartmentation: The room is of reinforced concrete block and reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
692.0-C7	NORTH WALL	AREA 1, ROOM 692.0-A31	II-28A, II-33A	3 Hours

Doors: None.

Dampers: None.

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided in the room. A standpipe and hose station is provided from the stairwell.

Deviations: None.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

3.54.6 Room 692.0-C9

Description: Communications Room

Fire Loading: The combustibles consist of plastics, resins, and paper associated with the communications equipment panels, furniture and insulation on cables in trays. The fire severity is classified as moderate.

Compartmentation: The room is of reinforced concrete block and reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
692.0-C9	NORTH	AREA 1, ROOM 692.0-A29	II-28A, II-33A	3 Hours
	WALL	AREA 1, ROOM 692.0-A30	II-28A, II-33A	3 Hours

Doors: None.

Dampers: None.

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided in the room. A standpipe and hose station is provided from the stairwell.

Deviations: None.

Evaluations: None.

3.54.7 Room 692.0-C10

Description: Mechanical Equipment Room

Fire Loading: The combustibles consist of lube oil in the chillers, plastics associated with the electrical panels, boxes and lights and insulation on piping. The fire severity is classified as insignificant.

Compartmentation: The room is of reinforced concrete construction. The equipment hatch in the ceiling is covered with a nonfire rated steel cover.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
692.0-C10	NORTH WALL	AREA 1, ROOM 692.0-A27	II-28A, II-33A	3 Hours
	CEILING	AREA 63, TURBINE BUILDING	II-33A	3 Hours

Doors: None.

PART VI – FIRE HAZARDS ANALYSIS

Dampers: None.

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided in the room. A standpipe and hose station is provided from the stairwell.

Deviations: The justification for the hatch opening through the ceiling of 692.0-C10 to the Turbine Building is documented in Part VII, Section 2.6.

Evaluations: None.

3.54.8 Room 708.0-C1

Description: Unit 1 Auxiliary Instrument Room

Fire Loading: The combustible materials consist of plastics associated with the electrical instrument panels and insulation on cables in trays. The fire severity is classified as moderately severe.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating

Detection: Ionization smoke detectors cross zoned with heat detectors are provided in the room.

Suppression: An automatic CO₂ suppression system is provided in the room. A standpipe and hose station is provided from the stairwell.

Deviations: The justification for a hose station having more than 100 feet of hose is documented in Part VII, Section 4.3.

Evaluations: The justification for the in situ combustible load in Room 708.0-C1 is provided in Part VII, Section 3.6.

3.54.9 Room 708.0-C2

Description: Corridor

Fire Loading: The combustible material consist of plastics associated with the electrical boxes and lights and insulation on the cables in trays. The fire severity is classified as low.

Compartmentation: The room is of reinforced concrete construction.

Detection: Ionization smoke detectors cross zoned with heat detectors are provided in the room.

Suppression: An automatic CO₂ suppression system, designed to achieve a CO₂ concentration of $\geq 50\%$, within 7 minutes and maintain at least 45% concentration at the end of 15 minutes, is provided in the room for property protection. This suppression system is not required for Appendix R separation. Standpipe and hose stations are provided from the stairwell.

Deviations: None.

Evaluations: The justification for the in situ combustible load in Room 708.0-C3 is provided in Part VII, Section 3.6.

3.54.11 Room 708.0-C4

Description: Unit 2 Auxiliary Instrument Room

Fire Loading: The combustibles consist of plastics associated with the electrical instrument panels and boxes and insulation on the cables in trays. The fire severity is classified as moderately severe.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating

Detection: Ionization smoke detectors cross zoned with heat detectors are provided in the room.

Suppression: An automatic CO₂ suppression system, designed to achieve a CO₂ concentration of ≥50% within 7 minutes and maintain at least 45% concentration at the end of 15 minutes, is provided in the room for property protection. This suppression system is not required for Appendix R separation. Standpipe and hose stations are provided from the stairwell.

Deviations: The justification for not having full area suppression and detection in III.G.3 area is documented in Part VII, Section 2.3. The justification for a hose station having more than 100 feet of hose is documented in Part VII, Section 4.3.

Evaluations: The justification for the in situ combustible load in Room 708.0-C4 is provided in Part VII, Section 3.6.

3.54.12 Room 729.0-C1

Description: Spreading Room

Fire Loading: The combustibles consist of plastics associated with electrical panels and lights and insulation on cables in the trays. The fire severity is classified as severe.

Compartmentation: The walls and floor of this room is of reinforced concrete construction. The ceiling is not claimed as a fire rated barrier.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating

	47A381-473F			47W930-2	

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic preaction sprinkler system with a ceiling layer and an intermediate layer of sprinklers is provided for the room. Standpipe and hose stations are provided from the two stairwells and from the Turbine Building.

Deviations: None.

Evaluations: The justification for the in situ combustible load in Room 729.0-C1 is provided in Part VII, Section 3.6.

3.54.13 Room 755.0-C1

Description: Mechanical Equipment Room

Fire Loading: The combustibles consist of charcoal in the filter units and plastics associated with electrical panels and radiation monitors. The fire severity is classified as low.

Compartmentation: The room is constructed of reinforced concrete block or reinforced concrete, except for the ceiling of the living area, which is constructed of gypsum board and plaster.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
755.0-C1	NORTH WALL	AREA 14, ROOM 737.0-A1A	II-30A, II-34A	3 Hours
		AREA 27, ROOM 757.0-A5	II-31A, II-34A	3 Hours
		AREA 36, ROOM 772.0-A5	II-32A	3 Hours
	SOUTH WALL	AREA 63, TURBINE BUILDING	II-34A	3 Hours
	FLOOR	AREA 63, TURBINE BUILDING	II-34A	3 Hours

Doors: None.

PART VI – FIRE HAZARDS ANALYSIS

Dampers: None

Detection: Ionization smoke detectors are provided in the room.

Suppression: Automatic sprinklers are provided in the room. The charcoal filter units are provided with a fixed water spray system. A standpipe and hose station is provided in this room.

Deviations: None.

Evaluations: None.

3.54.14 Stairwell C1

Description: Stairwell C1

Fire Loading: The combustibles consist of fire hoses and plastic associated with electrical panels and lights and pipe insulation. The fire severity is classified as low.

Compartmentation: The stairwell is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
STAIRWELL C1	SOUTH WALL (ALL ELEVATIONS EXCLUDING 692)	AREA 63, TURBINE BUILDING	II-33A, II-34A	3 Hours
	WEST WALL (ELS 708 AND 729)	AREA 63, TURBINE BUILDING	II-33A, II-34A	3 Hours
	WEST WALL (EL 755)	AREA 48, ROOM 755-C2	II-34A	1 Hour

Doors: None.

Dampers: None.

Detection: None.

Suppression: Standpipe and hose stations are located on elevations 692.0, 708.0, 729.0, and 755.0 in the stairwell.

Deviations: The justification for not providing detection and automatic suppression in the stairwell is documented in Part VII, Section 2.3. The justification for the gutter penetration in the wall separating the stairwell from corridor 692.0-C11 is documented in Part VII, Section 4.2.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

3.54.15 Stairwell C2

Description: Stairwell C2

Fire Loading: The combustibles consist of fire hoses and plastic associated with electrical panels, boxes and lights. The fire severity is classified as low.

Compartmentation: The stairwell is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
STAIRWELL C2	SOUTH WALL (ALL ELEVATIONS EXCLUDING 692)	AREA 63, TURBINE BUILDING	II-33A, II-34A	3 Hours
	EAST WALL (ELS 708 AND 729)	AREA 63, TURBINE BUILDING	II-33A, II-34A	3 Hours

Doors: None.

Dampers: None.

Detection: None.

Suppression: Standpipe and hose stations are located on elevations 692.0, 708.0, 729.0, and 755.0 in the stairwell.

Deviations: The justification for not providing detection and automatic suppression in the stairwell is documented in Part VII, Section 2.3. The justification for the gutter penetration in the wall separating the stairwell from corridor 692.0-C11 is documented in Part VII, Section 4.2.

Evaluations: None.

3.54.16 Room 755.0-C2

Description: Women's Restroom

Fire Loading: The combustibles consist of miscellaneous wood, paper and plastic. The fire severity is classified as low.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
755.0-C2	SOUTH WALL	AREA 63, TURBINE BUILDING	II-34A	3 Hours
	FLOOR	AREA 63, TURBINE BUILDING	II-34A	3 Hours

PART VI – FIRE HAZARDS ANALYSIS

Doors: None.

Dampers: None.

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided in the room. A standpipe and hose station is provided from the stairwell.

Deviations: None.

Evaluations: None.

3.54.17 Rooms 755.0-C4, C5, C6, C7, C8, C9 and C10

Description: These rooms constitute the kitchen, locker room, men's restroom and showers, and Shift Manager's office and conference room.

Fire Loading: The combustibles consist of miscellaneous wood, paper, plastic and furniture.

The fire severity classification for each room is as follows:

Room No.	Description:	Fire Loading
755.0-C4	Kitchen	Low
755.0-C5	Toilet	Low
755.0-C6	Locker Room	Insignificant
755.0-C7, C8	Showers	Insignificant
755.0-C9	Conference Room	Moderately severe
755.0-C10	Shift Manager's Office	Severe

Compartmentation: The rooms are of reinforced concrete block or reinforced concrete, except for the ceilings which are gypsum board and plaster.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
755.0-C4	FLOOR	AREA 63, TURBINE BUILDING	II-34A	3 Hours
	NORTH WALL	AREA 14, ROOM 737.0-A1A	II-34A	3 Hours
		AREA 27, ROOM 757.0-A5	II-34A	3 Hours
755.0-C6	NORTH WALL	AREA 14, ROOM 737.0-A1A	II-30A, II-34A	3 Hours
		AREA 27, ROOM 757.0-A5	II-31A, II-34A	3 Hours
	FLOOR	AREA 63, TURBINE BUILDING	II-34A	3 Hours
755.0-C8	NORTH WALL	AREA 14, ROOM 737.0-A1A	II-30A, II-34A	3 Hours
		AREA 27, ROOM 757.0-A5	II-31A, II-34A	3 Hours
755.0-C9	NORTH WALL	AREA 14, ROOM 737.0-A1A	II-30A, II-34A	3 Hours
		AREA 27, ROOM 757.0-A5	II-31A, II-34A	3 Hours

Doors: None.

PART VI – FIRE HAZARDS ANALYSIS

Dampers: None

Detection: Ionization smoke detectors are provided in the rooms, except for the showers. Thermal detectors are provided in the kitchen, women's toilet, toilet, and locker room cross zoned with the ionization smoke detectors in these rooms.

Suppression: An automatic preaction sprinkler system is provided in the rooms, except for the showers. A standpipe and hose station is provided from the adjacent corridor (755.0-C3).

Deviations: The justification for not providing total area detection and suppression in the showers is documented in Part VII, Section 2.3.

Evaluations: The justification for the in situ combustible load in Room 755.0-C9 and 755.0-C10 are provided in Part VII, Section 3.6.

3.54.18 Rooms 755.0-C3, C12, C15

Description:

Room No.	Description:
755.0-C3	Corridor (includes space above Operations office and living area)
755.0-C12	Main Control Room
755.0-C15	Corridor

Fire Loading: The combustibles in 755.0-C3 consist of paper, cloth, plastic and wood associated with the lockers and cabinets. The fire severity is classified as insignificant. The combustibles in 755.0-C12 consist of plastics associated with the electrical panels, furniture, and lights, miscellaneous paper, wood and plastics and cables for electrical panels. The fire severity is classified as low. There are no significant combustibles in 755.0-C15. The fire severity is classified as insignificant.

Compartmentation: The room is constructed of reinforced concrete block or reinforced concrete with the following exceptions.

1. The ceiling of the living area is composed of gypsum board and plaster.
2. The Main Control Room floor is not claimed as a fire rated barrier.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
755.0-C3	NORTH WALL	AREA 33, 772.0-A2	II-32A, II-34A	3 Hours
		AREA 36, 772.0-A5	II-32A, II-31A	3 Hours
		Area 27, 757.0-A5	II-31A, II-34A	3 Hours
		Area 19, 757.0-A4	II-31A, II-34A	3 Hours

755.0-C15	C54A	SOUTH	AREA 63, TURBINE BUILDING	II-34A	3 Hours*

* Sliding Fire Doors and Swinging Doors

Dampers: None

Detection: Ionization smoke detectors are provided in the rooms.

Suppression: Automatic sprinklers are provided for room C3. Standpipe and hose stations are provided in the stairwells and from the Turbine Building.

Deviations: The justification for not providing automatic suppression in the control room and corridor (755.0-C15) is documented in Part VII, Section 2.3. The justification for the fire doors for 755.0-C12 is documented in Part VII, Section 4.1.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

3.54.19 Rooms 755.0-C13, C19 and C20

Room No.	Description:
755.0-C13	Relay Room
755.0-C19	Corridor
755.0-C20	DPSO Shop

Fire Loading: The combustibles consist of plastics associated with the electrical relay boards and panels, paper and furniture. The fire severity classification for each room is as follows:

Room No.	Description:	Fire Loading
755.0-C13	Relay Room	Low
755.0-C19	Corridor	Low
755.0-C20	DPSO Shop	Low

Compartmentation: The rooms are of reinforced concrete block and reinforced concrete construction. There is a drop gypsum board ceiling in the corridor, but it is not a required fire barrier.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
755.0-C13	NORTH WALL	AREA 14, ROOM 737.0-A1B	II-30A, II-34A	3 Hours
		AREA 28, ROOM 757.0-A21	II-31A, II-34A	3 Hours
		AREA 42, ROOM 772.0-A12	II-32A	3 Hours

	FLOOR	AREA 63, TURBINE BUILDING	II-34A	3 Hours
755.0-C20	NORTH WALL	AREA 14, ROOM 737.0-A1B	II-30A, II-34A	3 Hours
		AREA 28, ROOM 757.0-A21	II-31A, II-34A	3 Hours
		AREA 45, ROOM 772.0-A15	II-32A	3 Hours

Doors: None.

Dampers: None

Detection: Ionization smoke detectors are provided in each room.

Suppression: Automatic sprinklers are provided in the Corridor. Standpipe and hose stations are provided from the adjacent stairwell C2 and from the Turbine Building.

Deviations: The justification for not having automatic suppression in the Relay Room and DPSO Shop is documented in Part VII, Section 2.3.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

3.54.20 Rooms 755.0-C14, C16, C17, and C18

Room No.	Description:
755.0-C14	Technical Support Center
755.0-C16	Conference Room
755.0-C17	Telephone Room
755.0-C18	NRC Office

Fire Loading: The combustibles consist of wood and cloth associated with the furniture, paper and plastic. The fire severity classification for each room is as follows:

Room No.	Description:	Fire Loading
755.0-C14	Technical Support Center	Low
755.0-C16	Conference Room	Low
755.0-C17	Telephone Room	Insignificant
755.0-C18	NRC Office	Low

Compartmentation: The rooms are of reinforced concrete block or reinforced concrete construction that is equivalent to at least one-hour to three-hour fire barriers.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
755.0-C14	SOUTH WALL AND FLOOR	AREA 63, TURBINE BUILDING	II-34A	3 Hours
755.0-C16	FLOOR	AREA 63, TURBINE BUILDING	II-34A	3 Hours
755.0-C17	FLOOR	AREA 63, TURBINE BUILDING	II-34A	3 Hours
755.0-C18	NORTH WALL	AREA 14, ROOM 737.0-A1B	II-30A, II-34A	3 Hours
		AREA 28, ROOM 757.0-A21	II-31A, II-34A	3 Hours
		AREA 42, ROOM 772.0-A12	II-32A, II-34A	3 Hours
	FLOOR	AREA 63, TURBINE BUILDING	II-34	3 Hours

Doors: None.

Dampers: None

Detection: Ionization smoke detectors are provided in each room, except the Telephone Room.

Suppression: Automatic sprinklers are provided in each room, except the Telephone Room. A standpipe and hose station is provided from Stairwell C2.

Deviations: The justification for not having total area detection and suppression in the Telephone Room is documented in Part VII, Section 2.3.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

3.54.21 Fire Area 48 Safe Shutdown Analysis By Analysis Volume

Fire Area 48 is considered an alternative shutdown area and must consider offsite power to be available and also consider offsite power being unavailable for 72 hours. For that reason there are two analyses for fire area 48 and both analyses cover the same physical area. Analysis volume AV-076 considers the case where offsite power may not be available and analysis volume AV-076A assumes that offsite power is available. That is, the fire is assumed to not damage the offsite power and control cables located in the control building. In both cases the fire is assumed to cause the Main Control Room to be abandoned and control of plant systems to be transferred to the Auxiliary Control System (ACS). After transfer the ACS provides controls and instrumentation necessary to achieve and maintain safe reactor shutdown from outside the MCR. Mitigating actions, including operator actions prior to abandoning the MCR, are identified below for each of the two analysis volumes.

3.54.21.1 AV-076 and AV-076A

Room No.	Description:
Stair C1	Stairwell, elevation 692 through 755
Stair C2	Stairwell, elevation 692 through 755
692.0-C1	Mechanical Equipment Room
692.0-C2	Mechanical Equipment Room
692.0-C3	250V Battery Room 1
692.0-C4	250V Battery Board Room 1
692.0-C5	250V Battery Board Room 2
692.0-C8	24V and 48V Battery Board and Charger Room
692.0-C11	Corridor
692.0-C12	Secondary Alarm Station Room
692.0-C6	250V Battery Room 2
692.0-C7	24V and 48V Battery Room
692.0-C9	Communications Room
692.0-C10	Mechanical Equipment Room
708.0-C1	Unit 1 Auxiliary Instrument Room
708.0-C2	Corridor
708.0-C3	Computer Room
708.0-C4	Unit 2 Auxiliary Instrument Room
729.0-C1	Spreading Room
755.0-C1	Mechanical Equipment Room
755.0-C2	Women's Restroom
755.0-C4	Kitchen
755.0-C5	Toilet
755.0-C6	Locker Room
755.0-C7	Shower
755.0-C8	Shower
755.0-C9	Conference Room
755.0-C10	Shift Manager's Office
755.0-C3	Corridor (includes space above Operations office and living area)
755.0-C12	Main Control Room
755.0-C15	Corridor
755.0-C13	Relay Room
755.0-C19	Corridor
755.0-C20	DPSO Shop
755.0-C14	Technical Support Center
755.0-C16	Conference Room

PART VI – FIRE HAZARDS ANALYSIS

Room No.	Description:
755.0-C17	Telephone Room
755.0-C18	NRC Office
CB Roof	Control Building Roof

PART VI – FIRE HAZARDS ANALYSIS

3.55 FIRE AREA 49

3.55.1 Room 742.0-D4

Description: Diesel Generator Unit 1A-A

Fire Loading: The combustibles in this room consist of lube oil in the diesel generator and valves, fuel oil in the diesel generator and the day tanks, plastics associated with electrical panels and boards and insulation on cables in trays. The fire severity is classified as moderately severe.

Compartmentation: This room is constructed of reinforced concrete.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
742.0-D4	South Wall	Area 53, Room 742.0-D9A	II-35A	3 Hours
	East Wall	Area 50, Room 742.0-D5	II-35A	3 Hours
	West Wall	Area 54, Room 742.0-D1	II-35A	3 Hours
		Area 54, Room 742.0-D2	II-35A	3 Hours
		Area 54, Stair D1	II-35A	3 Hours

Doors:					
Room	Door Number	Dir	Adjacent Area/Room	FPR Figure Reference	Door Rating
742.0-D4	D10	South	Area 53, Room 742.0-D9A	II-35A	3 Hours

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
742.0-D4	0-ISD-30-619 47A381-448F	E-W	Area 54, Room 742.0-D1	47W866-9 17W910-1	3 Hours

Detection: The room is provided with thermal detectors.

Suppression: The room is provided with a total flooding CO₂ suppression system. Standpipe and hose stations are provided within the Diesel Generator Building on both elevations, and fire hydrants from the Yard.

Deviations: The justification for the Appendix A deviation for the manway openings to the buried tanks is documented in Part VII, Section 4.4.

Evaluations: None.

3.55.2 DGB Rooms 760.5-D3, D4, and D5

Room No.	Description:
760.5-D3	Unit 1A-A Air Exhaust Room
760.5-D4	480V Board Room 1A-A
760.5-D5	Unit 1A-A Air Intake Room

PART VI – FIRE HAZARDS ANALYSIS

Fire Loading: The combustibles in room 760.5-D3 consist of grease for the fans and insulation on cables in trays. The fire severity classified as moderate. The combustibles in room 760.5-D4 consist of plastic associated with electrical boards and panels and insulation on cables in trays. The fire severity is classified as moderate. The combustibles in room 760.5-D5 consist of lube oil for the combustion air intake filters. The fire severity is classified as low.

Compartmentation: The rooms are of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating

Detection: Heat detectors are provided for rooms 760.5-D3 and -D5; ionization smoke detectors cross zoned with heat detectors are provided in room 760.5-D4.

PART VI – FIRE HAZARDS ANALYSIS

Suppression: Room 760.5-D4 is provided with a total flooding CO₂ suppression system designed to provide a CO₂ concentration of $\geq 50\%$ concentration for property protection. This suppression system is not required for Appendix R separation. Standpipe and hose stations are provided from rooms 742.0-D9 and 760.5-D1.

Deviations: None.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

3.56 FIRE AREA 50

3.56.1 Room 742.0-D5

Description: Diesel Generator Unit 2A-A

Fire Loading: The combustibles in this room consist of lube oil in the diesel generator and valves, fuel oil in the diesel generator and the day tanks, plastics associated with electrical panels and boards and insulation on cables in trays. The fire severity is classified as severe.

Compartmentation: This room is constructed of reinforced concrete.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
742.0-D5	South Wall	Area 53, Room 742.0-D9A	II-35A	3 Hours
		Area 53, Room 792.0-D9N	II-35A	3 Hours
	East Wall	Area 51, Room 742.0-D6	II-35A	3 Hours
	West Wall	Area 49, Room 742.0-D4	II-35A	3 Hours

Doors:					
Room	Door Number	Dir	Adjacent Area/Room	FPR Figure Reference	Door Rating
742.0-D5	D11	South	Area 53, Room 742.0-D9A	II-35A	3 Hours

Dampers: None.

Detection: This room is provided with thermal detectors.

Suppression: This room is provided with a total flooding CO₂ suppression system. Standpipe and hose stations are provided within the Diesel Generator Building on both elevations, and from the Yard.

Deviations: The justification for the Appendix A deviation for the manway openings to the buried tanks is documented in Part VII, Section 4.4.

Evaluations: The justification for the in situ combustible load in Room 742.0-D5 is provided in Part VII, Section 3.6.

3.56.2 Rooms 760.5-D6, D7, and D8

Room No.	Description:
760.5-D6	Unit 2A-A Air Exhaust Room
760.5-D7	480V Board Room 2A-A
760.5-D8	Unit 2A-A Air Intake Room

PART VI – FIRE HAZARDS ANALYSIS

Fire Loading: The combustibles in room 760.5-D6 consist of grease for the fans and insulation on cables in trays. The fire severity is classified as moderate. The combustibles in room 760.5-D7 consist of plastic associated with electrical boards and panels and insulation on cables in trays. The fire severity is classified as moderate. The combustibles in room 760.5-D8 consist of lube oil for the combustion air intake filters. The fire severity is classified as low.

Compartmentation: The rooms are of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
760.5-D6	East Wall	Area 51, Room 760.5-D9	II-35A	3 Hours
	West Wall	Area 49, Room 760.5-D3	II-35A	3 Hours
	Floor (partial)	Area 53, Room 742.0-D9A	II-35A	3 Hours
		Area 53, Room 742.0-D9N	II-35A	3 Hours
760.5-D7	East Wall	Area 51, Room 760.5-D10	II-35A	3 Hours
	West Wall	Area 49, Room 760.5-D4	II-35A	3 Hours
760.5-D8	East Wall	Area 51, Room 760.5-D11	II-35A	3 Hours
	West Wall	Area 49, Room 760.5-D5	II-35A	3 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
760.5-D7	D24	West	Area 49, Room 760.5-D4	II-35A	3 Hours
	D27	East	Area 51, Room 760.5-D10	II-35A	3 Hours

Dampers: None.

Detection: Heat detectors are provided for room 760.5-D6 and -D8; ionization smoke detectors cross zoned with heat detectors are provided in room 760.5-D7.

Suppression: Room 760.5-D7 is provided with a total flooding CO₂ suppression system that provides a CO₂ concentration of $\geq 50\%$ for property protection. Standpipe and hose stations are provided from rooms 742.0-D9 and 760.5-D1.

Deviations: None.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

3.57 FIRE AREA 51

3.57.1 Room 742.0-D6

Description: Diesel Generator Unit 1B-B

Fire Loading: The combustibles in this room consist of lube oil in the diesel generator and valves, fuel oil in the diesel generator and the day tanks, plastics associated with electrical panels and boards and insulation on cables in trays. The fire severity is classified as moderately severe.

Compartmentation: This room is constructed of reinforced concrete.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
742.0-D6	South Wall	Area 53, Room 742.0-D9B	II-35A	3 Hours
		Area 53, Room 742.0-D9N	II-35A	
	East Wall	Area 52, Room 742.0-D7	II-35A	3 Hours
	West Wall	Area 50, Room 742.0-D5	II-35A	3 Hours

Doors:					
Room	Door Number	Dir	Adjacent Area/Room	FPR Figure Reference	Door Rating
742.0-D6	D12	South	Area 53, Room 742.0-D9B	II-35A	3 Hours

Dampers: None.

Detection: This room is provided with heat detectors.

Suppression: This room is provided with a total flooding CO₂ suppression system. Standpipe and hose stations are provided within the Diesel Generator Building on both elevations, and from the yard.

Deviations: The justification for the Appendix A deviation for the manway openings to the buried tanks is documented in Part VII, Section 4.4.

Evaluations: None.

3.57.2 Rooms 760.5-D9, D10, and D11

Room No.	Description:
760.5-D9	Unit 1B-B Air Exhaust Room
760.5-D10	480V Board Room 1B-B
760.5-D11	Unit 1B-B Air Intake Room

PART VI – FIRE HAZARDS ANALYSIS

Fire Loading: The combustibles in room 760.5-D9 consist of grease for the fans and insulation on cables in trays. The combustible loading for this room is moderate. The combustibles in room 760.5-D10 consist of plastic associated with electrical boards and panels and insulation on cables in trays. The fire severity is classified as moderate. The combustibles in room 760.5-D11 consist of lube oil for the combustion air intake filters. The fire severity is classified as low.

Compartmentation: The rooms are of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
760.5-D9	East Wall	Area 52, Room 760.5-D12	II-35A	3 Hours
	West Wall	Area 50, Room 760.5-D6	II-35A	3 Hours
	Floor (partial)	Area 53, Room 742.0-D9B Area 53, Room 742.0-D9N	II-35A II-35A	3 Hours
760.5-D10	East Wall	Area 52, Room 760.5-D13	II-35A	3 Hours
	West Wall	Area 50, Room 760.5-D7	II-35A	3 Hours
760.5-D11	East Wall	Area 52, Room 760.5-D14	II-35A	3 Hours
	West Wall	Area 50, Room 760.5-D8		3 Hours

Doors:					
Room	Door Number	Dir	Adjacent Area/Room	FPR Figure Reference	Door Rating
760.5-D10	D27	West	Area 50, Room 760.5-D7	II-35A	3 Hours
	D30	East	Area 52, Room 760.5-D13	II-35A	3 Hours

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
760.5-D9	0-ISD-30-1090 47A381-757	F-C	Area 53, Room 742.0-D9N	47W866-9 17W910-2	3 Hours

Detection: Heat detectors are provided for room 760.5-D9 and D11; ionization smoke detectors cross zoned with heat detectors are provided in room 760.5-D10.

Suppression: Room 760.5-D10 is provided with a total flooding CO₂ suppression system that provides a CO₂ concentration of $\geq 50\%$ for property protection. This system is not required for Appendix R separation. Standpipe and hose stations are provided from rooms 742.0-D9 and 760.5-D1.

Deviations: None.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

3.57.3 Fire Area 51 Safe Shutdown Analysis By Analysis Volume

3.57.3.1 AV-079

DGB-1B - Diesel Generator Building 1B:	
Room No.	Description:
742.0-D6	Diesel Generator Unit 1B-B
760.5-D9	Unit 1B-B Air Exhaust Room
760.5-D10	480V Board Room 1B-B
760.5-D11	Unit 1B-B Air Intake Room

A fire in Analysis Volume 79 would not impact major equipment required to maintain safe shutdown functions. Shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Equipment affected and credited to achieve shutdown is identified below:

3.58 FIRE AREA 52

3.58.1 Room 742.0-D7

Description: Diesel Generator Unit 2B-B

Fire Loading: The combustibles in this room consist of lube oil in the diesel generator and valves, fuel oil in the diesel generator and the day tanks, plastics associated with electrical panels and boards and insulation on cables in trays. The fire severity is classified as severe.

Compartmentation: This room is constructed of reinforced concrete.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
742.0-D7	South Wall	Area 53, Room 742.0-D9B	II-35A	3 Hours
	West Wall	Area 51, Room 742.0-D6	II-35A	3 Hours

Doors:					
Room	Door Number	Dir	Adjacent Area/Room	FPR Figure Reference	Door Rating
742.0-D7	D13	South	Area 53, Room 742.0-D9B	II-35A	3 Hours

Dampers: None.

Detection: This room is provided with heat detectors.

Suppression: This room is provided with a total flooding CO₂ suppression system. Standpipe and hose stations are provided within the Diesel Generator Building on both elevations, and from the yard.

Deviations: The justification for the Appendix A deviation for the manway openings to the buried tanks is documented in Part VII, Section 4.4.

Evaluations: The justification for the in situ combustible load in Room 742.0-D7 is provided in Part VII, Section 3.6.

3.58.2 Rooms 760.5-D12, D13, and D14

Room No.	Description:
760.5-D12	Unit 2B-B Air Exhaust Room
760.5-D13	480V Board Room 2B-B
760.5-D14	Unit 2B-B Air Intake Room

Fire Loading: The combustibles in room 760.5-D12 consist of grease for the fans and insulation on cables in trays. The fire severity is classified as moderate. The combustibles in room 760.5-D13 consist of plastic associated with electrical boards and panels and insulation on cables in trays. The fire severity is classified as moderate. The combustibles in room 760.5-D14 consist of lube oil for the combustion air intake filters. The fire severity is classified as low.

PART VI – FIRE HAZARDS ANALYSIS

Compartmentation: The rooms are of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
760.5-D12	West Wall	Area 51, Room 760.5-D9	II-35A	3 Hours
	Floor (Partial)	Area 53, Room 742.0-D9B	II-35A	3 Hours
760.5-D13	West Wall	Area 51, Room 760.5-D10	II-35A	3 Hours
760.5-D14	West Wall	Area 51, Room 760.5-D11	II-35A	3 Hours

Doors:					
Room	Door Number	Dir	Adjacent Area/Room	FPR Figure Reference	Door Rating
760.5-D13	D30	West	Area 51, 760.5-D10	II-35A	3 Hours

DAMPERS:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
760.5-D12	0-ISD-30-616 47A381-449F	F-C	AREA 53, ROOM 742.0-D9B	47W866-9 17W910-2	3 Hours

Detection: Heat detectors are provided for room 760.5-D12 and -D14; ionization smoke detectors cross zoned with heat detectors are provided in room 760.5-D13.

Suppression: Room 760.5-D13 is provided with a total flooding CO₂ suppression system that provides a CO₂ concentration of $\geq 50\%$ for property protection. Standpipe and hose stations are provided from rooms 742.0-D9 and 760.5-D1.

Deviations: None.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

3.58.3 Fire Area 52 Safe Shutdown Analysis By Analysis Volume

3.58.3.1 AV-080

DGB-2B - Diesel Generator Building 2B:	
Room No.	Description:
742.0-D7	Diesel Generator Unit 2B-B
760.5-D12	Unit 2B-B Air Exhaust Room
760.5-D13	480V Board Room 2B-B
760.5-D14	Unit 2B-B Air Intake Room

A fire in Analysis Volume 80 would not impact major equipment required to maintain safe shutdown functions. Shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Equipment affected and credited to achieve shutdown is identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.59 FIRE AREA 53

3.59.1 Rooms 742.0-D3 and D9

Description:

Room No.	Description:
742.0-D3	Toilet
742.0-D9	Pipe Gallery and Corridor (742.0-D9A, D9B, & D9N)

Fire Loading: The fire severity is classified as low for 742.0-D3. The combustibles in 742.0-D9 consist of miscellaneous material in the storage cages, plastics associated with electrical panels and lights and insulation on cables in trays. The fire severity is classified as low.

Compartmentation: The walls separating the Fuel Oil Transfer room from the Pipe Gallery and Corridor are of reinforced concrete block construction and the ceiling is reinforced concrete. The Pipe Gallery and Corridor is of reinforced concrete construction. The walls and ceiling of the Toilet are reinforced concrete block and reinforced concrete.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
742.0-D3	South and West Walls	Area 54, Room 742.0-D10	II-35A	3 Hours

742.0-D9A	0-ISD-30-620 47A381-447	F-C	Area 49, Room 760.5-D3	47W866-9 17W910-2	1.5 Hours
742.0-D9N	0-ISD-30-1090 47A381-757	F-C	Area 51, Room 760.5-D9	47W866-9 17W910-2	3 Hours

Detection: Smoke detectors are provided in the Pipe Gallery and Corridor.

Suppression: An automatic preaction sprinkler system is provided in the Pipe Gallery and Corridor. A standpipe and hose station is provided in the Pipe Gallery and Corridor.

Deviations: The justification for the Appendix A deviation for the manway openings to the buried tanks in the pipe gallery/corridor is documented in Part VII, Section 4.4. The justification for the Appendix A deviation for the fire barrier separating the Fuel Oil Transfer Pump Room from the DG Building Corridor is documented in Part VII, Section 4.6. The justification for sliding fire doors having fusible links on only one side of barrier opening is documented in Part VII, Section 5.2. The justification for a hose station having more than 100 feet of hose is documented in Part VII, Section 4.3.

Evaluations: None.

3.59.2 Room 742.0-D8

Description: Fuel Oil Transfer Room

Fire Loading: The combustibles consist of plastics associated with electrical panels and lights and insulation. The fire severity is classified as insignificant.

Compartmentation: The room is of reinforced concrete block walls with a reinforced concrete ceiling.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
742.0-D8	South Wall	Area 54, Room 742.0-D10	II-35A	3 Hours

PART VI – FIRE HAZARDS ANALYSIS

Doors: None.

Dampers: None.

Detection: Heat detectors are provided in the room.

Suppression: An automatic total flooding CO₂ suppression system is provided in the room that provides a CO₂ concentration of $\geq 34\%$ for property protection. A standpipe and hose station is provided from the adjacent Pipe Gallery and Corridor.

Deviations: The justification for the Appendix A deviation for the fire barrier separating the Fuel Oil Transfer Pump Room from the DG Building Corridor is documented in Part VII, Section 4.6.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

3.60 FIRE AREA 54

3.60.1 Room 742.0-D10

Description: Conduit Interface Room

Fire Loading: The combustibles consist of insulation on cables in trays. The fire severity is classified as moderate.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
742.0-D10	North Wall	Area 53, Room 742.0-D3	II-35A	3 Hours
		Area 53, Room 742.0-D8	II-35A	3 Hours
		Area 53, Room 742.0-D9	II-35A	3 Hours
		Area 55, DGB Cable Chase A	II-35A	3 Hours
		Area 56, DGB Cable Chase B	II-35A	3 Hours
	East Wall	Area 53, Room 742.0-D3	II-35A	3 Hours
		Area 55, DGB Cable Chase A	II-35A	3 Hours
		Area 56, DGB Cable Chase B	II-35A	3 Hours
	West Wall	Area 55, DGB Cable Chase A	II-35A	3 Hours
		Area 56, DGB Cable Chase B	II-35A	3 Hours

Doors: None.

Dampers: None.

Detection: Ionization smoke detectors are provided in the room.

Suppression: None. Fire hydrants are located across the street outside the entrance doors at each end of the room.

Deviations: None.

Evaluations: None.

3.60.2 Room 742.0-D2

Description: Lube Oil Storage Room

Fire Loading: The combustibles consist of insignificant amounts of in situ combustibles and various numbers of sealed 55 gallon drums of lube oil and fuel oil. A number of drums (21) were chosen to represent a conservative fixed combustible load. The fire severity classification with the above assumption is severe.

Compartmentation: The walls are of reinforced concrete construction. The ceiling is of reinforced construction.

PART VI – FIRE HAZARDS ANALYSIS

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
742.0-D2	East Wall	Area 49, Room 742.0-D4	II-35A	3 Hours
		Area 53, Room 742.0-D9	II-35A	3 Hours

Doors:					
Room	Door Number	Dir	Adjacent Area/Room	FPR Figure Reference	Door Rating
742.0-D2	D8A	East	Area 53, Room 742.0-D9	II-35A	3 Hours (Sliding)

Dampers:					
Room	Damper/Mark Number	Dir	Adjacent Area/Room	Drawing Reference	Damper Rating
742.0-D2	0-ISD-30-594	E-W	Area 53, Room 742.0-D9A	47W866-9	3 Hours
	47A381-627F			17W910-2	

Detection: Heat detectors are provided in the room.

Suppression: A total flooding CO₂ suppression system is provided in the room that provides a CO₂ concentration of $\geq 34\%$ for property protection. A standpipe and hose station is provided from the adjacent Corridor and Pipe Gallery 742.0-D9.

Deviations: The justification for the sliding fire doors only having fusible links on one side of the opening is documented in Part VII, Section 5.2.

Evaluations: The justification for the in situ combustible load in Room 742.0-D2 is provided in Part VII, Section 3.6.

3.60.3 Rooms 742.0-D1, Stairwell D1, 760.5-D1 and 760.5-D2

Room No.	Description:
742.0-D1	CO ₂ Storage Room
Stair D1	Stairwell
760.5-D1	Corridor
760.5-D2	Radiation Shelter

Fire Loading: The combustibles in these rooms consist of plastics, wood and paper associated with storage cabinets, electrical panels and lights. The fire severity classification for each room is as follows:

Room No.	Description:	Fire Loading:
742.0-D1	CO ₂ Storage Room	Insignificant
Stair D1	Stairwell	Low
760.5-D1	Corridor	Insignificant
760.5-D2	Radiation Shelter	Low

Compartmentation: The rooms are of reinforced concrete construction.

Detection: None.

Suppression: Standpipe and hose stations are provided in rooms 742.0-D1 and 760.5-D1.

Deviations: None.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

3.60.4 FIRE AREA 54 SAFE SHUTDOWN ANALYSIS BY ANALYSIS VOLUME

3.60.4.1 AV-082

DGB-CO - Diesel Generator Building Corridor:	
Room No.	Description:
742.0-D1	CO2 Storage Room
742.0-D10	Conduit Interface Room
742.0-D2	Lube Oil Storage Room
Stair D1	Stairwell
760.5-D1	Corridor
760.5-D2	Radiation Shelter

A fire in Analysis Volume 82 would not impact major equipment required to maintain safe shutdown functions. Shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Equipment affected and credited to achieve shutdown is identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.61 FIRE AREA 55

3.61.1 DGB Cable Chase A

Description: DGB Cable Chase A

Fire Loading: The combustibles are insulation on the cables in the trays. The fire severity is classified as severe.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
DGB Cable Chase A	North Wall	Area 53, Room 742.0-D9A	II-35A	3 Hours
	South, East, and West Walls	Area 54, Room 742.0-D10	II-35A	3 Hours
	Ceiling	Area 54, Room 742.0-D10	II-35A	3 Hours

Doors:					
Room	Door Number	Dir	Adjacent Area/Room	FPR Figure Reference	Door Rating
DGB Cable Chase A	D36	North	Area 53, Room 742.0-D9A	II-35A	3 Hours

Dampers: None.

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided in the room. A standpipe and hose station is provided from the adjacent Pipe Gallery and Corridor.

Deviations: None.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

3.61.2 Fire Area 55 Safe Shutdown Analysis By Analysis Volume

3.61.2.1 AV-083

Room No.	Description:
DGB-A	Cable Chase A (From 713.0-A1A3 to DG Building Pipe Gallery A)

A fire in Analysis Volume 83 would not impact major equipment required to maintain safe shutdown functions. Shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Equipment affected and credited to achieve shutdown is identified below:

3.62 FIRE AREA 56

3.62.1 DGB Cable Chase B

Description: DGB Cable Chase B

Fire Loading: The combustibles are insulation on the cables in the trays. The fire severity is classified as severe.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
DGB Cable Chase B	North Wall	Area 53, Room 742.0-D9B	II-35A	3 Hours
	South, East, and West Walls	Area 54, Room 742.0-D10	II-35A	3 Hours
	Ceiling	Area 54, Room 742.0-D10	II-35A	3 Hours

Doors:					
Room	Door Number	Dir	Adjacent Area/Room	FPR Figure Reference	Door Rating
DGB Cable Chase B	D35	North	Area 53, Room 742.0-D9B	II-35A	3 Hours

Dampers: None.

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic preaction sprinkler system is provided in the room. A standpipe and hose station is provided from the adjacent Pipe Gallery and Corridor.

Deviations: None.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

3.62.2 Fire Area 56 Safe Shutdown Analysis By Analysis Volume

3.62.2.1 AV-084

Room No.	Description:
DGB-B	Cable Chase B (From 713.0-A1B to DG Building Pipe Gallery B)

A fire in Analysis Volume 84 would not impact major equipment required to maintain safe shutdown functions. Shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Equipment affected and credited to achieve shutdown is identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.63 FIRE AREA 57

3.63.1 (Deleted - Formerly Assigned to the Additional Diesel Generator Building)

3.64 FIRE AREA 58

3.64.1 IPS EL 741 West

Description: ERCW Pump Room A (EL 741)

Fire Loading: The combustibles in the ERCW Pump Room A consist of lube oil associated with the pumps, pipe insulation, plastics associated with electrical panels and lights and insulation on cables in trays. The fire severity is classified as moderate.

Compartmentation: The walls and floor of this room are of reinforced concrete construction. The wall between the pump room and the Screen Wash pump room has two unprotected openings (scupper holes). The ceiling is an open steel missile barrier that allows air flow to the outside.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
ERCW Pump Room A	North, East and West Walls	Area 60, Roof Deck EL 728	II-36A	3 Hours
	South Wall	Area 58, Screen Wash and HPFP A Pump Room	II-36A	3 Hours
	East Wall	Area 59, ERCW Pump Room B	II-36A	3 Hours

Doors:					
Room	Door Number	Dir	Adjacent Area/Room	FPR Figure Reference	Door Rating
ERCW Pump Room A	W5	South	Area 58, Screen Wash and HPFP A Pump Room	II-36A	3 Hours
	W9	East	Area 60, Roof Deck EL 728	II-36A	3 Hours

Dampers: None.

Detection: Heat detectors are provided over the ERCW pumps. (See note below)

Suppression: Standpipe and hose stations are accessible from the ERCW Strainer room and the Screen Wash Pump room. (See note below)

Deviations: The justification for the unprotected openings (scupper holes) in the wall between this room and the Screen Wash Pump room is documented in Part VII, Section 2.6.

PART VI – FIRE HAZARDS ANALYSIS

Evaluations: The justification for the gap between the door and frame for Door W9 is documented in Part VII, Section 6.3. The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Section 8.3.57 and 64.

Note: Although this room is not provided with suppression and full area detection, per the guidelines of Appendix A, Section F.11, fire area barrier ratings are sufficient given the combustible loadings in the area. This fire area does not contain redundant safe shutdown equipment. Therefore, a fire in this area will not endanger other safety related equipment required for safe plant shutdown. Refer to Section F.11 of Part VIII of the FPR for information on conformance to Appendix A regarding this issue.

3.64.2 IPS EL 741 West

Description: Screen Wash and HPFP A Pump Room (EL 741)

Fire loading: The combustibles in the Screen Wash and HPFP A Pump room consist of lube oil in the pumps, hydraulic oil in the Crane, and plastic associated with electrical panels and lights. The fire severity is classified as low.

Compartmentation: The walls and floor of this room are of reinforced concrete construction. The wall between the Pump room and the Screen Wash Pump room has two unprotected openings (scupper holes). The ceiling of this room is an open steel missile barrier that allows air flow into the room.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
Screen Wash and HPFP A Pumps Room	North Wall	Area 58, ERCW Pump Room A	II-36A	3 Hours
		Area 59, ERCW Pump Room B	II-36A	3 Hours
	South Wall	Area 59, ERCW Strainer Room B	II-36A	3 Hours
	East Wall	Area 59, HPFP B Pump Room	II-36A	3 Hours
		Area 59, ERCW Strainer Room B	II-36A	3 Hours
	Floor (partial)	Area 59, ERCW Strainer Room B	II-36A	3 Hours

Doors:					
Room	Door Number	Dir	Adjacent Area/Room	FPR Figure Reference	Door Rating
Screen Wash and HPFP A Pumps Room	W5	North	Area 58, ERCW Pump Room A	II-36A	3 Hours
	W8	East	Area 59, HPFP B Pump Room	II-36A	3 Hours

Dampers: None.

Detection: None. (See note below)

PART VI – FIRE HAZARDS ANALYSIS

Suppression: Standpipe and hose stations are provided in this room and are accessible from the ERCW strainer room. (See note below)

Deviations: The justification for the unprotected openings (scupper holes) in the wall between this room and the ERCW Pump Room is documented in Part VII, Section 2.6. The justification for the non-listed, non-approved fire pumps and fire pump controllers is documented in Part VII, Section 5.1.

Evaluations: The justification of the adequacy of HPFP system pumps and controllers is documented in Part VII, Section 3.3

Note: Although this room is not provided with suppression and detection, per the guidelines of Appendix A, Section F.11, fire area barrier ratings are sufficient given the combustible loadings in the area. This fire area does not contain redundant safe shutdown equipment. Therefore, a fire in this area will not endanger other safety related equipment required for safe plant shutdown. Refer to Section F.11 of Part VIII of the FPR for information on conformance to Appendix A regarding this issue.

3.64.3 IPS EL 722 West

Description: ERCW Strainer Room A (EL 722)

Fire loading: The combustibles in this room consist of lube oil associated with the strainers and valves, and plastics associated with electrical panels and lights. The fire severity is classified as insignificant.

Compartmentation: This room is constructed of reinforced concrete.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
ERCW Strainer Room A	North Wall	Area 60, IPS 711 Board Room	II-36A	3 Hours
		Area 60, Roof Deck Area EL 728	II-36A	3 Hours
	East Wall	Area 59, ERCW Strainer Room B	II-36A	3 Hours

Doors:					
Room	Door Number	Dir	Adjacent Area/Room	FPR Figure Reference	Door Rating
ERCW Strainer Room A	W10A	East	Area 59, ERCW Strainer Room B	II-36A	EQ
	W10B	East	Area 59, ERCW Strainer Room B	II-36A	EQ

Dampers: None.

Detection: This room is provided with ionization smoke detectors.

PART VI – FIRE HAZARDS ANALYSIS

Suppression: Standpipe and hose stations are provided in this room and are accessible from the Screen Wash pump room.

Deviations: The justification for the fire doors is documented in Part VII, Section 4.1

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

3.64.4 Fire Area 58 Safe Shutdown Analysis by Analysis Volume

3.64.4.1 AV-086

Room No.	Description:
IPS-A El. 741	ERCW Pump Room A
IPS-A El. 741	Screen Wash and HPFP A Pump Room
IPS-A El. 722	ERCW Strainer Room A

A fire in Analysis Volume 86 could potentially affect systems and components necessary to maintain the long term decay heat removal, steam generator inventory control, containment HVAC, fire pumps and reactor coolant inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.65 FIRE AREA 59

3.65.1 IPS EL 741 East

Description: ERCW Pump Room B (EL 741)

Fire Loading: The combustibles in the ERCW Pump Room B consist of lube oil associated with the pumps, pipe insulation, plastics associated with electrical panels and lights and insulation on cables in trays. The fire severity is classified as moderate.

Compartmentation: The walls and floor of this room are of reinforced concrete construction. The wall between the pump room and the Screen Wash pump room has two unprotected openings (scupper holes). The ceiling is an open steel missile barrier that allows air flow to the outside.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
ERCW Pump Room B	North Wall	Area 60, Roof Deck EL 728	II-36A	3 Hours
		Area 60, IPS 711 Board Room	II-36	3 Hours
	South Wall	Area 58, Screen Wash and HPFP A Pump Room	II-36A	3 Hours
		Area 59, HPFP B Pump Room	II-36A	3 Hours
	West Wall	Area 58, ERCW Pump Room A	II-36A	3 Hours

Doors:					
Room	Door Number	Dir	Adjacent Area/Room	FPR Figure Reference	Door Rating
ERCW Pump Room B	W3	North	Area 60, STAIR	II-36A	3 Hours
	W6	South	Area 59, HPFP B Pump Room	II-36A	3 Hours

Dampers: None.

Detection: Heat detectors are provided over the ERCW pumps. (See note below)

Suppression: Standpipe and hose stations are provided from the ERCW strainer room and the Screen Wash Pump room. (See note below)

Deviations: The justification for the unprotected openings (scupper holes) in the wall between this room and the Screen Wash Pump room is documented in Section VII, Section 2.6.

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.58 and 65.

Note: Although this room is not provided with suppression and full area detection, per the guidelines of Appendix A, Section F.11, fire area barrier ratings are sufficient given the combustible loadings in the area. This fire area does not contain redundant safe shutdown

PART VI – FIRE HAZARDS ANALYSIS

equipment. Therefore, a fire in this area will not endanger other safety related equipment required for safe plant shutdown. Refer to Section F.11 of Part VIII of the FPR for information on conformance to Appendix A regarding this issue.

3.65.2 IPS EL 741 East

Description: HPFP B Pump Room (EL 741)

Fire loading: The combustibles in this room consist of lube oil in the pumps, and plastic associated with junction boxes. The fire severity is classified as low.

Compartmentation: The walls and floor of this room is of reinforced concrete construction. The ceiling of this room is an open steel missile barrier that allows air flow into the room.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
HPFP B Pump Room	North Wall	Area 59, ERCW Pump Room B	II-36A	3 Hours
	West Wall	Area 58, Screen Wash and HPFP A Pump Room	II-36A	3 Hours
	Floor	Area 59, ERCW Strainer Room B	II-36A	3 Hours

Doors:					
Room	Door Number	Dir	Adjacent Area/Room	FPR Figure Reference	Door Rating
HPFP B Pump Room	W6	North	Area 59, ERCW Pump Room B	II-36A	3 Hours
	W8	West	Area 58, Screen Wash and HPFP A Pump Room	II-36A	3 Hours

Dampers: None.

Detection: None. (See note below)

Suppression: Standpipe and hose stations are provided in this room and are accessible from the ERCW strainer room. (See note below)

Deviations: The justification for the non-listed, non-approved fire pumps and fire pump controllers is documented in Part VII, Section 5.1.

Evaluations: The justification for the adequacy of the HPFP system pumps and controllers is documented in Part VII, Section 3.3.

Note: Although this room is not provided with suppression and detection, per the guidelines of Appendix A, Section F.11, fire area barrier ratings are sufficient given the combustible loadings in the area. This fire area does not contain redundant safe shutdown equipment. Therefore, a fire in this area will not endanger other safety related equipment required for safe plant shutdown. Refer to Section F.11 of Part VIII of the FPR for information on conformance to Appendix A regarding this issue.

PART VI – FIRE HAZARDS ANALYSIS

3.65.3 IPS EL 722 East

Description: ERCW Strainer Room B (EL 722)

Fire loading: The combustibles in this room consist of lube oil associated with the strainers and valves, and plastics associated with electrical panels and lights. The fire severity is classified as insignificant.

Compartmentation: This room is constructed of reinforced concrete.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
ERCW Strainer Room B	North	Area 60, IPS 711 Board Room	II-36A	3 Hours
		Area 60, Roof Deck EL 728	II-36A	3 Hours
	West	Area 58, ERCW Strainer Room A	II-36A	3 Hours
		Area 58, Screen Wash and HPFP A Pump Room	II-36A	3 Hours
	Ceiling (partial)	Area 59, HPFP B Pump Room	II-36A	3 Hours
		Area 58, Screen Wash and HPFP A Pump Room	II-36A	3 Hours

Doors:					
Room	Door Number	Dir	Adjacent Area/Room	FPR Figure Reference	Door Rating
ERCW Strainer Room B	W10A	West	Area 58, ERCW Strainer Room A	II-36A	EQ
	W10B	West	Area 58, ERCW Strainer Room A	II-36A	EQ

Dampers: None.

Detection: This room is provided with ionization smoke detectors.

Suppression: Standpipe and hose stations are provided in this room and are accessible from the Screen Wash pump room.

Deviations: The justification for fire doors is documented in Part VII, Section 4.1.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

3.65.4 Fire Area 59 Safe Shutdown Analysis by Analysis Volume

3.65.4.1 AV-087

Room No.	Description:
IPS-B El. 741	ERCW Pump Room B
IPS-B El. 741	HPFP B Pump Room
IPS-B El. 722	ERCW Strainer Room B

A fire in Analysis Volume 87 could potentially affect systems and components necessary to maintain the long term decay heat removal, steam generator inventory control, containment HVAC, fire pumps and reactor coolant inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.66 FIRE AREA 60

3.66.1 Room IPS-711.0

Description: Board Room (Subdivided into IPS-CA, IPS-CC-A, IPS-CB, IPS-CC-B)

Fire Loading: The combustibles in the room consist of plastics associated with electrical panels and boards, oil in the transformers and insulation on cables in trays. The fire severity is classified moderate.

Compartmentation: The room is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
IPS-711.0	South Wall	Area 58, ERCW Strainer Room A	II-36A	3 Hours
		Area 59, ERCW Strainer Room B	II-36A	3 Hours
		Area 58, ERCW Pump Room A	II-36A	3 Hours
		Area 59, ERCW Pump Room B	II-36A	3 Hours

Doors:					
Room	Door Number	Dir	Adjacent Area/Room	FPR Figure Reference	Door Rating
IPS-711.0	W3	South	Area 59, STAIR B	II-36A	3 Hours

Dampers: None.

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic sprinkler system is provided in the room. A standpipe and hose station is provided in the room.

Deviations: The room contains intervening combustibles in the form of insulation on cables in trays. The justification for using an enhanced automatic preaction sprinkler system to compensate for these intervening combustibles is documented in Part VII, Section 2.4.

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.59, 60, 61, 64, and 65.

PART VI – FIRE HAZARDS ANALYSIS

3.66.2 Roof Deck EL 728

Description: RCW Pump Deck EL 728

Fire Loading: The combustibles in this area consist of lube oil in the pumps and plastics associated with junction and control boxes. The fire severity is classified as insignificant.

Compartmentation: The RCW Pump area is on the roof deck of the Board Room (IPS 711.0). The barrier separating the roof deck from Areas 58 and 59 is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
Roof Deck EL 728	South Wall	Area 58, ERCW Strainer Room A	II-36A	3 Hours
		Area 58, ERCW Pump Room A	II-36A	3 Hours
		Area 59, ERCW Strainer Room B	II-36A	3 Hours
		Area 59, ERCW Pump Room B	II-36A	3 Hours

Doors:					
Room	Door Number	Dir	Adjacent Area/Room	FPR Figure Reference	Door Rating
Roof Deck EL 728	W9	West	Area 58, ERCW Pump Room A	II-36A	3 Hours

Dampers: None.

Detection: None.

Suppression: None. A standpipe and hose station is provided.

Deviations: None.

Evaluations: Evaluation of gap between door and frame on door W9 is documented in Part VII, Section 6.3 of FPR.

The RCW pump area is on the roof of the Intake Pumping Station Electrical Board Room and open to the atmosphere. There are no required fire safe shutdown (FSSD) components (equipment or cables) located on the deck, and a fire on the deck will not impact any FSSD components. The pump deck is thus not included in the analysis for the Intake Pumping Station (AV-088, AV-089, AV-090) because it has no impact.

PART VI – FIRE HAZARDS ANALYSIS

3.66.3 Fire Area 60 Safe Shutdown Analysis by Analysis Volume

3.66.3.1 AV-088

Room No.	Description:
IPS-CA El. 711.0	Board Room, 20ft West of 480V Bd/Transformer
IPS-CC-A El. 711.0	Board Room, Mid to 20ft West of 480V Bd/Transformer

A fire in Analysis Volume 88 could potentially affect systems and components necessary to maintain the long term decay heat removal, steam generator inventory control, containment HVAC, fire pumps and reactor coolant inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.66.3.3 AV-090

Room No.	Description:
IPS-CB EI. 711.0	Board Room, 20ft East of 480V Bd/Transformer
IPS-CC-B EI. 711.0	Board Room, Mid to 20ft East of 480V Bd/Transformer

A fire in Analysis Volume 90 could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 long term decay heat removal, steam generator inventory control, containment HVAC, fire pumps and reactor coolant inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.67 FIRE AREA 61

3.67.1 Unit 1 Reactor Building - Annulus

Description: Annulus

Fire Loading: The combustibles consist of foam plastic insulation, plastic associated with electrical panels and boxes, rubber expansion joints, and insulation on cables in trays. The fire severity is classified as severe.

Compartmentation: The Annulus is separated from Primary Containment by the Steel Containment Vessel which prevents the passage of flames, smoke and hot gases, but allows heat transfer. The Annulus is separated from the Auxiliary Building fire areas by reinforced concrete construction.

Barriers:			
Room	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
ANNULUS	AREA 1, ROOM 713.0-A28	II-29A	3 Hours
	AREA 5, ROOM 692.0-A7	II-28A	3 Hours
	AREA 9, ROOM 713.0-A6	II-29A	3 Hours
	AREA 9, ROOM 713.0-A8	II-29A	3 Hours
	AREA 10, ROOM 729.0-A8	II-29A	3 Hours
	AREA 12, ROOM 729.0-A1	II-30A, II-31A, II-32A	3 Hours
	AREA 13, ROOM 729.0-A2	II-38A	3 Hours
	AREA 13, ROOM 729.0-A12	II-38A	3 Hours
	AREA 13, ROOM 729.0-A14	II-38A	3 Hours
	AREA 13, ROOM 729.5-A16	II-38A	3 Hours
	AREA 12, ROOM 737.0-A6	II-30A	3 Hours
	AREA 16, ROOM 737.0-A5	II-30A	3 Hours
	AREA 13, ROOM 737.0-A13	II-30A	3 Hours
	AREA 13, ROOM 775.25-A1	II-32A	3 Hours
	AREA 13, ROOM 763.5-A1	II-38A	3 Hours
	AREA 13, ROOM 786.5-A1	II-32A	3 Hours
	AREA 25, ROOM 757.0-A10	II-31A	3 Hours
	AREA 25, ROOM 757.0-A12	II-31A	3 Hours
	AREA 25, ROOM 782.0-A1	II-32A	3 Hours
	AREA 25, ROOM 782.0-A2	II-32A	3 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
ANNULUS	A65	EAST	AREA 9, ROOM 713.0-A8A	II-29A	EQ

Dampers: None.

Detection: Photoelectric smoke detectors provide partial coverage in the Annulus.

Suppression: Automatic preaction sprinkler systems provide partial coverage in the Annulus. Standpipe and hose stations are provided throughout the Annulus.

PART VI – FIRE HAZARDS ANALYSIS

Deviations: The justification for the radiant energy shields not meeting the ASTM E136 criteria of non-combustibility is documented in Part VII, Section 2.2. The justification for using dedicated hand-held portable lanterns in lieu of installed battery pack lighting is documented in Part VII, Section 2.7.

Evaluations: The lack of fire dampers for the containment purge air system return and exhaust air duct openings to the 713.0-A6 pipe gallery is documented in Part VII, Section 3.2. The justification for the in situ combustible load in Room Unit 1 Annulus is provided in Part VII, Section 3.6.

3.67.2 Unit 1 Reactor Building - Primary Containment

Description: Primary Containment (Subdivided into RO-1, RO-2, RO-3, RO-4, RI-1, RI-2, RI-3, RI-4, RIR, RA1, RA2, RA3, RA4, RF1, RF2, RU)

Fire Loading: The combustibles consist of foam plastic insulation, plastic associated with electrical panels and boxes, rubber expansion joints, lube oil in pumps, motors and valves, insulation on cables in trays and wood (used only for insulation and framing of the ice condenser intermediate deck end wall doors). The fire severity for individual areas, range from a classification of insignificant to moderate.

Compartmentation: The Primary Containment is separated from the Annulus by the Steel Containment Vessel which prevents the passage of flames, smoke and hot gases, but allows heat transfer.

Barriers: None.

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
PRIMARY CONTAINMENT	A94	WEST	AREA 9, ROOM 713.0-A8	II-29A	3 HR AC
	A95	WEST	AREA 9, ROOM 713.0-A8	II-29A	3 HR AC
	A96	WEST	AREA 9, ROOM 713.0-A8	II-29A	3 HR AC
	A164	EAST	AREA 25, ROOM 757.0-A12	II-31A	3 HR AC
	A165	EAST	AREA 25, ROOM 757.0-A12	II-31A	3 HR AC

Dampers: None.

Detection: Ionization smoke detectors are provided in the LOWER and upper compartment cooler units. Heat detectors are provided over the Reactor Coolant Pumps.

Suppression: Automatic fixed water spray systems are provided for each Reactor Coolant Pump. Standpipes and hose stations are provided inside containment.

PART VI – FIRE HAZARDS ANALYSIS

Deviations: The justification for the radiant energy shields not meeting the ASTM E136 criteria of non-combustibility is documented in Part VII, Section 2.2. The justification for using dedicated hand-held portable lanterns in lieu of installed battery pack lighting is documented in Part VII, Section 2.7. The justification to allow for minor amount of oil to escape the RCP oil collection system is documented in Part VII, Section 2.8.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

3.67.3 Fire Area 61 Safe Shutdown Analysis by Analysis Volume

3.67.3.1 AV-091

Room No.	Description:
ANN	Unit 1 Reactor Building - Annulus

A fire in Analysis Volume 91 could potentially affect systems and components necessary to maintain the Unit 1 steam generator inventory control functions and Unit 1 long term decay heat removal, containment integrity, containment HVAC, reactor coolant inventory control and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include providing smoke detectors, automatic fire suppression, and non-combustible radiant energy shields to protect redundant Unit 1 safe shutdown cables in the event of a fire and manual operations of Unit 1 equipment required for safe shutdown and repair procedures. These features and equipment affected and credited are identified below. Since compliance in this area utilizes options III.G.2.d, e, and / or f the equipment train which is affected or credited for containment cooling, primary system depressurization during cooldown and RHR cooldown is determined subsequent to firefighting activities by the location of the fire. Adequate time is available to make this determination since the earliest safe shutdown requirement for these functions is approximately 2 hours when containment cooling must be established.

Unit 1 Reactor Building – Lower Containment	
Room No.	Description:
RO-2	Outside Crane Wall (90° - 180°)
RO-3	Outside Crane Wall (180° - 270°)
RA2	Accumulator Room 2
RF2	Fan Room 2

A fire in Analysis Volume 92A could potentially affect systems and components necessary to maintain the Unit 1 long term decay heat removal, containment HVAC, reactor coolant inventory control, reactor pressure control and steam generator inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features for Unit 1 include providing radiant energy shields to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown. The following is an exception to the general methodology for providing cable protection (ERFBS) from analysis volume boundary to analysis boundary as described in FPR Part III, Section 10.3.1. The redundant control cables and/or equipment are separated greater than 20 feet inside containment. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.67.3.4 AV-092C

Unit 1 Reactor Building – Lower Containment	
Room No.	Description:
RO-3	Outside Crane Wall (180° - 270°)
RO-4	Outside Crane Wall (270° - 360°)
RA3	Accumulator Room 3
RA4	Accumulator Room 4

A fire in Analysis Volume 92C could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control functions and Unit 1 long term decay heat removal, containment integrity, reactor coolant inventory control and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include manual operation of Unit 1 equipment required for safe shutdown and repair procedures. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.67.3.5 AV-092D

Unit 1 Reactor Building – Lower Containment	
Room No.	Description:
RO-1	Outside Crane Wall (0° - 90°)
RO-4	Outside Crane Wall (270° - 360°)
RF1	Fan Room 1
RA4	Accumulator Room 4

A fire in Analysis Volume 92D could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control functions and Unit 1 long term decay heat removal, containment integrity, secondary side isolation, containment HVAC, reactor coolant inventory control and reactor pressure control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features for Unit 1 include providing radiant energy shields to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown and repair procedures. The following is an exception to the general methodology for providing cable protection (ERFBS) from analysis volume boundary to analysis boundary as described in FPR Part III, Section 10.3.1. The redundant control cables and/or equipment are separated greater than 20 feet inside containment. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.67.3.6 AV-092E

Unit 1 Reactor Building – Lower Containment	
Room No.	Description:
RO-1	Outside Crane Wall (0° - 90°)
RO-4	Outside Crane Wall (270° - 360°)
RF1	Fan Room 1
RA1	Accumulator Room 1

A fire in Analysis Volume 92E could potentially affect systems and components necessary to maintain the Unit 1 long term decay heat removal, containment HVAC, reactor coolant inventory control, reactor pressure control, containment integrity, secondary side isolation and steam generator inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features for Unit 1 include providing radiant energy shields to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown and repair procedures. The following is an exception to the general methodology for providing cable protection (ERFBS) from analysis volume boundary to analysis boundary as described in FPR Part III, Section 10.3.1. The redundant control cables and/or equipment are separated greater than 20 feet inside containment. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.67.3.9 AV-092H

Unit 1 Reactor Building – Lower Containment	
Room No.	Description:
RI-2	Inside Crane Wall (90° - 180°)
RI-3	Inside Crane Wall (180° - 270°)
RA2	Accumulator Room 2
RF2	Fan Room 2

A fire in Analysis Volume 92H could potentially affect Unit 1 systems and components necessary to maintain the long term decay heat removal, containment HVAC, reactor coolant inventory control, reactor pressure control and steam generator inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features for Unit 1 include providing radiant energy shields to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown. The following is an exception to the general methodology for providing cable protection (ERFBS) from analysis volume boundary to analysis boundary as described in FPR Part III, Section 10.3.1. The redundant control cables and/or equipment are separated greater than 20 feet inside containment. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.67.3.10 AV-092J

Unit 1 Reactor Building – Lower Containment	
Room No.	Description:
RI-2	Inside Crane Wall (90° - 180°)
RI-3	Inside Crane Wall (180° - 270°)
RA3	Accumulator Room 3
RF2	Fan Room 2

A fire in Analysis Volume 92J could potentially affect systems and components necessary to maintain the Unit 1 long term decay heat removal, containment integrity, containment HVAC, reactor coolant inventory control, reactor pressure control and steam generator inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features for Unit 1 include providing radiant energy shields to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown. The following is an exception to the general methodology for providing cable protection (ERFBS) from analysis volume boundary to analysis boundary as described in FPR Part III, Section 10.3.1. The redundant control cables and/or equipment are separated greater than 20 feet inside containment. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.67.3.11 AV-092K

Unit 1 Reactor Building – Lower Containment	
Room No.	Description:
RI-1	Inside Crane Wall (0° - 90°)
RI-4	Inside Crane Wall (270° - 360°)
RA4	Accumulator Room 4
RF1	Fan Room 1

A fire in Analysis Volume 92K could potentially affect Unit 1 systems and components necessary to maintain the long term decay heat removal, containment integrity, secondary side isolation, containment HVAC, reactor coolant inventory control, reactor pressure control and steam generator inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features for Unit 1 include providing radiant energy shields to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown and post fire repairs. The following is an exception to the general methodology for providing cable protection (ERFBS) from analysis volume boundary to analysis boundary as described in FPR Part III, Section 10.3.1. The redundant control cables and/or equipment are separated greater than 20 feet inside containment. These features and equipment affected and credited are identified below:

3.67.3.12 AV-092L

Unit 1 Reactor Building – Lower Containment	
Room No.	Description:
RI-1	Inside Crane Wall (0° - 90°)
RI-4	Inside Crane Wall (270° - 360°)
RA1	Accumulator Room 1
RF1	Fan Room 1

A fire in Analysis Volume 92L could potentially affect Unit 1 systems and components necessary to maintain the long term decay heat removal, containment HVAC, reactor coolant inventory control, reactor pressure control and steam generator inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features for Unit 1 include providing radiant energy shields to selected cables to preclude damage in the event of a fire and manual operation of equipment required for safe shutdown and post fire repairs. The following is an exception to the general methodology for providing cable protection (ERFBS) from analysis volume boundary to analysis boundary as described in FPR Part III, Section 10.3.1. The redundant control cables and/or equipment are separated greater than 20 feet inside containment. These features and equipment affected and credited are identified below:

3.68 FIRE AREA 62

3.68.1 CDWE Building

Description: Condensate Demineralizer Waste Evaporator Building

Fire Loading: The combustibles in this building consist of plastic associated with electrical equipment and lights and lubricating oil associated with various pumps and motors. The fire severity is classified as low.

Compartmentation: The CDWE building is of reinforced concrete construction.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
CDWE Building	West Wall	Area 10, Room 729.0-A5	II-38A	3 Hours

PART VI – FIRE HAZARDS ANALYSIS

3.69 FIRE AREA 63

3.69.1 Turbine Building

Description: Turbine Building

Fire Loading: The combustibles in the Turbine Building include lubricating oils and greases, plastics associated with electrical equipment and cables, fuel oil for the auxiliary boiler, and other miscellaneous materials associated with the function of an electrical generating facility. A combustible loading walkdown has not been performed for this building; however, this occupancy would be defined as mixed Ordinary Group 2 and 3 per NFPA 13.

Compartmentation: The Turbine Building is of steel frame construction with concrete floors and is separated from the Control Building and Auxiliary Building by reinforced concrete walls, ceilings and floors which are equivalent to 3 hour fire barriers. The floors separating the various elevations within the Turbine Building are not fire rated barriers.

Barriers:

Detection: Heat detectors are provided to actuate the various fixed suppression systems. Area detection is not provided.

Suppression: Fixed automatic water spray systems are provided for the feedwater pump turbine oil tanks, main turbine oil tanks, seal oil units and turbine head ends. An automatic sprinkler system is provided around the Auxiliary Boilers. A water curtain is provided for each tray penetration into the Control Building. Standpipes and hose stations are provided for each elevation.

PART VI – FIRE HAZARDS ANALYSIS

Deviations: The justification for the hatch openings through the floor to the Control Building Mechanical Equipment Rooms is documented in Part VII, Section 2.6. The justification for using DG Backed Standby Lighting in the Turbine Building is documented in Part VII, Section 2.7.

Evaluations: None

PART VI – FIRE HAZARDS ANALYSIS

3.70 FIRE AREA 64

3.70.1 Yard

Description: Above Ground – Yard
Below Ground – Duct Banks A and B

Fire Loading: The major combustibles in the Yard include fuel oil and turbine oil in storage tanks, transformers, hydrogen in storage tank/trailers, and various combustible structures.

Compartmentation: The oil tanks and transformers are located at least 50 feet from any safety related structure. The transformers are provided with an absorbent bed of gravel which drains spills away from all structures. The oil tanks are provided with spill containment dikes which are sized to collect the entire contents of the largest single tank within the dike. The hydrogen storage trailers are located 300 feet from any safety related structure. Other combustible structures are located at least 30 feet from safety related buildings.

Barriers: None. The Duct Banks are separated and are buried underground. They are separated from the Yard by locked covers.

Doors: None.

Dampers: None.

Detection: Heat detectors are provided to actuate water spray systems where provided.

Suppression: The yard is provided with a looped, cross connected, underground fire main and fire hydrants. The fire hydrants are spaced approximately every 250 feet with fire equipment houses located every 1000 feet. The transformers and hydrogen storage trailers are provided with fixed automatic water spray systems.

Deviations: The justification for the scupper openings in the manholes for the duct banks is documented in Part VII, Section 2.6. The justification for using dedicated portable hand-held lantern in lieu of installed battery pack lighting is documented in Part VII, Section 2.7

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions, needed for a fire in this area are documented in Part VII, Sections 8.3.55, 56, 64 and 65.

PART VI – FIRE HAZARDS ANALYSIS

3.70.2 Fire Area 64 Safe Shutdown Analysis by Analysis Volume

3.70.2.1 AV-095

Room No.	Description:
Yard	Yard Area

A fire in Analysis Volume 95 could potentially affect systems and components necessary to maintain the fire pump and reactor coolant inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Onsite power is available. The required mitigating features include manual operation of equipment required for safe shutdown. These features and equipment credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.70.2.3 DUCT BANK B

Duct Bank B runs from Auxiliary Building 713.0-A1B to Intake Pumping Station B and is analyzed as AV-098.

AV-098

Room No.	Description:
DBIPS-B	Cable Chase from Auxiliary Building 713.0-A1B to IPS-B

A fire in Analysis Volume 98 could potentially affect Unit 1 and Unit 2 systems and components necessary to maintain the long term decay heat removal, containment HVAC, fire pumps, steam generator inventory control and reactor coolant inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features for Unit 1 and Unit 2 include manual operation of equipment required for safe shutdown. These features and equipment credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.71 FIRE AREA 65

Fire Area 65 is the Unit 2 Auxiliary Building Pipe Gallery and Chase. The area is composed of rooms 676.0-A17, 692.0-A24, and 713.0-A29. Parts of this area go from floor elevation 676.0 to ceiling elevation 756.0 with only metal grating at intermediate elevations.

3.71.1 Room 676.0-A17, 692.0-A24 and 713.0-A29

Room No.	Description:
676.0-A17	Unit 2 Pipe Gallery and Chase
692.0-A24	Unit 2 Pipe Gallery and Chase
713.0-A29	Unit 2 Pipe Gallery and Chase

Fire Loading: The fire severity for these rooms (individually and combined) is classified as insignificant. The in situ combustibles consist of small amounts of lube oil in valves and plastics associated with electrical panels, boxes and lights; small amounts of rubber, cloth and paper in Health Physics cabinet; anticipated amounts of Radwaste trash and laundry; and miscellaneous other materials.

Compartmentation: These rooms are separated from adjacent fire areas in the Auxiliary Building by reinforced concrete that has a fire resistance of at least 2-hours and from the Unit 2 Reactor Building by reinforced concrete that has a fire resistance of at least 3-hours.

Barriers:

Detection: Ionization smoke detectors are provided in all three rooms.

PART VI – FIRE HAZARDS ANALYSIS

Suppression: There is no automatic suppression in these rooms. Fire hose stations are available from adjacent rooms (676.0-A1, 692.0-A1 and 713.0-A1).

Deviations: Non-Rated Hatch in room 676.0-A17 provides access into room 692.0-A27. Justification is documented in Part VII, Section 2.6.

Evaluations: The lack of total area suppression and detection is addressed in Part VII, Section 3.1.

PART VI – FIRE HAZARDS ANALYSIS

3.71.2 Fire Area 65 Safe Shutdown Analysis by Analysis Volume

AV-099

Room No.	Description:
676.0-A17	Unit 2 Pipe Gallery and Chase
692.0-A24	Unit 2 Pipe Gallery and Chase
713.0-A29	Unit 2 Pipe Gallery and Chase

A fire in Analysis Volume 99 could potentially affect Unit 2 systems and components necessary to maintain the long term decay heat removal, reactor coolant inventory control and steam generator inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Unit 1 major equipment required to maintain safe shutdown functions is not impacted such that shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Offsite power is available. The required mitigating features include manual operation of equipment required for safe shutdown. Equipment affected and credited is identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.72 FIRE AREA 66

3.72.1 Room 692.0- A21

Description: Charging Pump 2C Room

Fire Loading: The pump and valves have been abandoned in place. The fire severity is classified as low.

Compartmentation: The room is bounded by regulatory fire barriers.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
692.0-A21	North Wall	Area 1-1, Room 692.0-A20	II-28A	2 Hours
		Area 65, Room 692.0-A24	II-28A	2 Hours
	East Wall	Area 67, Room 692.0-A22	II-28A	2 Hours
	South Wall	Area 1, Room 692.0-A1B	II-28A	2 Hours
	West Wall	Area 1, Room 692.0-A1B	II-28A	2 Hours
	Floor	Area 1, Room 676.0-A14	II-27A, II-28A	2 Hours
		Area 1, Room 676.0-A15	II-27A, II-28A	2 Hours
		Area 65, Room 676.0-A17	II-27A, II-28A	2 Hours
	Ceiling	Area 8, Room 713.0-A1B	II-28A, II-29A	2 Hours
		Area 8, Room 713.0-A17	II-28A, II-29A	2 Hours
		Area 8, Room 713.0-A18	II-28A, II-29A	2 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
692.0-A21	A41	WEST	Area 1, Room 692.0-A1B	II-28A	3 Hours

Dampers:					
Room	Damper Mark Number	Dir.	Adjacent Area/Room	Drawing Reference	Damper Rating
692.0-A21	2-ISD-31-3858 47A381-394	N - S	Area 65, Room 692.0-A24	2-47W866-11 47W920-2	1.5 Hours

Detection: Ionization smoke detectors are provided in the room (except in the entrance labyrinth). See note below.

Suppression: An automatic, preaction suppression system is provided in the room (except in the entrance labyrinth). See note below. A standpipe and hose station is available from the adjacent room (Corridor 692.0-A1).

PART VI – FIRE HAZARDS ANALYSIS

Deviations: None.

Evaluations: None.

Note: Due to the insignificant quantity of in situ combustibles and robust rated fire barriers, this room is not provided with full area detection and suppression. The room is a separate fire area which does not contain redundant safe shutdown equipment. Therefore, a fire in this area/room will not endanger other safety related equipment required for safe plant shutdown

PART VI – FIRE HAZARDS ANALYSIS

3.72.2 Fire Area 66 Safe Shutdown Analysis by Analysis Volume

3.72.2.1 AV-103

Room No.	Description:
692.0-A21	Charging Pump 2C Room

A fire in Analysis Volume 103 could not impact safe shutdown. The only safe shutdown components in the room are circuits (routed in conduit) associated with Train B Containment Spray. The Positive Displacement charging pump has been abandoned in place as well as its associated components disabled. The room is constructed of reinforced concrete with a fire resistance rating of 2-hours; has insignificant quantities of combustible material; and is provided with detection and automatic suppression. Shutdown can be achieved by utilizing both Train A and B systems and components without mitigation actions. Offsite power is available. Equipment credited to achieve shutdown is identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.73 FIRE AREA 67

3.73.1 Room 692.0- A22

Description: Charging Pump 2B-B Room

Fire Loading: The combustibles consist of the lube oil in the charging pump and plastics associated with lights and junction boxes and anticipated amounts of radwaste trash and laundry. The fire severity is classified as low.

Compartmentation: The room is bounded by regulatory fire barriers.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
692.0-A22	North Wall	Area 65, Room 692.0-A24	II-28A	2 hours
	East Wall	Area 68, Room 692.0-A23	II-28A	2 hours
	South Wall	Area 1, Room 692.0-A1B	II-28A	2 hours
	West Wall	Area 1, Room 692.0-A1B	II-28A	2 hours
		Area 66, Room 692.0-A21	II-28A	2 hours
	Floor	Area 65, Room 676.0-A17	II-27A, II-28A	2 hours
	Ceiling	Area 8, Room 713.0-A1B	II-28A, II-29A	2 hours
		Area 8, Room 713.0-A18	II-28A, II-29A	2 hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
692.0-A22	A42	South	Area 1, Room 692.0-A1B	II-28A	3 hours

Dampers:					
Room	Damper Mark Number	Dir.	Adjacent Area/Room	Drawing Reference	Damper Rating
692.0-A22	2-ISD-31-3859	N - S	Area 65, Room 692.0-A24	2-47W866-11	1.5 hours
	47A381-394			47W920-2	

Detection: Ionization smoke detectors are provided in the room (except in the entrance labyrinth). See Evaluations below.

Suppression: An automatic, preaction suppression system is provided in the room (except in the entrance labyrinth). See Evaluations below. A standpipe and hose station is available from the adjacent room (Corridor 692.0-A1).

Deviations: None.

Evaluations: The justification for not having full area detection and suppression is documented in Part VII, Section 3.1. The feasibility and reliability evaluation for Unit 2 Operator Manual Action is documented in Part VII, Section 8.3.2.

PART VI – FIRE HAZARDS ANALYSIS

3.73.2 Fire Area 67 Safe Shutdown Analysis by Analysis Volume

3.73.2.1 AV-104

Room No.	Description:
692.0-A22	Charging Pump 2B-B Room

A fire in Analysis Volume 104 could potentially affect systems and components necessary to maintain the Unit 2 reactor coolant inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Unit 1 major equipment required to maintain safe shutdown functions is not impacted such that shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Offsite power is available. The required mitigating features include manual operation of Unit 2 equipment required for safe shutdown. These features and equipment affected and credited are identified below.

PART VI – FIRE HAZARDS ANALYSIS

3.74 FIRE AREA 68

3.74.1 Room 692.0- A23

Description: Charging Pump 2A-A Room

Fire Loading: The combustibles consist of the lube oil in the charging pump and plastics associated with lights and junction boxes and anticipated amounts of radwaste trash and laundry. The fire severity is classified as low.

Compartmentation: The room is bounded by regulatory fire barriers.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
692.0-A23	NORTH WALL	Area 65, Room 692.0-A24	II-28A	2 Hours
		Area 70, Room 692.0-A25	II-28A	2 Hours
	EAST AND SOUTH WALL	Area 1, Room 692.0-A1B	II-28A	2 Hours
	WEST WALL	Area 67, Room 692.0-A22	II-28A	2 Hours
	CEILING	Area 8, Room 713.0-A1B Area 8, Room 713.0-A18	II-28A, II-29A II-28A, II-29A	2 Hours 2 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
692.0-A23	A43	WEST	Area 1, Room 692.0-A1B	II-28A	3 Hours

Dampers:					
Room	Damper Mark Number	Dir.	Adjacent Area/Room	Drawing Reference	Damper Rating
692.0-A23	2-ISD-31-3860 47A381-394	N - S	Area 65, Room 692.0-A24	2-47W866-11 47W920-2	1.5 Hours

Detection: Ionization smoke detectors are provided in the room (except in the entrance labyrinth). See Evaluations below.

Suppression: An automatic, preaction suppression system is provided in the room (except in the entrance labyrinth). See Evaluations below. A standpipe and hose station is available from the adjacent room (Corridor 692.0-A1).

Deviations: None.

Evaluations: The Justification for not having full area suppression and detection is documented in Part VII, Section 3.1.

PART VI – FIRE HAZARDS ANALYSIS

3.74.2 Fire Area 68 Safe Shutdown Analysis by Analysis Volume

3.74.2.1 AV-105

Room No.	Description:
692.0-A23	Charging Pump 2A-A Room

A fire in Analysis Volume 105 could potentially affect systems and components necessary to maintain the Unit 2 reactor coolant inventory control and steam generator inventory control functions however no mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Unit 1 major equipment required to maintain safe shutdown functions is not impacted such that shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Offsite power is available. Equipment affected and credited to achieve shutdown are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.75 FIRE AREA 69

3.75.1 Room 692.0- A26

Description: Turbine Driven Auxiliary Feedwater Pump 2A-S Room

Fire Loading: The combustibles consist of the lube oil associated with the feedwater pump, turbine oil cooler, 2 sump pumps and 5 valves and various amounts of plastics associated with electrical panels and lights. The fire severity is classified as insignificant.

Compartmentation: The room is bounded by regulatory fire barriers constructed of reinforced concrete.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
692.0-A26	NORTH WALL	Area 70, Room 692.0-A25	II-28A	2 Hours
	SOUTH AND WEST WALL	Area 1, Room 692.0-A1B	II-28A	2 Hours
	CEILING	Area 1, Room 692.0-A1B	II-28A	2 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic, preaction suppression system is provided in the room. A standpipe and hose station is available from the adjacent room (692.0-A1).

Deviations: None.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

3.75.2 Fire Area 69 Safe Shutdown Analysis by Analysis Volume

3.75.2.1 AV-107

Room No.	Description:
692.0-A26	Turbine Driven Auxiliary Feedwater Pump 2A-S Room

A fire in Analysis Volume 107 could potentially affect Unit 2 systems and components used to maintain steam generator inventory control functions by affecting the Unit 2 Turbine-Driven AFW pump. Safe shutdown for Unit 1 and Unit 2 can be achieved through the remaining Train A and B systems and components without mitigating actions. These features and equipment affected and credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.76 FIRE AREA 70

3.76.1 Room 692.0- A25

Description: Unit 2 Pipe Gallery

Fire Loading: The combustibles located in the room consist of lube oil and grease associated with fans, pumps and valves and plastics associated with electrical panels, boxes and lights. The fire severity classification is insignificant.

Compartmentation: The room is bounded by regulatory fire barriers constructed of reinforced concrete.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
692.0-A25	North Wall	Area 77, Unit 2 Reactor Building	II-28A	3 Hours
	South Wall	Area 1, Room 692.0-A1B	II-28A	2 Hours
		Area 65, Room 692.0-A24	II-28A	2 Hours
		Area 69, Room 692.0-A26	II-28A	2 Hours
	West Wall	Area 65, Room 692.0-A24	II-28A	2 Hours
	Ceiling	Area 65, Room 713.0-A29	II-28A, II-29A	2 Hours
		Area 71, Room 713.0-A19	II-28A, II-29A	2 Hours
		Area 71-1, Room 713.0-A20	II-28A, II-29A	2 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
692.0-A25	A44	SOUTH	Area 1, Room 692.0-A1B	II-28A	3 Hours

Dampers:					
Room	Damper Mark Number	Dir.	Adjacent Area/Room	Drawing Reference	Damper Rating
692.0-A25	2-ISD-31-3861 47A381-396F	E-W	Area 65, Room 692.0-A24	2-47W866-11 47W920-2, 3	3 Hours
	2-ISD-31-2930 47A381-402F	E-W	Area 65, Room 692.0-A24	2-47W866-11 47W920-2, 3	3 Hours
	2-ISD-31-3862 47A381-393F	N-S	Area 1, Room 692.0-A1B	2-47W866-11 47W920-2	3 Hours

Detection: Ionization smoke detectors are provided in the room.

PART VI – FIRE HAZARDS ANALYSIS

Suppression: An automatic, preaction suppression system is provided in the room. A standpipe and hose station is available from the adjacent room (692.0-A1).

Deviations: None.

Evaluations: The feasibility and reliability evaluation for Unit 2 Operator Manual Action is documented in Part VII, Section 8.3.3.

PART VI – FIRE HAZARDS ANALYSIS

3.76.2 Fire Area 70 Safe Shutdown Analysis by Analysis Volume

3.76.2.1 AV-106

Room No.	Description:
692.0-A25	Unit 2 Pipe Gallery

A fire in Analysis Volume 106 could potentially affect Unit 2 systems and components necessary to maintain the long term decay heat removal, steam generator inventory control, reactor coolant inventory control and containment HVAC functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Unit 1 major equipment required to maintain safe shutdown functions is not impacted such that shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Offsite power is available. The required mitigating features for Unit 2 include manual operation of equipment required for safe shutdown. These features and equipment credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.77 FIRE AREA 71

3.77.1 Room 713.0- A19 and -A21

Description: Unit 2 Pipe Gallery and Unit 2 Reactor Building Access Room

Fire Loading: The combustibles located in the area consist of lube oil and grease associated with air handling units, charcoal in an air exhaust filter assembly, plastics associated with electrical panels, radiation monitors and lights, insulation on cables in cable trays and anticipated quantities of radwaste trash and laundry. The fire severity classification for room 713.0-A19 is moderate, and for room 713.0-A21 is insignificant.

Compartmentation: The room is bounded by regulatory fire barriers constructed of reinforced concrete.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
713.0-A19	NORTH WALL	Area 77, Unit 2 Reactor Building	II-29A	3 Hours
	SOUTH WALL	Area 8, Room 713.0-A1B	II-29A	2 Hours
		Area 71-1, Room 713.0-A20	II-29A	2 Hours
	WEST WALL	Area 65, Room 713.0-A29	II-29A	2 Hours
		Area 71-1, Room 713.0-A20	II-29A	2 Hours
	FLOOR	Area 65, Room 692.0-A24	II-28A, II-29A	2 Hours
		Area 70, Room 692.0-A25	II-28A, II-29A	2 Hours
	CEILING	Area 72, Room 729.0-A11	II-29A, II-30A	2 Hours
		Area 74, Room 737.0-A9	II-29A, II-30A	2 Hours
		Area 74, Room 737.0-A10	II-29A, II-30A	2 Hours
713.0-A21	NORTH	Area 77, Unit 2 Reactor Building	II-29A	3 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
713.0-A19	A75	SOUTH	Area 1, Room 713.0-A1B	II-29A	3 Hours
	A76		Area 71-1, Room 713.0-A20	II-29A	1.5 Hours
713.0-A21	A78	WEST	Area 77, Unit 2 Reactor Building	II-29A	3 Hours*

* See Note 4 on FPR Fig. II-28

Dampers:					
Room	Damper Mark Number	Dir.	Adjacent Area/Room	Drawing Reference	Damper Rating
713.0-A19	2-ISD-31-3871 47A381-403F	E-W	Area 8, Room 713.0-A1B	2-47W866-11 47W920-4	3 Hours
	2-ISD-31-3927 47A381-408F	E-W	Area 65, Room 713.0-A29	2-47W866-11 47W920-4	1.5 Hours

PART VI – FIRE HAZARDS ANALYSIS

Dampers:					
Room	Damper Mark Number	Dir.	Adjacent Area/Room	Drawing Reference	Damper Rating
	2-ISD-31-3970 47A381-331	N-S	Area 71-1, Room 713.0-A20	2-47W866-11 47W920-4	1.5 Hours
	2-ISD-31-3929 47A381-397F	F-C	Area 70, Room 692,0-A25	2-47W866-11 47W920-4	3 Hours

Detection: Ionization smoke detectors are provided in the Unit 2 Pipe Gallery, 713.0-A19 only.

Suppression: An automatic, preaction suppression system is provided in the Unit 2 Pipe Gallery, 713.0-A19 only. A standpipe and hose station is available from the adjacent room (713.0-A1).

Deviations: Intervening combustibles in the form of insulation on cables routed in cable trays are present, but are compensated for by an enhanced automatic preaction sprinkler system. Deviation has been reviewed/approved by NRC and is documented in Part VII, Section 2.4 of the FPR.

Evaluations: Justification for the lack of fire dampers in the containment purge air system return and exhaust air duct openings to the annulus is documented in Part VII, Section 3.2. The Unit 2 evaluation for performing a manual action in the room of fire origin is documented in Part VII, Section 8.4.1. The lack of total area suppression and detection is documented in Part VII, Section 3.1.

PART VI – FIRE HAZARDS ANALYSIS

3.77.2 Fire Area 71 Safe Shutdown Analysis by Analysis Volume

3.77.2.1 AV-110

Room No.	Description:
713.0-A19	Unit 2 Pipe Gallery
713.0-A21	Unit 2 Reactor Building Access Room

A fire in Analysis Volume 110 could potentially affect Unit 2 systems and components necessary to maintain the long term decay heat removal, containment HVAC, steam generator inventory control and reactor coolant inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Unit 1 major equipment required to maintain safe shutdown functions is not impacted such that shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Offsite power is available. The required mitigating features for Unit 2 include manual operation of equipment required for safe shutdown. These features and equipment credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.78 FIRE AREA 71-1

3.78.1 Room 713.0- A20

Description: Unit 2 Volume Control Tank (VCT) Room

Fire Loading: The combustibles located in the area consist of hydrogen in the VCT, lube oil associated with valves, plastics associated with electrical panels and lights, and anticipated quantities of radwaste trash and laundry. The fire severity classification is insignificant.

Compartmentation: The room is bounded by regulatory fire barriers constructed of reinforced concrete.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
713.0-A20	North Wall	Area 71, Room 713.0-A19	II-29A	2 Hours
	East Wall	Area 71, Room 713.0-A19	II-29A	2 Hours
	South Wall	Area 8, Room 713.0-A1B	II-29A	2 Hours
		Area 8, Room 713.0-A18	II-29A	2 Hours
	West Wall	Area 65, Room 713.0-A29	II-29A	2 Hours
	Floor	Area 65, Room 692.0-A24	II-28A, II-29A	2 Hours
		Area 70, Room 692.0-A25	II-28A, II-29A	2 Hours
	Ceiling	Area 74, Room 737.0-A9	II-29A, II-30A	2 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
713.0-A20	A76	SOUTH	Area 71-1, Room 713.0-A20	II-29A	1.5 Hours

Dampers:					
Room	Damper Mark Number	Dir.	Adjacent Area/Room	Drawing Reference	Damper Rating
713.0-A20	2-ISD-31-3870 47A381-401F	E-W	Area 71-1, Room 713.0-A29	47W920-4 47W866-11	1.5-Hours
	2-ISD-31-3970 47A381-331	N-S	Area 71, Room 713.0-A19	47W920-4 47W866-11	1.5-Hours

Detection: Ionization smoke detectors are provided in the room.

Suppression: An automatic, preaction suppression system is provided in the room (except in the entrance labyrinth). A standpipe and hose station is available from adjacent room (713.0-A1).

PART VI – FIRE HAZARDS ANALYSIS

Deviations: None

Evaluations: The fire damper in door A76 (Unit 2 VCT room) is the same configuration as door A63 (Unit 1 VCT room) which has been reviewed by NRC and documented in Part VII, Section 3.5 of the FPR. Refer to Part VII, Section 3.1 for the evaluation of the lack of full suppression. The Unit 2 evaluation for performing a manual action in the room of fire origin is documented in Part VII, Section 8.4.2.

PART VI – FIRE HAZARDS ANALYSIS

3.78.2 Fire Area 71-1 Safe Shutdown Analysis by Analysis Volume

3.78.2.1 AV-111

Room No.	Description:
713.0-A20	Unit 2 Volume Control Tank Room

A fire in Analysis Volume 111 could potentially affect Unit 2 systems and components necessary to maintain the reactor coolant inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Unit 1 major equipment required to maintain safe shutdown functions is not impacted such that shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Offsite power is available. The required mitigating features include manual operation of Unit 2 equipment required for safe shutdown. These features and equipment credited are identified below:

Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
737.0-A10	A130	WEST	Area 74, Room 737.0-A9	II-30A	3 Hours

Dampers: None

Detection: None.

PART VI – FIRE HAZARDS ANALYSIS

Suppression: Standpipe and hose stations are available from Room 737.0-A1B.

Deviations: The justification of compliance with III.G.1 with a FHA is in Part VII, Section 2.9.

Evaluations: The lack of total area suppression and detection is documented in Part VII, Section 3.1.

PART VI – FIRE HAZARDS ANALYSIS

3.79.2 Fire Area 72 Safe Shutdown Analysis by Analysis Volume

3.79.2.1 AV-113

Room No.	Description:
729.0-A11	Unit 2 South Main Steam Valve Room
737.0-A10	Air Lock

The in situ combustible loading for AV-113 consists of small quantities of lubricants in several valves and miscellaneous plastics associated with area radiation monitors, small electrical control panels and boxes, and lighting. The total combustible loading results in a fire severity classification of Insignificant (less than 1-minute). The area is designated a Combustible Control Zone which in conjunction with procedure NPG-SPP-18.4.7, Control of Transient Combustibles provides assurance that transient combustibles will not be introduced into the area without adequate compensatory measures. The valve motors are normally de-energized (power is only applied when an operator moves the valve from open to close (or close to open)); therefore, the valve motors are not considered an ignition source. The area radiation monitors are not considered a significant ignition source because they contain insignificant quantities of combustible material and their power supply is adequately protected with properly sized breakers/fuses. Procedure NPG-SPP-18.4.8, Control of Ignition Sources (Hot Work) ensures that ignition sources (e.g. cutting, welding, grinding) will not be introduced into the area without adequate compensatory measures. Since there are no concentrations of in situ combustibles and no credible ignition sources, it is concluded that there is no credible fire in the analysis volume that results in the loss of required fire safe shutdown (FSSD) components or other components that results in the necessity to shutdown either Unit 1 or Unit 2. Therefore, there is no impact to FSSD for this analysis volume. Operator Manual Actions (OMA's) are not required to mitigate fire in rooms 729.0-A11 or 737.0-A10 per deviation documented in Part VII, section 2.9.

PART VI – FIRE HAZARDS ANALYSIS

3.80 FIRE AREA 73

Fire Area 73 consists of several rooms within the Auxiliary Building associated with the Unit 2 North Main Steam Valve Room and the Unit 2 Additional Equipment Building.

3.80.1 Room 729.0- A10

Room No.	Description:
729.0-A10	Unit 2 North Main Steam Valve Room

Fire Loading: The combustibles located in the room consist of lube oil associated with valves and plastics associated with electrical panels and lights. The fire severity classification is insignificant.

Compartmentation: The room is bounded by regulatory fire barriers constructed of reinforced concrete.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
729.0-A10	SOUTH WALL	Area 77, Unit 2 Reactor Building	II-38A	3 Hours
		Area 73, Room 729.0-A13	II-38A	3 Hours
	WEST WALL	Area 73, Room 729.0-A13	II-38A	3 Hours

Doors: None

Dampers: None

Detection: None.

Suppression: Standpipe and hose stations are available from Room 729.0-A15.

Deviations: The justification of compliance with III.G.1 with a FHA is in Part VII, Section 2.9.

Evaluations: The lack of total area suppression and detection is documented in Part VII, Section 3.1.

3.80.2 Room 729.0- A13

Room No.	Description:
729.0-A13	Unit 2 North Main Steam Valve Instrument Room B

Fire Loading: The combustibles located in the room consist of plastics associated with electrical panels and lights. The fire severity classification is low.

Compartmentation: The room is bounded by regulatory fire barriers constructed of reinforced concrete.

PART VI – FIRE HAZARDS ANALYSIS

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
729.0-A13	NORTH WALL	Area 73, Room 729.0-A10	II-38A	3 Hours
	EAST WALL	Area 73, Room 729.0-A10	II-38A	3 Hours
	SOUTH WALL	Area 77, Unit 2 Reactor Building	II-38A	3 Hours
	CEILING	Area 73, Room 729.0-A10	II-38A	3 Hours

Doors: None.

Dampers: None

Detection: None.

Suppression: Standpipe and hose stations are available from the Unit 2 Additional Equipment Room Building 729.0-A15.

Deviations: The justification of compliance with III.G.1 with a FHA is in Part VII, Section 2.9.

Evaluations: The lack of total area suppression and detection is documented in Part VII, Section 3.1.

3.80.3 Room 729.5- A17

Room No.	Description:
729.5-A17	Unit 2 Shield Building Vent Radiation Monitoring Room

Fire Loading: The combustibles located in the room consist of lube oil associated with pumps and plastics associated with electrical panels and lights. The fire severity classification is insignificant.

Compartmentation: The room is bounded by regulatory fire barriers constructed of reinforced concrete.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
729.5-A17	SOUTH WALL	Area 77, Unit 2 Reactor Building	II-38A	3 Hours

Doors: None

Dampers: None

Detection: None.

Suppression: Standpipe and hose stations are available from the Unit 2 Additional Equipment Building 729.0-A15.

PART VI – FIRE HAZARDS ANALYSIS

Deviations: None

Evaluations: The lack of total area suppression and detection is documented in Part VII, Section 3.1.

3.80.4 Unit 2 Additional Equipment Building

Description: Unit 2 Additional Equipment Building (Rooms 729.0-A15, 737.0-A14, and 763.5-A2).

Fire Loading: The combustibles located in the rooms consist of lube oil and hydraulic fluid associated with valves, pumps and motors, and plastics associated with electrical panels and lights. The fire severity classification for room 737.0-A14 is insignificant and rooms 729.0-A15 and 763.5-A2 is low.

Compartmentation: The room is bounded by regulatory fire barriers constructed of reinforced concrete.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
UHI BLDG. (ALL ELEV.)	EAST WALL	Area 77, Unit 2 Reactor Building	II-38A	3 Hours
	SOUTH WALL	Area 10, Room 729.0-A9	II-30A, II-38A	3 Hours
		Area 74, Room 737.0-A9	II-30A, II-38A	3 Hours
		Area 73, Room 737.0-A14	II-30A, II-38A	3 Hours
		Area 75, Room 757.0-A14	II-31A, II-38A	3 Hours
		Area 75, Room 782.0-A4	II-32A, II-38A	3 Hours
	WEST WALL	Area 10, Room 729.0-A6	II-30A, II-38A	3 Hours
		Area 10, Room 741.5	II-38A	3 Hours
		Area 10, Room 757.0-A13	II-31A, II-38A	3 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
737.0-A14	A192	SOUTH	Area 74, Room 737.0-A9	II-30A	3 Hours

Dampers:					
Room	Damper Mark Number	Dir.	Adjacent Area/Room	Drawing Reference	Damper Rating
763.5-A2	2-ISD-31-2990 47A381-528F	E-W	Area 10, Room 757.0A13	47W920-7 47W866-8	3 Hours

Detection: Ionization smoke detectors are provided in the building on the 729.0 and 763.5 elevations. There are no detectors in room 737.0-A14.

PART VI – FIRE HAZARDS ANALYSIS

Suppression: Standpipe and hose stations are available in Room 729.0-A15.

Deviations: The justification of compliance with III.G.1 with a FHA for rooms 729.0-A15 and 763.5-A2 is in Part VII, Section 2.9.

Evaluations: None.

PART VI – FIRE HAZARDS ANALYSIS

3.80.5 Fire Area 73 Safe Shutdown Analysis by Analysis Volume

3.80.5.1 AV-112

Room No.	Description:
729.0-A13	Unit 2 North Main Steam Valve Instrument Room B
729.5-A17	Unit 2 Shield Building Vent Radiation Monitoring Room
729.0-A15	Unit 2 Additional Equipment Building
737.0-A14	Air Lock
763.5-A2	Unit 2 Additional Equipment Building

A fire in Analysis Volume 112 could potentially affect systems and components necessary to maintain the Unit 2 steam generator inventory control and secondary side isolation functions. The Appendix R required circuits that route through room 729.5-A17 are all routed in conduits that are embedded in the floor and are not affected by a postulated fire in the room; therefore, a fire in this room does not affect any required FSSD function. Operator Manual Actions (OMA's) are not required to mitigate fire in rooms 729.0-A13, 729.0-A15 or 763.5-A2 per deviation documented in Part VII, section 2.9.

Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Unit 1 major equipment required to maintain safe shutdown functions is not impacted such that shutdown can be achieved by utilizing both Train A and B system components. Offsite power is available. Safe shutdown for both units can be achieved without mitigating actions. These features and equipment credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.80.5.2 AV-112A

Room No.	Description:
729.0-A10	Unit 2 North Main Steam Valve Room

The in situ combustible loading for AV-112A consists of small quantities of lubricants in several valves and miscellaneous plastics associated with area radiation monitors, small electrical control panels and boxes, and lighting. The total combustible loading results in a fire severity classification of Insignificant. The area is designated a Combustible Control Zone which in conjunction with procedure NPG-SPP-18.4.7, Control of Transient Combustibles provides assurance that transient combustibles will not be introduced into the area without adequate compensatory measures. The valve motors are normally de-energized (power is only applied when an operator moves the valve from open to close (or close to open)); therefore, the valve motors are not considered an ignition source. The area radiation monitors are not considered a significant ignition source because they contain insignificant quantities of combustible material and their power supply is adequately protected with properly sized breakers/fuses. Procedure NPG-SPP-18.4.8, Control of Ignition Sources (Hot Work) ensures that ignition sources (e.g. cutting, welding, grinding) will not be introduced into the area without adequate compensatory measures. Since there are no concentrations of in situ combustibles and no credible ignition sources, it is concluded that there is no credible fire in the analysis volume that results in the loss of required fire safe shutdown (FSSD) components or other components that results in the necessity to shutdown either Unit 1 or Unit 2. Therefore, there is no impact to FSSD for this analysis volume. Operator Manual Actions (OMA's) are not required to mitigate fire in room 729.0-A10 per deviation documented in Part VII, section 2.9.

PART VI – FIRE HAZARDS ANALYSIS

3.81 FIRE AREA 74

3.81.1 Rooms 737.0-A9 and –A16

Room No.	Description:
737.0-A9	Unit 2 Ventilation and Purge Air Room (Subdivided into 737.0-A9S, -A9M, -A9N)
737.0-A16	Unit 2 Gross Failed Fuel Detector Room

Fire Loading: The combustibles in the rooms consist of lube oil in valves and plastic associated with electrical panels and lights. The fire severity classification for room 737.0-A9 is low and for room 737.0-A16 is insignificant.

Compartmentation: The area is enclosed by regulatory fire barriers constructed of reinforced concrete. Room 737.0-A16 is within Room 737.0-A9.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
737.0-A9	North Wall	Area 73, Room 729.0-A15	II-30A, II-38A	3 Hours

	2-ISD-31-3876 47A381-409F	N-S	Area 65, Room 713.0-A29	47W920-5 47W866-11	1.5-Hours
	2-ISD-31-3875 47A381-432F	N-S	Area 65, Room 713.0-A29	47W920-23 47W866-11	1.5-Hours
	2-ISD-31-3883 47A381-405F	F-C	Area 75, Room 737.0-A14	47W920-23 47W866-11	3-Hours

Detection: Ionization smoke detectors are provided in the area (see note below).

Suppression: Automatic preaction sprinkler system is provided in the area (see note below). Standpipe and hose stations are available from adjacent room (737.0-A1).

Note: Room 737.0-A16 is a small room inside room 737.0-A9 (see FPR Figure II-30A) and is of reinforced masonry construction. There are no detectors inside the room, but there is a sprinkler head. This sprinkler head is on the same suppression system piping that protects room 737.0-A9 and is activated by the detection system in 737.0-A9. This small room has an insignificant amount of combustibles and has no safe shutdown equipment or cables.

Deviations: HVAC ducts (spiral wound pipe ducts) penetrate two of the required fire barriers, but are not provided with fire dampers. The justification for these undampened HVAC penetrations is documented in Part VII, Section 2.6 of the FPR.

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.15, 16, 17, 63 and 64.

PART VI – FIRE HAZARDS ANALYSIS

3.81.2 Fire Area 74 Safe Shutdown Analysis by Analysis Volume

3.81.2.1 AV-114

Room No.	Description:
737.0-A9	Unit 2 Ventilation and Purge Air Room
737.0-A16	Unit 2 Gross Failed Fuel Detector Room

AV-114 is a large area and is divided into three analysis volumes AV-114M, AV-114N and AV-114S.

3.81.2.2 AV-114M

Room No.	Description:
737.0-A9M	Middle portion of the room extending from 2 feet north of column line V to 2'-6"
737.0-A16	south of the Unit 2 Reactor Building center line.

A fire in Analysis Volume 114M could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control functions and Unit 2 secondary side isolation and reactor coolant inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include providing fire wrap for selected Unit 2 cables and manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.81.2.4 AV-114S

Room No.	Description:
737.0-A9S	South portion of room 737.0-A9 extending from column line U to column line W.

A fire in Analysis Volume AV-114S could potentially affect systems and components necessary to maintain the Unit 1 and Unit 2 steam generator inventory control and Unit 2 reactor coolant pressure control, containment HVAC, secondary side isolation, long term decay heat removal and reactor coolant inventory control functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features include providing fire wrap to selected Unit 2 cables to preclude damage in the event of a fire and manual operation of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.82 FIRE AREA 75

3.82.1 Rooms 757.0-A14 and -A16 and 782.0-A3 and -A4

Room No.	Description:
757.0-A14	Unit 2 Reactor Building Access Room
757.0-A16	Emergency Gas Treatment Filter Room
782.0-A3	Unit 2 Control Rod Drive Equipment Room
782.0-A4	Pressurizer Heater Transformer Room 2

Fire Loading: The combustibles in the rooms consist of plastics associated with electrical transformers, panels and lights, oil in the transformers, charcoal in filter housings and insulation on cables in trays. The fire severity classification for rooms 757.0-A14 and 782.0-A3 is low. The fire severity classification for the other two rooms is moderate.

Compartmentation: The area is enclosed by regulatory fire barriers constructed of reinforced concrete. The floor slab separating Room 782.0-A3 from Room 757.0-A16 has an equipment hatch that is covered with a non-fire rated steel cover, two HVAC ducts without fire dampers, and a stairway entry enclosure that is a non-regulatory 2-hour rated fire barrier. The floor slab separating Room 782.0-A4 from Room 757.0-A14 also has a stairway entry enclosure that is a non-regulatory 2-hour rated fire barrier.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating

PART VI – FIRE HAZARDS ANALYSIS

Dampers:					
Room	Damper Mark Number	Dir.	Adjacent Area/Room	Drawing Reference	Damper Rating
782.0-A3	2-ISD-31-3239 47A381-256F	E-W	Area 10, Room 757.0-A13	47W920-9 47W866-11	3-Hours
	2-ISD-31-3240 47A381-253	E-W	Area 10, Room 757.0-A13	47W920-10 47W866-11	1.5-Hours

Detection: Ionization smoke detectors are provided in all four of the rooms.

Suppression: Automatic preaction sprinkler systems are provided in all four of the rooms. A standpipe and hose station is available from Rooms 782.0-A3 and 757.0-A16

Deviations: Intervening combustibles are present in all four rooms. The justification for intervening combustibles such as insulation on cables in trays and Thermo-Lag is documented in Part VII, Section 2.4. The justification of compliance with III.G.1 with a FHA for room 757.0-A14 is in Part VII, Section 2.9.

Evaluations: The feasibility and reliability evaluations for Unit 2 Operator Manual Actions are documented in Part VII, Sections 8.3.26, 53, 54, 63 and 64.

PART VI – FIRE HAZARDS ANALYSIS

3.82.2 Fire Area 75 Safe Shutdown Analysis by Analysis Volume

3.82.2.1 AV-115

Room No.	Description:
757.0-A16	Emergency Gas Treatment Filter Room
782.0-A3	Unit 2 Control Rod Drive Equipment Room
782.0-A4	Pressurizer Heater Transformer Room 2

A fire in Analysis Volume AV-115 could potentially affect systems and components necessary to maintain the Unit 1 steam generator inventory control and containment HVAC functions and Unit 2 steam generator inventory control, long term decay heat removal, containment HVAC, reactor coolant inventory control, reactor pressure control, containment integrity and secondary side isolation functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Offsite power is available. The required mitigating features for Unit 1 and Unit 2 include manual operation of equipment required for safe shutdown. These features and equipment credited are identified below:

PART VI – FIRE HAZARDS ANALYSIS

3.82.2.2 AV-116

Room No.	Description:
757.0-A14	Unit 2 Reactor Building Access Room

The in situ combustible loading for AV-116 consists of insulation on cables routed in two cable trays (accounts for 96% of the total combustibles in the room), small quantities of plastics associated with lighting units, control and junction boxes, and the fire hose. The total combustible loading results in a fire severity classification of Low. The lighting units, control and junction boxes are not credible ignition sources (electrical power to these devices is low voltage (120VAC) and these circuits are properly protected with fuses/breakers). The room is provided with automatic detection and suppression. NPG-SPP-18.4.7, Control of Transient Combustibles, and NPG-SPP-18.4.8, Control of Ignition Sources (Hot Work) provide assurances that transient combustibles and ignition sources (cutting, grinding, welding, etc.) will not be introduced into the room without adequate compensatory measures. Since there are no concentration of combustibles other than the cables in the trays and no credible ignition sources, it is concluded that the only damage from a postulated fire from a lighting unit, control or junction box would be to that individual device. Therefore, it is concluded that no credible fire in this room could result in damage to equipment that would require an emergency shutdown of either unit. Any postulated fire would be quickly detected by the area wide smoke detection system and the plant would quickly respond in accordance with normal plant procedure for a fire (0-AOI-30.1 - Part II, Reference 4.2.89). Since there is no impact to fire safe shutdown Operator Manual Actions (OMA's) are not required to mitigate fire in room 757.0-A14 per deviation documented in Part VII, Section 2.9.

PART VI – FIRE HAZARDS ANALYSIS

3.83 Fire Area 76

3.83.1 Room 757.0-A15

Description: Unit 2 Reactor Building Equipment Hatch

Fire Loading: The combustibles in the room consist of plastics associated with the lights and insulation on cables in trays. The fire severity classification is low.

Compartmentation: The room is of reinforced concrete construction with a fire resistive rating of 3-hours. During power operations the opening to Room 757.0-A13 is closed with concrete plugs that provide an equivalent fire resistive rating of 3-hours.

Barriers:				
Room	Direction	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
757.0-A15	North Wall	Area 10, Room 757.0-A13	II-31A	3 Hours
		Area 75, Room 757.0-A14	II-31A	3 Hours
	South Wall	Area 10, Room 757.0-A13	II-31A	3 Hours
		Area 75, Room 757.0-A16	II-31A	3 Hours
	West Wall	Area 10, Room 757.0-A13	II-31A	3 Hours
	Floor	Area 14, Room 737.0-A1C	II-30A, II-31A	3 Hours
		Area 74, Room 737.0-A9	II-30A, II-31A	3 Hours
		Area 74, Room 737.0-A9	II-30A, II-31A	3 Hours
	Ceiling	Area 75, Room 782.0-A3	II-31A, II-32A	3 Hours
		Area 75, Room 782.0-A4	II-31A, II-32A	3 Hours

Doors: None.

Dampers: None.

Detection: Ionization smoke detectors are provided in the room.

Suppression: Automatic preaction sprinkler system is provided in the room. Standpipe and hose stations are available from the adjacent room (757.0-A13) when the plugs are removed (i.e., during outages). This room is not accessible during power operations.

Deviations: The justification for intervening combustibles such as insulation on cables in trays and Thermo-Lag is documented in Part VII, Section 2.4. The justification of compliance with III.G.1 with a FHA is in Part VII, Section 2.9.

Evaluations: The justification for the relaxation in surveillance frequency for the sprinklers, smoke detectors and penetrations seals is documented in Part VII, Section 6.1.

PART VI – FIRE HAZARDS ANALYSIS

3.83.2 Fire Area 76 Safe Shutdown Analysis by Analysis Volume

3.83.2.1 AV-096

Room No.	Description:
757.0-A15	Unit 2 Reactor Building Equipment Hatch

The in situ combustible loading for AV-96 consists of insulation on cables routed in cable trays (accounts for 99% of the total combustibles in the room) and small quantities of plastics associated with lighting units,. The total combustible loading results in a fire severity classification of Low. The lighting units are not credible ignition sources and the room is provided with automatic detection and suppression. NPG-SPP-18.4.7, Control of Transient Combustibles, and NPG-SPP-18.4.8, Control of Ignition Sources (Hot Work) provide assurances that transient combustibles and ignition sources (cutting, grinding, welding, etc.) will not be introduced into the room without adequate compensatory measures. Since there are no concentration of combustibles other than the cables in the trays and no credible ignition sources, it is concluded that the only damage from a postulated fire from a lighting unit would be to that individual device. Therefore, it is concluded that no credible fire in this room could result in damage to equipment that would require an emergency shutdown of either unit. Any postulated fire would be quickly detected by the smoke detection system and the plant would quickly respond in accordance with normal plant procedure for a fire (0-AOI-30.1 - Part II, Reference 4.2.89). Since there is no impact to fire safe shutdown (FSSD), Operator Manual Actions (OMA's) are not required to mitigate fire in room 757.0-A15 per deviation documented in Part VII, section 2.9.

PART VI – FIRE HAZARDS ANALYSIS

3.84 FIRE AREA 77

3.84.1 Unit 2 Reactor Building Annulus

Description: Unit 2 Annulus.

Fire Loading: The combustible loading consists of foam plastic insulation, plastics associated with electrical panels and boxes, rubber expansion joints and insulation on cables routed in trays. The fire severity classification is severe.

Compartmentation: The Annulus is separated from Primary Containment by the Steel Containment Vessel which prevents the passage of flames, smoke and hot gases, but allows heat transfer. The Annulus is separated from the Auxiliary Building fire areas by reinforced concrete that provides a minimum fire resistance of 3-hours.

Barriers:			
Room	Adjacent Area/Room	FPR Figure Reference	Regulatory Barrier Rating
Unit 2 Annulus	Area 10, Room 729.0-A9	II-38A	3 Hours
	Area 65, Room 713.0-A29	II-29A	3 Hours
	Area 70, Room 692.0-A25	II-28A	3 Hours
	Area 71, Room 713.0-A19	II-29A	3 Hours
	Area 71, Room 713.0-A21	II-29A	3 Hours

	Area 73, Room 729.0-A15	II-38A	3 Hours
	Area 73, Room 763.5-A2	II-38A	3 Hours
	Area 74, Room 737.0-A9 (S, M & N)	II-30A	3 Hours
	Area 75, Room 757.0-A14	II-31A	3 Hours
	Area 75, Room 757.0-A16	II-31A	3 Hours
	Area 75, Room 782.0-A3	II-32A	3 Hours
	Area 75, Room 782.0-A4	II-32A	3 Hours

Doors:					
Room	Door Number	Direction	Adjacent Area/Room	FPR Figure Reference	Door Rating
Unit 2 Annulus	A78	EAST	Area 71, Room 713.0-A21	II-29A	3 Hours*

* See Note 4 on FPR Fig. II-28A

Dampers: None.

Detection: Photoelectric smoke detectors are provided for selected portions of the cable tray system in the Unit 2 Annulus.

Suppression: Automatic preaction sprinkler system is provided for selected portions of the cable tray system in the Unit 2 Annulus.

PART VI – FIRE HAZARDS ANALYSIS

Deviations: The justification for the radiant energy shield not meeting the ASTM E136 non-combustibility criteria is documented in Part VII, Section 2.2. The use of portable lanterns in lieu of fixed 8-hour battery powered lights inside the Reactor Building is documented in Part VII, Section 2.7 of the FPR.

Evaluations: The use of fire barrier wrap on the Purge Air System return and exhaust air ducts in lieu of fire damper in the openings that separate the Annulus for the Auxiliary Building is documented in Part VII, Section 3.2 of the FPR. The justification for the in situ combustible load in the Unit 2 Annulus is provided in Part VII, Section 3.6. The feasibility and reliability evaluation for Unit 2 operator manual actions is documented in Part VII, Section 8.3.7.

3.84.2 Unit 2 Reactor Building Primary Containment

Description: Primary Containment (Subdivided into 2RO-1, 2RO-2, 2RO-3, 2RO-4, 2RI-1, 2RI-2, 2RI-3, 2RI-4, 2RIR, 2RA1, 2RA2, 2RA3, 2RA4, 2RF1, 2RF2, 2RU)

Fire Loading: The combustibles loading consists of foam plastic insulation, plastic associated with electrical panels and boxes, rubber expansion joints, lube oil in pumps, motors and valves, insulation on cables in trays and wood (used only for insulation and framing of the ice condenser intermediate deck end wall doors). The fire severity for individual areas, range from a classification of insignificant to moderate.

Compartmentation: The Primary Containment is separated from the Annulus by the Steel Containment Vessel which prevents the passage of flames, smoke and hot gases, but allows radiant heat transfer.

Barriers: None.

Room	Door Number	Direction	Doors:		FPR Figure Reference	Door Rating
			Adjacent Area/Room			
PRIMARY	A166	WEST	Area 75, Room 757-A14		II-31A	3 HR AC
CONTAINMENT	A167	WEST	Area 75, Room 757-A14		II-31A	3 HR AC

Dampers: None.

Detection: Ionization smoke detectors are provided in the upper and lower compartment cooler units. Heat detectors are provided over the Reactor Coolant Pumps.

Suppression: Automatic fixed water spray systems are provided for each Reactor Coolant Pump. Standpipes and hose stations are provided inside containment.

Deviations: The use of portable lanterns in lieu of fixed 8-hour battery powered lights inside the Reactor Building is documented in Part VII, Section 2.7 of the FPR. The allowance for minor amounts of oil that could escape the oil collection system is documented in Part VII, Section 2.8 of the FPR. The justification of compliance to III.G.A with a FHA is documented in Part VII, Section 2.9.

Evaluations: None

PART VI – FIRE HAZARDS ANALYSIS

3.84.3 Fire Area 77 Safe Shutdown Analysis By Analysis Volume

3.84.3.1 AV-117

Room No.	Description:
2ANN	Unit 2 Annulus

A fire in Analysis Volume 117 could potentially affect systems and components necessary to maintain the Unit 2 steam generator inventory control functions and Unit 2 long term decay heat removal, containment HVAC, reactor coolant inventory control, reactor pressure control, containment integrity functions. Mitigating features are required to restore systems necessary for safe shutdown. Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below as credited. Unit 1 major equipment required to maintain safe shutdown functions is not impacted such that shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Offsite power is available. The required mitigating features include providing smoke detectors, automatic fire suppression, non-combustible radiant energy shields to protect redundant Unit 2 safe shutdown cables in the event of a fire and manual operations of Unit 1 and Unit 2 equipment required for safe shutdown. These features and equipment credited are identified below. Since compliance in this area utilizes options III.G.2.d, e, and/or f, the equipment train which is affected or credited for containment cooling, primary system depressurization during cooldown and RHR cooldown is determined subsequent to firefighting activities by the location of the fire. Adequate time is available to make this determination since the earliest safe shutdown requirement for these functions is approximately 2 hours when containment cooling must be established.

PART VI – FIRE HAZARDS ANALYSIS

3.84.3.2 AV-118A

Room No.	Description:
2RA2	Unit 2 Accumulator Room 2
2RF2	Unit 2 Fan Room 2
2RO-2	Outside Unit 2 Crane Wall (90° - 180°)
2RO-3	Outside Unit 2 Crane Wall (180° - 270°)

The in situ combustible loading for AV-118A consists of small quantities of lubricants in several valves (accounts for 89% of combustible load in 2RA2 and 39% in 2RF2) and miscellaneous plastics associated with small electrical control panels and boxes, and lighting. The cables to these devices are routed in conduit. The rooms designated 2RO-2 and 2RO-3 contain a rubberized joint sealant material used in the building joints that constitutes 90% of the combustible load. The total combustible loading in each room (not counting the joint sealant material) results in a fire severity classification of Insignificant (less than 1-minute) for each room. Access to the areas inside the Unit 2 Reactor Building is strictly controlled which, in conjunction with procedure NPG-SPP-18.4.7, Control of Transient Combustibles, provides assurance that transient combustibles will not be introduced into the area without adequate compensatory measures. Cables routed in conduit and lubricants in the valves/motors are not exposed; therefore, their contribution to a postulated fire is greatly reduced. The valve motors are normally de-energized (power is only applied when an operator moves the valve from open to close (or close to open); therefore, the valve motors are not considered an ignition source. The fan motor are not considered a significant ignition source because the fan housing contain insignificant quantities of combustible material and the power supply circuits to the fan motors are adequately protected with properly sized breakers/fuses. Procedure NPG-SPP-18.4.8, Control of Ignition Sources (Hot Work) ensures that ignition sources (e.g. cutting, welding, grinding) will not be introduced into the area without adequate compensatory measures. Since there are no concentrations of in situ combustibles and no credible ignition sources, it is concluded that there is no credible fire in the analysis volume that results in the loss of required fire safe shutdown (FSSD) components or other components that results in the necessity to shutdown either Unit 1 or Unit 2. Therefore, there is no impact to FSSD for this analysis volume. Operator Manual Actions (OMA's) are not required to mitigate fire in rooms 2RA2, 2RF2, 2RO-2 OR 2RO-3 per deviation documented in Part VII, section 2.9.

PART VI – FIRE HAZARDS ANALYSIS

3.84.3.3 AV-118B

Room No.	Description:
2RA3	Unit 2 Accumulator Room 3
2RF2	Unit 2 Fan Room 2
2RO-2	Outside Unit 2 Crane Wall (90° - 180°)
2RO-3	Outside Unit 2 Crane Wall (180° - 270°)

The in situ combustible loading for AV-118B consists of small quantities of lubricants in several valves (accounts for 88% of the combustible load in 2RA3 and 39% in 2RF2) and miscellaneous plastics associated with small electrical control panels and boxes, and lighting. The cables to these devices are routed in conduit. The rooms designated 2RO-2 and 2RO-3 contain a rubberized joint sealant material used in the building joints that constitutes 90% of their combustible load. The total combustible loading in each room (not counting the joint sealant material) results in a fire severity classification of Insignificant (less than 1-minute) for each room. Access to the areas inside the Unit 2 Reactor Building is strictly controlled which, in conjunction with procedure NPG-SPP-18.4.7, Control of Transient Combustibles, provides assurance that transient combustibles will not be introduced into the area without adequate compensatory measures. Cables routed in conduit and lubricants in the valves/motors are not exposed; therefore, their contribution to a postulated fire is greatly reduced. The valve motors are normally de-energized (power is only applied when an operator moves the valve from open to close (or close to open)); therefore, the valve motors are not considered an ignition source. The fan motor are not considered a significant ignition source because the fan housing contain insignificant quantities of combustible material and the power supply circuits to the fan motors are adequately protected with properly sized breakers/fuses. Procedure NPG-SPP-18.4.8, Control of Ignition Sources (Hot Work) ensures that ignition sources (e.g. cutting, welding, grinding) will not be introduced into the area without adequate compensatory measures. Since there are no concentrations of in situ combustibles and no credible ignition sources, it is concluded that there is no credible fire in the analysis volume that results in the loss of required fire safe shutdown (FSSD) components or other components that results in the necessity to shutdown either Unit 1 or Unit 2. Therefore, there is no impact to FSSD for this analysis volume. Operator Manual Actions (OMA's) are not required to mitigate fire in rooms 2RA2, 2RF2, 2RO-2 OR 2RO-3 per deviation documented in Part VII, section 2.9.

PART VI – FIRE HAZARDS ANALYSIS

3.84.3.4

AV-118C

Room No.	Description:
2RA3	Unit 2 Accumulator Room 3
2RA4	Unit 2 Accumulator Room 4
2RO-3	Outside Unit 2 Crane Wall (180° - 270°)
2RO-4	Outside Unit 2 Crane Wall (270° - 360°)

The in situ combustible loading for AV-118C consists of small quantities of lubricants in several valves (accounts for 88% of the combustible load in 2RA3 and 82% in 2RA4) and miscellaneous plastics associated with small electrical control panels and boxes, and lighting. The cables to these devices are routed in conduit. The rooms designated 2RO-3 and 2RO-4 contain a rubberized joint sealant material used in the building joints that constitutes 90% of their combustible load. The total combustible loading in each room (not counting the joint sealant material) results in a fire severity classification of Insignificant (less than 1-minute) for each room. Access to the areas inside the Unit 2 Reactor Building is strictly controlled which, in conjunction with procedure NPG-SPP-18.4.7, Control of Transient Combustibles, provides assurance that transient combustibles will not be introduced into the area without adequate compensatory measures. Cables routed in conduit and lubricants in the valves/motors are not exposed; therefore, their contribution to a postulated fire is greatly reduced. The valve motors are normally de-energized (power is only applied when an operator moves the valve from open to close (or close to open)); therefore, the valve motors are not considered an ignition source. The fan motor are not considered a significant ignition source because the fan housing contain insignificant quantities of combustible material and the power supply circuits to the fan motors are adequately protected with properly sized breakers/fuses. Procedure NPG-SPP-18.4.8, Control of Ignition Sources (Hot Work) ensures that ignition sources (e.g. cutting, welding, grinding) will not be introduced into the area without adequate compensatory measures. Since there are no concentrations of in situ combustibles and no credible ignition sources, it is concluded that there is no credible fire in the analysis volume that results in the loss of required fire safe shutdown (FSSD) components or other components that results in the necessity to shutdown either Unit 1 or Unit 2. Therefore, there is no impact to FSSD for this analysis volume. Operator Manual Actions (OMA's) are not required to mitigate fire in rooms 2RA3, 2RA4, 2RO-3 OR 2RO-4 per deviation documented in Part VII, section 2.9.

PART VI – FIRE HAZARDS ANALYSIS

3.84.3.5 AV-118D

Room No.	Description:
2RF1	Unit 2 Fan Room 1
2RA4	Unit 2 Accumulator Room 4
2RO-1	Outside Unit 2 Crane Wall (0° - 90°)
2RO-4	Outside Unit 2 Crane Wall (270° - 360°)

The in situ combustible loading for AV-118D consists of small quantities of lubricants in several valves (accounts for 82% of the combustible load in 2RA4 and 51% in 2RF1) and miscellaneous plastics associated with small electrical control panels and boxes, and lighting. The cables to these devices are routed in conduit. The rooms designated 2RO-1 and 2RO-4 contain a rubberized joint sealant material used in the building joints that constitutes 90% of their combustible load. The total combustible loading in each room (not counting the joint sealant material) results in a fire severity classification of Insignificant (less than 1-minute) for each room. Access to the areas inside the Unit 2 Reactor Building is strictly controlled which, in conjunction with procedure NPG-SPP-18.4.7, Control of Transient Combustibles, provides assurance that transient combustibles will not be introduced into the area without adequate compensatory measures. Cables routed in conduit and lubricants in the valves/motors are not exposed; therefore, their contribution to a postulated fire is greatly reduced. The valve motors are normally de-energized (power is only applied when an operator moves the valve from open to close (or close to open)); therefore, the valve motors are not considered an ignition source. The fan motor are not considered a significant ignition source because the fan housing contain insignificant quantities of combustible material and the power supply circuits to the fan motors are adequately protected with properly sized breakers/fuses. Procedure NPG-SPP-18.4.8, Control of Ignition Sources (Hot Work) ensures that ignition sources (e.g. cutting, welding, grinding) will not be introduced into the area without adequate compensatory measures. Since there are no concentrations of in situ combustibles and no credible ignition sources, it is concluded that there is no credible fire in the analysis volume that results in the loss of required fire safe shutdown (FSSD) components or other components that results in the necessity to shutdown either Unit 1 or Unit 2. Therefore, there is no impact to FSSD for this analysis volume. Operator Manual Actions (OMA's) are not required to mitigate fire in rooms 2RF1, 2RA4, 2RO-1 OR 2RO-4 per deviation documented in Part VII, section 2.9.

PART VI – FIRE HAZARDS ANALYSIS

3.84.3.6 AV-118E

Room No.	Description:
2RA1	Unit 2 Accumulator Room 1
2RF1	Unit 2 Fan Room 1
2RO-1	Outside Unit 2 Crane Wall (0° - 90°)
2RO-4	Outside Unit 2 Crane Wall (270° - 360°)

The in situ combustible loading for AV-118E consists of small quantities of lubricants in several valves (accounts for 61% of the combustible load in 2RA1 and 51% in 2RF1) and miscellaneous plastics associated with small electrical control panels and boxes, and lighting. The cables to these devices are routed in conduit. The rooms designated 2RO-1 and 2RO-4 contain a rubberized joint sealant material used in the building joints that constitutes 90% of the calculated combustible load. The total combustible loading in each room (not counting the joint sealant material) results in a fire severity classification of Insignificant (less than 1-minute) for each room. Access to the areas inside the Unit 2 Reactor Building is strictly controlled which, in conjunction with procedure NPG-SPP-18.4.7, Control of Transient Combustibles, provides assurance that transient combustibles will not be introduced into the area without adequate compensatory measures. Cables routed in conduit and lubricants in the valves/motors are not exposed; therefore, their contribution to a postulated fire is greatly reduced. The valve motors are normally de-energized (power is only applied when an operator moves the valve from open to close (or close to open)); therefore, the valve motors are not considered an ignition source. The fan motors are not considered a significant ignition source because the fan housings contain insignificant quantities of combustible material and the power supply circuits to the fan motors are adequately protected with properly sized breakers/fuses. Procedure NPG-SPP-18.4.8, Control of Ignition Sources (Hot Work) ensures that ignition sources (e.g. cutting, welding, grinding) will not be introduced into the area without adequate compensatory measures. Since there are no concentrations of in situ combustibles and no credible ignition sources, it is concluded that there is no credible fire in the analysis volume that results in the loss of required fire safe shutdown (FSSD) components or other components that results in the necessity to shutdown either Unit 1 or Unit 2. Therefore, there is no impact to FSSD for this analysis volume. Operator Manual Actions (OMA's) are not required to mitigate fire in rooms 2RA1, 2RF1, 2RO-1 OR 2RO-4 per deviation documented in Part VII, section 2.9.

PART VI – FIRE HAZARDS ANALYSIS

3.84.3.7 AV-118F

Room No.	Description:
Unit 2 Reactor Building 2RIR	Lower Containment Unit 2 Instrument Room

The in situ combustible loading for AV-118F consists of small quantities of lubricants in several small pumps (2RO-1 and -2 only) and miscellaneous plastics associated with small electrical control panels and boxes, and lighting. The cables for these devices are routed in conduit. The rooms designated 2RO-1 and 2RO-2 contain a rubberized joint sealant material used in the building joints that constitutes 90% of their combustible load. The total combustible loading in each room (not counting the joint sealant material) results in a fire severity classification of Insignificant (2RIR less than 2-minutes, 2RO-1 and 2 less than 1-minute). Access to the areas inside the Unit 2 Reactor Building is strictly controlled which, in conjunction with procedure NPG-SPP-18.4.7, Control of Transient Combustibles, provides assurance that transient combustibles will not be introduced into the area without adequate compensatory measures. The power supply circuits to the pump motors are adequately protected with properly sized breakers/fuses. Procedure NPG-SPP-18.4.8, Control of Ignition Sources (Hot Work) ensures that ignition sources (e.g. cutting, welding, grinding) will not be introduced into the area without adequate compensatory measures. Since there are no concentrations of in situ combustibles and no credible ignition sources, it is concluded that there is no credible fire in the analysis volume that results in the loss of required fire safe shutdown (FSSD) components or other components that results in the necessity to shutdown either Unit 1 or Unit 2. Therefore, there is no impact to FSSD for this analysis volume. Operator Manual Actions (OMA's) are not required to mitigate fire in room 2RIR per deviation documented in Part VII, section 2.9.

PART VI – FIRE HAZARDS ANALYSIS

3.84.3.9 AV-118H

Room No.	Description:
2RA2	Unit 2 Accumulator Room 2
2RF2	Unit 2 Fan Room 2
2RI-2	Inside Unit 2 Crane Wall (90° - 180°)
2RI-3	Inside Unit 2 Crane Wall (180° - 270°)

The in situ combustible loading for AV-118H consists of small quantities of lubricants in several valves and fan motors (accounts for 89% of combustible load in 2RA2 and 39% in 2RF2) and miscellaneous plastics associated with small electrical control panels and boxes, and lighting. The cables to these devices are routed in conduit. The zones designated 2RI-2 and 2RI-3 each contain a reactor coolant pump (RCP) that constitutes 98% and 97%, respectively of the combustible load and several valves. Each RCP is provided with an oil collection system that complies with Appendix R, Section III.O and is protected with an automatic suppression and detection system. The total combustible loading in rooms 2RA2 and 2RF2 results in a fire severity classification of Insignificant (less than 1-minute) for each room. Zones 2RI-2 and 2RI-3 have combustible loading that results in a fire severity classification of Low when including the RCP oil, but is Insignificant (less than 1-minute) not counting the oil. Access to the areas inside the Unit 2 Reactor Building is strictly controlled which, in conjunction with procedure NPG-SPP-18.4.7, Control of Transient Combustibles, provides assurance that transient combustibles will not be introduced into the area without adequate compensatory measures. Cables routed in conduit and lubricants in the valves/motors are not exposed; therefore, their contribution to a postulated fire is greatly reduced. The valve motors are normally de-energized (power is only applied when an operator moves the valve from open to close (or close to open)); therefore, the valve motors are not considered an ignition source. The fan motors are not considered a significant ignition source because the fan housings contain insignificant quantities of combustible material and the power supply circuits to the fan motors are adequately protected with properly sized breakers/fuses. Procedure NPG-SPP-18.4.8, Control of Ignition Sources (Hot Work) ensures that ignition sources (e.g. cutting, welding, grinding) will not be introduced into the area without adequate compensatory measures. Since there are no concentrations of in situ combustibles (other than the RCP oil which is provided with adequate compensatory protection) and no credible ignition sources, it is concluded that there is no credible fire in the analysis volume that results in the loss of required fire safe shutdown (FSSD) components or other components that results in the necessity to shutdown either Unit 1 or Unit 2. Therefore, there is no impact to FSSD for this analysis volume. Operator Manual Actions (OMA's) are not required to mitigate fire in rooms 2RA2, 2RF2, 2RI-2 OR 2RI-3 per deviation documented in Part VII, section 2.9.

2RA3	Unit 2 Accumulator Room 3
2RF2	Unit 2 Fan Room 2
2RI-2	Inside Unit 2 Crane Wall (90° - 180°)
2RI-3	Inside Unit 2 Crane Wall (180° - 270°)

The in situ combustible loading for AV-118J consists of small quantities of lubricants in several valves and fan motors (accounts for 88% of combustible load in 2RA3 and 39% in 2RF2) and miscellaneous plastics associated with small electrical control panels and boxes, and lighting. The cables to these devices are routed in conduit. The zones designated 2RI-2 and 2RI-3 each contain a reactor coolant pump (RCP) that constitutes 98% and 97%, respectively of the combustible load and several valves. Each RCP is provided with an oil collection system that complies with Appendix R, Section III.O and is protected with an automatic suppression and detection system. The total combustible loading in rooms 2RA3 and 2RF2 results in a fire severity classification of Insignificant (less than 1-minute) for each room. Zones 2RI-2 and 2RI-3 have combustible loading that results in a fire severity classification of Low when including the RCP oil, but is Insignificant (less than 1-minute) not counting the oil. Access to the areas inside the Unit 2 Reactor Building is strictly controlled which, in conjunction with procedure NPG-SPP-18.4.7, Control of Transient Combustibles, provides assurance that transient combustibles will not be introduced into the area without adequate compensatory measures. Cables routed in conduit and lubricants in the valves/motors are not exposed; therefore, their contribution to a postulated fire is greatly reduced. The valve motors are normally de-energized (power is only applied when an operator moves the valve from open to close (or close to open)); therefore, the valve motors are not considered an ignition source. The fan motors are not considered a significant ignition source because the fan housings contain insignificant quantities of combustible material and the power supply circuits to the fan motors are adequately protected with properly sized breakers/fuses. Procedure NPG-SPP-18.4.8, Control of Ignition Sources (Hot Work) ensures that ignition sources (e.g. cutting, welding, grinding) will not be introduced into the area without adequate compensatory measures. Since there are no concentrations of in situ combustibles (other than the RCP oil which is provided with adequate compensatory protection) and no credible ignition sources, it is concluded that there is no credible fire in the analysis volume that would result in the loss of required fire safe shutdown (FSSD) components or other components that results in the necessity to shutdown either Unit 1 or Unit 2. Therefore, there is no impact to FSSD for this analysis volume. Operator Manual Actions (OMA's) are not required to mitigate fire in rooms 2RA3, 2RF2, 2RI-2 OR 2RI-3 per deviation documented in Part VII, section 2.9.

PART VI – FIRE HAZARDS ANALYSIS

3.84.3.11 AV-118K

Room No.	Description:
2RA4	Unit 2 Accumulator Room 4
2RF1	Unit 2 Fan Room 1
2RI-1	Inside Unit 2 Crane Wall (0° - 90°)
2RI-4	Inside Unit 2 Crane Wall (270° - 360°)

The in situ combustible loading for AV-118K consists of small quantities of lubricants in several valves and fan motors (accounts for 82% of combustible load in 2RA4 and 51% in 2RF1) and miscellaneous plastics associated with small electrical control panels and boxes, and lighting. The cables to these devices are routed in conduit. The zones designated 2RI-1 and 2RI-4 each contain a reactor coolant pump (RCP) that constitutes 99% and 98%, respectively of the combustible load and several valves. Each RCP is provided with an oil collection system that complies with Appendix R, Section III.O and is protected with an automatic suppression and detection system. The total combustible loading in rooms 2RA4 and 2RF1 results in a fire severity classification of Insignificant (less than 1-minute) for each room. Zones 2RI-1 and 2RI-4 have combustible loading that results in a fire severity classification of Low when including the RCP oil, but is Insignificant (less than 1-minute) not counting the oil. Access to the areas inside the Unit 2 Reactor Building is strictly controlled which, in conjunction with procedure NPG-SPP-18.4.7, Control of Transient Combustibles, provides assurance that transient combustibles will not be introduced into the area without adequate compensatory measures. Cables routed in conduit and lubricants in the valves/motors are not exposed; therefore, their contribution to a postulated fire is greatly reduced. The valve motors are normally de-energized (power is only applied when an operator moves the valve from open to close (or close to open)); therefore, the valve motors are not considered an ignition source. The fan motors are not considered a significant ignition source because the fan housings contain insignificant quantities of combustible material and the power supply circuits to the fan motors are adequately protected with properly sized breakers/fuses. Procedure NPG-SPP-18.4.8, Control of Ignition Sources (Hot Work) ensures that ignition sources (e.g. cutting, welding, grinding) will not be introduced into the area without adequate compensatory measures. Since there are no concentrations of in situ combustibles (other than the RCP oil which is provided with adequate compensatory protection) and no credible ignition sources, it is concluded that there is no credible fire in the analysis volume that results in the loss of required fire safe shutdown (FSSD) components or other components that results in the necessity to shutdown either Unit 1 or Unit 2. Therefore, there is no impact to FSSD for this analysis volume. Operator Manual Actions (OMA's) are not required to mitigate fire in rooms 2RA4, 2RF1, 2RI-1 OR 2RI-4 per deviation documented in Part VII, section 2.9.

PART VI – FIRE HAZARDS ANALYSIS

3.84.3.12 AV-118L

Room No.	Description:
2RA1	Unit 2 Accumulator Room 1
2RF1	Unit 2 Fan Room 1
2RI-1	Inside Unit 2 Crane Wall (0° - 90°)
2RI-4	Inside Unit 2 Crane Wall (270° - 360°)

The in situ combustible loading for AV-118L consists of small quantities of lubricants in several valves and fan motors (accounts for 61% of combustible load in 2RA1 and 51% in 2RF1) and miscellaneous plastics associated with small electrical control panels and boxes, and lighting. The cables to these devices are routed in conduit. The zones designated 2RI-1 and 2RI-4 each contain a reactor coolant pump (RCP) that constitutes 99% and 98%, respectively of the combustible load and several valves. Each RCP is provided with an oil collection system that complies with Appendix R, Section III.O and is protected with an automatic suppression and detection system. The total combustible loading in rooms 2RA1 and 2RF1 results in a fire severity classification of Low (less than 6-minutes) for 2RA1 and Insignificant (less than 1-minute) for 2RF1. Zones 2RI-1 and 2RI-4 have combustible loading that results in a fire severity classification of Low when including the RCP oil, but is Insignificant (less than 1-minute) not counting the oil. Access to the areas inside the Unit 2 Reactor Building is strictly controlled which, in conjunction with procedure NPG-SPP-18.4.7, Control of Transient Combustibles, provides assurance that transient combustibles will not be introduced into the area without adequate compensatory measures. Cables routed in conduit and lubricants in the valves/motors are not exposed; therefore, their contribution to a postulated fire is greatly reduced. The valve motors are normally de-energized (power is only applied when an operator moves the valve from open to close (or close to open)); therefore, the valve motors are not considered an ignition source. The fan motors are not considered a significant ignition source because the fan housings contain insignificant quantities of combustible material and the power supply circuits to the fan motors are adequately protected with properly sized breakers/fuses. Procedure NPG-SPP-18.4.8, Control of Ignition Sources (Hot Work) ensures that ignition sources (e.g. cutting, welding, grinding) will not be introduced into the area without adequate compensatory measures. Since there are no concentrations of in situ combustibles (other than the RCP oil which is provided with adequate compensatory protection) and no credible ignition sources, it is concluded that there is no credible fire in the analysis volume that results in the loss of required fire safe shutdown (FSSD) components or other components that results in the necessity to shutdown either Unit 1 or Unit 2. Therefore, there is no impact to FSSD for this analysis volume. Operator Manual Actions (OMA's) are not required to mitigate fire in rooms 2RA1, 2RF1, 2RI-1 OR 2RI-4 per deviation documented in Part VII, section 2.9.

PART VII - DEVIATIONS AND EVALUATIONS

1.0 Introduction

Part VII documents deviations from Watts Bar (WBN) commitments against applicable NRC regulatory criteria and guidance documents and presents engineering evaluations of the adequacy of specific fire protection features. Section 2.0 contains the justifications for deviations (in accordance with the guidance in Generic Letter (GL) 86-10) from the applicable sections of 10CFR50 Appendix R. Section 3.0 contains the engineering evaluations on the adequacy of fire protection features developed in accordance with the guidance of Generic Letters 83-33 and 86-10. Section 4.0 contains the justifications for deviations from the guidance of Appendix A to BTP 9.5-1. Section 5.0 contains deviations from the requirements of NFPA codes and standards that could impact on the operational capabilities of fire protection features. NFPA Code deviations that do not impact on operational capabilities are identified in Part X, with technical justifications for existing configurations documented in the applicable system descriptions. Section 6.0 contains other general engineering evaluations that pertain to the fire protection program. Section 7 contains engineering evaluations of operator manual actions performed in the room of fire origin after the fire has been extinguished. Section 8 contains the evaluations and justifications (in accordance with Regulatory Guide (RG) 1.189 and NUREG 1852) of the Unit 2 operator manual actions.

2.0 Deviations to 10CFR50 Appendix R

This section documents the technical justifications for deviations from the criteria of Appendix R consistent with Generic Letter 86-10 guidance. A total of nine deviations are contained in this section. The deviations documented in this section include the following:

1. Required Instrumentation for Alternate Shutdown
2. Non-combustible Radiant Energy Shields
3. Fixed Suppression Systems for Alternate Shutdown Locations (Control Building)
4. Intervening Combustible Material
5. 1-Hour Rated Part-Height Wall Separating Redundant CCS Pumps
6. Openings in Regulatory Fire Barriers
7. Portable Lanterns
8. Reactor Coolant Pump Oil Collection System
9. Fire Hazards Analysis (FHA) in lieu of 10CFR50, Appendix R, Section III.G.2 Separation

The following sections present the bases for acceptability of the deviation requests.

2.1 Required Instrumentation for Alternate Shutdown

REQUIREMENT - Section III.L.2.d of 10CFR50, Appendix R, requires the process monitoring function for alternative or dedicated shutdown to be capable of providing direct readings of the process variables necessary to perform and control a plant cool down. In Attachment 1 of Information Notice No. 84-09 dated February 13, 1984, the NRC identified the instrumentation they considered necessary for alternative or dedicated shutdown.

DEVIATION - Contrary to these guidelines, the following instrumentation has not been provided (or assured) in the auxiliary control room (ACR):

PART VII - DEVIATIONS AND EVALUATIONS

1. Wide range steam generator level.
2. Tank level for the condensate storage tank (CST) and refueling water storage tank (RWST).
3. Cold leg temperature (T_c).

2.1.1 Justification for Wide Range Steam Generator Level

Narrow range steam generator level and auxiliary feedwater (AFW) flow indication to each generator is provided in the ACR. This instrumentation provides input to the automatic controls used to maintain steam generator level during plant shutdown during a fire.

Although wide range instrumentation is available in the main control room (MCR), no automatic control or safety system inputs are derived from this instrumentation. Using AFW flow indication, the operator is able to confirm adequate post trip steam generator inventory control should the level fall below the narrow range.

Narrow range level indication along with AFW flow indication, which provides primary indication of heat removal capability, is sufficient for use in safe shutdown procedures whenever the ACR is utilized. TVA therefore requests approval of this deviation.

2.1.2 Justification for CST and RWST Tank Level Indication

The CST level indication is not considered essential in the ACR due to automatic switchover capability to the essential raw cooling water (ERCW) header. During shutdown procedures, automatic switchover of the AFW pump suction from the CST to the ERCW header will be functional when control is established in the ACR.

RWST level indication is not considered essential in the ACR due to the large inventory and small demand. The RWST holds about 20 times the inventory necessary for cold shutdown and is primarily used as makeup for contraction due to cooldown over a period of hours. TVA therefore requests approval of this deviation.

2.1.3 Justification for Cold Leg Temperature (T_c)

The need for T_c in the ACR at WBN is based on the adequacy of the instrumentation and controls to safely achieve and maintain safe shutdown. The following factors are taken into consideration for this justification:

1. Unique ACR design as described in Part IV - Alternate Shutdown Capability
2. Level of control and instrumentation available in the ACR and in the adjacent shutdown board rooms
3. Westinghouse Owners Group (WOG) recommendations
4. Plant procedures and training on ACR
5. Accuracy of T_{sat} to infer T_c

The benefit of the operators ability to read T_c directly in the ACR does not offset the long term maintenance and ALARA considerations as well as the increased probability of a small break LOCA as a result of four additional penetrations to the RCS.

The ACR is designed to be the central control point when operating in the auxiliary control mode. Systems requiring frequent manipulations have the necessary controls located in the

PART VII - DEVIATIONS AND EVALUATIONS

ACR along with their associated transfer switches located in the adjacent transfer switch rooms. Adequate instrumentation is provided for monitoring conditions of the plant. A detailed identification of the instruments and controls available in the ACR for alternative shutdown is contained in Part IV of the FPR.

The instruments and controls located in the ACR are separate, or can be electrically isolated, from the corresponding instrumentation and controls located in the MCR. Operators are periodically trained in shutdown procedures from the ACR. The instrumentation and controls are adequate and sufficiently similar to those available in the MCR to permit a safe and orderly shutdown. In addition, Sequoyah Nuclear Plant (SQN) testing has adequately demonstrated the ability to safely shutdown from the ACR.

The following indications are available for the operator in the ACR to indicate loss of natural circulation cooling:

1. RCS subcooling (conversion of pressurizer pressure to T_{sat} and subtracting T_{hot})
2. T_{hot} stable or decreasing
3. SG pressure stable or decreasing

The WOG Emergency Response Guidelines (ERG), Revision 1, Generic Issue on Natural Circulation, offers specific guidelines on operator verification of natural circulation. The primary means recommended by this section for verifying natural circulation are:

1. Verification of RCS subcooling
2. Wide Range T_{hot}
3. SG Pressure

The natural circulation section further states that, "Cold leg temperature (T_c) readings can be used as additional verification that heat removal through the steam generators is occurring." It should be noted that T_c is an additional verification of natural circulation cooling, not the primary means. WOG ERG's also state that, "Actual tests have shown that loop T_c 's follow almost exactly (in trends) the steam generator pressure variations, with minimal time lag." NRC issued a Safety Evaluation Report (SER) of the WOG ERG's on June 3, 1983, stating that, "We have concluded that the guidelines are acceptable for implementation and will provide improved guidance for emergency operating procedure development." A supplemental SER was issued by NRC on December 26, 1985, for Revision 1 of WOG ERGs, and closing out open items from Rev. 0 (natural circulation was not an open item).

Steam Generator Pressure Instrumentation is adequate to infer T_c . From the data obtained during startup testing at SQN (ST-9B) and Diablo Canyon (Test Procedure 42.7), the following statistical evaluation was performed concerning the T_{sat} (obtained from S/G pressure) and T_c relationship ($T_c - T_{sat}$).

	<u>Sequoyah</u>	<u>Diablo Canyon</u>
Mean	4.33°F	4.67°F
Standard Deviation	3.29°F	1.65°F

The above temperature differences are well within the tolerance and accuracy levels of the instrumentation. The SQN cool down was terminated at approximately 465°F; however, the Diablo Canyon cool down was continued to below RHR initiation. Since both sets of data were obtained simultaneously (T_c and SG pressure), the data demonstrates the adequacy of using

PART VII - DEVIATIONS AND EVALUATIONS

SG pressure to determine Tsat and infer Tc, and the lack of significant time lag between the two indicators.

The natural circulation test at SQN was performed from the main control room and the equipment (not controls) used during the natural circulation tests is identical to the equipment which is used in fire initiated safe shutdown from the ACR. For example, the AFW pumps, the CCPs, ERCW pumps, and CCS pumps are used for natural circulation cool down from the ACR and were also used during the MCR natural circulation tests. Therefore, the test results are applicable to shutdown from the ACR.

Tc Summary and Conclusion

After a thorough review of the issues surrounding the Tc question, the facts support that Tsat, along with other plant features as discussed, will provide for adequate assurance that the plant can achieve and maintain a safe shutdown condition. Installation of additional Tc instrumentation in the ACR (per reactor) is not justified based on the following key considerations:

1. The uniqueness of the WBN ACR design
2. The large amount of instrumentation and controls available for shutdown from the ACR
3. Experience and training in plant shutdown from the ACR
4. Instrumentation provided for verification of natural circulation is consistent with WOG ERG's
5. Adequacy of SG pressure instrumentation to infer Tc
6. Increased probability of a small break LOCA as a result of four additional penetrations to the RCS.

The evaluation described above demonstrates the adequacy of the present design's capability to provide sufficient information to the operators to safely shutdown the plant. TVA therefore requests approval of this deviation.

2.2 Non-Combustible Radiant Energy Shields

REQUIREMENT - Section III.G.2.f of 10CFR50, Appendix R states that an acceptable means of ensuring that a redundant train of the systems located inside non-inerted containment and necessary to ensure safe hot shutdown will be protected from damage from a fire is to separate the trains by a non-combustible radiant energy shield (RES).

DEVIATION - The NRC recognized standard test method for the determination of the combustibility classification for a material is ASTM E136. The radiant energy shields installed inside the Reactor Buildings at WBN is Minnesota Mining and Manufacturing (3M) M-20A (Secondary Containment - Annulus) and M-20C (Unit 1 only Primary Containment). These materials do not meet the criteria for non-combustibility per ASTM E136.

JUSTIFICATION - Branch Technical Position (BTP) CMEB 9.5-1 (NUREG 0800) provides the guidelines for the design basis of the RES in Section C.7.a(1)b. It states that redundant trains should be separated "by a noncombustible radiant energy shield having a minimum fire rating of one-half hour." In NRC Generic Letter 86-10, the NRC states, "In our opinion, any material with a ½-hour fire rating should be capable of performing the required function. The guidelines of BTP CMEB 9.5-1 relating to a fire-rated radiant energy shield are being considered in our current reviews of NTOL plants. However, to the extent that an applicant can justify that a

PART VII - DEVIATIONS AND EVALUATIONS

proposed radiant energy shield can achieve an equivalent level of safety, we have been accepting shields that have not been tested against the acceptance criteria of ASTM E119. In our Appendix R reviews, we have accepted non-fire rated radiant energy shields that have been demonstrated by fire hazards analysis to provide an acceptable level of protection against the anticipated hazard of a localized fire within the containment."

TVA/WBN calculations (EPM-BFS-041895 and EPM-BFS-053195) provide the design basis for the number of layers of M20A (Annulus) and M20C (Primary Containment) necessary to provide approximately ½-hour radiant energy shields for electrical raceways containing fire safe shutdown circuits. These calculations were based on fire tests performed by the vendor (3M) to UL Subject 1724, "Outline of Investigation for Fire Tests for Electrical Circuit Protective Systems". The fire exposure used in the tests is the Standard Time-Temperature curve from ASTM E119. It was determined that 4 layers of M20A on the raceways (conduits, junction boxes, and penetration boxes) and 2 layers on the supports and intervening items are adequate for raceways located inside the Annulus. Since the combustible loading is substantially lower inside Primary Containment, 3 layers of M20C on the raceways and 2 layers on the supports and intervening items provide an adequate RES.

ASTM E136 test reports on the M20A or M20C were not available from the vendor; therefore, TVA had a series of fire resistance tests performed on the material at an independent, nationally recognized testing laboratory (Omega Point Laboratories). The following tests were performed:

ASTM E136 Standard Test Method for Behavior of Materials in a Vertical Tube Furnace at 750° C

ASTM E162 Standard Test Method for Surface Flammability of Materials Using a Radiant Heat Energy Source

ASTM E1354 Standard Test Method for Heat and Visible Smoke Release Rates for Materials and Products Using an Oxygen Consumption Calorimeter

In addition to the M20A and M20C, other common rated fire barrier materials (fire-rated gypsum and marinite boards) were included in the tests to provide reference information. The Vendor has previously performed UL 723 "Standard Tests for Surface Burning Characteristics of Building Materials" on M20A. (Note: UL 723 is equivalent to ASTM E84 "Standard Test Method for Surface Burning Characteristics of Building Materials") A detailed evaluation of these tests is documented in WBN calculation EPM-BFS-063095. The results are summarized below.

ASTM E136: RESULTS

The M20 material with the exterior covering (A=Aluminum; C=Stainless Steel) failed the flaming and temperature rise criteria. The fire rated gypsum board also failed the temperature rise criteria. The fire rated marinite board passed.

ASTM E162: RESULTS

This test method is used for research and development purposes in evaluating the response of a material when exposed to a radiant heat energy source. This test has been performed to augment the UL 723 testing in determining the flame spread of the M20A and M20C when exposed to the radiant heat flux of a fire. This standard does not have an acceptance criterion. All of the materials exhibited very low Flame Spread Index (I_s) values. Fire rated marinite board

PART VII - DEVIATIONS AND EVALUATIONS

had the lowest I_s value of 0.1, followed by gypsum at 0.9 and M20 materials with values from 0.9 to 1.2. Values for I_s of materials typically range from 0 to <100. By way of comparison, the pass/fail criteria used to rate interior panels in mass transit applications is $I_s < 35$.

ASTM E1354: RESULTS

ASTM E1354, Section 5 states, "This test method is used primarily to determine the heat evolved in, or contributed to, a fire involving products of the test material. Also included is a determination of the effective heat of combustion, mass loss rate, the time to sustain flaming and smoke production." In addition the Appendix states, "The rate of heat release is one of the most important variables, in many cases the single most important variable, in determining the hazard from fire."

The principle property to be determined by this test is the rate of heat released by a material. The heat flux used for the test was 75 kW/m^2 with external electric spark ignition. The time period was ten minutes. The peak Heat Release Rate (HRR) and the Total Heat Release rate (THR) for the M20A and M20C was lower than that of the fire rated gypsum and marinite boards. The M20A and M20C average HRR was $<10 \text{ kW/m}^2$ and the average THR was $<5 \text{ kJ}$. The average HRR for gypsum board was 134.1 kW/m^2 with an average THR of 31.3 kJ . The average HRR for marinite board was 11.6 kW/m^2 with an average THR of 31.1 kJ . This equates to a quantifiable effective heat of combustion of 4.1 MJ/kg for the gypsum board and 7.2 MJ/kg for the marinite board, but no quantifiable effective heat of combustion for the M20A and M20C. The average mass loss of the material showed marinite board with the lowest at 5.6% and the M20C with the highest at 15.9%. The average time to ignition was 19 seconds for the gypsum board, but the marinite board, M20A and M20C did not ignite.

UL 723: RESULTS

The flame spread rating for the M20A and M20C was determined to be 3.7 with 0 fuel contributed or smoke developed.

SUMMARY

Although not passing the ASTM E136 test for combustibility, the 3M M20A and M20C have been demonstrated by testing to be able to perform as effective radiant energy shields. The material can be defined as a "Limited Combustible" in accordance with NFPA 220 "Standard on Types of Building Construction". These materials as designed and installed at WBN will achieve an equivalent level of safety and adequately perform their intended function as radiant energy shields; therefore, WBN requests approval of this deviation.

2.3 Fixed Suppression for Alternate Shutdown Locations

REQUIREMENT - Appendix R Section III.G.3 states that alternative or dedicated shutdown capability and its associated circuits, independent of cables, systems or components in the area, room or zone under consideration, shall be provided:

PART VII - DEVIATIONS AND EVALUATIONS

1. Where the protection of systems whose function is required for hot shutdown does not satisfy the requirement of paragraph G.2; or
2. Where redundant trains of systems required for hot shutdown located in the same fire area may be subject to damage from fire suppression activities or from the rupture or inadvertent operation of fire suppressions systems.

In addition, fire detection and a fixed fire suppression system shall be installed in the area, room, or zone under consideration.

DEVIATION - A fire in the control building may result in abandonment of the MCR and shutting down from the ACR, which is considered alternative shutdown. The control building must therefore meet the criteria of Section III.G.3. Contrary to the criteria of Section III.G.3, fire detection and fixed fire suppression systems are not provided throughout the control building.

JUSTIFICATION - The control building is a single fire area and is separated from adjacent fire areas by reinforced concrete construction as identified in Part VI of the FPR. Fire detection is provided throughout the control building except for stairways C1 and C2 (all elevations), and the showers, telephone room, the space above the egg-crate ceiling in the main control room, and the space above the living area on elevation 755. Unit 2 Auxiliary Instrument Room 708.0-C4 is provided with full detection but has one detector that exceeds the allowed spacing to the south wall by 3 feet. The identified locations are enclosed with 1½ or 2 hour regulatory and/or non-regulatory fire barriers. The showers, telephone room, corridor (755.0-C15) and the space above the living area contain negligible amounts of combustibles.

Standpipe and hose stations and portable fire extinguishers are provided throughout the control building. Fixed fire suppression systems are provided throughout the control building except for the following rooms:

<u>Room Name</u>	<u>Room No.</u>	<u>Fire Severity</u>
250V Battery Board Room	692.0-C4 and C5	Low (per room)
24-48V Battery Board and Charger Room	692.0-C8	Low
Stairs	C1 and C2	Low (each stair)
Corridor	708.0-C2	Low
Shower Rooms	755.0-C7 and C8	Insignificant
Main Control Room	755.0-C12	Low
Relay Room	755.0-C13	Low
Corridor	755.0-C15	Insignificant
Telephone Room	755.0-C17	Insignificant
DPSO Shop	755.0-C20	low

The purpose of providing fire detection and fixed fire suppression in an area containing normal shutdown equipment is to limit the severity of a fire in the area such that it will not damage alternate safe shutdown capability. By design, there are no alternative shutdown cables or equipment in the control building. Therefore, the design intent has been achieved by an alternate design concept - the ACR which is installed in the auxiliary building. The limited quantity of in situ combustibles in the above listed rooms, fire compartmentation, fire detection, and fire protection features provided satisfy this purpose. TVA therefore requests approval of this deviation.

PART VII - DEVIATIONS AND EVALUATIONS

2.4 Intervening Combustibles

REQUIREMENT - Section III.G.2.b requires separation of redundant paths of safe shutdown cables and equipment by a horizontal distance of more than 20 feet with no intervening combustibles. In addition, fire detection and an automatic fire suppression system shall be installed in the area.

DEVIATION - Safe shutdown components in the auxiliary building and Electrical Equipment room in the Intake Pumping Station (IPS) are in compliance with III.G.2.b requirements except that intervening combustibles, in the form of fluid filled transformers (IPS only), insulation on cables in open ladder type cable trays and Thermo-Lag fire barrier material, are located between the redundant components.

JUSTIFICATION - The combustible loading in the areas of the auxiliary building where redundant safe shutdown components are spatially separated is primarily the insulation on the cables in the cable trays and the Thermo-Lag fire barrier material (90% to 96%). The remaining in situ combustible loading consists of lubricating oil in pumps, motors, and valves; transformer silicone liquid (IPS only); plastics in electrical panels and junction boxes, etc. The combustible loading in the Electrical Equipment room in the IPS consists primarily of transformer silicone liquid (approximately 13% of the load) and cables in cable trays (approximately 83% of the load) and the remainder is due to lubricating oil in small pumps and plastics associated with electrical panels and junction boxes, etc.

The presence of these intervening combustibles is a concern for two reasons. First, they could add to the fire's thermal plume. Second, they could provide a path for the fire to propagate between redundant components. TVA has addressed these concerns by relying upon existing ceiling level sprinkler systems coupled with supplemental sprinkler protection, where required, to compensate for the intervening combustibles.

Sprinkler protection has been provided at the ceiling level in rooms containing redundant FSSD components. Due to the presence of obstructions such as HVAC ducts, cable trays, pipes, and supports, these systems have been upgraded in accordance with the applicable design criteria (Part II Reference 4.2.4). These criteria applications have resulted in the addition of a significant number of sprinkler heads to provide full coverage at the ceiling level and to compensate for large intermediate level obstructions. Thus the modified systems will release large quantities of water in well developed patterns at the ceiling during a fire, and the water will cascade down through the cable trays and intermediate obstructions. The cooling effect of this water will prevent the formation of a high temperature heat plume and will control room temperatures.

The cascading effect of the water will stop the propagation of fire along cable trays and raceways protected with Thermo-Lag between redundant components. Therefore, transient combustibles at the floor level present the only significant fire exposure to the redundant components.

To mitigate the effects of an exposure fire from transient combustibles at the floor level, TVA has ensured that floor level sprinkler coverage is provided under intermediate obstructions for up to a 30-foot wide path for spatially separated redundant FSSD components. The criteria in Attachment 1 are used to ensure this floor coverage. The use of the sprinklers below intermediate level obstructions to compensate for intervening combustibles has been

PART VII - DEVIATIONS AND EVALUATIONS

recommended by the staff in meetings on August 29, 1984, and September 13, 1984, and in a letter from Thomas M. Novak to H. G. Parris dated November 6, 1984. Similar deviation requests at Sequoyah and exemption requests at Browns Ferry have been approved.

Sprinkler systems that meet the criteria of Part II, Reference 4.2.4 provide a level of protection that adequately compensates for the presence of intervening combustibles located between spatially separated redundant FSSD components. TVA therefore requests approval of this deviation.

2.5 Partial Fire Wall Between CCS Pumps

REQUIREMENT - 10CFR50, Appendix R, Section III.G.2.b and III.G.2.c require redundant safe shutdown components to be separated from each other by one of the following methods:

- III.G.2.b Separation of cables and equipment and associated non-safety circuits of redundant trains by a horizontal distance of more than 20 feet with no intervening combustibles or fire hazards. In addition, fire detectors and an automatic fire suppression system shall be installed in the fire area.
- III.G.2.c Enclosure of cables and equipment and associated non-safety circuits of one redundant train in a fire barrier having a 1-hour rating. In addition, fire detectors and an automatic fire suppression system shall be installed in the fire area.

DEVIATION - The redundant component cooling water system (CCS) pumps are protected by fire detectors and an automatic fire suppression system, but are separated by a part-height and part-width 1-hour fire barrier.

JUSTIFICATION - The five CCS pumps are located in the same area on elevation 713 of the auxiliary building. The two train B pumps are separated from the two train A pumps and the spare pump by a 1-hour barrier which extends 3 feet above the highest point of the pumps.

The majority (95%) of the in situ combustible loading in this area is due to the insulation on cables routed in cable trays and the Thermo-Lag fire barrier material. These cables are protected electrically with appropriately sized circuit protective devices (breakers and fuses). Therefore the probability of an internally generated cable tray fire is not considered to be a credible event. The majority of the remaining combustible loading in the immediate area is due to the approximately 6 gallons of lube oil associated with each CCS pump and approximately 45 gallons of lube oil associated with each of the two Unit 1 AFW pumps (there is approximately 12 feet separating the closest pumps – 1A-A AFW pump from 1A-A CCS pump. The fire safe shutdown analysis considered both pumps lost for a fire near them).

The redundant circuits for the CCS pumps are separated either by 1-hour barriers or more than 20 feet. A ceiling level preaction sprinkler system is provided for general area coverage. Additional sprinkler coverage has been provided under the steel grate mezzanine over the CCS pumps. Cross-zoned ionization smoke detectors are provided to actuate the preaction suppression system and provide early warning in the event of a fire.

The barrier between the trained CCS pumps prevents radiant heat transfer from a fire involving one train of pumps from affecting the redundant pumps. The large room volume of 391,000 cubic feet and the 23-foot high ceilings will dissipate the thermal effects of a transient combustible fire.

PART VII - DEVIATIONS AND EVALUATIONS

A fire due to transient combustibles located near the edge of the fire barriers at A3/T will not pose a threat to more than one CCS pump. The 3-foot square column at this end of the barrier ensures that an exposure fire that could damage the CCS pump 1A-A will be 20 feet away from CCS pump 1B-B. The location of electrical panels and instrumentation lines at A1/T will also prevent any appreciable amounts of transient combustibles from being placed near this edge of the barrier. The mezzanine above the CCS pumps is a combustible control zone (CCZ) to limit potential transient combustibles in the area above the pumps.

The lack of combustibles and the combination of ceiling level sprinklers, plus the sprinklers located under the mezzanine, will prevent a fire due to transient combustibles located near the edge of the barrier at A1/T from posing a threat to more than one CCS pump. The NRC staff previously reviewed the fire protection features provided in the vicinity of the CCS pumps for compliance with guidelines set forth in Appendix A of BTP APCSB 9-5.1 and found those features to be adequate (see section 9.5.1.5 of the WBN Safety Evaluation Report dated June 1982). The staff also approved a similar deviation at the Sequoyah plant (see letter from B. J. Youngblood to S. A. White, dated May 29, 1986).

In conclusion, the fire protection features for this area provide a level of fire protection consistent with the fire hazards identified for the area. The fire protection features provide reasonable assurance that at least one train of fire safe shutdown equipment and cables will remain free of fire damage following any credible fire in this area. TVA therefore requests approval of this deviation.

2.6 Openings in Fire Barriers

REQUIREMENT - Appendix R Section III.G.1 requires that one train of systems necessary for FSSD be free from fire damage. Where fire area boundaries are used to provide system separation, NRC generic letters and guidance documents require that penetrations in walls, floors, and ceilings forming part of a fire area boundary be protected with seals or closure devices having a fire resistive rating equivalent to that required of the barrier.

DEVIATION - The following deviations to these guidelines exist at WBN:

(NOTE: Some unprotected openings are the subject of deviation requests or engineering evaluations in this Part of the FPR. Where an unprotected opening is not the subject of either a deviation request or an engineering evaluation, the rooms on opposite sides of the unprotected openings were combined for purposes of the Appendix R separation analysis. The following items address those "unprotected" openings which are the subject of this deviation request.)

1. The walls and floor of the ventilation and purge air (VPA) rooms, Rooms 737.0-A5 and 737.0-A9, are equivalent to two hour fire barriers. HVAC penetrations through these barriers to the fuel transfer valve (FTV) rooms, also known as the post accident sampling (PAS) rooms, Rooms 729.0-A8 and 729.0-A9, do not have fire dampers.
2. The walls separating the ERCW pump rooms from the traveling screen room on elevation 741 of the Intake Pumping Station (IPS) are equivalent to 3-hour fire barriers, but have unprotected scupper openings. The common walls between yard manholes have unprotected scuppers.

PART VII - DEVIATIONS AND EVALUATIONS

3. Floor slabs in the Auxiliary Building are used as separation fire barriers between elevations, but some HVAC penetrations do not have fire dampers. Stairwells and equipment hatches are provided with water curtains in lieu of rated barriers.
4. The Control Building mechanical equipment rooms on elevation 692 are separated from turbine building elevation 708 by a 3-hour fire rated floor/ceiling assembly; however, an equipment hatch in the ceiling of each mechanical equipment room is only provided with a metal hatch cover.

2.6.1 Justification for Ventilation and Purge Air Room Ventilation Penetrations

The ventilation and purge air (VPA) rooms, Room 737.0-A5 located in Fire Area 16 and Room 737.0-A9 in Fire Area 74, contains safe shutdown components. Room 737.0-A5 and Room 737.0-A9, are separated from the fuel transfer valve (FTV) rooms, also known as the post accident sampling (PAS) rooms (Rooms 729.0-A8 and -A9), and nitrogen storage room (Room 729.0-A6) in Fire Area 10 by 2-hour rated fire barriers. Three round HVAC ducts per unit (8-, 10-, and 12-inches) in the FTV/PAS room pass through the VPA room for a short distance and then reenter the FTV/PAS and nitrogen storage rooms. These ducts have no openings into the VPA rooms.

In addition, one 12-inch round duct per unit associated with the VPA system penetrates the walls separating each VPA room from the nitrogen storage room. There are no openings in these ducts between the wall and the normally closed isolation dampers FCO-31-342 and FCO-31-343. These ducts are constructed from schedule 40 carbon steel pipe, ASTM A106, grade B and are seismically supported to category I(L) requirements. As is typical of mechanical penetrations, pipe sleeves are provided where the ducts penetrate the barriers between the VPA rooms and the FTV/PAS and nitrogen storage rooms.

The annular space between the sleeves and the pipes are sealed with a fire rated seal that has a fire rating equivalent to that of the barrier. The in situ combustible loads for the rooms are as follows:

Nitrogen Storage Room (Room 729.0-A6 in Fire Area 10)	$\leq 10,000 \text{ Btu/ft}^2$
FTV/PAS Room (Room 729.0-A8 in Fire Area 10)	$\leq 10,000 \text{ Btu/ft}^2$
FTV/PAS Room (Room 729.0-A9 in Fire Area 10)	$\leq 10,000 \text{ Btu/ft}^2$
VPA Rooms (Room 737.0-A5 in Fire Area 16, and Unit 2 VPA Room 737.0-A9 in Fire Area 74)	$\leq 20,000 \text{ Btu/ft}^2$

The major source of combustibles in the VPA rooms is charcoal filters. The charcoal filters are protected with closed head sprinkler (water spray nozzles) systems that are actuated by duct mounted ionization detectors. The FTV/PAS rooms are provided with preaction sprinkler systems (except in the entrance corridors to the rooms) that are actuated by ionization smoke detectors. Each VPA room is also provided with a preaction sprinkler system that is actuated by ionization smoke detectors. The nitrogen storage room is provided with ionization smoke detectors.

The only effect of a fire in the FTV/PAS or nitrogen storage rooms which could impact on the VPA room is radiant heat due to hot gases passing through the ducts. The absence of fixed

PART VII - DEVIATIONS AND EVALUATIONS

combustibles in the immediate area of the ducts, the typical mechanical penetration design which includes pipe sleeves for the ducts, and more than 20 feet of spacial separation between the ducts and the nearest safe shutdown circuit provides a high degree of assurance that this radiant heat will not be a threat to safe shutdown components located in the VPA rooms. The fire protection provided for these rooms is adequate for the hazards present and the addition of fire dampers in these ducts would not significantly enhance the fire protection in these areas. TVA therefore requests approval of this deviation.

2.6.2 Justification for Scupper Openings

Scupper openings penetrate fire barriers in two locations. One is in the IPS between the ERCW pump rooms and the traveling screen room. The other is between the Train A and Train B duct banks that run from the auxiliary building to the IPS where they share a common wall in three manholes in the yard. Each is discussed in more detail below.

2.6.2.1 ERCW Pump Room Scuppers

The scupper openings in the IPS that penetrate the fire wall between the ERCW pump rooms and traveling screen room are located at the floor and provide drainage of rainwater from the ERCW pump rooms to the traveling screen wells.

The floor at elevation 741 of the IPS slopes away from the ERCW pumps toward the scuppers. A postulated oil spill will drain away from the pumps to the scuppers, pass through the scupper openings, and immediately drop through floor grating into the traveling screen well. The high flash point of the lubricating oil (432°F) makes it highly unlikely that the spilled oil would ignite.

However, if it did, the wall separating the two ERCW pump rooms from the traveling screen room will provide radiant heat protection from the fire. The roof design permits free air flow between the missile shield beams and will also allow the heat from a fire to dissipate to the outside environment and minimize the temperature rise within the room.

A fire in one ERCW pump room will not propagate through the scuppers and jeopardize a redundant train of ERCW pumps. The existing separation between redundant ERCW pumps is adequate for the hazards present. The scupper holes in the IPS have been previously reviewed and accepted by the NRC in the WBN SER dated June 1982. TVA therefore requests approval of this deviation.

2.6.2.2 Yard Duct Bank Scuppers

The scupper openings in the common wall between duct banks in the yard are located at floor level for drainage purposes. Manholes 1A and 1B, 2A and 2B, and 3A and 3B are used to access the train A and train B duct banks that connect the auxiliary building to the IPS. The train A and train B duct banks are separated by a 12" reinforced concrete wall at each pair of manholes. One manhole in each pair (i.e., 2A or 2B) contains a sump pump. The other manhole is connected to the manhole with the sump pump by a 2 inch diameter scupper opening. There are no other openings in the common wall separating the train A and train B manholes.

The combustible material in the yard duct banks is insulation associated with cables. There are no other combustible materials or equipment (except for the sump pump) in the duct banks where they share a common wall. A postulated fire in the cable insulation of one duct bank or in

PART VII - DEVIATIONS AND EVALUATIONS

the sump pump will not propagate through the scupper openings to the adjacent duct bank due to the lack of continuity of combustible materials between duct banks. TVA therefore requests approval of this deviation.

2.6.3 Justification for Auxiliary Building HVAC, Stair, Elevator and Hatch Penetrations

The auxiliary building is a multi-level structure that is subdivided into separate fire areas. Each elevation contains fire areas that are separated from adjacent elevations. Each fire area contains individual or multiple rooms. Fire barriers within the auxiliary building are minimum 2-hour fire rated and fire barriers separating the auxiliary building from adjacent buildings are 3-hour rated.

Each elevation of the auxiliary building is provided with ionization smoke detectors and, with the exception of elevation 676, automatic suppression systems. (Individual rooms without detection and/or suppression are documented in Section 3 of this Part.) The mechanical pipe penetrations and electrical penetrations are provided with appropriate penetration seals. The in situ combustible loading for the open areas (e.g. general floor areas of elevations 692, 713, 737, etc.) consists primarily of insulation on cables in the cable trays and Thermo-Lag fire barrier material (approximately 90% or greater). Cables in trays containing more than nine that are not IEEE-383-qualified are coated with a fire retardant material, Vimasco 2B. As documented in Part III, Section 7.2, the cables are provided with appropriately sized circuit protective devices (breakers and fuses). This provides a high degree of confidence that an internally generated cable tray fire is highly improbable.

The rest of the in situ combustible loading is dispersed throughout the areas/rooms and consist of lubricating oil in valves and motors, plastics in panels and junction boxes, etc. The justifications for open stairs and hatches, undampened ducts, spare conduit sleeves, and non-rated personnel hatches in the auxiliary building are presented below.

2.6.3.1 Water Curtains for Open Stairs and Hatches

A water curtain designed in accordance with NFPA 13, section 4-4.8.2 has been provided for the following openings:

1. Stairwell number 5 located near column lines A11/S below elevations 713 and 737.
2. Stairwell number 6 located near column lines A5/S below elevations 713 and 737.
3. Stairwell number 3 located near column lines A8/U-V below elevations 713 and 737.
4. Normally closed equipment hatch located near column lines A3/S below elevation 772.
5. Normally closed equipment hatch located near column lines A13/S below elevation 772.
6. Equipment hatch openings located near column lines A8/U-W below elevations 713, 737, and 757.
7. The elevator door openings located at column lines A8/T below elevations 713, 737, and 757.

PART VII - DEVIATIONS AND EVALUATIONS

The water curtains provide an adequate level of protection to prevent a postulated fire on one elevation from propagating to another elevation through one of these openings.

2.6.3.2 Undampered HVAC Ducts

2.6.3.2.a Constructed of Spiral Welded Pipe

Round HVAC ducts (pipes) are not provided with fire dampers where the pipe penetrates fire barriers. The locations of the pipes are identified on the compartmentation drawings in Part II of the FPR. Such pipes penetrate the east wall of Room 676.0-A3 from an adjacent pipe chase, and through the north wall of Room 676.0-A3 to Room 676.0-A1. Neither of these walls is required for fire safe shutdown. The pipe inside the pipe chase passes up through the ceiling into Room 692.0-A1 near column line A10/S. The pipe then runs north and passes through the wall (not required for fire safe shutdown) of 692.0-A31 to the east side of the elevator shaft and passes up through the ceiling into Room 713.0-A1. The pipe continues up through the ceiling into Room 737.0-A1 in the same general location.

These ducts are constructed of either spiral welded pipe or schedule 10 pipe and are treated as normal pipe penetrations. Therefore they are provided with fire rated mechanical penetration seals and provide an adequate level of fire protection for these types of ducts.

2.6.3.2.b Heavy Sheet Metal Ducts

Sheet metal ducts that are not provided with fire dampers are identified on the Fire Compartmentation drawings (see Part II of this Report). They are constructed of minimum 22 gauge sheet metal and will provide a 1-hour equivalent level of protection. The safe shutdown analysis considered these opening as unprotected and ensured that a fire on either side of the opening could not impact both paths of redundant safe shutdown components (cable or equipment). Automatic suppression and detection is provided on at least one side of the opening.

2.6.3.3 Spare Conduit Sleeves with Both Ends Capped

Spare conduit sleeves which penetrate fire barriers are provided with approved sealant material, capped on each end with metal caps or plugs (for example Crouse-Hinds type PLG), or a combination of the two. Neither flames nor hot gases will propagate through these spare conduits sleeves and these sealing methods provide an adequate fire seal.

2.6.3.4 Non-Rated Personnel Hatches

There are specific locations where non-rated steel hatches are used in floor/ceiling assemblies to enclose personnel access routes between rooms on different elevations. The locations where these steel hatches exist are identified on the compartmentation drawings in Part II of the FPR. One such hatch provides access from Room 692.0-A31 up into a monolithic concrete filter enclosure on elevation 713 near column lines A10/S. A second location provides access into a monolithic concrete filter enclosure identified as Room 692.0-A27 from the Unit 2 Pipe Gallery 676.0-A17.

Neither monolithic enclosure in which the steel hatch is located is open to the remainder of the rooms on elevations 692 and 713. The steel hatches are provided from the elevations below specifically due to the lack of access into the monolithic enclosures from elevations 692 and

PART VII - DEVIATIONS AND EVALUATIONS

713. There are no safe shutdown cables or components within the monolithic enclosures on these two elevations; therefore, even should fire spread up through the steel hatch into an enclosure, there is no impact on fire safe shutdown capability.

Summary

The above described conditions provide a level of fire protection that is adequate to ensure that safe shutdown can be achieved and that additional modifications would not significantly improve the fire protection capability of the plant. TVA therefore requests approval of this deviation.

2.6.4 Control Building Equipment Hatches to the Turbine Building

The mechanical equipment rooms (692.0-C1 and C10) on elevation 692 of the control building are provided with equipment hatches in the ceiling separating them from elevation 708.0 of the turbine building. The equipment hatches are provided with metal covers flush with the floor that are not fire rated. Since the equipment hatches provide access from the turbine to the control building, the metal covers are vital area boundaries with access controlled and security contacts attached to the underside of the hatches. As such, the hatch covers will not be inadvertently removed.

The metal covers do not form a water-tight seal where they cover the hatch openings; however, the metal covers will limit flammable and combustible liquid spills through the hatch openings into the control building mechanical equipment rooms. Seepage could occur through the hatches around the perimeter where the covers are mounted to the floor and through the small diameter holes in the hatches which are provided to facilitate their removal.

There are no safe shutdown components in the turbine building within 20 feet of the equipment hatches; as such, fire spread up into the turbine building will not impact FSSD capability. The mechanical equipment rooms are provided with automatic detection and preaction sprinkler systems, including sidewall heads in the vicinity of the hatches. Detection and suppression in the mechanical equipment rooms control and/or extinguish postulated fires prior to arrival of the fire brigade. TVA therefore requests approval of this deviation.

2.7 Portable Lanterns for Containment, Post Fire Areas and Yard and DG Backed Lighting in Turbine Building

REQUIREMENT - Section III.J of Appendix R states, "Emergency lighting units with at least an 8-hour battery power supply shall be provided in all areas needed for operation of safe shutdown equipment and in access and egress routes thereto."

DEVIATION - Installed 8-hour battery pack emergency lighting units are not provided in either of the Containments, Turbine Building, or the Yard. Dedicated hand-held portable lanterns are provided in lieu of installed battery pack lighting units in both Containments. Emergency diesel generator (EDG) backed standby lighting is installed and maintained for the Turbine Building. Security diesel generator backed standby lighting is installed and maintained for the Yard. Additionally, portable hand-held lighting is available to supplement Yard and Turbine Building diesel backed lighting systems to provide task lighting capability (e.g., breaker tripping).

PART VII - DEVIATIONS AND EVALUATIONS

2.7.1 Justification for Containment

WBN has provided dedicated, hand-held portable lanterns in convenient locations that are maintained for the manual actions to be performed inside Containment. Manual operator actions requiring entry into primary containment only result from fire damage to the RHR isolation valves or cables near the valves which are located inside lower containment.

Ample time is available to extinguish the fire, obtain the portable lanterns, and operate the valves, because valve alignment may be performed anytime within four hours after reactor trip. Other actions identified for inside primary containment are optional. That is, closure of the cold leg accumulator valves is desirable, but not essential because reactor coolant pressure can be maintained above 150 psi. A fire affecting the RHR isolation valves could damage lighting circuits in the immediate vicinity, but does not disable all lower containment lighting because of circuit multiplicity and source diversity. Lower containment is equipped with both normal and diesel backed, standby lighting with fixtures located on three different elevations both inside and outside the crane wall. Fixtures at all elevations contribute to the general lighting level for access and egress.

The lights at each elevation are powered from two normal lighting circuits and, in general, different circuits are used at each elevation. Additionally, two standby lighting circuits, with fixtures strategically located throughout lower containment, provide adequate lighting in case of fire damage to the normal lighting cabinet. Batteries for the 8-hour emergency lighting units are not designed for the environmental conditions (e.g., high temperature and humidity) inside Containment. Due to ALARA considerations, access to the Containment during operations is very limited which means that inspection and testing of the battery units is only practical during an outage. Also, adding emergency lighting units inside Containment introduces additional material that could potentially impact the performance of the safety related equipment during accident conditions. TVA has provided dedicated hand-held portable lighting units for use in Containment. The portable lanterns provide an acceptable source of emergency lighting capability and ensure adequate lighting for Operators to be able to perform manual actions.

2.7.2 Justification Yard Area

Yard Area manual actions or manual actions for which traversing the Yard is necessary for fires in the Auxiliary Building or Control Building. The fires involving or requiring access to the Reactor Coolant Pump (RCP) trip breakers are an example. Lighting in the Yard is necessary for the manual action that trips the RCP breakers located in the breaker house in the switchyard. Tripping of the following breakers may be necessary for selected fires.

- 1-MTR-68-8 (local trip breaker 52-1A)
- 1-MTR-68-31 (local trip breaker 52-1B)
- 1-MTR-68-50 (local trip breaker 52-1C)
- 1-MTR-68-73 (local trip breaker 52-1D)
- 2-MTR-68-8 (local trip breaker 52-2A)
- 2-MTR-68-31 (local trip breaker 52-2B)
- 2-MTR-68-50 (local trip breaker 52-2C)
- 2-MTR-68-73 (local trip breaker 52-2D)

Access to these breakers is through the transformer/switchyard. Other manual actions are performed in the Diesel Generator Building and the Intake Pumping Station. The Yard is provided with normal lighting and security lighting. It is TVA's conclusion that the use of

PART VII - DEVIATIONS AND EVALUATIONS

portable lanterns (in the event the normal and security lighting was lost) provides a dependable source of light and therefore meets the intended purpose of ensuring adequate lighting for the Operator to access and perform the manual action. WBN has provided dedicated, hand-held portable lanterns in convenient locations that are maintained for the manual actions to be performed inside the Yard Area.

2.7.3 Justification for Turbine Building

The Turbine Building manual operator actions (breaker manipulation) are only necessary for fire that prevents access to the reactor trip switchgear in Rooms 757.0-A10 and 782-A1 for Unit 1 and 757-A16 and 782.0-A3 for Unit 2. The normal lighting and the emergency diesel generator backed standby lighting system provides adequate lighting to access and perform these actions in the Turbine Building. The standby lighting system is powered from a diesel generator backed power supply which is judged equivalent to 8-hour battery packs. The power supply cables to the Turbine Building standby lighting panel and the feeder cables are not routed in the rooms where a fire could create the need for the Turbine Building manual actions. Therefore, the standby lighting system will be available when needed.

2.7.4 Justification for Post-Fire Areas

For those areas in which a postulated fire occurred and a manual action is necessary to be performed after the fire has been extinguished, the Operator will use portable hand lanterns for lighting. Adequate installed emergency lighting is provided for the access routes to those areas. WBN has provided dedicated, hand-held portable lanterns in convenient locations that are maintained for the manual actions to be performed in the areas where manual action(s) must be performed after the fire has been extinguished. At least two diverse access routes are provided to each fire area.

It is TVA's conclusion that the above described alternatives to installing 8-hour battery pack emergency lighting and providing lighting in areas where manual actions are performed after the fire has been extinguished provides a reliable source of lighting for an Operator to perform the manual actions and therefore request approval of this deviation.

2.8 Reactor Coolant Pump Oil Collection System

REQUIREMENT - Section III.O of 10CFR50 Appendix R, "Oil Collection System for Reactor Coolant Pump", provides the guideline for an oil collection system for the Reactor Coolant pumps. WBN has provided an oil collection system for each reactor coolant pump which consists of splash shields, a collection basin directly below each RCP motor, and closed piping from the collection basin to the closed and vented concrete equipment drain sump. All potential leakage sites are protected by a combination of spray shields that are designed to direct the flow of oil into the collection basin in the event of a leak.

DEVIATION - The guideline of Section III.O of 10CFR50 Appendix R states in part that "Such collection systems shall be capable of collecting lube oil from all potential pressurized and unpressurized leakage sites in the reactor coolant pump lube oil systems". The guideline as stated means that any oil leakage that is not collected and found external to the oil collection system would not meet 10CFR50 Appendix R Section III.O. This deviation is to allow for minor amounts of oil that escape the oil collection system. There is also the potential of up to fourteen gallons of lube oil collecting in the lower motor housing. This deviation does not provide for

PART VII - DEVIATIONS AND EVALUATIONS

allowable leakage due to damage, disassembly, or improper maintenance of the oil collection system as designed.

JUSTIFICATION - The RCP oil collection system must function in an area with significant ventilation airflows from both the CRDM Cooling Units and the RCP motor itself. A minor leak in the lubrication system in the lower guide bearing and reservoir collects in the bottom of the lower motor support housing. This area is provided with a drain line to the oil collection system, but up to 14 gallons of oil could potentially accumulate before it begins to drain to the collection system. However, the amount of oil that could be in the housing is less than 2 gallons because the low level alarm on the lower oil reservoir is set for a loss of less than 2 gallons (Part II, Reference 4.3.16). Since the alarm response instruction includes problem investigation and online oil addition is not an accepted practice, the amount of undetected oil that may collect in the housing will be less than 2 gallons.

The high ventilation airflow between the lower guide bearing and reservoir and the bottom of the lower motor support housing can result in some of the oil becoming entrained in ventilation air, which in turn could prevent some of the leakage from ever entering the collection system. The need for ventilation around the RCP dictates that some ventilation flow areas must be present in areas around the lube oil system and the oil collection system. In designing the oil collection system, it is not feasible in all instances to prevent minor amounts of oil from becoming entrained in the ventilation air and escaping the collection system. This oil becomes a thin film on piping and supports in the vicinity of the RCPs.

A minor leak in the lubrication system in the lower guide bearing and reservoir collects in the bottom of the lower motor support housing. The lower motor support housing is provided with a drain pipe that will drain any accumulation of liquid (water and/or oil) over fourteen gallons from the lower support housing to the oil collection system. This ensures that postulated leakage will be contained and drained per the requirements of Appendix R, Section III.O. The combustible loading calculation considers the entire inventory of oil in each pump when determining the fire severity for each reactor building; therefore, the postulated accumulation of oil in the lower support housing has already been accounted for. Unit 1 has not experienced any accumulation of oil from any of the pumps. Section III.O states:

“Such collection systems shall be capable of collecting lube oil from all potential pressurized and unpressurized leakage sites in the reactor coolant pump lube oil systems. Leakage shall be collected and drained to a vented closed container that can hold the entire lube oil system inventory.”

Therefore this postulated accumulation of oil is considered to not present a hazard to fire safe shutdown and to be in compliance to the requirements of III.O for the following reasons:

- a. The oil is collected and amounts over fourteen gallons are drained to a vented closed container.
- b. Each pump is provided with automatic suppression and detection.
- c. The entire inventory of lube oil from each pump is accounted for in the combustible loading calculation and fire hazards analysis. The fire severity index is not affected.
- d. No measurable leakage has occurred in the operating life of Unit 1.
- e. The collected oil is not exposed to an ignition source.
- f. Each pump is provided with low oil level annunciation that alerts the main control room for lube oil loss of less than 2 gallons.

PART VII - DEVIATIONS AND EVALUATIONS

A modification to drain all postulated oil accumulation in the lower motor housing would not increase the safety of the plant.

Significant defense-in-depth measures exist to prevent a fire event due to a failure in the reactor coolant pump lube oil system. In the unlikely event that a fire did start, there are defense-in-depth measures to ensure that the fire is quickly identified and extinguished, and that the effects of the fire does not prevent the safe shutdown of the plant. These measures, in addition to the RCP oil collection system, include the use of suppression and detection above the RCPs, the proximity of manual hose stations, the use of mirror insulation on the RCS system piping, and the absence of ignition sources in the vicinity of the RCPs. A low oil level alarm annunciates once the oil loss reached the alarm setpoint and alert the operator to investigate the problem.

Oil used for the RCP motor bearings is Mobil SHC 824 Synthesized lubricant. This oil has a flash point of 480°F. This high flash point classifies the lubricant as a Class IIIB combustible liquid in accordance with NFPA 30. The normal operating temperature of the oil is 131°F. The oil at its normal operating temperature is well below its flashpoint and does not present a hazard.

The normal reactor coolant system temperature is 588°F. The reactor coolant piping could be a potential source of heat that could volatilize the lubricant if any leakage contacted the piping. This hazard is mitigated by the mirror insulation on the pump and reactor coolant piping. The stainless steel mirror insulation is non-combustible and at normal operation, the exterior of the insulation is 142°F. The surface of the high temperature piping is well insulated with non-combustible, non-permeable insulation such that the surface temperature of the insulation is well below the flash point of the lubricant and is not a potential ignition source. Minor amounts of oil that escape the collection system could potentially be deposited on mirror panels in the vicinity. The amount of oil, however, that is expected to escape the collection system is minor, so only a fine film coating is deposited on the panel. The mirror insulation panels are fitted together with overlapping seams and secured in place, which minimizes the likelihood that any oil seeps through the seams between panels. In addition, since only a minor amount of oil is present on the outside of the panel, it is not expected that a significant amount of oil could run into any of the panel seams.

Fire hazards due to electrical systems both within the pump assembly itself and those which are located in areas within possible range of leakage from the oil collection system have been evaluated. To prevent damage to the motor from interior oil leaks, the stator windings are coated with an epoxy resin and the oil sources are separated from electrical components by high silicone steel sheets. Electrical cables and terminals in the vicinity of the RCP have been shielded. As such, leakage will not come in contact with any potential electrical ignition source in the area of the RCP.

In addition, each of the RCPs is protected by fixed fire suppression and detection systems. These systems provide early detection and fire control until manual suppression activities can be achieved. The RCPs are protected by a closed head preaction automatic water spray system supplied by a common header. Each pump is protected by a ring header containing eight closed head spray nozzles. The header is located approximately four feet above the top of the RCP motor. Each nozzle has a temperature rating of 500 °F. The 500°F fusible bulb elements provide reasonable assurance that the nozzles will not operate during other design basis events, yet will open for fire conditions caused by a combustible liquid fire on the RCP.

PART VII - DEVIATIONS AND EVALUATIONS

Each of the RCPs is protected by automatic detection systems. Each RCP has four rate compensating / fixed temperature spot type thermal detectors. The detection circuits are Class A supervised. The temperature rating of the detectors is 225°F, and the detectors are cross-zoned (two in each zone). Upon actuation of one detector in each of the zones, the detection system automatically actuates the deluge valve to fill the supply piping for the closed head water spray system. The area above the RCPs is also equipped with a hood. In the event of a fire, the hood will act as a ceiling, forcing the heat to bank down, thus reducing the response time of the detectors and fusible elements in the spray nozzles.

In conclusion, based on the above discussion, there is reasonable assurance that adequate defense-in-depth measures are in place to prevent a RCP lube oil fire, and to quickly detect and suppress a postulated fire that might occur. Therefore, the allowance for minor leakage from the oil collection system does not affect the ability to achieve and maintain safe shutdown.

2.9.0 Fire Hazards Analysis (FHA) in Lieu of 10CFR50, Appendix R, Section III.G.2 Separation

REQUIREMENT – Section III.G.2 provides physical separation criteria applicable to fire areas where cables or equipment of redundant trains of systems necessary to achieve and maintain hot shutdown are located in the same fire area. Compliance with these criteria is one means of ensuring that one of the redundant trains is free of fire damage as required by Section III.G.1.

DEVIATION – For the purpose of addressing operator manual actions (OMAs), electrical raceway fire barrier systems (ERFBS) and radiant energy shields (RES), the rooms listed in the following table demonstrate compliance with the intent of Section III.G.1 by a fire hazards analysis with no OMA, ERFBS or RES in lieu of the prescriptive separation criteria described in Section III.G.2.

SECTION	ROOM NUMBER
2.9.1	692.0-A29 & 692.0-A30
2.9.2	729.0-A1 & 737.0-A6
2.9.3	729.0-A2
2.9.4	729.0-A6
2.9.5	729.0-A10
2.9.6	729.0-A11 & 737.0-A10
2.9.7	729.0-A12
2.9.8	729.0-A13
2.9.9	729.0-A15 & 763.5-A2
2.9.10	757.0-A13
2.9.11	757.0-A14
2.9.12	757.0-A15
2.9.13	2RIR
2.9.14	2RA1

PART VII - DEVIATIONS AND EVALUATIONS

2.9.15	2RA2
2.9.16	2RA3
2.9.17	2RA4
2.9.18	2RF1
2.9.19	2RF2
2.9.20	2RI (2RI-1, 2, 3, 4)
2.9.21	2RO (2RO-1, 2, 3, 4)

JUSTIFICATION – A fire hazards analysis (FHA) as documented below has been performed for each of the rooms listed in the above table and is provided here for NRC review and approval. The FHA has been performed in accordance with the guidelines of GL 86-10. When a barrier is identified as a rated fire barrier, the penetrations through that barrier are rated for the barrier and are maintained by appropriate engineering design and maintenance programs (e.g. fire doors, fire dampers, and penetration seal programs [Ref. 4.2.25, 4.2.50, 4.2.61, 4.2.62, 4.2.63, and 4.2.72]). The combustible loading information is derived from the Combustible Loading calculation (Ref. 4.2.18) and the fire rated barriers are documented on the Fire Protection Compartmentation drawings (Ref. 4.2.7).

FHA General Information

FSSD “path” refers to a set of components that are sufficient to accomplish a fire safe shutdown function. In this deviation the word “component” is used when discussing equipment or cables. “Equipment” is used in regard to an end device such as a motor control center, valve, handswitch, etc. Cable is referring to the electrical power, control and instrumentation circuits.

Motor operated valves (MOVs) are not considered credible ignition sources because it would take multiple failures (electrical and mechanical) to result in a fire. During normal operation, the power cables to the MOVs are de-energized (they are only energized when the valve is given a signal to move). The power cable (routed in conduit) is provided with circuit protective devices (fuses/breakers) that are designed to clear a fault prior to cable insulation ignition. The motor is enclosed and the gear box on the MOV would have to fail and leak lubricating oil at the same time that a power cable to the valve was energized and failed. The lubricating oil for the valves is not exposed combustibles, but the combustible loading calculation has assumed that the oil is exposed; therefore, the combustible loading for each room is very conservative. In addition, NUREG/CR-6850 identifies that any enclosed motor, including MOV drive motors, regardless of size are not considered as ignition sources.

Flow solenoid valves (FSVs) are not considered credible ignition sources because the cables (routed in conduit) are low voltage circuits that are provided with circuit protection (fuses and/or breakers) that are designed to clear a fault prior to cable ignition. There is insignificant combustible material associated with a FSV and the worst result of a fault on these circuits is to blow a fuse or open a breaker.

Small wall mounted transformers, electrical control panels (e.g. local control panels, push button stations, open instrument panels on which are mounted transmitters, indicators, etc.) and lighting units are not considered credible ignition sources because the cables (routed in conduit) terminating on/in these small transformers, panels or lighting units are low voltage circuits that

PART VII - DEVIATIONS AND EVALUATIONS

are provided with circuit protection (fuses/breakers) that are designed to clear a fault prior to cable insulation ignition. There is insignificant combustible material associated with these devices. In addition, NUREG/CR-6850 identifies that dry transformers with a rating of 45kVA or less are expected to have insufficient combustible material to produce a fire with the potential to spread beyond the bounds of the initiating component or to represent a direct threat to other plant equipment or cables. The electrical panels and lighting units are less of a hazard than the dry transformers.

Small motors of 5 hp or less are not considered credible ignition sources because there is insignificant combustible material associated with the motor. In addition some motors such as sump pump motors are normally de-energized. The power cables to the motors are properly sized and the protective devices (breaker/fuse) are designed to clear a fault before the cable reaches its auto-ignition temperature. NUREG/CR-6850 states: "Pumps with a rating of 5 hp or less are assumed to have little or no significant contribution to risk".

Radiation monitors are not considered credible ignition sources because they contain insignificant quantities of combustible material and the circuits to these devices are low voltage, routed in conduit and are protected by properly designed circuit protective devices (fuses/breakers) that will clear a circuit fault prior to the insulation on the cables reaching its auto-ignition temperature. As with a dry transformer (see above), the radiation monitors have insufficient combustible material to produce a fire with the potential to spread beyond the monitor or to represent a direct threat to other plant equipment or cables.

The following deviation requests address the individual rooms or group of closely related rooms. Each contains four parts:

- a. Description of Condition – Describes the room(s) and its relationship to the fire area and analysis volume it is in and gives a brief description of the OMAs and/or cable protection (i.e. electrical raceway fire barrier system (ERFBS) or radiant energy shields (RES)) that would be required in order to meet Section III.G.2 if an assumed fire damaged all of the components in the room. This part describes the approach which would be required if the deviation were not approved by the NRC.
- b. Fire Hazards Analysis – This part provides the following:
 1. A description of the room size, fire barriers and other fire protection features of the room(s).
 2. Identifies the fire load and fire severity associated with the room(s) and the type of combustibles.
 3. Defines the control of transient combustibles and ignition sources.
 4. Identifies the adjacent rooms and the potential for fire propagation from one room to another.
- c. System Evaluation – The System Evaluation considers expected, realistic fire damage (based on the FHA) and its effect on FSSD components in the room(s). The three subsections are:

PART VII - DEVIATIONS AND EVALUATIONS

1. Redundant FSSD Components in the Room – Identifies and evaluates the redundant FSSD components located in the room and justifies that no OMAs, ERFBSs or RESs must be implemented or installed since failure of redundant equipment or cables is not expected. The evaluation includes relative locations of the redundant components with respect to each other and to ignition sources and combustibles in the room(s). Additional factors providing defense-in-depth are included as appropriate.
 2. FSSD Components with Redundant FSSD Components in an Adjacent Room within the Same Analysis Volume – Evaluation of components in the room(s) whose redundant counterpart is located in another room within the same analysis volume. Specific consideration is given to adequacy of the barrier separating the redundant components.
 3. Other FSSD Components in the Room – Evaluates the potential impact to normal plant operation due to failure of the non-credited FSSD components in the room(s).
- d. Conclusion – The results of the FHA and system evaluation have determined that no credible fire could occur that would impact the FSSD analysis and that no OMAs or ERFBSs or RESs are necessary for the protection of the components in the room(s).

2.9.1 Rooms 692.0-A29 and 692.0-A.30: Boric Acid Evaporator Package Rooms A and B

2.9.1.1 Description of Condition

These two rooms are a part of fire area 1 (See Part III, Table 3-3 for room listing) and they are analyzed in analysis volume AV-005. Fire area 1 is considered a III.G.2 area; however, rooms 692.0-A29 and 692.0-A30 do not contain redundant shutdown paths, or any FSSD equipment. The only FSSD components located in rooms 692.0-A29 and 692.0-A30 are cables routed in conduits.

Physical separation in accordance with III.G.2 cannot be achieved in AV-005. An FSSD which assumes failure of all equipment and cables in the rooms would result in OMAs being credited in lieu of III.G.2 physical separation for these two rooms. Therefore, the following OMAs are implemented to achieve fire safe shutdown:

- a. Unit 1 – Stop primary makeup water pump within 75 minutes by tripping the breaker on the MCC.
- b. Unit 2 – Stop both primary makeup water pumps within 75 minutes by tripping the breaker on the MCC.
- c. Unit 2 – Reduce RCP seal injection flow within 60 minutes by operation of a manual valve on 713-A1B.

PART VII - DEVIATIONS AND EVALUATIONS

2.9.1.2 Fire Hazards Analysis

2.9.1.2.a Room Description

The Boric Acid Evaporator Package Room B (692.0-A29) and Room A (692.0-A30) are of reinforced concrete construction (walls, floors and ceiling thicknesses from 12 to 36-inches). The ceilings and part of the floors with a room below have a fire resistance rating of 2 hours and the walls separating the rooms from the Control Building have a fire resistance rating of 3 hours. The walls separating these rooms from adjacent rooms on 692.0 are minimum 24-inches thick reinforced concrete, but are not assigned a fire resistive rating because electrical and mechanical openings in these barriers are not provided with fire rated seals/closures. The doors into the rooms are heavy duty hollow metal doors that are similar to fire rated doors. The rooms have a floor area of 888-ft² (692.0-A29) and 850-ft² (692.0-A30) and a nominal ceiling height of 19-feet. Rooms 692.0-A29 and 692.0-A30 are designated as Combustible Control Zones (CCZs) (see Part II section 5.0 for definition of a CCZ).

2.9.1.2.b Fire Load

The fire severity classification due to the combustible loading in the room is insignificant. The minor amount of combustible material is due to a quart of lube oil for each pump associated with each Evaporator Package and plastics associated with a small wall mounted dry type transformer, junction boxes and light covers in each room. The Evaporator Packages are not in use and the pumps are not powered; therefore, they are not an ignition source. Cables in the room are routed in conduits and are not considered to be ignition sources.

The small wall mounted dry type transformer, junction boxes and lights are not considered to be ignition sources (see Justification in 2.9.0 above). It is concluded that the insignificant quantity of in situ combustibles and no ignition sources combined with the strict control of transient combustibles assures that no credible fire in 692.0-29 or 692.0-A30 could occur and propagate into an adjacent room.

2.9.1.2.c Control of Combustibles and Ignition Sources

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room. Rooms 692.0-A29 and 692.0-A30 are CCZs (see Part II, sections 10 and 11 and WBN Technical Instruction TI-291, Combustible Control Zones and Sensitive Areas). For compliance with TI-291, the approval of an evaluation must be obtained before any transient combustible can be introduced into the room or hot work performed in the room. Access to the rooms is not controlled; however, the lack of significant concentrations of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources provides assurance that no credible exposure fire would occur. Based on this, it is not expected that the plant will enter the fire safe shutdown procedure.

PART VII - DEVIATIONS AND EVALUATIONS

2.9.1.2.d Adjacent Rooms

The room below (676.0-A17) is provided with a fire detection system and contains insignificant quantities of in situ combustible. It is separated from rooms 692.0-A29 and 692.0-A30 by a 2 hour fire rated barrier. No credible fire in 676.0-A17 could propagate into 692.0-A29 or 692.0-A30.

Adjacent room 692.0-A1 is provided with fire detection and automatic suppression systems and is separated from the two rooms by at least 24-inch thick reinforced concrete walls that are not assigned a fire resistance rating because of electrical and mechanical opening not being provided with fire rated seals/closures. Over 97% of the combustible loading in 692.0-A1 is due to insulation on cables routed in cable trays. The combination of automatic suppression in 692.0-A1 and the concrete walls that separate 692.0-A1 from 692.0-A29 or 692.0-A30 provide assurance that no credible fire in 692.0-A1 could propagate into 692.0-A29 or 692.0-A30.

The wall between room 692.0-A27 and adjacent room 692.0-A29 is a 36-inch thick reinforced concrete barrier but is not assigned a fire rating. Room 692.0-A27 contains the concentrate filter (a high radiation area) and does not contain any in situ combustibles or ignition sources. There is no credible fire in 692.0-A27 that could propagate through the wall into 692.0-A29.

The wall between 692.0-A30 and 692.0-A31 is a 36-inch thick reinforced concrete wall that is assigned a 2 hour fire resistive rating. However, the wall is not credited for FSSD. Room 692.0-A31 is provided with a fire detection system and has low in situ combustible loading. The only significant penetration through this wall is an HVAC duct and it is provided with a fire damper. There is no credible fire in Room 692.0-A31 that could propagate through this wall separating room 692.0-A30 from 692.0-A31.

Adjacent room 713.0-A1 is separated from 692.0-A29 and 692.0-A30 by a 2 hour rated concrete floor. Part of 713.0-A1 containing the Boric Acid Tanks are above 692.0-A30 and this area does not have automatic suppression (See Part VII, section 3.1). The rest of the area of 713.0-A1 above 692.0-A29 and 692.0-A30 is protected with automatic suppression. Over 98% of the combustible load in 713.0-A1 is due to the insulation on cables routed in cable trays. It is concluded that the combination of 2 hour rated fire barrier and suppression on 713.0-A1 assures that no credible fire on 713.0-A1 could propagate into 692.0-A29 or 692.0-A30.

TVA concludes that, based on the above information, no credible fire could propagate from a room adjacent to 692.0-A29 or 692.0-A30 nor could a credible fire propagate from 692.0-A29 or 692.0-A30 into an adjacent room.

2.9.1.3 System Evaluation

2.9.1.3.a Redundant FSSD Components in the Room

Control circuits for a valve that controls reactor coolant pump seal water injection are routed through 692.0-A30 in a conduit; however, there are no FSSD equipment or redundant cables located in these rooms. The conduit is 16'-6" off the floor and 2'-6" below the ceiling. As described in section 2.9.1.2, there is no credible ignition sources and insignificant combustible loading in the rooms; therefore, it is concluded that no credible fire in the rooms could damage these circuits and necessitate the OMA listed in 2.9.1.1.c. Even if a failure of these control circuits resulted in a spurious operation of the valve, the MCR staff is alerted to a change in pressurizer level and manage the problem using normal plant procedures.

PART VII - DEVIATIONS AND EVALUATIONS

2.9.1.3.b FSSD Components with Redundant FSSD Components in an Adjacent Room within the same Analysis Volume

The cables whose failure could necessitate the OMAs listed in 2.9.1.1.a and .b are located in adjacent room 692-A1B which is part of AV-005. Based on the insignificant combustible materials and no ignition sources, no credible fire could propagate from 692.0-A29 or 692.0-A30 into 692.0-A1B and damage cables in 692.0-A1B that would necessitate the performance of OMAs.

2.9.1.3.c Other FSSD Components in the Room

Rooms 692.0-A29 or 692.0-A30 contains cables associated with FSSD equipment relied upon for fires in other areas of the plant (i.e., cables not credited for a fire in Rooms 692.0-A29 or 692.0-A30). The cables are routed in conduit. Although no fire induced failures are expected due to the insignificant fire hazard in the rooms, postulated failure of the non-credited FSSD cables has been evaluated to assess its effect on plant operation. Failure of these FSSD cables is detected and mitigated by normal plant procedures and would not initiate or result in a plant trip.

- Charging flow transmitter cables
- Turbine driven auxiliary feedwater pump governor valve and speed control valve cables
- Containment differential pressure transmitter channel G cable
- Refueling water storage tank level transmitter channel D cable
- Steam line pressure transmitter channel E cables
- Reactor building sump level transmitter channel G cable
- Steam generator #4 level transmitter cable
- Containment spray valve cables
- Steam generator #1 auxiliary feedwater inlet flow transmitter cable

2.9.1.4 Conclusion

Since there is insignificant threat from transient combustibles or in situ combustible material and no credible ignition sources; it is concluded that no cables routed in conduit could be damaged by any credible fire in either room and therefore, the performance of OMAs is not necessary. In addition, the redundant cables are routed in another room (692.0-A1B) which is provided with automatic suppression and detection. TVA concludes that the intent of III.G.1 is ensured and requests approval of this deviation demonstrating compliance to III.G.1 criteria with a fire hazard analysis in lieu of the prescriptive separation criteria of III.G.2.

2.9.2 Rooms 729.0-A1 and 737.0-A6 – Unit 1 South Main Steam Valve Room and Air Lock

2.9.2.1 Description of Condition

These two rooms make up fire area 12 which is analysis volume 34 (AV-034) in the FSSD analysis (see Part III, Table 3-3 for room listing). The fire area is considered a III.G.2 area because components related to both redundant shutdown paths are located in 729-A1.

PART VII - DEVIATIONS AND EVALUATIONS

The redundant components are not cables or equipment that must operate for FSSD, but rather control air users connected to the Train A and the Train B auxiliary control air system (ACAS) headers. The FSSD analysis generally assumes that fire damage to one ACAS air user could depressurize the header (Train A or Train B). If all the ACAS air users located in this area were assumed to fail due to postulated fire damage; both trains of the ACAS are assumed failed. Since the ACAS is common to both units, both units are affected.

Physical separation in accordance with III.G.2 cannot be achieved in this area. An FSSD analysis assuming failure of all equipment and cables in the room would result in OMAs being credited in lieu of III.G.2 physical separation. Therefore, the following OMAs are implemented to achieve fire safe shutdown:

- a. Unit 1 - Control level in two steam generators within 20 minutes by manual valve operation. (Unit 2 has an alternative motive air (nitrogen) supply for these valves to eliminate these OMAs)
- b. Unit 1 - Control motor driven auxiliary feed water pump discharge pressure within 20 minutes by manual valve operation. (Unit 2 has an alternative motive air (nitrogen) supply for these valves to eliminate these OMAs).
- c. Unit 1 and Unit 2 - Control pressure in two steam generators within 60 minutes by operation of SG PORV via local nitrogen control station.

2.9.2.2 Fire Hazard Analysis

2.9.2.2.a Room Description

Room 729.0-A1 is the Unit 1 South Main Steam Valve room and room 737.0-A6 is the entrance to the valve room from the Auxiliary Building. The walls and floor of 729.0-A1 are of reinforced concrete construction and have fire resistive ratings of 2-hours for the walls and floor that separate the valve room from adjacent areas of the Auxiliary Building and fire resistive rating of 3-hours for the wall separating it from the Unit 1 Reactor Building. The walls separating 729.0-A1 from the Yard are 36-inch thick reinforced concrete but are not assigned a fire resistive rating. There are two access paths into the valve room. One is from the Auxiliary Building into the labyrinth (the two doors in the labyrinth from the Auxiliary Building and into the valve room are interlocked such that only one door can be opened at a time). The other path is from the Yard. Access to the valve room is limited due to the hazardous environmental conditions in the room (high humidity, high temperature, and presence of high energy lines (main steam and feedwater)).

2.9.2.2.b Fire Load

The in situ combustible loading for 729.0-A1 and 737.0-A6 is insignificant. The in situ combustibles in 729.0-A1 consist of small quantities of lubricant in each valve and small quantities of miscellaneous plastics associated with area radiation monitors, small electrical control panels and boxes and lighting units. The in situ combustibles in 737.0-A6 are the light covers. The credible ignition sources in 729.0-A1 are the radiation monitors and the valve motors. None of these devices are considered to be significant ignition sources due to the small quantity of in situ combustible material associated with them and the circuit protection (properly sized and coordinated fuses/breakers) that is designed to clear an electrical fault before the cable insulation reaches ignition temperature.

PART VII - DEVIATIONS AND EVALUATIONS

2.9.2.2.c Control of Combustibles and Ignition Sources

NPG-SPP-18.4.7, “Control of Transient Combustibles” and NPG-SPP-18.4.8, “Control of Ignition Sources (Hot Work)” defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room. Room 729.0-A1 and 737.0-A6 are CCZs (see Part II, sections 10 and 11 and WBN Technical Instruction TI-291, Combustible Control Zones and Sensitive Areas). For compliance with TI-291, the approval of an evaluation must be obtained before any transient combustible can be introduced into the room or hot work performed in the room. Access to the room is limited due to the hazardous conditions in 729.0-A1. The lack of significant concentrations of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources provides assurance that no credible exposure fire would occur. Based on this, it is not expected that the plant will enter the fire safe shutdown procedure.

2.9.2.2.d Adjacent Rooms

There is no threat of a fire in an adjacent room in the Auxiliary Building propagating into 729.0-A1 or 737.0-A6 due to the combination of fire rated barriers and automatic fire suppression and detection in those rooms. The thick reinforced concrete walls separating 729.0-A1 from the Yard would prevent a fire in the Yard from propagating into the room. The door in this wall is located in a labyrinth which would shield the door from a transient fire in the Yard. In addition, main feedwater and steam lines which run alongside the wall prevent any significant transient combustibles from being in the vicinity of the wall, labyrinth and door. The 3 hour fire rated concrete wall separating the Unit 1 Reactor Building from 729.0-A1 and 737.0-A6 would prevent a fire in the Unit 1 Reactor Building propagating into the rooms.

TVA concludes, based on the above information that no credible fire could propagate from an adjacent room into room 729.0-A1 and 737.0-A6 or from 729.0-A1 or 737.0-A6 into an adjacent room.

2.9.2.3 System Evaluation

2.9.2.3.a Redundant FSSD Components in the Room

There are no redundant cables for FSSD equipment in 729.0-A1 or 737.0-A6 and 737.0-A6 does not contain any FSSD components. The only redundant FSSD equipment in room 729.0-A1 are train A and train B air endusers connected to the redundant ACAS headers. To achieve safe shutdown without OMAs at least one ACAS header must be operable to supply Unit 1 and Unit 2 air users in other plant locations. As described in calculation WBPEVAR9602001, “Appendix R – Auxiliary Control Air Analysis” (Part II, reference 4.2.74), the ACAS is a safety system and uses welded stainless steel piping and fittings; however, some of the air user devices may be susceptible to fire damage based on their physical construction and/or material make up (e.g., pressure regulators, diaphragms, controllers, etc.).

The ACAS air users in 729.0-A1 are two level control valves (LCVs) and two power operated relief valves (PORVs) associated with the steam generators #1 and #4. Their redundant counterparts are not in 729.0-A1. The FSSD analysis does not credit these steam generators nor the air supply to these valves to achieve safe shutdown with a fire in this room. However, at least one train of ACAS is needed to operate equipment located elsewhere in the plant. One

PART VII - DEVIATIONS AND EVALUATIONS

LCV and one PORV are connected to each train of the ACAS. The LCVs are in parallel horizontal piping runs three feet on center at elevation 748 (19 feet above the floor). The PORVs are in parallel horizontal piping runs 19'-2" on center at elevation 758 (29 feet above the floor).

As described in the FHA (2.9.2.2) the absence of ignition sources and insignificant in situ combustibles is sufficient to conclude that a credible fire could not damage air users connected to both ACAS headers. The existence of transient combustibles is reduced because this room is rarely entered during operations due to the high temperature and humidity in the main steam valve vaults. For additional defense-in-depth this room is maintained as a CCZ. A very large amount of transient combustibles and an ignition source would have to be brought into the valve vault to produce a fire that could damage the level control valves located a minimum of 19 feet above the floor in a room with a 55 foot high ceiling.

Based on the above information, it is concluded that no credible fire in 729.0-A1 could occur and the implementation of the OMAs identified in 2.9.2.1 is not necessary.

2.9.2.3.b Components with Redundant FSSD Components in an Adjacent Room within the Same Analysis Volume

Rooms 729.0-A1 and 737.0-A6 are the only rooms in AV-034 (fire area 12). The barriers that separate rooms 729.0-A1 and 737.0-A6 from adjacent rooms in the Auxiliary Building are 2 hour fire rated barriers and from the Unit 2 Reactor Building is a 3 hour fire rated barrier. The only non-fire rated barrier is the outside wall that separates 729.0-A1 from the Yard and there are no redundant FSSD equipment or cables in the Yard near this wall (see 2.9.2.2 above).

2.9.2.3.c Other FSSD Components in the Room

Room 729.0-A1 contains FSSD equipment and cables associated with FSSD equipment relied upon for fires in other areas of the plant (i.e., equipment and cables not credited for a fire in Room 729.0-A1). The cables are routed in conduit. Although no fire induced failures are expected due to the insignificant fire hazard in the rooms, postulated failure of the non-credited FSSD equipment and cables has been evaluated to assess its effect on plant operation. Failure of this FSSD equipment or cables are detected and mitigated by normal plant procedures and would not initiate or result in a plant trip.

- Steam line warming valves and associated cables (Valves are normally closed with power removed during normal operation.)
- Steam generator blowdown outboard containment isolation valve cables
- Main steam isolation valves and cables for steam generators #1 and #4
- Steam generators #1 and #4 main feedwater isolation MOVs and bypass line isolation valves and associated cables
- Steam generators #1 and #4 power operated relief valves and one train of control solenoids and associated cables
- Turbine driven auxiliary feedwater pump steam supply MOV cables
- Turbine driven auxiliary feedwater pump level control valves and cables for steam generators #3 and #4
- Pressurizer heater backup group 1B cables

PART VII - DEVIATIONS AND EVALUATIONS

2.9.2.4 Conclusion

There is insignificant threat from transient combustibles or in situ combustible material, no significant ignition sources; therefore, there is no fire hazard in 729.0-A1 or 737.0-A6 that could cause loss of ACAS pressure and necessitate any OMAs. TVA concludes that the intent of III.G.1 is ensured and requests approval of this deviation demonstrating compliance to III.G.1 criteria with a fire hazard analysis in lieu of the prescriptive separation criteria of III.G.2.

2.9.3 Room 729.0-A2 – Unit 1 North Main Steam Valve Room

2.9.3.1 Description of Condition

Room 729-A2 is part of fire area 13 and is analysis volume 35A (AV-035A) in the FSSD analysis (see Part III, Table 3-3 for room listing). Fire area 13 is considered a III.G.2 area because it contains components related to both redundant safe shutdown paths. Electrical Raceway Fire Barrier Systems (ERFBS) are credited to protect two Unit 1 cables and a FSSD analysis assuming failure of all equipment and cables in the room concludes that OMAs are necessary in lieu of III.G.2 physical separation.

The redundant components are not cables or equipment that must operate for FSSD, but rather control air users connected to the Train A and the Train B auxiliary control air system (ACAS) headers. The FSSD analysis generally assumes that fire damage to one ACAS air user could depressurize the header (Train A or Train B). If all the ACAS air users located in this area were assumed to fail due to postulated fire damage; both trains of the ACAS are assumed failed. Since the ACAS is common to both units, both units are affected.

Physical separation in accordance with III.G.2 cannot be achieved in this area. An FSSD analysis which assumes failure of all equipment and cables in this room results in OMAs being credited in lieu of III.G.2 physical separation. Therefore, the following OMAs are implemented to achieve fire safe shutdown:

- a. Unit 1 - Control level in two steam generators within 20 minutes by manual valve operation. (Unit 2 has an alternative motive air (nitrogen) supply for these valves to eliminate these OMAs)
- b. Unit 1 - Control motor driven auxiliary feed water pump discharge pressure within 20 minutes by manual valve operation. (Unit 2 has an alternative motive air (nitrogen) supply for these valves to eliminate these OMAs).
- c. Unit 1 and Unit 2 - Control pressure in two steam generators within 60 minutes by operation of SG PORV via local nitrogen control station.

2.9.3.2 Fire Hazard Analysis

2.9.3.2.a Room Description

Room 729.0-A2 is the Unit 1 North Main Steam Valve room. The walls of 729.0-A2 are of reinforced concrete construction and have fire resistive ratings of 3 hours that separate the valve room from adjacent areas of the Auxiliary Building and fire resistive rating of 3 hours for the wall separating it from the Unit 1 Reactor Building. The walls separating 729.0-A2 from the Yard are 36-inch thick reinforced concrete but are not assigned a fire resistive rating. Two

PART VII - DEVIATIONS AND EVALUATIONS

doors are located in these walls. One door is located in a labyrinth which would shield the door from a transient fire in the Yard. The other door is located in a labyrinth and behind the main feedwater and steam lines which run alongside the wall and prevent any significant transient combustibles in the Yard from being in the vicinity of the labyrinth and door.

2.9.3.2.b Fire Load

The in situ combustible loading for room 729.0-A2 is insignificant. The in situ combustibles in 729.0-A2 consist of small quantities of lubricant in each valve and small quantities of miscellaneous plastics associated with area radiation monitors, small electrical control panels and boxes and lighting units. The radiation monitors and the valve motors are not considered to be ignition sources due to the small quantity of in situ combustible material associated with them and the circuit protection (properly sized and coordinated fuses/breakers) for each (see Justification in 2.9.0). There are no credible ignition sources in the room.

2.9.3.2.c Control of Combustibles and Ignition Sources

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms. Compensatory measures must be implemented when transient combustibles or ignition sources are located in a room. Room 729.0-A2 is a CCZ (see Part II, sections 10 and 11 and WBN Technical Instruction TI-291, Combustible Control Zones and Sensitive Areas). For compliance with TI-291, the approval of an evaluation must be obtained before any transient combustible can be introduced into the room or hot work performed in the room. Access to the room is limited due to the hazardous conditions in 729.0-A2. The lack of significant concentrations of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources provides assurance that no credible exposure fire would occur. Based on this, it is not expected that the plant will enter the fire safe shutdown procedure.

2.9.3.2.d Adjacent Rooms

There is no threat of a fire in an adjacent room in the Auxiliary Building propagating into 729.0-A2 due to the 3 hour fire rated barriers and insignificant quantities of in situ combustibles in the adjacent rooms.

The Unit 1 Reactor Building is separated from 729.0-A2 by the 3 hour fire rated 36 inch thick reinforced concrete wall; therefore, there is no threat of a fire in the Unit 1 Reactor Building propagating into 729.0-A2.

The Yard area adjacent to the exterior walls of 729.0-A2 is maintained free of any significant combustibles. Two doors provide access from the Yard into 729.0-A2 and they are located in walls on opposite sides of 729.0-2. The door on the west side is back in a labyrinth and is behind the main feedwater and steam lines. The door on the east side is back in a labyrinth. No significant quantities of either in situ or transient combustibles are in the vicinity of either of the doors. There is no credible fire in the Yard near these walls that could propagate into 729.0-A2.

TVA concludes, based on the above information, that no credible fire could propagate from an adjacent room into 729.0-A2 nor from 729.0-A2 into an adjacent room.

PART VII - DEVIATIONS AND EVALUATIONS

2.9.3.3 System Evaluation

2.9.3.3.a Redundant FSSD Components in the Room

Cables for the train A and train B solenoid valves associated with the SG #2 and SG #3 power operated relief valves (PORVs) are routed in conduit through 729.0-A2. The cables for one train for each SG are protected with 3-hour rated ERFBS to ensure PORV closure capability. Even though there is no credible fire that necessitates cable protection, it continues to be credited. The only redundant FSSD equipment in the room are train A and train B air users connected to the redundant ACAS headers. To achieve safe shutdown without OMAs, at least one ACAS header must be operable to supply Unit 1 and Unit 2 air users in other plant locations. As described in calculation WBPEVAR9602001, "Appendix R – Auxiliary Control Air Analysis" (reference 4.2.74), the ACAS is a safety system and uses welded stainless steel piping and fittings; however some of the air user devices may be susceptible to fire damage based on their physical construction and/or material make up (e.g., pressure regulators, diaphragms, controllers, etc.).

The ACAS air users in 729.0-A2 are two power operated relief valves (PORVs) associated with the steam generators #2 and #3. The FSSD analysis does not credit these steam generators nor the air supply to these valves to achieve safe shutdown with a fire in this room. However, at least one train of ACAS is needed to operate equipment located elsewhere in the plant. One PORV is connected to each train of the ACAS. The PORVs are in parallel horizontal piping runs 19'-2" on center at elevation 758 (29 feet above the floor). As described in the 2.9.3.2 the absence of ignition sources and insignificant in situ combustibles is sufficient to conclude that a credible fire could not damage air users connected to both ACAS headers. For additional defense-in-depth this room is maintained as a CCZ. The existence of transient combustibles is further reduced because this room is rarely entered during operations due to the high temperature and humidity in the main steam valve vaults. A very large amount of transient combustibles and an ignition source would have to be brought into the valve vault to produce a fire that could damage the level control valves located a minimum of 19 feet above the floor in a room with a 53 foot high ceiling.

Based on the above information, it is concluded that the OMAs identified in 2.9.3.1 are not necessary.

2.9.3.3.b Components with Redundant FSSD Components in an Adjacent Room within the Same Analysis Volume

Room 729.0-A2 is the only room in AV-035A (fire area 13). The barriers that separate room 729.0-A2 from adjacent rooms in the Auxiliary Building and from the Unit 1 Reactor Building are 3 hour fire rated barriers. The only non-fire rated barrier is the outside wall that separates 729.0-A2 from the Yard and there are no redundant FSSD equipment or cables in the Yard near this wall (see 2.9.3.2 above).

2.9.3.3.c Other FSSD Components in the Room

Room 729.0-A2 contains FSSD equipment and cables associated with FSSD equipment relied upon for fires in other areas of the plant (i.e., equipment and cables not credited for a fire in Room 729.0-A2). The cables are routed in conduit. Although no fire induced failures are expected due to the insignificant fire hazard in the rooms, postulated failure of the non-credited FSSD equipment and cables has been evaluated to assess its effect on plant operation. Failure

PART VII - DEVIATIONS AND EVALUATIONS

of this FSSD equipment or cables is detected and mitigated by normal plant procedures and would not initiate or result in a plant trip.

- Steam line warming valves and associated cables (Valves are normally closed with power removed during normal operation.)
- Steam generator blowdown outboard containment isolation valve cables
- Main steam isolation valves and cables for steam generators #2 and #3
- Steam generators #2 and #3 main feedwater isolation MOVs and bypass line isolation valves and associated cables
- Steam generators #2 and #3 power operated relief valves and one train of control solenoids and associated cables
- Steam line pressure transmitter cable

2.9.3.4 Conclusion

There is insignificant threat from transient combustibles or in situ combustible material, no significant ignition sources; therefore, there is no fire hazard in 729.0-A2 that could cause loss of ACAS pressure and necessitate any OMAs. TVA concludes that the intent of III.G.1 is ensured and requests approval of this deviation demonstrating compliance with III.G.1 criteria with a fire hazard analysis in lieu of the prescriptive separation criteria of III.G.2.

2.9.4 Room 729.0-A6 – Nitrogen Storage Area

2.9.4.1 Description of Condition

This room is a part of fire area 10 (See Part III Table 3-3) and is analyzed in analysis volume AV-032. Fire area 10 is considered a III.G.2 area because it contains components related to both redundant shutdown paths. Room 729.0-A6 does not contain any FSSD equipment but does contain cables to redundant safe shutdown equipment.

Physical separation in accordance with III.G.2 cannot be achieved in this analysis volume. An FSSD analysis which assumes failure of all equipment and cables in the room results in OMAs being credited in lieu of III.G.2 physical separation. Therefore, the following OMAs are implemented to achieve fire safe shutdown for a fire in Room 729.0-A6:

- (Deleted - Previously referred to Table 6-2 which has been deleted)
- Unit 1 – Establish motor driven auxiliary feedwater pumps A & B pressure control and control steam generators #1 & #4 level within 20 minutes by manually controlling valves.
- Unit 1 – Operate steam generators #1 & #4 power operated relief valves to control secondary pressure within 60 minutes at local nitrogen control panels.
- Unit 1 & 2 – Provide alternate 480VAC power to battery charger and inverter for channel 3-F within 120 minutes.
- Unit 2 - Operate steam generator #3 power operated relief valve to control secondary pressure within 60 minutes at local nitrogen control panel.
- Unit 1&2 – Backwash and rotate essential raw cooling water strainers within 720 minutes to ensure strainer operation.

PART VII - DEVIATIONS AND EVALUATIONS

2.9.4.2 Fire Hazards Analysis

2.9.4.2.a Room Description

Room 729.0-A6, Nitrogen Storage Area, is part of Fire Area 10 and is of reinforced concrete construction. The ceiling separating 692.0-A14 from 729.0-A6 is a 2 hour fire rated barrier. The walls separating 729.0-A6 from 729.0-A14 and 729.0-A15 are 3 hour fire rated barriers; from the New Fuel Storage Vault, Spent Fuel Pit and Fuel Transfer Canal are 2 hour fire rated barriers; and the ceiling which separates 729.0-A6 from 757.0-A13 is a 2 hour fire rated barrier. The walls separating 729.0-A6 from 728.0-A7, 729.0-A5, A8 and A9 are not assigned a fire rating but are of reinforced concrete construction and the doors are heavy duty hollow-metal doors. The room has a floor area of 1,623 ft² and a ceiling height of 26-feet. Room 729.0-A6 is designated as a CCZ (see Part II, section 5.0).

2.9.4.2.b Fire Load

The in situ combustible load results in a fire severity classification of insignificant. The combustible loading for the room consists of the charcoal filters within the air filter units, various plastics associated with a small control panel, lighting units, junction boxes and instruments, and class A combustibles (plastic and paper) in the Post Accident Sampling cabinet. The small control panel, lighting units and junction boxes are not credible ignition sources (see Justification in 2.9.0).

There are two air filter units located in the room. The units contain charcoal filters which are the major equipment in the room and the only significant fire hazard. These filters are protected by dedicated closed nozzle fixed pipe water spray systems as defined in section 3.1.3.3 of N3-26-4002 (Part II, reference 4.2.4). The two air filter units are normally shutdown and are not an ignition source. They are in operation when they are being tested and if there is a Post Accident Sampling event. In either case, personnel at the units take immediate appropriate action to initiate suppression and secure the units.

The room is provided with a smoke detection system, but does not have an automatic suppression system for the room. The installed fire detection system would detect a fire in its insipient stage and alert the Main Control Room staff. The site fire brigade would quickly respond and have portable extinguishers and a standpipe and hose station readily available to extinguish any expected fire.

2.9.4.2.c Control of Combustibles and Ignition Sources

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms. Compensatory measures must be implemented when transient combustibles or ignition sources are located in a room. Room 729.0-A6 is a CCZ (see Part II, sections 10 and 11 and WBN Technical Instruction TI-291, Combustible Control Zones and Sensitive Areas). For compliance with TI-291, the approval of an evaluation must be obtained before any transient combustible can be introduced into the room or hot work performed in the room. Access to the room is via security control doors from 729.0-A5. The lack of significant concentrations of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources provides

PART VII - DEVIATIONS AND EVALUATIONS

assurance that no credible exposure fire would occur. Based on this, it is not expected that the plant will enter the fire safe shutdown procedure.

2.9.4.2.d Adjacent Rooms

Room 692.0-A14 is separated from 729.0-A6 by a 2 hour fire rated ceiling, except for the open stairs. Room 692.0-A14 has an insignificant combustible load and is provided with automatic suppression and detection. This room does not contain an ignition source. The room contains the Cask Decontamination Collector Tank and is not a normally accessed room.

Adjacent rooms 729.0-A14 and 729.0-A15 are separated from 729.0-A6 by reinforced concrete walls that are 3 hour fire rated barriers. The in situ combustible load in 729.0-A14 is moderate. The in situ combustible load in 729.0-A15 is low. Both rooms are provided with smoke detection. No credible fire in 729.0-A14 or 729.0-A15 could propagate through the 3 hour fire rated walls into 729.0-A6.

Rooms 729.0-A8 and 729.0-A9 are the Unit 1 and Unit 2 Post Accident Sampling rooms and separated from 729.0-A6 by concrete walls that are 2 hour fire rated barriers. The in situ combustible load in 729.0-A8 is low and there are no ignition sources in the rooms. Both rooms are provided with smoke detectors. The in situ combustible load in 729.0-A9 is insignificant. Access to these rooms is from 729.0-A6. No credible fire in 729.0-A8 or 729.0-A9 could propagate through the 2 hour fire barriers into 729.0-A6.

Room 728.0-A7 is separated from 729.0-A6 by 24 inch thick reinforced concrete walls/ceiling that are not assigned a fire rating. The in situ combustible load in 728.0-A7 is insignificant and there are no ignition sources in the room. This room is the Cask Decontamination Room and its only access is from 729.0-A6. No credible fire in 728.0-A7 could propagate into 729.0-A6.

Room 757.0-A13 (includes the New Fuel Storage Vault 741.5) is separated from 729.0-A6 by a reinforced concrete floor with a 2 hour fire rating. The in situ combustible load in 741.5 and 757.0-A13 is insignificant. No credible fire could propagate from 741.5 or 757.0-A13 into 729.0-A6.

TVA concludes that based on the above information, that no credible fire could propagate from an adjacent room into room 729.0-A6 or from 729.0-A6 into an adjacent room.

2.9.4.3 System Evaluation

2.9.4.3.a Redundant FSSD Components in the Room

There is no FSSD equipment located in this room, but there are some cables as described below.

Cables for Unit 2 steam generator #2 and #3 PORVs to control secondary pressure are routed in conduits and junction boxes that are embedded in the concrete wall with only the face of the junction boxes exposed in room 729.0-A6. The junction boxes are located more than 25-feet horizontally from the only ignition source (charcoal filters inside the metal housing of Air Cleanup Unit A) in the room. The charcoal filters are provided with a closed head water suppression system to handle a fire initiated in the charcoal. There is no credible ignition source that could cause damage to these circuits. Therefore, the OMA (2.9.4.1.e) to locally operate steam generator #3 PORV is not necessary.

PART VII - DEVIATIONS AND EVALUATIONS

Cables for the solenoid valves for Unit 2 steam generator # 2 and #3 redundant bypass line feedwater isolation and control valves and the main feed water line isolation and control valves are routed in conduits and junction boxes that are embedded in the concrete wall with only the face of the junction boxes exposed in room 729.0-A6. The junction boxes are located more than 25-feet horizontally from the only ignition source (charcoal filters inside the metal housing of Air Cleanup Unit A) in the room. The charcoal filters are provided with a closed head water suppression system to handle a fire initiated in the charcoal. There is no credible ignition source that could cause damage to these circuits.

As defense-in-depth it is noted that these units are seldom used and locally operated, any fire is identified by the operator in its early stages and extinguished. Additionally, the room is designated as a combustible control zone to ensure no combustible material or ignition sources are inadvertently left in the area.

Based on the small combustible loading and limited ignition sources, horizontal separation, and minimal cable exposure, it is concluded that there is no credible ignition source that could cause damage to these circuits. Therefore, the OMA (2.9.4.1.e) to locally operate steam generator #3 PORV is not necessary.

2.9.4.3.b FSSD Components with Redundant FSSD Components in an adjacent Room within the same Analysis Volume

Cables whose failure could necessitate the OMAs listed in 2.9.4.1.a through .d and .f are not in room 729.0-A6. They are located in other rooms (729.0-A8, 757.0-A13, and 772.0-A9) within AV-032. As described in 2.9.4.2, there is no credible fire that could propagate from 729.0-A6 to another room within AV-032 to damage these cables. Therefore the OMAs listed in 2.9.4.1.a through d and f are not necessary.

2.9.4.3.c Other FSSD Components in the Room

Room 729.0-A6 contains cables associated with Unit 1 and Unit 2 FSSD equipment relied upon for fires in other areas of the plant (i.e., equipment and cables not credited for a fire in Room 729.0-A6). The cables are routed in conduit. Although no fire induced failures are expected due to the insignificant fire hazard in the rooms, postulated failure of the non-credited FSSD cables has been evaluated to assess its effect on plant operation. Failure of these FSSD cables is detected and mitigated by normal plant procedures and does not initiate or result in a plant trip.

- Unit 1 steam generator #2 and #3 main feedwater isolation valve cables
- Unit 1 steam generator #2 and #3 power operated relief valve (PORV) control and pressure transmitter auxiliary cables
- Unit 1 steam generator #2 and #3 PORV control cables
- Unit 2 steam generator #2 and #3 steam line warming valve cables (Valves are normally closed with power removed during normal operation.)
- Unit 2 steam generator #2 and #3 main steam isolation valve solenoid valve cables

PART VII - DEVIATIONS AND EVALUATIONS

2.9.4.4 Conclusion

There is insignificant threat from transient combustibles or in situ combustible material, no credible ignition sources, ample horizontal separation, and no impact to FSSD; therefore, there is no fire hazard in 729.0-A6 that necessitates any OMAs. TVA concludes that the intent of III.G.1 is ensured and requests approval of this deviation demonstrating compliance to III.G.1 criteria with a fire hazard analysis in lieu of the prescriptive separation criteria of III.G.2.

2.9.5 Room 729.0-A10 – Unit 2 North Main Steam Valve Room

2.9.5.1 Description of Condition

Room 729.0-A10 is part of fire area 73 and is analysis volume 112A (AV-112A) in the FSSD analysis (see Part III, Table 3-3 for room listing). Fire area 73 is considered a III.G.2 area because it contains components related to both redundant shutdown paths.

The redundant components are not cables or equipment that must operate for FSSD, but rather control air users connected to the Train A and the Train B auxiliary control air system (ACAS) headers. The FSSD analysis generally assumes that fire damage to one ACAS air user could depressurize the header (Train A or Train B). If all the ACAS air users located in this area were assumed to fail due to postulated fire damage; both trains of the ACAS are assumed failed. Since the ACAS is common to both units, both units are affected.

Physical separation in accordance with III.G.2 cannot be achieved in this area. An FSSD analysis which assumes failure of all equipment and cables in the room would result in OMAs being credited in lieu of III.G.2 physical separation. Therefore, the following OMAs are implemented to achieve fire safe shutdown:

- a. Unit 1 - Control level in two steam generators within 20 minutes by manual valve operation. (Unit 2 has an alternative motive air (nitrogen) supply for these valves to eliminate these OMAs)
- b. Unit 1 - Control motor driven auxiliary feed water pump discharge pressure within 20 minutes by manual valve operation. (Unit 2 has an alternative motive air (nitrogen) supply for these valves to eliminate these OMAs).
- c. Unit 1 and Unit 2 - Control pressure in two steam generators within 60 minutes by operation of SG PORV via local nitrogen control station.

2.9.5.2 Fire Hazard Analysis

2.9.5.2.a Room Description

Room 729.0-A10 is the Unit 2 North Main Steam Valve room. The walls of 729.0-A10 are of reinforced concrete construction and have fire resistive ratings of 3-hours that separate the valve room from adjacent areas of the Auxiliary Building and fire resistive rating of 3-hours for the wall separating it from the Unit 2 Reactor Building. The walls separating 729.0-A10 from the Yard are 36-inch thick reinforced concrete but are not assigned a fire resistive rating. Two doors are located in these walls. One door is located in a labyrinth which would shield the door from a transient fire in the Yard. The other door is located in a labyrinth and behind the main feedwater and steam lines which run alongside the wall and prevent any significant transient

PART VII - DEVIATIONS AND EVALUATIONS

combustibles in the Yard from being in the vicinity of the labyrinth and door. The concrete walls and fire rated barriers surrounding 729.0-A10 will prevent any credible fire from propagating into an adjoining room or the Yard 729.0-A10.

2.9.5.2.b Fire Load

The in situ combustible loading for 729.0-A10 is insignificant. The in situ combustibles in 729.0-A10 consist of small quantities of lubricant in each valve and small quantities of miscellaneous plastics associated with area radiation monitors, small electrical control panels and boxes, and lighting units. The radiation monitors and the valve motors are not considered to be significant ignition sources due to the small quantity of in situ combustible material associated with them and the circuit protection (properly sized and coordinated fuses/breakers) for each (see Justification in 2.9.0 above).

2.9.5.2.c Control of Combustibles and Ignition Sources

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms. Compensatory measures must be implemented when transient combustibles or ignition sources are located in a room. Room 729.0-A10 is a CCZ (see Part II, sections 10 and 11 and WBN Technical Instruction TI-291, Combustible Control Zones and Sensitive Areas). For compliance with TI-291, the approval of an evaluation must be obtained before any transient combustible can be introduced into the room or hot work performed in the room. Access to the room is limited due to the hazardous conditions in 729.0-A10. The lack of significant concentrations of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources provides assurance that no credible exposure fire would occur. Based on this, it is not expected that the plant will enter the fire safe shutdown procedure.

2.9.5.2.d Adjacent Rooms

There is no threat of a fire in an adjacent room in the Auxiliary Building propagating into 729.0-A10 due to the 3 hour fire rated barriers and insignificant quantities of in situ combustibles in the adjacent rooms.

The Unit 2 Reactor Building is separated from 729.0-A10 by the 3 hour fire rated 36 inch thick reinforced concrete wall.

The Yard area adjacent to the exterior walls of 729.0-A10 is maintained free of any significant combustibles. There are two doors located in walls on opposite sides of 729.0-A10. The door on the east side is back in a labyrinth and is behind the main feedwater and steam lines. The door on the west side is back in a labyrinth. No significant quantities of either in situ or transient combustibles are in the vicinity of either of the doors.

TVA concludes, based on the above information, that no credible fire could propagate from an adjacent room into room 729.0-A10 or from 729.0-A10 into an adjacent room.

PART VII - DEVIATIONS AND EVALUATIONS

2.9.5.3 System Evaluation

2.9.5.3.a Redundant FSSD Components in the Room

There are no redundant cables for FSSD equipment in the room. The only redundant FSSD equipment in the room are train A and train B air users connected to the redundant ACAS headers. To achieve safe shutdown without OMAs at least one ACAS header must be operable to supply Unit 1 and Unit 2 air users in other plant locations. As described in calculation WBPEVAR9602001, "Appendix R – Auxiliary Control Air Analysis" (Part II, reference 4.2.74), the ACAS is a safety system and uses welded stainless steel piping and fittings; however some of the air user devices may be susceptible to fire damage based on their physical construction and/or material make up (e.g., pressure regulators, diaphragms, controllers, etc.).

The ACAS air users in 729.0-A10 are two power operated relief valves (PORVs) associated with the steam generators #2 and #3. The FSSD analysis does not credit these steam generators nor the air supply to these valves to achieve safe shutdown with a fire in this room. However, at least one train of ACAS is needed to operate equipment located elsewhere in the plant. One PORV is connected to each train of the ACAS. The PORVs are in parallel horizontal piping runs 19'-2" on center at elevation 758 (29 feet above the floor). As described in the FHA (2.9.5.2) the absence of ignition sources and insignificant in situ combustibles is sufficient to conclude that a credible fire could not damage air users connected to both ACAS headers. For additional defense-in-depth this room is maintained as a CCZ. The existence of transient combustibles is further reduced because this room is rarely entered during operations due to the high temperature and humidity in the main steam valve vaults. A very large amount of transient combustibles and an ignition source would have to be brought into the valve vault to produce a fire that could damage the level control valves located a minimum of 19 feet above the floor in a room with a 53 foot high ceiling.

Based on the above information, it is concluded that the OMAs identified in 2.9.5.1 are not necessary.

2.9.5.3.b Components with Redundant FSSD Components in an Adjacent Room within the Same Analysis Volume

Room 729.0-A10 is the only room in AV-112A (fire area 73). The barriers that separate room 729.0-A10 from adjacent rooms in the Auxiliary Building and from the Unit 2 Reactor Building are 3 hour fire rated barriers. The only non-fire rated barrier is the outside wall that separates 729.0-A10 from the Yard and there are no redundant FSSD equipment or cables in the Yard near this wall (see 2.9.5.2 above).

2.9.5.3.c Other FSSD Components in the Room

Room 729.0-A10 contains FSSD equipment and cables associated with FSSD equipment relied upon for fires in other areas of the plant (i.e., equipment and cables not credited for a fire in Room 729.0-A10). The cables are routed in conduit. Although no fire induced failures are expected due to the insignificant fire hazard in the rooms, postulated failure of the non-credited FSSD equipment and cables has been evaluated to assess its effect on plant operation. Failure of this FSSD equipment or cables is detected and mitigated by normal plant procedures and does not initiate or result in a plant trip.

PART VII - DEVIATIONS AND EVALUATIONS

- Steam line warming valves and associated cables (Valves are normally closed with power removed during normal operation.)
- Steam generator blowdown outboard containment isolation valve cables
- Main steam isolation valves and cables for steam generators #2 and #3
- Steam generators #2 and #3 main feedwater isolation MOVs and bypass line isolation valves and associated cables
- Steam generators #2 and #3 power operated relief valves and one train of control solenoids and associated cables
- Steam line pressure transmitter (channel E) cable

2.9.5.4 Conclusion

There is insignificant threat from transient combustibles or in situ combustible material, no significant ignition sources; therefore, there is no fire hazard in 729.0-A10 that could cause loss of ACAS pressure and necessitate any OMAs. TVA concludes that the intent of III.G.1 is ensured and requests approval of this deviation demonstrating compliance with III.G.1 criteria with a fire hazard analysis in lieu of the prescriptive separation criteria of III.G.2.

2.9.6 Rooms 729.0-A11 and 737.0-A10 – Unit 2 South Main Steam Valve Room and Air Lock

2.9.6.1 Description of Condition

These two rooms make up fire area 72 which is analysis volume 113 (AV-113) in the FSSD analysis (see Part III, Table 3-3 for room listing). The fire area is considered a III.G.2 area because it contains components related to both redundant shutdown paths.

The redundant components are not cables or equipment that must operate for FSSD, but rather control air users connected to the Train A and the Train B auxiliary control air system (ACAS) headers. The FSSD analysis generally assumes that fire damage to one ACAS air user could depressurize the header (Train A or Train B). If all the ACAS air users located in this area were assumed to fail due to postulated fire damage; both trains of the ACAS are assumed failed. Since the ACAS is common to both units, both units are affected.

Physical separation in accordance with III.G.2 cannot be achieved in this area. An FSSD analysis which assumes failure of all equipment and cables in the room would result in OMAs being credited in lieu of III.G.2 physical separation. Therefore, the following OMAs are implemented to achieve fire safe shutdown:

- a. Unit 1 - Control level in two steam generators within 20 minutes by manual valve operation. (Unit 2 has an alternative motive air (nitrogen) supply for these valves to eliminate these OMAs)
- b. Unit 1 - Control motor driven auxiliary feed water pump discharge pressure within 20 minutes by manual valve operation. (Unit 2 has an alternative motive air (nitrogen) supply for these valves to eliminate these OMAs).
- c. Unit 1 and Unit 2 - Control pressure in two steam generators within 60 minutes by operation of SG PORV via local nitrogen control station.

PART VII - DEVIATIONS AND EVALUATIONS

2.9.6.2 Fire Hazard Analysis

2.9.6.2.a Room Description

Room 729.0-A11 is the Unit 2 South Main Steam Valve room and room 737.0-A10 is the entrance labyrinth into the valve room from the Auxiliary Building. The walls and floor of 729.0-A11 are of reinforced concrete construction and have fire resistive ratings of 2 hours for the walls and floor that separate the valve room from adjacent areas of the Auxiliary Building and fire resistive rating of 3 hours for the wall separating it from the Unit 2 Reactor Building. The walls separating 729.0-A11 from the Yard are 36-inch thick reinforced concrete but are not assigned a fire resistive rating. The walls, floor and ceiling of room 737.0-A10 are of reinforced concrete construction and have fire resistive ratings of 2 hours for those barriers separating it from adjacent rooms in the Auxiliary Building and 3 hours from the Unit 2 Reactor Building. There are two access paths into the valve room. One is from the Auxiliary Building into the labyrinth (the two doors in the labyrinth from the Auxiliary Building and into the valve room are interlocked such that only one door can be opened at a time). The other path is from the Yard. Access to the valve room is limited due to the hazardous environmental conditions in the room (high humidity, high temperature, and presence of high energy lines (main steam and feedwater)).

2.9.6.2.b Fire Load

The in situ combustible loading index for 729.0-A11 and 737.0-A10 is insignificant. The in situ combustibles in 729.0-A11 consist of small quantities of lubricant in each valve and small quantities of miscellaneous plastics associated with area radiation monitors, small electrical control panels and boxes and lighting units. The electrical cables are routed in conduits. The in situ combustibles in 737.0-A10 are the light covers. There are no credible ignition sources in the rooms (see Justification in 2.9.0).

2.9.6.2.c Control of Combustibles and Ignition Sources

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms. Compensatory measures must be implemented when transient combustibles or ignition sources are located in a room. Room 729.0-A11 and 737.0-A10 are CCZs (see Part II, sections 10 and 11 and WBN Technical Instruction TI-291, Combustible Control Zones and Sensitive Areas). For compliance with TI-291, the approval of an evaluation must be obtained before any transient combustible can be introduced into the room or hot work performed in the room. Access to the room is limited due to the hazardous conditions in 729.0-A11. The lack of significant concentrations of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources provides assurance that no credible exposure fire would occur. Based on this, it is not expected that the plant will enter the fire safe shutdown procedure.

2.9.6.2.d Adjacent Rooms

The adjacent rooms in the Auxiliary Building are provided with automatic suppression and detection. The combination of automatic suppression and detection and the 2-hour fire rated barriers ensures that no credible fire in any of these adjacent rooms will propagate into 729.0-A11 or 737.0-A10. The thick reinforced concrete walls separating 729.0-A11 from the Yard would prevent a fire in the Yard from propagating into the room. The door in this wall is located

PART VII - DEVIATIONS AND EVALUATIONS

in a labyrinth which would shield the door from a transient fire in the Yard. In addition, main feedwater and steam lines which run alongside the wall prevent any significant transient combustibles from being in the vicinity of the wall, labyrinth and door. The 3 hour fire rated concrete wall separating the Unit 2 Reactor Building from 729.0-A11 and 737.0-A10 would prevent a fire in the Unit 2 Reactor Building propagating into the rooms.

TVA concludes, based on the above information that no credible fire could propagate from an adjacent room into room 729.0-A11 and 737.0-A10 or from 729.0-A11 or 737.0-A10 into an adjacent room.

2.9.6.3 System Evaluation

2.9.6.3.a Redundant FSSD Components in the Room

There are no redundant cables for FSSD equipment in the rooms. The only redundant FSSD equipment in the rooms are train A and train B air users connected to the redundant ACAS headers. To achieve safe shutdown without OMAs at least one ACAS header must be operable to supply Unit 1 and Unit 2 air users in other plant locations. As described in calculation WBPEVAR9602001, "Appendix R – Auxiliary Control Air Analysis" (Part II, reference 4.2.74), the ACAS is a safety system and uses welded stainless steel piping and fittings; however some of the air user devices may be susceptible to fire damage based on their physical construction and/or material make up (e.g., pressure regulators, diaphragms, controllers, etc.).

The ACAS air users in 729.0-A11 are two level control valves (LCVs) and two power operated relief valves (PORVs) associated with the steam generators #1 and #4. The FSSD analysis does not credit these steam generators nor the air supply to these valves to achieve safe shutdown with a fire in this room. However, at least one train of ACAS is needed to operate equipment located elsewhere in the plant. One LCV and one PORV are connected to each train of the ACAS. The LCVs are in parallel horizontal piping runs three feet on center at elevation 748 (19 feet above the floor). The PORVs are in parallel horizontal piping runs 19'-2" on center at elevation 758 (29 feet above the floor).

As described in the FHA (2.9.6.2) the absence of ignition sources and insignificant in situ combustibles is sufficient to conclude that a credible fire could not damage air users connected to both ACAS headers. For additional defense-in-depth this room is maintained as a CCZ. The existence of transient combustibles is further reduced because this room is rarely entered during operations due to the high temperature and humidity in the main steam valve vaults. A very large amount of transient combustibles and an ignition source would have to be brought into the valve vault to produce a fire that could damage the level control valves located a minimum of 19 feet above the floor in a room with a 55 foot high ceiling.

Based on the above information, it is concluded that the OMAs identified in 2.9.6.1 are not necessary.

2.9.6.3.b Components with Redundant FSSD Components in an Adjacent Room within the Same Analysis Volume

Rooms 729.0-A11 and 737.0-A10 are the only rooms in AV-113 (fire area 32). The barriers that separate rooms 729.0-A11 and 737.0-A10 from adjacent rooms in the Auxiliary Building are 2 hour fire rated barriers and from the Unit 2 Reactor Building is a 3 hour fire rated barrier. The

PART VII - DEVIATIONS AND EVALUATIONS

only non-fire rated barrier is the outside wall that separates 729.0-A11 from the Yard and there is no redundant FSSD equipment or cables in the Yard near this wall (see 2.9.6.2 above).

2.9.6.3.c Other FSSD Components in the Room

Room 729.0-A11 contains FSSD equipment and cables associated with FSSD equipment relied upon for fires in other areas of the plant (i.e., equipment and cables not credited for a fire in Room 729.0-A11). The cables are routed in conduit. Although no fire induced failures are expected due to the insignificant fire hazard in the rooms, postulated failure of the non-credited FSSD equipment and cables has been evaluated to assess its effect on plant operation. Failure of this FSSD equipment or cables is detected and mitigated by normal plant procedures and does not initiate or result in a plant trip.

- Steam line warming valves and associated cables (Valves are normally closed with power removed during normal operation.)
- Steam generator blowdown outboard containment isolation valve cables
- Main steam isolation valves and cables for steam generators #1 and #4
- Steam generators #1 and #4 main feedwater isolation MOVs and bypass line isolation valves and associated cables
- Steam generators #1 and #4 power operated relief valves and one train of control solenoids and associated cables
- Turbine driven auxiliary feedwater pump steam supply MOV cables
- Turbine driven auxiliary feedwater pump level control valves and cables for steam generators #1 and #4
- Reactor building lower compartment cooler and control rod drive cooler cables
- Containment pressure transmitter channel E cable
- Emergency raw cooling water discharge MOV cables for component cooling system heat exchanger
- Charging pump 2A room cooler cables
- Steam generator #2 level transmitter cable

2.9.6.4 Conclusion

There is insignificant threat from transient combustibles or in situ combustible material, no significant ignition sources; therefore, there is no fire hazard in 729.0-A11 or 737.0-A10 that could cause loss of ACAS pressure and necessitate any OMAs. TVA concludes that the intent of III.G.1 is ensured and requests approval of this deviation demonstrating compliance with III.G.1 criteria with a fire hazard analysis in lieu of the prescriptive separation criteria of III.G.2.

2.9.7 Room 729.0-A12 – Unit 1 Steam Valve Instrument Room A

2.9.7.1 Description of Condition

Room 729.0-A12 is a part of fire area 13 and is in analysis volume AV-035 (see Part III, Table 3-3 for room listing). The fire area is considered a III.G.2 area because it contains Unit 1 components related to both redundant shutdown paths. The following OMAs were previously identified for this room based on the assumption that all of the cables and equipment in AV-035 are damaged by a postulated fire:

PART VII - DEVIATIONS AND EVALUATIONS

- a. Unit 1 – Establish motor driven auxiliary feedwater pump A pressure control and control steam generators #1 & #2 level within 20 minutes by manually controlling valves.
- b. Unit 1 – Operate steam generators #1 & #2 power operated relief valves to control secondary pressure within 60 minutes at local nitrogen control panels.

In addition an embedded junction box whose cover plate is exposed in the room was previously protected with a 3-hour fire rated ERFBS (Thermo-Lag) to prevent postulated fire damage to the cables routed through the embedded box.

2.9.7.2 Fire Hazards Analysis

2.9.7.2.a Room Description

Room 729.0-A12 is the Unit 1 Steam Valve Instrument Room A and is of reinforced concrete construction which is 12 to 48 inches thick and has fire resistance rating of 3-hours for the barriers that separate the room from room 729.0-A2 and the Unit 1 Reactor Building. The wall separating 729.0-A12 from 729.5-A16 is not assigned a fire rating, but is a 12-inch thick reinforced concrete wall. Room 729.0-A12 has a floor area of 74-ft² and a ceiling height of 8-feet.

2.9.7.2.b Fire Load

The in situ combustible loading in the room is classified as low and is due to miscellaneous plastics inside electrical control panels and junction boxes, lights, and Thermo-Lag fire wrap on an embedded junction box cover. There are no credible ignition sources in the room. No credible fire in 729.0-A12 could propagate into an adjacent room.

2.9.7.2.c Control of Combustibles and Ignition Sources

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms. Compensatory measures must be implemented when transient combustibles or ignition sources are located in a room. Room 729.0-A12 is a CCZ (see Part II, sections 10 and 11 and WBN Technical Instruction TI-291, Combustible Control Zones and Sensitive Areas). For compliance with TI-291, an evaluation must be obtained before any transient combustible can be introduced into the room or hot work performed in the room. Access to the room is from the Yard into room 729.5-A16 and then into 729.0-A12. The lack of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources provides assurance that no credible exposure fire would occur. Based on this, it is not expected that the plant will enter the fire safe shutdown procedure.

2.9.7.2.d Adjacent Rooms

Room 729.0-A2 is separated from 729.0-A12 by 3 hour fire rated reinforced concrete walls and ceiling. The in situ combustible loading in 729.0-A2 is insignificant; therefore, no credible fire in 729.0-A2 could propagate into 729.0-A12.

The Unit 1 Reactor Building Annulus is separated from 729.0-A12 by a 36 inch thick, reinforced concrete wall that is 3 hour fire rated. The in situ combustible load in the Unit 1 Annulus is

PART VII - DEVIATIONS AND EVALUATIONS

severe, but insulation on cables in trays accounts for over 98% of the combustible load. Automatic suppression and detection are provided for selected cable tray separation in the Annulus. No credible fire in the Annulus could propagate into 729.0-A12.

Room 729.5-A16 is separated from 729.0-A12 by a 12 inch thick reinforced concrete wall, but electrical and mechanical openings in the wall are not provided with fire rated seals/closures. The in situ combustible loading in 729.5-A16 is insignificant and consists of a pint of lubricant in a small pump (less than 5 HP) and plastics associated with junction boxes, lighting and a telephone. There are no ignition sources in the room. It is concluded that no credible fire in 729.5-A16 that could propagate into 729.0-A12.

TVA concludes, based on the above information, that no credible fire could propagate from an adjacent room into room 729.0-A12 nor from 729.0-A12 into an adjacent room.

2.9.7.3 System Evaluation

2.9.7.3.a Redundant FSSD Components in the Room

Two Unit 1 steam generator pressure control valve solenoid valves (one per train) connected to the ACAS headers in this room are not air users but control the air flow to the air users that are located in another room. Typical control air users (e.g. air operated valves) have a flexible diaphragm or bellows that could rupture if overheated in a significant fire and cause an air leak assumed equal to the input line size. A fire of greater intensity than the in situ combustibles may damage solenoid valve o-rings or seals and even then the leakage rate is much less than a typical air user. Due to the lack of in situ combustibles and no credible ignition sources (See 2.9.7.2) in the room, it is concluded that there is no credible fire in 729.0-A12 that could cause failure of either solenoid valve or of the ACAS headers. The limited leakage associated with failure of either of these solenoid valves would not depressurize its train air header. Additional defense-in-depth is the ACAS is a safety system and utilizes welded stainless steel piping and fittings as described in calculation WBPEVAR9602001, "Appendix R – Auxiliary Control Air Analysis" (Part II, reference 4.2.74). Also the air operated components are supplied from the normal control air system whose compressors are located in the Turbine Building. This is a large capacity system and the failure of an individual end user would not impact the function of the system. In addition to the normal air compressors, the train A & B compressors provide backup support to ensure minimum system pressure is maintained. Therefore, the OMAs listed in 2.9.7.1 are not necessary.

Unit 1 steam generator #3 PORV has a train A and a train B solenoid valve. Energizing either solenoid ensures PORV closure. The train B solenoid valve is located in room 729.0-A12. The cable for the redundant train A solenoid valve is routed in embedded conduits and through the embedded junction box with an exposed cover plate. The junction box is more than five feet (horizontal distance) from the train B solenoid. Due to the lack of in situ combustibles and no credible ignition sources (See 2.9.7.2) in the room, it is concluded that there is no credible fire in 729.0-A12 that would damage both the train A solenoid cable and the train B solenoid or its cables; therefore, there is no need for the previously applied Thermo-Lag protection over the exposed junction box cover plate identified in 2.9.7.1.

PART VII - DEVIATIONS AND EVALUATIONS

2.9.7.3.b Components with Redundant FSSD Components in an Adjacent Room within the Same Analysis Volume

There are no redundant components in adjacent rooms within AV-035. The in situ combustible load in the adjacent room 729.5-A16 is insignificant and the potential for spread of a fire from 729.5-A16 into 729.0-A12 is not considered to be credible.

2.9.7.3.c Other FSSD Components in the Room

Room 729.0-A12 contains FSSD equipment and cables associated with FSSD equipment relied upon for fires in other areas of the plant (i.e., equipment and cables not credited for a fire in Room 729.0-A12). The cables are routed in conduit. Although no fire induced failures are expected due to the insignificant fire hazard in the rooms, postulated failure of the non-credited FSSD equipment and cables has been evaluated to assess its effect on plant operation. Failure of this FSSD equipment or cables are detected and mitigated by normal plant procedures and does not initiate or result in a plant trip.

- Unit 1 steam generator #3 steam line warming valve cable
- Unit 1 steam generator #2 & #3 feedwater isolation valve cables
- Unit 1 steam generator #2 & #3 PORV control cables
- Unit 1 steam generator #2 & #3 auxiliary pressure indicator and auxiliary PORV control cables
- Unit 1 steam generator #2 & #3 main steam header pressure indicator and safety injection (SI) low steam line 2 & 3 pressure (LSP2 & LSP3) cables

2.9.7.4 Conclusion

Since there is insignificant threat from transient combustibles or in situ combustible material and no credible ignition sources; it is concluded that no credible fire in 729.0-A12 could damage cables routed in the conduits or junction boxes nor the solenoid valves; therefore, no OMAs or fire wrap on the junction box cover are necessary. TVA concludes that the intent of III.G.1 is ensured and requests approval of this deviation demonstrating compliance to III.G.1 criteria with a fire hazard analysis in lieu of the prescriptive separation criteria of III.G.2.

2.9.8 Room 729.0-A13 – Unit 2 Steam Valve Instrument Room B

2.9.8.1 Description of Condition

Room 729.0-A13 is a part of fire area 73 and is in analysis volume 112 (AV-112) in the FSSD analysis (see Part III, Table 3-3 for room listing). Fire area 73 is considered a III.G.2 area because it contains Unit 2 components related to both shutdown paths.

Physical separation in accordance with III.G.2 cannot be achieved in this room. An FSSD analysis that assumes failure of all cables and equipment in AV-112 would result in the following OMAs and installation of electrical raceway fire barrier systems:

- a. Unit 1 – Control motor driven auxiliary feedwater pump A discharge pressure and control steam generators 1 & 2 level within 20 minutes by manually controlling valves.
- b. Unit 1 – Operate steam generators 1 & 2 power operated relief valves (PORV) to control secondary pressure within 60 minutes at local nitrogen control panels.

PART VII - DEVIATIONS AND EVALUATIONS

- c. Unit 2 - Operate steam generators 1 & 2 power operated relief valves to control secondary pressure within 60 minutes at local nitrogen control panel.
- d. An embedded junction box whose cover plate is exposed in the room was previously identified to be protected with a 3-hour fire rated cover (Thermo-Lag).

2.9.8.2 Fire Hazards Analysis

2.9.8.2.a Room Description

Room 729.0-A13 is the Unit 2 Steam Valve Instrument Room B and is of reinforced concrete construction which is 12 to 48 inches thick and has fire resistance rating of 3-hours for the barriers that separate the room from room 729.0-A10 and the Unit 2 Reactor Building. The wall separating 729.0-A13 from 729.5-A17 is not assigned a fire rating, but is a 12-inch thick reinforced concrete wall. Room 729.0-A13 has a floor area of 74-ft² and a ceiling height of 8-feet.

2.9.8.2.b Fire Load

The in situ combustible loading in the room is classified as low and is due to miscellaneous plastics associated with small electrical control panels and lights. There are no credible ignition sources in the room. No credible fire in 729.0-A13 could propagate into an adjacent room.

2.9.8.2.c Control of Combustibles and Ignition Sources

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms. Compensatory measures must be implemented when transient combustibles or ignition sources are located in a room. Room 729.0-A13 is a CCZ (see Part II, sections 10 and 11 and WBN Technical Instruction TI-291, Combustible Control Zones and Sensitive Areas). For compliance with TI-291, the approval of an evaluation must be obtained before any transient combustible can be introduced into the room or hot work performed in the room. Access to the room is from the Yard into room 729.5-A16 and then into 729.0-A12. The lack of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources provides assurance that no credible exposure fire would occur. Based on this, it is not expected that the plant will enter the fire safe shutdown procedure.

2.9.8.2.d Adjacent Rooms

Room 729.0-A10 is separated from 729.0-A13 by 12 to 36 inch thick reinforced concrete that is 3 hour fire rated barriers. The in situ combustible load in 729.0-A10 is insignificant and there are no credible ignition sources in the room. No credible fire could propagate from 729.0-A10 into 729.0-A13 or from 729.0-A13 into 729.0-A10.

Room 729.5-A17 is separated from 729.0-A13 by a 12 inch thick reinforced concrete wall that is not assigned a fire rating. The in situ combustible load in 729.5-A17 is insignificant and there are no credible ignition sources in the room. No credible fire in 729.5-A17 could propagate from 729.5-A17 into 729.0-A13 or from 729.0-A13 into 729.5-A17.

PART VII - DEVIATIONS AND EVALUATIONS

The Unit 2 Reactor Building Annulus is separated from 729.0-A13 by a 36 inch thick reinforced concrete wall that has a minimum 3 hour fire rating. No credible fire in the Unit 2 Annulus could propagate into 729.0-A13 or from 729.0-A13 into the Annulus.

2.9.8.3 System Evaluation

2.9.8.3.a Redundant FSSD Components in the Room

The two Unit 2 steam generator power operated relief valve (PORV) solenoid valves (one per train) connected to the ACAS headers in this room are not air users, but control the air flow to the air users that are located in another room. Typical control air users (e.g. air operated valves) have a flexible diaphragm or bellows that could rupture if exposed to a significant fire. The failure of a diaphragm or bellows is assumed to result in an air leak equal to the input line size. The insignificant quantity of in situ combustibles and lack of an ignition source would not produce a fire that could damage the solenoid valves. Even assuming a fire could damage the o-rings or seals in the solenoids, the leakage from that type of failure would not result in a depressurization of the auxiliary control air system. Due to the lack of in situ combustibles and no credible ignition sources (See 2.9.8.2) in the room, it is concluded that there is no credible fire in 729.0-A13 that could cause failure of either solenoid valve nor of the ACAS headers. As additional defense-in-depth, the air operated components are supplied from the normal control air system whose compressors are located in the Turbine Building. This is a large capacity system and the failure of an individual end user would not impact the function of the system. In addition to the normal air compressors, the train A & B auxiliary control air system (ACAS) headers are also backed up by the auxiliary air compressors located on the Refueling Floor. Each of these compressors is available as backup support to ensure minimum system pressure is maintained on each header (see WBPEVAR9602001, "Appendix R – Auxiliary Control Air Analysis", Part II, reference 4.2.74). Therefore, it is concluded that the OMAs listed in 2.9.8.1 are not necessary.

Unit 2 steam generator #3 PORV has a train A and a train B solenoid valve. Energizing either solenoid ensures PORV closure. The train B solenoid valve is located in room 729.0-A13 and the redundant train A solenoid valve cable is routed through embedded conduits and an embedded junction box. The junction box cover plate is exposed in 729-A13. The junction box and the train B solenoid valve (and cables) are separated horizontally by at least 5 feet. Due to the lack of in situ combustibles and no credible ignition sources (See 2.9.8.2) in the room, it is concluded that there is no credible fire in 729.0-A13 that could damage both of these components; therefore, there is no need for ERFBS (Thermo-Lag) protection on the junction box cover.

2.9.8.3.b Components with Redundant FSSD Components in an Adjacent Room within the Same Analysis Volume

There are no redundant components in adjacent rooms within AV-112. The insignificant in situ combustible loads and lack of ignition sources in 729.0-A13 and the adjacent rooms of the Auxiliary Building (see 2.9.8.2 above) ensures that no credible fire in 729.0-A13 could propagate into an adjacent room or from an adjacent room into 729.0-A13. Therefore, it is not necessary to implement an OMA, install an ERFBS, or enter the FSSD procedure.

PART VII - DEVIATIONS AND EVALUATIONS

2.9.8.3.c Other FSSD Components in the Room

Room 729.0-A13 contains FSSD equipment and cables associated with FSSD equipment relied upon for fires in other areas of the plant (i.e., equipment and cables not credited for a fire in Room 729.0-A13). The cables are routed in conduit. Although no fire induced failures are expected due to the insignificant fire hazard in the room, postulated failure of the non-credited FSSD equipment and cables has been evaluated to assess its effect on plant operation. Failure of FSSD equipment or cables are detected and mitigated by normal plant procedures and does not initiate or result in a plant trip.

- Unit 2 steam generator #2 & #3 steam line warming valve cable
- Unit 2 steam generator #2 & #3 feedwater isolation valve cables
- Unit 2 steam generator #2 & #3 main steam operating solenoid cables
- Unit 2 steam generator #2 PORV valve and cables
- Unit 2 steam generator #2 & #3 auxiliary pressure indicator and auxiliary PORV control cables
- Unit 2 main steam line pressure indicator and safety injection (SI) low steam line 2 & 3 pressure cables (Channel F).

2.9.8.4 Conclusion

Since there is insignificant threat from transient combustibles or in situ combustible material and no credible ignition sources; it is concluded that no credible fire in 729.0-A13 could damage cables routed in the conduits or junction boxes nor the solenoid valves; therefore, no OMAs or fire wrap on the junction box cover are necessary. TVA concludes that the intent of III.G.1 is ensured and requests approval of this deviation demonstrating compliance to III.G.1 criteria with a fire hazard analysis in lieu of the prescriptive separation criteria of III.G.2.

2.9.9 Room 729.0-A15 and 763.5-A2 – Unit 2 Additional Equipment Building

2.9.9.1 Description of Condition

Rooms 729.0-A15 and 763.5-A2 are part of fire area 73 and are analyzed in analysis volume AV-112 (see Part III, Table 3-3 for room listing). Fire area 73 is considered a III.G.2 area; however, 729.0-A15 and 763.5-A2 contains cables associated with both redundant shutdown paths. There is no FSSD equipment located in the Unit 2 Additional Equipment Building, but there are cables routed in conduit that are FSSD circuits. A FSSD analysis assuming failure of all cables and equipment in all of the rooms in AV-112 would result in the following OMAs and electrical raceway fire barrier system (ERFBS) applications:

- a. Unit 1 – Establish motor driven auxiliary feedwater pump A pressure control and control steam generators 1 & 2 level within 20 minutes by manually controlling valves.
- b. Unit 1 – Operate steam generators 1 & 2 power operated relief valves to control secondary pressure within 60 minutes at local nitrogen control panels.
- c. Unit 2 – Operate steam generators 1 & 2 power operated relief valves (PORV) to control secondary pressure within 60 minutes at local nitrogen control panels.

PART VII - DEVIATIONS AND EVALUATIONS

- d. Three-hour ERFBS cable protection to ensure closure of Unit 2 SG #2 and SG #3 PORVs.
- e. Three-hour ERFBS cable protection to ensure isolation of main feed water line and bypass feed water line.

2.9.9.2 Fire Hazards Analysis

2.9.9.2.a Room Description

The Unit 2 Additional Equipment Building consists of the bottom floor (room 729.0-A15) and a partial floor/mezzanine (763.5-A2) of reinforced concrete construction. The floor is at grade level and is constructed of reinforced concrete. The ceiling is the roof of the building and is of reinforced concrete construction. The walls that separate the Unit 2 Additional Equipment Building from adjacent rooms in the Auxiliary Building 729.0-A6, 729.0-A9, 737.0-A9, 757.0-A13, 757.0-A14, 782.0-A4 and the Unit 2 Reactor Building are 3-hour fire rated reinforced concrete (24 to 36 inches thick) barriers. The wall separating the Unit 2 Additional Equipment Building from 729.5-A17 is 12-inch thick reinforced concrete, but is not assigned as a rated fire barrier due to some unsealed conduits that penetrate the wall. The Unit 2 Additional Equipment Building has a floor area of 1,378 square feet (the mezzanine 763.5-A2 has a floor area of 344 square feet) is open from the floor (elevation 729.0) to the ceiling (elevation 773.25). The room is provided with a smoke detection system. No credible fire could go undetected and propagate into an adjacent room or to the Yard.

2.9.9.2.b Fire Load

The in situ combustible loading is classified as low and consists of a small quantity of lubricant for two sump pumps; small amounts of plastic associated with two electrical control panels; lighting and hoses (FLEX components stored in metal enclosures and are 90% of the combustible load). The two sump pumps are not considered to be ignition sources (see 2.9.0 above). The only conduits routed near the pumps are associated with the pumps. The lack of exposed combustibles and ignition sources ensures no credible fire could occur that would damage FSSD cables routed in conduits through the room or propagate from the room into an adjacent room.

2.9.9.2.c Control of Combustibles and Ignition Sources

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms. Compensatory measures must be implemented when transient combustibles or ignition sources are located in a room. Room 729.0-A15 is a CCZ (see Part II, sections 10 and 11 and WBN Technical Instruction TI-291, Combustible Control Zones and Sensitive Areas). For compliance with TI-291, the approval of an evaluation must be obtained before any transient combustible can be introduced into the room or hot work performed in the room. Access to the room is from the Yard. Room 729.0-A15 is not in a normal access path and entry to the room is not part of normal operations. The lack of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources provides assurance that no credible exposure fire that could damage FSSD component would occur. Based on this, it is not expected that the plant will enter the fire safe shutdown procedure.

PART VII - DEVIATIONS AND EVALUATIONS

2.9.9.2.d Adjacent Rooms

The walls that separate the Unit 2 Additional Equipment Building from adjacent rooms 729.0-A6, 729.0-A9, 737.0-A9, 757.0-A13, 757.0-A14, 782.0-A4 in the Auxiliary Building and the Unit 2 Reactor Building are 3-hour fire rated barriers. Three of the Auxiliary Building rooms have insignificant combustible loading, two have low combustible loading and one has a moderate combustible loading. They all have a smoke detection system and the three with combustible loading greater than 5 minutes are provided with an automatic suppression system. This ensures that no credible fire in these rooms could propagate into 729.0-A15.

The Unit 2 Annulus is also separated from 729.0-A15 by a 36 inch thick reinforced concrete wall that has a minimum 3 hour fire rating. In addition automatic suppression and detection is provided in the Unit 2 Annulus for selected cable tray protection. The conclusion is that no credible fire could propagate from the Unit 2 Annulus into 729.0-A15.

Room 729.5-A17 is separated from 729.0-A15 by a 12 inch thick reinforced concrete wall that does not have an assigned fire rating due to some conduits that are not provided with fire rated penetration seals. The in situ combustible load in 729.5-A17 is insignificant and the room is not susceptible to transient combustibles; therefore, no credible fire could occur that could propagate into 729.0-A15.

The Yard is separated from 729.0-A15 by a minimum 12-inch thick reinforced concrete wall that is not assigned a fire rating. The lack of in situ and transient combustibles near this wall provides assurance that no credible fire could occur that could propagate into 729.0-A15.

TVA concludes, based on the above, there is no credible fire that could occur that could propagate from 729.0-A15 into an adjacent room or from an adjacent room into 729.0-A15.

2.9.9.3 System Evaluation

2.9.9.3.a Redundant FSSD Components in the Room

There are two conduits (one Train A and one Train B) in room 729.0-A15 which contain cables for Steam Generator #2 and #3 Main Steam Isolation Valves (MSIVs). The cables in these conduits are normally energized and de-energizing either train will close the MSIV. There are no circuits in these conduits other than the MSIV solenoid valve circuits; therefore, fire damage could not create a hot short to energize the solenoid valves. As defense-in-depth main steam isolation can be achieved by closing the steam load valves (located in the turbine building) from the main control room.

Cables for SG #2 and SG #3 main feed water isolation valves (MOVs) are routed in conduit through this room. Cables for the train A and train B solenoid valve circuits for main feed water flow control valves (air operated) for these two steam generators are also routed in conduit through this room. For FSSD main feed water flow to the steam generators is terminated by closing either the isolation MOV or the air operated flow control valve. De-energizing either the train A or the train B solenoid valve circuit will close the flow control valve. If both solenoid valves (train A and train B) are energized, the control valve is closed from the main control room by manual operation of the flow indicating controller. Fire damage to the main feed water flow control and isolation valve circuits cannot prevent termination of main feed water flow.

PART VII - DEVIATIONS AND EVALUATIONS

Main feed water bypass line isolation valve circuit cables (both train A and Train B) for SG #2 and SG #3 are routed in conduits in the Unit 2 Additional Equipment Building. If either train is de-energized the isolation valve will close. Concurrent cable to cable hot shorts in both trains would have to occur to prevent isolation valve closure. The small bypass lines are used during startup and shutdown to maintain the desired low flow rates. During normal power operation the bypass line control valves are nearly closed and admit only enough flow to keep the pipes warm. Even if the bypass line isolation valves could fail to close, the control valve can be fully closed by manual operation of the flow controller in the main control room. Therefore the cable protection ERFBS listed in 2.9.9.1.e is not necessary.

2.9.9.3.b Components with Redundant FSSD Components in an Adjacent Room within the Same Analysis Volume

The OMAs listed in 2.9.9.1 are all due to the assumed loss of ACAS header pressure resulting from postulated fire damage to ACAS air users located in room 729.0-A13 which is part of analysis volume AV-112. A fire in the Unit 2 Additional Equipment Building (729.0-A15 and 763.5-A2) could not affect the air users in 729.0-A13 because to do so the fire would have to propagate into and across 729.5-A17 and then into 729.0-A13 (a horizontal distance greater than 9 feet). The in situ combustible loading in the Unit 2 Additional Equipment Building is low and 729.5-A17 is insignificant; therefore, there is no credible fire in the Unit 2 Additional Equipment Building that could result in damage to ACAS air users in 729.0-A13. Therefore, the OMAs listed in 2.9.9.1 are not necessary.

Closure of a steam generator PORV is ensured by energizing one of two opposite train solenoid valves. Cables for one of the two solenoid valves for SG #2 PORV and for SG #3 PORV are located in the Unit 2 Additional Equipment Building, and cables for the redundant (opposite train) solenoid valves are located in 729.0-A13. Energizing either solenoid (train A or train B) will close the PORV. As described above and in 2.9.9.2, a fire originating in the Unit 2 Additional Equipment Building could not propagate through two walls and across 729.5-A17 and damage cables routed in conduit in 729.0-A13. Therefore, fire damage cannot prevent closure of the PORVs and the ERFBS listed in 2.9.9.1.d is not necessary.

2.9.9.3.c Other FSSD Components in the Room

Rooms 729.0-A15 and 763.5-A2 contain FSSD equipment and cables associated with FSSD equipment relied upon for fires in other areas of the plant (i.e., equipment and cables not credited for a fire in Rooms 729.0-A15 or 763.5-A2). The cables are routed in conduit. Although no fire induced failures are expected due to the insignificant fire hazard in the rooms, postulated failure of the non-credited FSSD equipment and cables has been evaluated to assess its effect on plant operation. Failure of this function is detected and mitigated by normal plant procedures and does not initiate or result in a plant trip.

2.9.9.4 Conclusion

Since there is insignificant threat from transient combustibles or in situ combustible material and no credible ignition sources; it is concluded that no cables routed in the conduits could be damaged by any credible fire in the Unit 2 Additional Equipment Building; therefore, no OMAs or fire wrap on the conduits are necessary. TVA concludes that the intent of III.G.1 is ensured and requests approval of this deviation demonstrating compliance to III.G.1 criteria with a fire hazard analysis in lieu of the prescriptive separation criteria of III.G.2.

PART VII - DEVIATIONS AND EVALUATIONS

2.9.10 Room 757.0-A13 – Refueling Floor and New Fuel Storage Vault

2.9.10.1 Description of Condition

This room is part of fire area 10 (See Part III, Table 3-3 for room listing) and is analyzed in analysis volume 32 (AV-032) along with several other rooms. Fire area 10 is considered a III.G.2 area because it contains components associated with both shutdown paths. If all equipment and cables located in this analysis volume were assumed to fail due to postulated fire damage; both trains of the ACAS are assumed failed. The 480vac shutdown boards 2A1 and 2A2 are unavailable and a Unit 1 spurious SI signal is assumed. Therefore, the following OMAs are implemented to achieve fire safe shutdown:

- a. Unit 1 – mitigate effects of spurious SI signal.
- b. Unit 1 -- Control level in two steam generators within 20 minutes by manual valve operation. (Unit 2 has an alternative motive air (nitrogen) supply for these valves to eliminate these OMAs)
- c. Unit 1 -- Control motor driven auxiliary feed water pump discharge pressure within 20 minutes by manual valve operation. (Unit 2 has an alternative motive air (nitrogen) supply for these valves to eliminate these OMAs).
- d. Unit 1 and Unit 2 -- Control pressure in two steam generators within 60 minutes by operation of SG PORV via local nitrogen control station.
- e. Transfer normal battery charger for 125vdc vital battery board 3-F to its alternate 480vac supply within 120 minutes.
- f. Unit 1 and Unit 2 – Locally rotate and backwash ERCW strainer within 720 minutes.

2.9.10.2 Fire Hazard Analysis

2.9.10.2.a Room Description

Room 757.0-A13 is the Refueling Floor and also contains the New Fuel Storage Vault. The New Fuel Storage Vault is accessed through the floor of 757.0-A13 and is constructed of minimum 18-inch thick reinforced concrete. The opening in the floor to the New Fuel Storage Vault is normally closed with a steel hatch cover. There is also a non-fire rated steel hatch cover protecting the opening in the floor to room 728.0-A7. Room 757.0-A13 is of 24 to 36-inch thick reinforced concrete construction with 2 or 3 hour fire resistance rating. These concrete walls, floor and ceiling separates 757.0-A13 from adjacent rooms in the Auxiliary Building (except rooms 728.0-A7 and 772.0-A9) by either 2 or 3 hour fire barriers. The wall between 757.0-A13 and 772.0-A9 is 18-inch thick reinforced concrete, but is not a rated fire barrier. The adjacent rooms are provided with automatic suppression and detection except the heat exchanger rooms which have insignificant in situ combustible loading and room 729.0-A6 (see 2.9.4 above).

2.9.10.2.b Fire Load

The in situ combustible loading in the New Fuel Storage Vault is negligible and in room 757.0-A13 is classified as Insignificant. The in situ combustibles consist of hydraulic fluid associated

PART VII - DEVIATIONS AND EVALUATIONS

with the crane and hoists, plastics associated with various electrical and control panels, small dry type transformers and lights, etc. The credible ignition sources are the two auxiliary air compressor units and the 125-ton crane. The wall mounted area heaters, transformers, electrical control panels, hoists and junction boxes are not considered to be significant ignition sources (see FHA General Information 2.9.0 above) because there is negligible combustible material associated with them and the power cables associated with them are protected by properly sized circuit protection (breakers/fuses). Their failure would not damage any other component.

2.9.10.2.c Control of Combustibles and Ignition Sources

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms. Compensatory measures must be implemented when transient combustibles or ignition sources are located in a room. The area around and between the auxiliary air compressors are CCZ (see Part II, sections 10 and 11 and WBN Technical Instruction TI-291, Combustible Control Zones and Sensitive Areas). For compliance with TI-291, the approval of an evaluation must be obtained before any transient combustible can be introduced into the area or hot work performed in the area.

The 125-ton crane is only an ignition source when it is in use; therefore, if a fire occurs in the crane, it is immediately detected by personnel and extinguished before it could damage any other equipment in the immediate vicinity. There is no impact to FSSD.

If either of the two auxiliary air compressor units (A or B) fail and initiate a fire, the fire only damages the failed air compressor unit. The two auxiliary air compressor units are separated by more than 20 feet with no intervening combustibles. There are no other safe shutdown equipment or other plant equipment located close enough to either compressor unit that could be damaged.

2.9.10.2.d Adjacent Rooms

Rooms 713.0-A11, 713.0-A12, 713.0-A15 and 713.0-A16 are separated from 757.0-A13 by 2 hour fire rated ceilings except for the unrated concrete plugs that are in the openings that allow for pulling the heat exchangers. These four rooms contain heat exchangers and have insignificant in situ combustible load and no ignition sources.

Room 729.0-A5 is the receiving bay for new fuel and is separated from 757.0-A13 by a 2 hour fire rated reinforced concrete ceiling, except for the steel hatch covers which are not rated. The in situ combustible load in 729.0-A5 is low and the room is provided with automatic suppression and detection. The only time there is significant transient combustible material or ignition source in the room is during fuel receipt and the area is manned at that time.

Room 728.0-A7 is the Cask Decontamination room and is separate from 757.0-A13 by a 2 hour fire rated ceiling, except for the opening that is closed with a non-fire rated steel hatch cover. The in situ combustible load in 728.0-A7 is insignificant and is due to the small quantity of lube oil associated with two small motors (less than 5 HP), two small control boxes and a rubber water hose associated with the decontamination spray unit. The only time the hatch is open is during cask transfer activities and personnel are present.

PART VII - DEVIATIONS AND EVALUATIONS

Rooms 729.0-A14, 729.0-A15, 763.5-A1 and 763.5-A2 are separated from 757.0-A13 by 3 hour rated reinforced concrete walls. These rooms are provided with smoke detection.

Room 737.0-A1 is separated from 757.0-A13 by a 2 hour fire rated reinforced concrete ceiling, except for the equipment hatch and stair #3 which are provided with a water curtain (see Part VII, section 2.6). Room 737.0-A1 is provided with automatic suppression and detection.

Rooms 737.0-A7 and 737.0-A8 are separated from 757.0-A13 by 2 hour fire rated reinforced concrete ceilings. The in situ combustible load in 737.0-A8 is insignificant and in 737.0-A7 is low.

Room 772.0-A9 is separated from 757.0-A13 by a non-fire rated reinforced concrete wall. The in situ combustible load in the room is low and over 99% of the combustible material is due to insulation on cables in trays. There are no ignition sources in the room. The room is provided with automatic suppression and detection.

The remaining rooms adjacent to 757.0-A13 are separated from 757.0-A13 by 2 hour and 3 hour fire rated reinforced concrete walls. All of these rooms are provided with automatic suppression and detection.

The lack of significant concentrations of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources provides assurance that no credible exposure fire would occur that could propagate from 757.0-A13 into an adjacent room nor from an adjacent room into 757.0-A13.

2.9.10.3 System Evaluation

2.9.10.3.a Redundant FSSD Components in the Room

The redundant FSSD components in this room are the Auxiliary Control Air System (ACAS) compressor units (train A and train B) and their associated cables. The power and control cable are routed in conduits that are embedded in the floor until they turn up at the compressors. The compressor units are separated horizontally by more than 20 feet and there are no intervening combustibles between them and the area between them is a CCZ. Considering the insignificant quantity of combustible material associated with the oil-less compressor units, even if a compressor fails and causes a fire, it would only damage that compressor. A failure of one compressor unit could disable the compressor itself and possibly de-energize a nearby solenoid thereby closing the pressure regulating valve between the station control air system (normal supply to ACAS) and one train of the ACAS. The worst case effect is the loss of supply pressure to one train of ACAS. The other train of ACAS is not affected and is available and sufficient for a FSSD. Each train of ACAS header pressure is indicated in the main control room and decreasing pressure is alarmed. Based on at least one train of ACAS being available the OMAs identified in 2.9.10.2.b, c, & d are not needed.

There are also two train A conduits containing the power feeds to the unit 2 train A 480VAC shutdown board transformers in the room. Cables for the redundant Unit 2 Train B power system are not located in 757.0-A13 or any of the AV-032 rooms, but failure of these Unit 2 Train A power system cables would disable the train A ACAS compressor. Therefore, they are functionally redundant to the train B ACAS compressors. The two conduits run vertically near the south wall of the room and are separated from the train B compressor by more than 20 feet horizontally and would not be affected by an assumed ACAS train B compressor fire. Since

PART VII - DEVIATIONS AND EVALUATIONS

there are no other ignition sources in the room, there could be no fire damage to the power feeder cables for 480vac shutdown board transformers 2A1 and 2A2. Therefore the battery charger for 125vdc battery board 3-F would not have to be transferred to its alternate source. Additionally, power is available for ERCW strainer rotation and backwash. The implementation of OMAs (2.9.10.1.e & f) resulting from the postulated loss of 480vac shutdown boards 2A1 and 2A2 is not necessary.

As additional defense-in-depth the floor area between the ACAS compressor units is designated as a CCZ to ensure that no transient combustible material is inadvertently left there.

2.9.10.3.b Components with Redundant FSSD Equipment or Cables in an Adjacent Room within the Same Analysis Volume

Cables whose fire damage could initiate a spurious Unit 1 SI signal are actually located in room 729.0-A8 which is in AV-032, but as described in the FHA (2.9.10.2 above) no credible fire in room 757-A13 could propagate into 729.0-A8. Therefore OMA (2.9.10.1.a) to mitigate the Unit 1 spurious SI effects would not be needed.

2.9.10.3.c Other FSSD Components in the Room

Room 757.0-A13 contains cables associated with FSSD equipment relied upon for fires in other areas of the plant (i.e., equipment and cables not credited for a fire in Room 757.0-A13). The cables are routed in conduit. Although no fire induced failures are expected due to the insignificant fire hazard in the rooms, postulated failure of the non-credited FSSD equipment and cables has been evaluated to assess its effect on plant operation. Failure of these FSSD cables is detected and mitigated by normal plant procedures and does not initiate or result in a plant trip.

- Unit 1 cables for pressurizer heater backup group B
- Unit 1 cable for Channel D source range neutron monitoring

2.9.10.4 Conclusion

There is insignificant threat from transient combustibles or in situ combustible material except for a possible loss of one train of the ACAS. Loss of one train of ACAS would not prevent FSSD since FSSD only relies on one train of ACAS. Therefore, there is no fire hazard in 757.0-A13 or the New Fuel Storage Vault that necessitates any OMAs. TVA concludes that the intent of III.G.1 is ensured and requests approval of this deviation demonstrating compliance to III.G.1 with a fire hazard analysis in lieu of the prescriptive separation criteria of III.G.2.

2.9.11 Room 757.0-A14 – Unit 2 Reactor Building Access Room

2.9.11.1 Description of Condition

Room 757.0-A14 is a part of fire area 75 and is analyzed in analysis volume AV-116 (see Part III, Table 3-3 for room listing). Fire area 75 is considered a III.G.2 area because it contains equipment and/or cables associated with both redundant safe shutdown paths. There is no FSSD equipment in this room, but there are cables for redundant shutdown equipment. A FSSD analysis based on the assumption that all of the cables and equipment in AV-116 could be damaged would result in crediting the following OMAs in lieu of physical separation in accordance with III.G.2:

PART VII - DEVIATIONS AND EVALUATIONS

- a. Unit 2 - Reduce RCP seals injection flow within 60 minutes by operation of a manual valve.
- b. Unit 2 - Control pressure in steam generator #3 within 60 minutes by operation of steam generator #3 PORV via local nitrogen control station.

2.9.11.2 Fire Hazards Analysis

2.9.11.2.a Room Description

Room 757.0-A14 is the Unit 2 Reactor Building Access Room and is constructed of 12 to 36-inch thick reinforced concrete with a minimum fire resistance rating of 2 to 3-hours. The floor that separates room 757.0-A14 from 737.0-A9 is a 2-hour rated barrier. The ceiling that separates room 757.0-A14 from 782.0-A4 is a 2-hour rated barrier. The wall that separates room 757.0-A14 from 757.0-A13 is a 2-hour rated barrier. The walls that separate room 757.0-A14 from 757.0-A15 and the Unit 2 Reactor Building are 3-hour barriers. The room has a floor area of 540 square feet and a ceiling height of 23 feet. Room 757.0-A14 is provided with automatic fire suppression and detection and the rooms adjacent to 757.0-A14 are provided with automatic suppression and detection except for room 757.0-A13 (see 2.9.10 above). The fire rated barriers surrounding room 757.0-A14 will prevent any credible fire in 757.0-A14 from propagating into an adjoining room.

2.9.11.2.b Fire Load

The in situ combustible loading in 757.0-A14 is classified as low and consists of insulation on cables routed in trays (96% of the in situ combustible load), small quantities of plastics associated with small electrical control and junction boxes and lighting and the fire hose attached to the standpipe. Cables routed in the trays are provided with properly sized and coordinated circuit protection (breakers/fuses); therefore, they are not considered to be credible ignition sources. The circuits for small electrical boxes and the lighting are adequately protected with circuit protection (properly sized and coordinated fuses/breakers) that would preclude them from faulting and creating a fire. Therefore, they are not considered to present a fire hazard to any other components in the room.

2.9.11.2.c Control of Combustibles and Ignition Sources

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms. Compensatory measures must be implemented when transient combustibles or ignition sources are located in a room. Room 757.0-A14 is a CCZ (see Part II, sections 10 and 11 and WBN Technical Instruction TI-291, Combustible Control Zones and Sensitive Areas). For compliance with TI-291, the approval of an evaluation must be obtained before any transient combustible can be introduced into the room or hot work performed in the room. Access to the room is from the Refueling Floor (757.0-A13). The lack of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources in combination with the automatic suppression and detection in the room provides assurance that no credible exposure fire would occur. Based on this, it is not expected that the plant will enter the fire safe shutdown procedure.

PART VII - DEVIATIONS AND EVALUATIONS

2.9.11.2.d Adjacent Rooms

Room 737.0-A9 is separated from 757.0-A14 by a reinforced concrete floor that has a 2 hour fire rating. The fire severity of the in situ combustible load in 737.0-A9 is low. Room 737.0-A9 is provided with automatic suppression and detection. No credible fire could occur in 737.0-A9 and propagate into 757.0-A14.

The Unit 2 Additional Equipment Building (729.0-A15 and 763.5-A2) is separated from 757.0-A14 by a reinforced concrete wall that has a fire rating of 3 hours. The in situ combustible loading in the Unit 2 Additional Equipment Building is insignificant. The room is provided with a smoke detection system. No credible fire could occur in the Unit 2 Additional Equipment Building and propagate into 757.0-A14.

The Refueling Floor (741.5 and 757.0-A13) is separated from 757.0-A14 by a reinforced concrete wall that has a fire rating of 2 hours. The fire severity of the in situ combustible load in the Refueling Floor is insignificant. No credible fire could occur in the Refueling Floor that could propagate into 757.0-A14.

Room 757.0-A15 is separated from 757.0-A14 by a reinforced concrete wall that has a fire rating of 3 hours. The fire severity of the in situ combustible load (of which 99% is due to insulation on cables routed in trays near the ceiling) is low. Room 757.0-A15 is provided with automatic suppression and detection. No credible fire in 757.0-A15 could occur and propagate into 757.0-A14.

Room 782.0-A4 is separated from 757.0-A14 by a reinforced concrete floor that has a fire rating of 2 hours. The in situ combustible loading (insulation on cables in trays accounts for over 57% of the in situ combustibles) in 782.0-A4 is moderate. The room is provided with automatic suppression and detection. No credible fire in 782.0-A4 could occur and propagate into 757.0-A14.

The Unit 2 Annulus is separated from 757.0-A14 by a reinforced concrete wall that has a fire rating of 3 hours. The in situ combustible loading (insulation on cables in trays accounts for over 98% of the in situ combustibles) in the Unit 2 Annulus is severe. Automatic suppression and detection is provided for separation of redundant cables in the Unit 2 Annulus. No credible fire in the Unit 2 Annulus could occur and propagate into 757.0-A14.

TVA concludes that due to the combination of fire rated barriers, lack of in situ combustibles or ignition sources, and some of the rooms with automatic suppression, no credible fire could occur that would propagate from an adjacent room into 757.0-A14 or from 757.0-A14 into an adjacent room.

2.9.11.3 System Evaluation

2.9.11.3.a Redundant FSSD Components in the Room

There are conduits (train A and train B) in 757.0-A14 containing cables for SG #2 and SG #3 Main Steam Isolation Valves (MSIVs). These cables are normally energized and de-energizing either train will close the MSIV. The only fire damage failure mode that could prevent MSIV closure is sustained concurrent cable to cable hot shorts in both trains. Considering that there are no ignition sources in the room and practically no combustibles, other than cable insulation in trays, such a failure mode is not considered credible. As defense-in-depth these cables have

PART VII - DEVIATIONS AND EVALUATIONS

thermoset insulation making cable to cable hot shorts even less credible. Finally, main steam isolation can be achieved by closing the steam load valves (located in the turbine building) from the main control room.

An instrument cable for the control circuit of the valve that controls charging flow (RCP seal water injection) is routed through 757.0-A14 in a conduit located near the ceiling. If a fire could occur, it is detected by the ionization smoke detection system and the automatic sprinkler actuation prevents damage to the cable routed in conduit. For a fire to damage cables routed in conduit near the ceiling of this room, it is large enough to raise the temperature of the hot gas layer at the ceiling enough to damage the insulation on the cables routed in conduit. The sprinkler heads are located at the ceiling above the conduits. The activation temperature of the automatic sprinklers (212°F) in the room is well below the damage temperature (400°F) of the cable insulation; therefore, the sprinklers are activated and prevent damage to the cables routed in conduit. As described in section 2.9.11.2, there is no credible ignition sources and insignificant combustible loading in the room; therefore, it is concluded that no credible fire in this room could damage this circuit and necessitate the OMA listed in 2.9.11.1.a. As defense-in-depth even if a failure of this control circuit resulted in a spurious operation of the valve, the Main Control Room (MCR) staff is alerted to a change in pressurizer level and either select a different pressurizer level input for the valve control system or operate the valve controller in manual.

The FSSD analysis relies on two of the four steam generators and SG #3 and SG #4 are credited for FSSD in room 757.0-A14. A control cable for a solenoid valve for SG #3 power operated relief valve (PORV) is routed in a conduit through 757.0-A14. SG #4 is not affected as no SG #4 cables are in this room. The solenoid valve is normally de-energized to permit modulation of the PORV. Energizing the solenoid closes the PORV. A cable to cable hot short within the conduit is necessary to energize the solenoid. As stated above, there are no credible ignition sources and insignificant combustible loading in the room and it is provided with automatic suppression and detection which would actuate long before a postulated fire could damage the cable insulation. Defense-in-depth is provided in that the cable has thermoset insulation making a cable to cable hot short even less credible. Additionally, the conduit is 21 feet above the floor so an inconceivable quantity of transient combustibles is necessary to establish a floor based fire capable of damaging the cable of concern. It is concluded that no credible fire in this room could damage this circuit and necessitate the OMA listed in 2.9.11.1.b.

Cables for SG #2 and SG #3 main feed water isolation valves (MOVs) are routed in conduit through this room. Cables for the train A and train B solenoid valve circuits for main feed water flow control valves (air operated) for these two steam generators are also routed in conduit through this room. For FSSD main feed water flow to the steam generators is terminated by closing either the isolation MOV or the air operated flow control valve. De-energizing either the train A or the train B solenoid valve circuit will close the flow control valve. If both solenoid valves (train A and train B) are energized, the control valve is closed from the main control room by manual operation of the flow indicating controller. Fire damage to the main feed water flow control and isolation valve circuits cannot prevent termination of main feed water flow.

Main feed water bypass line isolation valve circuit cables (both train A and Train B) for SG #2 and SG #3 are routed in conduits in this room. If either train is de-energized the isolation valve will close. Concurrent cable to cable hot shorts in both trains would have to occur to prevent isolation valve closure. The small bypass lines are used during startup and shutdown to maintain the desired low flow rates. During normal power operation the bypass line control valves are nearly closed and admit only enough flow to keep the pipes warm. Even if the

PART VII - DEVIATIONS AND EVALUATIONS

bypass line isolation valves could fail to close, the control valve can be fully closed by manual operation of the flow controller in the main control room.

2.9.11.3.b FSSD Components with Redundant FSSD Components in an Adjacent Room within the same Analysis Volume

There are no adjacent rooms within analysis volume AV-116; only room 757-A14 is in the analysis volume.

2.9.11.3.c – Other FSSD Components in the Room

Room 757.0-A14 contains cables associated with FSSD equipment relied upon for fires in other areas of the plant (i.e., equipment and cables not credited for a fire in Room 757.0-A14). The cables are routed in conduit and in trays. Although no fire induced failures are expected due to the insignificant fire hazard in the room, postulated failure of the non-credited FSSD cables has been evaluated to assess its effect on plant operation. Failure of these FSSD cables are detected and mitigated by normal plant procedures and does not initiate or result in a plant trip.

- Steam generator #2 and #3 steam line warming valve cables
- Steam line and pressurizer pressure transmitter channel D cables
- Reactor building sump level channel D cables
- RCS multi-channel process monitoring system Loops 1 and 2 hot and cold leg temperature channel D cables
- Containment isolation phase B pressure instrumentation channel D cable

2.9.11.4 Conclusion

There is insignificant threat from transient combustibles or in situ combustible material, no credible ignition sources, and no impact to FSSD; therefore, there is no fire hazard in 757.0-A14 that necessitates any OMAs. TVA concludes that the intent of III.G.1 is ensured and requests approval of this deviation demonstrating compliance to III.G.1 criteria with a fire hazard analysis in lieu of the prescriptive separation criteria of III.G.2.

2.9.12 Room 757.0-A15 – Unit 2 Reactor Building Equipment Hatch

2.9.12.1 Description of Condition

Room 757.0-A15 is fire area 76 which is analyzed in analysis volume AV-096 (see Part III, Table 3-3 for room listing). The fire area is considered a III.G.2 area. Although there is no FSSD equipment located in this room there are cables for redundant FSSD equipment. A FSSD analysis based on the assumption that all cables in the room fail, credits the following OMAs in lieu of physical separation in accordance with III.G.2:

- a. Unit 2 - Limit RCP seals injection flow within 60 minutes by operation of a manual valve.
- b. Unit 2 - Control pressure in steam generator #3 within 60 minutes by operation of steam generator PORV via local nitrogen control station.

PART VII - DEVIATIONS AND EVALUATIONS

2.9.12.2 Fire Hazards Analysis

2.9.12.2.a Room Description

Room 757.0-A15 is the Unit 2 Reactor Building Equipment Hatch and is constructed of 24 to 36-inch thick reinforced concrete and the barriers have a minimum fire resistance rating of 3-hours. The room has a floor area of 673 square feet and a ceiling height of 22 feet. Full coverage automatic fire detection and suppression are provided in the room. The equipment hatch doors that separate the Unit 2 Reactor Building from 757.0-A15 are not fire rated doors; however, they are of heavy metal construction which is more than adequate to prevent any credible fire from propagating from one side of the door to another. The fire rated barriers surrounding room 757.0-A15 will prevent any credible fire in 757.0-A15 from propagating into an adjoining room.

2.9.12.2.b Fire Load

The in situ combustible loading in the 757.0-A15 is classified as low and consists of insulation on cables routed in trays (99% of the in situ combustible load) and a small amount of plastic associated with lighting. Cables routed in the trays are provided with properly sized and coordinated circuit protection (breakers/fuses); therefore, they are not considered ignition sources. The lighting (six lights) units in the room are not considered ignition sources (lights are not energized during normal plant operation). The circuits for these devices are adequately protected with circuit protection (properly sized and coordinated fuses/breakers) that would preclude them from faulting and creating a fire. Therefore, there are no credible ignition sources in the room (see Justification 2.9.0 above).

2.9.12.2.c Control of Combustibles and Ignition Sources

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms. Compensatory measures must be implemented when transient combustibles or ignition sources are located in a room. Room 757.0-A15 is a CCZ (see Part II, sections 10 and 11 and WBN Technical Instruction TI-291, Combustible Control Zones and Sensitive Areas). For compliance with TI-291, the approval of an evaluation must be obtained before any transient combustible can be introduced into the room or hot work performed in the room. Access to the room is from the Refueling Floor (757.0-A13), but only during an outage. There is no access to the room during operation of Unit 2. The lack of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources in combination with the automatic suppression and detection in the room provides assurance that no credible exposure fire would occur that could damage FSSD circuits. Based on this, it is not expected that the plant will enter the fire safe shutdown procedure.

2.9.12.2.d Adjacent Rooms

Room 737.0-A9 is separated from 757.0-A15 by a reinforced concrete floor that has a 3 hour fire rating. The fire severity of the in situ combustible load in 737.0-A9 is low. Room 737.0-A9 is provided with automatic suppression and detection. No credible fire could occur in 737.0-A9 and propagate into 757.0-A15.

The Refueling Floor (757.0-A13) is separated from 757.0-A15 by reinforced concrete walls and ceiling that have a fire rating of 3 hours. The fire severity of the in situ combustible load in the

PART VII - DEVIATIONS AND EVALUATIONS

Refueling Floor is insignificant. No credible fire could occur in the Refueling Floor that could propagate into 757.0-A15.

Room 757.0-A14 is separated from 757.0-A15 by a reinforced concrete wall that has a fire rating of 3 hours. The fire severity of the in situ combustible load (of which 96% is due to insulation on cables routed in trays near the ceiling) is low. Room 757.0-A14 is provided with automatic suppression and detection. No credible fire in 757.0-A14 could occur that would propagate into 757.0-A15.

Room 757.0-A16 is separated from 757.0-A15 by a reinforced concrete wall that has a fire rating of 3 hours. The fire severity of the in situ combustible load (of which 99% is due to insulation on cables routed in trays near the ceiling) is moderate. Room 757.0-A16 is provided with automatic suppression and detection. No credible fire in 757.0-A16 could occur that would propagate into 757.0-A15.

Room 782.0-A3 is separated from 757.0-A14 by a reinforced concrete floor that has a fire rating of 3 hours. The in situ combustible loading (insulation on cables in trays accounts for over 92% of the in situ combustibles) in 782.0-A3 is low. The room is provided with automatic suppression and detection. No credible fire in 782.0-A3 could occur that would propagate into 757.0-A15.

The Unit 2 Annulus is separated from 757.0-A15 by the heavy equipment doors. The in situ combustible loading in the Unit 2 Annulus is severe; however, insulation on cables in trays accounts for over 98% of the in situ combustibles. The remaining combustibles are dispersed throughout the Annulus and there are no credible ignition sources. Automatic suppression and detection is provided for separation of redundant cables in the Unit 2 Annulus. No credible fire in the Unit 2 Annulus could occur that would propagate into 757.0-A15.

2.9.12.3 System Evaluation

2.9.12.3.a Redundant FSSD Components in the Room

There are conduits (train A and train B) in 757.0-A15 containing cables for SG #2 and SG #3 Main Steam Isolation Valves (MSIVs). These cables are normally energized and de-energizing either train will close the MSIV. The only fire damage failure mode that could prevent MSIV closure is sustained concurrent cable to cable hot shorts in both trains. Considering that there are no ignition sources in the room and practically no combustibles, other than cable insulation in trays, such a failure mode is not considered credible. As defense-in-depth these cables have thermoset insulation making cable to cable hot shorts even less credible. Finally, main steam isolation can be achieved by closing the steam load valves (located in the turbine building) from the main control room.

An instrument cable for the control circuit of the valve that controls charging flow (RCP seal water injection) is routed through 757-A15 in a conduit located near the ceiling. If a fire could occur, it is detected by the ionization smoke detection system and the automatic sprinkler actuation prevents damage to the cable routed in conduit. For a fire to damage cables routed in conduit near the ceiling of this room, it is large enough to raise the temperature of the hot gas layer at the ceiling and damage the insulation on the cables routed in conduit. The sprinkler heads are located at the ceiling above the conduits. The activation temperature of the automatic sprinklers (212°F) in the room is well below the damage temperature (400°F) of the cable insulation; therefore, the sprinklers are activated and prevent damage to the cables routed

PART VII - DEVIATIONS AND EVALUATIONS

in conduit. As described in section 2.9.12.2, there is no credible ignition sources and practically no combustible loading in the room (excluding insulation on cables in trays which are either IEEE-323 qualified or covered with fire retardant); therefore, it is concluded that no credible fire in this room could damage this circuit and necessitate the OMA listed in 2.9.12.1.a. Even if a failure of this control circuit resulted in a spurious operation of the valve, the MCR staff is alerted to a change in pressurizer level and either select a different pressurizer level input for the valve control system or operate the controller in manual mode.

Only two of four steam generators are necessary for FSSD and SG #3 and SG #4 are credited for FSSD in room 757.0-A15, but a control cable for a solenoid valve for SG #3 power operated relief valve (PORV) is routed in a conduit through 757.0-A15. SG #4 is not affected as no SG #4 cables are in this room. The solenoid valve is normally de-energized to permit modulation of the PORV. Energizing the solenoid closes the PORV. A cable to cable hot short within the conduit is necessary to energize the solenoid. As stated above, there is no credible ignition source and practically no combustible loading in the room and it is provided with automatic suppression and detection; therefore, it is concluded that no credible fire in this room could damage this circuit and necessitate the OMA listed in 2.9.12.1.b. As defense-in-depth the cables have thermoset insulation which make a cable to cable hot short even less credible. Additionally, with the conduit over 20 feet above the floor, an inconceivable quantity of transient combustibles and an ignition source is necessary to establish a floor based fire capable of damaging the cable of concern.

Cables for SG #2 and SG #3 main feed water isolation valves (MOVs) are routed in conduit through this room. Cables for the train A and train B solenoid valve circuits for main feed water flow control valves (air operated) for these two steam generators are also routed in conduit through this room. For FSSD main feed water flow to the steam generators is terminated by closing either the isolation MOV or the air operated flow control valve. De-energizing either the train A or the train B solenoid valve circuit will close the flow control valve. If both solenoid valves (train A and train B) are energized, the control valve is closed from the main control room by manual operation of the flow indicating controller. Fire damage to the main feed water flow control and isolation valve circuits cannot prevent termination of main feed water flow.

Main feed water bypass line isolation valve circuit cables (both train A and Train B) for SG #2 and SG #3 are routed in conduits in this room. If either train is de-energized the isolation valve will close. Concurrent cable to cable hot shorts in both trains would have to occur to prevent isolation valve closure. The small bypass lines are used during startup and shutdown when low flow rates are desired. During normal power operation the bypass line control valves are nearly closed and admit only enough flow to keep the pipes warm. Even if the bypass line isolation valves could fail to close, the control valve can be fully closed by manual operation of the flow controller in the main control room.

2.9.12.3.b FSSD Components with Redundant FSSD Components in an Adjacent Room within the same Analysis Volume

There are no adjacent rooms within analysis volume AV-096; only room 757-A15 is in the analysis volume.

2.9.12.3.c Other FSSD Components in the Room

Room 757-A15 contains cables associated with FSSD equipment relied upon for fires in other areas of the plant (i.e., equipment and cables not credited for a fire in Room 757.0-A15). The

PART VII - DEVIATIONS AND EVALUATIONS

cables are routed in conduit and in trays. Although no fire induced failures are expected due to the insignificant fire hazard in the room, postulated failure of the non-credited FSSD cables has been evaluated to assess its effect on plant operation. Failure of these FSSD cables is detected and mitigated by normal plant procedures and does not initiate or result in a plant trip.

- Steam generator #2 and #3 steam line warming valve cables
- Steam line and pressurizer pressure transmitter channel D cables
- Reactor building sump level channel D cables
- RCS multi-channel process monitoring system Loops 1 and 2 hot and cold leg temperature channel D cables
- Containment isolation phase B pressure instrumentation channel D cable
- Steam generator #2 narrow range level indication cable
- Pressurizer spray valve cables
- Control rod drive cooler and reactor building lower compartment cooler temperature control valve cables

2.9.12.4 Conclusion

There is insignificant threat from transient combustibles or in situ combustible material, no credible ignition sources, and no impact to FSSD; therefore, there is no fire hazard in 757.0-A15 that necessitates any OMAs. TVA concludes that the intent of III.G.1 is ensured and requests approval of this deviation demonstrating compliance to III.G.1 criteria with a fire hazard analysis in lieu of the prescriptive separation criteria of III.G.2.

2.9.13 Room 2RIR Unit 2 Reactor Instrument Room

2.9.13.1 Description of Condition

Room 2RIR is part of fire area 77 and is analysis volume 118F (AV-118F) in the FSSD analysis (see Part III, Table 3-3 for room listing). Fire area 77 is considered a III.G.2 area because it contains components related to both redundant safe shutdown paths. Room 2RIR contains components related to both redundant safe shutdown paths.

Physical separation in accordance with III.G.2 cannot be achieved in this room. An FSSD analysis assuming failure of all equipment and cables in the room would result in OMAs being credited in lieu of III.G.2 physical separation. Therefore, the following OMAs are implemented to achieve fire safe shutdown:

- a. Reduce RCP seal injection flow rate within 60 minutes by operation of a manual valve in 713.0-A1B.
- b. Protecting a pressurizer level transmitter sense line and a conduit containing level transmitter cables with radiant energy shields to achieve III.G.2 separation.

2.9.13.2 Fire Hazard Analysis

2.9.13.2.a Room Description

The Unit 2 Reactor Building Instrument Room (2RIR) is separated from adjacent areas of the Unit 2 Reactor Building by non-fire rated (barriers contain electrical and mechanic openings that

PART VII - DEVIATIONS AND EVALUATIONS

are not provided with fire rated seals/closures) reinforced concrete barriers that are 24 to 36-inches thick and from the Unit 2 Annulus by the steel containment shield. Entry to the room is thru an opening in the 24-inch thick concrete floor via a ladder from 2RO-1 below and the Personnel Air Lock to the Auxiliary Building. The room has a floor area of 480-ft² and a ceiling height of 26-feet. Entry into the Reactor Building is strictly controlled.

2.9.13.2.b Fire Load

The combustible loading is classified as Insignificant and is due to small quantities of lubricating oil in control valves and plastics associated with small control panels and two I&C cabinets, a telephone and junction boxes. The electrical cables associated with these devices are low voltage/amp power or control circuits and are routed in conduit. Each circuit is adequately protected with properly sized and coordinated circuit protection (fuse/breaker) that will clear a cable fault prior to the cable insulation reaching auto-ignition. None of these combustible materials are associated with a credible ignition source. There are no credible ignition sources in the room. The lack of in situ combustibles and ignition sources combined with the barriers enclosing the room ensures that no credible fire could occur and propagate from 2RIR into an adjacent room in the Unit 2 Reactor Building.

2.9.13.2.c Control of Combustibles and Ignition Sources

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms. Compensatory measures must be implemented when transient combustibles or ignition sources are located in a room. Room 2RIR is a CCZ (see Part II, sections 10 and 11 and WBN Technical Instruction TI-291, Combustible Control Zones and Sensitive Areas). For compliance with TI-291, the approval of an evaluation must be obtained before any transient combustible can be introduced into the room or hot work performed in the room. Access to the room is from 2RO. The lack of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources provides assurance that no credible exposure fire would occur that could damage FSSD circuits. Based on this, it is not expected that the plant will enter the fire safe shutdown procedure.

2.9.13.2.d Adjacent Rooms

The Unit 2 Annulus is separated from 2RIR by the steel containment shield and the Personnel Air Lock. Over 98% of the in situ combustible load in the Unit 2 Annulus is due to insulation on the cables routed in trays. The remaining in situ combustible load is dispersed throughout the Annulus and there are no ignition sources. The Unit 2 Annulus is provided with automatic suppression and detection in this area. The steel containment shield and the Air Lock in combination with the automatic suppression and detection provide assurance that no credible fire in the Unit 2 Annulus could propagate into 2RIR.

Room 2RO-1 is separated from 2RIR by 24 inch thick non-fire rated reinforced concrete ceiling. The in situ combustible load in 2RO-1 is low of which the expansion joint seal material accounts for 91% of the load. Only the edge of the seal is exposed, the rest is between concrete walls. An opening in the floor of 2RIR provides access for personnel to the ladder to 2RO-1. The lack of exposed in situ combustibles and ignition sources provides assurance that no credible fire in 2RO-1 could propagate into 2RIR via this personnel access opening. Conduit, instrumentation lines and mechanical piping penetrate the floor and are not provided with fire rated penetration

PART VII - DEVIATIONS AND EVALUATIONS

seals. The lack of in situ combustibles and ignition sources provides assurance that no credible fire in 2RO-1 could propagate from 2RO-1 into 2RIR through these penetrations.

Part of room 2RO-2 extends 10 feet up into 2RIR and is separated from 2RIR by 36 inch thick non-fire rated reinforced concrete ceiling and walls. Conduit, instrumentation lines and mechanical piping penetrate the walls and ceiling and are not provided with fire rated penetration seals. Access from the lower part of 2RO-2 into this room is via a ladder and a personnel opening. The remaining part of 2RO-2 is separated from 2RIR by a 24 inch thick reinforced concrete ceiling. Conduit, instrumentation lines and mechanical piping penetrate the floor and are not provided with fire rated penetration seals. The in situ combustible load in lower part of 2RO-2 is low of which the expansion joint seal material accounts for 91% of the load. Only the edge of the seal is exposed, the rest is between concrete walls. The in situ combustible load in upper part of 2RO-2 is insignificant. The lack of ignition sources and exposed in situ combustibles provides assurance that no credible fire in 2RO-1 could propagate into 2RIR through these penetrations.

Room 2RA1 is separated from 2RIR by a 24 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping penetrate the wall and are not provided with fire rated penetration seals. The in situ combustible load in 2RA1 is low and is due to small quantities of lubricant in valves (61% of the load), expansion joint material (32% of the load) and small quantities of plastics associated with electrical control boxes and lights. The lack of ignition sources and concentrations of in situ combustibles provides assurance that no credible fire in 2RA1 could propagate into 2RIR through the unprotected penetrations.

Room 2RA2 is separated from 2RIR by a 24 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping penetrate the wall and are not provided with fire rated penetration seals. The in situ combustible load in 2RA2 is insignificant and is due to small quantities of lubricant in valves (89% of the load), and small quantities of plastics associated with electrical control boxes and lights. The lack of ignition sources and concentrations of in situ combustibles provides assurance that no credible fire in 2RA2 could propagate into 2RIR through the unprotected penetrations.

Room 2RI-1 is separated from 2RIR by a 36 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping and ventilation penetrate the wall and are not provided with fire rated penetration seals or closures. The in situ combustible load in 2RI-1 is low of which 99% is due to reactor coolant pump (RCP) lubricating oil. The RCP is provided with a oil collection system in accordance with Appendix R, Section III.O (see Part VII, section 2.8) and is protected with automatic suppression and detection. This assures that a postulated RCP fire would be contained to the RCP. The lack of other ignition sources or concentrations of in situ combustibles provides assurance that no credible fire in 2RI-1 could propagate into 2RIR through the unprotected penetrations.

Room 2RI-2 is separated from 2RIR by a 36 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping and ventilation penetrate the wall and are not provided with fire rated penetration seals or closures. The in situ combustible load in 2RI-2 is low of which 98% is due to reactor coolant pump (RCP) lubricating oil. The RCP is provided with a oil collection system in accordance with Appendix R, Section III.O (see Part VII, section 2.8) and is protected with automatic suppression and detection. This assures that a postulated RCP fire would be contained to the RCP. The lack of other ignition sources or concentrations of in situ combustibles provides assurance that no credible fire in 2RI-2 could propagate into 2RIR through the unprotected penetrations.

PART VII - DEVIATIONS AND EVALUATIONS

Room 2RU is separated from 2RIR by a 24 inch thick reinforced concrete floor. Conduit, instrumentation lines and mechanical piping penetrate the floor and are not provided with fire rated penetration seals or closures. The in situ combustible load in 2RU is insignificant and is due to small quantities of lubricant in valves and small quantities of plastics associated with electrical control boxes and lights. The lack of ignition sources and concentrations of in situ combustibles provides assurance that no credible fire in 2RU could propagate into 2RIR through the unprotected penetrations.

The lack of significant concentrations of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources provides assurance that no credible exposure fire would occur that could propagate from 2RIR into an adjacent room nor from an adjacent room into 2RIR.

2.9.13.3 System Evaluation

2.9.13.3.a Redundant FSSD Components in the Room

Room 2RIR contains three Pressurizer pressure transmitters (2-PT-68-323-F, -334-E, & -340-D) of which two must be operable to prevent a spurious safety injection (SI) signal. There are three Pressurizer level transmitters (2-LT-68-320-F, -335-E, & -339-D) of which one must be available. These six transmitters are located on panels 2-L-659, 660, & 661. Panels 659 and 660 are located on the same side of the Seal Table but are separated by more than 20-feet horizontally and a part of the Personnel Air Lock. Panels 661 and 660 are mounted on the concrete walls on opposite sides of the Seal Table; therefore the concrete Seal Table provides separation between the panels. Cables associated with these devices are routed in conduits and are separated from each other by at least 2 feet horizontally; there are no ignition sources and insignificant quantities of combustible material below them that could create a fire of sufficient magnitude to damage the cables in both conduits. Sense lines associated with these devices are also located in 2RIR. The sense lines are separated from each other by at least 3-feet horizontally. Due to the lack of ignition sources and insignificant quantities of combustible material; it is concluded that no credible fire in 2RIR could result in damage to either the sense lines or the cables in conduits. Therefore, there is no need to add radiant energy shielding for a sense line or conduit to obtain III.G.2.f separation from the other sense lines and conduits.

Two Pressurizer level transmitters (2-LT-68-320-F & -339-D) provide input to the charging flow control valve (2-FCV-62-93) control system. The transmitters are located in room 2RIR and horizontally separated by more than 20 feet as discussed above. The transmitter cables are routed in conduits and are separated from each other by at least 3 feet horizontally; there are no ignition sources and insignificant quantities of combustible material below them that could create a fire of sufficient magnitude to damage the cables in both conduits. Sense lines associated with these devices are also located in 2RIR. The sense lines are separated from each other by at least 3-feet horizontally. Due to the lack of ignition sources and insignificant quantities of combustible material; it is concluded that no credible fire in 2RIR could result in damage to either the sense lines or the cables in conduits. Failure of either or both of these cables could cause the charging flow control valve to open. However, for additional defense-in-depth the operator can control the charging flow control valve flow from the main control room even if one or both of the level circuits fail. Therefore, the OMA listed in 2.9.13.1.b is not necessary.

PART VII - DEVIATIONS AND EVALUATIONS

Cables for both train A and train B containment isolation valve circuits are located in 2RIR and they are horizontally separated by more than 20 feet.

Cables for the train A pressurizer PORV and the train A and B pressurizer PORV block valves are routed through 2RIR in dedicated conduits. A cable-to-cable hot short is the only failure mode that could operate these valves. For defense-in-depth the dedicated conduits contain no hot short sources (energized cables) which ensures that the valves could not spuriously operate even if there could be cable fire damage. The train B PORV is the credited letdown path and its cables and other credited FSSD equipment and cables are not located in 2RIR.

During FSSD, the RCP seal water injection flow regulating valve utilizes control air for operation. Control air is supplied from the large capacity compressors located in the Turbine Building. Failure of a few air users would not impact the function of the system. As described in section 2.9.13.2, there are no credible ignition sources and the insignificant amount of combustible material in the room could not generate a fire sufficient to damage any air users in 2RIR. As additional defense-in-depth, even if the air users could be fire damaged, the control air header containment isolation valve can be closed from the main control room to isolate the air leak and ensure operability of the control air system in the auxiliary building. Therefore it is concluded that the control air will remain available and the OMA listed in 2.9.13.1.a is not necessary.

Access to the reactor building is rigorously controlled which limits the possibility of transient combustibles being brought into 2RIR.

2.9.13.3.b FSSD Components with Redundant FSSD Components in an Adjacent Room within the Same Analysis Volume

Room 2RIR is the only room in analysis volume AV-118F. As discussed in 2.9.13.2, the lack of significant concentrations of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources provides assurance that no credible exposure fire could propagate from or into an adjacent room.

2.9.13.3.c Other FSSD Components in the Room

Room 2RIR contains FSSD cables associated with FSSD equipment relied upon for fires in other areas of the plant (i.e., equipment and cables not credited for a fire in Room 2RIR). The cables are routed in conduit. Although no fire induced failures are expected due to the insignificant fire hazard in the rooms, postulated failure of the non-credited FSSD cables has been evaluated to assess its effect on plant operation. Failure of these FSSD cables would be detected and mitigated by normal plant procedures and would not initiate or result in a plant trip.

- Reactor coolant pump #1 seal return flow control valve cable
- Reactor building sump level transmitter channel G cable
- Excess letdown flow control valve E/P module cable
- Pressurizer heater backup Group 2A-A & 2B-B cables
- Steam generator #2 & #3 level transmitter cables
- Steam generator #2 level transmitter (auxiliary control) cable
- Pressurizer level transmitter (auxiliary control) cables
- Pressurizer pressure transmitter cables
- Lower containment vent cooler supply valve cables
- Reactor coolant system hot & cold leg temperature normal and auxiliary cables

PART VII - DEVIATIONS AND EVALUATIONS

2.9.13.4 Conclusion

There is insignificant threat from transient combustibles, in situ combustible material, no credible ignition sources and no impact to FSSD; therefore, there is no fire hazard in 2RIR that necessitates any OMAs or radiant energy shields. TVA concludes that the intent of III.G.1 is ensured and requests approval of this deviation demonstrating compliance to III.G.1 criteria with a fire hazard analysis in lieu of the prescriptive separation criteria of III.G.2.

2.9.14 Room 2RA1 – Unit 2 Accumulator Room 1

2.9.14.1 Description of Condition

Room 2RA1 is a part of fire area 77 and is analyzed in analysis volumes AV-118E and AV-118L (see Part III, Table 3-3 for room listing). Fire area 77 is considered III.G.2 area, but room 2RA1 does not contain components for both redundant safe shutdown paths. Based on an FSSD analysis which assumes the failure of all cables and equipment in this room, radiant energy shields would need to be installed or OMAs performed.

2.9.14.2 Fire Hazards Analysis

2.9.14.2.a Room Description

Room 2RA1 is the Unit 2 Accumulator Room 1 and is separated from adjacent areas of the Unit 2 Reactor Building by reinforced concrete barriers that are 24 to 48-inches thick and from the Unit 2 Annulus by the steel containment shield. The concrete walls, ceiling and floor have mechanical and electrical penetrations that are not provided with fire rated seals/closures. Entry to the room is thru an opening in the 24-inch thick floor via a ladder from 2RO-1 below. The room has a floor area of 225-ft² and a ceiling height of 26-feet.

2.9.14.2.b – Fire Load

The combustible loading is classified as low and is due to the small quantities of lubricating oil in control valves (accounts for 61% of combustible load), expansion joint material (accounts for 32% of combustible load) in the expansion joints and these combustibles are not exposed except for the edge of the joint material. The plastics associated with a small control panel, telephone and junction boxes account for the remaining combustibles and its resultant fire severity is less than 1 minute. The electrical cables associated with these devices are low voltage power or control circuits and are routed in conduit. Each circuit is adequately protected with properly sized and coordinated circuit protection (fuse/breaker) that will clear a cable fault prior to the cable insulation reaching auto-ignition. None of these combustible materials are associated with a credible ignition source. There are no credible ignition sources in the room (see Justification in 2.9.0 above). The major piece of equipment in the room is the Accumulator Tank #1. Only one of the adjacent rooms has a combustible load that could create a credible fire and that is the Unit 2 Annulus. The steel containment vessel and suppression and detection in the Unit 2 Annulus would prevent a credible fire in the Annulus from propagating into 2RA1. Due to the lack of combustibles and ignition sources in adjacent rooms, it is concluded they do not present a fire hazard to components located in 2RA1 nor does 2RA1 present a fire hazard to adjacent rooms.

PART VII - DEVIATIONS AND EVALUATIONS

2.9.14.2.c Control of Combustibles and Ignition Sources

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into 2RA1. Compensatory measures must be implemented when transient combustibles or ignition sources are brought into a room due to work activities. Room 2RA1 is a CCZ (see Part II, sections 10 and 11 and WBN Technical Instruction TI-291, Combustible Control Zones and Sensitive Areas). For compliance with TI-291, the approval of an evaluation must be obtained before any transient combustible can be introduced into the room or hot work performed in the room. Access to the room is from 2RO-1 via a ladder. When Unit 2 is operating, access to the reactor building is strictly controlled. Prior to returning a unit to operation, transient material that might have been brought into the room is removed. The lack of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources in combination provides assurance that no credible exposure fire would occur in 2RA1 that could damage components in the room or propagate into an adjacent room. Based on this, it is not expected that the plant will enter the fire safe shutdown procedure.

2.9.14.2.d Adjacent Rooms

The Unit 2 Annulus is separated from 2RA1 by the steel containment shield. Over 98% of the in situ combustible load in the Unit 2 Annulus is due to insulation on the cables routed in trays. The remaining in situ combustible load is dispersed throughout the Annulus and there are no ignition sources. The Unit 2 Annulus is provided with automatic suppression and detection for cable separation in this area. The steel containment shield in combination with the automatic suppression and detection provides assurance that no credible fire in the Unit 2 Annulus could propagate into 2RA1 or from 2RA1 into the annulus.

Room 2RO-1 is separated from 2RA1 by 24 inch thick non-fire rated reinforced concrete ceiling. There is a ladder from 2RO-1 up to a hatch for entry into 2RA1. The in situ combustible load in 2RO-1 is low of which the expansion joint seal material accounts for 91% of the load. Only the edge of the seal is exposed, the rest is between concrete walls. The lack of exposed in situ combustibles and ignition sources provides assurance that no credible fire in 2RO-1 could propagate into 2RA1 via this personnel access opening. Conduit, instrumentation lines and mechanical piping penetrate the floor and are not provided with fire rated penetration seals. The lack of in situ combustibles and ignition sources provides assurance that no credible fire in 2RO-1 could propagate from 2RO-1 into 2RA1 through these penetrations. Since access to the reactor building is strictly controlled during operation and transient material brought into the reactor building for outage work is removed prior to start-up, it is concluded there is no fire hazard from transient material. Therefore, it is concluded that no credible fire in 2RO-1 could propagate into 2RA1 or from 2RA1 into 2RO-1.

The Reactor Instrument Room 2RIR is separated from 2RA1 by a 24 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping penetrate the wall and are not provided with fire rated penetration seals. The in situ combustible load in 2RIR is insignificant and is dispersed throughout the room. Transient combustibles are not considered since the access to 2RIR is strictly controlled during unit operation and any transient material brought in during an outage is removed prior to unit start-up. It is concluded that due to the insignificant combustible load and lack of credible ignition sources, there is no credible fire in 2RIR that could propagate into 2RA1 or from 2RA1 into 2RIR.

PART VII - DEVIATIONS AND EVALUATIONS

The Unit 2 Fan Room 1 (2RF1) is separated from 2RA1 by a 24 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping penetrate the wall and are not provided with fire rated penetration seals. The in situ combustible load in 2RF1 is insignificant and is dispersed throughout the room. Transient combustibles are not considered since the access to 2RF1 is strictly controlled during unit operation and any transient material brought in during an outage is removed prior to unit start-up. It is concluded that due to the insignificant combustible load and lack of credible ignition sources, there is no credible fire in 2RF1 that could propagate into 2RA1 or from 2RA1 into 2RF1.

Room 2RU is separated from 2RA1 by a 24 inch thick reinforced concrete floor. Conduit, instrumentation lines and mechanical piping penetrate the floor and are not provided with fire rated penetration seals or closures. The in situ combustible load in 2RU is insignificant and is due to small quantities of lubricant in valves and the crane and small quantities of plastics associated with electrical control boxes and lights. The lack of ignition sources and insignificant concentrations of in situ combustibles provides assurance that no credible fire in 2RU could propagate into 2RA1 or from 2RA1 into 2RU.

TVA concludes the lack of significant concentrations of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources provides assurance that no credible exposure fire would occur that could propagate from 2RA1 into an adjacent room or from an adjacent room into 2RA1.

2.9.14.3 System Evaluation

2.9.14.3.a Redundant FSSD Components in the Room

Reactor coolant pump (RCP) #1 seal return flow control valve cable is routed in conduit in room 2RA1. The valve is normally open and fails open on loss of power or air. There are no ignition sources and insignificant quantities of combustible material below the penetration or near the vertical conduit that could create a fire of sufficient magnitude to damage the cable or penetration. There are no other energized 125vdc cables in the conduit that could provide a hot short source to energize the valve even if there could be fire damage to the cables. If the valve does fail closed, the operator would close the RB non-essential control air header valve from the main control room thereby isolating control air which would open the valve.

2.9.14.3.b FSSD Components with Redundant FSSD Components in an Adjacent Room within the same Analysis Volume

Train A lower compartment purge isolation valve and its cables (routed in conduits) are in room 2RA1. Cables for the redundant lower compartment purge isolation valve are routed in conduits in room 2RF1. Room 2RA1 is separated from 2RF1 by a 24 inch thick reinforced concrete wall (see 2.9.14.2). The lack of ignition sources and concentrations of in situ combustibles provides assurance that no credible fire in 2RF1 could propagate into 2RA1.

A cable for train A block valve (associated with the pressurizer train A PORV) is routed in conduit in room 2RA1. A redundant RCS letdown path pressurizer train B PORV cable is routed in conduit through adjacent rooms 2RF1 and 2RI-1. The rooms are separated from each other by 24 – 48 inch thick walls (see 2.9.14.2). The lack of ignition sources and concentrations of in situ combustibles provides assurance that no credible fire in 2RF1 and 2RI-1 could propagate into 2RA1.

PART VII - DEVIATIONS AND EVALUATIONS

Cables for Lower containment vent cooler D (LCC-D) and control rod drive vent cooler D (CRDM-D) temperature control valves (TCVs) are routed in conduit in 2RA1. Cables for redundant lower containment vent cooler A & C and control rod drive vent cooler A & C TCVs are routed in conduits in 2RF1, 2RI-1, and 2RO-1. The rooms are separated from each other by 24 – 48 inch thick walls (see 2.9.14.2). The lack of ignition sources and concentrations of in situ combustibles provides assurance that no credible fire in 2RF1, 2RI-1, and 2RO-1 could propagate into 2RA1.

2.9.14.3.c Other FSSD Components in the Room

Room 2RA1 contains FSSD equipment and cables associated with FSSD equipment relied upon for fires in other areas of the plant (i.e., equipment and cables not credited for a fire in Room 2RA1). The cables are routed in conduit. Although no fire induced failures are expected due to the insignificant fire hazard in the rooms, postulated failure of the non-credited FSSD equipment and cables has been evaluated to assess its effect on plant operation. Failure of this FSSD equipment or cables would be detected and mitigated by normal plant procedures and would not initiate or result in a plant trip.

- Instrument purge isolation valve cables
- Safety injection system accumulator tank #1 flow isolation valve cable
- Containment sump level transmitter channel G cable
- Steam generator #2 & #3 level transmitter cables
- Motor driven auxiliary feedwater steam generator #1 & #3 level transmitter cables
- Turbine driven auxiliary feedwater steam generator #2 & 4 level transmitter cables
- Pressurizer level transmitter cable
- Pressurizer pressure transmitter cable
- Reactor coolant system loop #1 & #2 hot leg and #4 cold leg temperature (control power) cable

2.9.14.4 Conclusion

There is insignificant threat from transient combustibles, in situ combustible material, and no credible ignition sources; therefore, it is concluded that no cables routed in the conduits could be damaged by any credible fire in room 2RA1. In addition, hot shutdown OMAs are not necessary. TVA concludes that the intent of III.G.1 is ensured and requests approval of this deviation demonstrating compliance to III.G.1 criteria with a fire hazard analysis in lieu of the prescriptive separation criteria of III.G.2.

2.9.15 Room 2RA2 – Unit 2 Accumulator Room 2

2.9.15.1 Description of Condition

Room 2RA2 is a part of fire area 77 and is analyzed in analysis volumes AV-118A and AV-118H (see Part III, Table 3-3 for room listing). Fire area 77 is considered III.G.2 area, but room 2RA2 does not contain both redundant safe shutdown paths. If all equipment and cables located in analysis volumes AV-118A and AV-118H were assumed to fail due to postulated fire damage, fire safe shutdown would rely on:

- a. OMA to reduce RCP seal injection flow rate within 60 minutes by operation of a manual valve on 713-A1B.

PART VII - DEVIATIONS AND EVALUATIONS

- b. Radiant energy shielding to protect a conduit containing pressurizer pressure transmitter cables.

2.9.15.2 Fire Hazard Analysis

2.9.15.2.a Room Description

Room 2RA2 is the Unit 2 Accumulator Room 2 and is separated from adjacent areas of the Unit 2 Reactor Building by reinforced concrete barriers that are 24 to 48-inches thick and from the Unit 2 Annulus by the steel containment shield. The concrete walls, ceiling and floor have mechanical and electrical penetrations that are not provided with fire rated seals/closures. Entry to the room is thru an opening in the 24-inch thick floor via a ladder from 2RO-2 below. The room has a floor area of 225-ft² and a ceiling height of 26-feet.

2.9.15.2.b Fire Load

The combustible loading is classified as insignificant and is due to the small quantities of lubricating oil in control valves (accounts for 88% of combustible load), and small quantities of plastics associated with a small control panel, telephone and junction boxes account for the remaining combustibles. The electrical cables associated with these devices are low voltage power or control circuits and are routed in conduit. Each circuit is adequately protected with properly sized and coordinated circuit protection (fuse/breaker) that will clear a cable fault prior to the cable insulation reaching auto-ignition. None of these combustible materials are associated with a credible ignition source. There are no credible ignition sources in the room (see Justification in 2.9.0 above). The major piece of equipment in the room is the Accumulator Tank #2. Only one of the adjacent rooms has a combustible load that could create a credible fire and that is the Unit 2 Annulus. The steel containment vessel and suppression and detection in the Unit 2 Annulus would prevent a credible fire in the Annulus from propagating into 2RA2. Due to the lack of combustibles and ignition sources in adjacent rooms, it is concluded they do not present a fire hazard to components located in 2RA2 nor does 2RA2 present a fire hazard to adjacent rooms.

2.9.15.2.c Control of Combustibles and Ignition Sources

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into 2RA1. Compensatory measures must be implemented when transient combustibles or ignition sources are brought into a room due to work activities. Room 2RA2 is a CCZ (see Part II, sections 10 and 11 and WBN Technical Instruction TI-291, Combustible Control Zones and Sensitive Areas). For compliance with TI-291, the approval of an evaluation must be obtained before any transient combustible can be introduced into the room or hot work performed in the room. Access to the room is from 2RO-2 via a ladder. When Unit 2 is operating access to the reactor building is strictly controlled. Prior to returning a unit to operation, transient material that might have been brought into the room is removed. The lack of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources in combination provides assurance that no credible exposure fire would occur in 2RA2 that could damage components in the room or propagate into an adjacent room. Based on this, it is not expected that the plant will enter the fire safe shutdown procedure.

PART VII - DEVIATIONS AND EVALUATIONS

2.9.15.2.d Adjacent Rooms

The Unit 2 Annulus is separated from 2RA2 by the steel containment shield. Over 98% of the in situ combustible load in the Unit 2 Annulus is due to insulation on the cables routed in trays. The remaining in situ combustible load is dispersed throughout the Annulus and there are no ignition sources. The Unit 2 Annulus is provided with automatic suppression and detection for cable separation in this area. The steel containment shield in combination with the automatic suppression and detection provides assurance that no credible fire in the Unit 2 Annulus could propagate into 2RA2 or from 2RA2 into the annulus.

Room 2RO-2 is separated from 2RA2 by 24 inch thick non-fire rated reinforced concrete ceiling and a wall. There is a ladder from 2RO-2 up to a hatch for entry into 2RA2. The in situ combustible load in 2RO-2 is low of which the expansion joint seal material accounts for 91% of the load. Only the edge of the seal is exposed, the rest is between concrete walls. The lack of exposed in situ combustibles and ignition sources provides assurance that no credible fire in 2RO-2 could propagate into 2RA2 via this personnel access opening. Conduit, instrumentation lines and mechanical piping penetrate the floor and wall but are not provided with fire rated penetration seals. The lack of in situ combustibles and ignition sources provides assurance that no credible fire in 2RO-2 could propagate from 2RO-2 into 2RA2 through these penetrations. Since access to the reactor building is strictly controlled during operation and transient material brought into the reactor building for outage work is removed prior to start-up, it is concluded there is no fire hazard from transient material. Therefore, it is concluded that no credible fire in 2RO-2 could propagate into 2RA2 or from 2RA2 into 2RO-2.

The Reactor Instrument Room 2RIR is separated from 2RA2 by a 24 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping penetrate the wall and are not provided with fire rated penetration seals. The in situ combustible load in 2RIR is insignificant and is dispersed throughout the room. Transient combustibles are not considered since the access to 2RIR is strictly controlled during unit operation and any transient material brought in during an outage is removed prior to unit start-up. It is concluded that due to the insignificant combustible load and lack of credible ignition sources, there is no credible fire in 2RIR that could propagate into 2RA2 or from 2RA2 into 2RIR.

The Unit 2 Fan Room 2 (2RF2) is separated from 2RA2 by a 24 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping penetrate the wall and are not provided with fire rated penetration seals. The in situ combustible load in 2RF2 is insignificant and is dispersed throughout the room. Transient combustibles are not considered since the access to 2RF2 is strictly controlled during unit operation and any transient material brought in during an outage is removed prior to unit start-up. It is concluded that due to the insignificant combustible load and lack of credible ignition sources, there is no credible fire in 2RF2 that could propagate into 2RA2 or from 2RA2 into 2RF2.

Room 2RI-2 is separated from 2RA2 by a 36 to 48 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping and ventilation penetrate the wall and are not provided with fire rated penetration seals or closures. The in situ combustible load in 2RI-1 is low of which 99% is due to reactor coolant pump (RCP) lubricating oil. The RCP is provided with an oil collection system in accordance with Appendix R, Section III.O (see Part VII, section 2.8) and is protected with automatic suppression and detection. This assures that a postulated RCP fire would be contained to the RCP. The strict entry controls for the reactor building during operation ensures that transient combustibles will not be introduced into 2RI-2. The lack of

PART VII - DEVIATIONS AND EVALUATIONS

other ignition sources or concentrations of in situ combustibles provides assurance that no credible fire in 2RI-2 could propagate into 2RA2 or from 2RA2 into 2RI-2.

Room 2RU is separated from 2RA2 by a 24 inch thick reinforced concrete floor. Conduit, instrumentation lines and mechanical piping penetrate the floor and are not provided with fire rated penetration seals or closures. The in situ combustible load in 2RU is insignificant and is due to small quantities of lubricant in valves and the crane and small quantities of plastics associated with electrical control boxes and lights. The lack of ignition sources and insignificant concentrations of in situ combustibles provides assurance that no credible fire in 2RU could propagate into 2RA2 or from 2RA2 into 2RU.

TVA concludes the lack of significant concentrations of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources provides assurance that no credible exposure fire would occur that would necessitate an OMA or could propagate from 2RA2 into an adjacent room or from an adjacent room into 2RA2.

2.9.15.3 System Failure Evaluation

2.9.15.3.a Redundant FSSD Components in the Room

Cables for the excess letdown isolation valve and the flow modulating valve are both routed in conduit through 2RA2. The flow modulating valve is normally closed and fails closed on loss of air or signal. The only credible failure that could open the valve would be a cable to cable hot short (plus-to-plus and minus-to-minus without grounding) between two twisted shielded instrument cables. Such a fault is not credible considering the limited combustibles and lack of ignition sources in 2RA2. As additional defense-in-depth, there are no other cables in the conduit with the flow modulating valve signal cable (no hot short source).

Two Pressurizer level transmitters (2-LT-68-320-F & -339-D) provide input to the charging flow control valve (2-FCV-62-93) control system. The transmitter cables are routed in conduits in room 2RA2 and are separated from each other by at least 3 feet horizontally; there are no ignition sources and insignificant quantities of combustible material below them that could create a fire of sufficient magnitude to damage the cables in both conduits. Failure of either or both of these cables could cause the charging flow control valve to open. However, for additional defense-in-depth the operator can control the charging flow control valve flow from the main control room even if one or both of the level circuits fail. Therefore, OMA 2.9.15.1.a is not necessary.

Two pressurizer pressure transmitter cables (channel D and F) are routed in separate conduits of which one must be operable to prevent a spurious safety injection (SI) signal. The transmitter cables are routed in conduits in room 2RA2 and are separated from each other by at least 3 feet horizontally; there are no ignition sources and insignificant quantities of combustible material below them that could create a fire of sufficient magnitude to damage the cables in both conduits. For additional defense-in-depth these cables have thermoset insulation making open circuit or wire-to-wire short failure modes even more incredible. Therefore, there is no need to provide a radiant energy shield for one of the conduits.

PART VII - DEVIATIONS AND EVALUATIONS

2.9.15.3.b FSSD Components with Redundant FSSD Components in an Adjacent Room within the same Analysis Volume

One of the narrow range level indicators for steam generators for #2 and #3 has cables routed in room 2RA2. The redundant safe shutdown steam generators narrow range level indicators cables are routed in adjacent rooms 2RF2 and 2RI-2. The rooms are separated from each other by a 24 - 48 inch thick wall (see 2.9.15.2 above). The lack of in situ combustibles and lack of credible ignition sources in the rooms provides assurance that no credible fire could damage level indicator cables for both redundant safe shutdown paths.

The motor driven auxiliary feedwater steam generator #3 level control valve transmitter cable is routed in room 2RA2. The redundant safe shutdown auxiliary feedwater steam generators #1 and #2 level control valve transmitter cables are routed in adjacent room 2RF2. The redundant safe shutdown auxiliary feedwater steam generator #1 level control valve transmitter cable is also routed in adjacent room 2RI-2 which is in AV-118H. Room's 2RI-2, 2RF2 and 2RA2 are separated from each other by 24 - 48 inch thick walls (see 2.9.15.2 above). The lack of in situ combustibles and credible ignition sources in the rooms provides assurance that no credible fire could damage cables of both redundant safe shutdown paths.

The reactor coolant loop 3 normal letdown flow valve cables are routed in room 2RA2. The redundant valve cables are routed in adjacent room 2RI-2 which is in AV-118H. The rooms are separated from each other by a 48 inch thick wall (see 2.9.15.2 above). The lack of in situ combustibles and credible ignition sources in both rooms provides assurance that no credible fire could damage cables of both redundant safe shutdown paths.

The train B pressurizer power operated relief valve (PORV) block valve used for reactor coolant system letdown has a cable routed in room 2RA2. The redundant safe shutdown letdown path train A pressurizer PORV cable is routed in adjacent room 2RI-2 which is in AV-118H. The rooms are separated from each other by a 48 inch thick wall (see 2.9.15.2 above). The lack of in situ combustibles and credible ignition sources in both rooms provides assurance that no credible fire could damage cables for both redundant safe shutdown paths.

The lower containment vent cooler D supply valve cables are routed in room 2RA2. The redundant safe shutdown lower compartment coolers (LCC) are located in other rooms within the analysis volume. The rooms are separated from each other by 24 - 48 inch thick walls (see 2.9.15.2 above). The lack of ignition sources and concentrations of in situ combustibles provides assurance that no credible fire in 2RA2 could propagate to the other rooms or from the adjacent rooms into 2RA2. The lack of in situ combustibles and credible ignition sources in each room provides assurance that no credible fire could damage components for both redundant safe shutdown paths.

2.9.15.3.c Other FSSD Components in the Room

Room 2RA2 contains FSSD equipment and cables associated with FSSD equipment relied upon for fires in other areas of the plant (i.e., equipment and cables not credited for a fire in Room 2RA2). The cables are routed in conduit. Although no fire induced failures are expected due to the insignificant fire hazard in the rooms, postulated failure of the non-credited FSSD equipment and cables has been evaluated to assess its effect on plant operation. Failure of this FSSD equipment or cables would be detected and mitigated by normal plant procedures and would not initiate or result in a plant trip.

PART VII - DEVIATIONS AND EVALUATIONS

- Instrument room purge isolation valves cables
- Reactor coolant system spray valve cables
- Safety Injection system tank #2 flow isolation valve cables
- Steam Generator #3 narrow range level auxiliary cables
- Pressurizer level indicator auxiliary cables
- Turbine driven auxiliary feedwater pump steam generator #2 level transmitter cables
- Pressurizer pressure instrument loop normal and auxiliary cables

2.9.15.4 Conclusion

There is insignificant threat from transient combustibles, in situ combustible material, and no credible ignition sources; therefore, there is no fire hazard in 2RA2 that either warrants protecting conduits or junction boxes with radiant energy shields or necessitates any OMAs. TVA concludes that the intent of III.G.1 is ensured and requests approval of this deviation demonstrating compliance to III.G.1 criteria with a fire hazard analysis in lieu of the prescriptive separation criteria of III.G.2.

2.9.16 Room 2RA3 - Unit 2 Accumulator Room 3

2.9.16.1 Description of Condition

Room 2RA3 is a part of fire area 77 and is analyzed in analysis volumes AV-118B, AV-118C and AV-118J (see Part III, Table 3-3 for room listing). Fire area 77 is considered III.G.2 area, but room 2RA3 does not contain both redundant safe shutdown paths. The analysis volumes contain auxiliary control air system (ACAS) air users, but none of the air users are located in 2RA3.

Physical separation in accordance with III.G.2 cannot be achieved in these analysis volumes. An FSSD analysis for this room assuming failure of all equipment and cables in the room would result in OMAs being credited in lieu of III.G.2 physical separation. Therefore, the following OMAs would be implemented to achieve fire safe shutdown:

- a. Unit 2 – Open lower containment vent cooler valve within 120 minutes by opening breaker in the 125vdc board room.
- b. Unit 2 – Open residual heat removal (RHR) system isolation by-pass valve within 240 minutes to establish RHR flow path.

2.9.16.2 Fire Hazards Analysis

2.9.16.2.a Room Description

Room 2RA3 is the Unit 2 Accumulator Room 3 and is separated from adjacent areas of the Unit 2 Reactor Building by reinforced concrete barriers that are 24 to 48-inches thick and from the Unit 2 Annulus by the steel containment shield. The concrete walls, ceiling and floor have mechanical and electrical penetrations that are not provided with fire rated seals/closures. Entry to the room is thru an opening in the 24-inch thick floor via a ladder from 2RO-3 below. The room has a floor area of 348-ft² and a ceiling height of 26-feet.

PART VII - DEVIATIONS AND EVALUATIONS

2.9.16.2.b Fire Load

The combustible loading is classified as insignificant and is due to the small quantities of lubricating oil in control valves (accounts for 88% of combustible load), and small quantities of plastics associated with a small control panel, telephone and junction boxes account for the remaining combustibles. The electrical cables associated with these devices are low voltage power or control circuits and are routed in conduit. Each circuit is adequately protected with properly sized and coordinated circuit protection (fuse/breaker) that will clear a cable fault prior to the cable insulation reaching auto-ignition. None of these combustible materials are associated with a credible ignition source. There are no credible ignition sources in the room (see Justification in 2.9.0 above). The major piece of equipment in the room is the Accumulator Tank #3. Only one of the adjacent rooms has a combustible load that could create a credible fire and that is the Unit 2 Annulus. The steel containment vessel and suppression and detection in the Unit 2 Annulus would prevent a credible fire in the Annulus from propagating into 2RA3. Due to the lack of combustibles and ignition sources in 2RA3, it is concluded there is no fire hazard to components located in 2RA3 nor does 2RA3 present a fire hazard to adjacent rooms.

2.9.16.2.c Control of Combustibles and Ignition Sources

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into 2RA1. Compensatory measures must be implemented when transient combustibles or ignition sources are brought into a room due to work activities. Room 2RA3 is a CCZ (see Part II, sections 10 and 11 and WBN Technical Instruction TI-291, Combustible Control Zones and Sensitive Areas). For compliance with TI-291, the approval of an evaluation must be obtained before any transient combustible can be introduced into the room or hot work performed in the room. Access to the room is from 2RO-3 via a ladder. When Unit 2 is operating access to the reactor building is strictly controlled. Prior to returning a unit to operation, transient material that might have been brought into the room is removed. The lack of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources provides assurance that no credible exposure fire would occur in 2RA3 that could damage components in the room or propagate into an adjacent room. Based on this, it is not expected that the plant will enter the fire safe shutdown procedure.

2.9.16.2.d Adjacent Rooms

The Unit 2 Annulus is separated from 2RA3 by the steel containment shield. Over 98% of the in situ combustible load in the Unit 2 Annulus is due to insulation on the cables routed in trays. The remaining in situ combustible load is dispersed throughout the Annulus and there are no ignition sources. The Unit 2 Annulus is provided with automatic suppression and detection for cable separation in this area. The steel containment shield in combination with the automatic suppression and detection provides assurance that no credible fire in the Unit 2 Annulus could propagate into 2RA3 or from 2RA3 into the annulus.

Room 2RO-3 is separated from 2RA3 by 24 inch thick non-fire rated reinforced concrete ceiling and a wall. There is a ladder from 2RO-3 up to a hatch for entry into 2RA3. The in situ combustible load in 2RO-3 is low of which the expansion joint seal material accounts for 91% of the load. Only the edge of the seal is exposed, the rest is between concrete walls. The lack of exposed in situ combustibles and ignition sources provides assurance that no credible fire in 2RO-3 could propagate into 2RA3 via this personnel access opening. Conduit, instrumentation

PART VII - DEVIATIONS AND EVALUATIONS

lines and mechanical piping penetrate the floor, but are not provided with fire rated penetration seals. The lack of in situ combustibles and ignition sources provides assurance that no credible fire in 2RO-3 could propagate from 2RO-3 into 2RA3 through these penetrations. Since access to the reactor building is strictly controlled during operation and transient material brought into the reactor building for outage work is removed prior to start-up, it is concluded there is no fire hazard from transient material. Therefore, it is concluded that no credible fire in 2RO-3 could propagate into 2RA3 or from 2RA3 into 2RO-3.

The Unit 2 Fan Room 2 (2RF2) is separated from 2RA3 by a 24 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping penetrate the wall and are not provided with fire rated penetration seals. The in situ combustible load in 2RF2 is insignificant and is dispersed throughout the room. Transient combustibles are not considered since the access to reactor building is strictly controlled during unit operation and any transient material brought in during an outage is removed prior to unit start-up. It is concluded that due to the insignificant combustible load and lack of credible ignition sources, there is no credible fire in 2RF2 that could propagate into 2RA3 or from 2RA3 into 2RF2.

Room 2RI-3 is separated from 2RA3 by a 36 to 48 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping and ventilation penetrate the wall and are not provided with fire rated penetration seals or closures. The in situ combustible load in 2RI-3 is low of which 99% is due to reactor coolant pump (RCP) lubricating oil. The RCP is provided with an oil collection system in accordance with Appendix R, Section III.O (see Part VII, section 2.8) and is protected with automatic suppression and detection. This assures that a postulated RCP fire would be contained to the RCP. The strict entry controls for the reactor building during operation ensures that transient combustibles will not be introduced into 2RI-3. The lack of other ignition sources or concentrations of in situ combustibles provides assurance that no credible fire in 2RI-3 could propagate into 2RA3 or from 2RA3 into 2RI-3.

Room 2RU is separated from 2RA3 by a 24 inch thick reinforced concrete floor. Conduit, instrumentation lines and mechanical piping penetrate the floor and are not provided with fire rated penetration seals or closures. The in situ combustible load in 2RU is insignificant and is due to small quantities of lubricant in valves and the crane and small quantities of plastics associated with electrical control boxes and lights. The lack of ignition sources and insignificant concentrations of in situ combustibles provides assurance that no credible fire in 2RU could propagate into 2RA3 or from 2RA3 into 2RU.

TVA concludes the lack of significant concentrations of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources provides assurance that no credible exposure fire would occur that could propagate from 2RA3 into an adjacent room or from an adjacent room into 2RA3.

2.9.16.3 System Evaluation

2.9.16.3.a Redundant FSSD Components in the Room

Reactor coolant pump (RCP) #3 seal return flow control valve cable is routed in conduit in room 2RA3. The valve is normally open and fails open on loss of power or air. Since there is insignificant in situ combustible loading and no credible ignition sources in the room, it is concluded that there is not a fire hazard that could fail this valve circuit. The only other cable in the conduit is normally de-energized and would not provide a hot short source to energize the valve even if there could be fire damage to the cable. For additional defense-in-depth, if the

PART VII - DEVIATIONS AND EVALUATIONS

valve does fail close the operator will close the control air header valve from the main control room thereby isolating control air which will open the valve.

2.9.16.3.b FSSD Components with Redundant FSSD Components in an Adjacent Room within the same Analysis Volume

The FSSD analysis assumed failure of all FSSD components in the analysis volume. The control circuits for lower compartment coolers (LCC) valves were assumed to fail and cause the valves to close. The circuits for the LCC valves are not routed through 2RA3. They are located in other rooms within the analysis volume. The rooms are separated from each other by 24 – 48 inch thick walls (see 2.9.16.2 above). The lack of ignition sources and concentrations of in situ combustibles provides assurance that no credible fire in 2RA3 could propagate to the other rooms or from the adjacent rooms into 2RA3 (see 2.9.16.2). Therefore, the OMA listed in 2.9.16.1.a is not necessary.

The FSSD analysis assumed failure of all FSSD components in the analysis volume. The RHR system isolation valve and its by-pass valve and their associated control circuits are redundant and one must be operational. The RHR valves are not located in nor are their circuits routed through 2RA3. They are located in other rooms within the analysis volume. The rooms are separated from each other by 24 – 48 inch thick walls (see 2.9.16.2 above). The lack of ignition sources and concentrations of in situ combustibles provides assurance that no credible fire in 2RF2, 2RI-3 and 2RO-3 could propagate into 2RA3 or from 2RA3 into 2RF2, 2RI-3 or 2RO-3 (see 2.9.16.2). Therefore, OMA 2.9.16.1.b is not necessary.

2.9.16.3.c Other FSSD Components in the Room

Room 2RA3 contains FSSD equipment and cables associated with FSSD equipment relied upon for fires in other areas of the plant (i.e., equipment and cables not credited for a fire in Room 2RA3). The cables are routed in conduit. Although no fire induced failures are expected due to the insignificant fire hazard in the rooms, postulated failure of the non-credited FSSD equipment and cables has been evaluated to assess its effect on plant operation. Failure of this FSSD equipment or cables is detected and mitigated by normal plant procedures and does not initiate or result in a plant trip.

- Lower compartment and upper compartment purge isolation valve cables
- Safety injection system accumulator tank #3 flow isolation valve cables

2.9.16.4 Conclusion

There is insignificant threat from transient combustibles, in situ combustible material, and no credible ignition sources; therefore, no fire hazards exist in the room that would necessitate an OMA or protection of an electrical raceway with radiant energy shields. Since there is no fire hazard in 2RA3 that could cause loss of ACAS pressure or necessitate the OMAs listed in 2.9.16.1. TVA concludes that the intent of III.G.1 is ensured and requests approval of this deviation demonstrating compliance to III.G.1 criteria with a fire hazard analysis in lieu of the prescriptive separation criteria of III.G.2.

PART VII - DEVIATIONS AND EVALUATIONS

2.9.17 Room 2RA4 - Unit 2 Accumulator Room 4

2.9.17.1 Description of Condition

This room is a part of fire area 77 (see Part III, Table 3-3 for room listing) and is analyzed in analysis volumes AV-118C, AV-118D, and AV-118K. Fire area 77 is considered a III.G.2 area. Room 2RA4 contains redundant safe shutdown valves and auxiliary control air system (ACAS) train B air users.

Physical separation in accordance with III.G.2 cannot be achieved in these analysis volumes. An FSSD analysis assuming failure of all cables and equipment in this room would result in OMAs being credited in lieu of III.G.2 physical separation. Therefore, the following OMAs would be implemented to achieve fire safe shutdown:

- a. Unit 2 – Open lower containment vent cooler valves within 120 minutes by opening breaker in the board room.
- b. Unit 2 – Open residual heat removal (RHR) system isolation by-pass valve within 240 minutes to establish RHR flow path.

2.9.17.2 Fire Hazards Analysis

2.9.17.2.a Room Description

Room 2RA4 is the Unit 2 Accumulator Room 4 and is separated from adjacent areas of the Unit 2 Reactor Building by reinforced concrete barriers that are 24 to 48-inches thick and from the Unit 2 Annulus by the steel containment shield. The concrete walls, ceiling and floor have mechanical and electrical penetrations that are not provided with fire rated seals/closures. Entry to the room is thru an opening in the 24-inch thick floor via a ladder from 2RO-4 below. The room has a floor area of 489-ft² and a ceiling height of 26-feet.

2.9.17.2.b Fire Load

The combustible loading is classified as low and is due to the small quantities of lubricating oil in control valves (accounts for 90% of combustible load). The plastics associated with a small control panel, telephone and junction boxes account for the remaining combustibles and its resultant fire severity is less than 1 minute. The electrical cables associated with these devices are low voltage power or control circuits and are routed in conduit. Each circuit is adequately protected with properly sized and coordinated circuit protection (fuse/breaker) that will clear a cable fault prior to the cable insulation reaching auto-ignition. None of these combustible materials are associated with a credible ignition source. There are no credible ignition sources in the room (see Justification in 2.9.0 above). The major piece of equipment in the room is the Accumulator Tank #4. Only one of the adjacent rooms has a combustible load that could create a credible fire and that is the Unit 2 Annulus. The steel containment vessel and suppression and detection in the Unit 2 Annulus would prevent a credible fire in the Annulus from propagating into 2RA4. Due to the lack of combustibles and ignition sources in adjacent rooms, it is concluded they do not present a fire hazard to components located in 2RA4 nor does 2RA4 present a fire hazard to adjacent rooms.

PART VII - DEVIATIONS AND EVALUATIONS

2.9.17.2.c Control of Combustibles and Ignition Sources

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into 2RA4. Compensatory measures must be implemented when transient combustibles or ignition sources are brought into a room due to work activities. Room 2RA4 is a CCZ (see Part II, sections 10 and 11 and WBN Technical Instruction TI-291, Combustible Control Zones and Sensitive Areas). For compliance with TI-291, the approval of an evaluation must be obtained before any transient combustible can be introduced into the room or hot work performed in the room. Access to the room is from 2RO-4 via a ladder. When Unit 2 is operating access to the reactor building is strictly controlled. Prior to returning a unit to operation, transient material that might have been brought into the room is removed. The lack of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources in combination provides assurance that no credible exposure fire would occur in 2RA4 that could damage components in the room or propagate into an adjacent room. Based on this, it is not expected that the plant will enter the fire safe shutdown procedure.

2.9.17.2.d Adjacent Rooms

The Unit 2 Annulus is separated from 2RA4 by the steel containment shield. Over 98% of the in situ combustible load in the Unit 2 Annulus is due to insulation on the cables routed in trays. The remaining in situ combustible load is dispersed throughout the Annulus and there are no ignition sources. The Unit 2 Annulus is provided with automatic suppression and detection for cable separation in this area. The steel containment shield in combination with the automatic suppression and detection provides assurance that no credible fire in the Unit 2 Annulus could propagate into 2RA4 or from 2RA4 into the annulus.

Room 2RO-4 is separated from 2RA4 by 24 inch thick non-fire rated reinforced concrete ceiling. There is a ladder from 2RO-4 up to a hatch for entry into 2RA4. The in situ combustible load in 2RO-4 is low of which the expansion joint seal material accounts for 91% of the load. Only the edge of the seal is exposed, the rest is between concrete walls. The lack of exposed in situ combustibles and ignition sources provides assurance that no credible fire in 2RO-4 could propagate into 2RA4 via this personnel access opening. Conduit, instrumentation lines and mechanical piping penetrate the floor and are not provided with fire rated penetration seals. The lack of in situ combustibles and ignition sources provides assurance that no credible fire in 2RO-4 could propagate from 2RO-4 into 2RA4 through these penetrations. Since access to the reactor building is strictly controlled during operation and transient material brought into the reactor building for outage work is removed prior to start-up, it is concluded there is no fire hazard from transient material. Therefore, it is concluded that no credible fire in 2RO-4 could propagate into 2RA4 or from 2RA4 into 2RO-4.

The Unit 2 Fan Room 1 (2RF1) is separated from 2RA4 by a 24 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping penetrate the wall and are not provided with fire rated penetration seals. The in situ combustible load in 2RF1 is insignificant and is dispersed throughout the room. Transient combustibles are not considered since the access to 2RF1 is strictly controlled during unit operation and any transient material brought in during an outage is removed prior to unit start-up. It is concluded that due to the insignificant combustible load and lack of credible ignition sources, there is no credible fire in 2RF1 that could propagate into 2RA4 or from 2RA4 into 2RF1.

PART VII - DEVIATIONS AND EVALUATIONS

Room 2RI-4 is separated from 2RA4 by a 36 to 48 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping and ventilation penetrate the wall and are not provided with fire rated penetration seals or closures. The in situ combustible load in 2RI-4 is low of which over 97% is due to reactor coolant pump (RCP) lubricating oil. The RCP is provided with an oil collection system in accordance with Appendix R, Section III.O (see Part VII, section 2.8) and is protected with automatic suppression and detection. This assures that a postulated RCP fire is contained to the RCP. The strict entry controls for the reactor building during operation ensures that transient combustibles is not introduced into 2RI-4. The lack of other ignition sources or concentrations of in situ combustibles provides assurance that no credible fire in 2RI-4 could propagate into 2RA4 or from 2RA4 into 2RI-4.

Room 2RU is separated from 2RA4 by a 24 inch thick reinforced concrete floor. Conduit, instrumentation lines and mechanical piping penetrate the floor and are not provided with fire rated penetration seals or closures. The in situ combustible load in 2RU is insignificant and is due to small quantities of lubricant in valves and the crane and small quantities of plastics associated with electrical control boxes and lights. The lack of ignition sources and insignificant concentrations of in situ combustibles provides assurance that no credible fire in 2RU could propagate into 2RA4 or from 2RA4 into 2RU.

TVA concludes the lack of significant concentrations of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources provides assurance that no credible exposure fire would occur that could propagate from 2RA4 into an adjacent room nor from an adjacent room into 2RA4. TVA further concludes that the implementation of OMAs is not necessary.

2.9.17.3 System Evaluation

2.9.17.3.a Redundant FSSD Components in the Room

RHR system isolation valve 2-FCV-74-2-B and its by-pass valve 2-FCV-74-8-A are redundant safe shutdown valves and one must be operational for cold shutdown. The valves and their cables are at least 2 feet apart (horizontally) and have their power removed (breaker open). These valves are MOVs with their associated cables routed in dedicated conduit except one conduit that contains two other MOV power cables. The MOV power cables are not energized; therefore, even if there could be a fire that could damage the circuits in the conduit, no hot short is possible to cause spurious operation of the valves. There are no credible ignition sources and insignificant quantities of combustible material below them that could create a fire of sufficient magnitude to damage the cables. Based on 2.9.0 above these valves are not considered credible ignition sources and there are no in situ combustibles or ignition sources between the valves. Since there is very low in situ combustible loading and no credible ignition sources in the room, it is concluded that there is not a fire hazard that could fail both of these valves or their cables. Therefore, the OMA identified in 2.9.17.1.b is not necessary for a fire in 2RA4.

The FSSD analysis generally assumes that fire damage to one ACAS air user could depressurize the header (Train A or Train B). If auxiliary control air system (ACAS) train B air users located in this area were assumed to fail due to postulated fire damage; ACAS train B is assumed failed. Six air operated valves located in room 2RA4 are connected to the ACAS train B header. The valves are located at least 20 feet above the floor and there are no credible ignition sources and insignificant quantities of combustible material below them that could create a fire of sufficient magnitude to damage the valves. Loss of control air to the train B

PART VII - DEVIATIONS AND EVALUATIONS

components would cause them to fail to their desired FSSD position. For additional defense-in-depth there is no redundant ACAS train A air users located in 2RA4 thus plant safe shutdown capability is ensured. It is concluded that there is no credible fire in 2RA4 that could cause failure of the train B air operated valves and depressurize the ACAS train B header.

2.9.17.3.b FSSD Components with Redundant FSSD Components in an Adjacent Room within the same Analysis Volume

If the FSSD analysis assumed failure of all FSSD components in the analysis volume, the control circuits for lower compartment cooler (LCC) temperature control valves are assumed to fail and cause the valves to close. The circuits for the LCC valves are not routed through 2RA4. They are located in adjacent rooms 2RF1, 2RI-1, 2RI-4 within analysis volumes AV-118D and AV-118K. Therefore, the OMA listed in 2.9.17.1.a is not necessary for a fire in room 2RA4.

Two lower compartment purge isolation train B valves and associated cables are routed in conduits in room 2RA4. The redundant lower compartment purge isolation train A valve cables are routed in conduits in room 2RF1. Room 2RA4 is separated from 2RF1 by a 24 inch thick reinforced concrete wall (see 2.9.17.2 above). The lack of ignition sources and no concentrations of in situ combustibles provide assurance that no credible fire in 2RF1 could propagate into 2RA4 or from 2RA4 into 2RF1 (see 2.9.17.2).

2.9.17.3.c Other FSSD Components in the Room

Room 2RA4 contains FSSD equipment and cables associated with FSSD equipment relied upon for fires in other areas of the plant (i.e., equipment and cables not credited for a fire in Room 2RA4). The cables are routed in conduit. Although no fire induced failures are expected due to the insignificant fire hazard in the rooms, postulated failure of the non-credited FSSD equipment and cables has been evaluated to assess its effect on plant operation. Failure of this FSSD equipment or cables is detected and mitigated by normal plant procedures and does not initiate or result in a plant trip.

- Lower and upper compartment purge isolation valve cables
- Residual heat removal system supply test line valve cables
- Safety Injection system accumulator tank #4 flow isolation valve cables
- Containment sump level transmitter channel F cable
- Reactor coolant pump thermal barrier return containment isolation valve cable
- Steam generator #4 level transmitter cables
- Source range detector and indicator cable
- Reactor coolant system loops #1 & #2 hot leg and #4 cold leg temperature auxiliary cables
- Unit 2 containment non-essential header dump solenoid valve cables

2.9.17.4 Conclusion

There is insignificant threat from transient combustibles, in situ combustible material, and no credible ignition sources; therefore, there is no fire hazard in 2RA4 that could cause loss of ACAS pressure and necessitate any OMAs. TVA concludes that the intent of III.G.1 is ensured and requests approval of this deviation demonstrating compliance to III.G.1 criteria with a fire hazard analysis in lieu of the prescriptive separation criteria of III.G.2.

PART VII - DEVIATIONS AND EVALUATIONS

2.9.18 Room 2RF1 – Unit 2 Reactor Building Fan Room 1

2.9.18.1 Description of Condition

Room 2RF1 is a part of fire area 77 (see Part III, Table 3-3 for room listing) and is analyzed in analysis volumes AV-118D, AV-118E, AV-118K, and AV-118L. Fire area 77 is considered a III.G.2 area because it contains components related to both redundant shutdown paths.

Physical separation in accordance with III.G.2 cannot be achieved in these analysis volumes. An FSSD analysis assuming failure of all cables and equipment in this room would result in the following OMA's being credited in lieu of III.G.2 physical separation and radiant energy shields.

- a. Unit 2 – Open lower containment vent cooler valves within 120 minutes by opening breaker in the board room.
- b. Unit 2 – Open residual heat removal (RHR) system isolation by-pass valve within 240 minutes to establish RHR flow path.
- c. Radiant energy shields on two exposed conduits contain cables for reactor coolant system (RCS) loop 3 hot and cold leg temperatures indicators. The radiant energy shielding included penetration 19.
- d. Radiant energy shielding to protect train A head vent valves cables and penetration 27.
- e. Radiant energy shielding to protect RHR isolation and bypass valve cables at penetrations 6 and 9.

2.9.18.2 Fire Hazards Analysis

2.9.18.2.a Room Description

The Unit 2 Reactor Building Fan Room 1 is separated from adjacent areas of the Unit 2 Reactor Building by reinforced concrete barriers that are 24 to 48-inches thick and from the Unit 2 Annulus by the steel containment shield. The concrete walls, ceiling and floor have mechanical and electrical penetrations that are not provided with fire rated seals/closures. Entry to the room is thru an opening in the 24-inch thick floor via a ladder from 2RO-1 and 2RO-4 below. The room has a floor area of 719-ft² and a ceiling height of 26-feet.

2.9.18.2.b Fire Load

The combustible loading is classified as insignificant and is due to small quantities of lubricant within control valves (accounts for 51% of combustible load) and small quantities of plastics associated with small control panels, a telephone and junction boxes. Only one of the adjacent rooms has a combustible load that could create a credible fire and that is the Unit 2 Annulus. The Unit 2 Annulus is provided with a suppression and detection system for cable separation that would prevent a fire in the Annulus from propagating into 2RF1. The dispersed location of the insignificant quantities of in situ combustible material and the lack of credible ignition sources (see 2.9.0 above) result in no credible fire occurring that could propagate from 2RF1 into an adjacent room. Therefore no credible fire in 2RF1 presents a hazard to components located in 2RF1 or to an adjacent room.

PART VII - DEVIATIONS AND EVALUATIONS

2.9.18.2.c Control of Combustibles and Ignition Sources

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into 2RF1. Compensatory measures must be implemented when transient combustibles or ignition sources are brought into a room due to work activities. Room 2RF1 is a CCZ (see Part II, sections 10 and 11 and WBN Technical Instruction TI-291, Combustible Control Zones and Sensitive Areas). For compliance with TI-291, the approval of an evaluation must be obtained before any transient combustible can be introduced into the room or hot work performed in the room. Access to the room is from 2RO-1 and 2RO-4 via a ladder. When Unit 2 is operating access to the reactor building is strictly controlled. Prior to returning a unit to operation, transient material that might have been brought into the room is removed. The lack of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources provides assurance that no credible exposure fire would occur in 2RF1 that could damage components in the room or propagate into an adjacent room. Based on this, it is not expected that the plant will enter the fire safe shutdown procedure.

2.9.18.2.d Adjacent Rooms

The Unit 2 Annulus is separated from 2RF1 by the steel containment shield. Over 98% of the in situ combustible load in the Unit 2 Annulus is due to insulation on the cables routed in trays. The remaining in situ combustible load is dispersed throughout the Annulus and there are no ignition sources. The Unit 2 Annulus is provided with automatic suppression and detection for cable separation in this area. The steel containment shield in combination with the automatic suppression and detection provides assurance that no credible fire in the Unit 2 Annulus could propagate into 2RF1 or from 2RF1 into the annulus.

Room 2RA1 is separated from 2RF1 by a 24 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping penetrate the wall and are not provided with fire rated penetration seals. The in situ combustible load in 2RA1 is low and is due to small quantities of lubricant in valves (61% of the load), expansion joint material (32% of the load) and small quantities of plastics associated with electrical control boxes and lights. The lack of ignition sources and concentrations of in situ combustibles provides assurance that no credible fire in 2RA1 could propagate into 2RF1 through the unprotected penetrations.

Room 2RA4 is separated from 2RF1 by a 24 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping penetrate the wall and are not provided with fire rated penetration seals. The in situ combustible load in 2RA4 is low and is due to small quantities of lubricant in valves (90% of the load) and small quantities of plastics associated with electrical control boxes and lights. The lack of ignition sources and concentrations of in situ combustibles provides assurance that no credible fire in 2RA4 could propagate into 2RF1 through the unprotected penetrations.

Room 2RI-1 is separated from 2RF1 by a 36 to 48 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping and ventilation penetrate the wall and are not provided with fire rated penetration seals or closures. The in situ combustible load in 2RI-1 is low of which over 99% is due to reactor coolant pump (RCP) lubricating oil. The RCP is provided with an oil collection system in accordance with Appendix R, Section III.O (see Part VII, section 2.8) and is protected with automatic suppression and detection. This assures that a postulated RCP fire is contained to the RCP. The strict entry controls for the reactor building

PART VII - DEVIATIONS AND EVALUATIONS

during operation ensures that transient combustibles is not introduced into 2RI-1. The lack of other ignition sources or concentrations of in situ combustibles provides assurance that no credible fire in 2RI-1 could propagate into 2RF1 or from 2RF1 into 2RI-1.

Room 2RI-4 is separated from 2RF1 by a 36 to 48 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping and ventilation penetrate the wall and are not provided with fire rated penetration seals or closures. The in situ combustible load in 2RI-4 is low of which over 97% is due to reactor coolant pump (RCP) lubricating oil. The RCP is provided with an oil collection system in accordance with Appendix R, Section III.O (see Part VII, section 2.8) and is protected with automatic suppression and detection. This assures that a postulated RCP fire is contained to the RCP. The strict entry controls for the reactor building during operation ensures that transient combustibles is not introduced into 2RI-4. The lack of other ignition sources or concentrations of in situ combustibles provides assurance that no credible fire in 2RI-4 could propagate into 2RF1 or from 2RF1 into 2RI-4.

Room 2RO-1 is separated from 2RF1 by 24 inch thick non-fire rated reinforced concrete ceiling. There is a ladder from 2RO-1 up to a hatch for entry into 2RF1. The in situ combustible load in 2RO-1 is low of which the expansion joint seal material accounts for 91% of the load. Only the edge of the seal is exposed, the rest is between concrete walls. The lack of exposed in situ combustibles and ignition sources provides assurance that no credible fire in 2RO-1 could propagate into 2RF1 via this personnel access opening. Conduit, instrumentation lines and mechanical piping penetrate the floor and are not provided with fire rated penetration seals. The lack of in situ combustibles and ignition sources provides assurance that no credible fire in 2RO-1 could propagate from 2RO-1 into 2RF1 through these penetrations. Since access to the reactor building is strictly controlled during operation and transient material brought into the reactor building for outage work is removed prior to start-up, it is concluded there is no fire hazard from transient material. Therefore, it is concluded that no credible fire in 2RO-1 could propagate into 2RF1 or from 2RF1 into 2RO-1.

Room 2RO-4 is separated from 2RF1 by 24 inch thick non-fire rated reinforced concrete ceiling. There is a ladder from 2RO-4 up to a hatch for entry into 2RF1. The in situ combustible load in 2RO-4 is low of which the expansion joint seal material accounts for 91% of the load. Only the edge of the seal is exposed, the rest is between concrete walls. The lack of exposed in situ combustibles and ignition sources provides assurance that no credible fire in 2RO-4 could propagate into 2RF1 via this personnel access opening. Conduit, instrumentation lines and mechanical piping penetrate the floor and are not provided with fire rated penetration seals. The lack of in situ combustibles and ignition sources provides assurance that no credible fire in 2RO-4 could propagate from 2RO-4 into 2RF1 through these penetrations. Since access to the reactor building is strictly controlled during operation and transient material brought into the reactor building for outage work is removed prior to start-up, it is concluded there is no fire hazard from transient material. Therefore, it is concluded that no credible fire in 2RO-4 could propagate into 2RF1 or from 2RF1 into 2RO-4.

Room 2RU is separated from 2RF1 by a 24 inch thick reinforced concrete floor. Conduit, instrumentation lines and mechanical piping penetrate the floor and are not provided with fire rated penetration seals or closures. The in situ combustible load in 2RU is insignificant and is due to small quantities of lubricant in valves and the crane and small quantities of plastics associated with electrical control boxes and lights. The lack of ignition sources and insignificant concentrations of in situ combustibles provides assurance that no credible fire in 2RU could propagate into 2RF1 or from 2RF1 into 2RU.

PART VII - DEVIATIONS AND EVALUATIONS

TVA concludes the lack of significant concentrations of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources provides assurance that no credible exposure fire would occur that could propagate from 2RF1 into an adjacent room or from an adjacent room into 2RF1. TVA further concludes that the implementation of OMAs is not necessary.

2.9.18.3 System Evaluation

2.9.18.3.a Redundant FSSD Components in the Room

Lower compartment coolers A and D (LCC-A & LCC-D) and circuits associated with control rod drive mechanism coolers A and D (CRDM-A & CRDM-D) are located in 2RF1 along with the inboard containment isolation valves (FCV) supplying ERCW to those LCCs and CRDMs. Each cooler has an associated temperature control valve (TCV) that modulates ERCW flow to the cooler in response to area temperature. The TCVs fail open on loss of signal or loss of motive air pressure. LCC-A and CRDM-A FCVs and TCVs and associated train A cables are separated by at least 10 feet horizontally from LCC-D and CRDM-D FCVs and TCVs and associated train B cables except for the TCV modulating signal cables for LCC-D's TCV and CRDM-D's TCV. These two signal cables are routed in separate conduits with no other energized cables through the general area where LCC-A and CRDM-A cables are located. Even if a fire could damage these cables, the only credible failure modes (open, short, or ground) would cause a loss of signal and the TCV would fail to the desired position (open). Therefore, for any credible fire in 2RF1 at least one LCC and one CRDM are operable. Additionally LCC-B, which has no cables in 2RF1, is operable.

For FSSD, no lower compartment cooling is needed for two hours and ample cooling is provided by any combination of three LCCs or two LCCs and two CRDMs. As described above at least two LCCs and one CRDM are operable. The modulating signal cable for CRDM-C's TCV is routed through 2RF1 in a conduit with two other instrument signal cables. All three cables are two-conductor 16 AWG twisted, shielded cables with thermoset insulation. Considering the insignificant fire severity index of the room it is inconceivable that two of these cables could be damaged such as to create and sustain a cable-to-cable double hot short (plus-to-plus and minus-to-minus) without grounding. Such a fault is necessary to close the TCV. Temperature sensing (thermocouple) cables for CRDM-C and LCC-C temperature control valves are routed through 2RF1 in a vertical conduit with other thermocouple cables. These cables are two-conductor twisted shielded copper-constantan thermocouple extension leads. If these cables could be fire damaged, the most likely failures are the shorting between leads or shorting to ground. Either of these failures creates a new thermocouple junction in a high temperature environment causing the TCV to open. Likewise an open circuit (no signal) causes the valve to fail open. No credible fire damage could cause TCV closure. As additional defense-in-depth the thermocouple cable conduit is more than five feet horizontal from the conduit containing the CRDM-C TCV modulating signal cable. No credible fire in 2RF1 could damage cables in both conduits. The insignificant quantities of dispersed combustibles and lack of credible ignition sources provided additional assurance that containment cooling is maintained. Therefore, OMA listed in 2.9.18.1.a is not necessary.

The circuits for RHR system isolation valves and their by-pass valves are routed in 2RF1. The train A isolation valve and its by-pass valve (train B) (set 1) are in series with the Train B isolation valve and its by-pass valve (train A) (set 2). For hot shutdown, either set 1 or set 2 must remain closed. This is assured by removing motive power during normal plant operation and routing the power cables for one set of valves in dedicated conduit with no energized

PART VII - DEVIATIONS AND EVALUATIONS

cables. An FSSD analysis which assumes failure of all cables and equipment in the room would result in the need for radiant energy shields on penetrations 6 and 9 to prevent the RHR isolation valves from spuriously opening due to postulated 3-phase hot shorts between 480 vac power cables at the penetration. The train A power cables are routed through penetration 6 and the train B power cables are routed through penetration 9. These penetrations are located 22 feet above the floor and there are no credible ignition sources and insignificant quantities of combustible material below them that could create a fire of sufficient magnitude to damage the cables in the penetrations. In summation the following shows that no credible event could occur to create a flow path through these two sets of valves:

- a. Two 3-phase hot shorts must simultaneously occur on these normally closed sets of valves.
- b. The power cables for these valves are routed in dedicated conduits with no other cables in the conduits.
- c. The power to the cables has been removed during normal operation.

Therefore, it is concluded that there is not a fire hazard that would damage these cables and the addition of radiant energy shields on penetrations 6 and 9 is not needed.

The OMA listed in 2.9.18.1.b is not necessary to achieve and maintain hot shutdown but is for transitioning to cold shutdown. The RHR pumps would need to draw suction from the reactor coolant loop #4 hot leg by opening one valve from each set. A FSSD analysis applying III.G.2.d (20 feet horizontal) separation criteria would show that the cables for both isolation valves and either the train A or the train B bypass valve could be damaged by a large fire and one of the valves would have to be manually opened. The redundant valve circuits are routed in conduits in 2RF1 and train A cables are horizontally separated from the train B cables by at least 9 feet except for the main isolation valve (train A and train B) cables connecting to local panels L-358 and L-183. If a large fire could occur in this area, both main isolation valve circuits might be affected; however, all cables for both bypass valves are more than 9 feet (horizontal) from these panels and cables. Since there is insignificant in situ combustible loading and no credible ignition sources in the room, it is concluded that there is not a fire hazard that could fail these valves or their circuits. Therefore, OMA listed in 2.9.18.1.b is not necessary.

An FSSD analysis which assumes failure of all cables and equipment in the room would result in the need for radiant energy shields for train A head vent valve cables including penetration 27 to ensure the valves could be opened for RCS letdown. To prevent the head vent valves from spurious opening, power is removed during normal plant operation. The train A head vent valve cables are routed through penetration 27 and the train B valve cables are routed through penetration 30. These penetrations are located at least 10 feet above the floor and there are no credible ignition sources and insignificant quantities of combustible material below them that could create a fire of sufficient magnitude to damage the cables in the penetrations. For additional defense-in-depth an alternate RCS letdown path is provided by the train B pressurizer PORV whose cables are routed in conduit in 2RF1 and separated from the Train A head vent valve cables by more than 20 feet (horizontal). Cables for the train B PORV block valve are not located in 2RF1. Therefore, the radiant energy shields for the train A head vent valves including penetration 27 are not necessary.

Cables for the RCS normal letdown isolation valves which are normally open and fail closed on loss of power or air are routed in conduit in room 2RF1. Since there is insignificant in situ

PART VII - DEVIATIONS AND EVALUATIONS

combustible loading and no credible ignition sources in the room, it is concluded that there is not a fire hazard that could damage circuits and spuriously energize both valve circuits. For additional defense-in-depth, if both valves are assumed to fail to close, the operator will isolate and depressurize the Unit 2 reactor building non-essential control air header from the main control room thereby causing the valves to close.

Cables for redundant train A and train B lower compartment purge isolation valves (containment isolation) are routed in conduits in room 2RF1. However, the redundant valve cables in room 2RF1 are horizontally separated by more than 20 feet.

A cable for reactor coolant pump (RCP) 4 seal return flow control valve which is normally open and fails open on loss of power or air is routed in conduit in room 2RF1. Since there is insignificant in situ combustible loading and no credible ignition sources in the room, it is concluded that there is not a fire hazard that could fail this valve circuit. The other two cables in the conduit are normally de-energized and would not provide a hot short source to energize the valve even if there could be a large fire that caused damage to the cables. For additional defense-in-depth, if the valve does fail close the operator will close the control air header valve from the main control room thereby isolating control air which will open the valve.

2.9.18.3.b FSSD Components with Redundant FSSD Components in an Adjacent Room within the same Analysis Volume

There are no redundant FSSD components in the adjacent rooms within the analysis volumes.

2.9.18.3.c Other FSSD Components in the Room

Room 2RF1 contains FSSD equipment and cables associated with FSSD equipment relied upon for fires in other areas of the plant (i.e., equipment and cables not credited for a fire in Room 2RF1). The cables are routed in conduit. Although no fire induced failures are expected due to the insignificant fire hazard in the rooms, postulated failure of the non-credited FSSD equipment and cables has been evaluated to assess its effect on plant operation. Failure of this FSSD equipment or cables is detected and mitigated by normal plant procedures and does not initiate or result in a plant trip.

- Steam generator blow down isolation valve loops #1, #2, #3, & #4 cables
- Reactor coolant loop 3 letdown flow valve cables
- Safety injection system accumulator tank #1 & #4 flow isolation valve cables
- Pressurizer level and pressure transmitter cables
- Pressurizer power operated relief valve train B cables
- Reactor coolant system #1 & #2 hot leg and #4 cold leg temperature cables (auxiliary control)
- Pressurizer train A power operated relief valve block valve cable
- Reactor coolant pump thermal barrier return containment isolation valve cable
- Turbine driven auxiliary feedwater pump steam generator #1, #2, & #4 level transmitter cables

2.9.18.4 Conclusion

There is insignificant threat from transient combustibles, in situ combustible material, and no credible ignition sources; therefore, there is no fire hazard in 2RF1 that necessitates the use of

PART VII - DEVIATIONS AND EVALUATIONS

radiant energy shields or OMAs. TVA concludes that the intent of III.G.1 is assured and requests approval of this deviation demonstrating compliance to III.G.1 criteria with a fire hazard analysis in lieu of the prescriptive separation criteria of III.G.2.

2.9.19 Room 2RF2 – Unit 2 Reactor Building Fan Room 2

2.9.19.1 Description of Condition

This room is a part of fire area 77 which is analyzed in analysis volumes AV-118A, AV-118B, AV-118H, and AV-118J (see Part III Table 3-3 for room listing). Fire area 77 is considered a III.G.2 area because it contains components related to both redundant shutdown paths.

Physical separation in accordance with III.G.2 cannot be achieved in these analysis volumes. An FSSD analysis for this room assuming failure of all cables and equipment from a large fire would result in the installation of radiant energy shields and OMAs being credited in lieu of III.G.2 physical separation. Therefore, the following OMA and radiant energy shields are necessary to achieve fire safe shutdown:

- a. Unit 2 - Reduce RCP seal injection flow rate within 60 minutes by operation of a manual valve on 713-A1B.
- b. Unit 2 – Install radiant energy shielding for conduits containing cables for steam generator #1 & #4 level indication including penetration 45.
- c. Unit 2 – Install radiant energy shielding for conduits containing cables for pressurizer pressure transmitter input for safety injection (SI).
- d. Unit 2 – Install radiant energy shielding for conduits containing cables for hot and cold leg loop 1 temperatures including penetration 38.
- e. Unit 2 – Install radiant energy shielding for penetration 36.

2.9.19.2 Fire Hazard Analysis

2.9.19.2.a Room Description

The Unit 2 Reactor Building Fan Room 2 is separated from adjacent areas of the Unit 2 Reactor Building by reinforced concrete barriers that are 24 to 48-inches thick and from the Unit 2 Annulus by the steel containment shield. The concrete walls, ceiling and floor have mechanical and electrical penetrations that are not provided with fire rated seals/closures. Entry to the room is thru an opening in the 24-inch thick floor via a ladder from 2RO-2 and 2RO-3 below. The room has a floor area of 719-ft² and a ceiling height of 26-feet.

2.9.19.2.b Fire Load

The combustible loading is classified as insignificant and is due to small quantities of lubricant within control valves (accounts for 39% of combustible load) and small quantities of plastics associated with small control panels, a telephone and junction boxes. Only one of the adjacent rooms has a combustible load that could create a credible fire and that is the Unit 2 Annulus. The Unit 2 Annulus is provided with a suppression and detection system for cable separation that would prevent a fire in the Annulus from propagating into 2RF2. The dispersed location of

PART VII - DEVIATIONS AND EVALUATIONS

the insignificant quantities of in situ combustible material and the lack of credible ignition sources (see 2.9.0 above) result in no credible fire occurring that could propagate from 2RF2 into an adjacent room. Therefore no credible fire in 2RF2 presents a hazard to components located in 2RF2 or to an adjacent room.

2.9.19.2.c Control of Combustibles and Ignition Sources

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into 2RF2. Compensatory measures must be implemented when transient combustibles or ignition sources are brought into a room due to work activities. Room 2RF2 is a CCZ (see Part II, sections 10 and 11 and WBN Technical Instruction TI-291, Combustible Control Zones and Sensitive Areas). For compliance with TI-291, the approval of an evaluation must be obtained before any transient combustible can be introduced into the room or hot work performed in the room. Access to the room is from 2RO-4 via a ladder. When Unit 2 is operating access to the reactor building is strictly controlled. Prior to returning a unit to operation, transient material that might have been brought into the room is removed. The lack of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources in combination provides assurance that no credible exposure fire would occur in 2RF2 that could damage components in the room or propagate into an adjacent room. Based on this, it is not expected that the plant will enter the fire safe shutdown procedure.

2.9.19.2.d Adjacent Rooms

The Unit 2 Annulus is separated from 2RF2 by the steel containment shield. Over 98% of the in situ combustible load in the Unit 2 Annulus is due to insulation on the cables routed in trays. The remaining in situ combustible load is dispersed throughout the Annulus and there are no ignition sources. The Unit 2 Annulus is provided with automatic suppression and detection for cable separation in this area. The steel containment shield in combination with the automatic suppression and detection provides assurance that no credible fire in the Unit 2 Annulus could propagate into 2RF2 or from 2RF2 into the annulus.

Room 2RA2 is separated from 2RF2 by a 24 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping penetrate the wall and are not provided with fire rated penetration seals. The in situ combustible load in 2RA2 is insignificant and is due to small quantities of lubricant in valves (88% of the load), and small quantities of plastics associated with electrical control boxes and lights. The lack of ignition sources and concentrations of in situ combustibles provides assurance that no credible fire in 2RA2 could propagate into 2RF2 through the unprotected penetrations.

Room 2RA3 is separated from 2RF2 by a 24 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping penetrate the wall and are not provided with fire rated penetration seals. The in situ combustible load in 2RA3 is insignificant and is due to small quantities of lubricant in valves (88% of the load), and small quantities of plastics associated with electrical control boxes and lights. The lack of ignition sources and concentrations of in situ combustibles provides assurance that no credible fire in 2RA3 could propagate into 2RF2 through the unprotected penetrations.

Room 2RI-2 is separated from 2RF2 by a 36 to 48 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping and ventilation penetrate the wall and are not

PART VII - DEVIATIONS AND EVALUATIONS

provided with fire rated penetration seals or closures. The in situ combustible load in 2RI-2 is low of which over 98% is due to reactor coolant pump (RCP) lubricating oil. The RCP is provided with an oil collection system in accordance with Appendix R, Section III.O (see Part VII, section 2.8) and is protected with automatic suppression and detection. This assures that a postulated RCP fire is contained to the RCP. The strict entry controls for the reactor building during operation ensures that transient combustibles is not introduced into 2RI-2. The lack of other ignition sources or concentrations of in situ combustibles provides assurance that no credible fire in 2RI-2 could propagate into 2RF2 or from 2RF2 into 2RI-2.

Room 2RI-3 is separated from 2RF2 by a 36 to 48 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping and ventilation penetrate the wall and are not provided with fire rated penetration seals or closures. The in situ combustible load in 2RI-3 is low of which over 97% is due to reactor coolant pump (RCP) lubricating oil. The RCP is provided with an oil collection system in accordance with Appendix R, Section III.O (see Part VII, section 2.8) and is protected with automatic suppression and detection. This assures that a postulated RCP fire is contained to the RCP. The strict entry controls for the reactor building during operation ensures that transient combustibles is not introduced into 2RI-3. The lack of other ignition sources or concentrations of in situ combustibles provides assurance that no credible fire in 2RI-3 could propagate into 2RF2 or from 2RF2 into 2RI-3.

Room 2RO-3 is separated from 2RF2 by 24 inch thick non-fire rated reinforced concrete ceiling. There is a ladder from 2RO-2 up to a hatch for entry into 2RF2. The in situ combustible load in 2RO-2 is low of which the expansion joint seal material accounts for 91% of the load. Only the edge of the seal is exposed, the rest is between concrete walls. The lack of exposed in situ combustibles and ignition sources provides assurance that no credible fire in 2RO-2 could propagate into 2RF2 via this personnel access opening. Conduit, instrumentation lines and mechanical piping penetrate the floor and are not provided with fire rated penetration seals. The lack of in situ combustibles and ignition sources provides assurance that no credible fire in 2RO-2 could propagate from 2RO-2 into 2RF2 through these penetrations. Since access to the reactor building is strictly controlled during operation and transient material brought into the reactor building for outage work is removed prior to start-up, it is concluded there is no fire hazard from transient material. Therefore, it is concluded that no credible fire in 2RO-2 could propagate into 2RF2 or from 2RF2 into 2RO-2.

Room 2RO-3 is separated from 2RF2 by 24 inch thick non-fire rated reinforced concrete ceiling. There is a ladder from 2RO-3 up to a hatch for entry into 2RF2. The in situ combustible load in 2RO-3 is low of which the expansion joint seal material accounts for 91% of the load. Only the edge of the seal is exposed, the rest is between concrete walls. The lack of exposed in situ combustibles and ignition sources provides assurance that no credible fire in 2RO-3 could propagate into 2RF2 via this personnel access opening. Conduit, instrumentation lines and mechanical piping penetrate the floor and are not provided with fire rated penetration seals. The lack of in situ combustibles and ignition sources provides assurance that no credible fire in 2RO-3 could propagate from 2RO-3 into 2RF2 through these penetrations. Since access to the reactor building is strictly controlled during operation and transient material brought into the reactor building for outage work is removed prior to start-up, it is concluded there is no fire hazard from transient material. Therefore, it is concluded that no credible fire in 2RO-3 could propagate into 2RF2 or from 2RF2 into 2RO-3.

Room 2RU is separated from 2RF2 by a 24 inch thick reinforced concrete floor. Conduit, instrumentation lines and mechanical piping penetrate the floor and are not provided with fire rated penetration seals or closures. The in situ combustible load in 2RU is insignificant and is

PART VII - DEVIATIONS AND EVALUATIONS

due to small quantities of lubricant in valves and the crane and small quantities of plastics associated with electrical control boxes and lights. The lack of ignition sources and insignificant concentrations of in situ combustibles provides assurance that no credible fire in 2RU could propagate into 2RF2 or from 2RF2 into 2RU.

TVA concludes the lack of significant concentrations of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources provides assurance that no credible exposure fire would occur that could propagate from 2RF2 into an adjacent room or from an adjacent room into 2RF2. TVA further concludes that the implementation of OMAs is not necessary.

2.9.19.3 System Evaluation

2.9.19.3.a Redundant FSSD Components in the Room

Cables for train B pressurizer power operated relief valve (PORV) block valve and the redundant train A pressurizer PORV are routed in conduit in room 2RF2. Either the train A path or the train B path is needed for reactor coolant system letdown. Either the train B pressurizer PORV block valve must remain open or the redundant train A pressurizer

PORV must be operational to ensure a reactor coolant system letdown path is available. The redundant valve cables in room 2RF2 meet II.G.2.d separation criteria. Therefore, there is no fire damage to cables that could fail both valves.

The train B head vent block and throttle valve cables are routed through penetration 36 and the redundant train A head vent block and throttle valve cables are routed through penetration 37. Penetration 36 would have to be protected by radiant energy shield based on the assumption that a large fire could damage all cables in the penetration and cause the head vent valves to spuriously open. To prevent spurious opening power is removed from the head vent valves during normal plant operation. The penetrations 36 and 37 and associated train A and train B head vent valve cables are horizontally separated by at least 4 feet and the penetrations are located at least 18 feet from the floor. There are no credible ignition sources and insignificant quantities of combustible material below them that could create a large fire of sufficient magnitude to damage the cables in the penetrations. For additional defense-in-depth the train B head vent valve cables are routed in dedicated conduit and the train A head vent valve cables are routed in conduit with instrumentation loops that would not provide a hot short source to open the head vent valves. Therefore, there is no fire hazard that could cause the head vent valves to open. Further, no radiant energy shield would need to be provided for penetration 36.

Two Pressurizer level transmitters (2-LT-68-320-F & -339-D) provide input to the charging flow control valve (2-FCV-62-93) control system. The transmitter cables are routed in conduits in room 2RF2 and are separated from each other by at least 3 feet horizontally. There are no ignition sources and insignificant quantities of combustible material below them that could create a large fire of sufficient magnitude to damage the cables in both conduits. Failure of either or both of these cables could cause the charging flow control valve to open. However, for additional defense-in-depth the operator can control the charging flow control valve flow from the main control room even if one or both of the level circuits fail. Therefore, OMA 2.9.19.1.a is not necessary.

Steam generator #1 #2, #3, & #4 level transmitter channel F cables are routed in separate conduits from penetration 45 in room 2RF2. A FSSD analysis assuming failure of all cables in

PART VII - DEVIATIONS AND EVALUATIONS

the analysis volume due to a large fire would make it necessary that steam generator # 1 & #4 level transmitters channel F cables (including the penetration) be protected with radiant energy shields. However, two steam generators provide adequate decay heat removal and SGs #1 & #4 redundant channels E and G level transmitters and their cables are not located in room 2RF2. Therefore, there is no need to provide radiant shielding for a conduit or penetration to obtain III.G.2 separation.

Steam generator #1 level transmitter cables for steam generator #1 level control valves are routed in conduits in 2RF2 and terminate at penetration 37. There are no credible ignition sources and insignificant quantities of combustible material below them that could create a large fire of sufficient magnitude to damage the cables. Even if there could be a large fire of sufficient magnitude to damage the level control valve transmitter circuit, the operator can control the steam generator level control valve in manual mode from the main control room which provides additional defense-in-depth.

Signal cables for two pressurizer spray valves are routed in separate conduits in room 2RF2 and terminate at penetration 34. The valves are normally closed and fail closed on loss of signal or air. There are no credible ignition sources and insignificant quantities of combustible material below them that could create a large fire of sufficient magnitude to damage the cables in the penetrations. The cable for one valve is routed in dedicated conduit and the cable for the other valve is routed in conduit with other instrumentation loops. The cables in the conduit are all two-conductor twisted, shielded cables with thermoset insulation. Considering the insignificant quantities of in situ combustibles and lack of ignition sources in the room it is inconceivable that a large fire could develop and that two cables could be damaged such as to create and sustain a cable to cable double hot short (plus to plus and minus to minus) without grounding. No other failure mode could open the valve. For additional defense-in-depth, if one or both of the spray valves spuriously open, the operator would trip the reactor coolant pumps from the main control room which would stop pressurizer spray.

Two pressurizer pressure transmitter channel D and F cables are routed in separate conduits of which one must be free of fire damage to prevent a spurious safety injection (SI) signal. The transmitter cables are routed in conduits in room 2RF2 and are separated from each other by at least 3 feet horizontally; there are no ignition sources and insignificant quantities of combustible material below them that could create a large fire of sufficient magnitude to damage the cables in both conduits. All cables in the conduits are two-conductor 16 AWG twisted, shielded cables with thermoset insulation. Therefore, there is no need to provide radiant energy shielding for a conduit containing one channel to obtain III.G.2 separation from the other conduit containing the other channel.

Steam generator #1 T_{HOT} and T_{COLD} temperature channel D instrument cables are routed in conduit through 2RF2 and terminate at penetration 38. A FSSD analysis assuming failure of all cables due to a large fire in the room would make it necessary that steam generator #1 temperature channel D cables (including penetration 38) be protected with radiant energy shields. Since there are no ignition sources and insignificant quantities of combustible material below the penetration or near the vertical conduit that could create a large fire of sufficient magnitude to damage the cables or penetration, it is concluded that there is not a fire hazard that could fail these temperature circuits. Therefore, there is no need to wrap the conduit or penetration to obtain III.G.2 separation. As defense-in-depth these cables have thermoset insulation making them less susceptible to damage from any credible fire.

PART VII - DEVIATIONS AND EVALUATIONS

A cable for reactor coolant pump (RCP) 2 seal return flow control valve is routed in conduit in room 2RF2. The valve is normally open and fails open on loss of power or air. The conduit is routed from penetration 46 vertically to the floor and is embedded in the floor. There are three other cables in the conduit that are normally de-energized and would not provide a hot short source to energize the valve even if there could be fire damage to the cable. However, the lack of ignition sources and insignificant quantities of combustible material below the penetration or near the vertical conduit would prevent a fire of sufficient magnitude to damage the cable or penetration. It is concluded that there is not a fire hazard that could energize this valve circuit. For additional defense-in-depth, even if a postulated fire could cause the valve to fail closed, the operator would close the reactor building non-essential control air header isolation valve from the main control room thereby isolating control air which would open the valve.

Lower compartment coolers B and C (LCC-B and LCC-C) and circuits associated with the control rod drive mechanism (CRDM-B and CRDM-C) coolers are located in 2RF2 along with the inboard containment isolation valves (FCV) supplying ERCW to those LCCs and CRDMs. Each cooler has an associated temperature control valve (TCV) that modulates

ERCW flow to the cooler in response to area temperature. The TCVs fail open on loss of signal or loss of motive air pressure. The LCC-B and CRDM-B FCVs and TCVs and associated train B cables are separated by at least 10 feet horizontally from LCC-C and CRDM-C FCVs and TCVs and associated train A cables. The modulating signal cable for LCC-D's TCV is routed through 2RF2 in a conduit with another instrument signal cable. These cables are two-conductor 16 AWG twisted, shielded cables with thermoset insulation. Considering the insignificant quantities of in situ combustibles and lack of ignition sources in the room it is inconceivable that two of these cables could be damaged by a credible fire such as to create and sustain a cable-to-cable double hot short (plus-to-plus and minus-to-minus) without grounding. Such a fault is necessary to close the TCV. Temperature sensing (thermocouple) cables for LCC-D temperature control valves are routed through 2RF2 in a conduit with other thermocouple cables. These cables are two-conductor twisted shielded copper-constantan thermocouple extension leads. If these cables could be fire damaged, the most likely failures are shorting between leads or shorting to ground. Either of these failures would create a new thermocouple junction in a high temperature environment causing the TCV to open. Likewise an open circuit (no signal) would cause the valve to fail open. No credible fire damage could cause TCV closure. The insignificant quantities of dispersed combustibles and lack of credible ignition sources provided additional assurance that containment cooling is maintained. For additional defense-in-depth the LCC-A, CRDM-A, CRDM-D and either LCC-B and CRDM-B or LCC-C and CRDM-C are available and provide ample containment cooling.

2.9.19.3.b FSSD Components with Redundant FSSD Components in an Adjacent Room within the same Analysis Volume

A cable for the excess letdown isolation valve is located in room 2RF2 and a cable for redundant excess letdown flow control valve E/P module is located in room 2RA2 and 2RO-2. Rooms 2RA2 and 2RO-2 are separated from 2RF2 by a 24 inch thick reinforced concrete wall (see 2.9.19.2 above). The lack of ignition sources and concentrations of in situ combustibles provides assurance that no credible fire in 2RA2 or 2RO-2 could propagate into 2RF2 or from 2RF2 into 2RA2 or 2RO-2 (see 2.9.19.2).

A cable for reactor coolant loop 3 letdown flow valve is located in room 2RF2 and cables for redundant reactor coolant loop 3 letdown flow valve are located in rooms 2RI-2 and 2RO-2. Rooms 2RI-2 and 2RO-2 are separated from 2RF2 by a 24 inch thick reinforced concrete wall

PART VII - DEVIATIONS AND EVALUATIONS

(see 2.9.19.2 above). The lack of ignition sources and concentrations of in situ combustibles provides assurance that no credible fire in 2RI-2 or 2RO-2 could propagate into 2RF2 or from 2RF2 into 2RI-2 or 2RO-2 (see 2.9.19.2).

Train A PORV and train B PORV block valve cables are located in room 2RF2 and the redundant train B PORV and train A PORV block valve cables are located in room 2RI-2. Room 2RI-2 is separated from 2RF2 by a 24 inch thick reinforced concrete wall (see 2.9.19.2 above). The lack of ignition sources and concentrations of in situ combustibles provides assurance that no credible fire in 2RI-2 could propagate into 2RF2 or from 2RF2 into 2RI-2 (see 2.9.19.2).

2.9.19.3.c Other FSSD Components in the Room

Room 2RF2 contains FSSD equipment and cables associated with FSSD equipment relied upon for fires in other areas of the plant (i.e., equipment and cables not credited for a fire in Room 2RF2). The cables are routed in conduit. Although no fire induced failures are expected due to the insignificant fire hazard in the rooms, postulated failure of the non-credited FSSD equipment and cables has been evaluated to assess its effect on plant operation. Failure of this FSSD equipment or cables is detected and mitigated by normal plant procedures and does not initiate or result in a plant trip.

- Lower compartment, upper compartment, instrument room purge isolation valve (containment isolation valve) cables
- Reactor coolant system spray valve cables
- Containment sump level transmitter channel D & F cables
- Safety Injection system tank #2 & #3 flow isolation valve cables
- Pressurizer level transmitter normal and auxiliary cables
- Turbine driven auxiliary feedwater pump steam generator #2, #3, & #4 level transmitter cables
- Source range detector and indicator channel E cable
- Pressurizer pressure transmitter cable
- Reactor coolant system loop #2 hot and cold leg temperature cables

2.9.19.4 Conclusion

There is insignificant threat from transient combustibles, in situ combustible material, and no credible ignition sources; therefore, no fire hazards exist in the room that would necessitate an OMA or protection of an electrical raceway with radiant energy shields. TVA concludes that the intent of III.G.1 is ensured and requests approval of this deviation demonstrating compliance to III.G.1 criteria with a fire hazard analysis in lieu of the prescriptive separation criteria of III.G.2.

2.9.20 2RI– Unit 2 Reactor Building Inside Crane Wall [2RI-1 (0° to 90°), 2RI-2 (90° to 180°), 2RI-3 (180° to 270°), 2RI-4 (270° to 360°)]

2.9.20.1 Description of Condition

This area of the Unit 2 Reactor Building is a part of fire area 77 (see Part III, Table 3-3 for room listing) that is inside the Crane Wall and is analyzed in analysis volumes AV-118H, AV-118J, AV-118K and AV-118L. Fire area 77 is considered a III.G.2 area. An FSSD analysis of this room based on the assumption that all the cables and equipment in the room were assumed to fail due to postulated fire damage would result in reliance on radiant energy shields (RES) to

PART VII - DEVIATIONS AND EVALUATIONS

protect cables and an OMA in lieu of III.G.2 cable separation. Therefore, the following OMA and radiant energy shields are necessary to achieve fire safe shutdown:

- a. Open RHR isolation valve via hand wheel within 240 minutes in preparation to transition to cold shutdown.
- b. Protect RCP loop 1 hot and cold leg temperature monitoring cables with radiant energy shields.
- c. Protect steam generator #1 and #4 level transmitter cables with radiant energy shields.
- d. Protect Reactor Head Vent Cables with radiant energy shields.
- e. Protect pressurizer level transmitter sense line with radiant energy shields.

2.9.20.2 Fire Hazards Analysis

2.9.20.2.a Room Description

The area of Unit 2 Reactor Building inside the Crane Wall is designated as 2RI and is separated from adjacent areas of the Unit 2 Reactor Building by reinforced concrete barriers that are 30 to 48-inches thick. These barriers are not assigned a fire resistance rating and contain electrical and mechanical penetrations that are not provided with fire rated seals/closures. The room has a floor area of 4,276-ft² and a ceiling height of 40-feet to 51-feet.

2.9.20.2.b Fire Load

The combustible loading for 2RI is low and is due to Reactor Coolant Pump (RCP) lubricating oil (98% of the in situ combustible load) and small quantities of plastics associated with small control panels, telephones and junction boxes. The combustible loading for each quadrant is low (2RI-1, 2RI-2, 2RI-3 and 2RI-4). There is a Steam Generator, a RCP and a CRDM cooler located in each quadrant. Each RCP is provided with an oil collection system (per Appendix R, Section III.O – See FPR Part VII, Section 2.8) and detection and automatic suppression. A postulated fire on a RCP is detected by the detection system which would activate the suppression system and alarm in the Main Control Room. A CRDM cooler unit consists of a plenum, three air cooling coils and two vane axial fans and their motors. Each unit is designed to seismic category I(L) criteria. A postulated fire in a CRDM cooler unit is contained within the unit and the lack of combustibles associated with the unit provides assurance that no components outside the unit are damaged. None of the other combustible materials in 2RI are associated with an ignition source. There are no other credible ignition sources in 2RI (MOV motors are not considered ignition sources – see 2.9.0 above). In addition to each RCP being provided with suppression and detection, standpipes in each of the quadrants of 2RI are also available for fire brigade use. There is no credible fire in 2RI that could propagate into an adjacent area. The lack of combustible material other than the RCP oil in combination with the oil collection system and automatic suppression for each RCP provides assurance that no credible fire in one quadrant of 2RI would propagate into another quadrant of 2RI.

2.9.20.2.c Control of Combustibles and Ignition Sources

NPG-SPP-18.4.7, “Control of Transient Combustibles” and NPG-SPP-18.4.8, “Control of Ignition Sources (Hot Work)” defines the fire preventive measures to preclude introduction of significant

PART VII - DEVIATIONS AND EVALUATIONS

quantities of combustible material or ignition sources into 2RF1. Compensatory measures must be implemented when transient combustibles or ignition sources are brought into a room due to work activities. Room 2RI is a CCZ (see Part II, sections 10 and 11 and WBN Technical Instruction TI-291, Combustible Control Zones and Sensitive Areas). For compliance with TI-291, the approval of an evaluation must be obtained before any transient combustible can be introduced into the room or hot work performed in the room. Access to the room is from 2RIR via a ladder down to 2RO and through the Crane wall into 2RI. When Unit 2 is operating access to the reactor building is strictly controlled. Prior to returning a unit to operation, transient material that might have been brought into the room is removed. The lack of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources in combination provides assurance that no credible exposure fire would occur in 2RI that could damage components in the room or propagate into an adjacent room or from one quadrant of 2RI into an adjacent quadrant. Based on this, it is not expected that the plant will enter the fire safe shutdown procedure.

2.9.20.2.d Adjacent Rooms

Room 2RA1 is separated from 2RI-1 by a 36 to 48 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping penetrate the wall and are not provided with fire rated penetration seals. The in situ combustible load in 2RA1 is low and is due to small quantities of lubricant in valves (61% of the load), expansion joint material (32% of the load) and small quantities of plastics associated with electrical control boxes and lights. The lack of ignition sources and concentrations of in situ combustibles provides assurance that no credible fire in 2RA1 could propagate into 2RI-1 through the unprotected penetrations.

Room 2RA2 is separated from 2RI-2 by a 36 to 48 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping penetrate the wall and are not provided with fire rated penetration seals. The in situ combustible load in 2RA2 is insignificant and is due to small quantities of lubricant in valves (88% of the load), and small quantities of plastics associated with electrical control boxes and lights. The lack of ignition sources and concentrations of in situ combustibles provides assurance that no credible fire in 2RA2 could propagate into 2RI-2 through the unprotected penetrations.

Room 2RA3 is separated from 2RI-3 by a 36 to 48 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping penetrate the wall and are not provided with fire rated penetration seals. The in situ combustible load in 2RA3 is insignificant and is due to small quantities of lubricant in valves (88% of the load), and small quantities of plastics associated with electrical control boxes and lights. The lack of ignition sources and concentrations of in situ combustibles provides assurance that no credible fire in 2RA3 could propagate into 2RI-3 through the unprotected penetrations.

Room 2RA4 is separated from 2RI-4 by a 36 to 48 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping penetrate the wall and are not provided with fire rated penetration seals. The in situ combustible load in 2RA4 is low and is due to small quantities of lubricant in valves (90% of the load) and small quantities of plastics associated with electrical control boxes and lights. The lack of ignition sources and concentrations of in situ combustibles provides assurance that no credible fire in 2RA4 could propagate into 2RI-4 through the unprotected penetrations.

The Unit 2 Fan Room 1 (2RF1) is separated from 2RI-1 and 2RI-4 by a 36 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping penetrate the wall and are

PART VII - DEVIATIONS AND EVALUATIONS

not provided with fire rated penetration seals. The in situ combustible load in 2RF1 is insignificant and is dispersed throughout the room. Transient combustibles are not considered since the access to 2RIR is strictly controlled during unit operation and any transient material brought in during an outage is removed prior to unit start-up. It is concluded that due to the insignificant combustible load and lack of credible ignition sources, there is no credible fire in 2RF1 that could propagate into 2RI-1 or 2RI-4 from 2RI-1 or 2RI-4 into 2RF1.

The Unit 2 Fan Room 2 (2RF2) is separated from 2RI-2 and 2RI-3 by a 36 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping penetrate the wall and are not provided with fire rated penetration seals. The in situ combustible load in 2RF2 is insignificant and is dispersed throughout the room. Transient combustibles are not considered since the access to 2RF2 is strictly controlled during unit operation and any transient material brought in during an outage is removed prior to unit start-up. It is concluded that due to the insignificant combustible load and lack of credible ignition sources, there is no credible fire in 2RF2 that could propagate into 2RI-2 or 2RI-3 or from 2RI-2 or 2RI-3 into 2RF2.

The Reactor Instrument Room 2RIR is separated from 2RI-1 and 2RI-2 by a 36 inch thick reinforced concrete wall. Conduit, instrumentation lines and mechanical piping penetrate the wall and are not provided with fire rated penetration seals. The in situ combustible load in 2RIR is insignificant and is dispersed throughout the room. Transient combustibles are not considered since the access to 2RIR is strictly controlled during unit operation and any transient material brought in during an outage is removed prior to unit start-up. It is concluded that due to the insignificant combustible load and lack of credible ignition sources, there is no credible fire in 2RIR that could propagate into 2RI-1 or 2RI-2 or from 2RI-1 or 2RI-2 into 2RIR.

Room 2RO is separated from 2RI by 36 to 48 inch thick non-fire rated reinforced concrete Crane wall. The Crane wall contains electrical and mechanical openings that are not provided with fire rated seals/closures. There is a personnel access opening through the Crane wall from 2RO-3 into 2RI-3. The in situ combustible load in 2RO is low of which the expansion joint seal material accounts for 91% of the load. Only the edge of the seal is exposed, the rest is between concrete walls. The lack of exposed in situ combustibles and ignition sources provides assurance that no credible fire in 2RO could propagate into 2RI via this personnel access opening or these penetrations. Since access to the reactor building is strictly controlled during operation and transient material brought into the reactor building for outage work is removed prior to start-up, it is concluded there is no fire hazard from transient material. Therefore, it is concluded that no credible fire in 2RO could propagate into 2RI or from 2RI into 2RO.

Room 2RU is separated from 2RI by a 24 inch thick reinforced concrete floor. Conduit, instrumentation lines and mechanical piping penetrate the floor and are not provided with fire rated penetration seals or closures. The in situ combustible load in 2RU is insignificant and is due to small quantities of lubricant in valves and the crane and small quantities of plastics associated with electrical control boxes and lights. The lack of ignition sources and insignificant concentrations of in situ combustibles provides assurance that no credible fire in 2RU could propagate into 2RI or from 2RI into 2RU.

TVA concludes the lack of significant concentrations of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources provides assurance that no credible exposure fire would occur that could propagate from 2RI into an adjacent room or from an adjacent room into 2RI. TVA further concludes that the implementation of OMAs or the installation of radiant energy shields is not necessary.

PART VII - DEVIATIONS AND EVALUATIONS

2.9.20.3 System Evaluation

2.9.20.3.a Redundant Components in the Room

2RI is made up of four quadrants with a reactor coolant pump (RCP) and a steam generator (SG) and associated components in each. Any two steam generators provide adequate decay heat removal capability. The water level in each steam generator is monitored by three narrow range level transmitters and one wide range level transmitter. The transmitters for SG#1 and SG#4 (south side) are located in 2RF1 and the transmitters for SG#2 and SG#3 (north side) are located in 2RF2. Each SG has four pairs of instrument sensing lines connecting to the transmitters. The two steam generators and level instrumentation on the north side are horizontally separated from the two steam generators and level instrumentation on the south side by more than 20 feet.

Cables for RCS hot leg (HL) and cold leg (CL) temperature indication are located within the 2RI north side and south side with the corresponding SG except for RCS Loop 1 whose temperature indication cables are routed in conduit from quadrant 2RI-1 into 2RI-2 before entering 2RF2. The worst case is a fire in quadrant 2RI-2. For this case SG #3 and #4 are credited. The SG loop 3 temperature monitoring cables and level sense lines are horizontally separated by at least 10 feet from the SG loop 1 and loop 2 temperature monitoring cables and the SG loop 2 level sense lines. Based on the minimal fire hazards described in 2.9.20.2 there is no credible fire that could damage both the RCS Loop 1 cables and the Loop 2 and 3 cables or sense lines. Therefore, at least two steam generators and their associated level and temperature instrumentation are operable with a fire anywhere in 2RI. Therefore, radiant energy shields are not necessary for 2.9.20.1.b.

For a fire in quadrant 2RI-1 SG #2 and #3 are credited and for a fire in quadrant 2RI-3 SG #1 and #4 are credited and for both quadrants, one of the redundant level transmitters for the credited steam generator and its cables are not in 2RI. For a fire in quadrant 2RI-2 SG #3 and #4 are credited and one of the redundant level transmitters and its cables for SG #3 and SG #4 are located outside of 2RI. Based on the minimal fire hazards described in 2.9.20.2 there is no credible fire that could damage both the SG #3 temperature monitoring cables and the level transmitter cables. Therefore, radiant energy shields are not necessary for 2.9.20.1.c.

A RCP seal return flow isolation valve and cables are located in the quadrant with its associated RCP. The valves are air operated, normally open, solenoid controlled valves that fail open on loss of air or 125vdc electrical power and their desired position is open. The only fire induced failure that could energize the solenoid to close one of these valves is a cable-to-cable hot short and the conduits for these cables within 2RI do not contain any 125vdc energized cables. Therefore, even if fire could damage these cables the valves do not close.

One control rod drive mechanism cooler (CRDM) is located in each of the four quadrants along with a temperature control damper and a temperature control valve to regulate the amount of cooling provided by the cooler. Containment cooling is also provided by the four lower compartment coolers (LCCs) located in 2RF1 and 2RF2. Three LCCs alone or two LCCs and two CRDMS provide adequate containment cooling. Two LCCs and their temperature control valves and cables are located outside of 2RI in 2RF1 and 2RF2. The temperature sensing element (thermocouple) cables for the other two LCCs are routed through 2RI in conduits. Based on the limited fire hazard (2.9.20.2) there is no credible fire that could damage both of these cables. Even if they could be damaged, the most likely failure mode is a conductor to conductor short within the 2-conductor thermocouple extension wire cable which creates a new

PART VII - DEVIATIONS AND EVALUATIONS

thermocouple junction in a hot environment resulting in a higher cooling demand and the valve opens as desired. Therefore, the manual actions listed in 2.9.20.1 are not necessary to ensure containment cooling. As additional defense-in-depth there are two CRDM coolers available for a fire in quadrants 2RI-3 and 2RI-4 where both LCC thermocouple cables are located. Cables for the CRDM are separated horizontally at least 6 feet from at least one of the two LCC thermocouple cables. Even if fire could damage both thermocouple cables, two LCCs and two CRDMs are available to provide the needed cooling.

Each train of ACAS supplies one component (pressurizer spray valve) located in 2RI. These two ACAS air users are horizontally separated by at least 8 feet. Based on the limited fire hazard (2.9.20.2) there is no credible fire that could damage both ACAS headers. At least one train of ACAS is available. As additional defense-in-depth the reactor building ACAS headers can be isolated by closing their containment isolation valves from the main control room and thereby preserves the ACAS to operate equipment in the auxiliary building.

The modulating signal cables for one pressurizer spray valves are routed in conduit through 2RI. The valve is normally closed and fail closed on loss of signal or air. The only failure that could prevent closure of a spray valve is a double hot short (plus-to-plus and minus-to-minus) without grounding between two instrument cables in the conduit. Such a failure is not credible considering the minimal fire hazard identified in 2.9.20.2. If the spray valve could not be closed, the main control room operator trips the RCP providing the motive force for the spray.

The train A and train B pressurizer power operated relief valves (PORVs) and their associated block valves are located on top of the pressurizer in 2RI. The train A cables and train B cables are routed in conduit in opposite directions away from the pressurizer. Fire damage to a PORV or its cables could not spuriously open the valve and the head vent valves whose cables are routed in conduit outside of the pressurizer cavity are operable to depressurize the RCS if needed. Based on the minimal fire loading and ignition sources near the pressurizer, fire damage to the PORVs and their associated block valve or their cables and the head vent valve cables is not considered credible. The power is removed from the head vent valve circuits during normal plant operation to ensure they could not spuriously open. Therefore, radiant energy shields are not necessary for 2.9.20.1.d.

The pressurizer level transmitter sense lines originate near the top of the pressurizer and travel to the reactor instrument room. The sense lines from the tap on the pressurizer to the bellows (located outside of the pressurizer enclosure) consist of two parts. The parts are rigid tubing and flex hose (for thermal expansion/contraction). The flex hose is ASME Section III, class 2 flex hose assembly metal bellows. The rigid tubing is ASME Section III, class 2, schedule 160 welded stainless steel. The sense lines have horizontal separation at the taps in excess of four feet and they are located more than forty feet above the floor. Based on the minimal fire loading and ignition sources near the pressurizer, the design of the instrument sense lines utilizing only non-combustible material, the separation between the sense lines and the large distance from the floor of the pressurizer enclosure, fire damage to the sense lines is not considered credible. Therefore, radiant energy shields are not necessary for 2.9.20.1.e.

Redundant channel source range detector and indication cables are routed in 2RI. The cables are horizontally separated in excess of 20 feet. Therefore, even if there could be a fire of sufficient magnitude to damage one channel, the other channel could not be damaged based on physical separation.

PART VII - DEVIATIONS AND EVALUATIONS

Both RCS normal letdown flow control valves and associated cables are located in 2RI-2. These are normally open air operated valves that fail closed on loss of air or 125vdc electrical power. The desired position for FSSD is closed. There is insignificant in situ combustible loading and no credible ignition sources in the room; therefore, it is concluded that there is no fire hazard that could damage circuits and spuriously energize both valve circuits. For additional defense-in-depth, if both valves are assumed to fail to close, the operator will isolate and depressurize the Unit 2 reactor building non-essential control air header from the main control room thereby causing the valves to close.

2.9.20.3.b FSSD Components with Redundant FSSD Components in an Adjacent Room within the Same Analysis Volume

The RHR system piping is isolated from the RCS by two opposite train motor operated isolation valves in series. Each of the isolation valves has a by-pass valve of the opposite train. One set (main isolation valve and its opposite train by-pass valve) of RHR isolation valves are located in 2RI-4 and its redundant set is located in 2RA4. Cables for the train A main isolation valve and its by-pass valves are routed in conduits through a portion of 2RI (2RI-1 and 2RI-4). The valves of one set must remain closed to achieve and maintain hot shutdown. This is ensured by removing power from the valves in both trains during normal plant operation. For RHR operation (cold shutdown) one valve of each set must be opened. The performance of an OMA (2.9.20.1.a) is credited in the FSSD analysis to manually open one of the valves in 2RI-4 before containment became uninhabitable due to reactor coolant accumulation resulting from letdown through the PORV. As discussed in the fire hazard analysis (2.9.20.2) the combustible loading and ignition sources in 2RI are insufficient to create fire damage that results in entry into the fire safe shutdown procedures. Therefore the OMA to open one of the RHR isolation valves will not be necessary.

2.9.20.3.c Other FSSD Components in the Room

Room 2RI contains FSSD cables associated with FSSD equipment relied upon for fires in other areas of the plant (i.e., equipment and cables not credited for a fire in Room 2RI). The cables are routed in conduit. Although no fire induced failures are expected due to the insignificant fire hazard in the rooms, postulated failure of the non-credited FSSD cables has been evaluated to assess its effect on plant operation. Failure of these FSSD cables is detected and mitigated by normal plant procedures and would not initiate or result in a plant trip.

- Reactor building sump level transmitter cable (input to RHR to sump isolation valve circuits).
- Upper containment purge isolation valve cable.
- Pressurizer heater cables.
- Reactor coolant pump motor cables.
- Steam generator #1 and #4 level transmitter cables.
- Reactor coolant system hot and cold leg temperature auxiliary cables.

2.9.20.4 Conclusion

There is insignificant threat from transient combustibles, in situ combustible material, and no credible ignition sources. A credible fire would not cause loss of the station control air system, or damage equipment/cables and prevent FSSD in 2RI. There is no fire hazard in 2RI that necessitates any OMA or warrants protecting electrical raceways (conduits and junction boxes)

PART VII - DEVIATIONS AND EVALUATIONS

with radiant energy shields. TVA concludes that the intent of III.G.1 is ensured and requests approval of this deviation demonstrating compliance to III.G.1 criteria with a fire hazard analysis in lieu of the prescriptive separation criteria of III.G.2.

2.9.21 2RO– Unit 2 Reactor Building Outside Crane Wall [2RO-1 (0° to 90°), 2RO-2 (90° to 180°), 2RO-3 (180° to 270°), 2RO-4 (270° to 360°)]

2.9.21.1 Description of Condition

Room 2RO of the Unit 2 Reactor Building is a part of fire area 77 (See Part III, Table 3-3 for room listing). It is outside the Crane Wall and is included in analysis volumes AV-118A, AV-118B, AV-118C, AV-118D and AV-118E. Fire area 77 is considered a III.G.2 area. 2RO contains redundant safe shutdown components. No OMAs would need to be performed for room 2RO, but an FSSD analysis assuming failure of all cables in 2RO, indicates that radiant energy shielding to protect cable 2V2783A for 2-FCV-74-1-A would need to be installed.

2.9.21.2 Fire Hazards Analysis

2.9.21.2.a Room Description

The area of Unit 2 Reactor Building outside the Crane Wall is designated as 2RO and is separated from adjacent areas of the Unit 2 Reactor Building by reinforced concrete barriers that are 24 to 48-inches thick. These barriers have mechanical and electrical penetrations that are not provided with fire rated seals/closures. Room 2RO has a floor area of 4,179-ft² and a ceiling height of 14-feet.

2.9.21.2.b Fire Load

The combustible loading in 2RO is low and is due to the expansion joint seal (91% of the in situ combustible load), small quantity of lubricant associated with two sump pumps, HEPA filters and plastics associated with small control panels, telephones and junction boxes. The two sump pumps that contain less than a quart of lubricant are not considered to be ignition sources (see Justification in 2.9.0 above). The in situ combustibles are of such small quantity and so dispersed throughout 2RO that they would not be capable of creating a fire that could propagate through any unprotected opening in the concrete barriers separating 2RO from an adjacent room, or from propagating from one quadrant of 2RO into an adjacent quadrant of 2RO.

2.9.21.2.c Control of Combustibles and Ignition Sources

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into 2RO. Compensatory measures must be implemented when transient combustibles or ignition sources are brought into a room due to work activities. Room 2RO is a CCZ (see Part II, sections 10 and 11 and WBN Technical Instruction TI-291, Combustible Control Zones and Sensitive Areas). For compliance with TI-291, the approval of an evaluation must be obtained before any transient combustible can be introduced into the room or hot work performed in the room. Access to the room is from 2RIR via a ladder down to 2RO-1. When Unit 2 is operating access to the reactor building is strictly controlled. Prior to returning a unit to operation, transient material that might have been brought into the room is removed. The lack of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources provides assurance that no credible

PART VII - DEVIATIONS AND EVALUATIONS

exposure fire would occur in 2RO that could damage components in 2RO, or propagate into an adjacent room, or from one quadrant of 2RO into an adjacent quadrant. Based on this, it is not expected that the plant will enter the fire safe shutdown procedure.

2.9.21.2.d Adjacent Rooms

Room 2RA1 is separated from 2RO-1 by a 24 inch thick reinforced concrete floor. The floor contains an opening for personnel access from 2RO-1 into 2RA1. Conduits, instrumentation lines and mechanical piping penetrate the floor and are not provided with fire rated penetration seals. The in situ combustible load in 2RA1 is low and is due to small quantities of lubricant in valves (61% of the load), expansion joint material (32% of the load) and small quantities of plastics associated with electrical control boxes and lights. Transient combustibles are not considered since the access to the reactor building is strictly controlled during unit operation and any transient material brought in during an outage is removed prior to unit start-up. The lack of ignition sources and concentrations of in situ combustibles provides assurance that no credible fire in 2RA1 could propagate into 2RO-1.

Room 2RA2 is separated from 2RO-2 by a 24 inch thick reinforced concrete floor. The floor contains an opening for personnel access from 2RO-2 into 2RA2. Conduits, instrumentation lines and mechanical piping penetrate the floor and are not provided with fire rated penetration seals. The in situ combustible load in 2RA2 is insignificant and is due to small quantities of lubricant in valves (88% of the load), and small quantities of plastics associated with electrical control boxes and lights. Transient combustibles are not considered since the access to the reactor building is strictly controlled during unit operation and any transient material brought in during an outage is removed prior to unit start-up. The lack of ignition sources and concentrations of in situ combustibles provides assurance that no credible fire in 2RA2 could propagate into 2RO-2.

Room 2RA3 is separated from 2RO-3 by a 24 inch thick reinforced concrete floor. The floor contains an opening for personnel access from 2RO-3 into 2RA3. Conduit, instrumentation lines and mechanical piping penetrate the floor and are not provided with fire rated penetration seals. The in situ combustible load in 2RA3 is insignificant and is due to small quantities of lubricant in valves (88% of the load), and small quantities of plastics associated with electrical control boxes and lights. Transient combustibles are not considered since the access to the reactor building is strictly controlled during unit operation and any transient material brought in during an outage is removed prior to unit start-up. The lack of ignition sources and concentrations of in situ combustibles provides assurance that no credible fire in 2RA3 could propagate into 2RO-3 through the unprotected penetrations.

Room 2RA4 is separated from 2RO-4 by a 24 inch thick reinforced concrete floor. The floor contains an opening for personnel access from 2RO-4 into 2RA4. Conduit, instrumentation lines and mechanical piping penetrate the floor and are not provided with fire rated penetration seals. The in situ combustible load in 2RA4 is low and is due to small quantities of lubricant in valves (90% of the load) and small quantities of plastics associated with electrical control boxes and lights. Transient combustibles are not considered since the access to the reactor building is strictly controlled during unit operation and any transient material brought in during an outage is removed prior to unit start-up. The lack of ignition sources and concentrations of in situ combustibles provides assurance that no credible fire in 2RA4 could propagate into 2RO-4 through the unprotected penetrations.

PART VII - DEVIATIONS AND EVALUATIONS

The Unit 2 Fan Room 1 (2RF1) is separated from 2RO-1 and 2RO-4 by a 24 inch thick reinforced concrete floor. The floor contains an opening for personnel access from 2RO-1 and 2RO-4 into 2RF1. Conduit, instrumentation lines and mechanical piping penetrate the floor and are not provided with fire rated penetration seals. The in situ combustible load in 2RF1 is insignificant and is dispersed throughout the room. Transient combustibles are not considered since the access to the reactor building is strictly controlled during unit operation and any transient material brought in during an outage is removed prior to unit start-up. It is concluded that due to the insignificant combustible load and lack of credible ignition sources, there is no credible fire in 2RF1 that could propagate into 2RO-1 or 2RO-4 or from 2RO-1 or 2RO-4 into 2RF1.

The Unit 2 Fan Room 2 (2RF2) is separated from 2RO-2 and 2RO-3 by a 24 inch thick reinforced concrete floor. The floor contains an opening for personnel access from 2RO-2 and 2RO-3 into 2RF2. Conduit, instrumentation lines and mechanical piping penetrate the wall and are not provided with fire rated penetration seals. The in situ combustible load in 2RF2 is insignificant and is dispersed throughout the room. Transient combustibles are not considered since the access to 2RF2 is strictly controlled during unit operation and any transient material brought in during an outage is removed prior to unit start-up. It is concluded that due to the insignificant combustible load and lack of credible ignition sources, there is no credible fire in 2RF2 that could propagate into 2RO-2 or 2RO-3 or from 2RO-2 or 2RO-3 into 2RF2.

The Reactor Instrument Room 2RIR is separated from 2RO-1 and 2RO-2 by a 24 inch thick reinforced concrete floor. The floor contains an opening for personnel access from 2RO-1 into 2RIR. A portion of 2RO-2 extends into 2RIR and is separated from 2RIR by 36 inch thick reinforced concrete walls and ceiling. Conduit, instrumentation lines and mechanical piping penetrate the floor and are not provided with fire rated penetration seals. The in situ combustible load in 2RIR is insignificant and is dispersed throughout the room. Transient combustibles are not considered since the access to 2RIR is strictly controlled during unit operation and any transient material brought in during an outage is removed prior to unit start-up. It is concluded that due to the insignificant combustible load and lack of credible ignition sources, there is no credible fire in 2RIR that could propagate into 2RO-1 or 2RO-2 or from 2RO-1 or 2RO-2 into 2RIR.

Room 2RI is separated from 2RO by 36 to 48 inch thick non-fire rated reinforced concrete Crane wall. The Crane wall contains electrical and mechanical openings that are not provided with fire rated seals/closures. There is a personnel access opening through the Crane wall from 2RO-3 into 2RI-3. The in situ combustible load in 2RI is low of which the RCP oil accounts for 98% of the load. Each RCP is provided with an oil collection system and automatic suppression. The CRDM coolers are enclosed units and the lack of combustible material in each unit provides confidence that a failure of the motors within the units will not create a fire that could damage components near the CRDM coolers. The lack of exposed in situ combustibles and ignition sources provides assurance that no credible fire in 2RI could propagate into 2RO via this personnel access opening or these penetrations. Since access to the reactor building is strictly controlled during operation and transient material brought into the reactor building for outage work is removed prior to start-up, it is concluded there is no fire hazard from transient material. Therefore, it is concluded that no credible fire in 2RI could propagate into 2RO or from 2RO into 2RI.

TVA concludes the lack of significant concentrations of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources provides assurance that no credible exposure fire would occur that could propagate from 2RO into an adjacent room

PART VII - DEVIATIONS AND EVALUATIONS

or from an adjacent room into 2RO. TVA further concludes that the implementation of OMAs or the installation of radiant energy shields is not necessary.

2.9.21.3 System Evaluation

2.9.21.3.a Redundant FSSD Components in the Room

The RHR system piping is isolated from the RCS by two opposite train motor operated isolation valves in series. Each of the isolation valves has a by-pass valve of the opposite train. One set (main isolation valve and its opposite train by-pass valve) of RHR isolation valves are located in 2RA4 and its redundant set is located in 2RI-4. Cables for the train A main isolation valve and its by-pass valves are routed in conduits through a portion of 2RO (2RO-1 and 2RO-4). The valves of one set must remain closed to achieve and maintain hot shutdown. This is ensured by removing power from the valves in both trains during normal plant operation. For RHR operation (cold shutdown) one valve of each set must be opened. The train A main isolation valve cable is routed in 2RO-4 and is more than 5 feet horizontally from the conduits containing its train B by-pass valve cables. As discussed in the fire hazard analysis (2.9.21.2) the combustible loading and ignition sources in 2RO are insufficient to create a fire that could damage both of these cables. Therefore, no radiant energy shield must be installed. For additional defense-in-depth the cable for the train B main isolation valve has been relocated out of 2RO.

Reactor building lower compartment cooling is provided by four lower compartment coolers (LCC) and four control rod drive mechanism (CRDM) coolers. Three LCCs or 2 LCCS and 2 CRDMs provide adequate cooling. Cables for all four CRDM cooler motors are routed through 2RO in conduits. The cables for one CRDM motor and associated damper and temperature control valve (TCV) are located in each quadrant (2RO-1, 2RO-2, 2RO-3, and 2RO-4) such that no more than two CRDM motors could be affected by a postulated fire anywhere in 2RO. Cables for the TCVs for LCC-C and LCC-D are also routed through 2RO-1 and 2RO-2 respectively in conduits that are horizontally separated by more than 20 feet. Based on the limited combustible loading and ignition sources described in the FHA (2.9.21.2), and the four quadrant locations of the CRDMs, a fire could not disable all of the CRDM coolers and the TCVs for two of the LCCs. Adequate cooling is assured by the available LCCs and CRDMs.

Cables for the excess letdown isolation valve and the flow modulating valve are both routed in conduit through 2RO. One conduit containing the flow modulating valve cable is located below elevation 716.0 floor slab and the redundant valve (letdown isolation) and its associated conduit is located above elevation 716.0 floor slab. Both of these areas are part of 2RO. The 716.0 floor slab has a hatch that is located on the opposite side of the room from the letdown isolation valve and its conduit (more than 10 feet horizontal separation) and is in an offset such that the concrete wall of the offset shields the valve from the hatch opening. The lack of in situ combustible material and ignition sources and the controls for transient combustibles and ignition sources (see 2.9.21.2 above) in both areas of 2RO provides assurance that no credible exposure fire would occur in either area that could damage both of these components. The flow modulating valve is normally closed and fails closed on loss of air or signal. The only credible failure that could open the valve is a cable to cable hot short (plus-to-plus and minus-to-minus without grounding) between two twisted shielded instrument cables. Such a fault is not credible considering the limited combustibles and lack of ignition sources in 2RO. As additional defense-in-depth, there are no other cables in the conduit with the flow modulating valve signal cable (no hot short source).

PART VII - DEVIATIONS AND EVALUATIONS

The modulating signal cables for the pressurizer spray valves are routed in conduit through 2RO. These valves are normally closed and fail closed on loss of signal or air. The only failure that could prevent closure of a spray valve is a double hot short (plus-to-plus and minus-to-minus) without grounding between two instrument cables in the conduit. Such a fault is not credible considering the limited combustibles and lack of ignition sources in 2RO. As additional defense-in-depth, if the spray valve could not be closed the main control room operator would terminate the spray by tripping the RCP that provides pressure for the spray.

A cable for reactor coolant pump (RCP) 2 seal return flow control valve is routed in conduit in room 2RO. The valve is normally open and fails open on loss of power or air. There are three other cables in the conduit that are normally de-energized and would not provide a hot short source to energize the valve even if there could be fire damage to the cable. However, the lack of ignition sources and insignificant quantities of combustible material below or near the conduit could not create a fire of sufficient magnitude to damage the cable. It is concluded that there is not a fire hazard that could energize this valve circuit. For additional defense-in-depth, if the valve could fail closed the operator would close the RB non-essential control air header valve from the main control room thereby isolating control air which would open the valve.

Cables for the RCS normal letdown isolation valves which are normally open and fail closed on loss of power or air are routed in conduit in room 2RF1. Since there is insignificant in situ combustible loading and no credible ignition sources in the room, it is concluded that there is not a fire hazard that could damage circuits and spuriously energize both valve circuits. For additional defense-in-depth, if both valves are assumed to fail to close, the operator will isolate and depressurize the Unit 2 reactor building non-essential control air header from the main control room thereby causing the valves to close.

2.9.21.3.b FSSD Components with Redundant FSSD Components in an Adjacent Room within the same Analysis Volume

Cables for one of the RCS letdown flow control valves are located in 2RO along with the three regenerative letdown flow control valves. Cables for the redundant valve are located in 2RA2 and 2RF2. As described in FHA section 2.9.21.2.d no credible fire in 2RO could migrate into these adjacent rooms and cause cable damage. As defense-in-depth a third letdown isolation valve (located in the auxiliary building) can be closed from the main control room if needed.

2.9.21.3.c Other FSSD Components in the Room

Room 2RO contains cables associated with FSSD equipment relied upon for fires in other areas of the plant (i.e., equipment and cables not credited for a fire in Room 2RO). The cables are routed in conduit. Although no fire induced failures are expected due to the insignificant fire hazard in the rooms, postulated failure of the non-credited FSSD cables has been evaluated to assess its effect on plant operation. Failure of these FSSD cables is detected and mitigated by normal plant procedures and would not initiate or result in a plant trip.

- Pressurizer heater cables.
- Reactor building sump level sensor channel D, E, & G cables (permissive sump isolation valves).
- Safety injection system accumulator valve cables.
- Thermal barrier cooling system isolation valve cable.
- Pressurizer level & pressure normal & auxiliary cables.

PART VII - DEVIATIONS AND EVALUATIONS

- Reactor coolant system hot & cold leg temperature auxiliary cables.
- Pressurizer power operated relief valve (PORV) cable.

2.9.21.4 Conclusion

There is insignificant threat from transient combustibles, in situ combustible material, and no credible ignition sources. A credible fire would not damage equipment/cables and prevent FSSD in 2RO. There is no fire hazard in 2RO that warrants protecting electrical raceways (conduits and junction boxes) with radiant energy shields. TVA concludes that the intent of III.G.1 is ensured and requests approval of this deviation demonstrating compliance to III.G.1 criteria with a fire hazard analysis in lieu of the prescriptive separation criteria of III.G.2.

3.0 Engineering Evaluations

Per the Interpretations of Appendix R in Generic Letter 86-10, engineering evaluations may be performed to document the acceptability of specific fire protection features. The following sections document the engineering evaluations prepared to address Appendix R compliance.

3.1 Lack of Total Area Suppression and Detection

Requirement - Sections III.G.2.b and III.G.2.c of Appendix R state that, "In addition, fire detectors and automatic fire suppression system shall be installed in the fire area." Section III.G.2e also uses the phrase "fire detectors and an automatic fire suppression system in the fire area."

Per Item 5 of Enclosure 1 to Generic Letter 86-10, Interpretations of Appendix R, suppression and detection sufficient to protect against the hazards of the area must be installed. The generic letter identifies that detection and suppression providing less than full area coverage may be adequate to comply with the regulation. In order to justify less than full coverage, an evaluation must be performed to assess the adequacy of partial suppression and detection to protect against the hazards in the area. WBN has evaluated those plant locations with less than full detection and/or full suppression coverage where the criteria of Sections III.G.2.b, III.G.2.c, or III.G.2.e are utilized to demonstrate conformance with Appendix R requirements.

There are fire areas at WBN that contain FSSD components that either (1) rely on 20 feet of separation or 1-hour fire barriers outside of containment, or (2) rely on detection and suppression capabilities inside containment, but have less than full area detection and suppression capability. Each area is identified below, along with the rooms within the fire area that have less than full detection and suppression system coverage. The impact on fire safe shutdown capability is also identified.

3.1.1 Fire Area 1

The following table identifies those rooms in Fire Area 1 that have less than full detection and/or full suppression capability as required by Section III.G.2.b and/or III.G.2.c criteria.

PART VII - DEVIATIONS AND EVALUATIONS

<u>Rooms</u>	<u>Description</u>	<u>Detection</u>	<u>Suppression</u>	<u>FSSD</u>
674.0-A1	Waste Hold-up Tank Room	No	No	Yes (see note 1)
674.0-A2	Waste Evap Feed Pump Rm	No	No	None
676.0-A1	Corridor	Yes	No	Yes (RHR)
676.0-A2	Hold-up Tank Room A	No	No	None
676.0-A3	Hold-up Tank Room B	No	No	None
676.0-A4	Floor Drain Coll Pmp & Fltr Rm	No	No	None
676.0-A4a	Floor Drain Coll Tank Rm	No	No	None
676.0-A5	Gas Stripper Feed Pump Room	Yes	No	None
676.0-A6	Spare	Yes	No	None
676.0-A7	Spare	No	No	None
676.0-A8	Containment Spray Pump 1B-B	Yes (Partial)	No	Yes (Spurious)
676.0-A9	Containment Spray Pump 1A-A	Yes (Partial)	No	Yes (Spurious)
676.0-A14	Containment Spray Pump 2A-A	Yes (Partial)	No	Yes (Spurious)
676.0-A15	Containment Spray Pump 2B-B	Yes (Partial)	No	Yes (Spurious)
676.0-A16	Unit 1 Pipe Gallery and Chase	Yes	No	Yes
692.0-A1(*)	Tunnel to RWST from AB	No	No	Yes
692.0-A2	Valve Gallery	No	No	None
692.0-A3	Gas Decay Tank Room	No	No	None
692.0-A5	Gas Decay Tank Room	No	No	None
692.0-A8	Unit 1 Pipe Gallery and Chase	Yes	No	Yes
692.0-A9(**)	Charging Pump 1A-A	Yes (Partial)	Yes (Partial)	Yes
692.0-A17	Maintenance and Test Equipment Hot Tool Room	Yes	Yes (Partial)	None
692.0-A18	Hot Tool Room	Yes	Yes (Partial)	Yes
692.0-A27	Concentrate Filter Rm	No	No	None
692.0-A29	Boric Acid Evap Pkg Rm B	No	No	Yes
692.0-A30	Boric Acid Evap Pkg Rm A	No	No	Yes
692.0-A31	Spare	Yes	No	None
713.0-A28	Unit 1 Pipe Gallery and Chase	Yes	No	Yes

Note 1 Cables are auxiliary control (only required for a Control Building fire) and not necessary for FSSD in the Auxiliary Building.

(*) Room 692.0-A1 has full detection and suppression. Only the tunnels to the RWSTs, which open into 692.0-A1, are without detection and suppression.)

(**) The evaluation is also applicable to the other Charging Pump Rooms: 692.0-A10 (FA6), 692.0-A22 (FA67) and 692.0-A23 (FA68).

PART VII - DEVIATIONS AND EVALUATIONS

As shown in the above listing, of the rooms within Fire Area 1 that do not have full detection and suppression capability, thirteen have equipment or cables that are required for FSSD.

Evaluations of each of the rooms with FSSD capabilities follow.

Room 674.0-A1 Waste Hold-up Tank Room

The Waste Hold-up Tank Room (674.0-A1) is of reinforced concrete construction (walls, floor, and ceiling have thicknesses from 12 to 36-inches), but the barriers are not assigned a fire rating. The room has a floor area of 1,691-ft² and a ceiling height of 16-ft. The only major component in the room is the Waste Hold-up Tank. There are no ignition sources in the room and an insignificant quantity of in situ combustibles. Any transient combustibles that might be introduced due to work activities are addressed by NPG-SPP-18.4.7, "Control of Transient Combustibles". NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)", ensures that appropriate fire prevention actions are taken before performing work that could constitute an ignition source. It is highly unlikely that any fire would occur, but if it did, it would be very small, be contained within the room and would not cause damage to the FSSD circuits routed in conduits through the room.

The only FSSD circuits are required for fire in the Control Building. Therefore, since they are not needed for FSSD for a fire that might develop in the room, there is no impact to FSSD.

Room 676.0-A1 Corridor

The RHR pumps, power cables, and the RHR pump room coolers are required for cold shutdown after a fire. The RHR pump power cables are exposed in the Corridor, Room 676.0-A1 on opposite sides of the elevator shaft. These rooms are part of a larger fire area that has full area detection and suppression capabilities.

Room 676.0-A1 is provided with ionization smoke detectors, but not an automatic fire suppression system. In addition standpipe and hose stations and portable extinguishers are provided for the area.

The in situ combustible loading of the corridor is low. Since this area is accessible during normal operations, transient combustibles could be introduced into the area. The control of combustible materials in the plant is via Site Implementing Instructions.

The exposed conduit on elevation 676.0 that contains one train of RHR pump power cables is protected with a 3-hour fire barrier wrap where routed along the wall of the elevator shaft enclosure. Considering the combination of low in situ combustibles, fire rated barriers, spacial separation and administrative controls, an adequate level of protection exists for the RHR pump circuits and the addition of automatic suppression on elevation 676.0 would not significantly increase fire protection of safe shutdown capability of the area.

Rooms 676.0-A8, 676.0-A9, 676.0-A14 and 676.0-A15: Containment Spray Pump Rooms

Each containment spray pump room is bounded by 2-hour fire rated regulatory fire barriers. Automatic detection is provided in each room except for the entrance labyrinth; however, automatic suppression capability is not provided.

PART VII - DEVIATIONS AND EVALUATIONS

Each containment spray pump is identified as a potentially spuriously operating component which must be prevented from starting. Each pump room contains the pump, its associated power cable and room cooler. A fire in any of these pump rooms will damage the power cable for the pump. As such, the pump will be prevented from spurious operation given a fire in the room. The combustible loads in each room result in an equivalent fire severity of less than five minutes, which is significantly less than the capabilities of the barriers that bound the room. Therefore, postulated fires will not spread from the containment spray pump rooms to adjacent rooms. Considering the combustible loading and 2-hour fire rated regulatory fire barriers, in combination with the existing detection system (except in the entrance labyrinth) and lack of fire safe shutdown impact given a fire in any pump room, an adequate level of protection exists for the containment spray pump rooms, Rooms 676.0-A8, 676.0-A9, 676.0-A14 and 676.0-A15.

Extending detection into the entrance labyrinth, and the addition of automatic suppression in the rooms, would not significantly increase fire protection of safe shutdown capability in the area.

Rooms 676.0-A16, 692.0-A8, and 713.0-A28: Auxiliary Building Pipe Chase

The pipe chase extends from elevation 676.0 to elevation 737.0 and is made up of Rooms 676.0-A16, 692.0-A8, and 713.0-A28. The pipe chase is separated from elevations 692, 713, and 737 by reinforced concrete construction that is equivalent to at least 2-hour fire rated barriers. The in situ combustible loading of the pipe chase is insignificant. Smoke detectors are installed in the pipe chase.

The pipe chase contains one path of FSSD equipment consisting of a volume control tank (VCT) level transmitter and its associated cabling, and cables for narrow and wide range level indication for two steam generators. The redundant path instrumentation is located outside the pipe chase. The chase also contains redundant RHR mini-flow valves and containment spray pump suction valves. These valves are required for FSSD only if a fire causes spurious pump actuation of an RHR or containment spray pump. Cables that could cause such spurious pump actuation are located outside the pipe chase.

Transient combustibles are minimized in the pipe chase. Rooms 676.0-A16 and 692.0-A8 are locked rooms with access controlled by Radiation Protection personnel. Room 713.0-A28 is a combustible control zone. Based on these considerations, fires involving transient combustible materials are not considered to be a credible event.

The addition of automatic fire suppression in the pipe chase would not significantly enhance the fire protection of FSSD capability of the plant. This is based on the insignificant combustible loading, access limitations, and administrative controls to limit the introduction of transient combustible materials, adequate compartmentation, and provision of fire detection in the pipe chase.

Tunnels from Auxiliary Building to Refueling Water Storage Tanks (RWSTs)

The RWST tunnels are underground tunnels of reinforced concrete construction equivalent to 3-hour fire rated barriers, except at each end. One end of each tunnel opens into the auxiliary building on elevation 692.0 into Room 692.0-A1 at column lines A1/U and A15/U. Each tunnel is considered as part of Fire Area 1. The other end of each tunnel is accessed via a manhole located in the yard near the RWSTs. The in situ combustible loading inside each tunnel is insignificant. Each tunnel is accessed by climbing a ladder to the roof of the turbine-driven AFW pump rooms at column lines A1/U and A15/U in the auxiliary building, crossing the roof of each

PART VII - DEVIATIONS AND EVALUATIONS

TDAFW pump room, and entering into the tunnel. From the yard end, each tunnel is accessed through a manhole cover, down a ladder, and into the tunnel. This limited access minimizes the probability and amount of transient combustibles that can be expected in the tunnel.

Fire detection and automatic fire suppression on elevation 692.0 of the auxiliary building protects the entrance of the tunnel from an exposure fire in the auxiliary building.

Level transmitter circuits for the RWST are routed through the tunnel in conduits. These circuits are required for FSSD if a fire causes spurious actuation of RHR or containment spray pumps, or opening of RB sump valves. A fire in the tunnel cannot cause the identified spurious actuations.

Considering the limited FSSD circuits present, the configuration of the tunnel, insignificant in situ combustibles, and limited access; the addition of fire detection and fixed automatic suppression in the tunnel would not significantly increase fire protection of safe shutdown capability in the area.

Room 692.0-A9, -A10, -A22, -A23: Centrifugal Changing Pump 1A-A, 1B-B, 2A-A, 2B-B

The CCP rooms and the corridor outside the rooms are provided with fire detection and automatic suppression, but detection and suppression have not been extended into the entrance labyrinth to each pump room. Each pump room contains a single path of safe shutdown equipment consisting of a charging pump and its power and control circuits and cooling equipment. None of this equipment is located in the entrance labyrinth.

Each CCP room and entrance labyrinth is enclosed by reinforced concrete construction that is equivalent to at least 2-hour fire rated barriers. The in situ combustible loading for each pump room is low. Each CCP room is a radiological controlled area and access is administratively controlled. No significant quantities of transient combustibles are anticipated in the room during power operation.

If a fire did occur in a labyrinth, it is detected by a smoke detectors located in the pump room or corridor. The sprinklers in the pump room or corridor provide containment of the fire until the fire brigade responded to extinguish it.

The combination of fire rated construction, low in situ combustible loads, and installed detection and suppression systems provide an adequate level of fire protection. Providing additional fire detection and suppression in the entrance labyrinth of the CCP rooms would not significantly increase fire protection of safe shutdown capability in the area.

Room 692.0-A18: Hot Tool Room

The room is provided with fire detection and automatic suppression, but suppression has not been extended into the entrance labyrinth of the room. The room contains one cable required for fire safe shutdown and it is routed in a conduit with no other cables.

The room and entrance labyrinth is enclosed by reinforced concrete construction that is equivalent to at least 2-hour fire rated barriers. The in situ combustible loading for the room is insignificant. The room is a radiological controlled area and access is administratively controlled. No significant quantities of transient combustibles are anticipated in the rooms during power operation.

PART VII - DEVIATIONS AND EVALUATIONS

In the unlikely event a fire did occur in the labyrinth, it is detected by smoke detectors located in the room. The sprinklers in the room provide containment of the fire until the fire brigade responded to extinguish it.

The combination of fire rated construction, insignificant in situ combustible loads, and installed fire detectors and suppression systems provide a level of fire protection that is adequate. Additional suppression in the entrance labyrinth of the room would not significantly increase fire protection of safe shutdown capability in the area.

Rooms 692.0-A29 and 692.0-A.30: Boric Acid Evap Package Rooms A and B

See section 2.9.1 above for the justification for concluding that the addition of detection and suppression in these rooms would not significantly increase fire protection of safe shutdown capability in the rooms.

Remaining Rooms of Fire Area 1 Without Full Detection and/or Suppression

The remaining rooms in the tabular list of Fire Area 1 rooms without full detection and/or suppression capability do not contain any equipment or cables required for fire safe shutdown. Each of the rooms has a combustible loading that result in an equivalent fire severity of less than ten minutes. Based on the lack of safe shutdown equipment and cables, combined with the low fire loading in each of the rooms, an adequate level of protection is currently provided. The addition of automatic detection and/or suppression in the rooms would not significantly increase fire protection of safe shutdown capability in the area.

3.1.2 Fire Area 8

The following table identifies those rooms in Fire Area 8 that have less than full detection and/or full suppression capability as required by Section III.G.2.b and/or III.G.2.c criteria.

<u>Rooms</u>	<u>Description</u>	<u>Detection</u>	<u>Suppression</u>	<u>FSSD</u>
713.0-A1(*)	Aux Bldg, Boric Acid Area	Yes	No	Yes
713.0-A1(*)	Demin and Fltr Enclosure	No	No	None
713.0-A1(*)	Boric Acid Fltr Enclosures	No	No	None
713.0-A1(*)	Ion Exchgr, Demin & Fltr	No	No	None
713.0-A1(*)	Demineralizer and Fltr	No	No	None
713.0-A9	Unit 1 Mixed Bed and Cation Valve Gallery	No	No	None
713.0-A10	Seal Water Hx Room 1A	No	No	None
713.0-A11	Hx Room 1B	No	No	Yes
713.0-A12	Hx Room 1A	No	No	Yes
713.0-A15	Hx Room 2A	No	No	Yes
713.0-A16	Hx Room 2B	No	No	Yes
713.0-A17	Seal Water Hx Room 2A	No	No	None
713.0-A18	Unit 2 Mixed Bed and Cation Valve Gallery	No	No	None
713.0-A23	CVCS Valve Gallery	No	No	None
713.0-A24	WGC Valve Gallery	No	No	None
713.0-A25	Waste Gas Compressor B	No	No	None
713.0-A26	Waste Gas Compressor A	No	No	None

PART VII - DEVIATIONS AND EVALUATIONS

<u>Rooms</u>	<u>Description</u>	<u>Detection</u>	<u>Suppression</u>	<u>FSSD</u>
713.0-A30	Air Lock	No	No	None
713.0-A31	Waste Gas Analyzer Rm	No	No	None

As shown in the above listing, of the rooms within Fire Area 8 that do not have full detection and suppression capability, only five have any equipment or cables that are required for FSSD. (* Room 713.0-A1 has full detection and suppression except for the boric acid tank area between column lines A11-A14/Q-R, which only has detection, and the filter and demineralizer units inside concrete monolithic enclosures, which are not provided with detection or suppression.) Evaluations of each of the rooms with FSSD capabilities follow.

Room 713.0-A1: Auxiliary Building Room (Boric Acid Tank Area)

The general floor area on elevation 713.0 is provided with fire detection and automatic suppression except for the portion of the room over the boric acid transfer pumps, tanks, and filters located between column lines A11-A13/Q-R which is not provided with automatic suppression.

This room is an open area with a 21-foot high ceiling, a floor area of 20,337 ft², and a volume of 427,000 ft³. The room has a moderately severe in situ combustible loading which predominantly consists of insulation on cables in trays and Thermo-Lag fire barrier material. There are no significant quantities of in situ combustibles located within the curbed area that contains the boric acid pumps, tanks, and filters. The boric acid tank area has been designated as a combustible control zone (CCZ) as identified on the compartmentation drawings in Part II of the FPR.

The ceiling over this area is level and relatively unobstructed; therefore, in the unlikely event of a fire in this area, it is detected by the fire detectors in the boric acid tank area. The sprinklers in the immediate vicinity of this area control the spread of the fire until the fire brigade could extinguish it.

An adequate level of protection exists and the extension of the automatic suppression system into the area over the boric acid pumps, tanks, and filters would not significantly increase the fire protection of FSSD capability.

Rooms 713.0-A11, 713-A12, 713.0-A15, and 713.0-A16: RHR Hx Rooms 1B, 1A, 2A and 2B

Each RHR heat exchanger room is bounded by 2-hour fire rated regulatory fire barriers. Neither automatic detection nor automatic suppression capability is provided in the rooms.

Each RHR heat exchanger is a passive safe shutdown component without required cables for FSSD purposes. A fire in any room will not damage the heat exchangers or their associated valves. The combustible loads in each room results in an equivalent fire severity of less than five minutes, which is significantly less than the capabilities of the barriers that bound the room. Introduction of transient combustible materials into the rooms is minimized because access to each room is a radiological controlled location. Considering the combustible loading and 2-hour fire rated regulatory fire barriers, in combination with the lack of fire safe shutdown impact given a fire in either room, an adequate level of protection exists for Rooms 713.0-A11, 713.0-A12, 713.0-A15, and 713.0-A16. The addition of automatic suppression and detection in the rooms would not significantly increase fire protection of safe shutdown capability in the area.

PART VII - DEVIATIONS AND EVALUATIONS

Remaining Rooms of Fire Area 8 Without Full Detection and/or Suppression

The remaining rooms in the tabular list of Fire Area 8 rooms without full detection and/or suppression capability do not contain any equipment or cables required for fire safe shutdown. Each of the rooms has a combustible loading that results in an equivalent fire severity of less than ten minutes. Based on the lack of safe shutdown equipment and cables, combined with the low fire loading in each of the rooms, an adequate level of protection is currently provided. The addition of automatic detection and/or suppression in the rooms would not significantly increase fire protection of safe shutdown capability in the area.

3.1.3 Fire Area 9

Fire Area 9 contains two rooms (713.0-A6 and A8). Room 713.0-A6 is provided with full detection and suppression system capability. Room 713.0-A8, the Reactor Building Access Room, is not provided with automatic detection or suppression systems. This room contains no equipment or cables that are required for fire safe shutdown. It has a combustible loading that result in an equivalent fire severity of less than five minutes. Based on the lack of safe shutdown equipment and cables, combined with the insignificant fire loading in the room, an adequate level of protection is currently provided. The addition of automatic detection and suppression in the rooms would not significantly increase fire protection of safe shutdown capability in the area.

3.1.3a Fire Area 9-1

Fire Area 9-1 contains the VCT room itself and the entrance labyrinth into the room. The VCT room is provided with full automatic suppression, but the entrance labyrinth is not. Lack of suppression in the entrance labyrinth is acceptable because there are insufficient in situ combustibles and no credible ignition sources. The combustibles in the labyrinth consists of a small amount of lube oil associated with two valves, insulation on cables in a small junction/control boxes, and a small amount of plastics associated with light covers and an emergency lighting unit. Even considering the total quantity of hydrogen that could be in the VCT, the combustible loading for the entire area results in an equivalent fire severity that is under 5 minutes. Room 713.0-A7 is identified as a combustible control zone (CCZ), which prohibits storage of transient combustible material unless compensatory measures are established. The Control of Transient Combustibles Program (Ref. Part II, Section 4.2.73) and the Control of Ignition Sources (Hot Work) Program (Ref. Part II, Section 4.2.65) provide assurance that no credible fire could occur in the labyrinth. The lack of suppression in the entrance labyrinth does not adversely impact the fire safe shutdown capabilities of the plant.

3.1.4 Fire Area 10

Room 729.0-A6 (Nitrogen Storage Area)

See section 2.9.4 above for the justification for concluding that the addition of suppression in room 729.0-A6 would not significantly increase fire protection of safe shutdown capability in the room.

PART VII - DEVIATIONS AND EVALUATIONS

3.1.5 Fire Area 12

Rooms 729.0-A1 and 737.0-A6 (Unit 1 South Main Steam Valve Room and Air Lock)

See section 2.9.2 above for the justification for concluding that the addition of detection and suppression in rooms 729.0-A1 and 737.0-A6 would not significantly increase fire protection of safe shutdown capability in the rooms.

3.1.6 Fire Area 13

Room 729.0-A2 (Unit 1 North Main Steam Valve Room)

See section 2.9.3 above for the justification for concluding that the addition of detection and suppression in room 729.0-A2 would not significantly increase fire protection of safe shutdown capability in the room.

Room 729.0-A12 (Unit 1 Steam Valve Instrument Room A)

See section 2.9.7 above for the justification for concluding that the addition of detection and suppression in these rooms would not significantly increase fire protection of safe shutdown capability in the rooms.

3.1.7 Fire Area 14

The following table identifies those rooms in Fire Area 14 that have less than full detection and/or full suppression capability as required by Section III.G.2.b and/or III.G.2.c criteria.

<u>Rooms</u>	<u>Description</u>	<u>Detection</u>	<u>Suppression</u>	<u>FSSD</u>
737.0-A4	Air Lock	No	No	None
737.0-A7	Let Down Hx Rm	No	No	Yes
737.0-A8	Let Down Hx Rm	No	No	Yes
737.0-A11	Air Lock	No	No	None
737.0-A2	Hot Instrument Shop	Yes	No	None

As shown in the above listing, the rooms within Fire Area 14 that do not have full detection and suppression capability also do not have any equipment or cables that are required for FSSD, except for rooms 737.0-A7 and 737.0-A8. These two rooms each contain one FSSD circuit routed in conduit and have no significant ignition sources or combustible materials. Redundant circuits are located in other rooms with suppression and detection to provide separation in accordance with Section III.G.2. Each of the rooms has a combustible loading that results in an equivalent fire severity of less than ten minutes (with the exception of 737.0-A2 which has a fire severity of less than 20 minutes). Based on the lack of safe shutdown equipment and cables combined with the low fire loading in all of the rooms an adequate level of protection is currently provided. The addition of automatic detection and/or suppression in the rooms would not significantly increase fire protection of safe shutdown capability in the area.

PART VII - DEVIATIONS AND EVALUATIONS

3.1.8 Fire Areas 33 and 45: 480V Board Rooms 1B and 2B

Fire Areas 33 and 45, Rooms 772.0-A2 and 772.0-A15, are the 480V Board Rooms. Ionization smoke detectors are provided throughout both of these rooms. Preaction sprinkler systems are provided throughout both rooms except for the portion of the room that contains one set of vital battery inverters and charger. These portions of Rooms 772.0-A2 and 772.0-A15 are between column lines A6-A8/Q-R and A8-10/Q-R, respectively, and each has an area of 315 ft².

The in situ combustible load in the unsprinklered area consists of the insulation on cables in a single vertical tray located on the wall near column line A8/R in both rooms and the insulation on the internal wiring of the inverters, chargers and transfer switches. In addition room 772.0-A2 has one conduit that is wrapped with Thermo-Lag 770 (3-hour protection). The in situ combustible load in room 772.0-A2 is severe, of which the insulation on cables routed in trays and Thermo-Lag fire barrier accounts for over 90%. The in situ combustible load in room 772.0-A15 is severe, of which insulation on cables in trays and Thermo-Lag fire barriers also accounts for over 90%.

The redundant inverters and chargers in each room are located at opposite ends of the rooms and are separated by a minimum of 42 feet. Other redundant components in the rooms are located within the protected area of the rooms and are separated in accordance with Section III.G.2. A single conduit routed in the unsprinklered portion of 772.0-A2 is protected with 3-hour fire rated Thermo-Lag 770.

An adequate level of fire protection is provided for redundant FSSD components in the two rooms. Extension of the suppression systems into the small unprotected areas would not significantly increase fire protection of safe shutdown capability in the area.

3.1.9 Fire Area 65:

The below listed rooms in Fire Area 65 have less than full detection and/or full suppression capability as required by Section III.G.2.b and/or III.G.2.c criteria.

<u>Rooms</u>	<u>Description</u>	<u>Detection</u>	<u>Suppression</u>	<u>FSSD</u>
676.0-A17	Unit 2 Pipe Gallery and Chase	Yes	No	Yes
692.0-A24	Unit 2 Pipe Gallery and Chase	Yes	No	Yes
713.0-A29	Unit 2 Pipe Gallery and Chase	Yes	No	Yes

Room 676.0-A17, 692.0-A24, and 713.0-A29: Auxiliary Building Unit 2 Pipe Chase

The pipe chase extends from elevation 676.0 to elevation 737.0 and is comprised of Rooms 676.0-A17, 692.0-A24, and 713.0-A29. The pipe chase is separated from other fire zones on elevations 676, 692, 713, and 737 by reinforced concrete construction that is equivalent to at least 2-hour fire rated barriers. Smoke detectors are installed in the pipe chase. The in situ combustible loading of the pipe chase is insignificant.

The pipe chase contains one path of FSSD equipment consisting of a Volume Control Tank (VCT) level transmitter and associated cabling, and cables for narrow and wide range level

PART VII - DEVIATIONS AND EVALUATIONS

indication for two steam generators. The redundant path instrumentation is located outside the pipe chase. The chase also contains redundant RHR mini-flow valves and Containment Spray pump suction valves. These valves are required for FSSD only if a fire causes spurious pump actuation of an RHR or Containment Spray pump. Cables that could cause such spurious pump actuation are located outside the pipe chase.

Transient combustibles are minimized in the pipe chase. Rooms 676.0-A17 and 692.0-A24 are locked rooms with access controlled by Radiation Protection personnel. Room 713.0-A29 is a combustible control zone. Based on these considerations, fires involving transient combustible materials are not considered to be a credible event.

The addition of automatic fire suppression in the pipe chase would not significantly enhance the fire protection of FSSD capability of the plant. This is based on the insignificant combustible loading, access limitations and administrative controls to limit the introduction of transient combustible materials, adequate compartmentation, and provision of fire detection in the pipe chase.

3.1.10 Fire Area 71

Fire Area 71 consists of Rooms 713.0-A19 and -A21. Room 713.0-A19 is provided with full detection and suppression system capability. Room 713.0-A21, the Reactor Building Access Room, is not provided with automatic detection or suppression systems. This room contains no equipment or cables that are required for fire safe shutdown. It has a combustible loading that results in a fire severity classification of insignificant.

Based on the lack of safe shutdown equipment and cables, combined with the insignificant fire loading in the room, an adequate level of protection is currently provided. The addition of automatic detection and suppression in the rooms would not significantly increase fire protection of safe shutdown capability in the area.

3.1.10a Fire Area 71-1

Fire Area 71-1 contains the VCT room itself and the entrance labyrinth into the room. The VCT room is provided with full automatic suppression, but the entrance labyrinth is not. Lack of suppression in the entrance labyrinth is acceptable because there are insufficient in situ combustibles and no credible ignition sources. The combustibles in the labyrinth consists of a small amount of lube oil associated with two valves, insulation on cables in small junction/control boxes, and a small amount of plastics associated with light covers and an emergency lighting unit. Even considering the total quantity of hydrogen that could be in the VCT, the combustible loading for the entire area results in an equivalent fire severity that is under 5 minutes. Room 713.0-A20 is identified as a combustible control zone (CCZ), which prohibits storage of transient combustible material unless compensatory measures are established. The Control of Transient Combustibles Program (Ref. Part II, Section 4.2.73) and the Control of Ignition Sources (Hot Work) Program (Ref. Part II, Section 4.2.65) provide assurance that no credible fire could occur in the labyrinth. The lack of suppression in the entrance labyrinth does not adversely impact the fire safe shutdown capabilities of the plant.

PART VII - DEVIATIONS AND EVALUATIONS

3.1.11 Fire Area 72

Room 729.0-A11 and 737.0-A10 (Unit 2 South Main Steam Valve Room and Air Lock)

See section 2.9.6 above for the justification for concluding that the addition of detection and suppression in these rooms would not significantly increase fire protection of safe shutdown capability in the rooms.

3.1.12 Fire Area 73

Room 729.0-A10 (Unit 2 North Main Steam Valve Room)

See section 2.9.5 above for the justification for concluding that the addition of detection and suppression in these rooms would not significantly increase fire protection of safe shutdown capability in the rooms.

Room 729.0-A13 (Unit 2 Steam Valve Instrument Room B)

See section 2.9.8 above for the justification for concluding that the addition of detection and suppression in these rooms would not significantly increase fire protection of safe shutdown capability in the rooms.

Room 729.5-A17: (Unit 2 Shield Building Vent Radiation Monitoring Room)

Room 729.5-A17 is separated from the Unit 2 Reactor Building by 36-inch thick reinforced concrete that has been assigned a fire rating of 3-hours. The room is separated from adjacent Auxiliary Building rooms by 12-inch thick reinforce concrete, but these barriers have not been assigned a fire resistance rating. Entry to room is via a heavy duty hollow metal door from the Yard area. The room has a floor area of 107-ft² and a ceiling height of 8-feet. The combustible loading in the room is classified as insignificant and is due to very small quantities of lubricating oil in a pump and plastics associated with a telephone, light covers and electrical panels. There are no credible ignition sources in the room. Nearby Yard hydrants are available for fire brigade use.

Procedures NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" ensure that appropriate fire preventive control measures are taken to ensure that introduction of transient combustibles and/or ignition sources do not present a fire hazard to components located in the room. Therefore, there is insignificant threat from transient combustibles to any component or cable (cables are routed in conduit) required for normal plant operation or fire safe shutdown operation.

Since there is insignificant threat from transient combustibles; very low quantities of in situ combustible material (what is there is dispersed throughout the room); and no credible ignition sources, it is concluded that the addition of automatic suppression and detection in room 729.5-A17 would not increase the safety of the plant.

PART VII - DEVIATIONS AND EVALUATIONS

3.1.13 Fire Area 77

Room 2RA1: Unit 2 Accumulator Room 1

See section 2.9.14 above for the justification for concluding that the addition of detection and suppression in these rooms would not significantly increase fire protection of safe shutdown capability in the rooms.

Room 2RA2: Unit 2 Accumulator Room 2

See section 2.9.15 above for the justification for concluding that the addition of detection and suppression in these rooms would not significantly increase fire protection of safe shutdown capability in the rooms.

Room 2RA3: Unit 2 Accumulator Room 3

See section 2.9.16 above for the justification for concluding that the addition of detection and suppression in these rooms would not significantly increase fire protection of safe shutdown capability in the rooms.

Room 2RA4: Unit 2 Accumulator Room 4

See section 2.9.17 above for the justification for concluding that the addition of detection and suppression in these rooms would not significantly increase fire protection of safe shutdown capability in the rooms.

Room 2RF1: Unit 2 Fan Room 1

See section 2.9.18 above for the justification for concluding that the addition of detection and suppression in these rooms would not significantly increase fire protection of safe shutdown capability in the rooms.

Room 2RF2: Unit 2 Fan Room 2

See section 2.9.19 above for the justification for concluding that the addition of detection and suppression in these rooms would not significantly increase fire protection of safe shutdown capability in the rooms.

Room 2RIR: Unit 2 Reactor Building Instrument Room

See section 2.9.13 above for the justification for concluding that the addition of detection and suppression in these rooms would not significantly increase fire protection of safe shutdown capability in the rooms.

Room 2RI: Unit 2 Reactor Building – Inside Crane Wall [2RI-1(0° to 90°), 2RI-2 (90° to 180°), 2RI-3 (180° to 270°), and 2RI-4 (270° to 360°)]

See section 2.9.20 above for the justification for concluding that the addition of detection and suppression in these rooms would not significantly increase fire protection of safe shutdown capability in the rooms.

PART VII - DEVIATIONS AND EVALUATIONS

Room 2RO: Unit 2 Reactor Building – Outside Crane Wall [2RO-1(0° to 90°), 2RO-2 (90° to 180°), 2RO-3 (180° to 270°), and 2RO-4 (270° to 360°)]

See section 2.9.21 above for the justification for concluding that the addition of detection and suppression in these rooms would not significantly increase fire protection of safe shutdown capability in the rooms.

3.2 Containment Purge Air System Return And Exhaust Air Duct Openings Protection Between 713.0-A6 Pipe Gallery and the Unit 1 Annulus and the Unit 2 Pipe Gallery (713.0-A19) and Unit 2 Annulus

REQUIREMENT - The walls separating the Unit 1 pipe gallery (713.0-A6) from the Unit 1 Annulus and the Unit 2 pipe gallery (713.0-A19) from the Unit 2 Annulus are 3-hour regulatory fire barriers. The containment purge air system return and exhaust ducts penetrate these walls. The penetrations (three per unit) are not provided with fire dampers.

EVALUATION - The containment purge air system ductwork penetrating the fire barriers are constructed of ¼" steel plates. The ductwork is rigidly connected to the wall opening by steel angle irons embedded in the structural concrete. The wall penetrations are not straight through openings but are instead offset openings to provide radiation protection. Beyond the opening, the rectangular portion of the duct transitions to a round duct constructed of spiral weld 10 gauge steel and terminates into the stainless steel housing of the purge air filtration unit. A flexible connection in Room 713.0-A6 is provided between the purge air duct and the embedded containment duct penetration. The flexible connection is protected with 3M M20A fire barrier mat to give a 3-hour rating to the connection. The flexible connection in room 713.0-A19 is protected with 3M E54C (M20A is no longer available and E54C is a superior fire rated replacement for M20A) fire barrier mat to give a 3-hour rating to the connection.

No vent openings exist in the ductwork within the room. The area underneath the ductwork in Room 713.0-A6 and 713.0-A19 are combustible control zones (CCZ) to limit potential transient combustibles under the penetrations. On the containment side of the wall, the ¼" steel plate ductwork continues for more than 20 feet within the annulus. Each unit's annulus is also a combustible control zone (CCZ) to limit potential transient combustibles in the area.

The combination of ductwork construction, its attachment to the wall, and the offset wall opening will provide an equivalent level of protection similar to that of a fire damper exceeding a 2-hour rating. Modification of the existing ductwork would not significantly increase fire protection of safe shutdown capability in either area.

3.3 Adequacy of HPFP Pumps

REQUIREMENT - Section E.2.c of Appendix A to BTP 9.5-1 identifies that the number of fire pumps provided at WBN should be based on the number required to satisfy the largest flow and pressure demands of the fire protection water system (including sprinkler and hose stream requirements) in safety related areas, with one pump inactive.

EVALUATION - The WBN fire protection program is based on a defense-in-depth design that incorporates fire detection and suppression capabilities, separation of redundant safe shutdown equipment and cables by either distance or fire barriers, and administrative controls of combustible materials. The intent of the defense-in-depth design is to prevent fires from

PART VII - DEVIATIONS AND EVALUATIONS

starting, detect fires in their incipient stages, suppress those fires that occur, limit fire damage by compartmentation, and design plant systems such that a fire will not prevent essential plant safety functions from being performed. Plant locations/rooms that contain redundant safe shutdown capabilities are provided with 3-hour fire barriers for one train of safe shutdown capability, or one train in the location/room is provided with either 1-hour fire barriers and/or 20 feet of separation with automatic detection and suppression systems. Specific locations/rooms that have significant obstructions between ceiling-based sprinklers and the floor are also provided with obstruction level sprinklers to protect against floor-based fires. WBN has taken a conservative approach to regulatory compliance in the area of fire safe shutdown capability, with extensive modifications performed to ensure that the spacing and location of sprinkler heads conform to NFPA code requirements. The detectors that actuate the preaction sprinkler systems in rooms that contain redundant safe shutdown capabilities have been located in accordance with code requirements. This approach to regulatory compliance ensures the most rapid and effective application of sprinkler water discharge to postulated fires, thereby minimizing the time that a fire can grow and burn freely prior to sprinkler system actuation.

NRC Guidance and Regulatory Documents

The HPFP pumps at WBN are evaluated against the guidelines of BTP 9.5-1, Appendix A, Section E.2.c for each location provided with automatic fire protection water suppression capabilities. The HPFP pumps are also evaluated as Safe Shutdown components in the Appendix R fire safe shutdown analysis. Appendix A guidance and Appendix R criteria cover overlapping issues since they both address fire safe shutdown capability.

The guidance of Appendix A is reviewed in context of the requirements of Appendix R where issues overlap due to the differences in regulatory significance between the two documents. Appendix R was promulgated to resolve issues between NRC and utilities about the acceptable methods of satisfying Appendix A guidelines. While both documents address safe shutdown capability given a fire, three specific sections of Appendix R are applicable to all plants, even if the associated issues had been closed out and accepted by NRC as part of the Appendix A review process. The three specific areas are: III.G (fire protection of safe shutdown capability); III.J (emergency lighting); and III.O (RCP lube oil collection system). Only the separation requirements of Appendix R Section III.G are applicable to this evaluation.

Appendix A to BTP 9.5-1 Guidelines

BTP APCS 9.5-1 and its Appendix A address fire safe shutdown capability. The purpose of the BTP is to provide assurance, through a defense-in-depth design, that a fire will not prevent the performance of necessary plant shutdown functions. Appendix A is to identify alternate acceptable fire protection designs when compared to the BTP. The ultimate purpose of both documents is as stated in Section 1.0 of the BTP, which is to ensure through a defense-in-depth design that a fire will not prevent the performance of necessary plant shutdown functions.

The issue of defense-in-depth as applied to fire pumps is addressed in Appendix A, E.2.c, which states in part "If pumps are required to meet system pressure or flow requirements, a sufficient number of pumps should be provided so that 100% capacity will be available with one pump inactive (e.g., three 50% pumps or two 100% pumps)." This criterion is applied to establish the total number of pumps necessary to be operable during normal plant conditions and to ensure, through defense-in-depth, that fire will not prevent the fire protection water system from performing its intended system functions.

PART VII - DEVIATIONS AND EVALUATIONS

WBN has demonstrated that the guidance of Appendix A, Section E.2.c is met by installation of four safety-related ASME electric pumps to supply the fire protection water distribution system. Each of the four electric pumps located in the IPS can provide 50% of the necessary pressure and flow to the largest demanding fire protection water system serving safety-related areas. A 100% capacity diesel fire pump with auto-start on system pressure and annunciation in the main control room has also been provided. The diesel pump is located in the yard. Compensatory actions have been developed for whenever less than three of the pumps are operable during normal operation with the diesel fire pump being one of the three pumps. WBN thereby exceeds Section E.2.c guidance for three 50% pumps by ensuring operability of two 50% electric fire pumps and the 100% capacity diesel fire pump.

The largest demanding fire protection water system in non-safety related areas of the plant is a fire that involves transformers in the yard. For this event it is assumed that three transformer water spray systems operate simultaneously. This assumption is made due to the close proximity of the three main transformers. Two electric fire pumps and the diesel fire pump, for which operability requirements are imposed, provide the necessary pressure and flow for this fire in the Yard. WBN maintains the operability of all four electric fire pumps and the diesel fire pump to the full extent practical in accordance with standard engineering practices, maintenance procedures, and testing and inspection programs. However, WBN does not impose operability requirements and compensatory actions to ensure that four electric fire pumps and the diesel fire pump are available in the event of a transformer fire in the yard.

Appendix A to BTP 9.5-1 requires that transformers be located at least 50 feet from buildings containing safety-related systems. The transformers are at least 50 feet south of the south wall of the turbine building. The nearest safety-related building to the transformers is the control building. The turbine building, which is non-safety-related, is located in between the transformers and the control building. While transformer suppression is not required to meet regulatory criteria or guidance documents, the fire suppression system for the transformers represents adequate fire protection practice for the type of fire hazard associated with the transformers.

Appendix R Requirements

The requirements of Appendix R and GL 81-12, Enclosure 1, and the response to Question 7.2 in Generic Letter 86-10, are applied in the evaluation of the HPFP pumps as safe shutdown equipment. Section III.G of Appendix R states that fire protection features shall be provided to ensure that one train of systems remains free of fire damage.

All HPFP equipment is initially assumed operable per Generic Letter 86-10, response to Question 7.2, which states that worst-case fires need not be postulated to be simultaneous with non-fire related failures. As such, at the time the worst-case Appendix R fire is initiated, at least three of the pumps provided to satisfy the guidelines of Section E.2.c of Appendix A are considered operable.

The consequences of a full analysis volume burnout is evaluated on all functions in accordance with the criteria of GL 81-12, Enclosure 1, Section 3.8 to ensure that the required system function is met by the equipment protected from the effects of the postulated burnout. In the case of the HPFP pumps, for a fire in an area, the HPFP system flow for the area are compared with the capacity and capability of the pump(s) unaffected by the fire.

PART VII - DEVIATIONS AND EVALUATIONS

The WBN Appendix R safe shutdown analysis guarantees that sufficient pump capacity remains free of fire damage and will be available for fire suppression activities in safety-related areas of the plant. WBN has demonstrated that the requirements of Appendix R Section III.G are met by identifying the specific pumps which survive the Appendix R fire in the location of the fire.

HPFP Hydraulic Calculation Results

The fire suppression system design criteria incorporated into the hydraulic calculations include the necessary fire protection water flow and pressure for the most hydraulically remote location of each system, hose stream application (500 gpm), and those portions of the RSW loads that are not automatically isolated from the fire protection water system upon fire pump start due to a fire in safety-related areas. Four conditions are evaluated in the calculations to demonstrate hydraulic capabilities with clean pipe and corroded pipe to reflect a 40 year service life with and without a single impairment. Clean pipe calculations were based on actual pipe inside diameters and a Hazen-Williams C-factor of 100. Unlined steel pipe corrosion calculations were based on actual pipe inside diameters minus 8/10ths of an inch and a C-factor of 55 (i.e., the expected condition at the end of a 40 year service life).

The results of clean pipe calculations demonstrate that the available number of pumps in each location per the Appendix R analysis can meet the design criteria for fire suppression systems. The results of corroded pipe calculations demonstrate that approximately the highest hose stations of three standpipe systems may not be capable of providing their design basis flows at 40 years. These systems are, however, capable of providing design basis flows for a number of years and will be trended to ensure functionality.

WBN has previously committed to testing fire pump capabilities at the rated head and at two diverse points, one above and one below the rated head. WBN also committed to a 3 year evaluation period (beginning at startup) to monitor the performance of the HPFP System. During the 3 year evaluation period, testing of the HPFP distribution system was performed once a year. The results of the monitoring program were to evaluate the adequacy of the existing fire suppression systems for testing frequency or possibly replacement plans. The results of this evaluation (Reference 4.2.59) determined that the appropriate testing frequency is once every three years which is in compliance with industry standards.

To address the adequacy of the specific standpipe systems that may not provide design basis flows at 40 years, WBN will perform start-up flow tests on the specific systems to assure that adequate flow and pressure can be delivered. This start-up testing has become the hydraulic baseline for the systems. Flow tests are conducted once per year to ensure the systems can meet design basis requirements. The data is trended to promote corrective actions prior to the systems becoming inoperable. (Note: The performance of the flow tests was conducted once per year starting at Unit 1 fuel load. After three years of test data, TVA corporate engineering evaluated the data and determined that WBN could extend the testing to once per every three years to match industry practice (see FPR Part II, Section 12.1.)

Summary of HPFP Adequacy Evaluation

The impacts of these issues on the availability of HPFP capabilities before, during, and after the fire are as follows:

1. WBN is designed to have three 50% fire pumps installed based on the largest demand to safety related areas per BTP 9.5-1 Appendix A Section E.2.c guidance. WBN

PART VII - DEVIATIONS AND EVALUATIONS

exceeds the guidance of Appendix A in this regard by ensuring operability (with associated compensatory actions) of two 50% capacity electric fire pumps and the 100% capacity diesel fire pump.

2. Appendix R, via Generic Letter 86-10 Q&A 7.2, allows WBN to assume that equipment required for fire safe shutdown is operable at the time the fire occurs; as such, at least three fire pumps are operable at the time of the fire.
3. Appendix R requires that one train of systems required to support the safe shutdown function must be available to mitigate the impact of the worst case fire in (1) any plant location that contains systems, components, or cables required for safe shutdown, and (2) plant locations that present an exposure fire hazard to such FSSD locations.
4. WBN has evaluated the requirements for the HPFP system during the worst case Appendix R fire and has demonstrated that the available numbers of fire pumps are capable of meeting HPFP system demands in the location of the Appendix R fire.
5. WBN trends the performance of the HPFP system, and the specific standpipe systems that may not provide design basis flow for 40 years, to promote corrective actions prior to the systems becoming inoperable.

The Safe Shutdown Analysis sections in Part VI of the WBN Fire Protection Report identify on a location by location basis the number of fire pumps that are not affected by a fire in the location and which are available for fire suppression activities.

3.4 Large Fire Dampers

REQUIREMENT - Fire dampers shall be tested and approved by a nationally recognized laboratory and the tests shall bound the installed configurations.

EVALUATION - Fire dampers 1-ISD-31-3807 and 2-ISD-31-3882 are installed in wall openings that are approximately 100-inches by 25-inches. The dampers are 98 $\frac{5}{8}$ -inches by 24 $\frac{1}{2}$ -inches. The maximum size damper shown on the vendor drawing is 90-inches by 72-inches.

The wall openings for each of the above listed dampers is approximately 100-inches wide by 25-inches high as shown on drawings 48N1251-1 and -3. The overall damper size to protect the openings is 98 $\frac{5}{8}$ -inches wide by 24 $\frac{1}{2}$ -inches high. Fire tests reports dated June 15, 1984 and July 19, 1984 document the results of tests conducted by Underwriters Laboratories (UL) for Ruskin (damper manufacturer) on large size damper installations. The report dated December 12, 1984 documented UL's evaluation of TVA's installation of the large dampers.

The large damper configurations in the two tests (100-in. by 91-in. and 100-in. by 72-in.) both passed the 3-hour fire endurance acceptance criteria by remaining in place and not having an opening in the damper configuration. Both configurations however failed the hose stream test at the end of the 3-hour fire exposure. UL stated in the December 12, 1984 report that, "It is judged that the reduction in size from 100 by 91 in. to 100 by 36 in. would significantly minimize the buckling and twisting of the vertical mullions noted in the June 15, 1984 Report".

UL also stated that the maximum sizes of dampers covered by their classification and follow-up service program are 90-inches wide by 72-inches high in multiple assemblies (maximum

PART VII - DEVIATIONS AND EVALUATIONS

sections being 30-inches wide by 36-inches high) and that dampers exceeding this are not eligible to be labeled.

It is however concluded that the large damper installations at Watts Bar provide adequate protection to their HVAC penetration. This conclusion is based on the following:

1. The individual sections are smaller than the maximum allowed for the UL listed multiple section damper assemblies. Watts Bar damper sections are approximately 24½-in. by 24-in. where the approved sections are 30-in. by 36-in.
2. The overall damper dimensions for the Watts Bar installations are 98⅝-in. by 24½-in.; however, the UL report refers to sizes of 100-in. by 36-in. The smaller overall assembly would further minimize the buckling and twisting of the vertical mullions.
3. The listed damper assembly is 3-sections wide by 2-sections high, but the Watts Bar assembly is only one section high. This makes the Watts Bar assembly more rigid and less likely to experience significant buckling or twisting of the vertical mullions.
4. The tested assemblies were subjected to a 3-hour fire test. The Watts Bar assemblies are only designed to be rated for 1½-hours (good for installations in fire barriers rated up to 2-hours). The tested assemblies passed the fire endurance tests but allowed small openings at the side of the damper curtains which allowed the passage of water. This resulted in a failure of the hose stream test. Since the failure occurred at the end of a 3-hour test, it is reasonable to conclude (as UL did) that the smaller assembly would not be subjected to significant buckling or twisting. The reduction in exposure to the fire by one half (1½-hour duration verses 3-hour) would also significantly reduce buckling and twisting. Therefore, it is conservative to conclude that the Watts Bar configurations would pass the hose stream test and provide an adequate level of fire protection to the HVAC penetration.

3.5 Fire Damper in VCT Room Fire Door

REQUIREMENT - Fire doors shall be tested and approved by a nationally recognized laboratory and the tests shall bound the installed configuration.

EVALUATION - The door (A63) into Unit 1 Volume Control Tank (VCT) Room was purchased with a fire damper and was a labeled fire door. The damper was a blade type damper and restricted the air flow through the opening. The damper was replaced with a curtain type damper. The fire door has not been tested with the curtain type damper.

Door A63 is in the wall that separates the VCT Room (713.0-A7) from the Pipe and Valve Gallery (713.0-A6). The Pipe Gallery has a combustible loading of approximately 150,000 Btu/ft² of which 82% is attributed to the cable trays (Thermo-Lag fire rated wrap on some trays and cable insulation on the other trays). The remaining combustibles consist of lube oil and grease associated with valves, fans, motors, wiring insulation associated with various panels and control stations, used C-zone clothing and waste at the step off pads, and other miscellaneous items (e.g., light covers, telephone, etc.). The VCT Room has a combustible loading of only 3,200 Btu/ft². Both the pipe gallery and the VCT room (except the entrance labyrinth) are provided with automatic detection and suppression.

PART VII - DEVIATIONS AND EVALUATIONS

The entrance to the Unit 1 VCT Room (door A63) is located near the entrance to the Pipe Gallery (door A62). Due to the close proximity of the two entrances, there is no significant amount of in situ combustibles located near the door. The access/egress path to the Unit 1 Reactor Building is through door A62; therefore, the storage of transient combustibles does not present a hazard.

The opening size in the door did not change. Only the type of damper changed (blade type to curtain type). The new damper is a damper/sleeve assembly and is installed with the damper inside the door. The sleeve extends a short distance on each side of the door (i.e., it is not cut off flush with the door as was the original damper). The change of damper types does not adversely affect the fire resistance capability of the fire door. The fire protection capability is considered to be adequate and equivalent to the door with the original damper for the following reasons:

1. The combustible loading in the immediate vicinity of the door is insignificant
2. The new damper is a listed damper
3. Rooms on both sides of the door are provided with automatic fire detection and suppression

Therefore, the change from a blade type damper to a curtain type damper is acceptable.

3.6 Fire Barrier Rating

REQUIREMENT – Appendix R, Section II.C.4 states: “Fire barriers or automatic suppression systems or both shall be installed as necessary to protect redundant systems or components necessary for safe shutdown.”

EVALUATION – There are rooms as shown in Part I, Table I-1 and Part VI for which the Combustible Load, Fire Severity (i.e., duration) exceeds the fire rating of the barrier (e.g. Auxiliary Building Corridor 713.0-A1 combustible loading exceeds 2-hours).

As discussed below, Watts Bar’s “Defense-in-depth” fire protection program serves to compensate for these higher Combustible Loadings. The program addresses combustible loads, preventing fires from starting, and detecting/extinguishing fires that occur. The fire barriers separating the Auxiliary, Control and Turbine Buildings from each other are 3-hour fire rated barriers. The individual rooms within each of these building are separated from each other by combinations of 3-hour, 2-hour and 1-hour fire barriers. Each of the rooms shown in Part I, Table I-1 that have combustible loads that exceed the fire barrier rating are provided with automatic detection and suppression.

Combustible Loads

In most of these rooms, the combustible load is due primarily to insulation on cables routed in cable trays. The calculations conservatively assume the cable trays are 100% filled with cables when in reality the cable trays are not full and sometimes only contain a few cables. Similarly, the calculations conservatively assume maximum quantities of other combustibles such as transformer oil, lubricating oil, etc. The calculation further assumes complete combustion of the fuel. WBN has a Transient Combustible Loads program to minimize temporary/periodic risks from an exposure fire.

PART VII - DEVIATIONS AND EVALUATIONS

Fire Prevention

Circuit protective devices (breakers/fuses) ensure that an electrical fault on a cable will be cleared prior to the insulation reaching its auto-ignition temperature; therefore, an internally generated cable tray fire is not a credible fire ignition source. The transient combustible control program (Part II, Section 10.0) minimizes the potential for a significant exposure fire. The control of ignition sources (Part II, Section 11.0) requires that a fire watch is posted for hot work (e.g. welding, cutting, grinding, etc.) except for unique situations like underwater welding.

Detection/Extinguishment of Fires

It would take a large exposure fire to generate sufficient heat energy to ignite the insulation on the cables that are either IEEE 383 fire retardant rated or coated with a fire retardant material. A fire that would produce a heat release rate great enough to cause ignition of the cable insulation would activate the fire detection and the automatic suppression. The fire detection in these areas will provide early warning of a fire to the Main Control Room. The majority of the sprinkler heads have a nominal activation temperature rating of 212 °F. For areas with CO₂ suppression, at least one detection zone uses thermal fire detection instruments which are rated at either 135 °F or 200 °F. The automatic suppression would suppress any postulated fire such that the fire would not present a credible challenge to the existing barriers. The fire brigade response to the fire provides additional defense-in-depth to ensure that the fire would not challenge the barrier.

Special Cases

Rooms 755.0-C9 and -C10 are the Operations Conference Room and Shift Engineer's Office and the combustibles are paper and furniture (none of which are ignition sources). There is no significant ignition source in either room and the rooms are in frequent use which would minimize the potential for a fire to propagate into a large fire. Room 742.0-D2 is the Diesel Generator Building Lube Oil Storage room and the lube oil in the 55 gallon drums accounts for 99.9% of the combustibles. There is no credible ignition source in the room and the steel barrels themselves would help prevent the spread of a fire.

Rooms 713.0-A1, 772.0-A2, 772.0-A15, and each Reactor Building Annulus have part of the area not covered by the sprinkler systems. These areas without sprinklers are limited and the combustible loading in these non-sprinkled areas is limited.

Conclusion

The WBN Fire Protection Program relies on defense-in-depth to minimize the potential for a fire by limiting combustible material, preventing fires from occurring, early detection of a fire that might occur, limiting the spread of the fire by fire rated barriers and automatic suppression, rapid response by a well trained, dedicated on-site Fire Brigade and supplemented with a local fire department if needed. Appendix R, Section III.G.2.c allows a combination of 1-hour fire barrier and automatic suppression and detection as an acceptable means of separating redundant safe shutdown components. The conservative determination of the in situ combustible loading (e.g. all cable trays are assumed to be 100% loaded of which some only have a few cables) and the defense-in-depth of the fire prevention/protection provides a high degree of confidence that the fire rated barriers at WBN would prevent any credible fire that might occur from impacting an adjacent room.

PART VII - DEVIATIONS AND EVALUATIONS

4.0 Deviations to BTP 9.5-1 Appendix A

Deviations from the guidance of Appendix A to BTP 9.5-1 are identified in this section. They address: (1) fire rating of fire doors; (2) Control Building stair openings; (3) lengths of fire hose provided at hose stations; (4) fire barrier between diesel generator storage tanks and diesel generator corridor; (5) the lack of automatic detection on the Refuel Floor, and (6) embedded CO₂ control panel in fire barrier in Diesel Generator Building Corridor. Additional alternatives to the guidelines of Appendix A are identified in part VIII of the FPR.

4.1 Fire Doors

REQUIREMENT - Section D.1.j of BTP 9.5-1 Appendix A states that door openings should be protected with equivalent rated doors, frames, and hardware that have been tested and approved by a nationally recognized laboratory.

DEVIATION - A number of fire doors have been altered by the addition of signs and security hardware, or have been damaged and repaired onsite.

EVALUATION - To ensure that modifications which have been made to fire doors do not compromise the fire barrier, TVA contracted with Underwriters Laboratories, Inc. (UL), to provide an evaluation of the fire doors as they existed in the plant. TVA letter from J. W. Hufham to E. Adensam (NRC) dated January 4, 1985, summarized their evaluation and provides recommendations for modifications necessary to ensure the performance of the fire doors. Appropriate door repair criteria for fire doors is documented and controlled by General Engineering Specification -73, "Installation, Modification and Maintenance of Fire Protection Systems and Features". Generally TVA has addressed the recommendations of UL as follows:

1. Signs installed on fire doors are listed by UL for use on hollow-core, metal, swinging fire doors with up to a 3-hour fire rating.
2. Gasket material is approved for use on fire doors.
3. Conduit penetrations into the door frame are anchored either in accordance with ILL.2 of UL letter or by a continuously welded fitting (item 4 of UL letter).
4. Small holes (3/16-inch or smaller diameter) in fire doors and frames may be repaired by either of the following methods:
 - (1) Slightly dimple the hole 1/16-inch, weld the hole completely closed, and grind smooth.
 - (2) Install self-sealing rivets or steel pan head self-tapping sheet metal screws to seal the holes closed.

Holes 3/16-inch to 2 inches in diameter or rectangular holes with the longest side being less than 1-1/2 inches may be repaired by welding a 16 gauge steel plate overlapping the edge of the hole by a minimum of 3/4-inch.

Other repair criteria must be reviewed and approved by a fire protection engineer to ensure that the fire resistance rating of the fire door is maintained.

PART VII - DEVIATIONS AND EVALUATIONS

5. Hardware on fire doors are checked to ensure they are UL listed or FM approved.
6. Fire doors, except A188, C49, and C50, are adjusted to ensure the gap between the door and the frame is 3/16-inch or less. Fire door frames with excessive gaps between the frame and wall openings are provided with spacers and with 1-1/2" x 1/2", 12 gauge angles in accordance with ILL.1 of UL letter. Fire rated sealant is used to seal the small openings caused by slight irregularities in the wall construction.

The frames for doors A188, C49, and C50 have been filled with grout and cannot be moved to adjust the door-to-frame gaps without destroying the frames. TVA has left the doors as-is with gaps of up to 3/8-inch. Door A188 is located between a mechanical equipment room (772.0-A10) and 480-V board room 2A (772.0-A16). Doors C49 and C50 are located between the main control room (755.0-C12) and 480-V shutdown board room 1B (757.0-A5) and 2A (757.0-A21), respectively. These rooms, except for the main control room, are provided with preaction sprinkler systems actuated by cross-zoned ionization smoke detectors.

The automatic suppression systems in the Auxiliary Building and manual firefighting actions that could be rapidly initiated in the main control room provide adequate compensation for the excessive door-to-frame gaps on the subject fire doors.

7. Labeled fire doors and frames that are missing their labels have been evaluated. If documentation from the manufacturer is on file indicating that the door assembly was originally shipped to WBN as UL labeled equipment or can be evaluated by a fire protection engineer as providing equivalent protection as a labeled door, that door assembly will not be replaced.
8. Fire doors with unlabeled louvers were provided by the manufacturer as a labeled assembly; therefore, no additional action is required.

The following information addresses responses to specific findings that were not covered by UL's general recommendations:

9. A continuous astragal that extends the full height of the door is provided on door A189.
10. Doors A188, C49, and C50 were supplied as part of labeled assemblies and the existing piano hinges are an integral part of these assemblies. Although the hinges are not labeled separately, they are identical to the piano hinges that were used to obtain the UL approval for the assemblies; therefore, no corrective action is required.

The corrective actions identified above will restore the fire doors to their required fire resistive rating, except for doors A188, C49, and C50. Adequate compensation is provided for these gaps as discussed above; therefore, the doors were left as-is.

Door A154 (shown on Figure II-31A) and doors W10A and W10B (shown on Figure II-36A) are special purpose doors. Door manufacturers do not provide these types of doors as an UL listed door. They are of heavy welded steel construction with multiple latch points on the sides, top, and bottom and provide a level of fire resistance that is equivalent to a fire rated door.

PART VII - DEVIATIONS AND EVALUATIONS

These types of doors are similar to the doors evaluated, accepted, and submitted to the NRC for approval (Letter from L. M. Mills to A. Schwencer dated 9/9/80) as providing an equivalent fire rating commensurate to the fuel loading in the areas or cells they separate the doors submitted to the NRC were accepted (SER June 1982). Therefore, based upon the similarity with these doors, doors A154, W10A, and W10B are acceptable.

4.2 Openings in Fire Walls

REQUIREMENT - Section D.1.j of Appendix A to BTP 9.5-1 identifies that fire area boundaries should be capable of withstanding the fire hazards to which they could be exposed. NRC generic letters and guidance documents require that penetrations in walls, floors, and ceilings forming part of a fire area boundary be protected with seals or closure devices having a fire resistive rating equivalent to that required of the barrier.

DEVIATION - A 6-inch wide by 3-inch deep gutter penetrates each stairwell enclosure (Stairwells C1 and C2) from the corridor (Room 692.0-C11) in the control building.

JUSTIFICATION - The gutter penetrates the walls separating the stairwells from the corridor. Floor drains, one in each stairwell and two in the corridor, are provided in the gutter. The only in situ liquids on this elevation is the 35 gallons of lube oil associated with each electrical board room chiller packages (O-CHL-31-128 and -129) that are located in the Unit 2 mechanical equipment room. The room is separated from stairwell C2 by a two-hour reinforced concrete wall.

The in situ combustible loading for the corridor is low and results in an equivalent fire severity of less than 20 minutes. The corridor is provided with a preaction sprinkler system that is actuated by an ionization detection system. Standpipe and hose stations are in the two stairwells. Portable extinguishers are provided in the corridor.

The two stairwells are located at opposite ends of the corridor (approximately 170 feet apart). Postulated fires would not prevent fire brigade access to the corridor from both stairwells at the same time. The unprotected openings caused by the gutter do not pose a significant hazard to the fire protection capability and are acceptable.

4.3 Manual Hose Stations

REQUIREMENT - Section E.3.d of Appendix A to BTP 9.5-1 identifies that interior manual hose installations should be able to reach any location with at least one effective hose stream. To accomplish this, standpipes with hose connections equipped with a maximum of 75 feet of 1-1/2 inch woven jacket lined fire hose and suitable nozzles should be provided.

DEVIATION - Manual hose stations with 100 feet of 1-1/2 inch UL listed or FM approved fire hose are located throughout the plant. Some hose stations are provided with more than 100 feet of hose.

JUSTIFICATION - The standpipe and hose stations at WBN have been designed along the guidelines of NFPA 14 which allow up to 100 feet of hose connected to the standpipe. Consideration was given to locating fire hose stations in areas with lower potential fire loading, as well as to ensure that they were readily accessible to ensure full hose coverage of fire areas.

The following hose racks are equipped with hose lengths in excess of 100 feet:

PART VII - DEVIATIONS AND EVALUATIONS

<u>Hose Valve</u>	<u>Building</u>	<u>Elevation</u>	<u>Hose length (ft)</u>	<u>Minimum Pressure (psig)</u>
0-26-1077	Diesel Generator	742.0	125	71
0-26-1188	Control	708.0	150	77
0-26-1193	Control	708.0	150	77
1-26-664	Auxiliary	772.0	125	71
2-26-664	Auxiliary	772.0	125	71
1-26-665	Auxiliary	757.0	150	77
2-26-665	Auxiliary	757.0	150	77

The hose stations listed above have 1.5-inch hoses and are required to have 65 psig at 100 gpm flowing. They were not pre-operationally tested, but 2.5-inch hose stations at higher elevations for each of the three buildings listed were pre-operationally tested for a minimum of 65 psig at 500 gpm; therefore, it is concluded that the lower hose stations will meet the pressure/flow requirements.

4.4 **Fire Barrier Between DG Storage Tanks and DG Corridor**

REQUIREMENT - Section F.10 of Appendix A to BTP 9.5-1 identifies that diesel fuel oil tanks with a capacity of over 1100 gallons should not be located inside buildings containing safety-related equipment. If located inside such buildings, they should be separated by 3-hour fire barriers. Buried tanks are considered as meeting the 3-hour fire resistance requirements.

DEVIATION - The diesel generator fuel oil storage tank assembly for each diesel generator consists of four interconnected tanks, each with its own man-way access openings, one at either end of the tank. One set of access openings are located in each respective diesel generator room, Rooms 742.0-D4, - D5, - D6, and -D7. The other set of access openings are located in the common corridor, Room 742.0-D9. There are a total of sixteen man-way access openings to the tanks from the corridor, and four in each diesel generator room. Each man-way access opening is in a pit covered by a removable plate cover sitting over the top of the pit flush with the floor. The four access openings in, and the four openings directly outside of, each diesel compartment are associated with the four interconnected tanks for the diesel generator in the compartment.

JUSTIFICATION - Each man-way opening is in its own pit, and each pit is about 2-1/2 feet wide by 2-1/2 feet deep. The man-way access is the only portion of the tank not buried underneath the floor of the diesel building. The man-way openings in each of the tanks are 7'6" apart, centerline-to-centerline. The man-way has an inside diameter of 18 inches, and is constructed of pressed steel. The cover is 1/4 inch thick steel plate, secured to the top of the tank by (18) 1/2 inch bolts.

There are three normally closed openings in the man-way covers located on the South end of the DG Fuel Oil Storage Tanks in the DG Corridor; Fire Area 53 Room 742.0-D9.

Two of the openings are provided for fuel oil circulation, and the other is for taking fuel oil samples. These normally closed openings preclude the need to remove the man-way access cover to circulate the oil and take the required sample.

PART VII - DEVIATIONS AND EVALUATIONS

The corridor and each diesel generator compartment are provided with full automatic detection and suppression systems to control postulated fires prior to arrival of the fire brigade. Postulated fires involving the man-way openings, while reasonably remote, are very severe and could result in damage to equipment and cables in the corridor and in the diesel generator compartments.

Damage to equipment and cables associated with operation of the emergency diesel generators would not impact on safe shutdown capability. The diesel generators are only required for those fire scenarios that either result in, or require postulation of, a loss of offsite power. Offsite power capabilities would not be affected by a fire in any portion of the diesel generator building, including the corridor. Loss of offsite power need only be postulated for those locations that require alternative shutdown, and alternative shutdown capability is not required for a fire in the diesel generator building. Therefore, WBN requests approval for this deviation for the man-way openings in the corridor and in each diesel generator compartment of the diesel generator building.

4.5 Lack of Automatic Detection in 757.0-A13 (Refueling Room) and New Fuel Storage Vault (741.5)

REQUIREMENT – Sections F.12 and F.13 of Appendix A to BTP 9.5-1 identifies that automatic fire detectors should be installed in the areas of new fuel and spent fuel pools.

DEVIATION - The refueling Area (Refueling Room 757.0-A13 which includes the New Fuel Storage Vault (741.5), Spent Fuel Pool and Fuel Transfer Canal) is not provided with an automatic detection system.

JUSTIFICATION - Based on the information provided in section 2.9.10 above, TVA requests approval for not providing automatic detection and suppression for the Refueling Room and the New Fuel Storage Vault.

4.6 Fire Barrier Between Fuel Oil Transfer Pump Room and Diesel Generator Building Corridor

REQUIREMENT - Section D.1.j of Appendix A to BTP 9.5-1 states, "Penetrations in these fire barriers, including conduits and piping, should be sealed or closed to provide a fire resistance rating at least equal to that of the fire barrier itself. The fire hazard in each area should be evaluated to determine barrier requirements."

DEVIATION - The fire barrier separating the Fuel Oil Transfer Pump Room (742-D8) from the Diesel Generator Building Corridor (742-D9) is a 2-hour rated fire barrier and contains a penetration containing a steel box. This penetration is not a tested fire rated penetration assembly.

JUSTIFICATION - The fire barrier separating the Fuel Oil Transfer Pump Room and the Corridor is constructed of 8" thick reinforced concrete block and is fire rated for 2-hours. The opening which contains the steel box is approximately 41" x 24" and the box is approximately 39" x 23". The annular gap between the block wall and the box is filled with concrete grout, but no sealant material is installed within the box. The box back (inside the Fuel Oil Transfer Pump Room) is a steel plate. The front of the panel is a steel plate with cutouts for three metal junction boxes. These boxes contain the following devices:

PART VII - DEVIATIONS AND EVALUATIONS

Box 1	0-HS-39-27A
Box 2	0-FSV-39-27
Box 3	0-ARB-39-27, 0-HS-39-27R, 0-SW-39-27

The in situ combustible loading of the Fuel Oil Transfer Pump Room is approximately 3,730 Btu/ft² and is due to insulation on cables associated with panel 0-L-162, hand switches, an emergency lighting unit, and foam plastic insulation. The in situ combustible loading of the Corridor is approximately 77,700 Btu/ft² of which approximately 96% is due to insulation on cables in cable trays.

The Fuel Oil Transfer Pump Room is provided with an automatic detection system and a total flooding automatic CO₂ suppression system. The detection system alarms in the Main Control Room (MCR) and actuates the suppression system. Upon receipt of a detection alarm, the MCR staff notifies the site Fire Brigade. The Corridor is provided with an automatic detection system and an automatic sprinkler system. The detection system alarms in the MCR and actuates the suppression system. Upon receipt of a detection alarm, the MCR staff notifies the site Fire Brigade.

The Fuel Oil Transfer Pump Room does not contain components required for safe shutdown in the event of a fire in the room or for a fire in the Corridor. The small amount of in situ combustibles and the lack of free floor space limit the quantity of transient combustibles thereby limiting the severity of a postulated fire in the room. The failure of a fuel oil line or pump that resulted in a fire is addressed by the total flooding, automatic CO₂ suppression system which will also control a postulated transient fire until the Fire Brigade responds.

Neither fire is expected to challenge the steel box. In the event of a failure of the suppression system in the room, the fire would not challenge the ability of the box to prevent the passage of flames, hot gases or water from one side of the barrier to the other. This is based on observations of 3-hour fire tests of penetrations which contained pipe (diameters from as large as 30" to as small as 2") with a similar thickness steel plate welded on the end of the pipe placed in the test furnace. The single layer of steel in these tests did not allow the passage of flames, hot gases or water from one side of the barrier to the other. It is concluded that two layers of steel separated by an air gap would perform as well or better. Therefore, the penetration containing the steel box is adequately protected for the fire hazards in the Fuel Oil Transfer Pump Room.

The Corridor does not contain components required for safe shutdown in the event of a fire in the Corridor or for a fire in the Fuel Oil Transfer Pump Room. The majority (approximately 96%) of the in situ combustible loading is due to insulation on cables in the trays. The trays are routed across the ceiling except where they run down the south wall of the Corridor (approximately 13 feet away). The corner of the Fuel Oil Transfer Pump Room shields the box from direct exposure of a postulated fire in the cable trays. The other in situ combustibles are dispersed throughout the Corridor and do not present a direct exposure hazard to the box.

The Corridor width at the panel is approximately 6 feet. The door into the 2B-B Diesel Generator is across from the box and the door to the Fuel Oil Transfer Pump Room is next to the box. The end of the Corridor is less than 6 feet from this door and a high pressure fire protection system deluge valve station is located there. This arrangement minimizes the probability of transient combustibles being stored near the box. Since the top of the box is located approximately 13 feet below the ceiling, a fire in the Corridor would actuate the sprinkler

PART VII - DEVIATIONS AND EVALUATIONS

system before the hot gas layer could bank down to challenge the box. The actuation of the sprinkler system will control the fire and keep the box face cool. In the event the sprinkler system failed to operate, the two layers of steel and the air gap between them would prevent the passage of flames, hot gases or water from propagating from the Corridor into the Fuel Oil Transfer Pump Room. Therefore, the penetration containing the box is adequately protected from the fire hazards in the Corridor.

The penetration configuration consisting of a steel box grouted in place in the reinforced concrete block wall and containing three metal boxes with components of the CO₂ suppression system is adequate to prevent the passage of flames, hot gases or water from the Corridor to the Fuel Oil Transfer Pump Room or vice versa. Therefore, WBN requests approval of this deviation from the requirements of Appendix A of BTP 9.5-1.

5.0 NFPA Code Deviations

The purpose of this section is to document the justifications for those NFPA code deviations that impact on the operational capabilities of the fire protection feature that is not in direct compliance with code criteria. The deviations that do not impact on the operational capability of the fire protection feature are identified in Part X of the FPR, with justifications contained in the appropriate WBN system description.

5.1 Non-Listed, Non-Approved Fire Pumps and Fire Pump Controllers

NFPA 20 requires that fire pumps and fire pump controllers be listed and approved for use. Four electric motor driven pumps provide water to the fire protection water system at WBN. The pumps, while not listed and approved for use as fire pumps, are ASME Section III seismic Category I high pressure vertical turbine motor-driven pumps due to their primary safety function (i.e. flood mode). The pumps do not start on pressure drop in the fire main; rather, they automatically start upon actuation of the fire detection systems in those plant locations provided with preaction suppression systems. The pumps can also be manually started and stopped from the main control room, and manually started via push buttons at specific hose stations in the plant. Conventional fire pump controllers are not used.

The existing configuration of four ASME Section III pumps and controllers are acceptable based on the following considerations:

1. The HPFP fire protection system has a primary safety function to serve as a backup water supply to the auxiliary feedwater system in the event of a flood above plant grade and, as such, requires the use of ASME Section III pumps as opposed to traditional UL/FM fire pump installations.
2. The pump curve verification tests have been revised to include multiple diverse points on the pump curve to replicate fire pump test requirements as opposed to the single point verification applicable to ASME Section III pumps.
3. Hydraulic calculations, based on the ratings and pump curve verification tests, have been performed to demonstrate that the pumps can provide adequate flow and pressure to the most hydraulically remote suppression systems in the plant.
4. The design and construction of electrical circuits for pump power and control meet IEEE Class 1E standards and, even though the pumps do not start on pressure drop in the

PART VII - DEVIATIONS AND EVALUATIONS

pipng system, they do automatically start when the Function B fire detectors actuate. (Refer to Part II of the FPR.)

5. The electric fire pumps can only be manually stopped from the main control room, which is constantly manned by operations personnel, or the shutdown board rooms. The diesel fire pump can only be stopped locally at the pump. These features provide adequate controls over when the fire pumps can be stopped.
6. The existing configuration of four ASME Section III pumps has been previously reviewed and approved by NRC in the June 1982 Safety Evaluation Report for WBN.
7. System pressure is normally maintained by the RCW system.

The use of non-listed and non-approved fire pumps and fire pump controllers do not pose a significant hazard to the fire protection capability and are acceptable. TVA therefore requests approval of this deviation.

5.2 Sliding Fire Doors with Fusible Links on One Side of Door Only

NFPA 80-1975 requires that fusible links be installed on both sides of the wall and interconnected so that the operation of any single fusible link will cause the door to close. For hollow metal doors a fusible link is required to be centered just above the opening and another at or near the ceiling. The sliding fire door at Watts Bar (Door D8A) is provided with fusible links but only on one side.

The configuration in NFPA 80 consists of an opening in a fire barrier that is protected by a sliding door. The configuration at Watts Bar is provided with swinging hollow metal door in the opening and a sliding fire door. The normally closed swinging hollow metal door is similar to labeled fire doors. The sliding fire door is installed to provide additional protection to the opening. The sliding fire door and its fusible links are installed in the room that presented a significant hazard to an adjacent room. In the event of a fire, the swinging hollow metal door would protect the opening until a fusible link melted and allowed the sliding door to close. A fire in the adjacent room would not impact the fire safe shutdown analysis and would not present any threat to fire safe shutdown even if it did propagate into the room containing the sliding fire door. Door D8A, located in the Diesel Generator Building Lube Oil Storage Room, is provided with two fusible links (one directly above the center line of the door and the other higher up) and the door has a CO₂ actuated door release.

While this configuration is not in verbatim compliance with NFPA 80, it provides an adequate level of protection that will perform the function as intended by NFPA 80. Therefore the as constructed configuration of the sliding fire door at Watts Bar is considered acceptable.

6.0 General Engineering Evaluations

The purpose of this section is to document the fire protection engineering evaluations other than those related to 10CFR50 Appendix R, BTP 9.5-1 Appendix A, and NFPA Codes. The evaluations are presented in the following format:

1. Statement of the condition being evaluated
2. Discussion and justification
3. Conclusion

PART VII - DEVIATIONS AND EVALUATIONS

6.1 Justification for Relaxation in Surveillance Frequency for the Reactor Building Equipment Hatches - 757.0-A11 And 757.0-A15

6.1.1 Statement of Condition

The Reactor Building Equipment Hatches (757.0-A11 and 757.0-A15) are inaccessible during plant operations; therefore, surveillance of sprinklers, fire detectors, penetration seals, and Thermo-Lag (757.0-A11 only) fire wrap cannot be performed per the regular schedules. The surveillances for these items will be performed only during outages when the room is accessible.

6.1.2 Discussion and Justification

These rooms are the equipment access areas between the Refueling Room and the Reactor Building. They are considered as part of the Reactor Building during plant operations. They are constructed of reinforced concrete (minimum 3-feet thick) and are provided with smoke detectors and automatic (preaction) sprinkler system. The room barriers are 3-hour fire rated with the exception of the blast door into the Reactor Building. This door is of heavy metal construction and would prevent a fire from propagating from either the Reactor Building into the room or from the room into the Reactor Building.

Each room area is 673 square feet with a ceiling height of 24 feet. The in situ combustible loading in the rooms is comprised of the insulation on the cable trays that traverse the room, the light covers on the lights in the room, and Thermo-Lag (757.0-A11 only) on conduits that pass through the room. This load is approximately 32,000 Btu/ft² which equates to a fire severity of approximately 24 minutes. There are no ignition sources in the room during power operation.

6.1.3 Conclusion

Performing the required surveillance during plant outages is acceptable for the following reasons:

1. The rooms are not accessible during plant operations,
2. Transient combustibles are not present during plant operations,
3. No ignition sources are in the rooms during operation,
4. More than adequate fire compartmentation.

6.2 Justification for Fire Damper Surveillance Requirements

6.2.1 Statement of Condition

Fire dampers are inspected periodically ($\geq 20\%$ per 18 months) to ensure proper operation and thus prevent a postulated fire from propagating from one side of the fire barrier to the other through the ventilation opening. Some of the fire dampers are not being inspected due to the potential for spreading of contamination.

PART VII - DEVIATIONS AND EVALUATIONS

6.2.2 Discussion and Justification

The following fire dampers are located in contaminated areas and to keep radiation exposure levels as low as reasonably achievable are considered to be inaccessible.

- 0-ISD-31-3846
- 0-ISD-31-3847
- 0-ISD-31-3848

The consequences of failure of any or all of these dampers to close during a fire event are evaluated below. The evaluations consider the damper location, proximity to combustibles, and construction features for the applicable rooms on each side of the damper. Accidental closure of the dampers is not considered because each of the dampers is held open by mechanical means (S-hooks and fusible links).

6.2.2.1 Damper 0-ISD-31-3846

This fire damper is located in a 24-inch diameter embedded duct that starts at an embedded collector box (4'x4'x2') located at column line A8 and runs for 40 feet where it exits the concrete wall (A5 column line) and immediately (within 2 feet) enters a 64-inch by 54-inch duct. This is located in the Ventilation and Purge Air Room (737.0-A5). The other ducts that enter the collector box are 20-inch diameter embedded ducts and they are the common ducts for the openings to the fuel transfer canal (the vent openings are located just above the water level in the fuel transfer canal).

There is no combustible hazard in the fuel transfer canal. There are negligible quantities of combustible in the vicinity of the duct in the Ventilation and Purge Air Room. In addition, the room is also provided with smoke detection and automatic suppression.

The combustible loading for the Ventilation and Purge Air Room is less than 14,000 Btu/ft² which equates to a fire severity of approximately 11 minutes. Heavy gauge metal duct is generally considered to be equivalent to a 1-hour fire barrier. However, even if a fire in the room did breach the duct, it would have to travel more than 40 feet down the embedded duct before it could reach the fuel transfer canal.

Therefore, failure of the fire damper to close during a fire in the Ventilation and Purge Air Room would not affect the capability to contain the fire and thus there is no threat to the fire safe shutdown capability of the plant. Since there is no adverse affect to the plant if the fire damper fails to close, the need to perform surveillance and maintenance on the damper can be deleted.

6.2.2.2 Dampers 0-ISD-31-3847 and 0-ISD-31-3848

One of these fire damper is located in a 24-inch diameter embedded duct that starts at an embedded collector box (4'-3" x 4'-3" x 1'-10") located in the Spent Fuel Pit wall between column lines A5 and A6, runs for approximately 5 feet where it exits the concrete wall, traverses a corridor (5' - 6' wide), and penetrates the concrete wall at A5 column line and immediately (within 2 feet) enters a 58-inch by 54-inch duct. This is located in the Ventilation and Purge Air Room (737.0-A5). Two other ducts that enter the collector box are 20-inch diameter embedded ducts and they are the common ducts for the openings to the Spent Fuel Pit (the vent openings are located just above the water level). The other fire damper is located in a 30-inch diameter embedded duct that starts at an embedded collector box (2'-6" x 4'-6" x 4'-6") located in the

PART VII - DEVIATIONS AND EVALUATIONS

opposite wall of the Spent Fuel Pit, runs for approximately 80 feet where it exits the Spent Fuel Pit wall (near the 24-inch duct), traverses the corridor, and penetrates the wall at A5 column line and immediately (within 2 feet) enters the 58-inch by 54-inch duct. Both of these round ducts are coated with 2-inches of fire protective material (Pyrocrete) where they traverse the corridor.

There is no combustible hazard in the Spent Fuel Pit. There are negligible quantities of combustible in the vicinity of the duct in the corridor (connects the Post Accident Sampling Room, 729.0-A8, to the Nitrogen Storage Area, 729.0-A6) and the Ventilation and Purge Air Room. In addition, the corridor and the Ventilation and Purge Air Room are also provided with smoke detection and the Ventilation and Purge Air Room is provided with automatic suppression.

The combustible loading for the Ventilation and Purge Air Room is less than 14,000 Btu/ft² which equates to a fire severity of approximately 11 minutes and the corridor has a combustible load less than 4,700 Btu/ft² which equates to a fire severity of less than 5 minutes. Heavy gauge metal duct is generally considered to be equivalent to a 1-hour fire barrier. However, even if a fire in either room did breach the duct, it would have to travel approximately 10 feet down the 24-inch embedded duct and 80 feet down the 30-inch embedded duct before it could reach the Spent Fuel Pit.

6.2.3 Conclusion

Therefore, failure of the fire damper to close during a fire in the Ventilation and Purge Air Room or the corridor would not affect the capability to contain the fire and thus there is no threat to the fire safe shutdown capability of the plant. Since there is no adverse affect to the plant if the fire damper fails to close, the need to perform surveillance and maintenance on the damper can be deleted.

6.3 Justification of Gap Between Door and Frame for Fire Door W9

6.3.1 Statement of Condition

General Engineering Specification G-73, "Installation, Modification and Maintenance of Fire Protection Systems and Features," Section 4.2.3.1.9.b states, "The clearance between the door and frame and between the meeting edges of doors swinging in pairs shall be 3/16-inch or less as long as the door does not scrape." A portion of the gap between the door and frame of fire door W9 exceeds the maximum 3/16-inch clearance.

6.3.2 Discussion and Justification

Fire door W9 is in a 3-hour fire barrier that ensures that a fire on the RCW pump deck cannot endanger both safe shutdown paths of ERCW. The fire door is located in the wall that separates the RCW pump deck from a labyrinth that opens into the Train A ERCW pump room. The RCW pump deck is open to the atmosphere on the other three sides and does not have a roof over it. The in situ combustible load of the RCW pump deck is very low (approximately 4,200 Btu/ft²) and consists primarily of lube oil associated with the RCW pumps. The nearest pump is located a horizontal distance of 17 feet from the door and the bottom of the door is 13.5 feet above the RCW pump deck. There are no in situ combustibles located directly under the door and the stairs and landings prevent any appreciable quantities of transient combustibles from being stored under the door. The door opens into a labyrinth that does not contain any in situ combustibles, nor are transient combustibles stored in the labyrinth.

PART VII - DEVIATIONS AND EVALUATIONS

6.3.3 Conclusion

Even if a fire on the RCW pump deck occurs, it does not impact an ERCW pump for the following reasons:

1. Distance from nearest combustible source is 17 feet horizontally and 13.5 feet vertically.
 2. The RCW pump deck is open to the atmosphere on three sides.
 3. There is a labyrinth between the fire door and the ERCW pump room.
 4. The ERCW pump room is open to the atmosphere at the top.
 5. There are no intervening combustibles between the RCW pump and the door.
 6. There are no intervening combustibles between the door and the ERCW pumps.
- Therefore, the door not being in compliance with the gap specifications as stated in G-73 does not create a violation to Appendix R separation requirements because the door still provides an adequate fire resistive barrier.

6.4 Justification for Relaxation of Penetration Seal Surveillance Requirements in High Radiation Areas

6.4.1 Statement of Condition

Penetration seals are inspected periodically (approx. 20% per 12 months) to ensure seal integrity and thus prevent a postulated fire from propagating from one side of a fire barrier to the other through a penetration opening. Some penetration seals in rated fire barriers cannot be inspected due to being located in a high radiation area.

6.4.2 Discussion and Justification

The penetration seals in the following rooms are located in high radiation areas. To keep radiation exposure levels as low as reasonably achievable, these penetration seals are considered to be inaccessible.

- Spent Resin Tank Room - 692.0-A15
- Hold-Up Tank Room A - 676.0-A2
- Hold-Up Tank Room B - 676.0-A3
- Waste Hold-Up Tank Room - 674.0-A1
- Gas Decay Tank Room - 692.0-A3
- Gas Decay Tank Room - 692.0-A5

The consequence of a failure of the penetration seals in the rated fire barriers between these rooms and adjacent rooms is evaluated below. The evaluations consider the areas not inspected, proximity to combustibles, and construction features for the applicable rooms on either side of the seals in question.

6.4.2.1 Spent Resin Tank Room - 692.0-A15

The Spent Resin Tank Room is separated from Pipe Gallery and Chase Room 692.0-A24 by a 2 hour rated fire barrier of reinforced concrete construction. The barriers adjacent to other rooms are considered non-rated barriers. There is no safe shutdown equipment in the Spent Resin Tank room. The penetration seals in the rated barrier are accessible for surveillance

PART VII - DEVIATIONS AND EVALUATIONS

inspection from room 692.0-A24; however, they are not accessible for inspection from the Spent Resin Tank Room due to the radiation posting of the room.

The combustible loading in the Spent Resin Tank Room is less than 6,500 Btu/ft², which equates to a fire severity index of insignificant and a fire severity of less than 5 minutes. The combustible loading in adjacent room 692.0-A24 is also less than 6,500 Btu/ft². There is a very low probability of a fire in the Spent Resin Tank Room and Pipe Chase Room 692.0-A24 challenging the safety of the plant, based on the small amount of combustibles and the absence of safety equipment in the tank room. Based on the low combustible loading in the two rooms and the low probability of a fire in either room, it is unlikely that a fire could start in either room and spread to an adjacent room. It is therefore determined that the need to perform surveillance of the penetration seals on this fire barrier from inside room 692.0-A15 can be deleted.

6.4.2.2 Hold-Up Tank Rooms A and B - 676.0-A2 and 676.0-A3

Hold-Up Tank Rooms A and B are separated from adjacent rooms by both 2 and 3 hour fire barriers constructed of reinforced concrete. The barrier between the two rooms is a non-rated wall of reinforced concrete construction. There is no safe shutdown equipment in either of these rooms, nor is there any equipment that could be considered a plant trip initiator. Adjacent rooms containing safe shutdown equipment are accessible for surveillance inspection of the penetrations, with the exception of the barrier between Room 676.0-A2 and 692.0-A3. The penetrations are not accessible from inside the Hold-Up Tank Rooms for surveillance inspection due to the radiation posting of the rooms.

The combustible loading in Hold-Up Tank Rooms A and B is less than 900 Btu/ft², which equates to a fire severity index of insignificant and a fire severity of under 5 minutes. There is a very low probability of a fire in either room challenging the safety of the plant, based on the small amount of combustibles and the absence of safe shutdown equipment in the rooms. Likewise, a fire spreading from another plant area into either Hold-Up Tank Room will not affect any safety shutdown equipment or affect any equipment that could initiate a plant trip. The rooms are both classified as high radiation areas and are not generally accessible, which reduces the likelihood that combustibles are moved or stored in these rooms.

Based on the low combustible loading of the rooms, it is very unlikely that a fire could start in Hold-Up Tank Room A or B and spread to an adjacent room. It is therefore determined that the need to perform surveillance of the penetration seals on the fire barriers from inside Hold-Up Tank Rooms 676.0-A2 and 676.0-A3 can be deleted.

6.4.2.3 Waste Hold-Up Tank Room - 674.0-A1

The Waste Hold-Up Tank Room is separated from RHR Pump Room 1A-A (Room 676.0-A11) by a 2 hour reinforced concrete fire barrier. The barriers adjacent to other rooms are considered non-rated barriers. The penetration seals in the rated fire barrier are accessible for surveillance inspection from room 676.0-A11; however, they are not accessible for inspection from room 674.0-A1 due to the radiation posting of the room.

The combustible loading in the Waste Hold-Up Tank Room is insignificant, making it highly unlikely that a fire could ever start in this area and spread to the adjacent Room 676.0-A11. The combustible loading in adjacent room 676.0-A11 is less than 6,500 Btu/ft², which equates to a fire severity index of insignificant and a fire severity of less than 5 minutes. There is a very

PART VII - DEVIATIONS AND EVALUATIONS

low probability of a fire in the Waste Hold-Up Tank Room challenging the safety of the plant, based on the negligible combustible loading and the absence of safe shutdown equipment required for a fire in this room or any adjacent rooms. The circuits routed in conduit in this room are only necessary for a control building fire that results in Main Control Room abandonment. Based upon the negligible combustible loading in the Waste Hold-Up Tank Room and the low probability of fire in the room, it is unlikely that a fire could start in the room and spread to adjacent rooms. Therefore, it is determined that the need to perform surveillance inspections of the penetration seals of this fire barrier from inside room 674.0-A1 can be deleted.

6.4.2.4 Gas Decay Tank Rooms - 692.0-A3 and 692.0-A5

The Gas Decay Tank Rooms are separated from adjacent rooms by both 2 and 3 hour rated fire barriers constructed of reinforced concrete. The barrier between the two rooms is a 2 hour rated barrier. The penetration seals are not accessible for inspection from the Gas Decay Tank Rooms due to the radiation posting of the rooms. The penetration seals in the barrier between the two rooms are not accessible from either side for surveillance inspection. Likewise, the barrier between Room 692.0-A3 and Room 676.0-A2 is not accessible for surveillance inspection. The penetration seals in the remaining barriers are accessible for surveillance inspection from the adjacent rooms.

The combustible loading in the two Gas Decay Tank Rooms is insignificant, making it very unlikely that a fire could ever start in either room and spread to an adjacent room. There is a very low probability of a fire in either of the Gas Decay Tank Rooms challenging the safety of the plant, based on the insignificant amount of combustibles in the rooms and the fact that neither room contains any safety shutdown equipment or plant trip initiators. Likewise, a fire spreading from another plant area into either Gas Decay Tank Room will not affect any safe shutdown equipment or affect any equipment that could initiate a plant trip. The rooms are both classified as high radiation areas and are not generally accessible, which reduces the likelihood that combustibles are moved or stored in these rooms.

Based on the negligible combustible loading in the two rooms and the low probability of a fire in either room, it is unlikely that a fire could start in either room and spread to an adjacent room. Therefore, it is determined that the need to perform surveillance inspections of the penetration seals of the fire barriers from inside these two rooms can be deleted.

7.0 Unit 1 Operator Manual Actions

Unit 1 operator manual actions (OMAs) were originally identified in calculation WBN-OSG4-165 and were evaluated and approved in SSER 18 (Part II, Reference 4.3.9). The Unit 1 OMA's are presently defined in calculation EDQ00099920090016 (Part II, Reference 4.2.59).

7.1 Manual Actions Performed in Location of the Fire

Manual operator actions in the location of the fire fall into two categories: (1) tripping circuit breakers to remove power from motors or motor operated valves (MOVs), and (2) manual valve manipulations to be performed after the fire is extinguished. The first category of manual actions need not be taken in the location of the fire. For the second category of manual actions, access to the location of the fire is necessary for performance of manual actions. Each is discussed separately below.

PART VII - DEVIATIONS AND EVALUATIONS

7.1.1 Tripping Breakers to Remove Power from Motors or MOVs

Actions to remove power from motors or MOVs are taken either in the location of the fire if the breaker is accessible, or outside of the location of the fire and electrically upstream at the board feeder breakers. Where circuit breakers must be opened to remove power from motors or MOVs, fire safe shutdown analysis requires that the board feeder breakers be tripped if the board itself is inaccessible due to the fire. (It is also normal practice for the fire Incident Commander to de-energize electrical power boards upstream from the energized electrical equipment involved in the fire.) The board feeder breakers are located outside of the area of the fire. As such, this type of manual action is not performed in the location of the fire.

7.1.2 Manual Valve Manipulations in Location of Fire

Actions to manually manipulate valve positions are performed in the location of the fire when the valve is located in the same room as the fire. A few rooms must be entered for valve position manipulations approximately 1-hour after reactor trip. The following is a more detailed discussion of the manual actions, time to perform them, and fire hazards in the area.

7.1.3 Identification of Manual Actions: Performance, Completion and Access Times

7.1.3.1 Elevation 692

For a fire in Room 692.0-A7, the handwheel opening of RWST valves 1-LCV-62-135-A or -136-B must be performed after the fire is extinguished in the room. The valves are located near the wall just inside the room. The manual action in the room has a performance time of 10 minutes and must be completed within 75 minutes after reactor trip. Access to the room must take place within 65 minutes after reactor trip.

7.1.3.2 Elevation 713.0

For a fire in Room 713.0-A7, the handwheel closure of VCT valve 1-LCV-62-132-A must be performed after the fire is extinguished in the room. The valve is located in the entrance labyrinth to the room which leads to, but is segregated from, the volume control tank by a concrete wall and wire mesh door. The manual action in the room has a performance time of 10 minutes and must be completed within 70 minutes after reactor trip. Access to the room must take place 60 minutes after reactor trip.

7.2 Justification for Room Access Time

Where manual valve manipulations are necessary, the combustible loading will not damage the valve(s) or valve stem(s). Automatic detection and suppression, rapid fire brigade response, and the heat sink provided by the process piping fluid, provide a high degree of assurance that the valve(s) can be manually operated after the fire is extinguished. The bases for allowing access into the rooms in the identified time frames and the ability to perform the requisite manual actions are described in more detail below.

PART VII - DEVIATIONS AND EVALUATIONS

7.2.1 Combustible Materials, Combustible Loads, and Fire Severities

Room 692.0-A7, the Pipe Gallery, has a combustible load that results in an equivalent fire severity of less than 5 minutes. The majority of the combustible loading is the lube oil and grease associated with the fans, pumps and valves in the room. Room 692.0-A7 is identified as a CCZ in order to control potential storage of transient combustible materials in the room. The valves are located just inside the room near the door to room 692.0-A1A and are next to the wall with easy access.

Room 713.0-A7 is the Unit 1 Volume Control Tank room. The combustible material in the VCT portion of the room is associated with the maximum quantity of hydrogen which can be in the VCT, assuming that the tank is completely filled with hydrogen and pressurized to 75 psig. In the event of a leak in the hydrogen piping or the VCT itself in excess of 50 scfm, flow of hydrogen is automatically isolated by an excess flow device. Leaks less than 50 scfm are dispersed by the Auxiliary Building Ventilation system, precluding the danger of an explosion. The labyrinth contains the balance of combustible materials in the room (small amount of lube oil associated with the two valves, insulation on cables in a small junction box and three control boxes, and small amount of plastics associated with seven light covers and one emergency lighting unit). Even considering the total quantity of hydrogen that can be in the VCT, the combustible loading results in an equivalent fire severity that is under 5 minutes. In addition, Room 713.0-A7 is identified as a combustible control zone (CCZ), which prohibits storage of transient combustible material unless compensatory measures are established.

The fire severity in the rooms where manual actions may be necessary, especially considering the nature and location of combustible materials in each room, would not preclude the ability to enter the rooms within the identified times. Room 713.0-A7 is a normally locked room, thereby further limiting the potential for introduction of transient combustible materials in the room. The residual heat of a postulated fire in this room should not impact operator actions in the room. The possibility exists, however, that residual smoke from the postulated fire may require the Operator to wear a self contained breathing apparatus (SCBA); therefore, SCBAs are available for use if needed.

7.2.2 Automatic Detection and Suppression Capabilities

Each room is provided with an automatic detection system ensuring prompt notification of the fire brigade to initiate manual firefighting activities if necessary. Each of the rooms is also provided with an automatic suppression system. The only portion of Room 713.0-A7 that is not protected by automatic suppression is the entrance labyrinth.

The automatic detection and suppression systems in the identified room are provided to minimize postulated fire events. Prompt notification of the fire brigade upon detection of the fire will result in initiation of manual firefighting and smoke removal activities. Firefighting and smoke removal activities, when combined with the positive impact of automatic suppression, provide reasonable assurance that operators can enter the rooms within the identified times after reactor trip.

7.2.3 Potential Fire Damage to Valve Stems and Handwheels

The valve stems and handwheels that must be manipulated in the room in which the fire occurs are of steel construction. Aluminum is not used in the construction of the subject valve stems

PART VII - DEVIATIONS AND EVALUATIONS

and handwheels. Given the short duration of postulated fires in the rooms of concern, it is reasonable to conclude that the valve stems and handwheels will not be damaged by the fire and will remain operable. The combustible materials in each room would not produce a high enough heat flux for a sufficient amount of time to result in damage to the valves stems or handwheels

7.2.4 Summary and Conclusions

The combustible loading, along with its location and configuration in each room, will not result in a fire of sufficient energy and duration to either prevent operator access in the required time periods or result in damage to valve stems and handwheels that must be manually operated. Automatic detection is provided in each of the rooms to detect postulated fires in the incipient stages, thereby ensuring notification of the fire brigade. The automatic suppression system installations will act to minimize postulated fire events.

8.0 Feasibility and Reliability Evaluations for Operator Manual Actions

8.1 Background

The WBN Appendix R safe shutdown compliance strategy requires local manual actions to accomplish various safe shutdown functions and to prevent or terminate spurious equipment operation having the potential to interfere with safe shutdown.

Operator manual actions (OMAs) that are required for compliance with 10CFR50 Appendix R at Watts Bar Nuclear (WBN) Unit 2 must be assessed for feasibility and reliability. Unit 1 OMAs required for safe shutdown and added after SSERs 18 and 19 are included in this feasibility and reliability evaluation. The assumptions and methodology used to assure the action is feasible and reliable are consistent with the requirements of 10CFR50 Appendix R, Section III.G.2 and the guidance of NUREG-1852. However, the use of feasible and reliable manual actions alone does not address all levels of defense-in-depth. Therefore, additional considerations that are addressed in Regulatory Guide 1.189 such as fire detection and automatic suppression are also considered to ensure that adequate defense-in-depth is maintained. For additional detail regarding codes and standards applicable to fire detection and automatic suppression systems, refer to Part II, Section 4.4.

8.2 Generic Evaluation Information

NUREG-1852 indicates that a manual action used as a compliance strategy is considered acceptable if eleven conditions are met. These conditions are given below with a summary of the NUREG guidance and, where applicable, additional information regarding WBN application of the guidance.

a. Adequate Time Available to Perform Actions

This criterion addresses the need for an analysis to determine that there is adequate time available for the operator to perform the manual actions necessary to achieve and maintain hot shutdown after a single fire. The analysis should determine that the time available is long enough to allow the action to be diagnosed and executed. The adequacy of time and manpower must consider all of the operator manual actions that must be performed for a room, and the potential for concurrent performance of these actions.

PART VII - DEVIATIONS AND EVALUATIONS

b. Adequate Time Available to Ensure Reliability

This criterion addresses uncertainties to ensure that the OMA can be dependably and repeatedly performed within the available time. Per the guidance of NUREG-1852, Appendix B, an OMA is considered reliable provided that a 100% time margin remains when considering fire indicated time, diagnosis time, and OMA implementation, within the OMA event timeline. This margin allows for a high confidence of a low probability of failure for local operator manual actions in response to a fire. It is implied by these criteria that NUREG-1852 feasibility and reliability criteria for the actions are addressed and sound demonstrations are performed.

The time margin is calculated using the analyzed times from the OMA calculation (Reference Part II, section 4.2.59) and also with the actual demonstrated (validated) performance times for each OMA. A time margin greater than 500% is not meaningful for actions with short completion times; therefore, the maximum time margin reported for WBN OMAs given in Section 8.3 of this Part is 500%.

c. Environmental Factors

Environmental factors are those that could negatively impact the ability to perform manual actions, including radiation, lighting, temperature, humidity (caused, for instance, by water from a sprinkler operation), smoke, toxic gases, firefighting activities, and noise. Inaccessible areas are defined and listed in Part II, Section 5.0.

WBN emergency lighting units with at least an 8-hour battery power supply are provided in areas needed for operation of safe shutdown equipment and in access and egress routes (except as described in Section 2.7 of this Part). The operators also carry a portable lantern to perform a manual action in an area that has experienced a fire.

d. Equipment Functionality and Accessibility

This criterion addresses the need to ensure that the equipment that is necessary to enable implementation of an operator manual action to achieve and maintain post fire hot shutdown is accessible, available, and not damaged or otherwise adversely affected by the fire and its effects such as heat, smoke, water, combustible products, and spurious actuation. Per NUREG-1852:

- i The component to be operated is physically accessible (e.g., the component is within reach without a ladder, unless the ladder is staged).
- ii The manual action can be performed by the operator(s), e.g., opening an MOV is not feasible if the valve has no handwheel operator.
- iii Actions requiring entry into or travel through the affected Analysis Volume have been evaluated successfully based on factors such as combustible loading, location of combustibles, availability of detection and suppression equipment, and the physical properties of the component. Typically, entry into or through the affected room is acceptable after 1 hour without further evaluation.

Abnormal Operating Procedure 0-AOI-30.2, "Fire Safe Shutdown" (Part II, Reference 4.2.90) documents the credited manual action(s) that must take place given an Appendix R fire in any room of the plant. On an operator-by-operator basis, procedure 0-AOI-30.2 documents the

PART VII - DEVIATIONS AND EVALUATIONS

locations and sequence in which operator manual actions must be performed. The equipment accessibility criteria, given above, are also addressed.

e. Available Indications

Available equipment needs to include indications relevant to the desired operator manual actions. As necessary equipment, indications should also meet functionality and accessibility criterion.

As described above in item d, procedure 0-AOI-30.2 documents the locations and sequence in which manual actions must be performed. Available indications are also addressed in these procedures.

f. Communications

There are several means of communication available to the Operations staff. They include telephones, code alarm and paging, sound powered phones, and two-way radios. The in-plant radio signal will be the primary means of communication for performing manual actions and for the fire brigade use.

The trunked in-plant radio system consists of multiple base radios, portable radios (including tri-band), and redundant in-plant distributed antenna systems. To ensure communication availability, one of the radios and associated power cabling is located in a separate fire zone or is separated by a minimum of 20 feet with no intervening combustibles. The base radios are located at floor elevation 772.0 of the Auxiliary Building within the 480V Board Room 2A and the 480V Transformer Room 2A. The radios (multiple frequencies) are available for use by the fire brigade and for operations personnel for performing safe shutdown manual actions. The radio equipment features redundant diesel and battery backed power supplies. Antennas for the radios are located on the Aux. Building exhaust stack (above elevation 814.75) to transmit and receive the radio signal. In addition to the antennas on the exhaust stack, the internal distributed antenna systems (Radiax) are located in the control and turbine buildings and two widely separated trunk lines feed the radio signal to redundant distributed antenna systems located throughout the auxiliary building.

In some rooms, two-way radio communications may not be adequate in the room; however, adequate communications are available immediately outside the room. The action to be performed does not require that communication be established at the device (e.g., open/close valve or breaker).

g. Portable Equipment

Portable equipment necessary to successfully accomplish operator manual actions may include tools such as keys to open locked areas or manipulate locked controls, flashlights, ladders to reach high places, torque devices to turn valve handwheels, and electrical breaker rackout tools. This equipment should be readily available and its location should be known and constant. This equipment should be in working order (functional) and access to this equipment should be unimpeded so that it will not delay the operator manual actions. As described above, procedure 0-AOI-30.2 documents the locations and sequence in which operator manual actions must be performed. Necessary portable equipment is also addressed in these procedures.

PART VII - DEVIATIONS AND EVALUATIONS

h. Personnel Protection Equipment

Equipment needed to successfully implement operator manual actions may also include personnel protection equipment such as protective clothing, gloves, and self-contained breathing apparatus (SCBA). Access to this equipment should be unimpeded. It should also be in working order so that it will not delay the operator manual actions.

As described above, procedure 0-AOI-30.2 documents the locations and sequence in which operator manual actions must be performed. Necessary protective equipment is addressed in these procedures. Per general employee training descriptions, WBN Auxiliary Unit Operators (AUOs) and others who are expected to use an SCBA are trained annually in the proper use of an SCBA. This Personnel Protection Equipment (PPE) is readily available and is picked up as the AUOs report to the MCR for their assignments.

i. Procedures and Training

Procedures governing manual actions need to be written and maintained. They should cover all of the manual actions and the need for each operator which may perform the actions to achieve and maintain hot shutdown.

WBN procedures and training are in place for implementation of operator manual actions. Abnormal Operating Procedure 0-AOI-30.2, "Fire Safe Shutdown" documents the necessary manual action(s) that must take place given an Appendix R fire in any room of the plant. On an operator-by-operator basis, 0-AOI-30.2 documents the locations and sequence in which manual actions must be performed.

Fire Safe Shutdown training is provided for operators every 4 years at Watts Bar Nuclear. This classroom training (3-OT-AOI3000, 0-AOI-30.1, "Plant Fires" and 0-AOI-30.2, "Fire Safe Shutdown") includes licensed and non-licensed operators.

j. Staffing

The intent of the staffing criterion is to ensure that an adequate number of qualified personnel are available so that hot shutdown conditions can be achieved and maintained in the event of a fire. Individuals who might be needed to perform the operator manual actions during the evolution of the fire scenario should not have collateral duties such as firefighting, security duties, or control room operation.

The minimum WBN staffing level to perform the manual actions for the worst case Appendix R fire is provided in Part V, Section 2.2. Operator manual actions are shown to be achievable within the analyzed time available and using the minimum staffing levels. The staffing evaluations provided for rooms addressed in Section 8.3 of this Part are based on validations of 0-AOI-30.2 per 0-TI-2018 (Part II, Reference 4.2.92). They demonstrate the adequacy of staffing and include manual actions performed within 120 minutes that are either required or important for fire safe shutdown.

Note that the fire brigade is a dedicated group that does not include the Shift Manager or the other members of the minimum shift crew necessary for safe shutdown of the unit, or any personnel needed for other essential functions during a fire emergency.

PART VII - DEVIATIONS AND EVALUATIONS

k. Demonstrations

This criterion provides a degree of overall assurance that the operator manual actions can be performed in the analyzed time available, i.e., the actions are feasible. The desired operator manual actions are shown to be achievable within the constraints, including the analyzed time available, using the minimum staffing levels, with the expected operable equipment, under the expected environmental conditions (to the extent that they can be reasonably simulated), using the procedures and training provided for the manual actions.

Demonstrations of manual actions at WBN are performed to actual conditions to the extent possible. Plant walkdowns were conducted using the dual unit 0-AOI 30.2 procedures to ensure the proper sequence operator actions, verify the amount of time needed to accomplish the manual action, and to identify the minimum number of operators necessary to support manual actions given a fire in any plant location. During the demonstrations AUOs pick up their PPE (including SCBA) as they go to the MCR for their assignments just as they would in an actual fire. Since PPE is included in the demonstration, additional PPE time allowance is not added in the performance time evaluation. Future walkdowns must demonstrate acceptable margins but the original validation times need not be demonstrated. The plant walkdowns are conducted for those manual actions that must be performed within the first 2-hours following reactor trip as a result of the Appendix R fire. The 2-hour time frame is selected to coincide with predicted minimal operator staffing prior to availability of additional personnel for manual actions as a result of plant callback procedure.

8.3 Fire Area Evaluations

8.3.1 Fire Zone 692.0-A1B (Auxiliary Building Corridor)

8.3.1.1 Fire Prevention

The Auxiliary Building Corridor, 692.0-A1 has been subdivided into major volumes 692.0-A1A, 692.0-A1B and 692.0-A1C. The walls, floor, ceiling and penetration seals separating 692.0-A1B from other fire areas have a fire resistance rating of 2-hours or greater. The fire doors and fire dampers in this room are fire resistance rated for 3-hours. The entire Auxiliary Building Corridor on elevation 692.0 has a floor area of 11,903 ft² and a nominal ceiling height of 19-feet.

The presence of intervening combustibles (insulation on cables in trays) in 692.0-A1 is justified and documented in Section 2.4 of this Part. The openings in the ceiling of room 692.0-A1B (Stairwell No. 5 and elevator door opening) are justified and documented in Section 2.6 of this Part. There are two round spiral welded HVAC ducts that penetrates the floor of 692.0-A1B from 676.0-A1. These combine into one duct that continues through the ceiling of 692.0-A1B onto elevation 713. The penetrations are not provided with fire dampers. This duct work is part of the Emergency Gas Treatment System (EGTS). Spiral welded pipe is treated like a pipe and is provided with fire rated penetration seals between the pipe and the sleeve. Justification for treating round spiral welded HVAC ducts as pipe is documented in Section 2.6 of this Part.

The combustible loading of the Auxiliary Building Corridor, all volumes of 692.0-A1 results in a fire severity classification of Moderate. The combustible material in the room consists of lube oil associated with pumps and valves, plastics associated with electrical panels and boxes, insulating oil associated with transformers; insulation on cables routed in cable trays and anticipated amounts of radwaste trash and laundry. Over 97% of the combustibles in this room come from insulation on cable trays. The assumed ignition sources in this room are

PART VII - DEVIATIONS AND EVALUATIONS

transformers, electrical switchgear and panels, radiation monitors, and pumps. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures needed when transient combustibles or ignition sources are in a room.

8.3.1.2 Detection, Control, and Extinguishment

The Auxiliary Building Corridor is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). The corridor is also provided with an installed automatic sprinkler system. The tunnel to the RWST on the far east side of the room is not provided with detection or suppression. This is justified and documented in Section 3.1.1 of this Part.

Any fire that starts in area 692.0-A1B is quickly detected and personnel are dispatched from the MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. A larger fire activates the installed automatic sprinkler system provided for the room. This extinguishes or limits the magnitude of the fire until the fire brigade arrives. A standpipe and hose station system is available in 692.0-A1A, 692.0-A1C, and 713.0-A1B for fire brigade use. This room is also provided with enhanced sprinkler coverage below obstructions as documented in Attachment 1 of this Part. With fire detection, an enhanced automatic suppression system, and fire resistance barriers, a fire in this area is either extinguished or contained until the fire brigade responds.

8.3.1.3 OMAs 1159 and 1160 – Isolate Normal Charging/Safety Injection Flowpath

These OMAs are necessary if a fire in the immediate vicinity of 2-PNL-276-L112, in 692.0-A1B, damages instrumentation that could disable the pneumatic stop that ensures a minimum flow through 2-FCV-62-93 for Reactor Coolant Pump seal cooling. Thermal barrier cooling would provide this capability for up to 75 minutes before OMAs 1159 and 1160 have to be performed. For OMAs 1159 and 1160, an operator enters room 692.0-A23 to close valve, 2-ISV-62-527, and open valve, 2-ISV-62-526, respectively, using handwheels. It is assumed that the operator may be delayed access to room 692.0-A23 for up to 60 minutes due to a fire located in 692.0-A1B near Panel 2-PNL-276-L112 which will leave 15 minutes to perform the action. The panel does not constitute a credible ignition source and is not located within the fire damage Zone of Influence of any credible ignition source in the room. Given the provisions for fire detection and suppression, as well as the lack of credible ignition sources in the vicinity of this panel, there are no credible fires in 692.0-A1B for which a manual action is necessary. The operator will be able to enter room 692.0-A23 in 60 minutes or less and has at least 15 minutes to perform the actions.

OMAs 1159 and 1160 are both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 75-minutes before the OMAs must be completed. The analyzed travel and performance time was estimated to be 15 minutes for these actions. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The

PART VII - DEVIATIONS AND EVALUATIONS

demonstrated transit time and time to perform the action was 3 minutes 47 seconds; therefore, there is adequate time to perform the action.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel and perform the actions is 15 minutes. It is assumed the AUO will obtain a SCBA when originally mobilized and travel to a safe location near the room during the 60 minutes allowed for fire suppression activities. For a worst case condition the AUO will have 15 minutes to perform the action which takes 3 minutes 47 seconds to complete. This provides a margin of 11 minutes 13 seconds which is adequate time available to ensure the reliability of performing these actions.

c. Environmental Factors

Normal and Standby lighting for the access routes and at the location of these OMAs is assumed to be affected; therefore, 8-hour emergency battery pack lighting is provided. For that reason, there is adequate lighting to access the components and perform the necessary OMAs. In order to perform these OMAs, the operator will have to traverse the fire zone. There may be impediments associated with fire suppression or firefighting activities, such as smoke, noise and water; however, these impediments would not prevent the operator from performing these OMAs. There are no other adverse environmental factors, such as radiation, associated with this OMA.

d. Equipment Functionality and Accessibility

The postulated fire in 692.0-A1B does not impact the functionality or prevent the accessibility of the components needed to be manually operated in room 692.0-A23. The fire is contained within room 692.0-A1.

e. Available Indications

Available local indications for ensuring valve position and MCR indications for control of CVCS charging/seal injection flow is adequate.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is necessary for these actions.

h. Personnel Protection Equipment

It may be necessary for the AUO to don an SCBA. The AUOs are trained in the use of SCBAs which are readily available for fire emergencies.

PART VII - DEVIATIONS AND EVALUATIONS

i. Procedures and Training

The Appendix R operator manual actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.1.4 Staffing Requirements for a Fire in 692.0-A1B

For a fire in 692.0-A1B, seven Unit 2 actions are performed by four AUOs and four Unit 1 actions are performed by two AUOs for a total of six AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1 and Unit 2 manual actions, should there be a fire in room 692.0-A1B.

8.3.2 Room 692.0-A22 (Charging Pump 2B-B Room)

8.3.2.1 Fire Prevention

The Charging Pump 2B-B Room, 692.0-A22, is bounded by 2-hour fire rated regulatory fire barriers. Openings in these barriers are provided with fire doors, dampers and penetration seals that have a rating at least equivalent to the barriers. The room has a floor area of 412 ft² and a nominal ceiling height of 19 feet. The combustible loading in room 692.0-A22 results in a fire severity classification of Low. Lube oil for Charging Pump 2B-B is 86% of the total combustible material in the room. The remaining 14% is from various plastic associated with emergency lighting and light covers, as well as assumed Rad Waste trash and laundry. The charging pump is the only credible ignition source in the room. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.2.2 Detection, Control, and Extinguishment

The Charging Pump 2B-B Room is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). An automatic sprinkler system is provided for the room, except in the entrance labyrinth (Section 3.1 of this Part provides justification and documentation of acceptance of the lack of suppression in the labyrinth). However, given that this room is a separate fire area with low combustible loading, the fire barrier ratings of the room, and the lack of redundant safe shutdown equipment in the room, a fire in this area/room will not endanger other safety-related equipment required for safe plant shutdown.

Any fire that starts in this area is quickly detected and personnel are dispatched from the MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. A larger fire activates the installed automatic, preaction suppression system provided for the room. This extinguishes or limits the magnitude of the fire until the fire brigade arrived. A standpipe and hose station system is also available in the adjacent room (692.0-A1) for fire brigade use. Even if the postulated fire starts and is not extinguished, the fire rating of the room's barriers would contain the fire and not allow it to propagate to adjacent rooms. Therefore, a fire in this room is contained within the room and does not present an exposure hazard to any adjacent rooms.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.2.3 OMA 1159 and 1160 – Isolate Normal Charging/Safety Injection Flowpath

The Charging Header Flow Control Valve (2-FCV-62-93) is in room 692.0-A22 and could potentially be damaged by a fire in this room, inhibiting the ability to maintain minimum flow through the valve. The fire safe shutdown requirement is to isolate normal charging/safety injection flow and provide a RCP seal injection flow path within 75 minutes by operation of valves 2-ISV-62-526 and 2-ISV-62-527, located in room 692.0-A23.

OMAs 1159 and 1160 are both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 75-minutes before the OMA must be completed. The analyzed travel and performance time was estimated to be 15 minutes for these actions. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The demonstrated transit time and time to perform the action was 3 minutes 47 seconds; therefore, there is adequate time to perform the action.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel and perform the actions (15 minutes) provides 60 minutes (400%) margin and the demonstrated validation (3 minutes 47 seconds) provides 71 minutes 13 seconds (>500%) margin. The operator will have obtained a SCBA and there is adequate time available to ensure reliability of performing these actions.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of these OMA's. If they were unavailable, 8-hour emergency battery pack lighting is provided; therefore, there is adequate lighting to access room 692.0-A23 and perform the necessary OMA's. The room with the postulated fire, room 692.0-A22, is adjacent to the room where the OMA's are performed, room 692.0-A23. The access to room 692.0-A23 is via the 692.0-A1B corridor which could potentially be affected by the fire or firefighting activities. There may be smoke from room 692.0-A22, as well as fire hoses and water in the access path. However, these factors would not prevent the performance of the OMA's.

d. Equipment Functionality and Accessibility

The fire that results in the fire-induced damage requiring implementation of these OMA's is contained within room 692.0-A22. Though the fire is adjacent to the room where the OMA's are being performed, it would not affect the functionality and accessibility of the equipment needed to perform these OMA's.

e. Available Indications

Available local indications for ensuring valve position and MCR indications for control of CVCS charging/seal injection flow are adequate.

PART VII - DEVIATIONS AND EVALUATIONS

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is needed for these OMAs.

h. Personnel Protection Equipment

This action is to be performed in a room near the fire location; therefore, the AUO may be required to use the SCBA, which was obtained when originally mobilized.

i. Procedures and Training

The Appendix R operator manual actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.2.4 Staffing Requirements for a Fire in Room 692.0-A22

For a fire in 692.0-A22, five Unit 2 actions are performed by three AUOs and three Unit 1 actions are performed by two AUOs for a total of five AUOs. The staffing of eight AUOs is more than sufficient to accomplish all of the needed Unit 1 and Unit 2 manual actions, should there be a fire in room 692.0-A22.

8.3.3 Room 692.0-A25 (Unit 2 Pipe Gallery)

8.3.3.1 Fire Prevention

The Unit 2 Pipe Gallery, 692.0-A25 is bounded by 2-hour regulatory fire barriers constructed of reinforced concrete. The openings through these barriers are protected with doors, dampers and penetration seals that are equivalent to the rating of the barrier. Room 692.0-A25 has a floor area of 2,003 ft² and a nominal ceiling height of 19-feet. The combustibles in 692.0-A25 consist of lube oil and grease associated with fans, pumps and valves and plastics associated with electrical panels, boxes and lights. The combustible loading in the room results in a fire severity classification of insignificant.

The potential ignition sources consist of four small recirculating chilled water pumps and two large valves. The chilled water pumps contain less than ½-gallon of lubricants each and the valves contain approximately 5-½ gallons of lubricant each. None of these are considered credible ignition sources and are not in the immediate vicinity of a significant quantity of combustibles. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.3.2 Detection, Control and Extinguishment

The Unit 2 Pipe Gallery Room is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. If a larger fire occurs, the installed automatic preaction sprinkler system provided for the room activates. A standpipe and hose station system is also available from the adjacent room (692.0-A1) for fire brigade use.

8.3.3.3 OMA 1065 – Establish RWST Suction

The fire safe shutdown requirement for a fire in 692.0-A25 is to manually open 2-LCV-62-136-B (RWST to Charging Pumps Valve) to establish RWST suction. A fire that is contained within room 692.0-A25 could potentially damage cables (2V2777B, 2M166, 2M162, 2V2767A, 2V2100B, 2V2101B, 2V2102B, 2V1202B, 2V1203A, 2V2070A, 2V2071A, and 2V2072A) requiring implementation of this OMA. The operator must open breaker 2-BKR-62-136-B on 2-MCC-213-B1-B to allow operation of a handwheel. This OMA is completed within 75 minutes and performed in room 772.0-A15.

OMA 1065 is both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 75-minutes before the OMA must be completed. The analyzed time estimated to travel and complete the action is 5 minutes. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The demonstrated transit time and time to perform the action was 2 minutes 23 seconds; therefore, there is adequate time to perform the action. A fire in 692.0-A25 would not affect the performance of this OMA.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel and perform the action (5 minutes) provides 70 minutes (>500%) margin and the demonstrated validation (2 minutes 23 seconds) provides 72 minutes 37 seconds (>500%) margin which is adequate time to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of this OMA. If they were unavailable, 8-hour emergency battery pack lighting is provided; therefore, there is adequate lighting to access the local panel and perform the needed OMA. Because the operator does not have to traverse or enter the fire zone, there are no impediments associated with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

PART VII - DEVIATIONS AND EVALUATIONS

d. Equipment Functionality and Accessibility

By comparison to similar Unit 1 actions (OMA 450), equipment necessary for the manual action is functional and accessible. The fire that results in the fire-induced damage requiring implementation of this OMA is contained in room 692.0-A25.

e. Available Indications

Available local indications for verifying the breaker is open are adequate.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is needed to complete this action.

h. Personnel Protection Equipment

Based on the location of the fire in relation to the areas where the OMA is performed, no personnel protection equipment is needed as part of the OMA.

i. Procedures and Training

The Appendix R operator manual actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.3.4 OMA 1066 – Establish RWST Suction

The fire safe shutdown requirement for a fire in 692.0-A25 is to manually open 2-LCV-62-136-B (RWST to Charging Pumps Valve) to establish RWST suction. A fire that is contained within room 692.0-A25 could potentially damage cables (2V2777B, 2M166, 2M162, 2V2767A, 2V2100B, 2V2101B, 2V2102B, 2V1202B, 2V1203A, 2V2070A, 2V2071A, and 2V2072A) requiring implementation of these OMAs. The operator is to open the valve 2-LCV-62-136-B using the local handwheel. This action is performed in conjunction with OMA 1065, opening a breaker to allow operation of the handwheel. This OMA must be completed in 75 minutes.

It is assumed the AUO will obtain a SCBA when originally mobilized and travel to a safe location near the room during the 60 minutes allowed for fire suppression activities.. For a worst case condition the AUO will have 15 minutes to perform the action which takes 6 minutes 53 seconds to complete. The in situ combustible loading in the room is insignificant and is dispersed throughout the room. The room is provided with automatic suppression and detection and is a combustible controlled area. There are no credible ignition sources or quantities of combustible material near the valve; therefore, there it is concluded that access to and manipulation of the valve will not be delayed for 60 minutes.

OMA 1066 is both feasible and reliable based on NUREG-1852 criteria, as follows:

PART VII - DEVIATIONS AND EVALUATIONS

a. Adequate Time Available to Perform Actions

The operator has 75-minutes before the OMA must be completed. The analyzed time estimated to travel and complete the action is 15 minutes. This action is to be performed in the same room as the fire, but since the combustible loading is insignificant, it is expected that the fire will be extinguished in less than an hour, allowing the operator to perform the OMA within the 75 minute time limit. The demonstrated time to complete the action is 6 minutes 53 seconds. Assuming 60 minutes delay still leaves 15 minutes to complete the action which results in a margin of 8 minutes 7 seconds. This is adequate time available to perform the action.

b. Adequate Time Available to Ensure Reliability

It is assumed the AUO will access room 692.0-A25 within 60 minutes (time allowed for fire suppression activities in 692.0-A25) which leaves 15 minutes to perform the actions that take 6 minutes 53 seconds to complete. This provides a margin of 8 minutes 7 seconds which is adequate time available to ensure the reliability of performing these actions.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of this OMA. It is highly unlikely that a credible fire in the room would affect the normal or standby lighting; however, if they were unavailable, 8-hour emergency battery pack lighting is provided; therefore, there is adequate lighting to access the local panel and perform the OMA. The AUO would also be expected to carry a portable lantern, which is readily available. In order to perform this OMA, the operator will have to enter the fire zone and there may be impediments associated with fire suppression or firefighting activities, such as smoke, water, and the fire brigade. However, these impediments would not prevent the operator from performing this OMA. There are no other adverse environmental factors, such as radiation, associated with this OMA.

d. Equipment Functionality and Accessibility

The combustible loading in room 692.0-A25 is insignificant; the valve is not in the immediate vicinity of a credible ignition source or significant quantity of combustible material and is located just inside the door. Therefore, the valve will remain functional and is easily accessible.

e. Available Indications

Available local indications and MCR indications for verifying RWST suction are adequate.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

The AUO is expected to carry a portable lantern, which is readily available.

PART VII - DEVIATIONS AND EVALUATIONS

h. Personnel Protection Equipment

This action is to be performed in the room after the fire has been extinguished; therefore, the AUO may be required to use the SCBA, which was obtained when originally mobilized.

i. Procedures and Training

The Appendix R operator manual actions procedures (0-AOI-30.2 series - Part II, Reference 4.2.90) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.3.5 Staffing Requirements for a Fire in Room 692.0-A25

For a fire in 692.0-A25, five Unit 2 actions are performed by four AUOs and three Unit 1 actions are performed by two AUOs for a total of six AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the dual unit manual actions, should there be a fire in room 692.0-A25.

8.3.4 Fire Zone 713.0-A1A (Auxiliary Building General Area)

8.3.4.1 Fire Prevention

The Auxiliary Building Corridor (713.0-A1) is a large area constructed of reinforced concrete which is subdivided into smaller areas. The north, south, west walls and penetration seals of room 713.0-A1A have a fire resistance rating of 2-hours or greater. The ceiling and floor have a fire resistance rating of 2-hours. The door and fire dampers in this room are fire resistance rated for 3-hours, or have been evaluated as equivalent to fire barriers.

The presence of intervening combustibles (insulation on cables in trays) in 713.0-A1A are compensated for by an enhanced automatic preaction sprinkler system and is documented and justified in Section 2.4 of this Part. The 713.0-A1A floor and ceiling slabs contains stairwell #6 that is not provided with fire rated closures. Draft stops and a water curtain are utilized in lieu of rated barriers as documented in Section 2.6.3.1 of this Part.

The Auxiliary Building Corridor, all portions of 713.0-A1, has a floor area of 17,693 ft² and a nominal ceiling height of 23-feet. The combustible loading of 713.0-A1 results in a fire severity classification of Moderately Severe. The combustible material in the room consists of lube oil in the pumps, motors and valves, plastics associated with electrical panels, boxes and lights, insulation on cables routed in cable trays and anticipated amounts of radwaste trash and laundry. Insulation on cables in trays accounts for approximately 98% of the combustible loading in 713.0-A1. The assumed ignition sources in this room are transformers and motor control centers (MCCs). NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.4.2 Detection, Control and Extinguishment

The Auxiliary Building Corridor is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). A fire is quickly detected and personnel are dispatched from the

PART VII - DEVIATIONS AND EVALUATIONS

MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. If a larger fire occurs, the installed automatic sprinkler system provided for the room activates, and delay the spread of the fire until the fire brigade arrives. The suppression system in this area does not extend over the boric acid equipment; however, the area is designated as a Combustible Control Zone (CCZ). In addition, the ceiling over this area is level and relatively unobstructed; therefore, detection is reliable. The sprinklers in the immediate vicinity of this area control the spread of the fire until the fire brigade responds. A standpipe and hose station system is also available in the room for fire brigade use.

8.3.4.3 OMA 1022 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 713.0-A1A could damage the Auxiliary and Control Air Header B (ACAS-ENDUSER-B, 1-PCV-3-132 and 1-L-222B). Damage to this valve or panel would prevent the ability to modulate the power relief valve (2-PCV-1-30) to relieve pressure on #4 Steam Generator when necessary. The fire safe shutdown requirement is to have an air source for 2-PCV-1-30 within 60 minutes for operation of the PCV and thereby maintain pressure control of the #4 Steam Generator. Emergency air is provided for operation of the PCV, which is implemented by an OMA (SG PORV Nitrogen Station panel 2-L-1000) in 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1022 following a fire in this room is covered in a bounding evaluation (Section 8.3.63).

8.3.4.4 OMA 1023 – Operating Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 713.0-A1A could potentially damage the Auxiliary and Control Air Header A (ACAS-ENDUSER-A, 1-PCV-3-122 and 1-L-214B). Damage to this valve or panel would prevent the ability to modulate the power relief valve (2-PCV-1-23) to relieve pressure on #3 Steam Generator when necessary. The fire safe shutdown requirement is to have an air source for 2-PCV-1-23 within 60 minutes for operation of the PCV and thereby maintain pressure control of the #3 Steam Generator. Emergency air is provided for operation of the PCV, which is implemented by an OMA (SG PORV Nitrogen Station panel 2-L-1000) in 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in a bounding evaluation (Section 8.3.64).

8.3.4.5 Unit 1 OMAs 1411, 1447 and 1614 – Control Steam Supply to TDAFW Pump

A fire in room 713.0-A1A could potentially damage control cable or a power cable for flow control valves (1-FCV-1-51-S and 1-FCV-1-52) which prevents the ability to control steam supply to the Turbine Driven Auxiliary Feedwater Pump (TDAFW-14). The fire safe shutdown requirement is to manually control steam supply to the TDAFW within 20 minutes by operating transfer switches (1-XSW-46-AC-S, 1-XSW-46-DC-S, 1-XS-46-57-S and 1-XS-46-57A-S) in AB room 692-A1A1.

OMAs 1411, 1447 and 1614 are feasible and reliable based on NUREG-1852 criteria, as follows:

PART VII - DEVIATIONS AND EVALUATIONS

a. Adequate Time Available to Perform Actions

The operator has 20-minutes before the OMAs must be completed. The analysis estimated a travel and performance time of 10 minutes (OMA 1614) and 11 minutes (OMAs 1411 & 1447). Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The demonstrated times to travel and to perform the actions were 3 minutes 21 seconds for OMA 1447, 3 minutes 36 seconds for OMA 1411 and 5 minutes 31 seconds for OMA 1614. Total time to complete all OMAs is 5 minutes 31 seconds which leaves a margin of 14 minutes 29 seconds; therefore, there is adequate time available to perform the actions.

b. Adequate Time Available to Ensure Reliability

The analyzed time conservatively estimated to travel and perform the longest action (11 minutes) provides 9 minutes (81%) margin. The demonstrated validation (5 minutes 31 seconds) provides 14 minutes 29 seconds of margin. This results in 263% margin. The time available for the AUO to perform the action is more than adequate to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of the OMAs. Even if they were not available, 8-hour emergency battery pack lighting is available; therefore, there is adequate lighting to access the local panel and perform the OMA. The control location would be unaffected by the fire or other adverse environmental conditions, such as radiation. The AUO should not need an SCBA, but it is readily available if needed. There are no impediments associated with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

d. Equipment Functionality and Accessibility

The fire that results in the fire induced damage requiring implementation of these OMAs is on a separate elevation of the Auxiliary Building, and will not affect the functionality and accessibility of 1-FCV-1-51-S, 1-FCV-1-52 or 1-XS-46-57-S and -57A-S.

e. Available Indications

No local indications are needed.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is needed to complete this action.

PART VII - DEVIATIONS AND EVALUATIONS

h. Personnel Protection Equipment

No special PPE is needed to access and complete this OMA.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.4.6 Staffing Requirements for a Fire in Room 713.0-A1A

For a fire in 713.0-A1A, thirteen Unit 1 actions requiring five AUOs and five Unit 2 actions are performed by three AUOs for a total of eight AUOs. Therefore, a total of eight AUOs is sufficient to complete all of the OMAs for Unit 1 and Unit 2.

8.3.5 Fire Zone 713.0-A1B (Auxiliary Building General Area)

8.3.5.1 Fire Prevention

The Auxiliary Building Corridor (713.0-A1) is a very large area constructed of reinforced concrete. The area is subdivided into smaller overlapping fire zones as described in Part III, Section 10.3. The south walls of Room 713.0-A1B have a fire resistance rating of 3-hours. The ceiling, floor, north and east walls, elevator shaft walls and penetration seals are fire resistance rated to 2-hours or greater. The door and fire dampers in this room are fire resistance rated for 3-hours. The Auxiliary Building Corridor (713.0-A1) has a floor area of 17,693 ft² and a nominal ceiling height of 23-feet. The combustible loading of 713.0-A1 results in a fire severity classification of Moderately Severe.

The presence of intervening combustibles (insulation on cables in trays) in 713.0-A1B is documented and justified in Section 2.4 of this Part.

A water curtain is utilized in lieu of rated barriers for the Stair #5 opening in the floor and ceiling as documented in Section 2.6.3.1 of this Part. There is a 12 inch round spiral welded HVAC duct that penetrates the floor and ceiling of 713.0-A1B. The penetration is not provided with a fire damper. This duct is part of the Emergency Gas Treatment system. Spiral welded pipe is treated as normal pipe penetrations. Therefore they are provided with fire rated mechanical penetration seals and provide an adequate level of fire protection for these types of ducts as documented in Section 2.6.3.2.a of this Part.

The combustible material in the room consists of lube oil in the pumps, motors and valves, plastics associated with electrical panels, boxes and lights, insulation on cables routed in cable trays and anticipated amounts of radwaste trash and laundry. Approximately 90% of the combustibles in this room are from insulation on cables in trays.

The assumed ignition sources in this room are dry transformers and 480V Fuel & Waste Handling Board. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are required in a room.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.5.2 Detection, Control and Extinguishment

The Auxiliary Building Corridor (713.0-A1) is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. A larger fire activates the installed automatic sprinkler system provided for the room. This extinguishes or limits the magnitude of the fire until the fire brigade arrives. The 713.0-A1 Corridor is provided with a standpipe and hose station system (3 standpipes with hose stations) for fire brigade use. Additional hose stations from the floors above and below are also available.

The suppression system in this area does not extend over the boric acid tank area; however, this area is designated as a CCZ. The engineering evaluation for less than full suppression capability in 713.0-A1 is documented in Section 3.1.1 of this Part.

8.3.5.3 OMA 1016 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 713.0-A1B could potentially damage the Train A Auxiliary Control Air System (ACAS-ENDUSER-A, 2-PCV-3-122) or damage a control cable to the Steam Generator #1 Pressure Indicator Controller 2-PIC-1-6A, cable 2PM1372. Damage to 2-PCV-3-122 (AFW Pump Outlet Pressure Control Valve) in this room could result in a loss of air to operate the SG PORV (2-PCV-1-5). In addition, damage to cable 2PM1372 in this room could prevent the ability to modulate the pressure control valve to the SG PORV (2-PCV-1-5) when needed.

The fire safe shutdown requirement is to have an air source for 2-PCV-1-5 within 60 minutes for operation of the PCV and thereby maintain pressure control of the #1 Steam Generator. Emergency air is provided for operation of the 2-PCV-1-5, which is implemented by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1001) in 757.0-A21. However, based on a review of the ignition source walkdown results, and the location of valve 2-PCV-3-122 and cable 2PM1372, there is no credible fire in 713.0-A1B that would necessitate this action. Cable 2PM1372 is outside the fire damage zone of influence created by credible ignition sources in room 713.0-A1 as identified by ignition source walkdown documentation. However, as additional defense-in-depth, the following is provided to show that the manual action is both feasible and reliable.

OMA 1016 is both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 60-minutes before the OMA must be completed. The analysis estimated a travel and performance time of 25 minutes. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The demonstrated time to travel and to perform the action was 12 minutes 6 seconds. The fire that results in the fire-induced damage requiring implementation of this OMA will be contained within room 713.0-A1B and will not present an exposure hazard to the access paths from the Control Room to 480V Shutdown Board Room 2A (757.0-A21). The room in which this OMA is performed is unaffected by the fire. There is adequate time available to perform the OMA.

PART VII - DEVIATIONS AND EVALUATIONS

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel to the 480V Shutdown Board Room 2A (757.0-A21) and perform the action (25-minutes) provides 35-minutes (140%) margin. The demonstrated validation time of 12 minutes 6 seconds provides 47 minutes 54 seconds (>400%) margin. The time available for the AUO to perform the action is more than adequate to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of this OMA. If they were unavailable, 8-hour emergency battery pack lighting is provided; therefore, there is adequate lighting to access the local panel and perform the OMA. Because the operator does not have to traverse or enter the fire zone, there are no impediments associated with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

d. Equipment Functionality and Accessibility

Equipment for this manual action is functional and accessible. Also, the fire that results in the fire-induced damage requiring implementation of this OMA is on a separate elevation of the Auxiliary Building, and will not affect the functionality and accessibility of equipment.

e. Available Indications

Available local indications for monitoring N₂ cylinder pressure and regulator adjustment, as well as MCR SG pressure indications, are adequate.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is necessary to perform these OMAs. Spare N₂ cylinders for SG PORV control are available, if needed. The reliability of the N₂ station is assured by the Operational Requirements and Testing and Inspection program as described in Part II, Section 14.10.

h. Personnel Protection Equipment

No special PPE is needed to access and perform this OMA.

i. Procedures and Training

The Appendix R operator manual actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.5.4 OMA 1023 – Operating Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 713.0-A1B could potentially damage the Train A Auxiliary Control Air System (ACAS-ENDUSER-A) or damage a control cable to the Steam Generator #3 Power Operated Relief Valve (2-PCV-1-23). Damage to 2-PCV-3-122 in this room could result in a loss of air to operate the SG PORV. In addition, damage to cable 2PM1617 in this room could prevent the ability to modulate the pressure control valve to the SG PORV when needed.

The fire safe shutdown requirement is to have an air source for 2-PCV-1-23 within 60 minutes for operation of 2-PCV-1-23, thereby establishing pressure control of the #3 Steam Generator. Emergency air is provided for operation of the 2-PCV-1-23, which is implemented by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) located in room 757.0-A24. However, based on a review of the ignition source walkdown results, and the location of valve 2-PCV-3-122 and cable 2PM1617, there is no credible fire in 713.0-A1B that would necessitate this action. Both valve 2-PCV-3-122 and cable 2PM1617 are outside the fire damage zone of influence created by the credible ignition sources in room 713.0-A1B. However, as additional defense-in-depth the following is provided to show that the manual action is both feasible and reliable.

OMA 1023 is both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 60-minutes before the OMA must be completed. The analysis estimated a travel and performance time of 28 minutes for this action. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The demonstrated time to travel and to perform the action was 12 minutes 6 seconds; therefore, adequate time is available to perform the action.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel and perform the action (28-minutes) provides 32-minutes (114%) margin. The demonstrated time to complete this action was 12 minutes 6 seconds which provides 47 minutes 54 seconds (>400%) margin. The time available for the AUO to perform the action is more than adequate to ensure reliability.

c. Environmental Factors

The normal route to room 757.0-A24 from the MCR is through the 480V Shutdown Board Room 2A and this lighting would not be affected by a postulated fire in 713.0-A1B. Eight hour emergency battery pack lighting is available in 757.0-A24; therefore, there is adequate lighting to access the local panel and perform the OMA. Because the operator does not have to traverse or enter the fire zone, there are no impediments associated with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

PART VII - DEVIATIONS AND EVALUATIONS

d. Equipment Functionality and Accessibility

The fire that results in the fire induced damage requiring implementation of this OMA is on a separate elevation of the Auxiliary Building, and therefore will not affect the functionality and accessibility of equipment.

e. Available Indications

Available local indications for monitoring N₂ cylinder pressure and regulator adjustment, as well as MCR SG pressure indications, are adequate.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is necessary to perform these OMAs. Spare N₂ cylinders for SG PORV control are available, if needed. The reliability of the N₂ station is assured by the Operational Requirements and Testing and Inspection program as described in Part II, Section 14.10.

h. Personnel Protection Equipment

No special PPE is needed to access and perform this OMA.

i. Procedures and Training

The Appendix R operator manual actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.5.5 OMA 1615 and 1275 – Control Steam Supply to TDAFW Pump

A fire in room 713.0-A1B could potentially damage control cables or a power cable to the flow control valve (2-FCV-1-51-S) which prevents the ability to control steam supply to the Turbine Driven Auxiliary Feedwater Pump (2-TDAFW-14). The fire safe shutdown requirement is to manually control steam supply to the TDAFW within 20 minutes by operating transfer switches (2-XS-46-57 and 2-XS-46-57A) and hand switch (2-HS-46-56B) in AB rooms 692-A1B1 and 692.0-A26, respectively

OMAs 1615 and 1275 are both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 20-minutes before the OMAs must be completed. The analysis estimated a travel and performance time of 10 minutes. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction.0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The demonstrated times to travel and to perform the actions were 3 minutes 36 seconds for OMA 1615 and 5 minutes 31 seconds for OMA 1275.

PART VII - DEVIATIONS AND EVALUATIONS

Therefore, total time to complete both OMAs (1615 followed by 1275) is 5 minutes 31 seconds which leaves a margin of 14 minutes 29 seconds; therefore, there is adequate time available to perform the actions.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel and perform the action (10-minutes) provides 10-minutes (100%) margin. The demonstrated validation (5 minutes 31 seconds) provides 14 minutes 29 seconds of margin. The time available for the AUO to perform the action is more than adequate to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of the OMAs. Even if they were not available, 8-hour emergency battery pack lighting is available; therefore, there is adequate lighting to access the local panel and perform the OMA. The access through 713.0-A1 is through 713.0-A1A and the closest point of access is more than 40-feet from 713.0-A1B. The AUO should not need an SCBA, but it is readily available if needed. There are no impediments associated with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

d. Equipment Functionality and Accessibility

The fire that results in the fire induced damage requiring implementation of these OMAs is on a separate elevation of the Auxiliary Building, and will not affect the functionality and accessibility of 2-FCV-1-51-S or 2-HS-46-55B, 2-XS-46-57 and -57A.

e. Available Indications

No local indications are needed.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is needed to complete this action.

h. Personnel Protection Equipment

No special PPE is needed to access and complete this OMA.

i. Procedures and Training

The Appendix R operator manual actions procedures (0-AOI-30.2 series) are clear, complete and current.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.5.6 Staffing Requirements for a Fire in Room 713.0-A1B

For a fire in 713.0-A1B, 12 Unit 2 actions are performed by six AUOs and six Unit 1 actions are performed by two AUOs for a total of eight AUOs. This is within the minimum staffing for operating two units.

8.3.6 Room 713.0-A27 (Decontamination Room)

8.3.6.1 Fire Prevention

The Decontamination Room (713.0-A27) is constructed of reinforced concrete and has a fire resistance rating of a minimum of 2 or 3-hours except the walls separating it from rooms 713.0-A1A3 and 713.0-A26. Openings in the fire rated barriers are provided with dampers and penetration seals equivalent to the barrier rating. Room 713.0-A27 has a floor area of 487 ft² and a nominal ceiling height of 23-feet. The combustibles in 713.0-A27 consist of plastics associated with the electrical panels, equipment, light covers, trash, and temporary shielding blankets. The combustible loading in the room results in a fire severity classification of Low.

The small electrical panels, equipment, light covers, trash, and temporary shielding blankets in this room do not constitute credible ignition sources. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.6.2 Detection, Control, and Extinguishment

The Decontamination Room (713.0-A27) is provided with detection or automatic suppression. Portable extinguishers are available throughout the plant for extinguishing any small credible fire. If a larger fire occurs, a standpipe and hose station system is available in adjacent room 713.0-A1 for fire brigade use.

8.3.6.3 OMA 1022 – Operate Steam Generator Relief Valves to Control Secondary Pressure

The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-30 (SG 4 Power Relief Valve) to control secondary pressure. This OMA is not necessary for 713.0-A27. In addition there are no credible ignition sources in this room. If the OMA is needed, the operator must operate 2-ISIV-1-406E2 at the N2 Operating Station for 2-PCV-1-30 (2-L-1000) to open/close 2-PCV-1-30 if MDAFW Pump B is used. This OMA is to be completed within 60 minutes and is performed in room 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1022 following a fire in this room is covered in the OMA 1022 bounding evaluation (Section 8.3.63).

8.3.6.4 OMA 1023 - Operate Steam Generator Relief Valves to Control Secondary Pressure

The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-23 (SG 3 Power Relief Valve) to control secondary pressure. This OMA is not necessary for 713.0-A27. In

PART VII - DEVIATIONS AND EVALUATIONS

addition there are no credible ignition sources in this room. If the OMA is needed, the operator must operate 2-ISIV-1-407E2 at the N2 Operating Station for 2-PCV-1-23 (2-L-1000) to open/close 2-PCV-1-23 if MDAFW Pump B is used. This OMA is to be completed within 60 minutes and is performed in room 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in the OMA 1023 bounding evaluation (Section 8.3.64).

8.3.6.5 Unit 1 OMAs 1411, 1447 and 1614 – Control Steam Supply to TDAFW Pump

A fire in room 713.0-A27 could potentially damage control cable or a power cable for flow control valves (1-FCV-1-51-S and 1-FCV-1-52) which prevents the ability to control steam supply to the Turbine Driven Auxiliary Feedwater Pump (TDAFW-14). The fire safe shutdown requirement is to manually control steam supply to the TDAFW within 20 minutes by operating transfer switches (1-XSW-46-AC-S, 1-XSW-46-DC-S, 1-XS-46-57-S and 1-XS-46-57A-S) in AB room 692-A1A1.

OMAs 1411, 1447 and 1614 are feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 20-minutes before the OMAs must be completed. The analysis estimated a travel and performance time of 10 minutes (OMA 1614) and 11 minutes (OMAs 1411 & 1447). Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The demonstrated times to travel and to perform the actions were 3 minutes 21 seconds for OMA 1447, 3 minutes 36 seconds for OMA 1411 and 5 minutes 31 seconds for OMA 1614. Total time to complete all OMAs is 5 minutes 31 seconds which leaves a margin of 14 minutes 29 seconds; therefore, there is adequate time available to perform the actions.

b. Adequate Time Available to Ensure Reliability

The analyzed time conservatively estimated to travel and perform the longest action (11-minutes) provides 9-minutes (81%) margin. The demonstrated validation (5 minutes 31 seconds) provides 14 minutes 29 seconds of margin. This results in 263% margin. The time available for the AUO to perform the action is more than adequate to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of the OMAs. Even if they were not available, 8-hour emergency battery pack lighting is available; therefore, there is adequate lighting to access the local panel and perform the OMA. The control location would be unaffected by the fire or other adverse environmental conditions, such as radiation. The AUO should not need an SCBA, but it is readily available if needed. There are no impediments associated with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

PART VII - DEVIATIONS AND EVALUATIONS

d. Equipment Functionality and Accessibility

The fire that results in the fire induced damage requiring implementation of these OMAs is on a separate elevation of the Auxiliary Building, and will not affect the functionality and accessibility of 1-FCV-1-51-S, 1-FCV-1-52 or 1-XS-46-57-S and -57A-S.

e. Available Indications

No local indications are needed.

f. Communications

Adequate communications between the location of the OMA and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is needed to complete this action.

h. Personnel Protection Equipment

No special PPE is needed to access and complete this OMA.

i. Procedures and Training

The Appendix R operator manual actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.6.6 Staffing Requirements for a Fire in Room 713.0-A27

For a fire in 713.0-A27, thirteen Unit 1 actions are performed by five AUOs and five Unit 2 actions are performed by three AUOs for a total of eight AUOs. This is the minimum staffing for operating two units.

8.3.7 2ANN – Unit 2 Annulus

8.3.7.1 Fire Prevention

The Unit 2 Annulus (2ANN) is separated from the Unit 2 Auxiliary Building by reinforced concrete that has a fire barrier rating of at least 3-hours and from Unit 2 Primary Containment by the steel shield wall. The penetrations through the concrete wall are provided with 3-hour rated penetration seals. The door penetrations are provided with 3-hour equivalent doors. The Annulus has a floor area of 1,901square feet.

The combustible loading of the Unit 2 Annulus results in a fire severity classification of Severe. The insulation on the cables routed in the cable trays constitutes 98% of the in situ fuel load. The remaining in situ fuel load is due to miscellaneous plastics associated with small electrical panels and junction boxes, insulating oil in small sump pumps, expansion joint material, HEPA filters and lighting fixtures. These materials are dispersed throughout the Annulus and none are credible ignition sources. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8. "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to

PART VII - DEVIATIONS AND EVALUATIONS

preclude introduction of significant quantities of combustible material or ignition sources into the area and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.7.2 Detection, Control, and Extinguishment

The Unit 2 Annulus is provided with automatic suppression and detection in the selected portions of the Annulus containing the cable trays to ensure that redundant fire safe shutdown components in the area are protected in accordance with Appendix R, section III.G.2.e. A fire that started in the Unit 2 Annulus would be detected by the detection system and personnel would be dispatched to investigate. Portable extinguishers are available for extinguishing any small credible fire. A large fire near the cable trays would activate the installed automatic suppression system. The suppression system would extinguish or limit the magnitude of the fire and prevent it from spreading outside the Annulus. Standpipe and hose stations are available throughout the Unit 2 Annulus for Fire Brigade use.

8.3.7.3 OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in 2ANN could damage control cable (2V4031B) to the Power Relief Solenoid Valve (2-PSV-1-24C-B) which prevents the ability to modulate the Power Relief Valve (2-PCV-1-23) to relieve pressure on #3 Steam Generator when needed. The fire safe shutdown requirement for a fire in 2ANN is to have an air source for 2-PCV-1-23 within 60 minutes to maintain pressure control of the #3 Steam Generator. Emergency air is provided for operation of the PCV, via an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in the OMA 1023 bounding evaluation (Section 8.3.64).

8.3.7.4 Staffing Requirements for a Fire in Room 2ANN

For a fire in 2ANN, three Unit 2 actions are performed by three AUOs. Therefore, a total of eight AUOs is more than sufficient to complete all of the OMAs for Unit 2, should there be a fire in 2ANN.

8.3.8 Room 737.0-A1A (Auxiliary Building General Area)

8.3.8.1 Fire Prevention

Room 737.0-A1 of the Auxiliary Building is a large area that is subdivided into 737.0-A1A, 737.0-A1B, 737.0-A1CN, and 737.0-A1C. The Auxiliary Building Corridor (737.0-A1) is constructed of reinforced concrete walls, ceiling, and floor with a fire resistance rating of 2 hours or greater. 737.0-A1A is separated from other parts of Room 737.0-A1 by an overlapping analysis as described in Part III, Section 10.3. Doors, HVAC dampers and penetration seals in 737.0-A1 are fire resistance rated for 3-hours with the exception of two doors and one damper which are rated for 1.5 hours. Deviations are noted below. Room 737.0-A1 has a floor area of 23,144 ft² and a nominal ceiling height of 19-feet. The combustibles in 737.0-A1 consist of lube oil in the pumps, motors, and valves; plastic associated with electrical panels, boxes, and lights; and insulation on cables in trays. The majority (approximately 95%) of the combustibles is the insulation on the cables in trays. The combustible loading in the room results in a fire severity index of moderately severe.

PART VII - DEVIATIONS AND EVALUATIONS

The presence of intervening combustibles (insulation on cables in trays) in 737.0-A1 is justified and documented in Section 2.4 of this Part. The 737.0 floor slab has stairwell and hatch openings (various locations) that are not provided with fire rated closures. The justification for these openings, water curtain in lieu of rated barriers, is documented in Section 2.6 of this Part. There is a 12 inch round spiral welded HVAC duct that penetrates the floor of 737.0-A1B. The penetration is not provided with a fire damper.

This duct is part of the Emergency Gas Treatment system. Spiral welded pipe is treated like a pipe and is provided with fire rated seals between the pipe and the sleeve. Justification is documented in Section 2.6 of this Part.

There are a number of assumed ignition sources in 737.0-A1 including chillers, lighting boards and transformers, switchgear and a Motor Control Center (MCC). NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.8.2 Detection, Control, and Extinguishment

The Auxiliary Building Corridor, 737.0-A1, is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the MCR to investigate the detector alarm. Portable extinguishers are available throughout the plant for extinguishing any small credible fire. If a larger fire occurs, the automatic sprinkler system provided for the room activates. A standpipe and hose station system is also available for fire brigade use. The lack of total area suppression and detection in the airlocks (AV-036, rooms 737.0-A4 and A11) is documented in Section 3.1 of this Part.

Even if the postulated fire starts and is not extinguished, the fire barriers contain the fire until the fire brigade responds.

8.3.8.3 OMA 1022 - Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in 737.0-A1A potentially damages control cables (2PV6756) to the Pressure Indicator Controller (2-PIC-1-31A), a control cable (2V7581B) to the Power Relief Solenoid Valve (2-PSV-1-31B-B), or directly damage an Auxiliary Control Air Header B (ACAS ENDUSER-B, 1-LCV-3-148, 1-LCV-3-148A, 1-LCV-3-171, 1-LCV-3-171A) which prevents the ability to modulate Power Relief Valve 2-PCV-1-30 to relieve pressure on the #4 Steam Generator when necessary. The fire safe shutdown requirement for a fire in this room is to have an air source for 2-PCV-1-30 within 60 minutes to maintain pressure control of the #4 Steam Generator. Emergency air is provided for operation of the PCV by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

OMA 1022 is both feasible and reliable based on NUREG-1852 criteria, as follows:

PART VII - DEVIATIONS AND EVALUATIONS

a. Adequate Time Available to Perform Actions

The operator has 60-minutes before this action must be completed. Analysis provided an estimated travel and performance time of 28 minutes for this action. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The demonstrated time for travel from the MCR to the nitrogen station and to perform the comparable actions was 12 minutes 6 seconds which leaves 47 minutes 54 seconds of margin. There is adequate time available to perform the actions.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated for travel to the N₂ station in room 757.0-A24 and to perform the action (28-minutes) provides 32-minutes (114%) margin. The demonstrated validation time was 12 minutes 6 seconds which provides 47 minutes 54 seconds (400%) margin. This is more than adequate time available to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of this OMA. If they were unavailable, 8-hour emergency battery pack lighting is provided; therefore, there is adequate lighting to access the local panel and to perform the OMA. Because the operator does not have to traverse or enter the fire zone to perform the action in room 757.0-A24, there are no impediments associated with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

d. Equipment Functionality and Accessibility

The fire that results in the fire-induced damage requiring implementation of this OMA is on a separate elevation of the Auxiliary Building, on the opposite side of the building from the control location, and therefore will not affect the functionality and accessibility of equipment.

e. Available Indications

Available local indications for monitoring N₂ cylinder pressure and regulator adjustment, as well as MCR SG pressure indications, are adequate.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is necessary to perform these OMAs. Spare N₂ cylinders for SG PORV control are available, if needed. The reliability of the N₂ station is assured by the Operational Requirements and Testing and Inspection program as described in Part II, Section 14.10.

PART VII - DEVIATIONS AND EVALUATIONS

h. Personnel Protection Equipment

Standard personnel protection equipment is used for the performance of this action.

i. Procedures and Training

The Appendix R operator manual actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.8.4 OMA 1023 - Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in 737.0-A1A potentially damages a control cable (2PV6756) to the Pressure Indicator Controller (2-PIC-1-24A), a control cable (2PM1621) to the Power Relief Valve Modifier (2-PM-1-24), a control cable (2V7539A) to the Power Relief Solenoid Valve (2-PSV-1-24B-A), or damage control cable 2PL3786A or equipment supporting ACAS ENDUSER-A for the Auxiliary Control Air Compressor A (0-MTR-32-60-A) which prevents the ability to modulate Power Relief Valve 2-PCV-1-23 to relieve pressure on the #3 Steam Generator when needed. The fire safe shutdown requirement for a fire in this room is to have an air source for 2-PCV-1-23 within 60 minutes to maintain pressure control of the #3 Steam Generator. Emergency air is provided for operation of the PCV by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

OMA 1023 is both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 60-minutes before this action must be completed. Analysis provided an estimated travel and performance time of 28 minutes for this action. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The demonstrated time for travel from the MCR to the nitrogen station and performance of the actions was 12 minutes 6 seconds which provides 47 minutes 54 seconds of margin. This is adequate time available to perform the actions.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated for travel to the N₂ station in room 757-A24 and to perform the action (28-minutes) provides 32-minutes (114%) margin. The demonstrated validation time 12 minutes 6 seconds provides 47minutes 54 seconds (400%) margin. This is more than adequate time available to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of this OMA. If they were unavailable, 8-hour emergency battery pack lighting is provided; therefore, there is adequate lighting to access the local panel and to perform the OMA. Because the operator does not have to traverse or enter the fire zone to perform the action in room 757.0-A24, there are no impediments associated with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

PART VII - DEVIATIONS AND EVALUATIONS

d. Equipment Functionality and Accessibility

The fire that results in the fire-induced damage requiring implementation of this OMA is on a separate elevation of the Auxiliary Building, on the opposite side of the building from the control location, and therefore will not affect the functionality and accessibility of equipment.

e. Available Indications

Available local indications for monitoring N₂ cylinder pressure and regulator adjustment, as well as MCR SG pressure indications are adequate.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is necessary to perform these OMAs. Spare N₂ cylinders for SG PORV control are available, if needed. The reliability of the N₂ station is assured by the Operational Requirements and Testing and Inspection program as described in Part II, Section 14.10.

h. Personnel Protection Equipment

Standard personnel protection equipment is used for the performance of this action.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.8.5 Unit 1 OMAs 1411, 1447 and 1614 – Control Steam Supply to TDAFW Pump

A fire in room 737.0-A1A could potentially damage a power cable for flow control valves (1-FCV-1-51-S and 1-FCV-1-52) which prevents the ability to control steam supply to the Turbine Driven Auxiliary Feedwater Pump (TDAFW-14). The fire safe shutdown requirement is to manually control steam supply to the TDAFW within 20 minutes by operating transfer switches (1-XSW-46-AC-S, 1-XSW-46-DC-S, 1-XS-46-57-S and 1-XS-46-57A-S) in AB room 692-A1A1.

OMAs 1411, 1447 and 1614 are feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 20-minutes before the OMAs must be completed. The analysis estimated a travel and performance time of 10 minutes (OMA 1614) and 11 minutes (OMAs 1411 & 1447). Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II,

PART VII - DEVIATIONS AND EVALUATIONS

Reference 4.2.92). The demonstrated times to travel and to perform the actions were 3 minutes 21 seconds for OMA 1447, 3 minutes 36 seconds for OMA 1411 and 5 minutes 31 seconds for OMA 1614. Total time to complete all OMAs is 5 minutes 31 seconds which leaves a margin of 14 minutes 29 seconds; therefore, there is adequate time available to perform the actions.

b. Adequate Time Available to Ensure Reliability

The analyzed time conservatively estimated to travel and perform the longest action (11-minutes) provides 9-minutes (81%) margin. The demonstrated validation (5 minutes 31 seconds) provides 14 minutes 29 seconds of margin. This results in 263% margin. The time available for the AUO to perform the action is more than adequate to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of the OMAs. Even if they were not available, 8-hour emergency battery pack lighting is available; therefore, there is adequate lighting to access the local panel and perform the OMA. The control location would be unaffected by the fire or other adverse environmental conditions, such as radiation. The AUO should not need an SCBA, but it is readily available if needed. There are no impediments associated with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

d. Equipment Functionality and Accessibility

The fire that results in the fire induced damage requiring implementation of these OMAs is on a separate elevation of the Auxiliary Building, and will not affect the functionality and accessibility of 1-FCV-1-51-S, 1-FCV-1-52 or 1-XS-46-57-S and -57A-S.

e. Available Indications

No local indications are needed.

f. Communications

Adequate communications between the location of the OMA and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is needed to complete this action.

h. Personnel Protection Equipment

No special PPE is needed to access and complete this OMA.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.8.6 Staffing Requirements for a Fire in Room 737.0-A1A

For a fire in 737.0-A1A, Nineteen Unit 1 actions are performed by three AUOs (#1, #2 & #5); seven Unit 2 actions are performed by one AUO (#6); eight Unit 1 and one Unit 2 actions are performed by one AUO (#4); seventeen Unit 1 and one common actions are performed by one AUO (#3); one Unit 2 and two common actions are performed by one AUO (#7) and one Unit 1, two Unit 2 and one common actions are performed by one AUO (#8) for a total of eight AUOs. The staffing of eight AUOs is sufficient to accomplish all of the “common”, Unit 1 and Unit 2 manual actions, should there be a fire in room 737.0-A1A.

8.3.9 Room 737.0-A1B (Auxiliary Building General Area)

8.3.9.1 Fire Prevention

The Auxiliary Building Corridor (737.0-A1B), a subdivision of 737.0-A1, is constructed of reinforced concrete and has a fire resistance rating of 2 or 3-hours. Doors, dampers, penetration seals and barriers (walls, floors, ceiling etc.) in 737.0-A1 are fire resistance rated for a minimum of 2-hours. Room 737.0-A1 has a floor area of 23,144 ft² and a nominal ceiling height of 19-feet. The combustibles in 737.0-A1 consist of lube oil in the pumps, motors, and valves, plastic associated with electrical panels and boxes and lights and insulation on cables in trays. The majority (approximately 97%) of the combustibles are the insulation on the cables. The combustible loading in the room has a fire severity classification of moderately severe.

The presence of intervening combustibles (insulation on cables in trays) is justified and documented in Section 2.4 of this Part. The 737.0 floor slab has stairwell and hatch openings that are not provided with fire rated closures, they are instead provided with water curtains. The justification for these openings is documented in Section 2.6 of this Part. There is a 12 inch round spiral welded HVAC duct that penetrates the floor of 737.0-A1B. The penetration is not provided with a fire damper. This duct is part of the Emergency Gas Treatment system. Spiral welded pipe is treated like a pipe and is provided with fire rated seals between the pipe and the sleeve. Justification is documented in Section 2.6 of this Part.

There are a number of assumed ignition sources in 737.0-A1 including chillers, lighting boards, transformers, switchgear and a Motor Control Center (MCC). NPG-SPP-18.4.7, “Control of Transient Combustibles” and NPG-SPP-18.4.8, “Control of Ignition Sources (Hot Work)” defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.9.2 Detection, Control, and Extinguishment

The Auxiliary Building Corridor, 737.0-A1, is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the nearby MCR to investigate the detector alarm. Portable extinguishers are available throughout the plant for extinguishing any small credible fire. If a larger fire occurs, the automatic sprinkler system provided for the room activates. A standpipe and hose station system is also available for fire brigade use.

Even if the postulated fire starts and is not extinguished, the fire barriers contain the fire; therefore, propagation to adjacent rooms is unlikely. A fire in this room does not present an

PART VII - DEVIATIONS AND EVALUATIONS

exposure hazard to the access path to the manual action locations in 713.0-A20, 757.0-A2, 757.0-A21, 757.0-A24, 757.0-A28 and 772.0-A16.

8.3.9.3 OMA 1016 - Operate Steam Generator Relief Valves to Control Secondary Pressure

The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-5 (SG 1 Power Relief Valve) to control secondary pressure. A fire that is contained within 737.0-A1B could potentially fail Train A Auxiliary Control Air System or damage cables 2PV6750, or 2PM1369 and necessitate implementation of this OMA. The operator must operate 2-ISIV-1-408E2 at the local N2 station 2-L-1001. This OMA is to be completed within 60 minutes. This Action is performed in room 757.0-A21.

OMA 1016 is both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 60-minutes before the OMA must be completed. The analysis provided an estimated travel and performance time of 25 minutes. Verification and validation for common 0-AOI-30.2 C-series procedure (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The Validation Walkdown for this action demonstrated that the time to travel and to perform the action was 12 minutes 6 seconds which provides 47 minutes 54 seconds of margin. There is adequate time available to perform the action.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel to the SD BD Room and perform the action (25-minutes) provides 35-minutes (140%) margin. The demonstrated validation time was 12 minutes 6 seconds which provides 47 minutes 54 seconds (>400%) of margin. There is more than adequate time available to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of this OMA. If they were unavailable, 8-hour emergency battery pack lighting is provided; therefore, there is adequate lighting to access the local panel and to perform the OMA. The AUO does not have to enter or traverse the fire zone to perform this OMA. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

d. Equipment Functionality and Accessibility

Actions are performed at local control panels that are unaffected by the fire and are easily accessible. A fire in 737.0-A1 would not affect the functionality and accessibility of equipment necessary to perform this OMA. The control panels in room 757.0-A21 are readily accessible.

PART VII - DEVIATIONS AND EVALUATIONS

e. Available Indications

Available local indications for monitoring N₂ cylinder pressure and regulator adjustment, as well as MCR SG pressure indications, are adequate.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is necessary to perform these OMAs. Spare N₂ cylinders for SG PORV control are available, if needed. The reliability of the N₂ station is assured by the Operational Requirements and Testing and Inspection program as described in Part II, Section 14.10.

h. Personnel Protection Equipment

Standard personnel protection equipment is used for the performance of this action.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.9.4 OMA 1024 – Operate Steam Generator Relief Valves to Control Secondary Pressure

The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-12 (SG 2 Power Relief Valve) to control secondary pressure. A fire that is contained within room 737.0-A1B could potentially fail Train A Auxiliary Control Air System or damage cables (2PM1499, 2PM1501, 2PV6750, or 2PM1502) requiring implementation of these OMA. The operator must operate 2-ISIV-1-405E2 on 2-L-1001 at the N2 local station. This OMA is to be completed within 60 minutes and is performed in room 757.0-A21.

OMA 1024 is both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 60-minutes before the OMA must be completed. The analyses provided an estimated travel and performance time of 25 minutes. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The Validation Walkdown for this action demonstrated that the time to travel and to perform the action was 12 minutes 6 seconds which provides 47 minutes 54 seconds of margin. This provides adequate time to perform the action.

PART VII - DEVIATIONS AND EVALUATIONS

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel to the SD BD Room and perform the action (25-minutes) provides 35-minutes (140%) margin. The demonstrated validation time was 12 minutes 6 seconds which provides 47 minutes 54 seconds (>400%) of margin. There is more than adequate time available to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of this OMA. If they were unavailable, 8-hour emergency battery pack lighting is provided; therefore, there is adequate lighting to access the local panel and to perform the OMA. Because the operator does not have to traverse or enter the fire zone to perform the action in room 757.0-A21, there are no impediments associated with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

d. Equipment Functionality and Accessibility

Actions are performed at local control panels that are unaffected by the fire and are easily accessible. The control panels in room 757.0-A21 are readily accessible.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is necessary to perform these OMAs. Spare N₂ cylinders for SG PORV control are available, if needed. The reliability of the N₂ station is assured by the Operational Requirements and Testing and Inspection program as described in Part II, Section 14.10.

h. Personnel Protection Equipment

Standard personnel protection equipment is used for the performance of this action.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.9.5 OMAs 1540 and 1542 – Control 2-LCV-3-173 and 2-LCV-3-174

A fire in room 737.0-A1B could damage control cables 2V1041B, 2V7027B, 2SG398B, 2SG403B, 2SG476B, 2PM4501B 2PM4502B, or 2PM5655 which could spuriously close the TDAFW Pump Steam Generator #1 Level Control Valve (2-LCV-3-174) or cables 2V1031B, 2V7026B, 2SG400B, 2SG402B, 2SG473B, 2PM4496B 2PM4497B, or 2PM5654 which could spuriously close the TDAFW Pump Steam Generator #2 Level Control Valve (2-LCV-3-173). The fire safe shutdown requirement for a fire in 737.0-A1B is to transfer from normal to auxiliary control. The operator must operate transfer switches 2-XS-3-174 for SG1 (OMA 1542) and 2-

PART VII - DEVIATIONS AND EVALUATIONS

XS-3-173 for SG2 (OMA 1540). These actions must be completed within 20 minutes and are performed in 757.0-A28.

OMAs 1540 and 1542 are both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 20 minutes to complete these actions. The analysis provided an estimated travel and performance time of five minutes for each action. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The Validation Walkdown demonstrated that the travel time and time to perform the actions was 2 minutes 10 seconds which provides 17 minutes 50 seconds of margin. There is adequate time available to perform the actions.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel to the Auxiliary Control Instrument Room 2B and perform the actions (5 minutes) provides 15-minutes (300%) margin. The demonstrated validation time 2 minutes 10 seconds which provides >17 minutes (>500%) of margin which is more than adequate time available to ensure reliability.

c. Environmental Factors

Normal and standby lighting is provided for the access routes and at the location of the OMAs. If they were unavailable, 8-hour emergency battery pack lighting is provided; therefore, there is adequate lighting to access the local panel and perform the OMAs. Because the operator does not have to traverse or enter the fire zone, there are no impediments associated with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with these OMAs.

d. Equipment Functionality and Accessibility

The fire that results in fire-induced damage requiring implementation of the OMAs is on a separate elevation of the Auxiliary Building from the control location, and therefore will not affect the functionality of the equipment. The actions are performed on panel 2-L-11B and are therefore easily accessible.

e. Available Indications

The MCR Operator has adequate indications available and there are no local indications needed for the operation of the transfer switches.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

PART VII - DEVIATIONS AND EVALUATIONS

g. Portable Equipment

No portable equipment is necessary to access and perform this OMA.

h. Personnel Protection Equipment

No special PPE is needed to access and perform this OMA.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.9.6 Staffing Requirements for a Fire in Room 737.0-A1B

For a Fire in 737.0-A1B, 14 Unit 1 actions are performed by four AUOs, 17 Unit 2 actions are performed by three AUOs and 1 Unit 2 and 2 common actions are performed by 1 AUO for a total of eight AUOs. Therefore, the staffing of eight AUOs is sufficient to accomplish all of the Unit 1, Unit 2 and common manual actions, should there be a fire in 737.0-A1B.

8.3.10 Room 737.0-A1C (Auxiliary Building General Area)

8.3.10.1 Fire Prevention

The Auxiliary Building Corridor (737.0-A1C), a subdivision of 737.0-A1, is constructed of reinforced concrete. The fire walls, floors, ceiling, and penetration seals have a fire resistance rating of 2 hours or greater. Doors and dampers are at least equivalent to the rating of the barriers. Room 737.0-A1 has a floor area of 23,144 ft² and a nominal ceiling height of 19-feet. The combustibles in 737.0-A1 consist of lube oil in the pumps, motors, and valves, plastic associated with electrical panels and boxes and lights and insulation on cables in trays. The majority (approximately 97%) of the combustibles are the insulation on the cables in trays. The combustible loading in 737.0-A1 room has a fire severity classification of moderately severe.

The presence of intervening combustibles (insulation on cables in trays) is justified and documented in Section 2.4 of this Part. The 737.0-A1C floor slab has stairwell and hatch openings that are not provided with fire rated closures, they are instead provided with water curtains. The justification for these openings is documented in Section 2.6 of this Part.

There are a number of assumed ignition sources in 737.0-A1 including chillers, lighting boards, transformers, switchgear and a Motor Control Center (MCC). NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.10.2 Detection, Control, and Extinguishment

The Auxiliary Building Corridor, 737.0-A1, is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the nearby MCR to investigate the detector alarm. Portable extinguishers are available throughout the plant for extinguishing any small credible fire. If a larger fire occurs, the

PART VII - DEVIATIONS AND EVALUATIONS

automatic sprinkler system provided for the room activates. A standpipe and hose station system is also available for fire brigade use.

8.3.10.3 OMA 1023 - Operate Steam Generator Relief Valves to Control Secondary Pressure

The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-23 (SG #3 Power Relief Valve) to control secondary pressure. A fire in 737.0-A1C could potentially damage cable 2PM1621 for 2-PM-1-24 and cable 2PM1617 for 2-PIC-1-24A requiring implementation of this OMA. The operator must operate 2-ISIV-1-407E2 at the local station 2-L-1000 (N₂) if MDAFW Pump A or TDAFW Pump is used. This required for fire safe shutdown OMA is to be completed within 60 minutes and is performed in room 757.0-A24.

OMA 1023 is both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 60-minutes before the OMA must be completed. The analysis provided an estimated travel and performance time of 28 minutes. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The demonstrated time to perform this action was 12 minutes 6 seconds. There is adequate time available to perform the action.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel to the 6.9kV and 480V Shutdown Board Room B and perform the action (28-minutes) provides 32-minutes (114%) margin. The demonstrated validation (12 minutes 6 seconds) provides 47 minutes 54 seconds (400%) of margin. This is adequate time to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access route and at the location of the OMA. The access path and control location are unaffected by the fire or other adverse environmental conditions. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

d. Equipment Functionality and Accessibility

This OMA is performed in room 757.0-A24, on a separate elevation from the fire in room 737.0-A1; therefore, the equipment needed for the performance of this OMA is not affected by the fire and will remain functional and accessible.

e. Available Indications

The AUO will have adequate indications of the N₂ pressure when performing this OMA. Also, the MCR will have adequate indications available in order to instruct the AUO regarding the pressure control for the SG PORV (2-PCV-1-23).

PART VII - DEVIATIONS AND EVALUATIONS

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is needed in order to perform this action. Spare N₂ cylinders for SG PORV control are available, if needed. The reliability of the N₂ station is assured by the Operational Requirements and Testing and Inspection program as described in Part II, Section 14.10.

h. Personnel Protection Equipment

No special PPE is needed to access and perform this OMA.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.10.4 Staffing Requirements for a Fire in Room 737.0-A1C

For a fire in 737.0-A1C, four Unit 2 actions are performed by three AUOs and four Unit 1 actions are performed by three AUOs for a total of six AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1 and Unit 2 manual actions, should there be a fire in 737.0-A1C.

8.3.11 Room 737.0-A1N (Auxiliary Building General Area)

8.3.11.1 Fire Prevention

The Auxiliary Building Corridor (737.0-A1N) is a subdivision of room 737.0-A1. Room 737.0-A1 is constructed of reinforced concrete and the walls, floor, ceiling, and penetration seals have a fire resistance rating of 2 hours or greater. Doors and dampers are least equivalent to the rating of the barriers. None of the doors or dampers discussed in Part VI are identified as being in 737.0-A1N. Room 737.0-A1 has a floor area of 23,144 ft² and a nominal ceiling height of 19-feet. The combustibles in 737.0-A1 consist of lube oil in the pumps, motors, and valves, plastic associated with electrical panels, boxes, and lights; and insulation on cables in trays. The majority (approximately 97%) of the combustibles are the insulation on cables in trays. The combustible loading in the room 737.0-A1 has a fire severity classification of moderately severe.

The presence of intervening combustibles (insulation on cables in trays) is justified and documented in Section 2.4 of this Part. The 737.0 floor slab has stairwell and hatch openings that are not provided with fire rated closures. The stairwells and hatches are protected by water curtains. The justification for these openings is documented in Section 2.6 of this Part. There is a 12 inch round spiral welded HVAC duct that penetrates the floor of 737.0-A1B. The penetration is not provided with a fire damper. This duct is part of the Emergency Gas Treatment system. Spiral welded pipe is treated like a pipe and is provided with fire rated seals between the pipe and the sleeve. Justification is documented in Section 2.6 of this Part.

PART VII - DEVIATIONS AND EVALUATIONS

There are a number of assumed ignition sources in 737.0-A1 including chillers, lighting boards, transformers, switchgear and a Motor Control Center (MCC). NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.11.2 Detection, Control, and Extinguishment

The Auxiliary Building Corridor, 737.0-A1, is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the nearby MCR to investigate the detector alarm. Portable extinguishers are available throughout the plant for extinguishing any small credible fire. If a larger fire occurs, the automatic sprinkler system provided for the room activates. A standpipe and hose station system is also available for fire brigade use. The lack of total area suppression and detection in the airlocks is documented in Section 3.1 of this Part.

A fire in this room does not present an exposure hazard to the access path to the manual action located in 757.0-A24, the 6.9kV and 480V Shutdown Board Room B.

8.3.11.3 OMA 1016 - Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in 737.0-A1N could damage the control cable 2PM1369 and 2PV6756 to the Pressure Indicator Controller (2-PIC-1-6A) or control cable 2V7521A to the Solenoid Valve A (2-PSV-1-6B-A) which would prevent the ability to modulate the Power Operated Relief Valve (2-PCV-1-5) and relieve pressure on the #1 Steam Generator when needed.

The fire safe shutdown requirement for a fire in 737.0-A1N is to have an air source for 2-PCV-1-5 within 60 minutes for operation of 2-PCV-1-5, thereby establishing pressure control of the Steam Generator #1. Emergency control air is provided by a nitrogen bottle for operation of the 2-PCV-1-5 which is actuated by an Operator Manual Action (OMA) at the SG PORV Nitrogen Station (PNL 2-L-1001) in 757.0-A21.

OMA 1016 is both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 60-minutes before the OMA must be completed. The analysis provided an estimated travel and performance time of 25 minutes. Verification and validation for common AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The Validation Walkdown for this action demonstrated that the time to travel and to perform the action was 12 minutes 6 seconds which provides 47 minutes 54 seconds of margin. There is adequate time available to perform the action.

PART VII - DEVIATIONS AND EVALUATIONS

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel to the Unit 2 480V SD BD Room 2A and perform the action (25-minutes) provides 35-minutes (>140%) margin. The demonstrated validation time was 12 minutes 6 seconds which provides 47 minutes 54 seconds (>400%) of margin. There is more than adequate time available to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of the OMA. If they were not available, 8-hour emergency battery pack lighting is available; therefore, there is adequate lighting to access the local panel and perform the OMA. The control location would be unaffected by the fire or other adverse environmental conditions, such as radiation.

d. Equipment Functionality and Accessibility

The fire that results in the fire-induced damage requiring implementation of this OMA will be contained within room 737.0-A1. The control location is separated from the location of the fire by rated fire barriers and therefore the fire would not affect the functionality and accessibility of equipment needed to perform this OMA.

e. Available Indications

Available local indications for monitoring N₂ cylinder pressure and regulator adjustment, as well as MCR SG pressure indications, are adequate.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is necessary to perform these OMAs. Spare N₂ cylinders for SG PORV control are available, if needed. The reliability of the N₂ station is assured by the Operational Requirements and Testing and Inspection program as described in Part II, Section 14.10.

h. Personnel Protection Equipment

No special PPE is needed to access and perform this OMA.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.11.4 OMA 1024 - Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in 737.0-A1N could damage various control cables for equipment 2-MCC-214-B1-B and ERCW-HDR-2B supporting the Control Air Compressor B-B (0-MTR-32-86-B), control cable

PART VII - DEVIATIONS AND EVALUATIONS

2PM1501 to the Steam Generator Power Relief Valve Modifier (2-PM-1-13) or control cables 2PM1502 and 2PM1499 to the Pressure Indicator Controller (2-PIC-1-13A) which would prevent the ability to modulate the Power Operated Relief Valve (2-PCV-1-12) and relieve pressure on the #2 Steam Generator when needed.

The fire safe shutdown requirement for a fire in 737.0-A1N is to have an air source for 2-PCV-1-12 within 60 minutes for operation of 2-PCV-1-12, thereby establishing pressure control of the #2 Steam Generator. Emergency control air is provided for operation of the 2-PCV-1-12, which is actuated by an Operator Manual Action (OMA) at the SG PORV Nitrogen Station (PNL 2-L-1001) in 757.0-A21.

The analysis provided an estimated travel and performance time of 25 minutes. Verification and validation for common AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The Validation Walkdown for this action demonstrated that the time to travel and to perform the action was 12 minutes 6 seconds which provides 47 minutes 54 seconds of margin. There is adequate time available to perform the action.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel to the Unit 2 480V SD BD Room 2A and perform the action (25-minutes) provides 35-minutes (140%) margin. The demonstrated validation time was 12 minutes 6 seconds which provides 47 minutes 54 seconds (>400%) of margin. There is more than adequate time available to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of the OMA. If they were not available, 8-hour emergency battery pack lighting is available; therefore, there is adequate lighting to access the local panel and perform the OMA. The control location would be unaffected by the fire or other adverse environmental conditions, such as radiation.

d. Equipment Functionality and Accessibility

The fire that results in the fire-induced damage requiring implementation of this OMA will be contained within room 737.0-A1. The control location is separated from the location of the fire by rated fire barriers and therefore the fire would not affect the functionality and accessibility of equipment to perform this OMA.

e. Available Indications

Available local indications for monitoring N₂ cylinder pressure and regulator adjustment, as well as MCR SG pressure indications, are adequate.

f. Communications

Adequate communications between the location of the OMA and the MCR is provided by the communication system described in Part II, Section 12.8.

PART VII - DEVIATIONS AND EVALUATIONS

g. Portable Equipment

No portable equipment is necessary to perform these OMAs. Spare N₂ cylinders for SG PORV control are available, if needed. The reliability of the N₂ station is assured by the Operational Requirements and Testing and Inspection program as described in Part II, Section 14.10.

h. Personnel Protection Equipment

No special PPE is needed to access and perform this OMA.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.11.5 OMAs 1535 and 1536 – Control 2-LCV-3-156 and 2-LCV-3-164

A fire in room 737.0-A1N could damage control cables 2SG392A, 2SG394A, 2V1062A, 2V1082A, 2V7023A or 2V7024A which could spuriously close the MDAFW Pump Steam Generator #1 (2-LCV-3-164) or #2 (2-LCV-3-156) Level Control Valves. The fire safe shutdown requirement for a fire in 737.0-A1N is to transfer from normal to auxiliary control. The operator must operate transfer switches 2-XS-3-164 for SG1 (OMA 1535) and 2-XS-3-156 for SG2 (OMA 1536). These actions must be completed within 20 minutes and are performed in 757.0-A27.

OMAs 1535 and 1536 are both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 20 minutes to complete these OMAs. The analyzed time estimated to travel and perform each action is five minutes. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The Validation Walkdown for this action demonstrated that the time to travel and to perform the action was 2 minutes 10 seconds which provides 17 minutes 50 seconds of margin. There is adequate time available to perform the action.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel and perform the actions (5 minutes) provides 15 minutes (300%) margin. The demonstrated validation time was 2 minutes 10 seconds which provides 17 minutes 50 seconds (>500%) of margin. There is more than adequate time available to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of the OMAs. If they were not available, 8-hour emergency battery pack lighting is available; therefore, there is adequate lighting to access the local panel and perform the OMAs. Access paths and control location are unaffected by the fire or other adverse environmental conditions.

PART VII - DEVIATIONS AND EVALUATIONS

d. Equipment Functionality and Accessibility

The transfer switches for this manual action are not affected by the fire and remain functional and accessible. The fire that results in the fire-induced damage requiring implementation of these OMAs is contained within 737.0-A1. Therefore, the fire does not affect the functionality and accessibility of the equipment needed for these OMAs.

e. Available Indications

The MCR operator has adequate indications available and there are no local indications needed for the operation of the transfer switches.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is necessary to perform these OMAs.

h. Personnel Protection Equipment

Only standard PPE is needed to perform these OMAs.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.11.6 Staffing Requirements for a Fire in Room 737.0-A1N

For a fire in 737.0-A1N, 13 Unit 1 actions are performed by four AUOs, 12 Unit 2 actions are performed by three AUOs and three common actions are performed by one AUO for a total of eight AUOs. The staffing of eight AUOs is sufficient to accomplish all of the Unit 1 and Unit 2 manual actions, should there be a fire in 737.0-A1N.

8.3.12 Room 737.0-A5M (U1 Purge Air Penetration Room)

8.3.12.1 Fire Prevention

The Ventilation and Purge Air Room (737.0-A5) is subdivided into three areas; 737.0-A5M, 737.0-A5N and 737.0-A5S. There are no barriers between the three areas that comprise 737.0-A5. Room 737.0-A5 is constructed of reinforced concrete. The walls, floors and ceiling separating 737.0-A5 from other fire areas have a fire resistance rating of 2-hours or greater. Openings in these barriers are provided with fire doors, dampers and penetration seals that are at least equivalent to the rating of the barriers. HVAC ducts penetrate two of the fire barriers in this room but are not provided with fire dampers. Justification for the lack of fire dampers is provided in Section 2.6.1 of this Part.

PART VII - DEVIATIONS AND EVALUATIONS

The Ventilation and Purge Air Room (737.0-A5) has a floor area of 2933 ft² with a nominal ceiling height of 19 feet. The combustible loading of the room results in a fire severity classification of Low. The combustible material in the room consists of charcoal in the gas treatment system filter, plastics associated with panels, junction boxes, fans and lighting, minor amounts of lube oil associated with valves (2 gallons), radiation protection related trash, rubber expansion joints and insulation on cables in trays. The presence of intervening combustibles (insulation on cables in trays) in 737.0-A5 is justified and documented in Section 2.4 of this Part.

There are no significant ignition sources in 737.0-A5. The air supply fans have small motors with minimal combustibles (2 pounds plastic) and are not significant ignition sources. The panels are a small wall mounted type, and the junction boxes are relatively small and do not constitute credible ignition sources (circuits are properly protected and insignificant quantity of combustibles associated with the boxes to create and sustain a large fire). NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.12.2 Detection, Control, and Extinguishment

The Ventilation and Purge Air Room is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the MCR to investigate the alarm. Portable extinguishers are available for extinguishing any small credible fire. A larger fire activates the installed automatic preaction sprinkler system provided for the room. This extinguishes or limits the magnitude of the fire until the fire brigade arrives. A standpipe and hose station system is also available for fire brigade use from the adjacent room (737.0-A1).

8.3.12.3 OMA 1023 - Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 737.0-A5M could damage the Auxiliary Control Air Header A (ACAS-ENDUSER-A, 1-FCO-30-146B) which prevents the ability to modulate the Power Relief Valve (2-PCV-1-23) to relieve pressure on #3 Steam Generator when needed. The fire safe shutdown requirement for a fire in 737.0-A5M is to have an air source for 2-PCV-1-23 within 60 minutes to maintain pressure control of the #3 Steam Generator. Emergency air is provided for operation of the PCV, via an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

However, due to the low combustible loading and lack of significant ignition sources in the Ventilation and Purge Air Room (as indicated by the combustible loading calculation and ignition source walkdown documentation) it is unlikely that a fire originating in room 737.0-A5M could result in this manual action.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in the OMA 1023 bounding evaluation (Section 8.3.64).

8.3.12.4 Staffing Requirements for a Fire in Room 737.0-A5M

For a fire in 737.0-A5M, three Unit 1 actions and four Unit 2 actions are performed. Five AUOs will perform these seven actions. Therefore, a total of eight AUOs is more than sufficient to complete all of the OMAs for Unit 1 and Unit 2, should there be a fire in 737.0-A5M.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.13 Room 737.0-A5N (U1 Purge Air Penetration Room)

8.3.13.1 Fire Prevention

The Ventilation and Purge Air Room (737.0-A5) is subdivided into three areas; 737.0-A5M, 737.0-A5N and 737.0-A5S. There are no barriers between the three areas that comprise 737.0-A5. The rooms are constructed of reinforced concrete. The walls, floors and ceiling separating these rooms from other fire areas have a fire resistance rating of 2-hours or greater. Openings in these barriers are provided with fire doors, dampers and penetration seals that are at least equivalent to the rating of the barriers. HVAC ducts penetrate two of the fire barriers in this room but are not provided with fire dampers. Justification for the lack of fire dampers is provided in Section 2.6.1 of this Part.

The Ventilation and Purge Air Room (737.0-A5) has a floor area of 2933 ft² with a nominal ceiling height of 19 feet. The combustible loading of the room results in a fire severity classification of Low. The combustible material in the room consists of charcoal in the gas treatment system filter, plastics associated with panels, junction boxes, fans and lighting, minor amounts of lube oil associated with valves (2 gallons), radiation protection related trash, rubber expansion joints and insulation on cables in trays. The presence of intervening combustibles (insulation on cables in trays) in 737.0-A5 is justified and documented in Section 2.4 of this Part.

There are no significant ignition sources in 737.0-A5. The air supply fans have small motors with minimal combustibles (2 pounds plastic) and are not significant ignition sources. The panels are a small wall mounted type, and the junction boxes are relatively small and do not constitute credible ignition sources (circuits are properly protected and insignificant quantity of combustibles associated with the boxes to create and sustain a large fire). NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.13.2 Detection, Control, and Extinguishment

The Ventilation and Purge Air Room is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the MCR to investigate the alarm. Portable extinguishers are available for extinguishing any small credible fire. A larger fire activates the installed automatic preaction sprinkler system provided for the room. This extinguishes or limits the magnitude of the fire until the fire brigade arrives. A standpipe and hose station system is also available for fire brigade use from the adjacent room (737.0-A1).

8.3.13.3 OMA 1023 - Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 737.0-A5N could damage the Auxiliary Control Air Header A (ACAS-ENDUSER-A, 1-FCO-30-146A) which prevents the ability to modulate the Power Relief Valve (2-PCV-1-23) to relieve pressure on #3 Steam Generator when needed. The fire safe shutdown requirement for a fire in 737.0-A5N is to have an air source for 2-PCV-1-23 within 60 minutes to maintain pressure control of the #3 Steam Generator. Emergency air is provided for operation of the PCV, via an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

PART VII - DEVIATIONS AND EVALUATIONS

However, due to the low combustible loading and lack of significant ignition sources in the Ventilation and Purge Air Room (as indicated by the combustible loading calculation and ignition source walkdown documentation) it is unlikely that a fire originating in room 737.0-A5N could result in this manual action.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in the OMA 1023 bounding evaluation (Section 8.3.64).

8.3.13.4 Staffing Requirements for a Fire in Room 737.0-A5N

For a fire in 737.0-A5N, three Unit 1 actions and four Unit 2 actions are performed. Five AUOs will perform these seven actions. Therefore, a total of eight AUOs is more than sufficient to complete all of the OMAs for Unit 1 and Unit 2, should there be a fire in 737.0-A5N.

8.3.14 Room 737.0-A5S (U1 Purge Air Penetration Room)

8.3.14.1 Fire Prevention

The Ventilation and Purge Air Room (737.0-A5) is subdivided into three areas; 737.0-A5M, 737.0-A5N and 737.0-A5S. There are no barriers between the three areas that comprise 737.0-A5. The rooms are constructed of reinforced concrete. The walls, floors and ceiling separating these rooms from other fire areas have a fire resistance rating of 2-hours or greater. Openings in these barriers are provided with fire doors, dampers and penetration seals that are at least equivalent to the rating of the barriers. HVAC ducts penetrate two of the fire barriers in this room but are not provided with fire dampers. Justification for the lack of fire dampers is provided in Section 2.6.1 of this Part.

The Ventilation and Purge Air Room (737.0-A5) has a floor area of 2933 ft² with a nominal ceiling height of 19 feet. The combustible loading of the room results in a fire severity classification of Low. The combustible material in the room consists of charcoal in the gas treatment system filter, plastics associated with panels, junction boxes, fans and lighting, minor amounts of lube oil associated with valves (2 gallons), radiation protection related trash, rubber expansion joints and insulation on cables in trays. The presence of intervening combustibles (insulation on cables in trays) in 737.0-A5 is justified and documented in Section 2.4 of this Part.

There are no significant ignition sources in 737.0-A5. The air supply fans have small motors with minimal combustibles (2 pounds plastic) and are not significant ignition sources. The panels are a small wall mounted type, and the junction boxes are relatively small and do not constitute credible ignition sources (circuits are properly protected and insignificant quantity of combustibles associated with the boxes to create and sustain a large fire). NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.14.2 Detection, Control, and Extinguishment

The Ventilation and Purge Air Room is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the MCR to investigate the alarm. Portable extinguishers are available for

PART VII - DEVIATIONS AND EVALUATIONS

extinguishing any small credible fire. A larger fire activates the installed automatic preaction sprinkler system provided for the room. This extinguishes or limits the magnitude of the fire until the fire brigade arrives. A standpipe and hose station system is also available for fire brigade use from the adjacent room (737.0-A1).

8.3.14.3 OMA 1022 - Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 737.0-A5S could damage the Auxiliary Control Air Header B (ACAS-ENDUSER-B, 1-LCV-3-173, 1-PSV-1-31C/1-L-762) which prevents the ability to modulate the Power Relief Valve (2-PCV-1-30) to relieve pressure on #4 Steam Generator when needed. The fire safe shutdown requirement for a fire in 737.0-A5S is to have an air source for 2-PCV-1-30 within 60 minutes to maintain pressure control of the #4 Steam Generator. Emergency air is provided for operation of the PCV, via an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

However, due to the low combustible loading and lack of significant ignition sources in the Ventilation and Purge Air Room (as indicated by the combustible loading calculation and ignition source walkdown documentation) it is unlikely that a fire originating in room 737.0-A5S could result in this manual action.

The Feasibility and Reliability Evaluation for OMA 1022 following a fire in this room is covered in the OMA 1022 bounding evaluation (Section 8.3.63).

8.3.14.4 OMA 1023 - Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 737.0-A5S could damage the Auxiliary Control Air Header A (ACAS-ENDUSER-A, 1-FCO-30-146B, 1-LCV-3-172, 1-PSV-1-6C/1-L-761) which prevents the ability to modulate the Power Relief Valve (2-PCV-1-23) to relieve pressure on #3 Steam Generator when needed. The fire safe shutdown requirement for a fire in 737.0-A5S is to have an air source for 2-PCV-1-23 within 60 minutes to maintain pressure control of the #3 Steam Generator. Emergency air is provided for operation of the PCV, via an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

However, due to the low combustible loading and lack of significant ignition sources in the Ventilation and Purge Air Room (as indicated by the combustible loading calculation and ignition source walkdown documentation) it is unlikely that a fire originating in room 737.0-A5S could result in this manual action.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in the OMA 1023 bounding evaluation (Section 8.3.64).

8.3.14.5 Staffing Requirements for a Fire in Room 737.0-A5S

For a fire in 737.0-A5S, six Unit 1 actions are performed by three AUOs and five Unit 2 actions are performed by three AUOs for a total of six AUOs. Therefore, a total of eight AUOs is more than sufficient to complete all of the OMAs for Unit 1 and Unit 2, should there be a fire in 737.0-A5S.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.15 Room 737.0-A9M (U2 Purge Air Penetration Room)

8.3.15.1 Fire Prevention

The Unit 2 Ventilation and Purge Air Room (737.0-A9) is subdivided into three areas; 737.0-A9M, 737.0-A9N and 737.0-A9S. There are no barriers between the three areas that comprise 737.0-A9. The rooms are constructed of reinforced concrete. The walls, floors, ceiling and penetration seals separating these rooms from other fire areas have a fire resistance rating of 2-hours or greater. The doors are 3-hour fire rated doors. The dampers in 737.0-A9 have a fire resistance rating 3-hours. HVAC ducts penetrate two of the fire barriers in this room but are not provided with fire dampers. Justification for the lack of fire dampers is provided in Section 2.6.1 of this Part.

The Unit 2 Ventilation and Purge Air Room (737.0-A9) has a floor area of 2933 ft² and a nominal ceiling height of 19 feet. The combustible loading of the room results in a fire severity classification of Low. The combustible material in the room consists of charcoal in the gas treatment system filter, plastics associated with panels, junction boxes, fans and lighting, minor amounts of lube oil associated with valves (3 gallons), cloth and plastic from hazardous material spill kits, rubber expansion joints and insulation on cables in trays. The presence of intervening combustibles (insulation on cables in trays) in 737.0-A9 is justified and documented in Section 2.4 of this Part. There are no significant ignition sources in 737.0-A9. The air supply fans have small motors with minimal combustibles (2 pounds plastic each) and are not significant ignition sources. The panels are a small wall mounted type, and the junction boxes are relatively small and do not constitute credible ignition sources (circuits are properly protected and insignificant quantity of combustibles associated with the boxes to create and sustain a large fire). NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.15.2 Detection, Control, and Extinguishment

The Unit 2 Ventilation and Purge Air Room is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the MCR to investigate the alarm. Portable extinguishers are available for extinguishing any small credible fire. A larger fire activates the installed automatic preaction sprinkler system provided for the room. This extinguishes or limits the magnitude of the fire until the fire brigade arrives. A standpipe and hose station system is also available in 737.0-A1 for fire brigade use.

8.3.15.3 OMA 1022 - Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 737.0-A9M could damage the Auxiliary Control Air Header B (ACAS-ENDUSER-B, 2-FCO-30-157B) which prevents the ability to modulate the Power Relief Valve (2-PCV-1-30) to relieve pressure on #4 Steam Generator when needed. The fire safe shutdown requirement for a fire in 737.0-A9M is to have an air source for 2-PCV-1-30 within 60 minutes to maintain pressure control of the #4 Steam Generator. Emergency air is provided for operation of the PCV, via an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

PART VII - DEVIATIONS AND EVALUATIONS

However, due to the low combustible loading and lack of significant ignition sources in the Ventilation and Purge Air Room (as indicated by the combustible loading calculation and ignition source walkdown documentation) it is unlikely that a fire originating in room 737.0-A9M could result in this manual action.

The Feasibility and Reliability Evaluation for OMA 1022 following a fire in this room is covered in the OMA 1022 bounding evaluation (Section 8.3.63).

8.3.15.4 OMA 1023 - Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 737.0-A9M could damage a control cable (2PM1617) to the Pressure Indicator Controller (2-PIC-1-24A) or a control cable (2PM1621) to the Power Relief Valve Modifier (2-PM-1-24) which prevents the ability to modulate the Power Relief Valve (2-PCV-1-23) to relieve pressure on #3 Steam Generator when needed. The fire safe shutdown requirement for a fire in 737.0-A9M is to have an air source for 2-PCV-1-23 within 60 minutes to maintain pressure control of the #3 Steam Generator. Emergency air is provided for operation of the PCV, via an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

However, due to the low combustible loading and lack of significant ignition sources in the Ventilation and Purge Air Room (as indicated by the combustible loading calculation and ignition source walkdown documentation) it is unlikely that a fire originating in room 737.0-A9M could result in this manual action.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in the OMA 1023 bounding evaluation (Section 8.3.64).

8.3.15.5 Staffing Requirements for a Fire in Room 737.0-A9M

For a fire in 737.0-A9M, four Unit 1 actions and four Unit 2 actions are performed by a total of five AUOs. Therefore, a total of eight AUOs is more than sufficient to complete all of the OMAs for Unit 1 and Unit 2, should there be a fire in 737.0-A9M.

8.3.16 Room 737.0-A9N (U2 Purge Air Penetration Room)

8.3.16.1 Fire Prevention

The Unit 2 Ventilation and Purge Air Room (737.0-A9) is subdivided into three areas; 737.0-A9M, 737.0-A9N and 737.0-A9S. There are no barriers between the three areas that comprise 737.0-A9. The rooms are constructed of reinforced concrete. The walls, floors, ceiling and penetration seals separating these rooms from other fire areas have a fire resistance rating of 2-hours or greater. The doors are 3-hour fire rated doors. The dampers in 737.0-A9 have a fire resistance rating 3-hours. HVAC ducts penetrate two of the fire barriers in this room but are not provided with fire dampers. Justification for the lack of fire dampers is provided in Section 2.6.1 of this Part.

The Unit 2 Ventilation and Purge Air Room (737.0-A9) has a floor area of 2933 ft² and a nominal ceiling height of 19 feet. The combustible loading of the room results in a fire severity classification of Low. The combustible material in the room consists of charcoal in the gas treatment system filter, plastics associated with panels, junction boxes, fans and lighting, minor amounts of lube oil associated with valves (3 gallons), cloth and plastic from hazardous material

PART VII - DEVIATIONS AND EVALUATIONS

spill kits, rubber expansion joints and insulation on cables in trays. The presence of intervening combustibles (insulation on cables in trays) in 737.0-A9 is justified and documented in Section 2.4 of this Part.

There are no significant ignition sources in 737.0-A9. The air supply fans have small motors with minimal combustibles (2 pounds plastic each) and are not significant ignition sources. The panels are a small wall mounted type, and the junction boxes are relatively small and do not constitute credible ignition sources (circuits are properly protected and insignificant quantity of combustibles associated with the boxes to create and sustain a large fire). NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.16.2 Detection, Control, and Extinguishment

The Unit 2 Ventilation and Purge Air Room is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the MCR to investigate the alarm. Portable extinguishers are available for extinguishing any small credible fire. A larger fire activates the installed automatic preaction sprinkler system provided for the room. This extinguishes or limits the magnitude of the fire until the fire brigade arrives. A standpipe and hose station system is also available in 737.0-A1 for fire brigade use.

8.3.16.3 OMA 1022 - Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 737.0-A9N could damage the Auxiliary Control Air Header B (ACAS-ENDUSER-B, 2-FCO-30-157A) which prevents the ability to modulate the Power Relief Valve (2-PCV-1-30) to relieve pressure on #4 Steam Generator when needed. The fire safe shutdown requirement for a fire in 737.0-A9N is to have an air source for 2-PCV-1-30 within 60 minutes to maintain pressure control of the #4 Steam Generator. Emergency air is provided for operation of the PCV, via an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

However, due to the low combustible loading and lack of significant ignition sources in the Ventilation and Purge Air Room (as indicated by the combustible loading calculation and ignition source walkdown documentation) it is unlikely that a fire originating in room 737.0-A9N could result in this manual action.

The Feasibility and Reliability Evaluation for OMA 1022 following a fire in this room is covered in the OMA 1022 bounding evaluation (Section 8.3.63).

8.3.16.4 OMA 1023 - Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 737.0-A9N could damage a control cable (2PM1617) to the Pressure Indicator Controller (2-PIC-1-24A) or a control cable (2PM1621) to the Power Relief Valve Modifier (2-PM-1-24) which prevents the ability to modulate the Power Relief Valve (2-PCV-1-23) to relieve pressure on #3 Steam Generator when needed. The fire safe shutdown requirement for a fire in 737.0-A9N is to have an air source for 2-PCV-1-23 within 60 minutes to maintain pressure

PART VII - DEVIATIONS AND EVALUATIONS

control of the #3 Steam Generator. Emergency air is provided for operation of the PCV, via an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

However, due to the low combustible loading and lack of significant ignition sources in the Ventilation and Purge Air Room (as indicated by the combustible loading calculation and ignition source walkdown documentation) it is unlikely that a fire originating in room 737.0-A9N could result in this manual action.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in the OMA 1023 bounding evaluation (Section 8.3.64).

8.3.16.5 Staffing Requirements for a Fire in Room 737.0-A9N

For a fire in 737.0-A9N, four Unit 1 actions performed by three AUOs and four Unit 2 actions performed by two AUOs requires a total of five AUOs. Therefore, a total of eight AUOs is more than sufficient to complete all of the OMAs for Unit 1 and Unit 2, should there be a fire in 737.0-A9N.

8.3.17 Room 737.0-A9S (U2 Purge Air Penetration Room)

8.3.17.1 Fire Prevention

The Unit 2 Ventilation and Purge Air Room (737.0-A9) is subdivided into three areas; 737.0-A9M, 737.0-A9N and 737.0-A9S. There are no barriers between the three areas that comprise 737.0-A9. The rooms are constructed of reinforced concrete. The walls, floors, ceiling and penetration seals separating these rooms from other fire areas have a fire resistance rating of 2-hours or greater. The doors are 3-hour fire rated doors. The dampers in 737.0-A9 have a fire resistance rating 3-hours. HVAC ducts penetrate two of the fire barriers in this room but are not provided with fire dampers. Justification for the lack of fire dampers is provided in Section 2.6.1 of this Part.

The Unit 2 Ventilation and Purge Air Room (737.0-A9) has a floor area of 2933 ft² and a nominal ceiling height of 19 feet. The combustible loading of the room results in a fire severity classification of Low. The combustible material in the room consists of charcoal in the gas treatment system filter, plastics associated with panels, junction boxes, fans and lighting, minor amounts of lube oil associated with valves (3 gallons), cloth and plastic from hazardous material spill kits, rubber expansion joints and insulation on cables in trays. The presence of intervening combustibles (insulation on cables in trays) in 737.0-A9 is justified and documented in Section 2.4 of this Part.

There are no significant ignition sources in 737.0-A9. The air supply fans have small motors with minimal combustibles (2 pounds plastic each) and are not significant ignition sources. The panels are a small wall mounted type, and the junction boxes are relatively small and do not constitute credible ignition sources (circuits are properly protected and insignificant quantity of combustibles associated with the boxes to create and sustain a large fire). NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.17.2 Detection, Control, and Extinguishment

The Unit 2 Ventilation and Purge Air Room is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the MCR to investigate the alarm. Portable extinguishers are available for extinguishing any small credible fire. A larger fire activates the installed automatic preaction sprinkler system provided for the room. This extinguishes or limits the magnitude of the fire until the fire brigade arrives. A standpipe and hose station system is also available in 737.0-A1 for fire brigade use.

8.3.17.3 OMA 1022 - Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in 737.0-A9S could damage the Auxiliary Control Air Header B (ACAS-ENDUSER-B, 2-FCO-30-157B, 2-LCV-3-173, 2-PSV-1-31C/2-L-762) or a control cable (2V4035A) to the Power Relief Solenoid Valve (2-PSV-1-31C-A) which prevents the ability to modulate the Power Relief Valve (2-PCV-1-30) to relieve pressure on #4 Steam Generator when needed. The fire safe shutdown requirement for a fire in 737.0-A9S is to have an air source for 2-PCV-1-30 within 60 minutes to maintain pressure control of the #4 Steam Generator. Emergency air is provided for operation of the PCV, via an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

However, due to the low combustible loading and lack of significant ignition sources in the Ventilation and Purge Air Room (as indicated by the combustible loading calculation and ignition source walkdown documentation) it is unlikely that a fire originating in room 737.0-A9S could result in this manual action.

The Feasibility and Reliability Evaluation for OMA 1022 following a fire in this room is covered in the OMA 1022 bounding evaluation (Section 8.3.63).

8.3.17.4 OMA 1023 - Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in 737.0-A9S could damage the Auxiliary Control Air Header A (ACAS-ENDUSER-A, 2-LCV-3-172, 2-PSV-1-6C/2-L-761) or a control cable (2V4031B) to the Power Relief Solenoid Valve (2-PSV-1-24C-B) which prevents the ability to modulate the Power Relief Valve (2-PCV-1-23) to relieve pressure on #3 Steam Generator when needed. The fire safe shutdown requirement for a fire in 737.0-A9S is to have an air source for 2-PCV-1-23 within 60 minutes to maintain pressure control of the #3 Steam Generator. Emergency air is provided for operation of the PCV, via an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

However, due to the low combustible loading and lack of significant ignition sources in the Ventilation and Purge Air Room (as indicated by the combustible loading calculation and ignition source walkdown documentation) it is unlikely that a fire originating in room 737.0-A9S could result in this manual action. The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in the OMA 1023 bounding evaluation (Section 8.3.64).

PART VII - DEVIATIONS AND EVALUATIONS

8.3.17.5 Staffing Requirements for a Fire in Room 737.0-A9S

For a fire in 737.0-A9S, five Unit 1 actions are performed by three AUOs and four Unit 2 actions are performed by two AUOs for a total of five AUOs. Therefore, a total of eight AUOs is more than sufficient to complete all of the OMAs for Unit 1 and Unit 2, should there be a fire in 737.0-A9S.

8.3.18 Room 737.0-A12 (U2 AB Gen Sup Fan Room)

8.3.18.1 Fire Prevention

Room 737.0-A12, the Unit 2 Heat and Vent Equipment Room of the Auxiliary Building, is constructed of reinforced concrete walls, floors, ceilings, and penetration seals with a fire resistance rating of 2-hours. Doors and HVAC dampers in 737.0-A12 have a fire resistance rating of 3-hours. Room 737.0-A12 has a floor area of 2,545 ft² and a nominal ceiling height of 19-feet. The combustibles in 737.0-A12 consist of lubricants for fans, plastic associated with electrical panels, boxes and lights and insulation on cables in trays. The majority (approximately 97%) of the combustibles is the insulation on cables in trays. The combustible loading in the room results in a fire severity index of Low.

The two Auxiliary Building general supply fans, a panel, emergency lighting and junction boxes, small motors, small wall mounted panels, junction boxes, and motor operated valves (MOVs), etc., with small combustible loadings, such as these, are not considered significant fire sources capable of damaging other equipment and cables. Room 737.0-A12 is not subject to incidental transient combustibles. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.18.2 Detection, Control, and Extinguishment

The Unit 2 Heat and Vent Equipment Room, 737.0-A12, is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the MCR to investigate the detector alarm. Portable extinguishers are available throughout the plant for extinguishing small credible fires. A larger fire activates the automatic preaction sprinkler system provided for the room. This extinguishes or limits the magnitude of the fire until the fire brigade arrives. A standpipe and hose station system is available for fire brigade use from the adjacent corridor, 737.0-A1.

Even if the postulated fire starts and is not extinguished, the 2 and 3-hour fire rating of the walls, floors and ceiling and door, fire dampers and penetration seals contain the fire until the fire brigade responds.

8.3.18.3 OMA 1024 - Operate Steam Generator Relief Valves to Control Secondary Pressure

The fire safe shutdown requirement for this operator action is to operate 2-ISIV-1-400E2 at the N₂ operating station to provide an air source for 2-PCV-1-12 within 60 minutes to maintain pressure control of the #2 Steam Generator. Nitrogen (N₂) cylinders are provided at Panel 2-L-1001 for emergency operation of the PCV from room 757.0-A21.

PART VII - DEVIATIONS AND EVALUATIONS

A fire that is contained within room 737.0-A12 potentially damages supporting equipment to the Power Relief Valve 2-PCV-1-12 requiring implementation of this OMA. However, given the low combustible loading in this room, the lack of significant ignition sources (as indicated by the combustible loading calculation and ignition source walkdown documentation), and the detection, control and extinguishment provisions, there is no credible fire originating in room 737.0-A12 and therefore this manual action is not necessary.

The Feasibility and Reliability Evaluation for OMA 1024 following a fire in this room is covered in the OMA 1024 bounding evaluation (Section 8.3.65).

8.3.18.4 Staffing Requirements for a Fire in Room 737.0-A12

For a fire in room 737.0-A12, four Unit 1 actions are performed by three AUOs and four Unit 2 actions are performed by three AUOs for a total of six AUOs. Therefore, a total of eight AUOs is more than sufficient to complete all of the OMAs for Unit 1 and Unit 2.

8.3.19 Room 757.0-A1 (Auxiliary Control Room)

8.3.19.1 Fire Prevention

The Auxiliary Control Building room 757.0-A1 is constructed of reinforced concrete. The walls, floor, ceiling and penetration seals separating 757.0-A1 from other fire areas and analysis volumes have a fire resistance rating of 2-hours or greater. Fire doors and dampers are least equivalent to the rating of the barriers. Room 757.0-A1 has a floor area of 431ft² and a nominal ceiling height of 14-feet.

The combustibles in 757.0-A1 consist of plastics associated with electrical panels and boxes and lights, and insulation on cables in trays. The combustible loading in the room is approximately 119,160 Btu/ft², which results in a fire severity classification of moderate. The potential ignition sources in this room consist of two large panels and several smaller panels. The large panels are an assumed ignition source. The smaller panels are relatively small and do not constitute credible ignition sources (circuits are properly protected and insignificant quantity of combustibles associated with the boxes to create and sustain a large fire). NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.19.2 Detection, Control, and Extinguishment

Room 757.0-A1 is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the nearby MCR to investigate the detector alarm. Portable extinguishers are available throughout the plant for extinguishing any small fires. If a larger fire occurs, the automatic preaction sprinkler system that is provided for the room activates. A standpipe and hose station system is also available in adjacent rooms 757.0-A2 and 757.0-A24 for fire brigade use. Even if the postulated fire starts and is not extinguished, the 2 and 3-hour fire rating of the walls, floors and ceiling and doors, fire dampers and penetration seals contain the fire and prevents it from propagating to adjacent rooms. In addition, a fire in this room does not present an exposure

PART VII - DEVIATIONS AND EVALUATIONS

hazard to the access path to the manual action located in 757.0-A24, the 6.9kV and 480V Shutdown Board Room B.

8.3.19.3 OMA 1016 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 757.0-A1 could potentially damage cable 2PL3786A to 0-MTR-32-60-A Control Air Compressor A-A, cables 2V7521A and 2V7523A to Solenoid Valve 2-PSV-1-6B-A or cable 2PM1371 to 2-PM-1-6, which could result in loss of control of the Steam Generator #1 Power Operated Relief Valve (2-PCV-1-5). The fire safe shutdown requirement is to have an air source for 2-PCV-1-5 within 60 minutes for operation of 2-PCV-1-5, thereby establishing pressure control of the #1 Steam Generator. Emergency air is provided for operation of the 2-PCV-1-5, via an OMA at the SG PORV Nitrogen Station (PNL 2-L-1001) in 757.0-A21.

OMA 1016 is both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 60-minutes before the OMA must be completed. The analysis provided an estimated travel and performance time of 25 minutes. The demonstrated time to travel to room 757.0-A21 and perform the action was 12 minutes 6 seconds. There is adequate time available to perform this action.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel to room 757.0-A21 and perform the action (25-minutes) provides 35-minutes (140%) margin. The validation time was 12 minutes 6 seconds) provides 47 minutes 54 seconds (>300%) margin. This is adequate time available to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of this OMA. If they were unavailable, 8-hour emergency battery pack lighting is provided; therefore, there is adequate lighting to access the local panel and to perform the OMA. Because the operator does not have to traverse or enter the fire zone, there are no impediments associated with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

d. Equipment Functionality and Accessibility

Equipment needed for this manual action is functional and accessible. Also, the fire that results in fire-induced damage requiring implementation of this OMA is on a separate elevation of the Auxiliary Building, and therefore will not affect the functionality and accessibility of equipment.

e. Available Indications

Available local indications for monitoring N₂ cylinder pressure and regulator adjustment, as well as MCR SG pressure indications, are adequate.

PART VII - DEVIATIONS AND EVALUATIONS

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is necessary to perform these OMAs. Spare N₂ cylinders for SG PORV control are available, if needed. The reliability of the N₂ station is assured by the Operational Requirements and Testing and Inspection program as described in Part II, Section 14.10.

h. Personnel Protection Equipment

Only standard PPE is needed to access and perform this OMA.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.19.4 OMA 1024 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 757.0-A1 could potentially damage multiple cables to 0-MTR-32-86-B Control Air Compressor B-B, cable 2V4016A to Solenoid Valve 2-PSV-1-13C-A, or damage a control cable 2PV258 to pressure controller 2-PIC-1-13A which are necessary to operate the Steam Generator #2 Power Operated Relief Valve (2-PCV-1-12). Damage to 2-PSV-1-13C-A and 0-MTR-32-86-B in this room could result in a loss of air to operate the SG PORV. In addition, damage to cable 2PV258 in this room could prevent the ability to modulate the pressure control valve to the SG PORV when needed.

The fire safe shutdown requirement is to have an air source for 2-PCV-1-12 within 60 minutes for operation of 2-PCV-1-12, thereby establishing pressure control of the #2 Steam Generator. Emergency air is provided for operation of the 2-PCV-1-12, via an OMA at the SG PORV Nitrogen Station (PNL 2-L-1001) in 757.0-A21.

OMA 1024 is both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 60-minutes before the OMA must be completed. The analysis provided an estimated travel and performance time of 25 minutes. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The validated time to access and perform this action was 12 minutes 6 seconds. There is adequate time available to perform the action.

PART VII - DEVIATIONS AND EVALUATIONS

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel to the Unit 2 Purge Air Penetration Room and perform the action (25-minutes) provides 35-minutes (140%) margin. The validated time to access and perform the actions was 12 minutes 6 seconds which leaves 47 minutes 54 seconds (>300%) margin. There is sufficient time available to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of this OMA. If they were unavailable, 8-hour emergency battery pack lighting is provided; therefore, there is adequate lighting to access the local panel and to perform the OMA. Because the operator does not have to traverse or enter the fire zone, there are no impediments associated with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

d. Equipment Functionality and Accessibility

The fire that results in fire-induced damage requiring implementation of this OMA is on a separate elevation of the Auxiliary Building, and therefore will not affect the functionality and accessibility of equipment.

e. Available Indications

Available local indications for monitoring N₂ cylinder pressure and regulator adjustment, as well as MCR SG pressure indications, are adequate.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is necessary to perform these OMAs. Spare N₂ cylinders for SG PORV control are available, if needed. The reliability of the N₂ station is assured by the Operational Requirements and Testing and Inspection program as described in Part II, Section 14.10.

h. Personnel Protection Equipment

Only standard PPE is needed to access and perform this OMA.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.19.5 Staffing Requirements for a Fire in Room 757.0-A1

For a fire in 757.0-A1, eight Unit 2 actions are performed by three AUOs and eight Unit 1 actions are performed by three AUOs and two common actions are performed by one AUO for a

PART VII - DEVIATIONS AND EVALUATIONS

total of seven AUOs. Therefore, the staffing of eight AUOs is sufficient to accomplish all of the Unit 1, Unit 2 and common manual actions, should there be a fire in 757.0-A1.

8.3.20 Room 757.0-A2 (6.9kV and 480V Shutdown Board Room A)

8.3.20.1 Fire Prevention

The 6.9kV & 480V Shutdown Board A Room (757.0-A2) is constructed reinforced concrete. With the exception of the barriers separating 757.0-A2 and 757.0-A9, which are in a common fire area, the walls, floor, ceiling and penetration seals have a fire resistance rating of 2-hours or greater. The doors in this room are 3-hour fire resistance rated doors, or have been evaluated as equivalent to a fire door. The fire dampers in this room are equivalent to the rating of the barriers.

The presence of intervening combustibles (insulation on cables in trays) is justified and documented in Section 2.4 of this Part. The non-rated steel equipment hatch in the ceiling of room 757.0-A2 is protected with a water curtain designed in accordance with NFPA 13, section 4-4.8.2.

The 6.9kV & 480V Shutdown Board A Room has a floor area of 6,147 ft² and a nominal ceiling height of 14 feet. The combustible loading of room 757.0-A2 results in a fire severity classification of Moderately Severe. The combustible material in the room consists of plastics associated with electrical boards, MCCs, switches panels, boxes and lights, rubber hoses, other miscellaneous plastics and paper, as well as insulation on cables in trays. However, insulation on cables in trays accounts for over 95% of the combustibles in this room. The assumed ignition sources are the Electrical Panels and Boards, Motor Control Centers, Switches and Multiplexer.

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.20.2 Detection, Control, and Extinguishment

The 6.9kV & 480V Shutdown Board A Room is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the nearby MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. A larger fire activates the installed automatic preaction sprinkler system provided for the room. This extinguishes or limits the magnitude of the fire until the fire brigade arrives. A standpipe and hose station system is also available in the room for fire brigade use.

8.3.20.3 OMA 1022 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 757.0-A2 could potentially damage the Auxiliary Control Air Header B (ACAS-ENDUSER-B, 0-TT-31-54), several cables supporting board 0-BD-236-3-F, and control cables (2V4034A and 2V4035A) to the Steam Generator #4 Power Relief Solenoid Valve (2-PSV-1-31C-A) which prevents the ability to modulate valve 2-PCV-1-30 to relieve pressure on #4 Steam Generator, when needed. The fire safe shutdown requirement is to have an air source

PART VII - DEVIATIONS AND EVALUATIONS

for 2-PCV-1-30 within 60 minutes to maintain pressure control of the #4 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

OMA 1022 is both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 60-minutes before the OMA must be completed. The analysis provided an estimated travel and performance time of 28 minutes. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The validated time to complete this action is 12 minutes 6 seconds. This is adequate time to perform the action.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel to the room 757.0-A24 and perform the action (28-minutes) provides 32-minutes (>100%) margin. The validated time to complete this action is 12 minutes 6 seconds which leaves 47 minutes 54 seconds (>300%) margin. There is sufficient time to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of this OMA. If they were unavailable, 8-hour emergency battery pack lighting is provided; therefore, there is adequate lighting to access the local panel and to perform the OMA. Because the operator does not have to traverse or enter the fire zone, there are no impediments associated with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

d. Equipment Functionality and Accessibility

The fire that results in the fire-induced damage requiring implementation of this OMA is contained within Fire Area 17. Therefore, equipment needed to perform this OMA will be functional and accessible.

e. Available Indications

Available local indications for monitoring N₂ cylinder pressure and regulator adjustment, as well as MCR SG pressure indications, are adequate.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

PART VII - DEVIATIONS AND EVALUATIONS

g. Portable Equipment

No portable equipment is needed for this action.

h. Personnel Protection Equipment

No special PPE is needed to access and perform this OMA.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.20.4 OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 757.0-A2 could potentially damage many control and power cables to the train A 6.9KV and 480V Shutdown Boards and many cables and equipment needed for the Steam Generator #3 Power Relief Solenoid Valve (2-PSV-1-24B-A) which prevents the ability to modulate valve 2-PCV-1-23 to relieve pressure on #3 Steam Generator, when needed. The fire safe shutdown requirement is to have an air source for 2-PCV-1-23 within 60 minutes to maintain pressure control of the #3 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

OMA 1023 is both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 60-minutes before the OMA must be completed. The analysis provided an estimated travel and performance time of 28 minutes for this action. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The demonstrated time to travel to room 757.0-A24 and perform the action was 12 minutes 6 seconds. This is adequate time to perform the action.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel to room 757.0-A24 and perform the action (28-minutes) provides 32-minutes (>100%) margin. The demonstrated validation time is 12 minutes 6 seconds) provides 47 minutes 54 seconds (>300%) margin. An AUO would have sufficient time to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of the OMAs. Even if they were not available, 8-hour emergency battery pack lighting is available; therefore, there is adequate lighting to access the local panel and perform the OMA. Because the operator does not have to traverse or enter the fire zone, there are no impediments associated

PART VII - DEVIATIONS AND EVALUATIONS

with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

d. Equipment Functionality and Accessibility

The fire that results in the fire-induced damage requiring implementation of this OMA is contained within the associated fire area and does not affect the functionality and accessibility of equipment needed for this OMA.

e. Available Indications

Available local indications for monitoring N₂ cylinder pressure and regulator adjustment, as well as MCR SG pressure indications, are adequate.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is necessary to perform these OMAs. Spare N₂ cylinders for SG PORV control are available, if needed. The reliability of the N₂ station is assured by the Operational Requirements and Testing and Inspection program as described in Part II, Section 14.10.

h. Personnel Protection Equipment

No special PPE is needed to access and perform this OMA.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.20.5 Staffing Requirements for a Fire in Room 757.0-A2

For a fire in 757.0-A2, three AUOs perform a combination of eighteen Unit 1, three Unit 2 and five common actions, three AUOs perform eight Unit 1 actions and two AUOs perform three Unit 2 actions for a total of eight AUOs. Therefore, the staffing of eight AUOs is sufficient to accomplish all of the Unit 1, Unit 2 and common manual actions, should there be a fire in room 757.0-A2.

8.3.21 Room 757.0-A3 (125V Vital Battery Board Room II)

8.3.21.1 Fire Prevention

The 125V Vital Battery Board Room II (757.0-A3) is constructed of reinforced concrete. The walls, floor, ceiling, penetration seals, doors and dampers in this room have a fire resistance rating of 3-hours. Room 757.0-A3 has a floor area of 329 ft² and a nominal ceiling height of 14-feet. The combustibles in 757.0-A3 consist of plastics associated with electrical panels, boxes, and lights; and insulation on cables in trays. The fire severity rating of this room is low.

PART VII - DEVIATIONS AND EVALUATIONS

The potential ignition sources in this room consist of 125V DC Vital battery board, 120V AC Instrument boards, transformers, control panels and junction boxes. The control panels and the junction boxes are relatively small and do not constitute credible ignition sources (circuits are properly protected and insignificant quantity of combustibles associated with the boxes to create and sustain a large fire). NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.21.2 Detection, Control, and Extinguishment

The 125V Vital Battery Board Room II (757.0-A3), is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts would be quickly detected and personnel would be dispatched from the nearby MCR to investigate the detector alarm. Portable extinguishers are available throughout the plant for extinguishing any small credible fire. If a larger fire were to occur, the manual sprinkler system that is provided for the room would be manually actuated. A standpipe and hose station system is also available in adjacent room 757.0-A24 for fire brigade use.

Even if the postulated fire were to start and not be extinguished, the 3-hour fire rating of the walls, floors and ceiling and doors, fire dampers and penetration seals would contain the fire and prevent it from propagating to adjacent rooms. In addition, a fire in this room would not present an exposure hazard to the access path to the manual action located in 757.0-A21, the 480V Shutdown Board Room 2A.

8.3.21.3 OMA 1024 – Operate Steam Generator Relief Valves to Control Secondary Pressure

The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-12 (SG #2 Power Relief Valve) to control secondary pressure. A fire that is contained within room 757.0-A3 could potentially damage the equipment requiring implementation of this OMA due to SG 2 Pressure Indicator/Controller (2-PIC-1-13A) control cable (2PV6756) failure and 0-MTR-32-86-B fails due to supporting equipment (2-MCC-214-B1-B, ERCW-HDR-2B, 0-MTR-32-462, and various cables) failure. The operator must operate 2-ISIV-1-405E2 on the N₂ Operating Station for 2-PCV-1-12 (2-L-1001) to open/close 2-PCV-1-12 if MDAFW Pump B or TDAFW Pump is used. This OMA must be completed within 60 minutes and is performed in room 757.0-A21.

The Feasibility and Reliability Evaluation for OMA 1024 following a fire in this room is covered in the OMA 1024 bounding evaluation (Section 8.3.65).

8.3.21.4 Staffing Requirements for a Fire in Room 757.0-A3

For a fire in 757.0-A3, two AUOs perform six Unit 1 actions, two AUOs perform four Unit 2 actions and one AUO performs one common and one Unit 1 action for a total of five AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1, Unit 2 and common manual actions, should there be a fire in 757.0-A3.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.22 Room 757.0-A4 (125V Vital Battery Board Room I)

8.3.22.1 Fire Prevention

The 125V Vital Battery Board Room I, 757.0-A4, is constructed of reinforced concrete. The walls, floor, ceiling, penetration seals, doors and dampers in this room have a fire resistance rating of 3-hours. Room 757.0-A4 has a floor area of 329 ft² and a nominal ceiling height of 14 feet. The combustible loading in the room results in a fire severity classification of low. The combustibles in 757.0-A4 consist of plastics associated with the electrical boards, panels, boxes and lights and insulation on the cables in the trays.

The potential ignition sources in this room consist of 125V DC Vital battery board, 120V AC Instrument boards, transformers, control panels and junction boxes. The control panels and the junction boxes are relatively small and do not constitute credible ignition sources (circuits are properly protected and insignificant quantity of combustibles associated with the boxes to create and sustain a large fire). NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.22.2 Detection, Control, and Extinguishment

The 125V Vital Battery Board Room I (757.0-A4), is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the nearby MCR to investigate the detector alarm. Portable extinguishers are available throughout the plant for extinguishing any small credible fire. If a larger fire occurs, the manual sprinkler system provided for the room is manually actuated. A standpipe and hose station system is also available in adjacent room 757.0-A2 for fire brigade use.

Even if the postulated fire were to start and not be extinguished, the 3-hour fire rating of the walls, floors and ceiling and doors, fire dampers and penetration seals would contain the fire and prevent it from propagating to adjacent rooms. In addition, a fire in this room would not present an exposure hazard to the access path to the manual action located in 757.0-A24, the 6.9kV and 480V Shutdown Board Room B.

8.3.22.3 OMA 1022 – Operate Steam Generator Relief Valves to Control Secondary Pressure

The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-30 (SG 4 Power Relief Valve) to control secondary pressure. A fire that is contained within room 757.0-A4 potentially damages equipment requiring implementation of this OMA if supporting equipment (2-PM-1-31) fails. The operator must operate 2-ISIV-1-406E2 at the N₂ Operating Station (2-L-1000) to open/close 2-PCV-1-30. This OMA must be completed within 60 minutes and is performed in room 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1022 following a fire in this room is covered in the OMA 1022 bounding evaluation (Section 8.3.63).

PART VII - DEVIATIONS AND EVALUATIONS

8.3.22.4 OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure

The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-23 (SG 3 Power Relief Valve) to control secondary pressure. A fire that is contained within room 757.0-A4 potentially damages equipment requiring implementation of this OMA if supporting equipment (2-PM-1-24 and 0-MTR-32-60-A) fails. The operator must operate 2-ISIV-1-407E2 at the N₂ Operating Station (2-L-1000) to open/close 2-PCV-1-23. This OMA must be completed within 60 minutes and is performed in room 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in the OMA 1023 bounding evaluation (Section 8.3.64).

8.3.22.5 Staffing Requirements for a Fire in Room 757.0-A4

For a fire in 757.0-A4, two AUOs perform four Unit 2 actions, three AUOs perform seven Unit 1 actions, one AUO performs a common, one Unit 1 and one Unit 2 actions and one AUO performs one common action for a total of seven AUOs. Therefore, the staffing of 8 AUOs is more than sufficient to accomplish all of the Unit 1 and 2 manual actions, should there be a fire in Room 757.0-A4.

8.3.23 Room 757.0-A5 (480V Shutdown Board Room 1B)

8.3.23.1 Fire Prevention

The 480V Shutdown Board Room 1B (757.0-A5) is constructed of reinforced concrete. The walls, floor, ceiling and penetration seals have a fire resistance rating of 2-hours or greater. All doors in this room have a fire rating of 3-hours. The dampers are at least equivalent to the rating of the barriers. The room has a floor area of 2,223 ft² and a nominal ceiling height of 14-feet.

The fire severity classification of combustible loading in 757.0-A5 is Moderately Severe. The presence of intervening combustibles (insulation on cables in trays) in 757.0-A5 is justified and documented in Section 2.4 of this Part. The combustible material in the room consists of plastics associated with MCCs, electrical panels, boards, annunciators, boxes, lights, fire response equipment and insulation on cables in trays. Insulation on cables in trays accounts for approximately 92% of the combustible loading in this room.

The assumed ignition sources are the shutdown boards, MCCs and annunciators. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.23.2 Detection, Control, and Extinguishment

The 480V Shutdown Board Room 1B is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts would be quickly detected and personnel would be dispatched from the nearby MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. A larger fire would activate the installed automatic sprinkler system provided for the room. This would extinguish or limit the

PART VII - DEVIATIONS AND EVALUATIONS

magnitude of the fire until the fire brigade arrived. A standpipe and hose station system is also available in the adjacent room for fire brigade use.

8.3.23.3 OMA 1016 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in 757.0-A5 could potentially damage a control cable (1PV72A) for the Auxiliary Air Compressor A-A CAM Timer/Air Dryer Flow Control Valve (0-MTR-32-461) and a control cable to the Steam Generator #1 Power Relief Solenoid Valve for 2-PSV-1-6C-B which prevents the ability to modulate Power Relief Valve 2-PCV-1-5 to relieve pressure on #1 Steam Generator when needed. The fire safe shutdown requirement is to have an air source for 2-PCV-1-5 within 60 minutes for operation of the PCVs and thereby maintain pressure control of the #1 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1001) in 757.0-A21.

OMA 1016 is both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 60-minutes before the OMA must be completed. The analysis provided an estimated travel and performance time of 25 minutes. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The demonstrated time to travel to and perform the action was 12 minutes 6 seconds. This is adequate time to perform the action.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel to the Unit 2 480V SD BD Room 2A and perform the action (25-minutes) provides 35-minutes (140%) margin. The demonstrated time was validated to be 12 minutes 6 seconds which provides 47 minutes 54 seconds (>300%) margin. This is more than adequate time to ensure reliability.

Normal and Standby lighting is provided for the access routes and at the location of this OMA. If they were still unavailable, 8-hour emergency battery pack lighting is provided; therefore, there is adequate lighting to access the local panel and perform the OMA. Because the operator does not have to traverse or enter the fire zone, there are no impediments associated with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

d. Equipment Functionality and Accessibility

The fire that results in the fire-induced damage requiring implementation of this OMA will be contained within 757.0-A5 and will not affect the functionality and accessibility of the N₂ control panels in 757.0-A21.

PART VII - DEVIATIONS AND EVALUATIONS

e. Available Indications

Available local indications for monitoring N₂ cylinder pressure and regulator adjustment, as well as MCR SG pressure indications, are adequate.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is necessary to perform these OMAs. Spare N₂ cylinders for SG PORV control are available, if needed. The reliability of the N₂ station is assured by the Operational Requirements and Testing and Inspection program as described in Part II, Section 14.10.

h. Personnel Protection Equipment

No special PPE is needed to access and perform this OMA.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.23.4 OMA 1024 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in 757.0-A5 could potentially damage a control cable to a flow control valve for the Essential Raw Cooling Water Strainer 2B-B Backwash and Flush (2-FCV-67-10A-B and 2-FCV-67-10B-B) which prevents the ability to modulate the Power Relief Valve 2-PCV-1-12 to relieve pressure on #2 Steam Generator when needed. The fire safe shutdown requirement is to have an air source for 2-PCV-1-12 within 60 minutes for operation of the PCV and thereby maintain pressure control of the #2 Steam Generator. Emergency air is provided for operation of the PCV, via an OMA at the SG PORV Nitrogen Station (PNL-2-L-1001) in 757.0-A21.

OMA 1024 is both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 60-minutes before the OMA must be completed. The analysis provided an estimated travel and performance time of 25 minutes. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The demonstrated time to travel and perform the action was 12 minutes 6 seconds. There is adequate time available to perform the action.

PART VII - DEVIATIONS AND EVALUATIONS

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel to the Unit 2 Purge Air Penetration Room and perform the action (25-minutes) provides 35-minutes (140%) margin. The demonstrated time was validated to be 12 minutes 6 seconds (>300%) margin. This is more than adequate time to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of this OMA. If they were still unavailable, 8-hour emergency battery pack lighting is provided; therefore, there is adequate lighting to access the local panel and perform the OMA. Because the operator does not have to traverse or enter the fire zone, there are no impediments associated with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

d. Equipment Functionality and Accessibility

The fire that results in the fire-induced damage requiring implementation of this OMA will be contained within 757.0-A5 and will not affect the functionality and accessibility of the N₂ control panels in 757.0-A21.

e. Available Indications

Available local indications for monitoring N₂ cylinder pressure and regulator adjustment, as well as MCR SG pressure indications, are adequate.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is necessary to perform these OMAs. Spare N₂ cylinders for SG PORV control are available, if needed. The reliability of the N₂ station is assured by the Operational Requirements and Testing and Inspection program as described in Part II, Section 14.10.

h. Personnel Protection Equipment

No special PPE is needed to access and perform this OMA.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.23.5 Staffing Requirements for a Fire in Room 757.0-A5

For a fire in 757.0-A5, two AUOs perform seven Unit 2 actions, four AUOs perform fifteen Unit 1 actions and one AUO performs three common actions for a total of seven AUOs. Therefore,

PART VII - DEVIATIONS AND EVALUATIONS

the staffing of eight AUOs is sufficient to accomplish all of the Unit 1, Unit 2 and common manual actions, should there be a fire in room 757.0-A5.

8.3.24 Room 757.0-A9 (Personnel and Equipment Access Room)

8.3.24.1 Fire Prevention

The Personnel and Equipment Access Room (757.0-A9) is constructed of reinforced concrete. The barriers separating 757.0-A9 and 757.0-A2 are non-rated barriers. The remaining barriers have a fire resistance rating of 2-hours or greater. Openings in these barriers are provided with fire doors, dampers and penetration seals that are at least equivalent to the rating of the barriers. The door separating this room from other fire areas is not a UL listed fire door but has been evaluated as being equivalent to fire rated doors.

The Personnel and Equipment Access Room (757.0-A9) has a floor area of 821 ft² nominal ceiling height of 14-feet. The combustible loading of the room results in a fire severity classification of Moderate. The combustible material in the room consists of plastics associated with a panel, junction boxes and insulation on cables in trays. Insulation on the cables accounts for approximately 79% of the combustibles in room 757.0-A9.

The potential ignition sources in this room consist of the air handling units (AHU), an electrical panel and junction boxes. The air handling units' motors are completely enclosed by the heavy sheet metal housing of the AHU and are not considered as fire sources. The panel is a small, wall mounted panel, and the junction boxes are relatively small and do not constitute credible ignition sources (circuits are properly protected and insignificant quantity of combustibles associated with the boxes to create and sustain a large fire). NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.24.2 Detection, Control, and Extinguishment

The Personnel and Equipment Access Room is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the nearby MCR to investigate the alarm. Portable extinguishers are available for extinguishing any small credible fire. If a larger fire occurs, the installed automatic preaction sprinkler system provided for the room activates. A standpipe and hose station system is also available in the room for fire brigade use.

8.3.24.3 OMA 1022 – Operating Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 757.0-A9 could potentially damage the Auxiliary Control Air Header B, ACAS ENDUSER B, 0-TT-31-54 which could prevent the ability to modulate Power Relief Valve 2-PCV-1-30 to relieve pressure on #4 Steam Generator, when needed. The fire safe shutdown requirement is to have an air source for 2-PCV-1-30 within 60 minutes to maintain pressure control of the #4 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24. Due to the lack of credible ignition sources in 757.0-A9 and the provisions provided for detection and extinguishment, it is unlikely that a fire in 757.0-A9 would necessitate the performance of this

PART VII - DEVIATIONS AND EVALUATIONS

manual action. However, the following is an evaluation of the feasibility and reliability of the OMA that provides additional defense-in-depth for FSSD assurance.

OMA 1022 is both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 60-minutes before the OMA must be completed. The analyzed time estimated to travel and perform the action is 28 minutes. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The demonstrated time to travel and perform the action was 12 minutes 6 seconds. There is adequate time available to perform the action.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel to the 6.9kV and 480V Shutdown Board Room B and perform the action (28-minutes) provides 32-minutes (114%) margin. The demonstrated time was validated to be 12 minutes 6 seconds (>300%) margin. This is more than adequate time to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of the OMAs. Even if they were not available, 8-hour emergency battery pack lighting is available; therefore, there is adequate lighting to access the local panel and perform the OMA. Because the operator does not have to traverse or enter the fire zone, there are no impediments associated with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

d. Equipment Functionality and Accessibility

The postulated fire in 757.0-A9 does not affect the N₂ station in 757.0-A24; therefore, it remains functional and accessible.

e. Available Indications

Available local indications for monitoring N₂ cylinder pressure and regulator adjustment, as well as MCR SG pressure indications, are adequate.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

PART VII - DEVIATIONS AND EVALUATIONS

g. Portable Equipment

No portable equipment is necessary to perform these OMAs. Spare N₂ cylinders for SG PORV control are available, if needed. The reliability of the N₂ station is assured by the Operational Requirements and Testing and Inspection program as described in Part II, Section 14.10.

h. Personnel Protection Equipment

No special PPE is needed to access and perform this OMA.

i. Procedures and Training

0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.24.4 OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 757.0-A9 could potentially damage the Auxiliary Control Air Header A, ACAS ENDUSER A, 0-TT-31-41, which prevents the ability to modulate the power relief valve 2-PCV-1-23 to relieve pressure on #3 Steam Generator, when needed. The fire safe shutdown requirement is to have an air source for 2-PCV-1-23 within 60 minutes to maintain pressure control of the #3 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24. However, given the lack of credible ignition sources in 757.0-A9 and the provisions provided for detection and extinguishment, it is unlikely that a fire in 757.0-A9 would damage an ACAS Enduser and necessitate the performance of this manual action.

OMA 1023 is both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 60-minutes before the OMA must be completed. The analysis provided an estimated travel and performance time of 28 minutes for this action. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The demonstrated time to travel and perform the action was 12 minutes 6 seconds. There is adequate time available to perform the action.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel to the 6.9kV and 480V Shutdown Board Room B and perform the action (28-minutes) provides 32-minutes (114%) margin. The demonstrated time was validated to be 12 minutes 6 seconds (>300%) margin. This is more than adequate time to ensure reliability.

PART VII - DEVIATIONS AND EVALUATIONS

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of the OMAs. Even if they were not available, 8-hour emergency battery pack lighting is available; therefore, there is adequate lighting to access the local panel and perform the OMA. Because the operator does not have to traverse or enter the fire zone, there are no impediments associated with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

d. Equipment Functionality and Accessibility

The fire that results in the fire-induced damage requiring implementation of this OMA will be contained within the associated room.

e. Available Indications

Available local indications for monitoring N₂ cylinder pressure and regulator adjustment, as well as MCR SG pressure indications, are adequate.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is necessary to perform these OMAs. Spare N₂ cylinders for SG PORV control are available, if needed. The reliability of the N₂ station is assured by the Operational Requirements and Testing and Inspection program as described in Part II, Section 14.10.

h. Personnel Protection Equipment

No special PPE is needed to access and perform this OMA.

i. Procedures and Training

The Appendix R manual operator actions procedures (AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.24.5 Staffing Requirements for a Fire in Room 757.0-A9

For a fire in 757.0-A9, three AUOs perform a combination of eighteen Unit 1, three Unit 2 and five common actions, three AUOs perform eight Unit 1 actions and two AUOs perform three Unit 2 actions for a total of eight AUOs. Therefore, the staffing of eight AUOs is sufficient to accomplish all of the Unit 1, Unit 2 and common manual actions, should there be a fire in room 757.0-A9

PART VII - DEVIATIONS AND EVALUATIONS

8.3.25 Room 757.0-A10 (Reverse Osmosis Equipment Room)

8.3.25.1 Fire Prevention

The Reverse Osmosis Equipment Room (757.0-A10) is constructed of reinforced concrete. The walls, floor, ceiling, and penetration seals have a fire resistance rating of 2-hours or greater. The floor slab in Room 782.0-A1 to 757.0-A10 has an equipment hatch that is covered with a non-fire rated steel cover, two HVAC ducts without fire dampers, and a stairway enclosed by 2 hour non-regulatory fire barriers. There is one fire door in the room which has been evaluated as equivalent to a UL listed door. The fire dampers are at least equivalent to the rating of the barriers. 757.0-A10 has a floor area of 2,271ft² and a nominal ceiling height of 24-feet. The combustibles in 757.0-A10 consist of plastics associated with the electrical panels, and lights, wood storage racks, nylon ropes, and the insulation on the cables in the trays. The insulation and Thermo-Lag on the cables accounts for over 98% of the combustibles in the room. The combustible loading in the room results in a fire severity classification of moderate (insignificant if Thermo-Lag and cable insulation are not included). There are no credible ignition sources in 757.0-A10. The junction boxes are small, with minimal associated combustibles (2 pounds of plastic), and are not considered ignition sources.

The justification for intervening combustibles such as insulation on cables in trays and Thermo-Lag is documented in Section 2.4 of this Part.

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.25.2 Detection, Control, and Extinguishment

Reverse Osmosis Equipment Room (757.0-A10) is provided with ionization smoke detection that alarms in the Main Control Room (MCR). Portable extinguishers are available throughout the plant for extinguishing any small credible fire. If a larger fire occurs, the automatic sprinklers in the room activate. A standpipe and hose station system is available in the room and in adjacent room 757.0-A13 for fire brigade use. With fire detection, an automatic suppression system, and fire resistant barriers, a fire in this area is contained until the fire brigade responds and does not cause an exposure hazard to any adjacent rooms.

8.3.25.3 OMA 1016 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in AV-050 could damage the Auxiliary and Control Air Header A (ACAS ENDUSER-A, specifically components 1-L-44 in 782.0-A1 and 0-FCO-30-149 in 782.0-A2) which could prevent the ability to modulate Steam Generator #1 Power Operated Relief Valve (2-PCV-1-5) to relieve pressure on #1 Steam Generator if Motor Driven AFW Pump A or Turbine Driven AFW Pump is used. The fire safe shutdown requirement is to have an air source for 2-PCV-1-5 within 60 minutes for operation of the PCV and thereby maintaining pressure control of the #1 Steam Generator. Emergency Air is provided for operation of the PCV, is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1001) in 757.0-A21.

The insignificant combustible loading in this room (if cable insulation and Thermo-Lag are not considered in the combustible loading), the insignificant credible ignitions sources (as indicated

PART VII - DEVIATIONS AND EVALUATIONS

by the combustible loading calculation), the suppression and detection in the room, and because the ACAS air users which cause this failure are located in rooms 782.0-A1 and 782.0-A2 rather than room 757.0-A10 (these rooms are separated by a 2 hour rated floor / ceiling but are analyzed together despite the separation) there is no credible fire originating in room 757.0-A10 that could result in the need for this manual action.

The Feasibility and Reliability Evaluation for OMA 1016 following a fire in this room is covered in the OMA 1016 bounding evaluation (Section 8.3.62).

8.3.25.4 OMA 1024 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 757.0-A10 could potentially damage control cables to the Steam Generator #2 Power Relief Solenoid Valve (2-PSV-1-13C-A, 2V4017A). The fire is also assumed to spread to 782.0-A1 or 782.0-A2, and damage the Auxiliary and Control Air Header B (ACAS-ENDUSER-B). This damage prevents the ability to modulate the Power Relief Valve (2-PCV-1-12) to relieve pressure on the #2 Steam Generator if Motor Driven AFW Pump A or Turbine Driven AFW Pump is used. The fire safe shutdown requirement is to have an air source for 2-PCV-1-12 within 60 minutes for operation of the PCV and thereby maintain pressure control of the #2 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1001) in 757.0-A21.

The insignificant combustible loading in this room (if cable insulation and Thermo-Lag are not considered in the combustible loading), the insignificant credible ignitions sources, the suppression and detection in the room, and because the ACAS air users which cause this failure are located in rooms 782.0-A1 and 782.0-A2 rather than room 757.0-A10 (these rooms are separated by a 2 hour rated floor / ceiling but are analyzed together) result in no credible fire originating in room 757.0-A10 that could result in the need for this manual action.

The Feasibility and Reliability Evaluation for OMA 1024 following a fire in this room is covered in the OMA 1024 bounding evaluation (Section 8.3.65).

8.3.25.5 Staffing Requirements for a Fire in Room 757.0-A10

For a fire in 757.0-A10, 14 Unit 1 actions are performed by four AUOs and five Unit 2 actions are performed by two AUOs for a total of six AUOs. Therefore a total of eight AUOs is sufficient to complete all of the OMAs for Unit 1 and Unit 2.

8.3.26 Room 757.0-A16 (Emergency Gas Treatment Filter Room)

8.3.26.1 Fire Prevention

The Emergency Gas Treatment Filter Room, 757.0-A16, is constructed of reinforced concrete. The walls, floor, ceiling, and penetration seals in 757.0-A16 have a fire rating of 2-hours or greater. The fire damper is fire rated for 3-hours. The only door in this room separating another fire area has been evaluated as equivalent to a 3-hour UL listed door. The room has a floor area of 2174 ft² and a nominal ceiling height of 24-feet.

The combustible loading in 757.0-A16 is Moderate (80,197 Btu/ft²). The combustible material in the room consists of lube oil, plastics associated with electrical panels, boxes, a telephone,

PART VII - DEVIATIONS AND EVALUATIONS

lights, charcoal in filter housings and insulation on cables in trays. Insulation on cable trays makes up over 93% of the combustibles in this room.

The possible ignition sources in 757.0-A16 are two motors, panels and junction boxes. Small motors and wall mounted panels and junction boxes, with small combustible loadings, such as these, are not considered significant fire sources capable of damaging other equipment and cables.

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.26.2 Detection, Control and Extinguishment

The Emergency Gas Treatment Filter Room, 757.0-A16, is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the nearby MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire.

If a larger fire occurs, the installed automatic preaction sprinkler system provided for the room activates. A standpipe and hose station system is also available in the room for fire brigade use.

8.3.26.3 OMA 1022 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 757.0-A16 could potentially damage Auxiliary Control Air Header B (ACAS ENDUSER B) or damage a control cable to the Steam Generator #4 Power Relief Solenoid Valve 2-PSV-1- 31C-A which prevents the ability to modulate the valve to relieve pressure on #4 Steam Generator when needed.

The fire safe shutdown requirement for a fire in 757.0-A16 is to have an air source for 2-PCV-1-30 within 60 minutes to maintain pressure control of the #4 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1022 following a fire in this room is covered in a bounding evaluation (Section 8.3.63).

8.3.26.4 OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 757.0-A16 potentially damages Auxiliary Control Air Header A (ACAS ENDUSER A) or damages a control cable to the Steam Generator #3 Power Relief Solenoid Valve 2-PSV-1- 24B-A which prevents the ability to modulate the valve to relieve pressure on #3 Steam Generator when needed.

The fire safe shutdown requirement for a fire in 757.0-A16 is to have an air source for 2-PCV-1-23 within 60 minutes to maintain pressure control of the #3 Steam Generator. Emergency air is

PART VII - DEVIATIONS AND EVALUATIONS

provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in a bounding evaluation (Section 8.3.64).

8.3.26.5 Staffing Requirements for a Fire in Room 757.0-A16

For a fire in 757.0-A16, six Unit 2 actions are performed by four AUOs and five Unit 1 actions are performed by two AUOs for a total of six AUOs. Therefore, the staffing of 8 AUOs is more than sufficient to accomplish all of the Unit 1 and 2 manual actions, should there be a fire in Room 757.0-A16.

8.3.27 Room 757.0-A17 (Personnel and Equipment Access Room)

8.3.27.1 Fire Prevention

The Unit 2 Personnel and Equipment Access Room (757.0-A17) is constructed of reinforced concrete with a fire resistance rating of at least 2-hours. The openings through these barriers are protected with door, damper and penetration seals that are equivalent to the rating of the barrier. The walls separating 757.0-A17 and 757.0-A24, which are in the same fire area, are not fire rated barriers. The room has a floor area of 821 ft² and a nominal ceiling height of 14-feet.

The combustible loading in 757.0-A17 results in a fire severity classification of Low. The combustible material in the room consists of plastics associated with electrical panels, boxes, lights and insulation on cables in trays. Insulation on cable trays makes up for over 92% of the combustibles in this room. The potential ignition sources in 757.0-A17 are the air handling units (AHU), panels and junction boxes. The air handling units' motors are completely enclosed by the heavy sheet metal housing of the AHU and are not considered as fire sources. Small wall mounted panels and junction boxes, with small combustible loadings, such as these, are not considered significant fire sources capable of damaging other equipment and cables.

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.27.2 Detection, Control, and Extinguishment

The Unit 2 Personnel and Equipment Access Room is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the nearby MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire.

If a larger fire occurs, the installed automatic sprinkler system provided for the room activates. A standpipe and hose station system is also available in room 757.0-A24 for fire brigade use.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.27.3 OMA 1016 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 757.0-A17 could potentially damage Auxiliary Control Air Header A (ACAS ENDUSER A, 0-TCV-31-108) and damage control cables (2V4012B, 2V4010B, 2V4011B, and 2V4013B) to the Steam Generator #1 Power Relief Solenoid Valve 2-PSV-1- 6C-B or a control cable (2PM1371) to SG #1 Power Relief Valve Modifier 2-PM-1-6, which prevents the ability to modulate the valve to relieve pressure on #1 Steam Generator when needed. The fire safe shutdown requirement for a fire in 757.0-A17 is to have an air source for 2-PCV-1-5 within 60 minutes to maintain pressure control of the #1 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1001) located in room 757-A21.

However, given the low combustible loading in this room, the lack of significant ignition sources (as indicated by the combustible loading calculation and ignition source walkdown documentation), and the detection, control and extinguishment provisions, it is not likely that this manual action is needed for a fire in 757.0-A17.

The Feasibility and Reliability Evaluation for OMA 1016 following a fire in this room is covered in the OMA 1016 bounding evaluation (Section 8.3.62).

8.3.27.4 OMA 1024 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 757.0-A17 could potentially damage Auxiliary Control Air Header B (ACAS ENDUSER B, 0-TCV-31-138) and damage a control cable (2V7570B) to the Steam Generator #2 Power Relief Solenoid Valve 2-PSV-1-13B-B, which prevents the ability to modulate the valve to relieve pressure on #2 Steam Generator when needed. The fire safe shutdown requirement for a fire in 757.0-A17 is to have an air source for 2-PCV-1-12 within 60 minutes to maintain pressure control of the #2 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1001) located in room 757-A21.

However, given the low combustible loading in this room, the lack of significant ignition sources (as indicated by the combustible loading calculation and ignition source walkdown documentation), and the detection, control and extinguishment provisions, it is not likely that this manual action is needed for a fire in 757.0-A17.

The Feasibility and Reliability Evaluation for OMA 1024 following a fire in this room is covered in the OMA 1024 bounding evaluation (Section 8.3.65).

8.3.27.5 Staffing Requirements for a Fire in Room 757.0-A17

For a fire in 757.0-A17, five Unit 2 actions are performed by three AUOs, three Unit 1 actions are performed by two AUOs, and one Unit 1 and two "common" actions are performed by one AUO for a total of six AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1 and Unit 2 actions, should there be a fire in room 757.0-A17.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.28 Room 757.0-A21 (480V Shutdown Board Room 2A)

8.3.28.1 Fire Prevention

The 480V Shutdown Board Room 2A, 757.0-A21 is constructed of reinforced concrete. The walls, doors, floors and ceiling have a fire resistance rating of 2 hours or greater. The fire dampers provided in this room are at least equivalent to the rating of the barriers. Room 757.0-A21 has a floor area of 2,244 ft² and a nominal ceiling height of 14-feet. The combustibles in 757.0-A21 consist of plastics associated with the electrical panels and boxes, lights, and insulation on the cables in the trays (trays account for 97% of the combustibles in this room). The combustible loading in the room results in a fire severity classification of moderately severe.

Intervening combustibles (in the form of insulation on cables in trays and ERFBS) are present in the room. The justification is documented in Section 2.4 of this Part.

The assumed ignition sources are the shutdown boards, MCCs and transformers. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.28.2 Detection, Control, and Extinguishment

The 480V Shutdown Board Room 2A (757.0-A21) is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the nearby MCR to investigate the detector alarm. Portable extinguishers are available throughout the plant for extinguishing any small credible fire. If a larger fire occurs, the automatic sprinkler system provided for the room activates. A standpipe and hose station system is also available in adjacent room 757.0-A24 for fire brigade use.

Even if the postulated fire starts and is not extinguished, the fire barriers contain the fire and prevent propagation to adjacent rooms.

8.3.28.3 OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure

The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-23 (SG 3 Power Relief Valve) to control secondary pressure. The operator must operate 2-ISIV-1-407E2 at the N₂ Operating Station for 2-PCV-1-23 (2-L-1000) to open/close 2-PCV-1-23. A fire that is contained within room 757.0-A21 potentially damages equipment requiring implementation of this OMA. This OMA must be completed within 60 minutes. This action is performed in room 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in the OMA 1023 bounding evaluation (Section 8.3.64).

8.3.28.4 OMA 1516 – Control 2-PCV-3-132-B

A fire in room 757.0-A21 could damage control cables 2PV830G or PV360G which could prevent the ability to operate the B Motor Driven Auxiliary Feedwater Pump (MDAFW) Outlet

PART VII - DEVIATIONS AND EVALUATIONS

Pressure Control Valve (2-PCV-3-132-B). The fire safe shutdown requirement for a fire in 757.0-A21 is to control discharge pressure on the MDAFW Pump by transferring from normal to auxiliary control and operating the PCV from auxiliary control room. Discharge pressure of the MDAFW pump must be controlled in within 20 minutes. The operator must transfer from normal to auxiliary control (OMA 1516) using transfer switch 2-XS-3-132, located on local control station 2-L-11B in room 757.0-A28 and enter the adjacent Auxiliary Control Room, 757.0-A1, and ensure the discharge pressure controller 2-PDIC-3-132C on local control station 2-L-10 is in the auto position.

OMA 1516 is feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The Operator has 20 minutes before the OMA must be completed. The analysis provided an estimated travel and performance time of 5 minutes. The demonstrated transit and performance time was 2 minutes 55 seconds. The fire that results in the fire-induced damage requiring implementation of this OMA is contained within room 757.0-A21 and does not present an exposure hazard to the operator on the access path or the control location.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel to the board, operate 2-XS-3-132 and 2-PDIC-3-132C, and accomplish these actions (5 minutes) provides 15-minutes (300%) margin and the validated time of 2 minutes 55 seconds, provides 17 minutes 5 seconds (>500% margin). An AUO would have sufficient time to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of this OMA. If they were unavailable, 8-hour emergency battery pack lighting is provided; therefore, there is adequate lighting to access the controls and to perform the OMA. Because the operator does not have to traverse or enter the fire zone, there are no impediments associated with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

d. Equipment Functionality and Accessibility

The board in room 757.0-A28 is remote from the fire and is readily accessible; therefore it is ensured that they are functional and accessible.

e. Available Indications

Auxiliary Control Room and MCR indications for performing these OMAs are adequate.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

PART VII - DEVIATIONS AND EVALUATIONS

g. Portable Equipment

No portable equipment is needed to complete these actions.

h. Personnel Protection Equipment

Only standard PPE is needed to perform this action.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series - Part II, Reference 4.2.90) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.28.5 Staffing Requirements for a Fire in Room 757.0-A21

For a fire in 757.0-A21, two “common” actions are performed by one AUO, six Unit 2 actions are performed by two AUOs and five Unit 1 actions are performed by two AUOs for a total of five AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1 and 2 manual actions, should there be a fire in Room 757.0-A21.

8.3.29 Room 757.0-A22 (125V Vital Battery Board Room IV)

8.3.29.1 Fire Prevention

The 125V Vital Battery Board Room IV (757.0-A22) is constructed of reinforced concrete and the fire barriers (walls, floors, ceiling, floors, and penetration seals) have a fire resistance rating of 3-hours. Doors and dampers are fire resistance rated for 3-hours. Room 757.0-A22 has a floor area of 329 ft² and a nominal ceiling height of 14-feet. The combustibles in 757.0-A22 consist of plastics associated with electrical panels and boxes and lights and insulation on cables in trays. The insulation on cable trays accounts for 58% of the total combustibles in the room. The fire severity classification is Low.

There are a number of assumed ignition sources in 757.0-A22 including 120V Vital Power boards, 125V Vital Battery boards and a transformer. NPG-SPP-18.4.7, “Control of Transient Combustibles” and NPG-SPP-18.4.8, “Control of Ignition Sources (Hot Work)” defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.29.2 Detection, Control, and Extinguishment

The 125V Vital Battery Board Room IV (757.0-A22), is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the nearby MCR to investigate the detector alarm. Portable extinguishers are available throughout the plant for extinguishing any small credible fire. If a larger fire occurs, the sprinkler system provided for the room is manually actuated. A standpipe and hose station system is also available in adjacent room 757.0-A24 for fire brigade use. Even if the postulated fire starts and is not extinguished, the 3-hour fire rating of the walls, floors, ceiling, doors, dampers and penetration seals contain the fire and prevent it from propagating to adjacent rooms. A fire in this room does not present an exposure hazard to the

PART VII - DEVIATIONS AND EVALUATIONS

access path to the manual action located in 757.0-A24, the 6.9kV and 480V Shutdown Board Room B.

8.3.29.3 OMA 1016 – Operate Steam Generator Relief Valves to Control Secondary Pressure

The fire safe shutdown requirement of this OMA is to operate 2-PCV-1-5 (SG 1 Power Relief Valve) to control secondary pressure. A fire that is contained within room 757.0-A22 could potentially damage cable 2PL3786A for motor 0-MTR-32-60-A, cable 2V4010B for valve 2-PSV-1-6C-B, and many cables for board 0-BD-236-4-G, all supporting 2-PCV-1-5 which results in the implementation of this OMA. The operator is required to operate 2-ISIV-1-408E2 at the N₂ Operating Station for 2-PCV-1-5 (2-L-1001). This OMA must be completed within 60 minutes and is performed in room 757.0-A21.

The Feasibility and Reliability Evaluation for OMA 1016 following a fire in this room is covered in the OMA 1016 bounding evaluation (Section 8.3.62).

8.3.29.4 OMA 1024 – Operate Steam Generator Relief Valves to Control Secondary Pressure

The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-12 (SG 2 Power Relief Valve) to control secondary pressure. A fire that is contained within room 757.0-A22 could potentially damage cable 2V7567B for valve 2-PSV-1-13B-B, many cables for board 0-BD-236-4-G supporting 2-PCV-1-12 which results in the implementation of this OMA. The operator must operate 2-ISIV-1-405E2 on the N₂ Operating Station for 2-PCV-1-12 (2-L-1001) if MDAFW Pump B or TDAFW Pump is used. This OMA must be completed within 60 minutes and is performed in room 757.0-A21.

The Feasibility and Reliability Evaluation for OMA 1024 following a fire in this room is covered in the OMA 1024 bounding evaluation (Section 8.3.65).

8.3.29.5 Staffing Requirements for a Fire in Room 757.0-A22

For a fire in 757.0-A22, two “common” actions are performed by one AUO, eight Unit 2 actions are performed by three AUOs and five Unit 1 actions are performed by three AUOs for a total of seven AUOs. The staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1 and Unit 2 manual actions, should there be a fire in 757.0-A22.

8.3.30 Room 757.0-A23 (125V Vital Battery Board Room III)

8.3.30.1 Fire Prevention

The 125V Vital Battery Board Room III, 757.0-A23, is constructed of reinforced concrete. Doors, dampers, penetration seals and barriers (walls, floors, and ceiling) in 757.0-A23 are fire resistance rated for 3-hours. Room 757.0-A23 has a floor area of 329 ft² and a nominal ceiling height of 14-feet.

The combustible loading in the room results in a fire severity classification of low. The combustibles in 757.0-A23 consist of plastics associated with the electrical boards, panels, boxes, and lights and insulation on the cables in the trays. The combustible loading in the room results in a fire severity classification of low.

PART VII - DEVIATIONS AND EVALUATIONS

There are a number of assumed ignition sources in 757.0-A23 including 120V Vital Power boards, 125V Vital Battery boards, and a transformer. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.30.2 Detection, Control, and Extinguishment

The 125V Vital Battery Board Room III (757.0-A23), is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the nearby MCR to investigate the detector alarm. Portable extinguishers are available throughout the plant for extinguishing any small credible fire. If a larger fire occurs, the sprinkler system provided for the room is manually actuated. A standpipe and hose station system is also available in adjacent room 757.0-A24 for fire brigade use.

Even if the postulated fire were to start and not be extinguished, the 3-hour fire rating of the walls, floors and ceiling and doors, fire dampers and penetration seals would contain the fire and prevent it from propagating to adjacent rooms.

8.3.30.3 OMA 1022 – Operate Steam Generator Relief Valves to Control Secondary Pressure

The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-30 (SG 4 Power Relief Valve) to control secondary pressure. A fire that is contained within room 757.0-A23 potentially damages equipment (2-PSV-1-31C-A because of cable 2V4032A and upstream power supply failures) requiring implementation of this OMA. The operator must operate 2-ISIV-1-406E2 at the local N₂ Operating Station for 2-PCV-1-30 (2-L-1000). This OMA must be completed within 60 minutes and is performed in room 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1022 following a fire in this room is covered in the OMA 1022 bounding evaluation (Section 8.3.63).

8.3.30.4 OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure

The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-23 (SG 3 Power Relief Valve) to control secondary pressure. A fire that is contained within room 757.0-A23 potentially damages equipment (2-PSV-1-24B-A because of cable 2V7536A and upstream power supply failures and 0-MTR-32-60-A because of 2PL3786A and upstream power supply failures) requiring implementation of this OMA. The operator must operate 2-ISIV-1-407E2 at the local N₂ Operating Station for 2-PCV-1-23 (2-L-1000). This OMA must be completed within 60 minutes and is performed in room 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in the OMA 1023 bounding evaluation (Section 8.3.64).

PART VII - DEVIATIONS AND EVALUATIONS

8.3.30.5 Staffing Requirements for a Fire in Room 757.0-A23

For a fire in 757.0-A23, two “common” actions are performed by two AUOs, eight Unit 2 actions are performed by three AUOs and four Unit 1 actions are performed by three AUOs for a total of eight AUOs. The staffing of eight AUOs is sufficient to accomplish all of the Unit 1 and Unit 2 manual actions, should there be a fire in room 757.0-A23.

8.3.31 Room 757.0-A24 (6.9kV & 480V Shutdown Board Room B)

8.3.31.1 Fire Prevention

The 6.9kV & 480V Shutdown Board B Room (757.0-A24) is constructed reinforced concrete with a fire resistance rating of at least 2-hours. The openings through these barriers are protected with door, damper and penetration seals that are equivalent to the rating of the barrier.

The presence of intervening combustibles (insulation on cables in trays) is justified and documented in Section 2.4 of this Part. The non-rated steel equipment hatch in the ceiling of room 757.0-A24 is protected with a water curtain designed in accordance with NFPA 13, section 4-4.8.2.

The 6.9kV & 480V Shutdown Board B Room has a floor area of 6,134 ft² and a nominal ceiling height of 14 feet. The combustible loading of room 757.0-A24 results in a fire severity classification of Moderately Severe. The combustible material in the room consists of plastics associated with electrical boards, MCCs, switches, panels, boxes and lights, rubber hoses, other miscellaneous plastics and paper, as well as insulation on cables in trays. However, insulation on cable trays accounts for over 93% of the combustibles in this room. The assumed ignition sources are the Electrical Panels and Boards and Motor Control Centers.

NPG-SPP-18.4.7, “Control of Transient Combustibles” and NPG-SPP-18.4.8, “Control of Ignition Sources (Hot Work)” defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.31.2 Detection, Control, and Extinguishment

The 6.9kV & 480V Shutdown Board B Room is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the nearby MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. A larger fire activates the installed automatic sprinkler system provided for the room. This extinguishes or limits the magnitude of the fire until the fire brigade arrives. A standpipe and hose station system is also available in the room for fire brigade use. In addition, a water curtain is provided for the stairwell.

Even if the postulated fire were to start and not be extinguished, the 3-hour fire rating of the walls, floors and ceiling and doors, fire dampers and penetration seals would contain the fire and prevent it from propagating to adjacent rooms.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.31.3 OMA 1016 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 757.0-A24 could potentially damage control cables (2V4010B, 2V4011B, 2V4012B, and 2V4013B) to the Power Relief Solenoid Valve (2-PSV-1-6C-B) and a control cable (2PM1371) to the Power Relief Valve Modifier (2-PM-1-6) which prevents the ability to modulate the Power Relief Valve (2-PCV-1-5) to relieve pressure on #1 Steam Generator when needed. The fire safe shutdown requirement for a fire in 757.0-A24 is to have an air source for 2-PCV-1-5 within 60 minutes to maintain pressure control of the #1 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1001) in 757.0-A21.

The Feasibility and Reliability Evaluation for OMA 1016 following a fire in this room is covered in the OMA 1016 bounding evaluation (Section 8.3.62).

8.3.31.4 OMA 1024 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 757.0-A24 could potentially damage many control cables to the Control Air Compressor (0-MTR-32-86-B) and a control cable (2V7570B) to the Power Relief Solenoid Valve (2-PSV-1-13B-B) which prevents the ability to modulate the Power Relief Valve (2-PCV-1-12) to relieve pressure on #2 Steam Generator when needed. The fire safe shutdown requirement is to have an air source for 2-PCV-1-12 within 60 minutes for operation of the PCV and thereby maintain pressure control of the #2 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1001) located in 757-A21.

The Feasibility and Reliability Evaluation for OMA 1024 following a fire in this room is covered in the OMA 1024 bounding evaluation (Section 8.3.65).

8.3.31.5 Staffing Requirements for a Fire in Room 757.0-A24

For a fire in 757.0-A24, five Unit 2 actions are performed by three AUOs, three Unit 1 actions are performed by two AUOs, and one Unit 1 and two “common” actions are performed by one AUO for a total of six AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1 and Unit 2 manual actions, should there be a fire in room 757.0-A24.

8.3.32 Room 757.0-A26 (Auxiliary Control Instrument Room 1B)

8.3.32.1 Fire Prevention

The Auxiliary Control Instrument Room 1B (757.0-A26) is constructed of reinforced concrete. The walls, floor, ceiling, and penetration seals separating this room from other fire areas have a fire resistance rating of 2-hours or greater. The fire dampers and doors are rated for 3-hours. The room has a floor area of 114 ft² and a nominal ceiling height of 14-feet.

The combustible loading in 757.0-A26 results in a fire severity classification of Moderately Severe. The combustible material in the room consists of plastics associated with electrical panels, boxes, lights, Thermo-Lag and insulation on cables in trays. Insulation on cable trays

PART VII - DEVIATIONS AND EVALUATIONS

makes up for over 86% of the combustibles in this room. The only assumed ignition source in 757.0-A26 is panel 1-L-11B.

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.32.2 Detection, Control, and Extinguishment

The Auxiliary Control Instrument Room 1B is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the nearby MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire.

If a larger fire occurs, the installed automatic preaction sprinkler system provided for the room activates. A standpipe and hose station system is also available in rooms 757.0-A2 and 757.0-A24 for fire brigade use.

8.3.32.3 OMA 1024 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 757.0-A26 could potentially damage a control cable (1PV210B) to the Auxiliary Air Compressor B-B Cam Timer/Air Dryer Flow Control Valve 0-MTR-32-462-B which supports Auxiliary Air Compressor 0-MTR-32-86-B thereby preventing the ability to modulate valve 2-PCV-1-12 to relieve pressure on #2 Steam Generator when needed. The fire safe shutdown requirement for a fire in 757.0-A26 is to have an air source for 2-PCV-1-12 within 60 minutes to maintain pressure control of the #2 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1001) located in room 757-A21.

The Feasibility and Reliability Evaluation for OMA 1024 following a fire in this room is covered in a bounding evaluation (Section 8.3.65).

8.3.32.4 Staffing Requirements for a Fire in Room 757.0-A26

For a fire in 757.0-A26, six Unit 1 actions are performed by three AUOs and four Unit 2 actions are performed by two AUOs for a total of five AUOs. Therefore, a total of eight AUOs is more than sufficient to complete all of the OMAs for Unit 1 and Unit 2 should there be a fire in 757.0-A26.

8.3.33 Room 757.0-A27 (Auxiliary Control Instrument Room 2A)

8.3.33.1 Fire Prevention

The Auxiliary Control Instrument Room 2A (757.0-A27) is constructed of reinforced concrete with a fire resistance rating of at least 2 hours. The openings through these barriers are protected with door, damper, and penetration seals that are equivalent to the rating of the barrier. The room has a floor area of 114 ft² and a nominal ceiling height of 14-feet.

PART VII - DEVIATIONS AND EVALUATIONS

The combustible loading in 757.0-A27 results in a fire severity classification of Moderate. The combustible material in the room consists of plastics associated with an electrical panel, lighting, and insulation on cables in trays. The only assumed ignition source in this room is a control panel (PNL 2-L-11A).

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.33.2 Detection, Control, and Extinguishment

The Auxiliary Control Instrument Room 2A is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the nearby MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. A larger fire activates the installed automatic sprinkler system provided for the room. This extinguishes or limits the magnitude of the fire until the fire brigade arrives. A standpipe and hose station system is also available in the nearby rooms (757.0-A2 and 757.0-A24) for fire brigade use.

8.3.33.3 OMA 1022 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 757.0-A27 could potentially damage control cables (2V4033A and 2V4034A) to the Power Relief Solenoid Valve (2-PSV-1-31C-A) which prevents the ability to relieve pressure on #4 Steam Generator when needed. A fire in this room could also damage four cables (B12F, B65F, B67F and 2PL4904S) resulting in the loss of the 125V Vital Battery Board III (0-BD-236-3-F). The fire safe shutdown requirement for this operator action is to have an air source for 2-PCV-1-30 within 60 minutes to maintain pressure control of the #4 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an Operator Manual Action (OMA) at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1022 following a fire in this room is covered in a bounding evaluation (Section 8.3.63).

8.3.33.4 OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 757.0-A27 could potentially damage control cables (2V7537A or 2V7539A) to the Power Relief Solenoid Valve (2-PSV-1-24B-A), a control cable (2PM1621) to the Pressure Modifier (2-PM-1-24), a control cable (2PM1619) to the Pressure Indicator Controller (2-PIC-24A) or a control cable (2PL3786A) to the Control Air Compressor A-A (0-MTR-32-60) which prevents the ability to relieve pressure on #3 Steam Generator when needed. The fire safe shutdown requirement for this operator action is to have an air source for 2-PCV-1-23 within 60 minutes to maintain pressure control of the #3 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in a bounding evaluation (Section 8.3.64).

PART VII - DEVIATIONS AND EVALUATIONS

8.3.33.5 Staffing Requirements for a Fire in Room 757.0-A27

For a fire in 757.0-A27, eight Unit 2 actions are performed by three AUOs, one Unit 1 and one "common" action is performed by one AUO, one common action is performed by one AUO, and three Unit 1 actions are performed by two AUOs for a total of seven AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1 and Unit 2 manual actions, should there be a fire in room 757.0-A27.

8.3.34 Room 757.0-A28 (Auxiliary Control Instrument Room 2B)

8.3.34.1 Fire Prevention

The Auxiliary Control Instrument Room 2B, 757.0-A28, is constructed of reinforced concrete. The walls, floors, ceiling and penetration seals have a fire resistance rating of 2-hours or greater. The doors and dampers are fire resistance rated for 3-hours. The room has a floor area of 114 ft² and a nominal ceiling height of 14-feet.

The combustible loading in room 757.0-A28 results in a fire severity classification of moderately severe. The combustible material in the room consists of plastics associated with an electrical panels and boxes, lighting, and insulation on cables in trays. Insulation on cable in trays makes up approximately 70% of the combustibles in this room. The only assumed ignition source in this room is a control panel, 2-L-11B.

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.34.2 Detection, Control, and Extinguishment

The Auxiliary Control Instrument Room 2B is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the nearby MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. A larger fire activates the installed automatic sprinkler system provided for the room. This extinguishes or limits the magnitude of the fire until the fire brigade arrives. A standpipe and hose station system is also available in the nearby rooms 757.0-A2 and 757.0-A24 for fire brigade use.

8.3.34.3 OMA 1016 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 757.0-A28 could potentially damage control cables (2V4011B and 2V4012B) to the Power Relief Solenoid Valve, 2-PSV-1-6C-B, which prevents the ability to relieve pressure via Power Relief Valve 2-PCV-1-5 on #1 Steam Generator when needed.

The fire safe shutdown requirement for this operator action is to have an air source for 2-PCV-1-5 within 60 minutes to maintain pressure control of the #1 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1001) located in room 757.0-A21.

PART VII - DEVIATIONS AND EVALUATIONS

The Feasibility and Reliability Evaluation for OMA 1016 following a fire in this room is covered in a bounding evaluation (Section 8.3.62).

8.3.34.4 OMA 1024 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 757.0-A28 could potentially damage control cables (2V7568B and 2V7570B) to the Power Relief Solenoid Valve (2-PSV-1-13B-B), a control cable (2PM1499) to the Power Relief Valve Pressure Indicator Controller (2-PIC-1-13A), and a control cable (2PM1501) to the Pressure Modifier (2-PM-1-13) which prevents the ability to modulate valve 2-PCV-1-12 to relieve pressure on #2 Steam Generator when needed. The fire safe shutdown requirement for a fire in 757.0-A28 is to have an air source to 2-PCV-1-12 within 60 minutes to maintain pressure control of the #2 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1001) located in room 757-A21.

The Feasibility and Reliability Evaluation for OMA 1024 following a fire in this room is covered in a bounding evaluation (Section 8.3.65).

8.3.34.5 Staffing Requirements for a Fire in Room 757.0-A28

For a fire in 757.0-A28, four Unit 1 actions are performed by two AUOs and six Unit 2 actions are performed by three AUOs, for a total of five AUOs. Therefore, a total of eight AUOs is more than sufficient to complete all of the OMAs for Unit 1 and Unit 2, should there be a fire in 757.0-A28.

8.3.35 Room 772.0-A1 (480V Board Room 1A)

8.3.35.1 Fire Prevention

The 480V Board Room 1A (772.0-A1) is constructed of reinforced concrete. The walls and floors have a fire resistance rating of 2 hours. Openings in these barriers are provided with fire doors, dampers and penetration seals that are at least equivalent to the rating of the barriers. Room 772.0-A1 has a floor area of 2,202 ft² and a nominal ceiling height of 13 feet. The combustibles in 772.0-A1 consist of plastics associated with the electrical panels, boards, and lights; oil in a hoist, and insulation on cables in trays. Insulation on cable trays accounts for over 90% of the combustibles in this room. The combustible loading in the room results in a fire severity classification of moderately severe.

The room contains intervening combustibles in the form of insulation on cables in trays and Electric Raceway Fire Barrier Systems (ERFBS). The justification for using an enhanced automatic preaction sprinkler system to compensate for these intervening combustibles is documented in Section 2.4 of this Part. The floor has an equipment hatch with a non-rated cover that is protected by a water curtain, as justified and documented in 2.6 of this Part. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.35.2 Detection, Control, and Extinguishment

The 480V Board Room 1A (772.0-A1) is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the MCR to investigate the detector alarm. Portable extinguishers are available throughout the plant for extinguishing any small credible fire. If a larger fire occurs, the automatic sprinkler system provided for the room activates. A standpipe and hose station system is also available for fire brigade use in 772.0-A7.

8.3.35.3 OMA 1022 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 772.0-A1 potentially damages cable (2V4035A) to the Power Relief Solenoid Valve (2-PSV-1-31C-A). Damage to this cable prevents the ability to operate the pressure control valve (PCV) to maintain the pressure in #4 Steam Generator when needed. The fire safe shutdown requirement is to have an air source for 2-PCV-1-30 within 60 minutes for operation of the PCV and thereby maintain pressure control of the #4 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1022 following a fire in this room is covered in the OMA 1022 bounding evaluation (Section 8.3.63).

8.3.35.4 OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 772.0-A1 potentially damages a cable (2V7539A) to Power Relief Solenoid Valve (2-PSV-1-24B-A) or damages cables or equipment supporting the Control Air Compressor A (0-MTR-32-60-A). Damage to these components prevents the ability to modulate the pressure control valve to maintain the pressure in #3 Steam Generator when needed. The fire safe shutdown requirement is to have an air source for 2-PCV-1-23 within 60 minutes for operation of the PCV and thereby maintain pressure control of the #3 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in the OMA 1023 bounding evaluation (Section 8.3.64).

8.3.35.5 Staffing Requirements for a Fire in Room 772.0-A1

For a fire in 772.0-A1, four Unit 2 actions are performed by two AUOs, one Unit 1 action, one Unit 2 action, and two "common" actions are performed by one AUO, one "common" action is performed by one AUO, and 14 Unit 1 actions are performed by three AUOs for a total of seven AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1 and Unit 2 manual actions, should there be a fire in room 772.0-A1.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.36 Room 772.0-A2 East (480V Board Room 1B East)

8.3.36.1 Fire Prevention

The 480V Board Room 1-B, 772.0-A2 East, a subdivision of 772.0-A2 is constructed of reinforced concrete. Walls, floor, ceiling, and penetration seals in 772.0-A2 are fire resistance rated for 2 hours or greater. Doors and dampers are fire resistance rated for 3 hours except for one door. This door is not a qualified fire door; however, the door has been evaluated as equivalent for use as a fire door. Room 772.0-A2 has a floor area of 2,171 ft² and a nominal ceiling height of 13-feet. The room contains intervening combustibles in the form of insulation on cables in trays and ERFBS. The justification for using an enhanced suppression system to compensate for the intervening combustibles is documented in Section 2.4 of this Part.

The combustible loading in the room results in a fire severity classification of severe. The combustibles in 772.0-A2 consist of plastics associated with the electrical boards, panels, boxes and lights; HVAC ducts insulation; and insulation on the cables in trays. Over 90% of the combustibles in this room are insulation on cables in trays.

There are a number of assumed ignition sources in 772.0-A2 including inverters, multiplexer, battery chargers, and motor control centers. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.36.2 Detection, Control, and Extinguishment

The 480V Board Room is provided with ionization smoke detectors throughout that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the nearby MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. If a larger fire occurs, the installed automatic preaction sprinkler system provided for the room activates. A preaction sprinkler system is provided throughout except for the portion of the room (A6-A8/Q-R) that contains one set of vital battery inverters and charger. The portion of Room 772.0-A2 without sprinklers has an area of 315 ft². The in situ combustible load in the area without sprinkler protection consists of the insulation on cables in a single vertical tray and the insulation on the internal wiring of the inverters, chargers, and transfer switches. In addition, there is one conduit that is wrapped with Thermo-Lag 770. Justification for partial suppression in this room is documented in Section 3.1.8 of this Part. A standpipe and hose station system is also available from room 772.0-A7 for fire brigade use.

If a fire starts and is not extinguished, the fire barriers contain the fire and prevent propagation to adjacent rooms. Therefore, a fire in this room does not present an exposure hazard to the access paths to the manual actions performed in 757.0-A24 and 757.0-A21.

8.3.36.3 OMA 1016 – Operate Steam Generator Relief Valves to Control Secondary Pressure

The fire safe shutdown requirement of this OMA is to open/close SG 1 Power Relief Valve (2-PCV-1-5) to control secondary pressure. A fire that is contained within room 772.0-A2 East could potentially damage cables 2V4010B and 2V4011B for the SG 1 Power Relief Solenoid

PART VII - DEVIATIONS AND EVALUATIONS

Valve (2-PSV-1-6C-B) and result in the implementation of this OMA. The operator must operate valve 2-ISIV-1-408E2 at the local station 2-L-1001 (N₂) to open/close 2-PCV-1-5 if MDAFW Pump A or TDAFW Pump is used. This OMA must be completed within 60 minutes and is performed in room 757.0-A21.

The Feasibility and Reliability Evaluation for OMA 1016 following a fire in this room is covered in the OMA 1016 bounding evaluation (Section 8.3.62).

8.3.36.4 OMA 1024 – Operate Steam Generator Relief Valves to Control Secondary Pressure

The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-12 (SG 2 Power Relief Valve) to control secondary pressure. A fire that is contained within room 772.0-A2 East could potentially damage various cables for the C & A Building Vent Board 2B1-B (2-MCC-214-B1-B) and the Essential Raw Cooling Water Supply Header 2B (ERCW-HDR-2B) which fails the Control Air Compressor B-B (0-MTR-32-86-B) requiring implementation of this OMA. The operator must operate valve 2-ISIV-1-405E2 at local station 2-L-1001 (N₂) to open/close 2-PCV-1-12 if MDAFW Pump B or TDAFW Pump is used. This OMA must be completed within 60 minutes and is performed in room 757.0-A21.

The Feasibility and Reliability Evaluation for OMA 1024 following a fire in this room is covered in the OMA 1024 bounding evaluation (Section 8.3.65).

8.3.36.5 Staffing Requirements for a Fire in Room 772.0-A2 East

For a fire in 772.0-A2 East, five Unit 2 actions are performed by three AUOs, fourteen Unit 1 actions are performed by three AUOs, and one Unit 1 action along with one "common" action is performed by one AUO for a total of seven AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1 and Unit 2 manual actions, should there be a fire in 772.0-A2 East.

8.3.37 Room 772.0-A2 West (480V Board Room 1B West)

8.3.37.1 Fire Prevention

The 480V Board Room 1-B, 772.0-A2 West, a subdivision of 772.0-A2 is constructed of reinforced concrete. Walls, floor, ceiling, and penetration seals in 772.0-A2 are fire resistance rated for 2 hours or greater. Doors and dampers are fire resistance rated for 3 hours except for one door. This door is not a qualified fire door; however, the door has been evaluated as equivalent for use as a fire door. Room 772.0-A2 has a floor area of 2,171 ft² and a nominal ceiling height of 13-feet. The room contains intervening combustibles in the form of insulation on cables in trays and ERFBS. The justification for using an enhanced suppression system to compensate for the intervening combustibles is documented in Section 2.4 of this Part.

The combustible loading in the room results in a fire severity classification of severe. The combustibles in 772.0-A2 consist of plastics associated with the electrical boards, panels, boxes and lights; HVAC ducts insulation; and insulation on the cables in the trays. Over 90% of the combustibles in this room come from insulation on cable trays.

There are a number of assumed ignition sources in 772.0-A2 including inverters, multiplexer, battery chargers, and motor control centers. NPG-SPP-18.4.7, "Control of Transient

PART VII - DEVIATIONS AND EVALUATIONS

Combustibles” and NPG-SPP-18.4.8, “Control of Ignition Sources (Hot Work)” defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.37.2 Detection, Control, and Extinguishment

The 480V Board Room is provided with ionization smoke detectors throughout that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the nearby MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. If a larger fire occurs, the installed automatic preaction sprinkler system provided for the room activates. A preaction sprinkler system is provided throughout except for the portion of the room that contains one set of vital battery inverters and charger. The portion of Room 772.0-A2 without sprinklers has an area of 315 ft². The in situ combustible load in the area without sprinkler protection consists of the insulation on cables in a single vertical tray and the insulation on the internal wiring of the inverters, chargers, and transfer switches. A standpipe and hose station system is also available from room 772.0-A7 for fire brigade use.

If a fire starts and is not extinguished, the room’s fire barriers contain the fire and prevent propagation to adjacent rooms. Therefore, a fire in this room does not present an exposure hazard to the access path to the manual actions performed in room 757.0-A24.

8.3.37.3 OMA 1022 – Operate Steam Generator Relief Valves to Control Secondary Pressure

The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-30 (SG 4 Power Relief Valve) to control secondary pressure. A fire that is contained within room 772.0-A2 West could potentially damage various cables for the 120V AC Vital Power Board 2-I (2-BD-235-1-D). The board failure will cause failure of the Pressure Indicator Controller (2-PIC-1-31A) for SG 4 Pressure Relief Valve and will result in the implementation of this OMA. The operator must operate valve 2-ISIV-1-406E2 at the local station 2-L-1000 (N₂) to open/close 2-PCV-1-30 if MDAFW Pump B or TDAFW Pump is used. This OMA must be completed within 60 minutes and is performed in room 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1022 following a fire in this room is covered in the OMA 1022 bounding evaluation (Section 8.3.63).

8.3.37.4 OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure

The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-23 (SG 3 Power Relief Valve) to control secondary pressure. A fire that is contained within room 772.0-A2 West could potentially damage various cables for the 120V AC Vital Power Board 2-I (2-BD-235-1-D). The board failure will cause failure of the Pressure Indicator Controller (2-PIC-1-24A) for SG 3 Power Relief Valve and result in the implementation of this OMA. The operator must operate valve 2-ISIV-1-407E2 at the local station 2-L-1000 (N₂) to open/close 2-PCV-1-23 if MDAFW Pump A or TDAFW Pump is used. This OMA must be completed within 60 minutes and is performed in room 757.0-A24.

PART VII - DEVIATIONS AND EVALUATIONS

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in the OMA 1023 bounding evaluation (Section 8.3.64).

8.3.37.5 Staffing Requirements for a Fire in Room 772.0-A2 West

For a fire in 772.0-A2 West, nineteen Unit 1 actions are performed by 4 AUOs, four Unit 2 actions are performed by two AUOs and one Unit 1 action, one Unit 2 action along with two “common” actions are performed by one AUO for a total of 7 AUOs. Therefore, a total of eight AUOs is more than sufficient to complete all of the OMAs for Unit 1 and Unit 2 should there be a fire in 772.0-A2 (West).

8.3.38 Room 772.0-A4 (125V Vital Battery Room I)

8.3.38.1 Fire Prevention

The 125V Vital Battery Room I (772.0-A4) is constructed of reinforced concrete. The walls, floor, ceiling and penetration seals have a fire resistance rating of 3-hours. The 125V Vital Battery Room I has a floor area of 344 ft² and a ceiling height of 13-feet. The combustible loading of room 772.0-A4 consists of plastics associated with electrical panels, boxes and battery cases. Adequate ventilation is provided to preclude explosive concentrations of hydrogen. The combustible loading in the room results in a fire severity classification of low. Over 85% of the combustibles in this room are due to the battery cases.

The potential ignition sources in this room consist of the batteries, two control panels and two junction boxes. The panels and the junction boxes are relatively small and do not constitute credible ignition sources (circuits are properly protected and insignificant quantity of associated combustibles) to create and sustain a large fire. NPG-SPP-18.4.7, “Control of Transient Combustibles” and NPG-SPP-18.4.8, “Control of Ignition Sources (Hot Work)” defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.38.2 Detection, Control, and Extinguishment

The 125V Vital Battery Room I is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. If a larger fire occurs, the installed manually actuated sprinkler system provided for the room is activated (valve located on wall in on elevation 757) by the fire brigade. A standpipe and hose station system is also available from room 772.0-A7 for fire brigade use.

Even if the postulated fire starts and is not extinguished, the 3-hour fire rating of the room’s fire barriers contain the fire and do not allow it to present an exposure hazard to adjacent rooms.

8.3.38.3 OMA 1022 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in the 125V Vital Battery Room I potentially damages cables (2PV824D, 2B441D, B56D, B55D, and B57D needed for 2-BD-235-1-D, which supports controller 2-PIC-1-31A) which prevents the ability to modulate the power relief valve (2-PCV-1-30) to relieve pressure on #4 Steam Generator when needed. The fire safe shutdown requirement is to have an air source

PART VII - DEVIATIONS AND EVALUATIONS

for 2-PCV-1-30 within 60 minutes to maintain pressure control of the #4 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24. The Feasibility and Reliability Evaluation for OMA 1022 following a fire in this room is covered in the OMA 1022 bounding evaluation (Section 8.3.63).

8.3.38.4 OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in the 125V Vital Battery Room I potentially damages three control cables (B56D, B55D, and B57D), cables 2PV824D and 2B441D supporting the Control Air Compressor A-A (0-MTR-32-60-A), or equipment supporting the #3 Steam Generator Power Relief Valve Modifier (2-PM-1-24) which prevents the ability to modulate the power relief valve (2-PCV-1-23) to relieve pressure on #3 Steam Generator, when needed. The fire safe shutdown requirement is to have an air source for 2-PCV-1-23 within 60 minutes to maintain pressure control of the #3 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in the OMA 1023 bounding evaluation (Section 8.3.64).

8.3.38.5 Staffing Requirements for a Fire in Room 772.0-A4

For a fire in 772.0-A4, four Unit 2 actions are performed by two AUOs, eight Unit 1 actions are performed by three AUOs, one Unit 2 action along with a “common” action is performed by one AUO and one “common” action is performed by one AUO for a total of seven AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1 and Unit 2 manual actions, should there be a fire in room 772.0-A4.

8.3.39 Room 772.0-A5 (480V Transformer Room 1B)

8.3.39.1 Fire Prevention

The 480V Transformer Room 1B (772.0-A5) is constructed of reinforced concrete. The walls, floor, and penetration seals have a fire resistance rating of 2 or 3 hours. The door in this room has fire resistance rating of 3 hours. The 480V Transformer Room 1B has a floor area of 1762 ft² and a nominal ceiling height of 13-feet. The combustible loading of room 772.0-A5 results in a fire severity classification of Moderate. The combustible material in the room consists of transformers, plastics associated with panels, cable trays, protective covers, and ERFBS. Approximately 94% of the combustibles in this room are due to the insulation on cables in trays. The assumed ignition sources are the three transformers in room 772.0-A5.

NPG-SPP-18.4.7, “Control of Transient Combustibles” and NPG-SPP-18.4.8, “Control of Ignition Sources (Hot Work)” defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room. The room contains intervening combustibles in the form of insulation on the cables in trays and ERFBS. The justification for using an enhanced automatic preaction sprinkler system to compensate for these intervening combustibles is documented in Section 2.4 of this Part.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.39.2 Detection, Control, and Extinguishment

The 480V Transformer Room 1-B, elevation 772.0' is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). The room is also provided with an automatic suppression sprinkler system. Any fire that starts is quickly detected and personnel are dispatched from the MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. A larger fire activates the installed automatic preaction sprinkler system provided for the room. This extinguishes or limits the magnitude of the fire until the fire brigade arrives. A standpipe and hose station system is available in room 772.0-A7 for fire brigade use.

Even if the postulated fire starts and is not extinguished, the minimum 2-hour fire rating of the room's walls, floors and door, and penetration seals contain the fire and not allow it to propagate to adjacent rooms. Therefore, a fire in this room does not present an exposure hazard to the access paths to the manual action located in 757.0-A21, the 480V Shutdown Board Room 2A.

8.3.39.3 OMA 1016 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in the 480V Transformer Room 1B potentially damages cables 2V4010B, 2V4011B which support the #1 Steam Generator Power Relief Solenoid Valve (2-PSV-1-6C-B). The fire safe shutdown requirement is for the AUO to operate 2-ISIV-1-408E2 at the local N₂ station 2-L-1001 in order to control secondary pressure if MDAFW Pump A, or TDAFW Pump is used. This OMA must be completed within 60 minutes and is performed in room 757.0-A21. This action has been validated and completed in 12 minutes and 6 seconds.

The Feasibility and Reliability Evaluation for OMA 1016 following a fire in this room is covered in a bounding evaluation (Section 8.3.62).

8.3.39.4 Staffing Requirements for a Fire in Room 772.0-A5

For a fire in room 772.0-A5, 1 "common" action is performed by one AUO, 16 Unit 1 actions are performed by four AUOs and four Unit 2 actions are performed by two AUOs for a total of seven AUOs. Therefore, a total of eight AUOs is more than sufficient to complete all of the OMAs for Unit 1 and Unit 2, should there be a fire in 772.0-A5.

8.3.40 Room 772.0-A6 (480V Transformer Room 1A)

8.3.40.1 Fire Prevention

The 480V Transformer Room 1A (772.0-A6) is constructed of reinforced concrete with a fire resistance rating of 2 hours. There are two doors that are fire rated for 3 hours and penetration seals are equivalent to or greater than the barrier rating. The room has a floor area of 1,852 ft² and a nominal ceiling height of 13 feet.

The room contains intervening combustibles in the form of insulation on the cables in the trays and ERFBS. The justification for using an enhanced automatic preaction sprinkler system to compensate for these intervening combustibles is documented in Section 2.4 of this Part.

The combustible loading in the room results in a fire severity classification of moderately severe. The combustibles in 772.0-A6 consist of transformer insulating oil and insulation on cables in

PART VII - DEVIATIONS AND EVALUATIONS

cable trays. Insulation on cables in trays accounts for over 70% of the combustibles in the room. The assumed ignition sources in this room are electrical boards and transformers. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.40.2 Detection, Control, and Extinguishment

The 480V Transformer Room 1A (772.0-A6) is provided with ionization smoke detection that alarms in the MCR. The room is also provided with an installed automatic sprinkler system. Portable extinguishers are available throughout the plant for extinguishing any small credible fire. If a larger fire occurs, the automatic sprinklers located in the room activate. A standpipe and hose station system is available in the adjacent room (772.0-A7) for fire brigade use. With fire detection, an enhanced automatic suppression system, and fire resistant barriers, a fire in this area is contained and does not present an exposure hazard to adjacent rooms.

8.3.40.3 OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 772.0-A6 could result in the loss of the transformer that provides power to the Control Air Compressor Motor A (0-MTR-32-60-A) or damage a control cable associated with the Power Operated Relief Valve (2-PCV-1-23). Either of these results in the use of this OMA to modulate 2-PCV-1-23 to control pressure on the Steam Generator #3.

The fire safe shutdown requirement is to have an air source for 2-PCV-1-23 within 60 minutes for operation of 2-PCV-1-23, thereby establishing pressure control of the #3 Steam Generator. Emergency air is provided for operation of the 2-PCV-1-23, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24. This action has been validated and completed in 12 minutes and 6 seconds.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in a bounding evaluation (Section 8.3.64).

8.3.40.4 Staffing Requirements for a Fire in Room 772.0-A6

For a fire in 772.0-A6, one Unit 1 action and one "common" action are performed by one AUO, four Unit 2 actions are performed by two AUOs and four Unit 1 actions are performed by two AUOs for a total of five AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1 and Unit 2 manual actions, should there be a fire in room 772.0-A6.

8.3.41 Room 772.0-A8 (Fifth Vital Battery and Board Room)

8.3.41.1 Fire Prevention

The Fifth Vital Battery and Board Room (772.0-A8) is constructed of reinforced concrete with a minimum fire rating of 2 hours for the walls and the floor. There is one 3 hour fire rated door in the room that leads to 772.0-A1 and one 3 hour fire damper. Room 772.0-A8 has a floor area of 480 ft² and a nominal ceiling height of 13-feet.

PART VII - DEVIATIONS AND EVALUATIONS

The combustible loading of the Fifth Vital Battery and Board Room results in a fire severity classification of low. The combustibles in 772.0-A8 consist of lube oil for motors, polycarbonate in batteries, PVC cell covers, polyethylene of the rack rail insulation and plastic associated junction boxes, electrical jumper cables and the vital battery board. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.41.2 Detection, Control, and Extinguishment

The Fifth Vital Battery and Board Room (772.0-A8) is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Room 772.0-A8 is also provided with an installed automatic preaction sprinkler system.

Any fire that starts is quickly detected and personnel are dispatched from the MCR to investigate the detector alarm. Portable extinguishers are available throughout the plant for extinguishing any small credible fire. A larger fire activates the installed automatic preaction sprinkler system provided for the room. A standpipe and hose station system is also available for fire brigade use in adjacent room 772.0-A7. With fire detection, an automatic suppression system, and fire resistant barriers, a fire in this area is contained and does not present a hazard to adjacent rooms.

8.3.41.3 OMA 1016 – Operate Steam Generator Relief Valves to Control Secondary Pressure

For a fire in the Fifth Vital Battery and Board Room (772.0-A8), when vital battery is in service for replacement of Channel IV, the potential for damage to cables B202S, B80S, B81S or battery 0-BAT-236-5-S failing the 125V Vital Battery Board IV (0-BD-236-4-G) which prevents the ability to modulate the power relief valve (2-PCV-1-5) to relieve pressure on #1 Steam Generator, when needed. The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-5 (SG 1 Power Relief Valve) to control secondary pressure. The operator must align N2 supply and operate 2-ISIV-1-408E2 at the local station 2-L-1001 to open/close 2-PCV-1-5. This OMA must be completed within 60 minutes and is performed in room 757.0 A21.

The Feasibility and Reliability Evaluation for OMA 1016 following a fire in this room is covered in a bounding evaluation (Section 8.3.62).

8.3.41.4 OMA 1022 – Operate Steam Generator Relief Valves to Control Secondary Pressure

For a fire in the Fifth Vital Battery and Board Room (772.0-A8), when vital battery is in service for replacement of Channels I or III the potential for damage to cables B201S, B80S, B81S or battery 0-BAT-236-5-S failing the 125V Vital Battery Board I or III (0-BD-236-1-D or 0-BD-236-3-F) can prevent the ability to modulate the power relief valve (2-PCV-1-30) to relieve pressure on #4 Steam Generator, when needed. The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-30 (SG 4 Power Relief Valve) to control secondary pressure. The operator must align N2 supply and operate 2-ISIV-1-406E2 on 2-L-1000 at the local station to open/close 2-PCV-1-30. This OMA must be completed within 60 minutes and is performed in room 757.0-A24.

PART VII - DEVIATIONS AND EVALUATIONS

The Feasibility and Reliability Evaluation for OMA 1022 following a fire in this room is covered in a bounding evaluation (Section 8.3.63).

8.3.41.5 OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure

For a fire in the Fifth Vital Battery and Board Room (772.0-A8), when vital battery is in service for replacement of Channels I or III the potential for damage to cables B201S, B80S, B81S or battery 0-BAT-236-5-S failing the 125V Vital Battery Board I or III (0-BD-236-1-D or 0-BD-236-3-F) can prevent the ability to modulate the power relief valve (2-PCV-1-23) to relieve pressure on #3 Steam Generator, when needed. The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-23 (SG 3 Power Relief Valve) to control secondary pressure. The operator must align N2 supply and operate 2-ISIV-1-407E2 on 2-L-1000 at the local station to open/close 2-PCV-1-23. This OMA must be completed within 60 minutes and is performed in room 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in a bounding evaluation (Section 8.3.64).

8.3.41.6 OMA 1024 – Operate Steam Generator Relief Valves to Control Secondary Pressure

For a fire in the Fifth Vital Battery and Board Room (772.0-A8), when vital battery is in service for replacement of Channel IV, the potential for damage to cables B202S, B80S, B81S or battery 0-BAT-236-5-S failing the 125V Vital Battery Board IV (0-BD-236-4-G) can prevent the ability to modulate the power relief valve (2-PCV-1-12) to relieve pressure on #2 Steam Generator, when needed. The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-12 (SG 2 Power Relief Valve) to control secondary pressure. The operator must align N2 supply and operate 2-ISIV-1-405E2 on 2-L-1001 at the local station to open/close 2-PCV-1-12. This OMA must be completed within 60 minutes and is performed in room 757.0-A21.

The Feasibility and Reliability Evaluation for OMA 1024 following a fire in this room is covered in a bounding evaluation (Section 8.3.65).

8.3.41.7 Staffing Requirements for a Fire in Room 772.0-A8

There are no manual actions for safe shutdown for a fire in 772.0-A8, when the 5th vital battery is not in service as a replacement for Channels I, II, III, or IV, then; three Unit 1 actions are performed by two AUOs and three Unit 2 actions are performed by two AUOs for a total four AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1 and Unit 2 manual actions.

For a fire in 772.0-A8, if 5th vital battery is in service as a replacement for Channel I, then; four Unit 2 actions are performed by two AUOs, eight Unit 1 actions are performed by three AUOs, one Unit 2 action along with a “common” action is performed by one AUO and one “common” action is performed by one AUO for a total of seven AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1 and Unit 2 manual actions.

There are no manual actions for safe shutdown for a fire in 772.0-A8, if 5th vital battery is in service as a replacement for Channel II, then; one “common” action is performed by one AUO, three Unit 2 actions are performed by one AUO and six actions are performed by three AUOs

PART VII - DEVIATIONS AND EVALUATIONS

for a total of five AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1 and Unit 2 manual actions.

For a fire in 772.0-A8, if 5th vital battery is in service as a replacement for Channel III, then; three “common” actions are performed by two AUOs, eight Unit 2 actions are performed by three AUOs and three Unit 1 actions are performed by two AUOs for a total of seven AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1 and Unit 2 manual actions.

For a fire in 772.0-A8, if 5th vital battery is in service as a replacement for Channel IV, two “common” actions are performed by one AUO, seven Unit 2 actions are performed by three AUOs and three Unit 1 actions are performed by two AUOs for a total of six AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1 and Unit 2 manual actions.

8.3.42 Room 772.0-A9 (HEPA Filter Plenum Room)

8.3.42.1 Fire Prevention

The HEPA Filter Plenum Room (772.0-A9) is constructed of reinforced concrete with a minimum fire rating of 2 hours for the walls and the floor except for A11 wall which is not assigned a fire rating. There are two 3 hour fire rated doors in the room that lead to 772.0-A10 and no dampers. Room 772.0-A9 has a floor area of 480 ft² and a nominal ceiling height of 13-feet.

The combustible loading of the HEPA Filter Plenum Room results in a fire severity classification of low. The combustibles in 772.0-A9 consist of plastic associated with the lights and insulation on cables in the trays. Insulation on cables in trays accounts for over 99% of the combustibles in this room. There are no credible ignition sources in room 772.0-A9. NPG-SPP-18.4.7, “Control of Transient Combustibles” and NPG-SPP-18.4.8, “Control of Ignition Sources (Hot Work)” defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.42.2 Detection, Control, and Extinguishment

The HEPA Filter Plenum Room (772.0-A9) is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Room 772.0-A9 is also provided with an installed automatic sprinkler system.

Any fire that starts is quickly detected and personnel are dispatched from the MCR to investigate the detector alarm. Portable extinguishers are available throughout the plant for extinguishing any small credible fire. A larger fire activates the installed automatic sprinkler system provided for the room. A standpipe and hose station system is also available for fire brigade use in adjacent room 772.0-A10. With fire detection, an automatic suppression system, and fire resistant barriers, a fire in this area is contained and does not present a hazard to adjacent rooms.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.42.3 OMA 1022 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 772.0-A9 was assumed to spread to another room (757.0-A13) and damage equipment or control cables for the Auxiliary and Control Air Header B (0-MTR-32-86-B) which prevents the ability to modulate the Power Relief Valve (2-PCV-1-30) to relieve pressure on #4 Steam Generator when needed. The fire safe shutdown requirement for a fire in 772.0-A9 is to have an air source for 2-PCV-1-30 within 60 minutes to maintain pressure control of the #4 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

However, due to the low combustible loading and lack of credible ignition sources in the HEPA Filter Plenum Room (as indicated by the combustible loading calculation and ignition source walkdown documentation) there is no credible fire originating in room 772.0-A9 that could result in the implementation of this manual action.

The Feasibility and Reliability Evaluation for OMA 1022 following a fire in this room is covered in a bounding evaluation (Section 8.3.63).

8.3.42.4 OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 772.0-A9 is assumed to spread to another room (757.0-A13) and damage equipment or control cable for the Auxiliary and Control Air Header A (0-MTR-32-60-A) which prevents the ability to modulate the Power Relief Valve (2-PCV-1-23) to relieve pressure on the #3 Steam Generator when needed. The fire safe shutdown requirement for a fire in 772.0-A9 is to have an air source for 2-PCV-1-23 within 60 minutes to maintain pressure control of the #3 Steam Generator. Emergency air is provided for operation of 2-PCV-1-23, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

However, due to the low combustible loading and lack of credible ignition sources in the HEPA Filter Plenum Room (as indicated by the combustible loading calculation and ignition source walkdown documentation) there is no credible fire originating in 772.0-A9 that could result in the need for this manual action.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in a bounding evaluation (Section 8.3.64).

8.3.42.5 Staffing Requirements for a Fire in Room 772.0-A9

For a fire in 772.0-A9, one Unit 1 action and one “common” action are performed by one AUO, four Unit 1 actions are performed by two AUOs and five Unit 2 actions are performed by three AUOs for a total of six AUOs. Therefore, a total of eight AUOs is more than sufficient to complete all of the OMAs for Unit 1 and Unit 2, should there be a fire in 772.0-A9.

8.3.43 Room 772.0-A10 (Mechanical Equipment Room)

8.3.43.1 Fire Prevention

Mechanical Equipment Room (772.0-A10) is constructed of reinforced concrete that has a minimum fire resistance rating of 2-hours. There are three fire doors in the room which are

PART VII - DEVIATIONS AND EVALUATIONS

rated for 3-hours. The fire dampers have a rating of 3-hours. Room 772.0-A10 has a floor area of 686 ft² and a nominal ceiling height of 13 feet. The combustibles in 772.0-A10 consist of lube oil in the air cooler equipment, plastic associated with lights, and insulation on pipes and cables in trays. Insulation on cable trays accounts for over 99% of the combustibles in this room. The combustible loading in the room results in a fire severity classification of Moderately Severe.

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.43.2 Detection, Control, and Extinguishment

Mechanical Equipment Room (772.0-A10) is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the MCR to investigate the detector alarm. Portable extinguishers are available throughout the plant for extinguishing any small credible fire. If a larger fire occurs, the automatic sprinkler system provided for the room activates. A standpipe and hose station system is also available in the room for fire brigade use.

8.3.43.3 OMA 1022 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 772.0-A10 could potentially damage the control cable to the #4 Steam Generator Power Relief Solenoid Valve (2-PSV-1-31C-A, 2V4035A). Damage to cable 2V4035A prevents the ability to modulate the Power Relief Valve (2-PCV-1-30) to relieve pressure on #4 Steam Generator when needed. The fire safe shutdown requirement is to have an air source for 2-PCV-1-30 within 60 minutes for operation of the PCV and thereby maintain pressure control of the #4 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA SG PORV Nitrogen Station (panel 2-L-1000) in 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1022 following a fire in this room is covered in a bounding evaluation (Section 8.3.63).

8.3.43.4 OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 772.0-A10 could potentially damage the Control Air Compressor A-A (0-MTR-32-60-A, cable 2PP756A fails upstream power supply to compressor) and the control cable to SG 3 Power Relief Solenoid Valve (2-PSV-1-24B-A, 2V7539A). Damage to this equipment could prevent the ability to modulate the Power Relief Valve (2-PCV-1-23) to relieve pressure on #3 Steam Generator when needed. The fire safe shutdown requirement is to have an air source for 2-PCV-1-23 within 60 minutes for operation of the PCV and thereby maintain pressure control of the #3 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the emergency nitrogen station (panel 2-L-1000) in 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in a bounding evaluation (Section 8.3.64).

PART VII - DEVIATIONS AND EVALUATIONS

8.3.43.5 Staffing Requirements for a Fire in Room 772.0-A10

For a fire in 772.0-A10, one Unit 1 action and one “common” action are performed by one AUO, three Unit 1 actions are performed by two AUOs and five Unit 2 actions are performed by three AUOs for a total of six AUOs. Therefore, a total of eight AUOs is more than sufficient to perform all of the Unit 1 and Unit 2 actions, should there be a fire in 772.0-A10.

8.3.44 Room 772.0-A11 (480V Transformer Room 2B)

8.3.44.1 Fire Prevention

The 480V Transformer Room 2B, 772.0-A11, is constructed of reinforced concrete. The walls, floor and penetration seals have a fire resistance rating of 2-hours. The doors are rated for 3-hours and there are no fire dampers in the room. 772.0-A11 has a floor area of 1,874 ft² and a nominal ceiling height of 13 feet.

The combustibles in 772.0-A11 consist of the oil in the transformers, plastic associated with hand switches and insulation on the cables in the trays. Cable insulation accounts for over 72% of the combustibles in this room. The combustible loading results in a fire severity classification of Moderately Severe. The room contains intervening combustibles in the form of insulation on the cables in the trays and Electric Raceway Fire Barrier Systems (ERFBS). The justification for using an enhanced automatic preaction sprinkler system to compensate for these intervening combustibles is documented in Section 2.4 of this Part.

The potential ignition sources in room 772.0-A11 are the transformers. NPG-SPP-18.4.7, “Control of Transient Combustibles” and NPG-SPP-18.4.8, “Control of Ignition Sources (Hot Work)” defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.44.2 Detection, Control, and Extinguishment

The 480V Transformer Room 2B Room (772.0-A11) is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the MCR to investigate the detector alarm. Portable extinguishers are available throughout the plant for extinguishing any small credible fire. If a larger fire occurs, automatic sprinklers in the room activate. A standpipe and hose station system is available in the adjacent room (772.0-A10) for fire brigade use.

8.3.44.3 OMA 1024 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 772.0-A11 could damage multiple cables needed for Control Air Compressor (0-MTR-32-86-B) which prevents the ability to modulate the Power Relief Valve (2-PCV-1-12) to relieve pressure on #2 Steam Generator when needed. The fire safe shutdown requirement is to have an air source for 2-PCV-1-12 within 60 minutes for operation of the PCV and thereby maintain pressure control of the #2 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1001) in 757.0-A21.

PART VII - DEVIATIONS AND EVALUATIONS

The Feasibility and Reliability Evaluation for OMA 1024 following a fire in this room is covered in a bounding evaluation (Section 8.3.65).

8.3.44.4 Staffing Requirements for a Fire in Room 772.0-A11

For a fire in 772.0-A11, one Unit 1 action and one “common” action are performed by one AUO, three Unit 1 actions are performed by two AUOs and four Unit 2 actions are performed by three AUOs for a total six AUOs. Therefore, a total of eight AUOs is more than sufficient to complete all of the OMAs for Unit 1 and Unit 2, should there be a fire in 772.0-A11.

8.3.45 Room 772.0-A12 (480V Transformer Room 2A)

8.3.45.1 Fire Prevention

The 480V Transformer Room 2A (772.0-A12) is constructed of reinforced concrete. The fire resistance rating walls, floor and penetrations seals are 2-hours or greater. The one door in this room is a 3-hour fire resistance rated door; there are no dampers in the room. The room has a floor area of 1783 ft² and a nominal ceiling height of 13-feet.

The combustible loading in room 772.0-A12 results in a fire severity classification of Moderately Severe. The presence of intervening combustibles (insulation on cables in trays) in 772.0-A12 is justified and documented in Section 2.4 of this Part. The combustible material in the room consists of oil in the transformers, plastic associated with a panel and insulation on cables in trays. Insulation on cable trays accounts for approximately 78% of the combustibles in room 772.0-A12. The potential ignition sources in this room are the transformers.

NPG-SPP-18.4.7, “Control of Transient Combustibles” and NPG-SPP-18.4.8, “Control of Ignition Sources (Hot Work)” defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.45.2 Detection, Control, and Extinguishment

The 480V Transformer Room 2A is provided with ionization smoke detectors that alarm in the Main Control Room (MCR) and an automatic preaction sprinkler system. Any fire that starts is quickly detected and personnel are dispatched from the nearby MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. A larger fire activates the installed automatic sprinkler system provided for the room. This extinguishes or limits the magnitude of the fire until the fire brigade arrives. A standpipe and hose station system is also available in a nearby room (772.0-A10) for fire brigade use.

8.3.45.3 OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 772.0-A12 could potentially damage a control cable to the 480V Shutdown Board 2A1-A (2-BD-212-A1-A) which prevents the ability to modulate Power Relief Valve 2-PCV-1-23 to relieve pressure on #3 Steam Generator, when needed. The fire safe shutdown requirement is to have an air source for 2-PCV-1-23 within 60 minutes to maintain pressure control of the #3 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1000) in 757.0-A24.

PART VII - DEVIATIONS AND EVALUATIONS

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in the 1023 bounding evaluation (Section 8.3.64).

8.3.45.4 Staffing Requirements for a Fire in Room 772.0-A12

For a fire in 772.0-A12, one Unit 1 action and one “common” action are performed by one AUO, seven Unit 2 actions are performed by four AUOs and four Unit 1 actions are performed by two AUOs for a total of seven AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1 and 2 manual actions, should there be a fire in Room 772.0-A12.

8.3.46 Room 772.0-A13 (125V Vital Battery Room IV)

8.3.46.1 Fire Prevention

The 125V Vital Battery Room IV, 772.0-A13, is constructed of reinforced concrete. Walls, floors, ceiling, doors, dampers, and penetration seals in 772.0-A13 are fire resistance rated for 3-hours. Room 772.0-A13 has a floor area of 341 ft² and a nominal ceiling height of 13-feet. The combustibles in 772.0-A13 consist of plastics associated with electrical panels, boxes and battery cases. Adequate ventilation is provided to preclude explosive concentrations of hydrogen. The combustible loading in the room results in a fire severity classification of low. Over 85% of the combustibles in this room are due to the battery cases.

The potential ignition sources in this room consist of the batteries, two control panels and two junction boxes. The panels and the junction boxes are relatively small and do not constitute credible ignition sources (circuits are properly protected and insignificant quantity of associated combustibles) to create and sustain a large fire. NPG-SPP-18.4.7, “Control of Transient Combustibles” and NPG-SPP-18.4.8, “Control of Ignition Sources (Hot Work)” defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.46.2 Detection, Control, and Extinguishment

The 125V Vital Battery Room IV is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts would be quickly detected and personnel would be dispatched from the MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. If a larger fire occurs, the installed manually actuated sprinkler system provided for the room is activated (valve located on wall in on elevation 757) by the fire brigade. preaction A standpipe and hose station system is also available from room 772.0-A10 for fire brigade use.

Even if the postulated fire starts and is not extinguished, the 3-hour fire rating of the room’s fire barriers contain the fire and does not allow it to present an exposure hazard to adjacent rooms.

8.3.46.3 OMA 1016 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 772.0-A13 could potentially damage cables (B70G, B71G and B72G) failing the 125V Vital Battery Board IV (0-BD-236-4-G) which prevents the ability to relieve pressure via Power Relief Valve 2-PCV-1-5 on #1 Steam Generator when needed.

PART VII - DEVIATIONS AND EVALUATIONS

The fire safe shutdown requirement for this operator action is to have an air source for 2-PCV-1-5 within 60 minutes to maintain pressure control of the #1 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1001) located in room 757.0-A21.

The Feasibility and Reliability Evaluation for OMA 1016 following a fire in this room is covered in a bounding evaluation (Section 8.3.62).

8.3.46.4 OMA 1024 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in the 125V Vital Battery Room IV (772.0-A13) potentially damages cables B70G, B71G and B72G failing the 125V Vital Battery Board IV (0-BD-236-4-G) which prevents the ability to modulate the power relief valve (2-PCV-1-12) to relieve pressure on #2 Steam Generator, when needed. The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-12 (SG 2 Power Relief Valve) to control secondary pressure. The operator must align N2 supply and operate 2-ISIV-1-405E2 on 2-L-1001 at the local station to open/close 2-PCV-1-12.

The Feasibility and Reliability Evaluation for OMA 1024 following a fire in this room is covered in a bounding evaluation (Section 8.3.65).

8.3.46.5 Staffing Requirements for a Fire in Room 772.0-A13

For a fire in 772.0-A13, two “common” actions are performed by one AUO, seven Unit 2 actions are performed by three AUOs and three Unit 1 actions are performed by two AUOs for a total of six AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1 and Unit 2 manual actions, should there be a fire in 772.0-A13.

8.3.47 Room 772.0-A14 (125V Vital Battery Room III)

8.3.47.1 Fire Prevention

The 125V Vital Battery Room III (772.0-A14) is constructed of reinforced concrete. The walls, floor, ceiling and penetration seals have a fire resistance rating of 3-hours. The 125V Vital Battery Room III has a floor area of 341 ft² and a nominal ceiling height of 13-feet. The combustible loading of room 772.0-A14 consists of plastics associated with electrical panels, boxes and battery cases. Adequate ventilation is provided to preclude explosive concentrations of hydrogen. The combustible loading in the room results in a fire severity classification of low. Over 85% of the combustibles in this room are due to the battery cases.

The potential ignition sources in this room consist of the batteries, two control panels and two junction boxes. The panels and the junction boxes are relatively small and do not constitute credible ignition sources (circuits are properly protected and insignificant quantity of associated combustibles) to create and sustain a large fire. NPG-SPP-18.4.7, “Control of Transient Combustibles” and NPG-SPP-18.4.8, “Control of Ignition Sources (Hot Work)” defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.47.2 Detection, Control, and Extinguishment

The 125V Vital Battery Room III is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. If a larger fire occurs, the installed manually actuated sprinkler system provided for the room is activated (valve located on wall in on elevation 757) by the fire brigade. A standpipe and hose station system is also available from room 772.0-A10 for fire brigade use.

Even if the postulated fire starts and is not be extinguished, the 3-hour fire rating of the room's fire barriers contains the fire and does not allow it to present an exposure hazard to adjacent rooms.

8.3.47.3 OMA 1022 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in the 125VDC Vital Battery Board Room III (772.0-A14) potentially damages cables B65F, B66F and B67F failing the 125V Vital Battery Board III (0-BD-236-3-F) which prevents the ability to modulate the power relief valve (2-PCV-1-30) to relieve pressure on #4 Steam Generator, when needed. The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-30 (SG 4 Power Relief Valve) to control secondary pressure. The operator must align N2 supply and operate 2-ISIV-1-406E2 on 2-L-1000 at the local station to open/close 2-PCV-1-30. This OMA must be completed within 60 minutes and is performed in room 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1022 following a fire in this room is covered in a bounding evaluation (Section 8.3.63).

8.3.47.4 OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in the 125VDC Vital Battery Board Room III (772.0-A14) potentially damages cables B65F, B66F and B67F failing the 125V Vital Battery Board III (0-BD-236-3-F) which prevents the ability to modulate the power relief valve (2-PCV-1-23) to relieve pressure on #3 Steam Generator, when needed. The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-23 (SG 3 Power Relief Valve) to control secondary pressure. The operator must align N2 supply and operate 2-ISIV-1-407E2 on 2-L-1000 at the local station to open/close 2-PCV-1-30. This OMA must be completed within 60 minutes and is performed in room 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1022 following a fire in this room is covered in a bounding evaluation (Section 8.3.64).

8.3.47.5 Staffing Requirements for a Fire in Room 772.0-A14

For a fire in 772.0-A14, three “common” actions are performed by two AUOs, eight Unit 2 actions are performed by three AUOs and three Unit 1 actions are performed by two AUOs for a total of seven AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1 and Unit 2 manual actions, should there be a fire in room 772.0-A14.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.48 Room 772.0-A15 East (480V Board Room 2B East)

8.3.48.1 Fire Prevention

The 480V Board Room 2B, 772.0-A15 East, a subdivision of 772.0-A15 is constructed of reinforced concrete and has a fire resistance rating of a minimum of 2 or 3-hours. Doors, dampers, penetration seals and barriers (walls, floors, ceiling etc.) in 772.0-A15 are fire resistance rated for 3-hours. Room 772.0-A15 has a floor area of 2153 ft² and a nominal ceiling height of 13-feet. The combustibles in 772.0-A15 consist of plastics associated with the electrical boards, panels, boxes and lights and insulation on the HVAC ducts and on the cables in the trays.

The combustible loading in the room results in a fire severity classification of severe. Over 91% of the combustibles in the room are in the form of cable insulation in trays.

The room contains intervening combustibles in the form of insulation on cables in trays and ERFBS. The justification for using an enhanced automatic preaction sprinkler system to compensate for these intervening combustibles is documented in Section 2.4 of this Part.

There are a number of assumed ignition sources in 772.0-A15 including inverters, multiplexer, battery chargers, and a Motor Control Center (MCC). NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.48.2 Detection, Control, and Extinguishment

The 480V Board Room is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the nearby MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. A larger fire activates the installed automatic preaction sprinkler system provided for the room. This extinguishes or limits the magnitude of the fire until the fire brigade arrives. A standpipe and hose station system is also available from room 772.0-A10 for fire brigade use.

The preaction sprinkler system covers all but that portion of the room between column lines A8-A10/Q-R. Given the small amount of combustibles in the area without automatic suppression, and separation between redundant FSSD components in this room, an adequate level of fire protection is provided. The justification for lack of full area automatic suppression coverage is documented in Section 3.1.5 of this part.

Even if the postulated fire starts and is not extinguished, the minimum 2-hour fire rating of the room's walls, floors and ceiling and door, fire dampers and penetration seals contain the fire and does not allow it to propagate to adjacent rooms.

8.3.48.3 OMA 1016 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in the 480V Board Room 2-B potentially damages cable B13G or supporting equipment 125V DC Transfer Switch, 0-XSW-236-79DC1-S or Charger (0-CHGR-236-4-G), which supports

PART VII - DEVIATIONS AND EVALUATIONS

the #1 Steam Generator Power Relief Solenoid Valve (2-PSV-1-6C-B). The fire safe shutdown requirement is for the AUO to operate 2-ISIV-1-408E2 at the local station 2-L-1001 (N₂) in order to control secondary pressure. This OMA must be completed within 60 minutes and is performed in room 757.0-A21.

The Feasibility and Reliability Evaluation for OMA 1016 following a fire in this room is covered in the OMA 1016 bounding evaluation (Section 8.3.62).

8.3.48.4 OMA 1024 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in the 480V Board Room 2-B potentially damages cable B13G or supporting equipment 125V DC Transfer Switch (0-XSW-236-79DC1-S) or charger (0-CHGR-236-4-G) which supports the #2 Steam Generator Power Relief Solenoid Valve (2-PSV-13B-B). There may also be failed supporting equipment to the Essential Raw Cooling Water Supply Header 2B (ERCW-HDR-2B) which supports the Control Air Compressor B-B (0-MTR-32-86-B). The fire safe shutdown requirement is for the AUO to operate 2-ISIV-1-405E2 at the local station 2-L-1001 (N₂) in order to control secondary pressure. This OMA must be completed within 60 minutes and is performed in room 757.0-A21.

The Feasibility and Reliability Evaluation for OMA 1024 following a fire in this room is covered in the OMA 1024 bounding evaluation (Section 8.3.65).

8.3.48.5 Staffing Requirements for a Fire in Room 772.0-A15 East

For a fire in 772.0-A15 (East), one Unit 2 action and three “common” actions are performed by one AUO, 15 Unit 2 actions are performed by four AUOs and five Unit 1 actions are performed by three AUOs for a total of eight AUOs. Therefore, the staffing of eight AUOs is sufficient to accomplish all of the Unit 1 and Unit 2 manual actions, should there be a fire in room 772.0-A15 (East).

8.3.49 Room 772.0-A15 West (480V Board Room 2B West)

8.3.49.1 Fire Prevention

The 480V Board Room 2-B, 772.0-A15 (West), a subdivision of 772.0-A15 is constructed of reinforced concrete and has a fire resistance rating of a minimum of 2 hours. Doors, dampers, penetration seals and barriers (walls, floors, ceiling etc.) in 772.0-A15 are fire resistance rated for a minimum of 2-hours, or have been rated as equivalent to a fire door. Room 772.0-A15 has a floor area of 2153 ft² and a nominal ceiling height of 13-feet. The combustibles in 772.0-A15 consist of plastics associated with the electrical boards, panels, boxes and lights and insulation on the HVAC ducts and on the cables in the trays.

The combustible loading in the room results in a fire severity classification of severe. Over 91% of the combustibles in the room are in the form of cable insulation in trays.

The room contains intervening combustibles in the form of insulation on cables in trays and ERFBS. The justification for using an enhanced automatic preaction sprinkler system to compensate for these intervening combustibles is documented in Section 2.4 of this Part.

PART VII - DEVIATIONS AND EVALUATIONS

There are a number of assumed ignition sources in 772.0-A15 including inverters, multiplexer, battery chargers, and a Motor Control Center (MCC). NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.49.2 Detection, Control, and Extinguishment

The 480V Board Room is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the nearby MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. A larger fire activates the installed automatic preaction sprinkler system provided for the room. This extinguishes or limits the magnitude of the fire until the fire brigade arrives. A standpipe and hose station system is also available from room 772.0-A10 for fire brigade use.

The preaction sprinkler system covers all but that portion of the room between column lines A8-A10/Q-R. Given the small amount of combustibles in the area without automatic suppression, and separation between redundant FSSD components this room, an adequate level of fire protection is provided. The justification for lack of full area automatic suppression coverage is documented in Section 3.1.5 of this Part.

Even if the postulated fire starts and is not extinguished, the minimum 2-hour fire rating of the room's walls, floors and ceiling and door, fire dampers and penetration seals contain the fire and does not allow it to propagate to adjacent rooms.

8.3.49.3 OMA 1016 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in the 480V Board Room 2-B potentially damages cables 2V4010B or 2V4011B which supports the #1 Steam Generator Power Relief Solenoid Valve (2-PSV-1-6C-B) which is necessary for Power Relief valve 2-PCV-1-5 to relieve pressure on the #1 Steam Generator when needed. The fire safe shutdown requirement is for the AUO to operate 2-ISIV-1-408E2 at the local station 2-L-1001 (N2) in order to control secondary pressure. This OMA must be completed within 60 minutes and is performed in room 757.0-A21.

The Feasibility and Reliability Evaluation for OMA 1016 following a fire in this room is covered in a bounding evaluation (Section 8.3.62).

8.3.49.4 OMA 1024 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in the 480V Board Room 2-B potentially damages charger (0-CHGR-236-3-F) in supporting #2 Steam Generator Power Relief Solenoid Valve (2-PSV-1-13C-A). There may also be failed supporting equipment to the Essential Raw Cooling Water Supply Header 2B (ERCW-HDR-2B) which supports the Control Air Compressor B-B (0-MTR-32-86-B). These components are needed for #2 Steam Generator power relief valve 2-PCV-1-12 which is needed to maintain pressure control of the #2 Steam Generator. The fire safe shutdown requirement is for the AUO to operate 2-ISIV-1-405E2 at the local station 2-L-1001 (N2) in order

PART VII - DEVIATIONS AND EVALUATIONS

to control secondary pressure. This OMA must be completed within 60 minutes and is performed in room 757.0-A21.

The Feasibility and Reliability Evaluation for OMA 1024 following a fire in this room is covered in a bounding evaluation (Section 8.3.65).

8.3.49.5 OMA 1495 – Operate PCV for MDAFW Pump A from ACR

A fire in room 772.0-A15 (West) could damage cables 2PV828F or PV240F which could prevent the ability to operate the A Motor Driven Auxiliary Feedwater Pump (MDAFW) Outlet Pressure Control Valve (2-PCV-3-122-A). The fire safe shutdown requirement for a fire in 772.0-A15 (West) is to control discharge pressure on the MDAFW Pump by transferring from normal to auxiliary control and operating the PCV from auxiliary control room. Discharge pressure of the MDAFW pump must be controlled in within 20 minutes. The operator must transfer from normal to auxiliary control (OMA 1495) using transfer switch 2-XS-3-122, located on auxiliary control panel 2-L-11A in room 757.0-A27. The operator enters the adjacent Auxiliary Control Room, 757.0-A1, and ensures the PCV is operable by verifying the discharge pressure controller 2-PDIC-3-122C on auxiliary control panel 2-L-10 is in "AUTO".

OMA 1495 is both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The Operator has 20 minutes before the OMA must be completed. The demonstrated time to transit and perform the action was 5 minutes 41 seconds. The fire that results in the fire-induced damage requiring implementation of this OMA will be contained within room 772.0-A15 (West) and will not present an exposure hazard to the operator on the access path or the control location.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel to the transfer switch and perform the action (5 minutes) provides 15-minutes (300%) margin. The validated time at 5 minutes 41 seconds, provides 14-minutes 19 seconds (252% margin). An AUO would have sufficient time to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of this OMA. If they were unavailable, 8-hour emergency battery pack lighting is provided; therefore, there is adequate lighting to access the transfer switch and to perform the OMA. Because the operator does not have to traverse or enter the fire zone, there are no impediments associated with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

d. Equipment Functionality and Accessibility

The Transfer Switch in room 757.0-A27 and the Controller in room 757.0-A1 are remote from the fire and are readily accessible, therefore it is ensured that they are functional and accessible.

PART VII - DEVIATIONS AND EVALUATIONS

e. Available Indications

Based on a review of actions documented in Reverification and Revalidation of Appendix R Manual Operator Actions, available local indications and MCR indications for ensuring Isolation of Normal Makeup are adequate.

f. Communications

Adequate communications between the location of the OMA and the MCR is provided by the VHF radio system and/or the 800 MHz cell radio system.

g. Portable Equipment

No portable equipment is needed to complete this action.

h. Personnel Protection Equipment

Only standard PPE is needed to perform these OMAs.

i. Procedures and Training

The Appendix R manual operator actions procedures (AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.49.6 Staffing Requirements for a Fire in Room 772.0-A15 West

For a fire in 772.0-A15 (West), 5 “common” actions are performed by one AUO, 15 Unit 2 actions are performed by four AUOs and five Unit 1 actions are performed by three AUOs for a total of eight AUOs. Therefore, the staffing of eight AUOs is sufficient to accomplish all of the Unit 1 and Unit 2 manual actions, should there be a fire in 772.0-A15 (West).

8.3.50 Room 772.0-A16 (480V Board Room 2A)

8.3.50.1 Fire Prevention

480-V Board Room 2A (772.0-A16) is constructed of reinforced concrete that has a minimum fire resistance rating of 2-hours. The equipment hatch opening in the floor slab is provided with a nonrated steel cover and is also protected by a water curtain. There are four fire doors in the room which are rated for 3-hours. The fire dampers have a minimum rating of 3-Hours. Room 772.0-A16 has a floor area of 2,190 ft² and a nominal ceiling height of 13 feet. The combustibles in 772.0-A16 consist of plastics associated with the 6-ton hoist, electrical boards, panels, boxes and lights, oil associated with the 6-ton hoist and the insulation on the cables in the trays. Insulation on cable trays accounts for over 91% of the combustibles in this room. The combustible loading in the room results in a fire severity classification of moderately severe.

Intervening combustibles in the form of insulation on cables routed in cable trays and ERFBS are present, but are compensated for by an enhanced automatic preaction sprinkler system. Justification is documented in Section 2.4 of this Part. The justification for the hatch opening through the floor is documented in Section 2.6 of this Part. This hatch is protected with a water curtain. The justification for hose stations with more than 100 foot hose is documented in Section 4.3 of this Part.

PART VII - DEVIATIONS AND EVALUATIONS

NPG-SPP-18.4.7, “Control of Transient Combustibles” and NPG-SPP-18.4.8, “Control of Ignition Sources (Hot Work)” defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.50.2 Detection, Control, and Extinguishment

480-V Board Room 2-A (772.0-A16) is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the MCR to investigate the detector alarm. Portable extinguishers are available throughout the plant for extinguishing any small credible fire. If a larger fire occurs, the automatic sprinkler system provided for the room activates. A standpipe and hose station system in room 772.0-A10 is also available for fire brigade use.

8.3.50.3 OMA 1022 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 772.0-A16 could potentially damage the control cable to the #4 Steam Generator Power Relief Solenoid Valve (2-PSV-1-31C-A, 2V4035A). Damage to this cable prevents the ability to modulate the Power Relief Valve (2-PCV-1-30) to relieve pressure on #4 Steam Generator when needed. The fire safe shutdown requirement is to have an air source for 2-PCV-1-30 within 60 minutes for operation of the PCV and thereby maintain pressure control of the #4 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA SG PORV Nitrogen Station (panel 2-L-1000) in 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1022 following a fire in this room is covered in a bounding evaluation (Section 8.3.63).

8.3.50.4 OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 772.0-A16 could potentially damage cables associated with the Control Air Compressor A (0-MTR-32-60-A, 2PL3785A) and an upstream power supply to the compressor (2-BD-212-A1-A – 480V Shutdown Board 2A1-A, 2PL5393A, and 2PL5404A) and the control cable to SG 3 Power Relief Solenoid Valve (2-PSV-1-24B-A, 2V7539A). Damage to this equipment would prevent the ability to modulate the Power Relief Valve (2-PCV-1-23) to relieve pressure on #3 Steam Generator when needed. The fire safe shutdown requirement is to have an air source for 2-PCV-1-23 within 60 minutes for operation of the PCV and thereby maintain pressure control of the #3 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an Operator Manual Action (OMA) at the emergency nitrogen station (panel 2-L-1000) in 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in a bounding evaluation (Section 8.3.64).

8.3.50.5 Staffing Requirements for a Fire in Room 772.0-A16

For a fire in 772.0-A16, two “common” actions are performed by two AUOs, fourteen Unit 2 actions are performed by four AUOs and four Unit 1 actions are performed by two AUOs for a

PART VII - DEVIATIONS AND EVALUATIONS

total of eight AUOs. Therefore, the staffing of eight AUOs is sufficient to accomplish all of the Unit 1 and Unit 2 manual actions, should there be a fire in room 772.0-A16.

8.3.51 Room 782.0-A1 (Control Rod Drive Equipment Room)

8.3.51.1 Fire Prevention

The Unit 1 Control Rod Drive Equipment Room (782.0-A1) is constructed of reinforced concrete and has a fire resistance rating at a minimum of 2 hours. The floor slab in Room 782.0-A1 to 757.0-A10 has an equipment hatch that is covered with a non-fire rated steel cover, two HVAC ducts without fire dampers, and a stairway enclosed by 2 hour non-regulatory fire barriers. There are two dampers in the room that are rated for 3-hours. 782.0-A1 has a floor area of 2,640 ft² and a nominal ceiling height of 18 feet.

The justification for intervening combustibles such as insulation on cables in trays and Thermo-Lag is documented in Section 2.4 of this Part. The justification for the HVAC ducts without fire dampers is documented in Section 2.6.3.2.b of this Part.

The combustible loading results in a fire severity classification of moderate. The combustibles in 782.0-A1 consist of plastics associated with the electrical panels, transformers, lights, oil in the transformers, and the insulation on cables in cable trays. Insulation on cables in trays accounts for over 96% of the combustibles in this room. The potential ignition sources in this room are electrical boards and transformers. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.51.2 Detection, Control, and Extinguishment

The Unit 1 Control Rod Drive Equipment Room (782.0-A1) is provided with ionization smoke detectors that alarm in the MCR. Room 782.0-A1 is also provided with an installed automatic sprinkler system.

Any fire that starts is quickly detected and personnel are dispatched from the MCR to investigate the alarm. Portable extinguishers are available throughout the plant for extinguishing any small credible fire. If a larger fire occurs, automatic sprinklers in the room activate. This extinguishes or limits the magnitude of the fire until the fire brigade arrives. A standpipe and hose station system is available for fire brigade use in 782.0-A1 and from the room (757.0-A10) below. With fire detection, an automatic suppression system, and fire resistant barriers, a fire in this area is contained within the room.

8.3.51.3 OMA 1016 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 782.0-A1 could damage the Auxiliary and Control Air Header A (ACAS ENDUSER-A) which could result in a loss of air to operate the SG PORV.

The fire safe shutdown requirement is to have an air source for 2-PCV-1-5 within 60 minutes for operation of the PCV and thereby maintaining pressure control of the #1 Steam Generator.

PART VII - DEVIATIONS AND EVALUATIONS

Emergency Air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1001) in 757.0-A21.

The Feasibility and Reliability Evaluation for OMA 1016 following a fire in this room is covered in a bounding evaluation (Section 8.3.62).

8.3.51.4 OMA 1024 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 782.0-A1 could potentially damage the Auxiliary and Control Air Header B (ACAS-ENDUSER-B) which prevents the ability to modulate the Power Relief Valve (2-PCV-1-12) to relieve pressure on the #2 Steam Generator.

The fire safe shutdown requirement is to have an air source for 2-PCV-1-12 within 60 minutes for operation of 2-PCV-1-12, thereby establishing pressure control of the #2 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (PNL-2-L-1001) in 757.0-A21.

The Feasibility and Reliability Evaluation for OMA 1024 following a fire in this room is covered in a bounding evaluation (Section 8.3.65).

8.3.51.5 Staffing Requirements for a Fire in Room 782.0-A1

For a fire in 782.0-A1, fourteen Unit 1 actions are performed by four AUOs and five Unit 2 actions are performed by two AUOs for a total of six AUOs. Therefore, a total of eight AUOs is more than sufficient to perform all of the Unit 1 and Unit 2 actions, should there be a fire in 782.0-A1.

8.3.52 Room 782.0-A2 (Pressurizer Heater Transformer Room 1)

8.3.52.1 Fire Prevention

The Pressurizer Heater Transformer Room 1 (782.0-A2) is constructed of reinforced concrete and has a fire resistance rating of a minimum of 2-hours. Penetration seals and barriers (walls, floors, ceiling etc.) in 782.0-A2 are fire resistance rated for 2 or 3-hours. Room 782.0-A2 has a floor area of 768 ft² and a nominal ceiling height of 18-feet. The combustibles in 782.0-A2 consist of plastics associated with the electrical panels, transformers and lights, oil in the transformers, and insulation on the cables in the trays. The combustible loading in the room results in a fire severity classification of Moderate.

The justification for intervening combustibles such as insulation on cables in trays and Thermo-Lag is documented in Section 2.4 of this Part.

The potential ignition sources in this room consist of transformers and electrical boards. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.52.2 Detection, Control, and Extinguishment

The Pressurizer Heater Transformer Room 1 is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the nearby MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. If a larger fire occurs, the installed automatic preaction sprinkler system provided for the room activates. A standpipe and hose station system is also available from room 782.0-A1 for fire brigade use. Even if the postulated fire starts and is not extinguished, the fire barriers contain the fire and does not allow it to propagate to adjacent rooms.

8.3.52.3 OMA 1016 – Operate Steam Generator Relief Valves to Control Secondary Pressure

The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-5 (SG 1 Power Relief Valve) to control secondary pressure. The operator must operate 2-ISIV-1-408E2 at the local station 2-L-1001 (N₂) to open/close 2-PCV-1-5. This OMA must be completed within 60 minutes. This action is performed in room 757.0-A21.

A fire that is contained within room 782.0-A2 could potentially damage the Auxiliary and Control Air Header A (ACAS-ENDUSER-A) requiring implementation of this OMA. The N₂ Operating Station for 2-PCV-1-5 (2-L-1001) remains usable.

The Feasibility and Reliability Evaluation for OMA 1016 following a fire in this room is covered in a bounding evaluation (Section 8.3.62).

8.3.52.4 OMA 1024 – Operate Steam Generator Relief Valves to Control Secondary Pressure

The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-12 (SG 2 Power Relief Valve) to control secondary pressure. The operator must operate 2-ISIV-1-405E2 on 2-L-1001 at the local station (N₂) to open/close 2-PCV-1-12. This OMA must be completed within 60 minutes. This action is performed in room 757.0-A21.

A fire that is contained within room 782.0-A2 could potentially damage the Auxiliary and Control Air Header B (ACAS-ENDUSER-B) requiring implementation of this OMA. The N₂ Operating Station for 2-PCV-1-12 (2-L-1001) remains usable.

The Feasibility and Reliability Evaluation for OMA 1024 following a fire in this room is covered in a bounding evaluation (Section 8.3.65).

8.3.52.5 Staffing Requirements for a Fire in Room 782.0-A2

For a fire in room 782.0-A2, fourteen Unit 1 actions are performed by four AUOs and five Unit 2 actions are performed by two AUOs for a total of six AUOs. Therefore, a total of eight AUOs is more than sufficient to complete all of the OMAs for Unit 1 and Unit 2, should there be a fire in 782.0-A2.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.53 Room 782.0-A3 (Unit 2 Control Rod Drive Equipment Room)

8.3.53.1 Fire Prevention

The Unit 2 Control Rod Drive Equipment Room, 782.0-A3 is constructed of reinforced concrete and has a fire resistance rating of a minimum of 2 or 3-hours. The floor slab in Room 782.0-A3 has an equipment hatch that is covered with a non-fire rated steel cover, two HVAC ducts without fire dampers, and a stairway entry enclosure that is a non-regulatory 2-hour rated fire barrier. Doors, dampers, penetration seals and barriers (walls, floors, ceiling etc.) in 782.0-A3 are fire resistance rated for 2 or 3-hours. Room 782.0-A3 has a floor area of 2657 ft² and a nominal ceiling height of 18-feet. The combustibles in 782.0-A3 consist of plastics associated with the electrical panels, transformers and lights, oil in the transformers, and insulation on the cables in the trays. The combustible loading in the room results in a fire severity classification of low.

The potential ignition sources in this room consist of transformers and electrical boards. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.53.2 Detection, Control, and Extinguishment

The Unit 2 Control Rod Drive Equipment Room is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Any fire that starts is quickly detected and personnel are dispatched from the nearby MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. If a larger fire occurs, the installed automatic preaction sprinkler system provided for the room activates. A standpipe and hose station system is also available in the room and in 757.0-A16 for fire brigade use.

Even if the postulated fire starts and is not extinguished, the fire rating of the room's barriers contain the fire and does not allow it to propagate to adjacent rooms. Therefore, a fire in this room does not present an exposure hazard to the access path to the manual action located in 757.0-A24, the 6.9kV and 480V Shutdown Board Room B.

8.3.53.3 OMA 1022 – Operate Steam Generator Relief Valves to Control Secondary Pressure

The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-30 (SG 4 Power Relief Valve) to control secondary pressure. The operator must operate 2-ISIV-1-406E2 at the local station 2-L-1000 (N₂) to open/close 2-PCV-1-30. This OMA must be completed within 60 minutes. This action is performed in room 757.0-A24.

A fire that is contained within room 782.0-A3 could potentially damage the equipment requiring implementation of this OMA. The N₂ Operating Station for 2-PCV-1-30 (2-L-1000) is considered usable. The SG 4 Power Relief Valve fails due to supporting equipment ACAS Enduser B (local instrument panel 2-L-45) which could disable the motive air supply to 2-PCV-1-30.

The Feasibility and Reliability Evaluation for OMA 1022 following a fire in this room is covered in a bounding evaluation (Section 8.3.63).

PART VII - DEVIATIONS AND EVALUATIONS

8.3.53.4 OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure

The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-23 (SG 3 Power Relief Valve) to control secondary pressure. The operator must operate 2-ISIV-1-407E2 at the local station 2-L-1000 (N₂) to open/close 2-PCV-1-23. This OMA must be completed within 60 minutes. This action is performed in room 757.0-A24.

A fire that is contained within room 782.0-A3 could potentially damage the equipment requiring implementation of this OMA. The N₂ Operating Station for 2-PCV-1-23 (2-L-1000) is considered usable. The SG 3 Power Relief Valve fails due to supporting equipment ACAS Enduser A (local instrument panel 2-L-44) which could disable the motive air supply to 2-PCV-1-23.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in a bounding evaluation (Section 8.3.64).

8.3.53.5 Staffing Requirements for a Fire in Room 782.0-A3

For a fire in 782.0-A3, six Unit 2 actions are performed by four AUOs and five Unit 1 actions are performed by two AUOs for a total of six AUOs. Therefore, the staffing of 8 AUOs is more than sufficient to accomplish all of the Unit 1 and 2 manual actions, should there be a fire in Room 782.0-A3.

8.3.54 Room 782.0-A4 (Unit 2 Pressurizer Heater Transformer Room 2)

8.3.54.1 Fire Prevention

The Unit 2 Pressurizer Heater Transformer Room (782.0-A4) is constructed of reinforced concrete. With the exception of the south wall, the walls, floor, and penetration seals in 782.0-A4 have a fire resistance rating of 2-hours or greater. The south wall and door separating 782.0-A4 and 782.0-A3 are 2-hour rated, but were not required for Appendix R separation. The Unit 2 Pressurizer Heater Transformer Room has a floor area of 768 ft² and a nominal ceiling height of 18-feet.

The floor slab separating Room 782.0-A4 from Room 757.0-A14 has a stairway entry enclosure that is a non-regulatory 2-hour rated fire barrier.

The combustible loading of room 782.0-A4 results in a fire severity classification of Moderate. The combustible material in the room consists of plastics associated with electrical panels and junction boxes, insulating oil associated with transformers and insulation on cables routed in cable trays. Over half of the combustibles in this room comes from transformer insulating oil, and approximately one quarter comes from the insulation on cables in trays. The potential ignition sources in this room are transformers and electrical boards. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.54.2 Detection, Control, and Extinguishment

The Unit 2 Pressurizer Heater Transformer room is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). The room is also provided with an automatic preaction sprinkler system. Any fire that starts is quickly detected and personnel are dispatched from the MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. A larger fire activates the installed automatic preaction sprinkler system provided for the room. The suppression system extinguishes or limits the magnitude of the fire and prevents it from spreading outside the room. A standpipe and hose station system is available in room 782.0-A3 and room 757.0-A16 below for fire brigade use. With fire detection, automatic suppression system, and fire resistance barriers, a fire in this area is contained to the room and does not present an exposure hazard to adjacent rooms.

8.3.54.3 OMA 1022 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 782.0-A4 could potentially result in the loss of the Auxiliary and Control Air Header B (ACAS-ENDUSER-B, 0-FCO-30-148). The fire safe shutdown requirement is to have an air source for 2-PCV-1-30 within 60 minutes for operation of the PCV and thereby maintain pressure control of the #4 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (panel 2-L-1000) in 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1022 following a fire in this room is covered in a bounding evaluation (Section 8.3.63).

8.3.54.4 OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in room 782.0-A4 could potentially result in loss of the Auxiliary and Control Air Header A (ACAS-ENDUSER-A, 0-FCO-30-280). The fire safe shutdown requirement is to have an air source for 2-PCV-1-23 within 60 minutes for operation of the PCV and thereby maintain pressure control of the #3 Steam Generator. Emergency air is provided for operation of the PCV, which is actuated by an OMA at the SG PORV Nitrogen Station (panel 2-L-1000) in 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in a bounding evaluation (Section 8.3.64).

8.3.54.5 Staffing Requirements for a Fire in 782.0-A4

For a fire in 782.0-A4, six Unit 2 actions are performed by four AUOs and five Unit 1 actions are performed by two AUOs for a total of six AUOs. Therefore, the staffing of 8 AUOs is more than sufficient to accomplish all of the Unit 1 and 2 manual actions, should there be a fire in Room 782.0-A4.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.55 Room DBIPS-A (Intake Pumping Station Duct Bank A)

8.3.55.1 Fire Prevention

The Duct Bank-Intake Pumping Station A (DBIPS-A) cable chase from Auxiliary Building 713.0-A1B to IPS-CA is an underground electrical conduit bank constructed of reinforced concrete, PVC conduit, and manholes with missile shields, cable trays and sump pumps.

The combustible material in DBIPS-A consists primarily of cable insulation. There are no credible ignition sources or transient combustibles in the DBIPS-A. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.55.2 Detection, Control and Extinguishment

There is no detection or suppression system in the DBIPS-A. However, there is detection and suppression in both Auxiliary Building 713.0-A1B and IPS-CA. The only credible fire scenarios that could ignite the cables inside DBIPS-A start in either 713.0-A1B or IPS-A. However, a fire is detected and suppressed before it enters the DBIPS-A.

8.3.55.3 OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in the Duct Bank-Intake Pumping Station A (DBIPS-A) could potentially damage one or more cables supporting Control Air Compressor A-A (0-MTR-32-60-A), which prevents the ability to modulate the power relief valve (2-PCV-1-23) to relieve pressure on #3 Steam Generator, which may result in the implementation of this OMA. The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-23 to control the pressure of #3 Steam Generator. The operator must operate 2-ISIV-1-407E2 at the SG PORV Nitrogen Station 2-L-1000, utilizing N₂ to operate the Steam Generator power relief valve if MDAFW Pump A or the TDAFW Pump is used. This OMA must be completed within 60 minutes. This action is performed in room 757.0-A24. However, since there are no credible ignition sources in the DBIPS-A, there are no credible fires originating in the DBIPS-A that results in the performance of this OMA.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this underground electrical duct bank is covered in a bounding evaluation for OMA 1023 (Section 8.3.64).

8.3.55.4 Staffing Requirements for a Fire in Room DBIPS-A

For a fire in DBIPS-A, one "common" action is performed by one AUO, four Unit 2 actions are performed by three AUOs and four Unit 1 actions are performed by three AUOs for a total of seven AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1 and Unit 2 manual actions, should there be a fire in room DBIPS-A.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.56 Room DBIPS-B (Intake Pumping Station Duct Bank B)

8.3.56.1 Fire Prevention

The Duct Bank-Intake Pumping Station B (DBIPS-B) cable chase from Auxiliary Building 713.0-A1B to IPS-CB is an underground electrical conduit bank constructed of reinforced concrete, PCV conduit, manholes with missile shields, cable trays and sump pumps.

The combustible material in DBIPS-B consists primarily of cable insulation. There are no credible ignition sources or transient combustibles in the DBIPS-B. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.56.2 Detection, Control and Extinguishment

There is no detection or suppression system in the DBIPS-B. However, there is detection and suppression in both Auxiliary Building 713.0-A1B, and IPS-CB. The only credible fire scenarios that could ignite the cables inside DBIPS-B start in either 713.0-A1B or IPS-B. However, a fire is detected and suppressed before it enters the DBIPS-B.

8.3.56.3 OMA 1024 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in the Duct Bank-Intake Pumping Station B (DBIPS-B) could potentially damage one or more cables supporting the Control Air Compressor B-B (O-MTR-32-86-B), which prevents the ability to modulate the power relief valve (2-PCV-1-12) to relieve pressure on the #2 Steam Generator, which may result in the implementation of this OMA. The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-12 to control the pressure of #2 Steam Generator. The operator must operate 2-ISIV-1-405E2 at the SG PORV Nitrogen Station 2-L-1001, utilizing N₂ to operate Steam Generator power relief valve if MDAFW Pump B or the TDAFW Pump is used. This OMA must be completed within 60 minutes. This action is performed in room 757.0-A21. However, since there are no credible ignition sources in the DBIPS-B, there are no credible fires originating in the DBIPS-B that results in the performance of this OMA. As additional defense-in-depth, the following evaluation of the OMA is provided to document the feasibility and reliability of the action.

The Feasibility and Reliability Evaluation for OMA 1024 following a fire in the underground electrical duct bank is covered in the bounding evaluation for OMA 1024 (Section 8.3.65).

8.3.56.4 Staffing Requirements for a Fire in DBIPS-B

For a fire in DBIPS-B, four Unit 1 actions are performed by three AUOs and four Unit 2 actions are performed by three AUOs for a total of six AUOs. Therefore, a total of eight AUOs is more than sufficient to complete all of the OMAs for Unit 1 and Unit 2, should there be a fire in DBIPS-B.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.57 Room IPS-A (Intake Pumping Station A)

8.3.57.1 Fire Prevention

The Intake Pumping Station – A (IPS-A) is constructed of reinforced concrete. IPS-A is made up of three rooms, ERCW Pump Room A, Screen Wash and HPFP A Pump Room, and ERCW Strainer Room A. The doors and walls for each of these rooms that are adjacent to other fire areas are rated barriers with a fire resistance rating of 3-hours. However, the wall between the ERCW Pump Room A and the Screen Wash Pump Room has two unprotected openings (scupper holes) with justification documented in Section 2.6.2 of this Part. The doors associated with these rooms have a regulatory barrier rating of 3 hours with doors W10A and W10B between ERCW Strainer Room A (Fire Area 58) and ERCW Strainer Room B (Fire Area 59) rated “equivalent”. The ceiling of the ERCW Pump Room A and the Screen Wash and HPFP A Pump Room is an open steel missile barrier that allows air flow into the rooms. The three rooms have a combined floor area of 4,991 ft² and a nominal ceiling height of 13-feet to the missile barrier in ERCW Pump Room A and the Screen Wash and HPFP A Pump Room (Elevation 741.0), and a nominal ceiling height of 16-feet in the ERCW Strainer Room A (Elevation 722.0).

The combustible loading of these rooms results in a fire severity classification of Moderate or less. The combustible material in these rooms consists of plastics associated with lights, electrical panels, transformer, junction boxes and flex conduit, lube oil, grease, hydraulic oil in the crane, and insulation on cables in trays. Approximately half of the combustibles in these rooms is due to insulation on cables in trays. The assumed ignition sources in these rooms are transformers and electrical panels. NPG-SPP-18.4.7, “Control of Transient Combustibles” and NPG-SPP-18.4.8, “Control of Ignition Sources (Hot Work)” defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.57.2 Detection, Control, and Extinguishment

The ERCW Pump Room A is provided with heat detectors over the ERCW pumps and the ERCW Strainer Room A is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Although the rooms are not provided with suppression and full area detection, the fire area barrier ratings are sufficient given the combustible loadings in the area. The fire area does not contain redundant safe shutdown equipment. Therefore, a fire in this area will not endanger redundant safety related equipment required for a safe plant shutdown. Portable extinguishers are available for extinguishing any small credible fire. A standpipe and hose station system is available in the Screen Wash Pumps and HPFP A Pump Room and the ERCW Strainer Room A and is accessible from ERCW Pump Room A for fire brigade use. With fire detection and fire resistant barriers, a fire in this area is contained until the fire brigade responds.

8.3.57.3 OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in the Intake Pumping Station - A could potentially damage one or more cables supporting the Control Air Compressor A-A (0-MTR-32-60-A) which prevents the ability to modulate the power relief valve (2-PCV-1-23) to relieve pressure on #3 Steam Generator, which may result in the implementation of this OMA. The fire safe shutdown requirement of this OMA is to

PART VII - DEVIATIONS AND EVALUATIONS

open/close 2-PCV-1-23 to control the pressure of #3 Steam Generator. The operator must operate 2-ISIV-1-407E2 at the SG PORV Nitrogen Station 2-L-1000, utilizing N2 to operate the Steam Generator power relief valve if MDAFW Pump A or the TDAFW Pump is used. This OMA must be completed within 60 minutes. This action is performed in room 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in the Intake Pumping Station A is covered in the bounding evaluation for OMA 1023 (Section 8.3.64).

8.3.57.4. Staffing Requirements for a Fire in IPS-A

For a fire in IPS-A, one “common” action is performed by one AUO, four Unit 2 actions are performed by three AUOs and four Unit 1 actions are performed by three AUOs for a total of seven AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1 and Unit 2 manual actions, should there be a fire in room IPS-A.

8.3.58 Room IPS-B (Intake Pumping Station B)

8.3.58.1 Fire Prevention

The Intake Pumping Station – B (IPS-B) is constructed of reinforced concrete. IPS-B is made up of three rooms, ERCW Pump Room B, HPFP B Pump Room, and ERCW Strainer Room B. The walls for each of these rooms that are adjacent to other fire areas are rated barriers with a fire resistance rating of 3-hours. However, the wall between the ERCW Pump Room B and the Screen Wash Pump Room has two unprotected openings (scupper holes) with justification provided in Section 2.6 of this Part. The doors associated with these rooms have a regulatory barrier rating of 3 hours with doors W10A and W10B between ERCW Strainer Room A (Fire Area 58) and ERCW Strainer Room B (Fire Area 59) rated “equivalent”. The ceiling of the ERCW Pump Room B and the HPFP B Pump Room is an open steel missile barrier that allows air flow into the rooms. The three rooms have a combined floor area of 3,567 ft² and a height of 13-feet to the missile barrier in ERCW Pump Room B and HPFP B Pump Rooms (Elevation 741.0), and a ceiling height of 16-feet in ERCW Strainer Room B (Elevation 722.0).

The combustible loading of these rooms results in a fire severity classification of Moderate or less. The combustible material in these rooms consists of plastics associated with lights, electrical panels, lube oil, dry type transformers and insulation on cables in trays. The assumed ignition sources in this room are transformers, motor control centers, heat trace panels, crane, ERCW Pumps and Strainers, and HPFP Pumps. NPG-SPP-18.4.7, “Control of Transient Combustibles” and NPG-SPP-18.4.8, “Control of Ignition Sources (Hot Work)” defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.58.2 Detection, Control and Extinguishment

The ERCW Pump Room B is provided with heat detectors over the ERCW pumps, while the ERCW Strainer Room B is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). Although the rooms are not provided with suppression and full area detection, the fire area barrier ratings are sufficient given the combustible loadings in the area. The fire area does not contain redundant safe shutdown equipment. Therefore, a fire in this area will not endanger redundant safety related equipment required for a safe plant shutdown. Portable extinguishers are available for extinguishing any small credible fire. A standpipe and

PART VII - DEVIATIONS AND EVALUATIONS

hose station system is available in HPFP B Pump Room and the ERCW Strainer Room B for fire brigade use. With fire detection and fire resistant barriers, a fire in this area is contained until the fire brigade responds.

8.3.58.3 OMA 1024 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in the Intake Pumping Station Room B could potentially damage one or more cables supporting the Control Air Compressor B-B (0-MTR-32-86-B), which prevents the ability to modulate the power relief valve (2-PCV-1-12) to relieve pressure on the #2 Steam Generator, which may result in the implementation of this OMA. The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-12 to control the pressure of #2 Steam Generator. The operator must operate 2-ISIV-1-405E2 at the SG PORV Nitrogen Station 2-L-1001, utilizing N₂ to operate Steam Generator power relief valve if MDAFW Pump B or the TDAFW Pump is used. This OMA must be completed within 60 minutes. This action is performed in room 757.0-A21.

The Feasibility and Reliability Evaluation for OMA 1024 following a fire in this room is covered in a bounding evaluation for OMA 1024 (Section 8.3.65).

8.3.58.4 Staffing Requirements for a Fire in IPS-B

For a fire in IPS-B, four Unit 1 actions are performed by three AUOs and four Unit 2 actions are performed by three AUOs for a total of six AUOs. Therefore, a total of eight AUOs is more than sufficient to complete all of the OMAs for Unit 1 and Unit 2, should there be a fire in IPS-B.

8.3.59 Room IPS-C (East) [Intake Pumping Station C (East)]

8.3.59.1 Fire Prevention

IPS-C of the Intake Pumping Station is a large area that is subdivided into three overlapping areas; IPS-C (East), IPS-C (Middle), and IPS-C (West). The Intake Pumping Station is constructed of reinforced concrete. The south wall, separating IPS-711.0 from the ERCW Strainer Rooms A and B (IPS-A and IPS-B el. 722.0) has a fire resistance rating of 3-hours. The Intake Pumping Station Room C has a floor area of 2,068 ft² and a ceiling height of 17-feet.

The combustible loading of room IPS-C results in a fire severity classification of Moderate of which approximately 83% is due to insulation on cables in trays. The combustible material in the room consists of plastics associated with electrical panels and boards, insulating oil associated with transformers and insulation on cables routed in cable trays. The assumed ignition sources in this room are transformers, motor control centers, lighting cabinets, and panels. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.59.2 Detection, Control and Extinguishments

The Intake Pumping Station, elevation 711.0 is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). The room is also provided with an automatic preaction sprinkler system. Any fire that starts is quickly detected and personnel are dispatched to

PART VII - DEVIATIONS AND EVALUATIONS

investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. A larger fire activates the installed automatic preaction sprinkler system provided for the room. This extinguishes or limits the magnitude of the fire until the fire brigade arrives. A standpipe and hose station system is available in the room and in the adjacent ERCW strainer rooms for fire brigade use. The room contains intervening combustibles in the form of insulation on cables in trays. The justification for using an enhanced automatic preaction sprinkler system to compensate for these intervening combustibles is documented in Section 2.4 of this Part. With fire detection, automatic suppression system, and fire resistant barriers, a fire in this area is contained within the room and does not present an exposure hazard to adjacent rooms. This also contributes to satisfying the requirements of Appendix R (Section III.G.2.b) for FSSD components within 711.0.

8.3.59.3 OMA 1024 – Operate SG Relief Valves to Control Secondary Pressure

A fire in the Intake Pumping Station Room C (East) could potentially damage a control cable supporting the Control Air Compressor B-B (0-MTR-32-86-B), which prevents the ability to provide air to modulate the power relief valve (2-PCV-1-12) to relieve pressure on the #2 Steam Generator. The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-12 to control the pressure of #2 Steam Generator. The operator must operate 2-ISIV-1-405E2 at the SG PORV Nitrogen Station 2-L-1001 (located in room 757.0-A21), to operate Steam Generator power relief valve if MDAFW Pump B or the TDAFW Pump is used. This OMA must be completed within 60 minutes.

The Feasibility and Reliability Evaluation for OMA 1024 following a fire in this room is covered in a bounding evaluation (Section 8.3.65).

8.3.59.4 Staffing Requirements for a Fire in IPS-C (East)

For a fire in IPS-C (East), four Unit 1 actions are performed by three AUOs and four Unit 2 actions are performed by three AUOs for a total of six AUOs. Therefore, a total of eight AUOs is more than sufficient to complete all of the OMAs for Unit 1 and Unit 2, should there be a fire in IPS-C (East).

8.3.60 Room IPS-C (Middle) [Intake Pumping Station C (Middle)]

8.3.60.1 Fire Prevention

IPS-C of the Intake Pumping Station is a large area that is subdivided into three overlapping areas; IPS-C (East), IPS-C (Middle), and IPS-C (West). The Intake Pumping Station is constructed of reinforced concrete. The south wall, separating IPS-711.0 from the ERCW Strainer Rooms A and B (IPS-A and -B el. 722.0) has a fire resistance rating of 3-hours. The Intake Pumping Station Room C has a floor area of 2,068 ft² and a nominal ceiling height of 13 to 16-feet.

The combustible loading of room IPS-C results in a fire severity classification of Moderate of which approximately 83% is due to the insulation on the cables in trays. The combustible material in the room consists of plastics associated with electrical panels and boards, insulating oil associated with transformers and insulation on cables routed in cable trays. The assumed ignition sources in this room are transformers, motor control centers, lighting cabinets, and panels. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of

PART VII - DEVIATIONS AND EVALUATIONS

significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.60.2 Detection, Control, and Extinguishment

The Intake Pumping Station, elevation 711.0 is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). The room is also provided with an automatic preaction sprinkler system. Any fire that starts is quickly detected and personnel are dispatched from the MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. A larger fire activates the installed automatic preaction sprinkler system provided for the room. This extinguishes or limits the magnitude of the fire until the fire brigade arrives. A standpipe and hose station system is available in the room and in the adjacent ERCW strainer rooms for fire brigade use. The room contains intervening combustibles in the form of insulation on cables in trays. The justification for using an enhanced automatic preaction sprinkler system to compensate for these intervening combustibles is documented in Section 2.4 of this Part. With fire detection, automatic suppression system, and fire resistant barriers, a fire in this area is contained within the room and does not present an exposure hazard to adjacent rooms. This also contributes to satisfying the requirements of Appendix R (Section III.G.2.b) for FSSD components within 711.0

8.3.60.3 OMA 1024 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in the Intake Pumping Station Room C (Middle) could potentially damage a control cable (2PM3330B) or equipment supporting the Control Air Compressor B-B (0-MTR-32-86-B) which would prevent the ability to provide air to modulate the power relief valve (2-PCV-1-12) to relieve pressure on #2 Steam Generator. The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-12 to control the pressure of #2 Steam Generator. The operator must operate 2-ISIV-1-405E2 at the SG PORV Nitrogen Station 2-L-1001 (located in room 757.0-A21), utilizing N₂ to operate the Steam Generator power relief valve if MDAFW Pump A or the TDAFW Pump is used. This OMA must be completed within 60 minutes.

The Feasibility and Reliability Evaluation for OMA 1024 following a fire in this room is covered in a bounding evaluation (Section 8.3.65).

8.3.60.4 Staffing Requirements for a Fire in IPS-C (Middle)

For a fire in IPS-C (Middle), four Unit 2 actions are performed by three AUOs and four Unit 1 actions are performed by three AUOs for a total of six AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1 and Unit 2 manual actions, should there be a fire in room IPS-C (Middle).

8.3.61 Room IPS-C (West) [Intake Pumping Station C (West)]

8.3.61.1 Fire Prevention

IPS-C of the Intake Pumping Station is a large area that is subdivided into three overlapping areas; IPS-C (East), IPS-C (Middle), and IPS-C (West). The Intake Pumping Station is constructed of reinforced concrete. The south wall, separating IPS-711.0 from the ERCW Strainer Rooms A and B (IPS-A and -B el. 722.0) has a fire resistance rating of 3-hours. The

PART VII - DEVIATIONS AND EVALUATIONS

Intake Pumping Station Room C has a floor area of 2,068 ft² and a nominal ceiling height of 13 to 16-feet.

The combustible loading of room IPS-C results in a fire severity classification of Moderate, of which approximately 83% is due to the insulation on the cables in trays. The combustible material in the room consists of plastics associated with electrical panels and boards, insulating oil associated with transformers and insulation on cables routed in cable trays. The assumed ignition sources in this room are transformers, motor control centers, lighting cabinets, and panels. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.61.2 Detection, Control, and Extinguishment

The Intake Pumping Station, elevation 711.0 is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). The room is also provided with an automatic preaction sprinkler system. Any fire that starts is quickly detected and personnel are dispatched from the MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. A larger fire activates the installed automatic preaction sprinkler system provided for the room. This extinguishes or limits the magnitude of the fire until the fire brigade arrives. A standpipe and hose station system is available in the room and in the adjacent ERCW strainer rooms for fire brigade use. The room contains intervening combustibles in the form of insulation on cables in trays. The justification for using an enhanced automatic preaction sprinkler system to compensate for these intervening combustibles is documented in Section 2.4 of this Part. With fire detection, automatic suppression system, and fire resistant barriers, a fire in this area is contained within the room and does not present an exposure hazard to adjacent rooms. This also contributes to satisfying the requirements of Appendix R (Section III.G.2.b) for FSSD components within 711.0.

8.3.61.3 OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure

A fire in the Intake Pumping Station Room C (West) could potentially damage a control cable (1PL3913A) or equipment supporting the Control Air Compressor A-A (0-MTR-32-60-A) which prevents the ability to modulate the power relief valve (2-PCV-1-23) to relieve pressure on #3 Steam Generator, which may result the implementation of this OMA. The fire safe shutdown requirement of this OMA is to open/close 2-PCV-1-23 to control the pressure of #3 Steam Generator. The operator must operate 2-ISIV-1-407E2 at the SG PORV Nitrogen Station 2-L-1000, utilizing N₂ to operate the Steam Generator power relief valve if MDAFW Pump A or the TDAFW Pump is used. This OMA must be completed within 60 minutes. This Action is performed in room 757.0-A24.

The Feasibility and Reliability Evaluation for OMA 1023 following a fire in this room is covered in a bounding evaluation (Section 8.3.64).

8.3.61.4 Staffing Requirements for a Fire in IPS-C (West)

For a fire in IPS-C (West), one "common" action is performed by one AUO, four Unit 2 actions are performed by three AUOs and four Unit 1 actions are performed by three AUOs for a total of

PART VII - DEVIATIONS AND EVALUATIONS

seven AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1 and Unit 2 manual actions, should there be a fire in room IPS-C (West).

8.3.62 Bounding Evaluation for OMA 1016 – Operate Steam Generator Relief Valves to Control Secondary Pressure

This is a bounding evaluation that shows it is both feasible and reliable to complete OMA 1016 following a fire in the following rooms:

Room Number	Part VII Section Number	Room Number	Part VII Section Number
757.0-A10	8.3.25	772.0-A5	8.3.39
757.0-A17	8.3.27	772.0-A8	8.3.41
757.0-A22	8.3.29	772.0-A13	8.3.46
757.0-A24	8.3.31	772.0-A15 East	8.3.48
757.0-A28	8.3.34	772.0-A15 West	8.3.49
772.0-A2 East	8.3.36	782.0-A1	8.3.51
		782.0-A2	8.3.52

This OMA is performed for a fire in the rooms listed above located on elevations 713.0' thru 782.0' of the Auxiliary Building. This OMA is performed in room 757.0-A21. The operator must operate SG power operated relief valves (PORV) to control secondary pressure and to provide a controlled means of removing decay heat. This action isolates the normal air supply, and enabling a local N₂ supply. Manual air valves are then manipulated to regulate the flow of nitrogen and control the operation of the SG Power Operated Relief Valve (2-PCV-1-5). This action is required for safe shutdown when using either MDAFW Pump A or the TDAFW Pump.

OMA 1016 is both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 60-minutes before the OMA must be completed. The analyzed time estimated to travel and perform the action is 25 minutes. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The demonstrated transit time plus time to perform the action was 12 minutes 6 seconds. There is adequate time available to perform this action.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel and perform the action (25 minutes) provides 35 minutes (140%) margin and the demonstrated validation (12 minutes 6 seconds) provides 47 minutes 54 seconds (>300%) margin. There is adequate time available for the AUO to reliably perform this action.

PART VII - DEVIATIONS AND EVALUATIONS

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of this OMA. If they were unavailable, 8-hour emergency battery pack lighting is provided; therefore, there is adequate lighting to access the local panel and perform the OMA. Because the operator does not have to traverse or enter the fire zone, there are no impediments associated with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

d. Equipment Functionality and Accessibility

Equipment needed for this manual action is functional and accessible. The fire that results in the fire-induced damage requiring implementation of this OMA is contained within the associated room. Also, based on the fire areas listed above that require the implementation of this OMA, there are no fire areas adjacent to or on the same elevation where this OMA is performed. Therefore, a fire in the areas listed above does not affect the functionality and accessibility of equipment needed for this OMA.

e. Available Indications

Available local indications for monitoring N₂ cylinder pressure and regulator adjustment, as well as MCR SG pressure indications, are adequate.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is expected to be needed for the Unit 2 actions. Spare N₂ cylinders for SG PORV control are available, if needed. The reliability of the N₂ station is assured by the Operational Requirements and Testing and Inspection program as described in Part II, Section 14.10.

h. Personnel Protection Equipment

Only standard PPE is needed to perform this OMA.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.63 Bounding Evaluation for OMA 1022 – Operate Steam Generator Relief Valves to Control Secondary Pressure

This is a bounding evaluation that shows it is both feasible and reliable to complete OMA 1022 following a fire in the following rooms:

PART VII - DEVIATIONS AND EVALUATIONS

Room Number	Part VII Section Number	Room Number	Part VII Section Number
713.0-A1A	8.3.4	772.0-A1	8.3.35
713.0-A27	8.3.6	772.0-A2 West	8.3.37
737.0-A5S	8.3.14	772.0-A4	8.3.38
737.0-A9M	8.3.15	772.0-A8	8.3.41
737.0-A9N	8.3.16	772.0-A9	8.3.42
737.0-A9S	8.3.17	772.0-A10	8.3.43
757.0-A4	8.3.22	772.0-A14	8.3.47
757.0-A16	8.3.26	772.0-A16	8.3.50
757.0-A23	8.3.30	782.0-A3	8.3.53
757.0-A27	8.3.33	782.0-A4	8.3.54

This OMA is performed for a fire in the rooms listed above located on elevations 713.0' through 782.0' of the Auxiliary Building. This OMA is performed in room 757.0-A24. When MD AFW Pump B or the TD AFW Pump is used, this OMA is required for controlling plant cooldown. A nitrogen (N₂) cylinder and supply valve (2-ISIV-1-402E2) are used for SG Power Operator Relief Valve (2-PCV-1-30) control at the N₂ station in room 757.0-A24. This action isolates the normal air supply, and enabling a local N₂ supply. Manual air valves are then manipulated to regulate the flow of nitrogen and control the operation of the SG PORVs. This action is one of two matching OMAs that must be completed within 60 minutes in room 757.0-A24 for SG PORV control.

OMA 1022 is both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 60-minutes before the OMA must be completed. The analyzed time estimated to travel and perform the action is 28 minutes. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The demonstrated time for travel from the MCR to the nitrogen station and to perform the actions was 12-minutes 6 seconds. Room 757.0-A24 would not be affected by a fire in any of the listed rooms. There is adequate time available to perform this action.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated for travel to the N₂ station in room 757.0-A24 and to perform the action (28-minutes) provides 32-minutes (114%) margin. The demonstrated time to travel to and perform the action was 12 minutes 6 seconds which leaves a margin of 47 minutes 54 seconds. This margin provides sufficient time to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of this OMA. If they were unavailable, 8-hour emergency battery pack lighting is provided; therefore, there is adequate lighting to access the local panel and perform the OMA. Because the operator does

PART VII - DEVIATIONS AND EVALUATIONS

not have to traverse or enter the fire zone, there are no impediments associated with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

d. Equipment Functionality and Accessibility

Equipment needed for this manual action is functional and accessible. The postulated fire that results in the fire-induced damage requiring implementation of this OMA is contained within the associated room, none of which are adjacent to the room where this OMA is performed. Therefore, a fire in the areas listed above does not affect the functionality or accessibility of equipment needed to perform this OMA.

e. Available Indications

Available local indications for monitoring N₂ cylinder pressure and regulator adjustment, as well as MCR SG pressure indications, are adequate.

f. Communications

Adequate communications between the location of the OMA and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is expected to be needed for Unit 2 actions. Spare N₂ cylinders for SG PORV control are available, if needed. The reliability of the N₂ station is assured by the Operational Requirements and Testing and Inspection program as described in Part II, Section 14.10.

h. Personnel Protection Equipment

Only standard PPE is needed to perform this OMA. Also, based on the location where this OMA is performed and the fire areas listed above, the AUO would not have to traverse or enter any fire areas to perform this action, therefore standard PPE is sufficient to accomplish this OMA.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.64 Bounding Evaluation for OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure

This is a bounding evaluation that shows it is both feasible and reliable to complete OMA 1023 following a fire in the following rooms:

Room Number	Part VII Section Number	Room Number	Part VII Section Number
713.0-A1A	8.3.4	772.0-A2 West	8.3.37
713.0-A27	8.3.6	772.0-A4	8.3.38
2ANN	8.3.7	772.0-A6	8.3.40

PART VII - DEVIATIONS AND EVALUATIONS

Room Number	Part VII Section Number	Room Number	Part VII Section Number
737.0-A5M	8.3.12	772.0-A8	8.3.41
737.0-A5N	8.3.13	772.0-A9	8.3.42
737.0-A5S	8.3.14	772.0-A10	8.3.43
737.0-A9M	8.3.15	772.0-A12	8.3.45
737.0-A9N	8.3.16	772.0-A14	8.3.47
737.0-A9S	8.3.17	772.0-A16	8.3.50
757.0-A4	8.3.22	782.0-A3	8.3.53
757.0-A16	8.3.26	782.0-A4	8.3.54
757.0-A21	8.3.28	DBIPS-A	8.3.55
757.0-A23	8.3.30	IPS-A	8.3.57
757.0-A27	8.3.33	IPS-C (WEST)	8.3.61
772.0-A1	8.3.35		

This OMA is performed for a fire in the rooms listed above located on elevations 713.0' thru 782.0' of the Auxiliary Building and the Intake Pumping Station. This OMA is performed in room 757.0-A24. The operator must operate SG power operated relief valves (PORVs) to control secondary pressure and to provide a controlled means of removing decay heat. This action isolates the normal air supply, and enabling a local N₂ supply. Manual air valves are then manipulated to regulate the flow of nitrogen and control the operation of the SG PORV (2-PCV-1-23). This action is required for safe shutdown when using either MDAFW Pump A or the TDAFW Pump.

OMA 1023 is both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 60-minutes before the OMA must be completed. The analyzed time estimated to travel and perform the action is 28 minutes. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The demonstrated transit time and time to perform the action was 12 minutes 6 seconds. Room 757.0-A24 would not be affected by a fire in any of the listed rooms. There is adequate time available to perform this action.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel and perform the action (28 minutes) provides 32 minutes (114%) margin. The demonstrated time to travel to and perform the action was 12 minutes 6 seconds which leaves a margin of 47 minutes 54 seconds. This margin provides sufficient time to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of this OMA. If they were unavailable, 8-hour emergency battery pack lighting is provided; therefore, there is adequate lighting to access the local panel and perform the OMA. Because the operator does

PART VII - DEVIATIONS AND EVALUATIONS

not have to traverse or enter the fire zone, there are no impediments associated with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

d. Equipment Functionality and Accessibility

The fire that results in the fire-induced damage requiring implementation of this OMA is contained within the associated room. Also, based on the fire areas listed above that require implementation of this OMA, there are no fire areas adjacent to the location where this OMA is performed. Therefore, a fire in the areas listed above does not affect the functionality and accessibility of equipment needed to perform this OMA.

e. Available Indications

Available local indications for monitoring N₂ cylinder pressure and regulator adjustment, as well as MCR SG pressure indications, are adequate.

f. Communications

Adequate communications between the location of the OMA and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is expected to be needed for Unit 2 actions. Spare N₂ cylinders for SG PORV control are available, if needed. The reliability of the N₂ station is assured by the Operational Requirements and Testing and Inspection program as described in Part II, Section 14.10.

h. Personnel Protection Equipment

Based on the location where this OMA is performed and the fire areas listed above, the AUO does not traverse or enter any fire areas to perform this action, therefore standard PPE is sufficient to accomplish this OMA.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.65 Bounding Evaluation for OMA 1024 – Operate Steam Generator Relief Valves to Control Secondary Pressure

This is a bounding evaluation that shows it is both feasible and reliable to complete OMA 1024 following a fire in the following rooms:

PART VII - DEVIATIONS AND EVALUATIONS

Room Number	Part VII Section Number	Room Number	Part VII Section Number
737.0-A12	8.3.18	772.0-A11	8.3.44
757.0-A3	8.3.21	772.0-A13	8.3.46
757.0-A10	8.3.25	772.0-A15 East	8.3.48
757.0-A17	8.3.27	772.0-A15 West	8.3.49
757.0-A22	8.3.29	782.0-A1	8.3.51
757.0-A24	8.3.31	782.0-A2	8.3.52
757.0-A26	8.3.32	DBIPS-B	8.3.56
757.0-A28	8.3.34	IPS-B	8.3.58
772.0-A2 East	8.3.36	IPS-C (East)	8.3.59
772.0-A8	8.3.41	IPS-C (MIDDLE)	8.3.60

This OMA is performed for a fire in the rooms listed above located on elevations 737.0' thru 782.0' of the Auxiliary Building and the Intake Pumping Station. This OMA is performed in room 757.0-A21. The operator must operate the SG power operated relief valves (PORVs) to control secondary pressure and to provide a controlled means of removing decay heat. This action isolates the normal air supply, and enabling a N₂ supply. Manual air valves are then manipulated to regulate the flow of nitrogen and control the operation of the SG PORV (2-PCV-1-12). This action is required for safe shutdown when using either MDAFW Pump A or the TDAFW Pump.

OMA 1024 is both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 60-minutes before the OMA must be completed. The analyzed time estimated to travel and perform the action is 25 minutes. Verification and validation for common 0- AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The demonstrated transit time and time to perform the action was 12 minutes 6 seconds. There is adequate time available to perform the action.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel and perform the action (25 minutes) provides 35 minutes (140%) margin and the demonstrated validation (12 minutes 6 seconds) provides 47 minutes 54 seconds (>300%) margin. An AUO would have sufficient time to ensure reliability.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of this OMA. If they were unavailable, 8-hour emergency battery pack lighting is provided; therefore, there is adequate lighting to access the local panel and perform the OMA. Because the operator does not have to traverse or enter the fire zone, there are no impediments associated with fire suppression or firefighting activities. There are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

d. Equipment Functionality and Accessibility

PART VII - DEVIATIONS AND EVALUATIONS

The fire that results in the fire-induced damage requiring implementation of this OMA is contained within the associated room. Also, based on the fire areas listed above that require implementation of this OMA, there are no fire areas adjacent to the location where this OMA is performed. Therefore, a fire in the areas listed above does not affect the functionality and accessibility of equipment needed to perform this OMA.

e. Available Indications

Available local indications for monitoring N₂ cylinder pressure and regulator adjustment, as well as MCR SG pressure indications, are adequate.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is expected to be needed for Unit 2 actions. Spare N₂ cylinders for SG PORV control are available, if needed. The reliability of the N₂ station is assured by the Operational Requirements and Testing and Inspection program as described in Part II, Section 14.10.

h. Personnel Protection Equipment

The AUO needs only standard PPE to perform this OMA. Also, based on the location where this OMA is performed and the fire areas listed above, the AUO does not traverse or enter any fire areas to perform this action, therefore standard PPE is sufficient to accomplish this OMA.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.66 Room 692.0-A1A WEST (Auxiliary Building Corridor)

8.3.66.1 Fire Prevention

The Auxiliary Building Corridor, 692.0-A1 has been subdivided into major volumes 692.0-A1A, 692.0-A1B and 692.0-A1C. The walls, floor, ceiling and penetration seals separating 692.0-A1A from other fire areas have a fire resistance rating of 2-hours or greater. The fire doors and fire dampers in this room are fire resistance rated for 3-hours. The entire Auxiliary Building Corridor on elevation 692.0 has a floor area of 11,903 ft² and a nominal ceiling height of 19-feet.

The presence of intervening combustibles (insulation on cables in trays) in 692.0-A1 is justified and documented in Section 2.4 of this Part. The openings in the ceiling of room 692.0-A1A (Stairwell No. 6 and elevator door opening) are justified and documented in Section 2.6 of this Part. There are two round spiral welded HVAC ducts that penetrates the floor of 692.0-A1B from 676.0-A1. These combine into one duct that continues through the ceiling of 692.0-A1B onto elevation 713. The penetrations are not provided with fire dampers. This duct work is part

PART VII - DEVIATIONS AND EVALUATIONS

of the Emergency Gas Treatment System (EGTS). Spiral welded pipe is treated like a pipe and is provided with fire rated penetration seals between the pipe and the sleeve. Justification for treating round spiral welded HVAC ducts as pipe is documented in Section 2.6 of this Part.

The combustible loading of the Auxiliary Building Corridor, all volumes of 692.0-A1 results in a fire severity classification of Moderate. The combustible material in the room consists of lube oil associated with pumps and valves, plastics associated with electrical panels and boxes, insulating oil associated with transformers; insulation on cables routed in cable trays and anticipated amounts of radwaste trash and laundry. Over 97% of the combustibles in this room come from insulation on cable trays. The assumed ignition sources in this room are transformers, electrical switchgear and panels, radiation monitors, and pumps. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures needed when transient combustibles or ignition sources are in a room.

8.3.66.2 Detection, Control, and Extinguishment

The Auxiliary Building Corridor is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). The corridor is also provided with an installed automatic sprinkler system. The tunnel to the RWST on the far west side of the room is not provided with detection or suppression. This is justified and documented in Section 3.1.1 of this Part.

Any fire that starts in area 692.0-A1A would be quickly detected and personnel would be dispatched from the MCR to investigate the detector alarm. A larger fire would activate the installed automatic sprinkler system provided for the room. This would extinguish or limit the magnitude of the fire until the fire brigade arrived. A standpipe and hose station system is available in 692.0-A1B, 692.0-A1C, and 713.0-A1A for fire brigade use. This room is also provided with enhanced sprinkler coverage below obstructions as documented in Attachment 1 of this Part. With fire detection, an enhanced automatic suppression system, and fire resistance barriers, a fire in this area would be either extinguished or contained until the fire brigade responded.

8.3.66.3 Unit 1 OMAs 1598 and 1599 – Establish RCP Seal Injection Flowpath

These OMAs are necessary if a fire in the immediate vicinity of 1-PNL-276-L112, in 692.0-A1A, damaged instrumentation that could disable the pneumatic stop that ensures a minimum flow through 1-FCV-62-93 for Reactor Coolant Pump seal cooling. Thermal barrier cooling would provide this capability for up to 75 minutes before OMAs 1598 and 1599 have to be performed. For OMAs 1598 and 1599, an operator enters room 692.0-A10 to close valve, 1-ISV-62-533, and open valve, 1-ISV-62-534, respectively, using handwheels. It is assumed that the operator may be delayed access to room 692.0-A10 for up to 60 minutes due to a fire located in 692.0-A1A (West) near Panel 1-PNL-276-L112 which will leave 15 minutes to perform the action. The panel does not constitute a credible ignition source and is not located within the fire damage Zone of Influence of any credible ignition source in the room. Given the provisions for fire detection and suppression, as well as the lack of credible ignition sources in the vicinity of this panel, there are no credible fires in 692.0-A1A for which these manual action are necessary. The operator will be able to enter room 692.0-A10 in 60 minutes or less and has at least 15 minutes to perform the actions.

OMAs 1598 and 1599 are both feasible and reliable based on NUREG-1852 criteria, as follows:

PART VII - DEVIATIONS AND EVALUATIONS

a. Adequate Time Available to Perform Actions

The operator has 75-minutes before the OMAs must be completed. The analyzed travel and performance time was estimated to be 15 minutes for these actions. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The demonstrated transit time and time to perform the action was 6 minutes 12 seconds; therefore, there is adequate time to perform the action.

b. Adequate Time Available to Ensure Reliability

It is assumed the AUO will obtain a SCBA when originally mobilized and travel to a safe location near the room during the 60 minutes allowed for fire suppression activities. For a worst case condition the AUO will have 15 minutes to perform the action which takes 6 minutes 12 seconds to complete. This provides a margin of 8 minutes 48 seconds which is adequate time available to ensure the reliability of performing these actions.

c. Environmental Factors

Normal and Standby lighting for the access routes and at the location of these OMAs is assumed to be affected; therefore, 8-hour emergency battery pack lighting is provided. For that reason, there is adequate lighting to access the components and perform the necessary OMAs. The AUO would also be expected to carry a portable lantern, which is readily available. In order to perform these OMAs, the operator will have to traverse the fire zone. There may be impediments associated with fire suppression or firefighting activities, such as smoke, noise and water; however, these impediments would not prevent the operator from performing these OMAs. There are no other adverse environmental factors, such as radiation, associated with this OMA.

d. Equipment Functionality and Accessibility

The postulated fire in 692.0-A1A (West) will not impact the functionality or prevent the accessibility of the components needed to be manually operated in room 692.0-A10. The fire will be contained within room 692.0-A1.

e. Available Indications

Available local indications for ensuring valve position and MCR indications for control of CVCS charging/seal injection flow is adequate.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is necessary for these actions.

PART VII - DEVIATIONS AND EVALUATIONS

h. Personnel Protection Equipment

This action is to be performed in a room near the fire location; therefore, the AUO may be required to use the SCBA, which was obtained when originally mobilized.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.66.4 Staffing Requirements for a Fire in 692.0-A1A WEST

For a fire in 692.0-A1A WEST, three Unit 2 actions are performed by two AUOs and seven Unit 1 actions are performed by four AUOs for a total of six AUOs. Therefore, the staffing of eight AUOs is more than sufficient to accomplish all of the Unit 1 and Unit 2 manual actions, should there be a fire in room 692.0-A1A WEST.

8.3.67 Room 692.0-A1A EAST (Auxiliary Building Corridor)

8.3.67.1 Fire Prevention

The Auxiliary Building Corridor, 692.0-A1 has been subdivided into major volumes 692.0-A1A, 692.0-A1B and 692.0-A1C. The walls, floor, ceiling and penetration seals separating 692.0-A1A from other fire areas have a fire resistance rating of 2-hours or greater. The fire doors and fire dampers in this room are fire resistance rated for 3-hours. The entire Auxiliary Building Corridor on elevation 692.0 has a floor area of 11,903 ft² and a nominal ceiling height of 19-feet.

The presence of intervening combustibles (insulation on cables in trays) in 692.0-A1 is justified and documented in Section 2.4 of this Part. The openings in the ceiling of room 692.0-A1A (Stairwell No. 6 and elevator door opening) are justified and documented in Section 2.6 of this Part. There are two round spiral welded HVAC ducts that penetrates the floor of 692.0-A1B from 676.0-A1. These combine into one duct that continues through the ceiling of 692.0-A1B onto elevation 713. The penetrations are not provided with fire dampers. This duct work is part of the Emergency Gas Treatment System (EGTS). Spiral welded pipe is treated like a pipe and is provided with fire rated penetration seals between the pipe and the sleeve. Justification for treating round spiral welded HVAC ducts as pipe is documented in Section 2.6 of this Part.

The combustible loading of the Auxiliary Building Corridor, all volumes of 692.0-A1 results in a fire severity classification of Moderate. The combustible material in the room consists of lube oil associated with pumps and valves, plastics associated with electrical panels and boxes, insulating oil associated with transformers; insulation on cables routed in cable trays and anticipated amounts of radwaste trash and laundry. Over 97% of the combustibles in this room come from insulation on cable trays. The assumed ignition sources in this room are transformers, electrical switchgear and panels, radiation monitors, and pumps. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures needed when transient combustibles or ignition sources are in a room.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.67.2 Detection, Control, and Extinguishment

The Auxiliary Building Corridor is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). The corridor is also provided with an installed automatic sprinkler system. The tunnel to the RWST on the far west side of the room is not provided with detection or suppression. This is justified and documented in Section 3.1.1 of this Part.

Any fire that starts in area 692.0-A1A would be quickly detected and personnel would be dispatched from the MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. A larger fire would activate the installed automatic sprinkler system provided for the room. This would extinguish or limit the magnitude of the fire until the fire brigade arrived. A standpipe and hose station system is available in 692.0-A1B, 692.0-A1C, and 713.0-A1A for fire brigade use. This room is also provided with enhanced sprinkler coverage below obstructions as documented in Attachment 1 of this Part. With fire detection, an enhanced automatic suppression system, and fire resistance barriers, a fire in this area would be either extinguished or contained until the fire brigade responded.

8.3.67.3 Unit 1 OMAs 1397 and 1398 – Establish RCP Seal Injection Flowpath

These OMAs are necessary if a fire in the immediate vicinity of 1-PNL-276-L112, in 692.0-A1A, damaged instrumentation that could disable the pneumatic stop that ensures a minimum flow through 1-FCV-62-93 for Reactor Coolant Pump seal cooling. Thermal barrier cooling would provide this capability for up to 75 minutes before OMAs 1397 and 1398 have to be performed. For OMAs 1397 and 1398, an operator enters room 692.0-A9 to close valve, 1-ISV-62-527, and open valve, 1-ISV-62-526, respectively, using handwheels. It is assumed that the operator may be delayed access to room 692.0-A9 for up to 60 minutes due to a fire located in 692.0-A1A (East) near Panel 1-PNL-276-L112 which will leave 15 minutes to perform the action. The panel does not constitute a credible ignition source and is not located within the fire damage Zone of Influence of any credible ignition source in the room. Given the provisions for fire detection and suppression, as well as the lack of credible ignition sources in the vicinity of this panel, there are no credible fires in 692.0-A1A for which these manual action are necessary. The operator will be able to enter room 692.0-A9 in 60 minutes or less and has at least 15 minutes to perform the actions.

OMAs 1397 and 1398 are both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 75-minutes before the OMAs must be completed. The analyzed travel and performance time was estimated to be 15 minutes for these actions. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The demonstrated transit time and time to perform the action was 6 minutes 12 seconds; therefore, there is adequate time to perform the action.

PART VII - DEVIATIONS AND EVALUATIONS

b. Adequate Time Available to Ensure Reliability

It is assumed the AUO will obtain a SCBA when initially mobilized and travel to a safe location near room 692.0-A9 during the 60 minutes allowed for fire suppression activities. For a worst case condition the AUO will have 15 minutes to perform the action which takes 6 minutes 15 seconds to complete. This provides a margin of 8 minutes 45 seconds which is adequate time available to ensure the reliability of performing these actions.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of these OMAs. If they were unavailable, 8-hour emergency battery pack lighting is provided; therefore, there is adequate lighting to access room 692.0-A9 and perform the necessary OMAs. The AUO would also be expected to carry a portable lantern, which is readily available. The room with the postulated fire, room 692.0-A1A (East), is adjacent to the room where the OMAs will be performed, room 692.0-A9. The access to room 692.0-A9 is via the 692.0-A1A (West) which could potentially be affected by the firefighting activities. There may be smoke as well as fire hoses and water in the access path. However, these factors would not prevent the performance of the OMAs.

d. Equipment Functionality and Accessibility

The postulated fire in 692.0-A1A (East) will not impact the functionality or prevent the accessibility of the components needed to be manually operated in room 692.0-A9. The fire will be contained within room 692.0-A1.

e. Available Indications

Available local indications for ensuring valve position and MCR indications for control of CVCS charging/seal injection flow are adequate.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is needed for these OMAs.

h. Personnel Protection Equipment

This action is to be performed in a room near the fire location; therefore, the AUO may be required to use the SCBA, which was obtained when originally mobilized.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

PART VII - DEVIATIONS AND EVALUATIONS

8.3.67.4 Staffing Requirements for a Fire in Room 692.0-A1A EAST

For a fire in 692.0-A1A EAST, three Unit 2 actions are performed by two AUOs and six Unit 1 actions are performed by three AUOs for a total of five AUOs. The staffing of eight AUOs is more than sufficient to accomplish all of the needed Unit 1 and Unit 2 manual actions, should there be a fire in room 692.0-A1A EAST.

8.3.68 Room 692.0-A10 (Unit 1 Charging Pump 1B-B)

8.3.68.1 Fire Prevention

The Charging Pump 1B-B Room, 692.0-A10, is bounded by 2-hour fire rated regulatory fire barriers. Openings in these barriers are provided with fire doors, dampers and penetration seals that have a rating at least equivalent to the barriers. The room has a floor area of 412 ft² and a nominal ceiling height of 19 feet. The combustible loading in room 692.0-A10 results in a fire severity classification of Low. Lube oil for Charging Pump 1B-B is 86% of the total combustible material in the room. The remaining 14% is from various plastic associated with emergency lighting and light covers, as well as assumed Rad Waste trash and laundry. The charging pump is the only credible ignition source in the room. NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures necessary when transient combustibles or ignition sources are in a room.

8.3.68.2 Detection, Control, and Extinguishment

The Charging Pump 1B-B Room is provided with ionization smoke detectors that alarm in the Main Control Room (MCR). An automatic sprinkler system is provided for the room, except in the entrance labyrinth (Section 3.1 of this Part provides justification and documentation of acceptance of the lack of suppression in the labyrinth). However, given that this room is a separate fire area with low combustible loading, the fire barrier ratings of the room, and the lack of redundant safe shutdown equipment in the room, a fire in this area/room will not endanger other safety-related equipment required for safe plant shutdown.

Any fire that starts in this area would be quickly detected and personnel would be dispatched from the MCR to investigate the detector alarm. Portable extinguishers are available for extinguishing any small credible fire. A larger fire would activate the installed automatic, preaction suppression system provided for the room. This would extinguish or limit the magnitude of the fire until the fire brigade arrived. A standpipe and hose station system is also available in the adjacent room (692.0-A1) for fire brigade use. Even if the postulated fire were to start and not be extinguished, the fire rating of the room's barriers would contain the fire and not allow it to propagate to adjacent rooms. Therefore, a fire in this room would be contained within the room and not present an exposure hazard to any adjacent rooms.

8.3.68.3 Unit 1 OMAs 1397 and 1398 – Isolate Normal Charging/Safety Injection Flowpath

The Charging Header Flow Control Valve (1-FCV-62-93) is in room 692.0-A10 and could potentially be damaged by a fire in this room, inhibiting the ability to maintain minimum flow through the valve. The fire safe shutdown requirement is to isolate normal charging/safety

PART VII - DEVIATIONS AND EVALUATIONS

injection flow and provide a RCP seal injection flow path within 75 minutes by operation of valves 1-ISV-62-526 and 1-ISV-62-527, located in room 692.0-A9.

OMAs 1397 and 1398 are both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Actions

The operator has 75-minutes before the OMA's must be completed. The analyzed travel and performance time was estimated to be 15 minutes for these actions. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The demonstrated transit time and time to perform the action was 6 minutes 12 seconds; therefore, there is adequate time to perform the action.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel and perform the actions (15 minutes) provides 60 minutes (400%) margin and the demonstrated validation (6 minutes 15 seconds) provides 68 minutes 45 seconds (>500%) margin. The operator will have obtained a SCBA and there is adequate time available to ensure reliability of performing these actions.

c. Environmental Factors

Normal and Standby lighting is provided for the access routes and at the location of these OMA's. If they were unavailable, 8-hour emergency battery pack lighting is provided; therefore, there is adequate lighting to access room 692.0-A9 and perform the necessary OMA's. The room with the postulated fire, room 692.0-A10, is adjacent to the room where the OMA's will be performed, room 692.0-A9. The access to room 692.0-A9 is via the 692.0-A1A corridor which could potentially be affected by the fire or firefighting activities. There may be smoke from room 692.0-A10, as well as fire hoses and water in the access path. However, these factors would not prevent the performance of the OMA's.

d. Equipment Functionality and Accessibility

The fire that results in the fire-induced damage requiring implementation of these OMA's will be contained within room 692.0-A10. Though the fire is adjacent to the room where the OMA's are being performed, it would not affect the functionality and accessibility of the equipment needed to perform these OMA's.

e. Available Indications

Available local indications for ensuring valve position and MCR indications for control of CVCS charging/seal injection flow are adequate.

f. Communications

Adequate communications between the location of the OMA's and the MCR is provided by the communication system described in Part II, Section 12.8.

PART VII - DEVIATIONS AND EVALUATIONS

g. Portable Equipment

No portable equipment is needed for these OMAs.

h. Personnel Protection Equipment

This action is to be performed in a room near the fire location; therefore, the AUO may be required to use the SCBA, which was obtained when originally mobilized.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.3.68.4 Staffing Requirements for a Fire in Room 692.0-A10

For a fire in 692.0-A10, three Unit 2 actions are performed by two AUOs and five Unit 1 actions are performed by two AUOs for a total of four AUOs. The staffing of eight AUOs is more than sufficient to accomplish all of the needed Unit 1 and Unit 2 manual actions, should there be a fire in room 692.0-A10.

8.4 Re-Entry into Room of Fire Origin for Unit 2 Important to Safe Shutdown Operator Manual Actions

8.4.1 Fire Zone 713.0-A19 (Unit 2 Pipe Gallery)

8.4.1.1 Fire Prevention

The Unit 2 Pipe Gallery is constructed of reinforced concrete. The floor, walls and ceiling of the Pipe Gallery that separate it from adjacent rooms of the Auxiliary Building are 2-hour fire resistive barriers. The wall that separates it from the Unit 2 Reactor Building is a 3-hour rated fire resistive barrier. Room 713.0-A19 has a floor area of 2,244 ft² and a nominal ceiling height of 22-ft.

The fire dampers are rated for the barriers. The doors are fire rated door assemblies that are equivalent to or greater than the barrier fire rating. Penetration seals are qualified fire rated seals that provide fire resistive protection that is equivalent to or greater than the barriers.

The combustible loading in the room results in a fire severity classification of Moderate. The combustible material consists of charcoal in the Purge Air Exhaust HEPA filter assembly (15% of the combustible material in the room), lubricant associated with valves, fans and motors, plastics associated with insulation on cables routed in cable trays, electrical control panels, two small dry type transformers and emergency lights and the small quantity of combustibles associated with the Radiation Protection entry station. The insulation on the cables in the cable trays accounts for 81% of the in situ combustible load. The valve motors, electrical panels, small dry type transformers and emergency lights are not considered to be credible ignition sources (See Section 4.10). It is concluded that no credible fire could occur that would result in these actions being required.

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant

PART VII - DEVIATIONS AND EVALUATIONS

quantities of combustible material or ignition sources into the rooms and the compensatory measures required when transient combustibles or ignition sources are required in a room.

8.4.1.2 Detection, Control, and Extinguishment

The room is provided with ionization smoke detectors that alarm in the MCR and an automatic sprinkler system. The charcoal filters inside the Purge Air Exhaust Filter Assembly are also provided with fire detection and automatic suppression. The fire rated barriers of the rooms are more than adequate to contain any postulated fire that might occur in the room. The combination of smoke detection system, automatic sprinklers and fire rated barriers provides assurance that no credible fire in the room would propagate into an adjacent room, nor would a postulated fire in an adjacent room propagate into 713.0-A19.

A standpipe and hose station, located in an adjacent room, is readily available for Fire Brigade use. The combination of dispersed combustibles (charcoal filters are inside the metal filter housing and protected by detection and automatic suppression), insignificant ignition sources, area wide smoke detectors and automatic suppression, adequate fire barriers, and manual suppression capabilities provides assurance that even if a fire in the room occurs it is quickly detected, contained and extinguished before it causes any significant damage and therefore does not present a significant threat to fire safe shutdown.

8.4.1.3 OMA 1060 (Isolate VCT)

The fire safe shutdown requirement for a fire in 713.0-A19 is to manually close 2-LCV-62-133-B (VCT to Charging Pump Valve) to prevent VCT cover gas ingestion into the charging pump suction. This action is important for fire safe shutdown. A fire that is contained within room 713.0-A19 could potentially damage cables that prevent remote valve operation. The operator is to close the valve using the local handwheel. This action is performed in conjunction with OMA 1061, opening a breaker to allow operation of the handwheel. This OMA must be completed within 70 minutes.

This OMA is performed in the entry labyrinth to the VCT room (713.0-A20) after the fire in 713.0-A19 is extinguished. OMA 1060 is both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Action

The AUO has 70-minutes before this action located in room 713.0-A20 must be completed. The analysis estimated the action could be completed within 15-minutes. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). To perform this action the operator must pass through a portion of the same room as the fire, but since the combustible loading is insignificant, it is expected that the fire would be extinguished in less than 60 minutes, allowing the AUO to perform the OMA within the 70 minute time limit. This action was demonstrated to be completed in 5 minutes 28 seconds. Assuming the AUO was delayed for 60 minutes due to fire suppression activities this leaves 10 minutes to perform the action which takes 5 minutes 28 seconds to complete. This is adequate time to perform the action.

PART VII - DEVIATIONS AND EVALUATIONS

b. Adequate Time Available to Ensure Reliability

For OMA 1060, the operator must traverse approximately 10 feet of the same room as the fire before entering 713.0-A20 to perform the OMA. However, for worst case, the operator would have one hour for the fire to be extinguished and then access room 713.0-A20. This leaves at least 10 minutes to perform the action which was validated to be completed in 5 minutes 28 seconds. This provides 4 minutes 32 seconds (81%) margin. There is time available to ensure reliability.

c. Environmental Factors

Normal and Standby lighting for the access routes and at the location of these OMAs is assumed to be affected; therefore, 8-hour emergency battery pack lighting is provided. For that reason, there is adequate lighting to access the components and perform the necessary OMA. The AUOs are expected to carry a portable lantern, which is readily available. One AUO does have to traverse the fire zone to perform this OMA, but there are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

One AUO will have to enter room 713.0-A19 via door A75 and travel approximately 10 feet to door A76 to access the valve located in the Labyrinth area of 713.0-A20. The in situ combustible loading in 713.0-A19 is moderate. The combustible material consists of insulation on cables in trays (81%), charcoal filters in the Containment Purge Air units (15%); small quantities of lubricant in valves and radiation monitors; plastics (cable insulation) associated with various electrical panels, dry transformers, lights, etc. The room is provided with automatic suppression and detection and the charcoal filters also are provided with a separate, hazard specific, automatic suppression and detection.

It is highly unlikely that a fire could occur and even if it did, the lack of significant concentrations of in situ combustibles or ignition sources would not create a fire that prevents access through 713.0-A19 to the valve located in the Labyrinth. Any credible fire in 713.0-A19 is extinguished in less than 60 minutes and allow access to 713.0-A20 and closure of the valve within the allowable time (70 minutes).

d. Equipment Functionality and Accessibility

Room 713.0-A19 does not have any concentration of combustibles/ignition sources in the immediate vicinity of the access path through 713.0-A19 to the Labyrinth of 713.0-A20; therefore, accessibility to the valve within the allowable time (70 minutes) is assured. The automatic suppression in 713.0-A19 and the fire rated barriers separating 713.0-A19 from 713.0-A20 assures that no postulated fire in 713.0-A19 could impact the valve.

e. Available Indications

Local indications are adequate to verify valve position.

f. Communications

Adequate communications between the location of the OMAs and the MCR is provided by the communication system described in Part II, Section 12.8.

PART VII - DEVIATIONS AND EVALUATIONS

g. Portable Equipment

No portable equipment is required for this OMA.

h. Personnel Protection Equipment

This action requires traversing the room after the fire has been extinguished. The AUO will be wearing a SCBA when responding for a fire in room 713.0-A19.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

8.4.1.4 Staffing Requirements for a Fire in 713.0-A19

For a fire in room 713.0-A19, three AUOs perform six Unit 2 actions and two AUOs perform three Unit 1 actions for a total of five AUOs; therefore, the minimum staffing of eight AUOs is more than sufficient to complete the actions that may be needed if a fire were to occur in room 713.0-A19.

8.4.2 Fire Zone 713.0-A20 (Unit 2 Volume Control Tank Room and Entry Labyrinth)

8.4.2.1 Fire Prevention

The Unit 2 VCT Tank room and Entry Labyrinth are constructed of reinforced concrete. The floor, walls and ceilings that separate them from adjacent rooms of the Auxiliary Building are 2-hour fire resistive barriers. Room 713.0-A20 has a floor area of 381 ft² and a nominal ceiling height of 22-ft for the Tank room and 8-ft for the Labyrinth.

The fire dampers are rated for the barriers. The door is a fire door assembly rated for the barrier. Penetration seals are qualified fire rated seals that provide fire resistive protection that is equivalent to or greater than the barriers.

The in situ combustible loading in the area results in a fire severity classification of insignificant. The combustible material in the Tank room consists of the hydrogen in the Tank. The combustible material in the Labyrinth consists of small amounts of lubricant associated with the valves located in the Labyrinth, the light covers and the step-off pad. There are no credible ignition sources.

NPG-SPP-18.4.7, "Control of Transient Combustibles" and NPG-SPP-18.4.8, "Control of Ignition Sources (Hot Work)" defines the fire preventive measures to preclude introduction of significant quantities of combustible material or ignition sources into the rooms and the compensatory measures required when transient combustibles or ignition sources are required in a room.

8.4.2.2 Detection, Control, and Extinguishment

The VCT room is provided with ionization smoke detectors that alarm in the MCR and an automatic sprinkler system. The Auxiliary Building ventilation system will disperse hydrogen leaks up to 50 scfm and leaks greater than 50scfm are automatically isolated by the excess flow

PART VII - DEVIATIONS AND EVALUATIONS

valve. The Labyrinth is provided with fire detection, but not suppression. The fire rated barriers of the rooms are more than adequate to contain any postulated fire that might occur in the room. The combination of smoke detection system, automatic sprinklers and fire rated barriers provides assurance that no credible fire in the room would propagate into an adjacent room, nor would a postulated fire in an adjacent room propagate into 713.0-A20.

A standpipe and hose station, located in an adjacent room, is readily available for Fire Brigade use. The combination of insignificant quantities of dispersed combustibles, lack of credible ignition sources, area wide smoke detectors and automatic suppression (in the VCT Tank room), adequate fire barriers, and manual suppression capabilities provides assurance that even if a fire in the room occurs it is quickly detected, contained and extinguished before it causes any significant damage and therefore does not present a significant threat to fire safe shutdown.

8.4.2.3 OMA 1060 (Isolate VCT)

The fire safe shutdown requirement for a fire in 713.0-A20 is to manually close 2-LCV-62-133-B (VCT to Charging Pump Valve) to prevent VCT cover gas ingestion into the charging pump suction. This action is important for fire safe shutdown. A fire that is contained within room 713.0-A20 could potentially damage cables that would prevent remote valve operation. The operator is to close the valve using the local handwheel. This action is performed in conjunction with OMA 1061, opening a breaker to allow operation of the handwheel. This OMA must be completed within 70 minutes.

This OMA is performed in the entry labyrinth to the VCT room after the fire is extinguished. OMA 1060 is both feasible and reliable based on NUREG-1852 criteria, as follows:

a. Adequate Time Available to Perform Action

The AUO has 70-minutes before this action located in room 713.0-A20 must be completed. The analysis estimated the action could be completed within 40-minutes. Verification and validation for common 0-AOI-30.2 C-series procedures (Part II, Reference 4.2.90) were performed for dual unit operation and documented per the requirements of a common WBN Technical Instruction. Specifically, Technical Instruction, 0-TI-2018, "Appendix R Walkdown of Manually Operated Components Required Following a Fire", Revision 0 (Part II, Reference 4.2.92). The action was validated to be completed in 5 minutes 28 seconds. This action is to be performed in the same room as the fire and assuming the AUO will be delayed for 60 minutes (worst case) because of fire suppression activities this leaves 10 minutes to perform an action that takes 5 minutes 28 seconds to complete. There is adequate time available to perform the action.

b. Adequate Time Available to Ensure Reliability

The analyzed time estimated to travel (30-minutes) and perform the action (10-minutes) provides 30-minutes of margin to complete the 10-minute action. The demonstrated validation time to complete the action was 5 minutes 28 seconds which leaves 4 minutes 32 seconds margin. This action is performed in the same room as the fire. However, the operator has one hour for the fire to be extinguished and to don appropriate PPE, if needed, in order to perform the OMA within the 70 minute time limit. An AUO has sufficient time margin to access the room and reliably complete the action.

PART VII - DEVIATIONS AND EVALUATIONS

c. Environmental Factors

Normal and Standby lighting for the access routes and at the location of these OMAs is assumed to be affected; therefore, 8-hour emergency battery pack lighting is provided. For that reason, there is adequate lighting to access the components and perform the necessary OMAs. The AUO is also expected to carry a portable lantern, which is readily available. The AUO does have to enter the fire zones to perform this OMA, but there are no other adverse environmental factors, such as radiation or temperature, associated with this OMA.

The AUO will have to enter room 713.0-A20 via door A76 to access the valve located in the Labyrinth area of the room. The Labyrinth in room 713.0-A20 is provided with detection but not suppression (the VCT Tank room portion of 713.0-A20 is provided with automatic suppression and detection. The Labyrinth has insignificant amount of in situ combustibles and no ignition sources. It is highly unlikely that a fire could occur and even if it did, the lack of significant concentrations of in situ combustibles or ignition sources would not create a fire that prevents access to the valve located in the Labyrinth. Since there are no ignition sources in the Labyrinth and insignificant quantity of combustibles, there is no credible fire that could occur in the Labyrinth to damage the valve or prevent access to the valve within the allowable time (70 minutes).

d. Equipment Functionality and Accessibility

The Labyrinth does not contain any ignition sources and insignificant combustible load; therefore, no credible fire could occur that could damage the valve or prevent access to the valve within the allowable time frame (70 minutes).

e. Available Indications

Local indications are adequate to verify valve position.

f. Communications

Adequate communications between the location of the OMA and the MCR is provided by the communication system described in Part II, Section 12.8.

g. Portable Equipment

No portable equipment is required for this OMA.

h. Personnel Protection Equipment

The action is to be performed in the room after the fire has been extinguished; therefore the AUO is expected to be wearing a SCBA when responding for a fire in room 713.0-A20.

i. Procedures and Training

The Appendix R manual operator actions procedures (0-AOI-30.2 series) are clear, complete and current. These procedures are part of the ongoing Operator training.

PART VII - DEVIATIONS AND EVALUATIONS

8.4.2.4 **Staffing Requirements for a Fire in 713.0-A20**

A fire in the Unit 2 VCT room or the Entry Labyrinth results in three AUOs performing six Unit 2 actions and two AUOs performing three Unit 1 actions for a total of five AUOs. Therefore, the minimum staffing of eight AUOs is more than sufficient to perform the actions.

PART VII - DEVIATIONS AND EVALUATIONS

ATTACHMENT 1 SPRINKLER SYSTEM CRITERIA FOR RESOLVING INTERVENING COMBUSTIBLE CONCERNS

1.0 OBJECTIVE

The objective of these criteria is to provide additional protection for the horizontal space in between redundant trains of safe shutdown capability that contains intervening combustible materials. Per Section III.G.2b of Appendix R, redundant safe shutdown capabilities are to be separated by a horizontal distance of more than 20 feet free of intervening combustibles. Additional protection is provided by installing, in the defined areas, supplemental sprinkler protection for floor level combustibles when adequate coverage by ceiling level sprinklers is not verified by these criteria.

2.0 AREAS OF CRITERIA APPLICATION

These criteria has been applied when redundant divisions are separated by a horizontal distance of more than 20 feet, but without a minimum horizontal separation of more than 20 feet free of intervening combustibles. These criteria have been applied to any continuous 30-foot wide path located between the redundant divisions if the divisions are greater than 30-feet apart. If the redundant divisions are greater than 20-feet, but less than 30-feet apart, these criteria have been applied to the entire horizontal space between the divisions.

3.0 ACCEPTANCE CRITERIA FOR EXISTING SPRINKLER HEADS

- 3.1 Existing sprinkler heads, which have been located to produce fully developed spray patterns at the ceiling, will provide acceptable floor coverage if there are no intermediate obstructions in their patterns which are greater than 48-inch wide. When individual obstructions overlap or have less than a 4-inch flue space between them when viewed from immediately below, they shall be considered a single obstruction for determining their cumulative horizontal width. No combination of obstructions may traverse the 4-inch flue space and block more than 2-feet of any 8-feet of flue space.
- 3.2 Lateral discharge from existing sprinkler heads may be utilized for floor coverage if the portion of their discharge pattern that is being relied on has no significant obstructions. Significance shall be evaluated considering the typical shape of a sprinkler spray pattern and the obstruction guidelines of NFPA 13.
- 3.3 Acceptance of existing heads shall be based on visual observations in the plant.

PART VII - DEVIATIONS AND EVALUATIONS

ATTACHMENT 1 SPRINKLER SYSTEM CRITERIA FOR RESOLVING INTERVENING COMBUSTIBLE CONCERNS

4.0 CORRECTIVE ACTIONS

- 4.1 When Section 3.0 is not satisfied, sprinkler heads shall be provided under the obstructions utilizing one of the following options:
- a. Relocate existing heads below intermediate level obstructions if adequate coverage can be maintained at the ceiling level, or,
 - b. Add new heads below intermediate level obstructions. System adequacy shall be demonstrated using NFPA 13 pipe schedules or hydraulic calculation. If necessary, pipe sizes and supply header arrangements shall be changed to satisfy this requirement.
- 4.2 The maximum floor area that can be protected by a single sprinkler head shall be 130 square feet.
- 4.3 When more than one head must be located below obstructions, the distance between heads shall not exceed 15 feet.
- 4.4 When hydraulic calculations are used to verify sprinkler system adequacy, the calculations shall be based upon the hydraulically most remote 1500 ft² area or the area of the largest room, whichever is smaller. The systems shall be capable of discharging a density of 0.16 gpm/ft² assuming all sprinkler heads in the analyzed area are open.
- 4.5 If a system designed in accordance with the NFPA 13 pipe schedules supplies sprinkler heads in two or more rooms that are separated by 2-hour rated construction, the maximum number of heads in each room must satisfy the pipe schedule limits for pipe size with each room considered separately. If this condition is satisfied, the maximum number of heads per pipe size may be exceeded for all the rooms taken together.

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

The information which follows is a comparison of the Watts Bar Nuclear Plant (WBN) against the guidelines of Appendix A to Branch Technical Position APCS 9.5-1 Guidelines for Fire Protection for Nuclear Power Plants Docketed Prior to July 1, 1976 (August 23, 1976).

Appendix A guidelines are given in the first (left-hand) column of the following tabulations, retaining the number sequence used in BTP Appendix A. An overview of various aspects of the WBN Fire Protection Program is given in the second column, with details provided in other parts of the FPR or other plant documentation, to demonstrate conformance to the BTP Appendix A guidelines. Alternate approaches are described in the third column. The fourth column provides supplemental information, as appropriate.

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

<u>Appendix A Guidelines</u>	<u>Plant Conformance</u>	<u>Alternatives</u>	<u>Remarks</u>
<p>A. <u>Overall Requirements of Nuclear Plant Fire Protection Program</u></p> <p>A.1 <u>Personnel</u></p> <p>Responsibility for the overall fire protection program should be assigned to a designated person in the upper level of management. This person should retain ultimate responsibility even though formulation and assurance of program implementation is delegated. Such delegation of authority should be to staff personnel prepared by training and experience in fire protection and nuclear plant safety to provide a balanced approach in directing the fire protection programs for nuclear power plants. The qualification requirements for the fire protection engineer or consultant who will assist in the design and selection of equipment, inspect, and test the completed physical aspects of the system, develop the fire protecting program, assist in the fire-fighting training for the operating plant should be stated. Subsequently, the FSAR should discuss the training and the updated provisions such as fire drills provided for maintaining the competence of the station fire-fighting and operating crew, including personnel responsible for maintaining and inspecting the fire protection equipment.</p>	<p>Refer to Part II, Sections 7 and 9 of the FPR.</p>		

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

<u>Appendix A Guidelines</u>	<u>Plant Conformance</u>	<u>Alternatives</u>	<u>Remarks</u>
<p>The fire protection staff should be responsible for:</p> <ul style="list-style-type: none"> a. Coordination of building layout and systems design with fire area requirements, including consideration of potential hazards associated with postulated design basis fires, b. Design and maintenance of fire detection, suppression, and extinguishing systems. c. Fire Prevention activities. d. Training and manual fire-fighting activities of plant personnel and the fire brigade. <p>(Note: NFPA 6 - <u>Recommendations for Organization of Industrial Fire Loss Prevention</u>, contains useful guidance for organization and operation of the entire loss prevention program.)</p>	<p>Refer to Part II, Sections 7, 8, 9, 10, 11 and 12 of the FPR for details.</p>		
<p>A.2 <u>Design Bases</u></p> <p>The overall fire protection program should be based upon evaluation of potential fire hazards throughout the plant and the effect of postulated design basis fires relative to maintaining ability to perform safety shutdown functions and minimize releases to the environment.</p>	<p>Not applicable to Watts Bar.</p> <p>The overall fire protection program is designed to maintain the plant's ability to achieve and maintain safe shutdown and minimize radioactive release to the environment in the event of a fire. It reflects good fire protection engineering practice and is guided by plant fire hazard analyses and by credible fire postulations.</p>		<p>See Part X of the FPR.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>A.3 <u>Backup</u></p> <p>Total reliance should not be placed on a single automatic fire suppression system. Appropriate backup fire suppression capability should be provided.</p> <p>A.4 <u>Single Failure Criterion</u></p> <p>A single failure in the fire suppression system should not impair both the primary and backup fire suppression capability. For example, redundant fire water pumps with independent power supplies and controls should be provided.</p> <p>Postulated fires or fire protection system failures need not be considered concurrent with other plant accidents or the most severe natural phenomena.</p> <p>The effects of lightning strikes should be included in the overall plant fire protection program.</p>	<p>Provisions for fire suppression for the various plant areas avoid total reliance on any single system, automatic or manual. Appropriate backup fire suppression capability is provided. Refer to Part II, Section 12 of the FPR for details.</p> <p>A single failure of the fire protection system will not render both the primary and backup systems inoperative.</p> <p>The plant fire protection water supply system is provided with redundant pumps with independent power supplies and controls. During an Appendix R fire, some fire pumps may not be available (i.e., a fire could damage the circuitry to some of the pumps); however, a sufficient number of pumps are available to meet suppression system (including hose stream) demands for each fire assuming all required equipment is operable at the time of the fire. Refer to Part VII, Section 3 of the FPR for details.</p> <p>Postulated fires or fire protection system failures are not considered concurrent with other plant accidents or the most severe natural phenomena.</p> <p>Lightning protection is incorporated in the facility design as documented in Part II, Section 12 of the FPR.</p>		

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>A.5 <u>Fire Suppression Systems</u></p> <p>Failure or inadvertent operation of the fire suppression systems should not incapacitate safety-related systems or components. Fire suppression systems that are pressurized during normal plant operation should meet the guidelines specified in APCS Branch Technical Position 3-1, "Protection Against Postulated Piping Failures in Fluid Systems Outside Containment."</p>	<p>Selection of fire suppression systems for areas containing safety-related equipment is such that failure or inadvertent suppression system operation will not incapacitate redundant essential equipment. For example, those areas requiring water suppression are provided with preaction systems to reduce the probability of false discharge occurring as a result of a single failure or inadvertent operation.</p>		<p>Refer to Part II of the FPR for a discussion of the fire suppression systems.</p>
<p>A.6 <u>Fuel Storage Areas</u></p> <p>The fire protection program (plans, personnel, and equipment) for buildings storing new reactor fuel and for adjacent fire zones which could affect the fuel storage zone should be fully operational before fuel is received at the site. Schedule for implementation of modifications, if any, will be established on a case-by-case basis.</p>	<p>A fire protection program is operational while fuel is on site. Modifications are scheduled on a case-by-case basis.</p>		
<p>A.7 <u>Fuel Loading</u></p> <p>The fire protection program for an entire reactor unit should be fully operational prior to initial fuel loading in that reactor unit.</p>	<p>A fire protection program for the plant will be in effect before fuel load.</p>		

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>Schedule for implementation of modifications, if any, will be established on a case-by-case basis.</p> <p>A.8 <u>Multiple-Reactor Sites</u></p> <p>On multiple-reactor sites where there are operating reactors and construction of remaining units is being completed, the fire protection program should provide continuing evaluation and include additional fire barriers, fire protection capability, and administrative controls necessary to protect the operating units from construction fire hazards. The superintendent of the operating plant should have the lead responsibility for site fire protection.</p> <p>A.9 <u>Simultaneous Fires</u></p> <p>Simultaneous fires in more than one reactor need not be postulated, where separation requirements are met. A fire involving more than one reactor unit need not be postulated except for facilities shared between units.</p> <p>B. <u>Administrative Procedures, Controls and Fire Brigade</u></p> <p>B.1 Administrative procedures consistent with the need for maintaining the performance of the fire protection systems and personnel in nuclear power plants should be provided.</p>	<p>Modifications are scheduled and approved through site established procedures.</p> <p>The fire protection program provides continuing evaluations and administrative controls necessary to protect one unit from fire hazards associated with the other unit's activities and to ensure that operation (normal and accident conditions) of one unit is not impacted by the other unit's activities. Site fire protection lead responsibilities are identified in Part II of the FPR.</p> <p>The current evaluation ensures safe shutdown for fires in all areas containing equipment required for safe shutdown in the event of a fire. Simultaneous fires are not postulated.</p> <p>Administrative procedures are provided with the intent of maintaining the performance of plant fire protection systems and personnel.</p>		

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>Guidance is contained in the following publications:</p> <p>NFPA 4 - Organization for Fire Services</p> <p>NFPA 4A - Organization for Fire Department</p> <p>NFPA 6 - Industrial Fire Loss Prevention</p> <p>NFPA 7 - Management of Fire Emergencies</p> <p>NFPA 8 - Management Responsibility for Effects of Fire on Operations</p> <p>NFPA 27 - Private Fire Brigades</p> <p>B.2 Effective administrative measures should be implemented to prohibit bulk storage or combustible materials inside or adjacent to safety-related buildings or systems during operation or maintenance periods. Regulatory Guide 1.39, "Housekeeping Requirements for Water-Cooled Nuclear Power Plants," provides guidance on housekeeping, including the disposal of combustible materials.</p>		<p>The organization and qualifications of the fire brigade at WBN are identified in Part II, Section 9 of the FPR and represents WBN's method of compliance with fire brigade requirements. Refer also to Part X of the FPR.</p> <p>Plant housekeeping procedures restrict the storage of combustibles in the vicinity of safety-related equipment. Plant procedures define good housekeeping requirements, including the control, handling and disposal of combustible material.</p>	<p>WBN has reviewed the identified codes for applicability. The codes are considered not applicable. WBN's method for addressing the technical issues covered by the codes are as described in this response and as documented in Part X of the FPR.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p data-bbox="155 215 640 581">B.3 Normal and abnormal conditions or other anticipated operations such as modifications (e.g., breaking fire stops, impairment of fire detection and suppression systems) and refueling activities should be reviewed by appropriate levels of management and appropriate special actions and procedures such as fire watches or temporary fire barriers implemented to assure adequate fire protection and reactor safety. In particular:</p> <p data-bbox="252 613 640 1068">a. Work involving ignition sources such as welding and flame cutting should be done under closely controlled conditions. Procedures governing such work should be reviewed and approved by persons trained and experienced in fire protection. Persons performing and directly assisting in such work should be trained and equipped to prevent and combat fires. If this is not possible, a person qualified in fire protection should directly monitor the work and function as a fire watch.</p> <p data-bbox="252 1101 640 1304">b. Leak testing and similar procedures, such as air flow determination, should use one of the commercially available aerosol techniques. Open flames or combustion generated smoke should not be permitted.</p>	<p data-bbox="665 215 1129 427">Operations and conditions which may impair fire protection features or refueling activities are reviewed and approved by the appropriate levels of management prior to the start of work. Work areas involving welding, etc., are made fire safe and fire watches are established as required. Refer to Part II of the FPR.</p> <p data-bbox="665 613 1129 824">Prior to the start of work, a hot work (welding, cutting, etc.) permit is issued and the work area is made "fire safe." A fire watch is established in accordance with plant procedures, which require adequate training of personnel assigned as fire watches. Refer to Part II, Section 11 of the FPR for details.</p> <p data-bbox="665 1101 1129 1157">Open flames or combustion generated smoke are not permitted for leak testing.</p>		

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>c. Use of combustible material, e.g., HEPA and charcoal filters, dry ion exchange resins or other combustible supplies, in safety-related areas should be controlled. Use of wood inside buildings containing safety-related systems or equipment should be permitted only when suitable noncombustible substitutes are not available. If wood must be used, only fire retardant treated wood (scaffolding, lay down blocks) should be allowed into safety-related areas only when they are to be used immediately.</p> <p>Their possible and probable use should be considered in the fire hazard analysis to determine the adequacy of the installed fire protection systems.</p> <p>B.4 Nuclear power plants are frequently located in remote areas at some distance from public fire departments. Also, first response fire departments are often volunteer. Public fire department response should be considered in the overall fire protection program. However, the plant should be designed to be self-sufficient with respect to the fire fighting activities and rely on the public only for supplemental or backup capability.</p>	<p>The use of combustible materials in safety-related areas is kept at the minimum extent practicable. The methods for controlling combustibles are included in plant procedures. The use of wood, with appropriate considerations, is kept to the minimum extent practicable.</p> <p>Only pressure treated fire retardant wood is allowed without specific fire protection staff prior approval.</p> <p>The types of detectors (smoke & thermal) and types of suppression (sprinklers, spray, CO₂) and location of standpipe and hoses stations have been considered in the fire hazard analysis and are adequate for the possible and probable use of combustible materials.</p> <p>The primary firefighting activities at WBN are provided by the plant fire brigade. However, the contracted off-site fire department will respond to the plant to provide assistance as requested. See Part II, Section 9 of the FPR.</p>		

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>B.5 The need for good organization, training, and equipping of fire brigades at nuclear power plant sites requires effective measures be implemented to assure proper discharge of these functions. The guidance is Regulatory Guide 1.101, "Emergency Planning for Nuclear Power Plants," and should be followed as applicable.</p> <p>a. Successful fire fighting requires testing and maintenance of the fire protection equipment, emergency lighting, and communication as well as practice as brigades for the people who must utilize the equipment. A test plan that lists the individuals and their responsibilities in connection with routine tests and inspections of the fire detection and protection systems should be developed.</p> <p>The test plan should contain the types, frequency, and detailed procedures for testing. Procedures should also contain instructions on maintaining fire protection during those periods when the fire protection system is impaired or during periods of plant maintenance, e.g., fire watches or temporary hose connections to water systems.</p>	<p>Plant procedures provide for maintaining the performance of plant fire protection systems and personnel, including the periodic inspection and testing of systems, and the alternate provisions to be made during temporary impairment of systems. Refer to Part II of the FPR.</p>	<p>The organization, training, and equipping of the fire brigade is based on the guidelines provided in the NRC letter, dated August 19, 1977 - Nuclear Plant Fire Protection Functional Responsibilities, Administrative Controls, and Quality Assurance, which is used as an alternative to Regulatory Guide 1.101.</p>	

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

<u>Appendix A Guidelines</u>	<u>Plant Conformance</u>	<u>Alternatives</u>	<u>Remarks</u>
<p>b. Basic training is a necessary element to effective fire fighting operation. In order for a fire brigade to operate effectively, it must operate as a team. All members must know what their individual duties are. They must be familiar with the layout of the plant and equipment location in order to permit effective fire fighting operations during times when a particular area is filled with smoke or insufficiently lighted. Such training can only be accomplished by conducting drills several times a year (at least quarterly) so that all members of the fire brigade have had the opportunity to train as a team, testing itself in the major areas of the plant. The drills should include the simulated use of equipment in each area and should be preplanned and post-critiqued to establish the training objective of the drills and determine how well these objectives have been met. These drills should periodically (at least annually) include local fire department participation where possible. Such drills also permit supervising personnel to evaluate the effectiveness of communications within the fire brigade and with the on-scene fire team leader, the reactor operator in the control room, and the off-site command post.</p>	<p>Training of the fire brigade includes classroom instruction and drills. Initial classroom instruction includes indoctrination to the plant with identification of the fire brigade's responsibilities and study of the location of firefighting equipment and plant layout, including access and egress from specific plant areas. Classroom instruction is reinforced and complemented with quarterly drills. See Part II, Section 9 of the FPR for more details.</p>		

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

<u>Appendix A Guidelines</u>	<u>Plant Conformance</u>	<u>Alternatives</u>	<u>Remarks</u>
<p>c. To have proper coverage during all phases of operation, members of each shift crew should be trained in fire protection. Training of the plant fire brigade should be coordinated with the local fire department so that responsibilities and duties are delineated in advance. This coordination should be part of the training course and implemented into the training of the local fire department staff. Local fire department should be educated in the operational precautions when fighting fires on nuclear power plant sites. Local fire departments should be made aware of the need for radioactive protection of personnel and the special hazards associated with a nuclear power plant site.</p> <p>d. NFPA 27, "Private Fire Brigade," should be followed in organization, training, and fire drills. This standard also is applicable for the inspection and maintenance of fire fighting equipment.</p>	<p>At least one drill per year is held on a back shift for each rotating shift fire brigade. Periodically, drills may include the local fire department such that responsibilities are delineated and local fire department staff is educated in specific precautions that must be taken and the special hazards associated with the plant. See Part II, Section 9 of the FPR for more details.</p>	<p>Organization, training, and drills for the fire brigade are provided. TVA operates a fire training facility at the Nickajack location and the WBN fire brigade is required to complete the comprehensive program. As discussed in Part X, NFPA 27 is an outdated code; therefore, refer to Part II of the FPR.</p>	

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

<u>Appendix A Guidelines</u>	<u>Plant Conformance</u>	<u>Alternatives</u>	<u>Remarks</u>
<p>Among the standards referenced in this document, the following should be utilized: NFPA 194, "Standard for Screw Threads and Gaskets for Fire Hose Couplings," NFPA 196, "Standard for Fire Hose," NFPA 197, "Training Standard on Initial Fire Attacks," NFPA 601, "Recommended Manual of Instructions and Duties for the Plant Watchman on Guard." NFPA booklets and pamphlets listed on page 27-11 of Volume 8, 1971-72 are also applicable for good training references. In addition, courses in fire prevention and fire suppression which are recognized and/or sponsored by the fire protection industry should be utilized.</p> <p>C. <u>Quality Assurance Program</u></p> <p>Quality Assurance (QA) programs of applicants and contractors should be developed and implemented to assure that the requirements for design, procurement, installation, testing, and administrative controls for the fire protection program for safety-related areas as defined in this Branch Position are satisfied. The program should be under the management control of the QA organization. The QA program criteria that apply to the fire protection program should include the following:</p>	<p>The fire protection QA program at WBN is part of the TVA QA program. See Part II, Section 6 and Part II, Reference 4.2.28.</p>		

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>C.1 <u>Design, Control and Procurement Document Control</u></p> <p>Measures should be established to assure that all design-related guidelines of the branch Technical Position are included in design and procurement documents and that deviations there from are controlled.</p>	<p>The QA program includes procedures that cover design, control, and procurement documents. Design changes including procurement are reviewed for impacts to maintain compliance to fire protection program requirements. Deviations to requirements must be justified and documented appropriately.</p>		
<p>C.2 <u>Instructions, Procedures, and Drawings</u></p> <p>Inspections, tests, administrative controls, fire drills, and training that govern the fire protection program should be prescribed by documented instructions, procedures, or drawings and should be accomplished in accordance with these documents.</p>	<p>The QA program includes procedures that cover inspection, tests, administrative controls, fire drills, and training that govern the fire protection program.</p>		
<p>C.3 <u>Control of Purchased Material, Equipment and Services</u></p> <p>Measures should be established to assure that purchased material, equipment, and services conform to the procurement documents.</p>	<p>The QA program includes procedures to assure that purchased material, equipment, and services conform to procurement documents.</p>		
<p>C.4 <u>Inspection</u></p> <p>A program for independent inspection of activities affecting fire protection should be established and executed by, or for, the organization performing the activity to verify conformance with documented installation drawings and test procedures and accomplishing the activities.</p>	<p>The QA program provides for independent inspection of activities affecting fire protection to verify conformance with documented installation drawings and test procedures for accomplishing the activities.</p>		

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>C.5 <u>Test and Test Control</u></p> <p>A test program should be established and implemented to assure that testing is performed and verified by inspection and audit to demonstrate conformance with design and systems readiness requirements. The tests should be performed in accordance with written test procedures; test results should be properly evaluated and acted on.</p>	<p>The QA program assures that testing is performed and verified by inspection and audit to demonstrate conformance to design and systems readiness requirements. Testing is conducted in accordance with procedures. Test results are evaluated and acted upon as necessary.</p>		
<p>C.6 <u>Inspection, Test, and Operating Status</u></p> <p>Measures should be established to provide for the identification of items that have satisfactorily passed required tests and inspections.</p>	<p>The QA program includes provisions for the identification of items that have satisfactorily passed required tests and inspections.</p>		
<p>C.7 <u>Nonconforming Items</u></p> <p>Measures should be established to control items that do not conform to specified requirements to prevent inadvertent use of installation</p>	<p>The QA program includes procedures regarding control of nonconforming material, parts, or components.</p>		
<p>C.8 <u>Corrective Action</u></p> <p>Measures should be established to assure that conditions adverse to fire protection such as failures, malfunctions, deficiencies, deviations, defective components, uncontrolled combustible material, and nonconformances are promptly identified, reported, and corrected.</p>	<p>The QA program includes a procedure to assure that conditions adverse to fire protection are properly identified, reported, and corrected.</p>		

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>C.9 <u>Records</u></p> <p>Records should be prepared and maintained to furnish evidence that the criteria enumerated above are being met for activities affecting the fire protection program.</p>	<p>The QA program provides for the proper collection and storage of QA records.</p>		
<p>C.10 <u>Audits</u></p> <p>Audits should be conducted and documented to verify compliance with the fire protection program including design and procurement documents, instructions, procedures, drawings, inspection, and test activities.</p>	<p>The QA program provides for audits which ensure compliance with the Fire Protection Program.</p>		
<p>D. <u>General Guidelines for Plant Protection</u></p>			
<p>D.1 <u>Building Design</u></p> <p>a. Plant lay-outs should be arranged to:</p> <p>1. Isolate safety-related systems from unacceptable fire hazards, and</p>	<p>Plant lay-outs are arranged so that:</p> <p>Safety-related systems are isolated from exposure fire hazards through the use of rated fire barriers, spacial separation, automatic suppression or any combination of the above deemed adequate.</p>		<p><u>General</u> fire protection principles (e.g., isolation, separation, detection, suppression, etc.) have been applied in protecting safety-related systems from unacceptable fire hazards. This is not to be confused with the <u>specific</u> fire protection principles that are applied to equipment required for FSSD (i.e., Appendix R).</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

<u>Appendix A Guidelines</u>	<u>Plant Conformance</u>	<u>Alternatives</u>	<u>Remarks</u>
<p>2. Alternatives:</p> <p>(a) Redundant safety-related systems that are subject to damage from a single fire hazard should be protected by a combination of fire retardant coatings and fire detection and suppression systems, or</p> <p>(b) A separate system to perform the safety function should be provided.</p> <p>b. In order to accomplish 1.a above safety-related systems and fire hazards should be identified throughout the plant. Therefore, a detailed fire hazard analysis should be made. The fire hazards analysis should be reviewed and updated as necessary.</p> <p>Additional fire hazards analysis should be done after any plant modifications.</p> <p>c. Alternative guidance for constructed plants is shown in section F.3, Cable Spreading Room.</p>	<p>Redundant safety-related functions necessary to shutdown in the case of a fire are separated from each other or protected as required to preclude damage by a single fire hazard. This is done by a combination of fire retardant coatings, fire detection, and/or fire suppression systems and spacial separation.</p> <p>To verify separation and isolation of critical equipment and components, a fire hazard analysis has been performed to identify safe shutdown systems and associated fire hazards, and is updated in accordance with FSAR update requirements. See Part VI.</p> <p>Plant modifications are reviewed to ensure conformance with fire protection requirements and to identify potential impact on the fire hazard analysis of the area involved.</p>		<p>Not applicable.</p> <p>See F.3 of this section.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Rev. 29

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>d. Interior wall and structural components, thermal insulation materials and radiation shielding materials and sound-proofing should be noncombustible. Interior finishes should be noncombustible or listed by a nationally recognized testing laboratory, such as Factory Mutual or Underwriters' Laboratory, Inc., for flame spread, smoke, and fuel contribution of 25 or less in its use configuration (ASTM E-84 Test, "Surface Burning Characteristics of Building Materials").</p>		<p>The facility is designed in accordance with General Design Criterion 3, which requires that noncombustible and fire-resistant materials be used throughout the facility. Noncombustible materials are used to the extent practicable. The fire protection standard and methodology that was in effect at that time for testing carpeting (interior finishes) was ASTM E-84 and NFPA 255. In 1990, the standard and methodology for testing carpeting changed to ASTM E-648 and NFPA 253. In light of the noted standard/methodology change, TVA installed carpeting in the control room that was tested in accordance with NFPA 253 and has a critical radiant flux (CRF) factor of $\geq 0.45 \text{ W/cm}^2$. The noted CRF of 0.45 W/cm^2 is consistent with our insurer's (Nuclear Electric Insurance Limited) loss prevention standard and is also consistent with previous NRC approvals such as that documented in the Safety Evaluation Report for Texas Utilities' Comanche Peak Steam Electric Station (NUREG-0797, Supplement No. 26, Section 9.5.1.7b). Additionally, our insurer has given us permission to install carpet with a smoke development rating of ≤ 450 when tested in accordance with ASTM E-662 and NFPA 258. The small anti-static mat installed at Panel 1-M-13 is provided to prevent static discharge to the panel. A non-combustible mat was not commercially available for this installation.</p>	<p>Fuel contribution values of 50 or less are acceptable based on BTP guidelines.</p> <p>The RADCON Control Point Building installed under DCN 51766 was built with Polycarbonate "Lexan" (plexiglass) windows. These windows exceed the maximum ASTM E-84 Flame Spread Rating of ≤ 25. However, for several reasons discussed here, the plexiglass windows were determined to be the best solution. This building is elevated approximately 8 feet above the 757.0' floor and based on an experience at Sequoyah Nuclear Plant (where there was a "near-miss" incident) glass windows posed a safety concern should a window(s) fall out. Secondly, the available alternative materials also did not meet the ASTM E-84 or they did not meet the ASTM E-84 but were clouded where they could not be seen through (defeating the purpose of the building). Also, volume of material is virtually negligible relative to the volume of the 757.0' Refueling Floor. Finally and most importantly, the building itself is not used for Safe Shutdown and the plexiglass windows have no effect on the Safe Shutdown Analysis.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>e. Metal deck roof construction should be noncombustible (see the building materials directory of the Underwriters' Laboratory, Inc.) or listed as Class I by Factory Mutual System Approval Guide.</p> <p>Where combustible material is used in metal deck roofing design, acceptable alternatives are:</p> <ol style="list-style-type: none"> 1. Replace combustibles with noncombustible materials, 2. Provide an automatic sprinkler system, or 3. Provide ability to cover roof exterior and interior with adequate water volume and pressure. <p>f. Suspended ceilings and their supports should be of noncombustible construction. Concealed spaces should be devoid of combustibles.</p> <p>Adequate fire detection and suppression systems should be provided where full implementation is not practicable.</p>	<p>Metal deck roof construction at WBN is noncombustible.</p> <p>Fire detection and suppression systems are provided as described in Part II of the FPR.</p>	<p>Suspended ceilings and supports are noncombustible to the extent practicable. If not noncombustible, the material has been included in combustible loading calculations. No significant combustibles are located in concealed spaces.</p>	

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>g. High Voltage - High amperage transformers installed inside buildings containing safety-related systems should be of the dry-type or insulated and cooled with noncombustible liquid.</p> <p>Safety-related systems that are exposed to flammable oil-filled transformers should be protected from the effects of a fire by:</p> <p>i. Replacing with dry transformers that are insulated and cooled with noncombustible liquid; or</p> <p>ii. Enclosing the transformer with a three-hour fire barrier and installing automatic water spray protection.</p> <p>h. Buildings containing safety-related systems, having openings in exterior walls closer than 50 feet to flammable oil-filled transformers should be protected from the effects of a fire by:</p> <p>i. Closing of the opening to have fire resistance equal to three hours,</p> <p>ii. Constructing a three-hour fire barrier between the transformers and the wall openings, or</p>	<p>High Voltage - High amperage transformers are not installed within building spaces. Transformers installed within safety-related buildings are either dry-type or insulated and cooled with "high fire point" (>600°F) liquid.</p> <p>Openings in exterior walls of safety-related buildings are greater than 50 feet from any flammable oil-filled transformer.</p>	<p>The transformers are in locations provided with detection and automatic suppression.</p>	

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>iii. Closing the opening and providing the capability to maintain a water curtain in case of a fire.</p> <p>i. Floor drains, sized to remove expected fire fighting water flow should be provided in those areas where fixed water fire suppression systems are installed. Drains should also be provided in other areas where hand hose lines may be used if such fire fighting water could cause unacceptable damage to equipment in the area.</p> <p>Equipment should be installed on pedestals, or curbs should be provided as required to contain water and direct it to floor drains. (See NFPA 92M, "Waterproofing and Draining of Floors.")</p> <p>Drains in areas containing combustible liquids should have provisions for preventing the spread of the fire throughout the drain system.</p> <p>Water drainage from areas which may contain radioactivity should be sampled and analyzed before discharge to the environment.</p>	<p>Means of drainage is provided in the main buildings. In areas containing fire suppression systems or hose stations, drainage provided removes expected fire protection water flows or controls accumulations such that water could not cause unacceptable damage to equipment in the area.</p> <p>Areas with equipment containing significant amounts of combustible liquids have containment curbing to prevent inadvertent oil flows to surrounding areas and the drainage system. A lube oil collection system is provided for the RCPs.</p> <p>Water drainage from areas which may contain radioactivity is sampled and analyzed before discharge to the environment.</p>	<p>Additional drainage can be achieved by opening doors and diverting the water into adjacent areas (rooms).</p>	<p>Pads or curbs are provided where required. NFPA 92M-1972 is considered not applicable. WBN's method for addressing the technical issues covered by the code is as described in this response and as documented in Part X of the FPR.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>In operating plants or plants under construction if accumulation of water from the operation of new fire suppression systems does not create unacceptable consequences, drains need not be installed.</p> <p>j. Floors, walls, and ceilings enclosing separate fire areas should have minimum fire rating of three hours.</p> <p>Penetrations in these fire barriers, including conduits and piping, should be sealed or closed to provide a fire resistance rating at least equal to that of the fire barrier itself.</p>	<p>See above.</p>	<p>Fire area barriers are 2-hour or 3-hour rated. WBN fire area and room compartmentation does not always comply with the specific fire barrier rating guidelines contained in Appendix A. The differences are judged acceptable given the extensive use of suppression systems at WBN, the low combustible loading in many areas of the plant, the detailed and rigorous Appendix R analysis performed, the conservative nature of the plant design evaluations and the fire hazard analysis performed.</p> <p>Penetrations in these barriers, including conduit and piping, are generally sealed or evaluated to provide a fire-resistance rating equivalent to the required rating of the barrier, but not more than 3-hours (see Part VII for additional discussion).</p>	

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>Door openings should be protected with equivalent rated doors, frames, and hardware that have been tested and approved by a nationally recognized laboratory. Such doors should be normally closed and locked or alarmed with alarm and annunciation in the control room.</p> <p>Penetrations for ventilation systems should be protected by a standard "fire door damper" where required. (Refer to NFPA 80, "Fire Doors and Windows.")</p> <p>The fire hazard in each area should be evaluated to determine barrier requirements. If barrier fire resistance cannot be made adequate, fire detection and suppression should be provided, such as: (i) water curtain in case of fire, (ii) flame retardant, (iii) additional fire barriers.</p>	<p>A fire hazard analysis was performed and appropriate barriers, suppression, detection, etc., are provided. See Part VI and Part VII of the FPR.</p>	<p>Normally, doors, frames, and hardware in required regulatory fire barriers have a fire rating equivalent to that required of the barrier, and have been tested and approved by a nationally recognized laboratory. Fire doors have been evaluated per the requirements of NFPA 80-1975. Refer to Part X of the FPR. Fire doors are normally provided with closing mechanisms. Closing mechanisms and latches provided on doors are inspected to ensure proper functioning. Special purpose doors (e.g., flood, heavy equipment, etc.) installed in fire barriers have been evaluated by a fire protection engineer for acceptability.</p> <p>Ventilation openings through required regulatory fire barriers are typically protected by fire dampers having a rating equivalent to that required of the barrier. Even though WBN is not committed to NFPA 90A-1975, fire dampers have been evaluated per the requirements of NFPA 90A-1975. Refer to Part X of the FPR. Penetrations for ventilation systems have been designed/evaluated as described in Part X of the FPR.</p>	<p>Security hardware incorporated into a fire door assembly does not adversely impact the fire rating of the assembly per the guidance of Generic Letter 86-10.</p> <p>Non-UL listed fire doors are identified on the compartmentation drawings (see Part II) and have been evaluated as equivalent to fire rated doors. Refer to Part VII of the FPR.</p> <p>Ventilation openings without dampers are identified on the fire compartmentation drawings and were considered in the Safe Shutdown Analysis. Refer to Part VII of the FPR.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>D.2 <u>Control of Combustibles</u></p> <p>a. Safety-related systems should be isolated or separated from combustible materials. When this is not possible because of the nature of the safety system or the combustible material, special protection should be provided to prevent a fire from defeating the safety system function. Such protection may involve a combination of automatic fire suppression, and construction capable of withstanding and containing a fire that consumes all combustibles present. Examples of such combustible materials that may not be separable from the remainder of its system are:</p> <ol style="list-style-type: none"> 1. Emergency diesel generator fuel oil day tanks. 2. Turbine-generator oil and hydraulic control fluid systems. 3. Reactor coolant pump lube oil system. 	<p>Safety-related systems are separated from combustible materials. This separation consists of spatial separation or rated fire barriers where possible, or a combination of these along with fire detection and suppression as required based on the Fire Hazards Analysis and Appendix R.</p> <p>The emergency diesel generator fuel oil day tanks are located in the room with its associated diesel. This room is provided with automatic suppression and detection as described under item F.9 of this section. The two FLEX diesel generators are in individual rooms that are separated from FSSD areas by 3-hour fire rated barriers. The 185 gallon fuel tank in each room is a double walled tank. Each room is provided with automatic detection and suppression.</p> <p>The turbine lube oil reservoir is provided with fixed water spray systems.</p> <p>The reactor coolant pumps in containment are provided with fire suppression systems with closed water spray heads. They also have integral oil collection systems as required by Section III.0 of 10 CFR Part 50, Appendix R.</p>		<p>Refer to the "Fire Hazard Analyses," for combustible loadings and fire protection provisions in each fire zone. The four emergency diesel generators are separated from each other by 3-hr rated, reinforced concrete barriers.</p> <p>Beyond-Design-Basis event scenarios require plant modifications to address mitigation strategies for Beyond-Design-Basis accidents.</p> <p>Additional 225 kVA Diesel Generators are Installed on EI 786.0 of the Auxiliary Building for Beyond-Design-Basis accidents. These units will provide power for battery charging and to maintain critical Instrumentation and control functions to protect the reactor core, spent fuel pool and containment. The fuel supply for these diesels is provided by the present 3 MW diesel fuel supply. Each 225 kVA diesel skid contains a built in double wall 185 gallon fuel tank. Detection and suppression are provided. <u>These diesels are not safety related or App. R equipment and are not required for safe shutdown.</u></p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>b. Bulk gas storage (either compressed or cryogenic), should not be permitted inside structures housing safety-related equipment. Storage of flammable gas such as hydrogen, should be located outdoors or in a separate detached building so that a fire or explosion will not adversely affect any safety-related systems or equipment. (Refer to NFPA 50A, "Gaseous Hydrogen Systems.")</p> <p>Care should be taken to locate high pressure gas storage containers with the long axis parallel to building walls. This will minimize the possibility of wall penetration in the event of a container failure. Use of compressed gases (especially flammable and fuel gases) inside buildings should be controlled. (Refer to NFPA 6, "Industrial Fire Loss Prevention.")</p>	<p>The hydrogen trailer port is located out in the Yard and is well separated from safety-related structures. Plant procedures control the use of compressed gases inside safety-related buildings.</p>	<p>Bulk storage of flammable gasses is located outdoors to avoid exposure to essential equipment, systems, or structures. NFPA 50A-1973 provided guidance for routing the piping system within the Aux Building that supplies hydrogen to the Volume Control Tanks (VCTs). The system is provided with excess flow valves such that in an accident the hydrogen concentration would stay below 4% by volume. Refer to Part X, Section 3.2.7 of the FPR.</p> <p>WBN has not reviewed NFPA 6 for compliance since it has been superseded by NFPA 1. The codes are considered not applicable. Procedures require containers to be secured to structures or vehicle racks. Safe permitted use of compressed gases inside buildings is controlled by operational procedures. Refer to Part X of the FPR.</p>	<p>Storage for operational quantities of nitrogen and breathing air are provided in designated rooms in the AB. Post Accident Sampling room has some quantities of operational gases including hydrogen required for PAS system functions. These gas containers are commercially designed and manufactured to meet appropriate compressed gas cylinder industry standards and are mounted to address seismic concerns. The combination of container design and mounting will provide restraint to minimize possible wall penetration in the event of container failure.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

<u>Appendix A Guidelines</u>	<u>Plant Conformance</u>	<u>Alternatives</u>	<u>Remarks</u>
<p>c. The use of plastic materials should be minimized. In particular, halogenated plastics such as polyvinyl chloride (PVC) and neoprene should be used only when substitute noncombustible materials are not available. All plastic materials, including flame and fire retardant materials, will burn with an intensity and BTU production in a range similar to that of ordinary hydrocarbons. When burning, they produce heavy smoke that obscures visibility and can plug air filters, especially charcoal and HEPA. The halogenated plastics also release free chlorine and hydrogen chloride when burning which are toxic to humans and corrosive to equipment.</p> <p>d. Storage of flammable liquids should as a minimum, comply with the requirements of NFPA 30, "Flammable and Combustible Liquids Code."</p>	<p>Plant design minimizes the use of combustible materials. Cables within certain areas are generally coated with a fire retardant coating or are qualified to the requirements of IEEE 383, 1974. Where appropriate, in situ plastics are included in fire area combustible inventories utilized in the Fire Hazard Analyses (Part VI).</p>	<p>Less than 10 uncoated non-IEEE 383 cables are allowed in a tray. New cables routed within safety-related buildings are, when possible, IEEE-383 qualified cables.</p> <p>The storage and handling of flammable and combustible liquids as transient combustible materials have been evaluated against the requirements of NFPA 30-1973. Refer to Part X of the FPR.</p>	
<p>D.3 <u>Electric Cable Construction, Cable Trays and Cable Penetrations</u></p>			
a. Only noncombustible materials should be used for cable tray construction.	Noncombustible material is used for cable tray construction.		
b. See section F.3 for fire protection guidelines for cable spreading rooms.			See F.3 of this section.

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>c. Automatic water sprinkler systems should be provided for cable trays outside the cable spreading room. Cables should be designed to allow wetting down with deluge water without electrical faulting. Manual hose stations and portable hand extinguishers should be provided as backup.</p> <p>Safety-related equipment in the vicinity of such cable trays, that does not itself require water fire protection, but is subject to unacceptable damage from sprinkler water discharge, should be protected from sprinkler system operation or malfunction. When safety-related cables do not satisfy the provisions of Regulatory Guide 1.75, all exposed cables should be covered with an approved fire retardant coating and a fixed automatic water fire suppression system should be provided.</p>	<p>Cables are designed to allow wetting without faulting.</p>	<p>Automatic suppression systems are provided in some areas to protect redundant safety-related cables. Refer to Part VI of the FPR</p> <p>Fire hose and extinguishers are generally available for manual firefighting. Refer to Part VI of the FPR.</p> <p>To address unacceptable damage to redundant safety-related equipment from sprinkler water discharge, electrical conduit is sealed if its physical configuration and location is such that automatic suppression water can be conducted into redundant electrical equipment and impact safe shutdown.</p> <p>Cables in safety-related or seismic category 1 areas are generally covered with an approved fire retardant coating or are qualified to the requirements of IEEE 383-1974. Less than 10 uncoated non-IEEE 383 cables are allowed in a tray.</p>	<p>Automatic suppression systems are provided in most areas of safety-related buildings. Ceiling level sprinklers provide general area coverage and additional sprinklers are provided under large obstructions (e.g., HVAC ducts).</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>d. Cable and cable tray penetration of fire barriers (vertical and horizontal) should be sealed to give protection at least equivalent to the fire barrier. The design of fire barriers for horizontal and vertical cable trays should, as a minimum, meet the requirements of ASTM E-119, "Fire Test of Building Construction and Materials," including the hose stream test. Where installed penetration seals are deficient with respect to fire resistance, these seals may be protected by covering both sides with an approved fire retardant material. The adequacy of using such material should be demonstrated by suitable testing.</p> <p>e. Fire breaks should be provided as deemed necessary by the fire hazards analysis. Flame or flame retardant coatings may be used as a fire break for grouped electrical cables to limit spread of fire in cable venting. (Possible cable derating owing to use of such coating materials must be considered during design.)</p> <p>f. Electric cable constructions should, as a minimum, pass the current IEEE No. 383 flame test. (This does not imply that cables passing this test will not require additional fire protection.)</p>	<p>Cable and cable tray penetration of fire barriers (vertical and horizontal) are sealed with fire barrier penetration seals to give protection equivalent to the barrier where required. These penetration designs have been tested and have been reviewed and approved as being equal to the required rating of the fire barrier. Electrical penetration openings are sealed with a configuration that has been tested to nationally recognized penetration seal testing criteria (e.g., IEEE 634, ASTM E814, etc.). See FPR Part II, Section 12.</p> <p>Configurations of cable routings are either such that no breaks are necessary or penetration seals are provided where cables pass through fire barriers. Power cables are evaluated for cable derating requirements.</p>		<p>Fire breaks are not necessary at WBN for fire protection purposes.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>For cable installation in operating plants and plants under construction that do not meet the IEEE No. 383 flame test requirements, all cables must be covered with an approved flame retardant coating and properly derated.</p> <p>g. To the extent practical, cable construction that does not give off corrosive gases while burning should be used. (Applicable to new cable insulations.)</p> <p>h. Cable trays, raceway, conduit, trenches or culverts should be used only for cables. Miscellaneous storage should not be permitted, nor should piping for flammable or combustible liquids or gases be installed in these areas.</p> <p>Installed equipment in cable tunnels or culverts, need not be removed if they present no hazard to the cable runs as determined by the fire hazards analysis.</p> <p>i. The design of cable tunnels, culverts, and spreading rooms should provide for automatic or manual smoke venting as required to facilitate manual fire fighting capability.</p>	<p>Electric cables used at WBN satisfy the requirements of IEEE 383-1974 flame test, or may be coated with an approved fire retardant coating. In specific areas, where cables have been coated with fire retardant materials, a derating factor has been applied.</p> <p>New cable insulation is IEEE-383-qualified cable, if possible.</p> <p>Cable trays, raceway, conduit and trenches are only used for cables.</p> <p>Plant ventilation systems are generally used for smoke removal, or manual smoke venting can be performed with portable smoke ejectors located on site.</p>	<p>Less than 10 uncoated non-IEEE 383 cables are allowed in a tray. New cables are required to be IEEE-383 qualified, if possible.</p> <p>Specialty cables such as fiber optic cable may not be IEEE 383 qualified, but are reviewed and accepted for use without fire retardant coating.</p>	

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>j. Cables in the control room should be kept to the minimum necessary for operation of the control room. All cables entering the control room should terminate there.</p> <p>Cables should not be installed in floor trenches or culverts in the control room. Existing cabling installed in concealed floor and ceiling spaces should be protected with an automatic total flooding Halon system.</p> <p>D.4 <u>Ventilation</u></p> <p>a. The products of combustion which need to be removed from a specific fire area should be evaluated to determine how they will be controlled. Smoke and corrosive gases should generally be automatically discharged directly outside to a safe location.</p> <p>Smoke and gases containing radioactive materials should be monitored in the fire area to determine if release to the environment is within the permissible limits of the plant technical specifications.</p>	<p>Electrical circuits in the control room are limited to those associated with lighting, instrumentation, and control. Cables entering the control room terminate there.</p> <p>Cables are not installed in floor trenches or culverts in the control room. The areas under the control room panels are extensions of the panels, not floor trenches. Areas beneath the US and SM work stations are considered to be a part of the work station.</p> <p>Plant ventilation systems are generally used for smoke removal, but smoke corrosive gases are not automatically discharged. Manual venting can be accomplished with portable smoke ejectors; discharge to the outside can be performed in most areas, either directly or using expandable duct.</p> <p>Non-recirculating ventilation systems are provided for fire areas which may contain airborne radioactive materials. Smoke from fires which might occur in areas containing radioactive materials is monitored for radioactivity.</p>	<p>No automatic suppression is provided. Portable extinguishers are provided, and hose stations are available to serve the control room.</p>	

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

<u>Appendix A Guidelines</u>	<u>Plant Conformance</u>	<u>Alternatives</u>	<u>Remarks</u>
<p>b. Any ventilation system designed to exhaust smoke or corrosive gases should be evaluated to ensure that inadvertent operation or single failures will not violate the controlled areas of the plant design. This requirement includes containment functions for protection of the public and maintaining habitability for operations personnel.</p> <p>c. The power supply and controls for mechanical ventilation systems should be run outside the fire area served by the system.</p> <p>d. Fire suppression systems should be installed to protect charcoal filters in accordance with Regulatory Guide 1.52, "Design Testing and Maintenance Criteria for Atmospheric Cleanup Air Filtration."</p> <p>e. The fresh air supply intakes to areas containing safety-related equipment or systems should be located remote from the exhaust air outlets and smoke vents of other fire areas to minimize the possibility of contaminating the intake air with the products of combustion.</p>	<p>General building fresh air intakes are remote from exhaust air outlets to minimize the possibility of contaminating the intake air with the products of combustion.</p>	<p>Ventilation systems at WBN are not specifically designed to exhaust smoke or corrosive gases. The fixed ventilation systems, in conjunction with portable fans and flexible ductwork, may be used to exhaust smoke from a room during and after manual firefighting activities to control and/or extinguish the fire.</p> <p>To the extent practicable, power supply and controls for ventilation systems are installed outside the areas they serve, or equipment isolation or protection is provided. Refer to Part VI of the FPR.</p> <p>An automatic, fixed pipe, thermally actuated closed nozzle water spray system is provided for each charcoal filter unit. See Part II, Section 12.3. The systems are designed to deliver 0.25 gpm/ft² across the face of the charcoal filter. Adequate hose stations and extinguishers are also provided.</p> <p>The air intake dampers and exhaust fans for the 480V shutdown board rooms are located on the roof of the Auxiliary Building.</p>	<p>An evaluation performed for Reg Guide 1.52 has concluded the temperature rise due to the collection of radioisotopes during an accident will not cause ignition of the charcoal. The fire suppression system is provided for general hazard fire protection.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>f. Stairwells should be designed to minimize smoke infiltration during a fire. Staircases should serve as escape routes and access routes for fire fighting. Fire exit routes should be clearly marked. Stairwells, elevators, and chutes should be enclosed in masonry towers with minimum fire rating of three hour and automatic fire doors at least equal to the enclosure construction, at each opening into the building. Elevators should not be used during fire emergencies.</p> <p>Where stairwells or elevators cannot be enclosed in three-hour fire rated barrier with equivalent fire doors, escape, and access routes should be established by Prefire Plan and practiced in drills by operating and fire brigade personnel.</p> <p>g. Smoke and heat vents may be useful in specific areas such as cable spreading rooms and diesel fuel oil storage areas and switchgear rooms. When natural-convection ventilation is used, a minimum ratio of one-square foot of venting area per 200ft² of floor area should be provided. If forced-convection ventilation is used, 300 cfm should be provided for every 200 square feet of floor area. See NFPA 204 for additional guidance on smoke control.</p>	<p>Stairwells in the Control Building and EDGB are enclosed and designed to minimize smoke infiltration.</p> <p>Access and egress points are shown in the Prefire Plans and are included as part of the drills practiced by operating and fire brigade personnel.</p>	<p>Stairwell Numbers 3, 5, and 6 in the Auxiliary Building are open and are provided with water curtains which are installed in the locations defined in Section 2.6.3.1 of Part VII. Separate stairwells are provided inside the intake pumping station for access to the strainer rooms so that one fire will not block all access routes for firefighting. Stairwell enclosures, when provided, are equivalent minimum two-hour fire-rated barriers and the doors are self-closing.</p> <p>NFPA 204-1968 has been superseded by NFPA 204M. This code is not applicable to WBN since it is primarily applicable to single story structures. Smoke is removed either by the use of the existing ventilation ductwork and fan system, or manually by the fire brigade using portable fans and flexible ductwork. Refer to Part X of the FPR. The diesel generator day tanks are in rooms that have doors that open to the outside. The cable spreading room has two doors that open into the Turbine Building. Portable smoke ejectors are available on site for supplemental ventilation.</p>	

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>Self-contained breathing apparatus, using full face positive pressure masks, approved by NIOSH (National Institute for Occupational Safety and Health - approval formerly given by the U.S. Bureau of Mines) should be provided for fire brigade, damage control, and control room personnel.</p> <p>Control room personnel may be furnished breathing air by a manifold system piped from a storage reservoir, if practical. Service or operating life should be a minimum of one-half hour for the self-contained units.</p> <p>At least two extra air bottles should be located onsite for each self-contained breathing unit. In addition, an onsite-6-hour supply of reserve air should be provided and arranged to permit quick and complete replenishment of exhausted supply air bottles as they are returned. If compressors are used as a source of breathing air, only units approved for breathing air should be used. Special care must be taken to locate the compressor in areas free of dust and contaminants.</p>	<p>NIOSH-approved self-contained full-face positive pressure breathing apparatus is available for the fire brigade, damage control, and control room personnel. The operating life of the self-contained units is a minimum of one-half hour.</p>	<p>At least one (1) one hour air bottle is available for each self-contained breathing unit. An additional (16) one hour bottles are available onsite to provide a minimum 16-hour supply of reserve air for the self-contained breathing units provided for use by the fire brigade, damage control, and control room personnel.</p>	<p>Not applicable.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>i. Where total flooding gas extinguishing systems are used, area intake and exhaust ventilation dampers should close upon initiation of gas flow to maintain necessary gas concentration. (See NFPA 12, "Carbon Dioxide Systems," and 12A, "Halon 1301 Systems.")</p> <p>D.5 <u>Lighting and Communication</u></p> <p>Lighting and two-way voice communication are vital to safe shutdown and emergency response in the event of fire. Suitable fixed and portable emergency lighting and communication devices should be provided to satisfy the following requirements:</p> <p>a. Fixed emergency lighting should consist of sealed beam units with individual 8-hour minimum battery power supplies.</p> <p>b. Suitable sealed beam battery powered portable hand lights should be provided for emergency use.</p> <p>c. Fixed emergency communication should use voice powered headsets at preselected stations.</p>	<p>The carbon dioxide systems have been evaluated against NFPA 12-1973. Refer to Part X of the FPR, and Item A.5.</p> <p>Emergency lighting and communication are provided as follows:</p> <p>Fixed emergency lighting consisting of units with individual 8-hour minimum battery power supplies are provided for access and egress routes to FSSD equipment with manual action requirements.</p> <p>Battery powered portable hand lights are also available for emergency use as a compensatory action to the installed 8 hour battery packs. Refer to Part II, Section 12 of the FPR.</p> <p>An alternate (emergency) communication system (sound powered phones with head sets) is provided. Refer to Part II, Section 12 of the FPR.</p>	<p>Diesel generator backed standby lighting is used for manual actions in the Turbine Building. Refer to Part VII of the FPR.</p> <p>Primary communications for FSSD is by radios.</p>	<p>Halon 1301 extinguishing systems are not used in safety-related areas at WBN.</p> <p>See the Fire Protection Plan (FPR Part II, Section 12) for descriptions of the emergency lighting and communications systems.</p> <p>Refer to Part VII, Section 2.7 for engineering evaluation of the Containment lighting and Turbine Building standby lighting.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>d. Fixed repeaters installed to permit use of portable radio communication units should be protected from exposure fire damage.</p> <p>E. <u>Fire Detection and Suppression</u></p> <p>E.1 <u>Fire Detection</u></p> <p>a. Fire detection systems should, as a minimum comply with NFPA 72D, "Standard for the Installation, Maintenance, and Use of Proprietary Protective Signaling Systems."</p> <p>Deviations from the requirements of NFPA 72D should be identified and justified.</p> <p>b. Fire detection system should give audible and visual alarm and annunciation in the control room. Local audible alarms should also sound at the location of the fire.</p> <p>c. Fire alarms should be distinctive and unique. They should not be capable of being confused with any other plant system alarms.</p> <p>d. Fire detection and actuation systems should be connected to the plant emergency power supply.</p>	<p>Fire detection systems that are required for regulatory compliance have been evaluated against NFPA 72D-1975. The spacing and location of fire detectors have been evaluated against NFPA 72E-1974. Refer to Part X of the FPR.</p> <p>See Part X of the FPR.</p> <p>The fire detection system gives audible and visual alarms and annunciates in the Main Control Room and indicates detector zone location at selected local panels.</p> <p>The fire alarm is distinctive and unique from those of other alarm systems.</p> <p>The fire detection system and actuation circuits are connected to the plant emergency power supply.</p>	<p>UHF/VHF cabinet and power cables are separated from the redundant UHF radio cabinets and power cables such that no single fire can prevent the use of both systems.</p>	

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>E.2 <u>Fire Protection Water Supply Systems</u></p> <p>a. An underground yard fire main loop should be installed to furnish anticipated fire water requirements.</p> <p>NFPA 24, "Standard for Outside Protection," gives necessary guidance for such installation. It references other design codes and standards developed by such organizations as the American National Standards Institute (ANSI) and the American Water Works Association (AWWA).</p> <p>Visible location marking signs for underground valves is acceptable. Alternative valve position indicators should also be provided.</p>	<p>The fire protection water distribution system provides sufficient fire protection water to plant fire protection systems.</p> <p>The fire protection water distribution system has been evaluated against NFPA 24-1973. Refer to Part X of the FPR.</p> <p>Underground valves are identified on fire protection system flow drawings which, when combined with the use of curb boxes in the field, provide sufficient identification of the locations of underground valves.</p>		<p>The Fire (Protection) Water Distribution System consists of the piping and appurtenances on TVA property between a source of fire protection water and the base of the riser (flange of flange and spigot piece or base tee) for automatic sprinkler systems, fixed water spray systems, standpipe systems, and other water based fire suppression systems. The fire protection water distribution system may be referred to as the underground fire loop, yard loop, or yard fire main loop in Columns 2 and 3 to more closely correlate with the wording in the various paragraphs of Appendix A Section E.2a.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>Lined steel or cast iron pipe should be used to reduce internal tuberculation. Such tuberculation deposits in an unlined pipe over a period of years can significantly reduce water flow through the combination of increased friction and reduced pipe diameter. Means for treating and flushing the system should be provided.</p> <p>Approved visually indicating sectional control valves, such as post indicator valves, should be provided to isolate portions of the main for maintenance or repair without shutting off the entire system.</p> <p>The fire main system piping should be separate from service or sanitary water system piping.</p> <p>For operating plants, fire main system piping that can be isolated from service or sanitary water system piping is acceptable.</p>	<p>Cement lined pipe is used for the common outside loop and unlined steel pipe is used for the outside Train A and B headers and inside loop. Hydraulic calculations on the system take into account the reduced pipe diameter and increased friction. The water is also treated and periodic flushing is performed.</p>	<p>The fire protection water distribution system is equipped with wrench-operated curb-box (non-indicating) valves and post indicator (indicating) valves such that portions of the loop may be isolated without impairing operation of the rest of the system.</p> <p>The high pressure fire protection system is shared with the raw service water (RSW) system. Automatic isolation valves are provided to isolate the raw cooling water supply from the HPFP system when any fire pump is started as a result of a fire in safety-related areas. Specific RSW loads are automatically isolated from the fire protection water system when the fire pump(s) start as a result of a fire in safety-related areas to reduce the <u>maximum designed</u> RSW load to 105 gpm during the fire event.</p>	

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>b. A common yard fire main loop may serve multi-unit nuclear power plant sites, if cross-connected between units.</p> <p>For operating plants, fire main system piping that can be isolated from service or sanitary water system piping is acceptable.</p> <p>Sectional control valves should permit maintaining independence of the individual loop around each unit. For such installations, common water supplies may also be utilized.</p> <p>The water supply should be sized for the largest single expected flow. For multiple reactor sites with widely separated plants (approaching one mile or more), separate yard fire main loops should be used. Sectionalized systems are acceptable.</p>	<p>A common fire protection water distribution system services both units and is cross-connected between units.</p> <p>Sectional isolation valves are provided such that maintenance may be performed on the loop or portions of the loop for one unit without affecting the firefighting capability of either unit.</p> <p>The electric HPFP pumps take suction from Chickamauga Reservoir, which is considered an unlimited water supply. The diesel fire pump takes suction from the Unit 1 cooling tower basin, which is also considered an unlimited water supply for fire protection purposes.</p>		

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>c. If pumps are required to meet system pressure or flow requirements, a sufficient number of pumps should be provided so that 100% capacity will be available with one pump inactive (e.g., three 50% pumps or two 100% pumps). The connection to the yard fire main loop from each fire pump should be widely separated, preferably located on opposite sides of the plant. Each pump should have its own driver with independent power supplies and control. At least one pump (if not powered from the emergency diesel) should be driven by non-electrical means, preferable diesel engine. Pumps and drivers should be located in rooms separated from the remaining pumps and equipment by a minimum three-hour fire wall.</p> <p>Alarms indicating pump running, driver availability, or failure to start should be provided in the control room.</p> <p>Details of the fire pump installation should, as a minimum, conform to NFPA 20, "Standard for the Installation of Centrifugal Fire Pumps."</p>	<p>There are four electric pumps rated at 1590 gpm at 300 feet-head located in the IPS. A diesel fire pump rated at 2500 gpm and 125 psig is located in the yard adjacent to the Unit 1 cooling tower. The fire pumps are connected to the yard loop in such a manner that a single impairment of one feed from the pumping station will not jeopardize the firefighting capability of the plant.</p> <p>For safety-related portions of the plant, two electric pumps, or the diesel pump, provide 100% of the firefighting water requirements in safety-related areas. See Part II of the FPR.</p> <p>The diesel fire pump installed in the Yard conforms with NFPA 20-1994. See Part X of the FPR.</p>	<p>During specific Appendix R fire events, the fire may damage single or multiple fire pumps. The diesel fire pump is always available for fires in safety-related plant locations. Calculations have been performed to demonstrate that the flow and pressure requirements of the fire protection systems are met by the number of available fire pumps. Specific RSW loads are automatically isolated from the fire protection water system when the fire pump(s) start as a result of a fire in safety-related areas to reduce the <u>maximum designed</u> RSW load to 105 gpm during the fire event.</p> <p>The four fire pumps in the IPS are electric motor-driven and each is supplied power from a separate emergency diesel generator. The two Train A pumps are separated from the two Train B pumps by an equivalent 3-hour fire barrier. In addition, a diesel fire pump rated at 2500 gpm at 125 psig is located in the yard.</p> <p>Each pump is equipped with alarms indicating pump running and power available, which annunciate in the MCR.</p> <p>The electric fire pumps are ASME Section III, Seismic Category I pumps, and as such, are not UL listed nor FM-approved. The electric fire pump installation does not comply with NFPA 20-1973. Refer to Part X of the FPR.</p>	<p>Adequate firefighting water requirements are considered to be the calculated flow and pressure to provide flow and pressure to meet suppression system design bases, including hose stream allowance and unisolated RSW loads simultaneously. HPFP water requirements for safety-related areas are satisfied by two of the four electric pumps, or by the diesel fire pump. See Part VII of the FPR.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>d. Two separate reliable water supplies should be provided. If tanks are used, two 100% (minimum of 300,000 gallons each) system capacity tanks should be installed. They should be so interconnected that pumps can take suction from either or both. However, a leak in one tank or its piping should not cause both tanks to drain. The main plant fire water supply capacity should be capable of refilling either tank in a minimum of eight hours. Common tanks are permitted for fire and sanitary or service water storage. When this is done, however, minimum fire water storage requirements should be dedicated by means of a vertical standpipe for other water services.</p>	<p>The electric fire pumps take suction from Chickamauga Reservoir which is considered an unlimited water supply. The diesel fire pump takes suction from the Unit 1 cooling tower basin which is also considered an unlimited water supply for fire protection purposes.</p>		
<p>e. The fire water supply (total capacity and flow rate) should be calculated on the basis of the largest expected flow rate for a period of two hours, but not less than 300,000 gallons. This flow rate should be based (conservatively on 1,000 gpm for manual hose streams plus the greater of:</p>	<p>Chickamauga Reservoir is considered an unlimited water supply. The Unit 1 cooling tower basis is also considered an unlimited water supply for fire protection purposes.</p>	<p>The flow rate and pressure of the system is based on providing 500 gpm for hose streams while flowing water at design capacity to the most hydraulically remote location for each sprinkler or deluge system protecting safety-related areas. Specific RSW loads are automatically isolated from the fire protection water system when the fire pump(s) start as a result of a fire in safety-related areas to reduce the <u>maximum designed</u> RSW load to 105 gpm during the fire event.</p>	

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<ol style="list-style-type: none"> 1. All sprinkler heads opened and flowing in the largest designed fire area; or 2. the largest open head deluge system(s) operating. <p>f. Lakes or fresh water ponds of sufficient size may qualify as sole source of water for fire protection, but require at least two intakes to the pump supply. When a common water supply is permitted for fire protection and the ultimate heat sink, the following conditions should also be satisfied:</p> <ol style="list-style-type: none"> 1. The additional fire protection water requirements are designed into the total storage capacity; and 2. Failure of the fire protection system should not degrade the function of the ultimate heat sink. 	<p>Two intakes are provided for the electric pumps in the IPS for all normal and flood levels. For water levels below minimum, flow is provided to the sump through a submerged line. Therefore, the pumps are capable of operating during any lake condition from minimum level (resulting from loss of downstream dam) to maximum design basis flood level. Ultimate heat sink requirements are provided by the ERCW pumps located in the intake pumping station and separated from other equipment by 3-hour fire barriers. (Refer to Part VII of the FPR for a discussion of unprotected openings.) Therefore, failure of the fire protection system will not degrade the ultimate heat sink.</p>	<p>One intake is provided for the diesel fire pump from the Unit 1 cooling tower basin, with a supply line connection to the underground fire protection water distribution system. A second intake can be achieved by the fire trucks serving as a backup pump taking suction from the Unit 1 and/or 2 cooling tower basin and supplying water through a separate line connecting to the underground fire protection water distribution system.</p>	

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>g. Outside manual hose installation should be sufficient to reach any location with an effective hose stream. To accomplish this, hydrants should be installed approximately every 250 feet on the yard main system. The lateral to each hydrant from the yard main should be controlled by a visually indicating or key-operated (curb) valve. A hose house, equipped with hose and combination nozzle, and other auxiliary equipment recommended in NFPA 24, "Outside Protection," should be provided as needed but at least every 1,000 feet.</p> <p>Threads compatible with those used by local fire departments should be provided on all hydrants, hose couplings, and standpipe risers.</p>	<p>Key-operated curb valves or PIV's are provided for each hydrant off the yard loop. Refer to Part X of the FPR.</p> <p>National standard fire hose threads are used throughout the plant. These are compatible with local fire departments.</p>	<p>Fire hydrant spacing ranges up to 700 feet between hydrants. A sufficient number of hydrants are installed to provide two streams for every part of the interior of each building not covered by standpipe protection and to provide hose stream protection for the exterior part of each building by the use of lengths of hose normally attached to the hydrants. There are sufficient hydrants to concentrate the required flow about any important building with no hose line exceeding 500 feet in length.</p> <p>Hose equipment houses are not relied on at WBN. In lieu of firefighting equipment houses, the fire brigade equips and maintains mobile apparatus equipped with hose, combination nozzles, and adequate auxiliary equipment to effectively perform firefighting activities using the fire hydrants in the Yard.</p>	

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>E.3 <u>Water Sprinklers and Hose Standpipe Systems</u></p> <p>a. Each automatic sprinkler system and manual hose station standpipe should have an independent connection to the plant underground water main.</p> <p>Headers fed from each end are permitted inside buildings to supply multiple sprinkler and standpipe systems. When provided, such headers are considered an extension of the yard main system. The header arrangement should be such that no single failure can impair both the primary and backup fire protection systems.</p> <p>Each sprinkler and standpipe system should be equipped with OS&Y (outside screw and yoke) gate valve, or other approved shutoff valve, and water flow alarm. Safety-related equipment that does not itself require sprinkler water fire protection, but is subject to unacceptable water discharge should be protected by water shields or baffles.</p>	<p>Each automatic sprinkler system and hose station standpipe is connected to the yard main or to headers within the buildings, except for each Reactor Building and the Intake Pumping Station (IPS).</p> <p>These headers are fed from each end of the building. No single failure can impair both the primary and backup fire protection systems.</p> <p>Each sprinkler and standpipe system is provided with an approved shutoff valve; sprinkler systems are provided with water flow alarms. Additionally, the activation of fire pumps annunciates in the control room. Spray shields are provided where necessary to protect safety-related equipment from water discharge.</p>	<p>In the Reactor Building a single header has separate connections for the RCP system, Annulus system, standpipes for the Annulus, and standpipes for containment. At the IPS separate connections are also provided for the sprinkler system and the standpipes.</p> <p>Redundant safety-related equipment is not subject to damage by sprinkler discharge.</p>	<p>Generally, where installed, fixed suppression systems are considered the primary system. Manual suppression systems (standpipe and hose stations) are considered backup. Where no fixed suppression is installed, the standpipe and hose station or adjacent fire hydrants are considered the primary system and other independent standpipe and hose stations or yard hydrants are the backup.</p> <p>The automatic fire suppression systems for charcoal type filter units and associated standpipe systems can be impaired by a single failure but the area sprinkler systems are not affected by the same failure.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>b. All valves in the fire water systems should be electrically supervised. The electrical supervision signal should indicate in the control room and other appropriate command locations in the plant (see NFPA 26, "Supervision of Valves").</p> <p>When electrical supervision of fire protection valves is not practicable, an adequate management supervision program should be provided. Such a program should include locking valves open with strict key control; tamper proof seals; and periodic, visual check of all valves.</p>		<p>WBN does not comply with NFPA 26-1958. Refer to Part X of the FPR. See below.</p> <p>WBN uses administrative controls to prevent improper use of fire protection valves that ensures the water supply to protected safety-related areas. A valve surveillance program ensures proper valve alignment on a periodic basis. Isolation valves in the flow path are locked or sealed and inspected periodically for proper alignment. Keys to the locks are restricted to authorized (normally operations) personnel.</p>	
<p>c. Automatic sprinkler systems should, as a minimum, conform to requirements of appropriate standards such as NFPA 13, "Standard for Installation of Sprinkler Systems" and NFPA 15, "Standard for Water Spray Fixed Systems.</p>	<p>Automatic sprinkler systems that are required for regulatory compliance have been evaluated against NFPA 13-1975. Refer to Part X of the FPR.</p>		<p>There are no true water spray systems that are required for regulatory compliance which must be evaluated against NFPA 15-1973.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>d. Interior manual hose installation should be able to reach any location with at least one effective hose stream. To accomplish this, standpipes with hose connections equipped with a maximum of 75 feet of 1-1/2-inch woven jacket lined fire hose and suitable nozzles should be provided in all buildings, including containment, on all floors and should be spaced at not more than 100-foot intervals.</p> <p>Individual standpipes should be of at least 4-inch diameter for multiple hose connections and 2-1/2-inch diameter for single hose connections. These systems should follow the requirements of NFPA No. 14 for sizing, spacing, and pipe support requirements (NELPIA). Hose stations should be located outside entrances to normally unoccupied areas and inside normally occupied areas. Standpipes serving hose stations in areas housing safety-related equipment should have shutoff valves and pressure reducing devices (if applicable) outside the area.</p>	<p>Hose stations are located outside of entrances to normally occupied areas where practical. Standpipe isolation capability outside the fire area is provided for areas containing safety-related equipment.</p>	<p>Manual hose stations with 100 feet of 1-1/2-inch approved fire hose are located throughout the plant. The hoses are provided with nozzles rated for use on Class A, B, or C type fires. Refer to Part VII, Section 4.3 of the FPR for discussion of hose stations with hose lengths greater than 100 feet.</p> <p>Standpipe systems are sized to supply a minimum of 500 gpm with a minimum residual pressure of 65 psi. Some standpipe risers are less than 4-inch diameter pipe. Refer to Part X of the FPR.</p> <p>Hose stations have been evaluated against NFPA 14-1974 for use by trained fire brigade members only. Refer to Part X of the FPR.</p> <p>Pressure reducing devices are not provided. The fire brigade is trained to properly handle high pressure hose streams around safety-related equipment.</p>	<p>Interior manual hose stations are provided for fire brigade use only. They are not provided for occupant use, since only the fire brigade has been trained in the use of hose stations.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>Provisions should be made to supply water at least to stand pipes and hose connections for manual fire fighting in areas within hose reach of equipment required for safe plant shutdown in the event of a Safe Shutdown Earthquake (SSE).</p> <p>The standpipe system serving such hose stations should be analyzed for SSE loading and should be provided with supports to assure system pressure integrity. The piping and valves for the portion of hose standpipe systems affected by this functional requirement should at least satisfy ANSI B31.1, "Power Piping." The water supply for this condition may be obtained by manual operator actuation of valve(s) in a connection to the hose standpipe header from a normal Seismic Category I water system such as Essential Service Water System. The cross connection should be (a) capable of providing flow to at least two hose stations (approximately 75 gpm/hose station), and (b) designed to the same standards as the seismic Category I water system; it should not degrade the performance of the Seismic Category I water system.</p>	<p>Provisions are made to supply water at least to standpipes and hose connections for manual firefighting in areas within hose reach of equipment required for safe plant shutdown in the event of a Safe Shutdown Earthquake.</p> <p>The piping and valves of these hose standpipe systems satisfy the applicable sections of ANSI B31.1 "Power Piping." Piping located in Category I structures have been analyzed to meet the requirement of pressure boundary requirements during a seismic event.</p>		

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>e. The proper type of hose nozzles to be supplied to each area should be based on the fire hazard analysis. The usual combination spray/straight stream nozzle may cause unacceptable mechanical damage (for example, the delicate electronic equipment in the control room) and be unsuitable. Electrically safe nozzles should be provided at locations where electrical equipment or cabling is located.</p> <p>f. Certain fires such as those involving flammable liquids respond well to foam suppression. Consideration should be given to use of any of the available foams for such specialized protection application. These include the more common chemical and mechanical low expansion foams, high expansion foam and the relatively new aqueous film foaming foam (AFFF).</p> <p>E.4 <u>Halon Suppression Systems</u></p> <p>Details omitted.</p>	<p>Hose nozzles provided for interior use are electrically safe and are UL-listed for use on Class A, B, and C fires.</p>		<p>AFFF closed-head foam-water preaction suppression systems do not protect systems, components, or cables required for fire safe shutdown. NFPA 11B-1977 is not applicable to WBN. Refer to Part X of the FPR.</p> <p>Total flooding Halon systems are not used in any safety-related structures at WBN.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>E.5 <u>Carbon Dioxide Suppression Systems</u></p> <p>The use of CO₂ extinguishing systems should, as a minimum, comply with the requirements of NFPA 12, "Carbon Dioxide Extinguishing Systems."</p> <p>Particular consideration should also be given to:</p> <ul style="list-style-type: none"> a. Minimum required CO₂ concentration and soak time: b. toxicity of CO₂; c. possibility of secondary thermal shock (cooling) damage; d. offsetting requirements for venting during CO₂ injection to prevent over pressurization versus sealing to prevent loss of agent; e. design requirements from overpressurization; and f. possibility and probability of CO₂ systems being out-of-service because of personnel safety consideration. CO₂ systems are disarmed whenever people are present in an area so protected. Areas entered frequently (even though duration time for any visit is short) have often been found with CO₂ systems shut off. 	<p>The CO₂ extinguishing systems that are required regulatory compliance have been evaluated against NFPA 12-1973. Items a through f were considered and factored into the design. Refer to Part X of the FPR.</p>		

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>E.6 <u>Portable Extinguishers</u></p> <p>Fire extinguishers should be provided in accordance with guidelines of NFPA 10 and 10A, "Portable Fire Extinguishers Installation, Maintenance, and Use." Dry chemical extinguishers should be installed with due consideration given to cleanup problems after use and possible adverse effects on equipment installed in the area.</p>		<p>Portable fire extinguishers are provided for use only by trained personnel. Fire brigade members and Fire Watch personnel have been trained in the use and location of portable extinguishers. WBN does not comply with NFPA 10-1975 for spacing and location since portable extinguishers are not provided for occupant use. Portable extinguishers of a size and type compatible with specific hazards are strategically located throughout the plant. Refer to Part X of the FPR.</p>	
<p>F. <u>Guidelines for Specific Plant Areas</u></p>			
<p>F.1 <u>Primary and Secondary Containment</u></p> <p>a. <u>Normal Operation</u></p> <p>Fire protection requirements for the primary and secondary containment areas should be provided on the basis of specific identified hazards. For example:</p> <ul style="list-style-type: none"> • Lubricating oil or hydraulic fluid system for the primary coolant pumps: • Cable tray arrangements and cable penetrations; or: • Charcoal filters. 	<p>Fire protection features suitable for the specific identified hazard are provided. Refer to Part VI of the FPR.</p>		

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>Fire suppression systems should be provided based on the fire hazards analysis.</p> <p>Fixed fire suppression capability should be provided for hazards that could jeopardize safe plant shutdown. Automatic sprinklers are preferred.</p> <p>An acceptable alternate is automatic gas (Halon or CO₂) for hazards identified as requiring fixed suppression protection.</p> <p>An enclosure may be required to confine the agent if a gas system is used. Such enclosures should not adversely affect safe shutdown, or other operating equipment in containment.</p> <p>Automatic fire suppression capability need not be provided in the primary containment atmospheres that are inerted during normal operation. However, special fire protection requirements during refueling and maintenance operations should be satisfied as provided below.</p>			

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>Fire detection systems should alarm and annunciate in the control room. The type of detection used and the location of the detectors should be most suitable to the particular type of fire that could be expected from the identified hazard. A primary containment general area fire detection capability should be provided as backup for the above described hazard detection. To accomplish this, suitable smoke detection (e.g., visual obscuration, light scattering, and particle counting) should be installed in the air recirculation system ahead of any filters.</p> <p>b. <u>Refueling and Maintenance</u></p> <p>Refueling and maintenance operations in containment may introduce additional hazards such as contamination control materials, decontamination supplies, wood planking, temporary wiring, welding, and flame cutting (with portable compressed fuel gas supply). Possible fires would not necessarily be in the vicinity of fixed detection and suppression systems.</p> <p>Management procedures and controls necessary to assure adequate fire protection are discussed in section 3.a.</p>	<p>Administrative procedures limit the amount and control the type of combustible materials within the area and control hot work activities.</p>		

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>Equivalent protection from portable systems should be provided if it is impractical to install standpipes with hose stations.</p> <p>Adequate self-contained breathing apparatus should be provided near the containment entrances for fire fighting and damage control personnel. These units should be independent of any breathing apparatus or air supply systems provided for general plant activities.</p> <p>F.2 <u>Control Room</u></p> <p>The control room is essential to safe reactor operation. It must be protected against disabling fire damage and should be separated by floors, walls, and roofs having minimum fire resistance ratings of three hours. Control room cabinets and consoles are subject to damage from two distinct fire hazards:</p>	<p>Standpipes are provided.</p>	<p>Self-contained breathing apparatus are provided at strategic locations in the plant. Fire brigade and appropriate operations personnel are trained in the use and location of self-contained breathing apparatus. Refer to Part II, Section 9 of the FPR.</p> <p>The Control Building is separated from other fire areas by 3-hour fire barriers and is evaluated under Appendix R Sections III.G.3 and III.L criteria. Refer to Part VII, Section 2 of the FPR for a discussion of non-rated metal hatch covers between the mechanical equipment rooms and the Turbine Building. The Control Room and the cable spreading room are considered the same fire area. This is judged acceptable given the extensive use of suppression in the Cable Spreading Room, the low combustible loading and automatic suppression and detection in adjacent areas, the independent ACR, the detailed Appendix R evaluation performed for the Control Building and/or the conservative fire hazards analysis performed for the Control Building.</p>	

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>a. Fire originating within a cabinet or console; and</p> <p>b. Exposure fire involving combustibles in the general room area.</p> <p>Hose stations adjacent to the control room with portable extinguishers in the control room are acceptable.</p> <p>Nozzles that are compatible with the hazards and equipment in the control room should be provided for the manual hose station. The nozzles chosen should satisfy electrical safety and minimize physical damage to electrical equipment from hose stream impingement.</p> <p>Fire detection in the control room cabinets and consoles should be provided by smoke and heat detectors in each fire area. Alarm and annunciation should be provided in the control room. Fire alarms in other parts of the plant should also be alarmed and annunciated in the control room.</p> <p>Breathing apparatus for control room operators should be readily available. Control room floors, ceiling, supporting structures, and walls, including penetrations and doors, should be designed to a minimum fire rating of three hours. All penetration seals should be airtight.</p>	<p>Fire extinguishers are provided in the main control room. Standpipe hose stations are located in both stairwells at each end of the main control room.</p> <p>The hose stations have electrically approved nozzles for the hazards.</p> <p>Ionization smoke detectors are provided in selected cabinets in the MCR. General area fire alarms in the MCR and other areas of the plant, alarm and annunciate in the constantly attended MCR to alert the operators of a fire.</p> <p>Breathing apparatus are provided for the control room. The Control Building is separated from other plant areas by three-hour rated barriers. Refer to Part VII, Section 2 of the FPR for a discussion of non-rated metal hatch covers between the mechanical equipment rooms and the Turbine Building.</p>	<p>Sealing of MCR floor/cable spreading room ceiling penetrations is not necessary because these rooms are considered the same fire area. (See above for detailed explanation.)</p>	

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>The control room ventilation intake should be provided with smoke detection capability to automatically alarm locally and isolate the control room ventilation system to protect operators by preventing smoke from entering the control room. Manually-operated venting of the control room should be available so that operators have the option of venting for visibility. Manually operated ventilation systems are acceptable.</p> <p>Cables should not be located in concealed floor and ceiling spaces. All cables that enter the control room should terminate in the control room. That is, no cabling should be simply routed through the control room from one area to another.</p>	<p>Smoke detection is supplied in the control room ventilation intake. This detection provides for local alarms. Control room ventilation air intakes are provided with remotely controlled dampers to prevent smoke from entering the control room. Manual venting of the control room can be conducted by portable smoke ejectors available onsite and by opening the doors.</p> <p>Lighting wiring terminates in the lighting fixtures. Instrumentation and control wiring terminates inside the panels or control boards. Cable is not routed through the control room from one area to another.</p>		

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>F.3 <u>Cable Spreading Room</u></p> <p>a. The preferred acceptable methods are:</p> <ol style="list-style-type: none"> Automatic water system such as closed head sprinklers, open head deluge, or open directional spray nozzles. Deluge and open spray systems should have provisions for manual operation at remote station; however, there should also be provisions to preclude inadvertent operation. Location of sprinkler heads or spray nozzles should consider cable tray sizing and arrangements to assure adequate water coverage. <p>Cables should be designed to allow wetting down with deluge water without electrical faulting.</p> <p>Open head deluge and open directional spray systems should be zoned so that a single failure will not deprive the entire area of automatic fire suppression capability.</p>	<p>Automatic preaction sprinkler system is provided. One level of sprinklers is near the ceiling. The sprinkler heads in the intermediate level are under the grating and staggered between the upper-level heads.</p> <p>Cables are designed to allow wetting without faulting.</p>		<p>Actuation of the sprinkler system has been evaluated against NFPA 13-1975 and the detection system against NFPA 72D-1975 and 72E-1974. The detector circuits are Class A, supervised. Refer to Part X of the FPR.</p> <p>Not applicable.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>Open head deluge and open directional spray systems should be zoned so that a single failure will not deprive the entire area of automatic fire suppression capability.</p>			Not applicable.
<p>2. Manual hoses and portable extinguishers should be provided as backup.</p>	<p>Portable extinguishers located inside and immediately outside the cable spreading room are available. A hose station located outside this area provides a backup to the fixed suppression system.</p>		
<p>3. Each cable spreading room of each unit should have divisional cable separation, and be separated from each other and the rest of the plant by a minimum three-hour rated fire wall. (Refer to NFPA 251 or ASTM E-119 for fire test resistance rating.)</p>		<p>The cable spreading room is common to both units and contains circuits for certain redundant safe shutdown features. As a result, alternative shutdown capability has been provided independent of the Control Building. See section III.G.3 of 10 CFR 50 Appendix R requirements. The Control Building which includes the cable spreading room is separated from the adjacent buildings by three-hour rated barriers.</p>	See Part VII of the FPR.
<p>4. At least two remote and separate entrances are provided to the room for access by fire brigade personnel.</p>	<p>Doors to the Turbine Building at each end and doors to enclosed stairways at each end of the cable spreading room are provided for fire brigade access.</p>		
<p>5. Aisle separation provided between tray stacks should be at least three feet wide and eight feet high.</p>			Not a design criterion for WBN.

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>b. For cable spreading rooms that do not provide divisional cable separation of F.3, (a) 3, in addition to meeting F.3, (a) 1, 2, 4, and 5 above, the following should be provided:</p> <ol style="list-style-type: none"> 1. Divisional cable separation should meet the guidelines of Regulatory Guide 1.75, "Physical Independence of Electrical Systems," 2. All cabling should be covered with a suitable fire retardant coating. 3. As an alternate to F.3 (a) 1 above, automatically initiated gas system (Halon or CO₂) may be used for primary fire suppression, provided a fixed water system is used as a backup. 4. Plants that cannot meet the guidelines of Regulatory Guide 1.75, in addition to meeting F.3 (a) 1, 2, 4, and 5 above, an auxiliary shutdown system with all cabling independent of the cable spreading room should be provided. 	<p>The auxiliary control room is independent of the cable spreading room.</p>	<p>The cable separation criterion is documented in WB-DC-30-4 Separation/Isolation.</p> <p>IEEE 383 cables are used or non-IEEE-383 cables installed in cable trays in the cable spreading room are generally provided with fire retardant coating.</p>	<p>Regulatory Guide 1.75 is not a design basis for WBN.</p> <p>Up to ten non-IEEE cables in a tray may be left uncoated.</p> <p>Not applicable.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>F.4 <u>Plant Computer Room</u></p> <p>Safety-related computers should be separated from other areas of the plant by barriers having a minimum three-hour fire resistant rating. Automatic fire detection should be provided to alarm and annunciate in the control room and alarm locally. Manual hose stations and portable water and Halon fire extinguishers should be provided.</p>			<p>The plant computer and computer room are not required for fire safe shutdown. The room is separated from adjacent fire areas by 3-hour barriers and from adjacent rooms within the Control Building by 2-hour barriers. In addition, the wall to the Auxiliary Building is 3-hour rated. The room is provided with an automatic total flooding CO₂ system that is actuated by a cross-zoned detection system. Extinguishers and hose stations are available.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>F.5 <u>Switchgear Rooms</u></p> <p>Switchgear rooms should be separated from the remainder of the plant by minimum three-hour rated fire barriers to the extent practicable. Automatic fire detection should alarm and annunciate in the control room and alarm locally. Fire hose stations and portable extinguishers should be readily available.</p> <p>Acceptable protection for cables that pass through the switchgear room is automatic water or gas agent suppression. Such automatic suppression must consider preventing unacceptable damage to electrical equipment and possible necessary containment of agent following discharge.</p>	<p>The detection system annunciates in the main control room. Fire hose station and portable extinguishers are provided.</p>	<p>Each trained 6.9kV and 480V switchgear room is separated from each other and from other rooms in the Auxiliary Building by a minimum of 2-hour fire barriers and from the Control Building by 3-hour fire barriers. Each room is provided with automatic preaction suppression system that is actuated by cross-zoned detection. The suppression systems have been evaluated against NFPA 13-1975 and the detection system is installed as a Class A, supervised system that has been evaluated against NFPA 72D-1975. Water spray shields have been provided for safety-related equipment, as necessary. The Appendix R evaluation demonstrates that a fire in these areas will not endanger other safety-related equipment required for plant safe shutdown. On this basis and based on the detailed fire hazards analysis performed, the use of 2 hour barriers has been judged to be acceptable. Refer to Parts VI and X of the FPR.</p>	<p>Cables of redundant components required for fire safe shutdown are protected per the requirements of Appendix R Section III.G.2.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>F.6 <u>Remote Safety-Related Panels</u></p> <p>The general area housing remote safety-related panels should be provided with automatic fire detectors that alarm locally and annunciate in the control room. Combustible materials should be controlled and limited to those required for operation. Portable extinguishers and manual hose stations should be provided.</p> <p>F.7 <u>Station Battery Rooms</u></p> <p>Battery rooms should be protected against fire explosions. Battery rooms should be separated from each other and other areas of the plant by barriers having a minimum fire rating of three hours inclusive of all penetrations and openings. (See NFPA 69, "Standard on Explosion Prevention Systems.") Ventilation systems in the battery rooms should be capable of maintaining the hydrogen concentration well below 2% by volume. Standpipes and hose and portable extinguishers should be provided.</p>	<p>Train Instrument Rooms, ACR, and 480V Shutdown Board Rooms are generally provided with detection and suppression systems. Plant procedures control the amount of combustibles in the plant. Portable fire extinguishers and hose stations are provided.</p> <p>The required vital battery rooms I through IV are separated from all other plant areas by three-hour rated fire barriers. Vital battery room V and the 250V and 24/48V battery rooms are separated by 2-hour barriers. A ceiling vent is provided in each battery room with a direct exhaust to outside the building to maintain the concentration of hydrogen below 2% by volume within the battery rooms. WBN does not comply with any other section of NFPA 69-1973. Portable extinguishers, standpipes, and hose stations are available.</p>		<p>Vital Battery V is a spare that can be used for any of the other 4 vital batteries.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>Alternatives:</p> <ul style="list-style-type: none"> a. Provide a total fire rated barrier enclosure of the battery room complex that exceeds the fire load contained in the room, or b. Reduce the fire load to be within the fire barrier capability of 1-1/2 hours, or, c. Provide a remote manual actuated sprinkler system in each room and provide the 1-1/2 hour fire barrier separation. 	<p>The 5th vital battery and board room is separated from other plant areas by 2-hour barriers, which exceed the hazards to which they could be exposed.</p>		<p>Not applicable.</p> <p>Detection and manually actuated sprinkler system is provided for vital battery and battery board rooms (I-IV). In addition, a preaction sprinkler system is provided for the 5th Vital Battery and Board Room.</p>
<p>F.8 <u>Turbine Lubrication and Control Oil Storage and Use Areas</u></p> <p>A blank fire wall having a minimum resistance rating of three hours should separate all areas containing safety-related systems and equipment from the turbine oil system. When a blank wall is not present, open head deluge protection should be provided for the turbine hazards and automatic open head water curtain protection should be provided for wall openings.</p>		<p>The turbine oil tank hazards are protected by fixed water spray systems. Cable tray and door penetrations through the wall that separates the Turbine Building from the Control Building are sealed with equivalent 3-hour seals and are provided with water curtain protection on the Turbine Building side.</p>	

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>F.9 <u>Diesel Generator Areas</u></p> <p>Diesel generators should be separated from each other and other areas of the plant by fire barriers having a minimum fire resistance rating of three hours.</p> <p>Automatic fire suppression such as AFFF foam, or sprinklers should be installed to combat any diesel generator or lubricating oil fires.</p> <p>Automatic fire detection should be provided to alarm and annunciate in the control room and locally. Drainage for fire fighting water and means for local manual venting of smoke should be provided.</p> <p>Day tanks with total capacity up to 1100 gallons are permitted in the diesel generator area under the following conditions:</p>	<p>The Diesel Generator Building is remotely located and is not adjacent to any other safety-related building or structure. Each diesel generator and its associated equipment are separated from each other by 3-hour fire barriers.</p> <p>Each area is provided with automatic fire detection which alarms and annunciates in the control room and alarms locally. Drainage is available in the diesel generator rooms. Portable smoke ejectors are available for use by the fire brigade.</p>	<p>Each diesel generator and its associated electrical board room are protected by an automatic, total flooding CO₂ suppression system that has been evaluated against NFPA 12-1973. The pipe gallery and corridor are protected by a preaction sprinkler system.</p>	<p>Additional 225 kVA Diesel Generators are Installed on EI 786.0 of the Auxiliary Building for Beyond-Design-Basis accidents. Each 225 kVA diesel skid contains a built in double wall 185 gallon fuel tank. Detection and suppression are provided.</p> <p>The diesel generator electrical board rooms do not have drains for manual fire fighting water. The only fire fighting water would be from standpipe systems and personnel would be in the area at the time to ensure equipment was not adversely affected.</p> <p>Each diesel generator room has two 550-gallon day tanks, one for each diesel engine.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>a. The day tank is located in a separate enclosure, with a minimum fire resistance rating of three hours, including doors or penetrations. These enclosures should be capable of containing the entire contents of the day tanks. The enclosure should be ventilated to avoid accumulation of oil fumes.</p> <p>b. The enclosure should be protected by automatic fire suppression systems such as AFFF or sprinklers.</p> <p>When day tanks cannot be separated from the diesel generator one of the following should be provided for the diesel generator areas:</p> <p>a. Automatic open head deluge or open head spray nozzle system(s).</p> <p>b. Automatic closed head sprinklers.</p> <p>c. Automatic AFFF that is delivered by a sprinkler deluge or spray system.</p> <p>d. Automatic gas system (Halon or CO₂) may be used in lieu of foam or sprinklers to combat diesel generator and/or lubricating oil fires.</p>	<p>The two 550-gallon day tanks are located in the same room as its associated diesel generator and the room is provided with a total flooding CO₂ suppression system.</p>		

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>F.10 <u>Diesel Fuel Oil Storage Areas</u></p> <p>Diesel fuel oil tanks with a capacity greater than 1100 gallons should not be located inside the buildings containing safety-related equipment. They should be located at least 50 feet from any building containing safety-related equipment, or if located within 50 feet, they should be housed in a separate building with construction having a minimum fire resistance rating of three hours. Buried tanks are considered as meeting the three-hour fire resistance requirements. See NFPA 30, "Flammable and Combustible Liquids Code," for additional guidance.</p> <p>When located in a separate building, the tank should be protected by an automatic fire suppression system such as AFFF or sprinklers.</p> <p>Tanks, unless buried, should not be located directly above or below safety-related systems or equipment regardless of the fire rating of separating floors or ceilings.</p>	<p>The above ground diesel fuel oil storage tanks are located in a remote yard area more than 50 feet from any safety-related building or structure. These tanks are located within a diked area that will contain leaks or spills of fuel oil. WBN complies with NFPA 30-1973 for storage and handling of flammable and combustible liquids as transient combustible materials.</p>	<p>The seven-day fuel oil storage tanks for each diesel generator are buried under the floor of the diesel generator building. The only portions of the tanks that are not buried are the man-way access openings to each tank within the diesel rooms and in the common corridor outside the diesel rooms. The access openings have been provided with a cover plate and are in separate pits covered by removable steel plate covers. The impact of these manway access openings have been addressed in Part VII, Section 4.4 of the FPR.</p>	<p>Two additional 225 kVA Diesel Generators are installed on El 786.0 (roof - 3 hour fire barrier section) of the Auxiliary Building for Beyond-Design-Basis accidents. Each 225 kVA diesel skid contains a built in double wall 185 gallon fuel tank. All penetrations are water tight.</p> <p>Not applicable.</p> <p>The 225 kVA Diesel Generators fuel oil tanks are double wall 185 gallon fuel tanks. All penetration seals are water tight.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

<u>Appendix A Guidelines</u>	<u>Plant Conformance</u>	<u>Alternatives</u>	<u>Remarks</u>
<p>In operating plants where tanks are located directly above or below the diesel generators and cannot reasonably be moved, separating floors and main structural members should, as a minimum, have a fire resistance rating of three hours. Floors should be liquid-tight to prevent leaking of possible oil spills from one level to another. Drains should be provided to remove possible oil spills and fire fighting water to a safe location.</p> <p>One of the following acceptable methods of fire protection should also be provided:</p> <ol style="list-style-type: none"> Automatic open head deluge or open head spray nozzle system(s); Automatic closed head sprinklers; or Automatic AFFF that is delivered by a sprinkler system or spray system. 			<p>Not applicable.</p> <p>The 225 kVA Diesel Generator Rooms A and B have detection and automatic closed head suppression installed to the original NFPA code of record (Reference 4.2.87).</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>F.11 <u>Safety-Related Pumps</u></p> <p>Pump houses and rooms housing safety-related pumps should be protected by automatic sprinkler protection unless a fire hazards analysis can demonstrate that a fire will not endanger other safety-related equipment required for safe plant shutdown. Early warning fire detection should be installed with alarm and annunciation locally and in the control room. Local hose stations and portable extinguishers should also be provided.</p> <p>Equipment pedestals or curbs and drains should be provided to remove and direct water away from safety-related equipment.</p> <p>Provisions should be made for manual control of the ventilation system to facilitate smoke removal if required for manual fire fighting operation.</p>	<p>Full or partial detection and suppression provided in safety-related pump rooms, except as justified by the fire hazards analysis. The fire hazards analyses for areas housing safety-related pumps which are not provided with full area detection and suppression indicate that fire barrier ratings are sufficient given the combustible loadings in these areas. These areas are separate fire areas and the capability to achieve safe shutdown has been demonstrated through analysis. Therefore, fire in these areas will not endanger other safety-related equipment required for safe plant shutdown. Standpipes, hose stations, and portable fire extinguishers are also provided. Refer to Part VI and VII of the FPR.</p> <p>Floor drains, pedestals and curbs are provided to accommodate the removal of water away from safety-related equipment.</p> <p>Generally, normal ventilation systems are used for area smoke venting. In addition, portable smoke ejectors are available for use by the site fire brigade.</p>		
<p>F.12 <u>New Fuel Area</u></p> <p>Hand portable extinguishers should be located within this area. Also, local hose stations should be located outside but within hose reach of this area. Automatic fire detection should alarm and annunciate in the control room and alarm locally.</p>	<p>Standpipe and hose stations and portable fire extinguishers are located in the area and in adjacent room within hose reach.</p> <p>Fire detection in room 729.0-A5 alarms and annunciates in the MCR and locally.</p>	<p>Detection is not provided in the Refueling Room. Refer to Part VII, Section 4.5 of the FPR.</p>	

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>Combustibles should be limited to a minimum in the new fuel area. The storage area should be provided with a drainage system to preclude accumulation of water.</p> <p>The storage configuration of new fuel should always be maintained as to preclude criticality for any water density that might occur during fire water application.</p> <p>F.13 <u>Spent Fuel Pool Area</u></p> <p>Protection for the spent fuel pool area should be provided by local hose stations and portable extinguishers. Automatic fire detection should be provided to alarm and annunciate in the control room and to alarm locally.</p> <p>F.14 <u>Radwaste Building</u></p> <p>The Radwaste Building should be separated from other areas of the plant by fire barriers having at least three-hour ratings. Automatic sprinklers should be used in all areas where combustible materials are located. Automatic fire detection should be provided to annunciate and alarm in the control room and alarm locally.</p>	<p>In situ combustibles in the new fuel areas are limited to a minimum and these areas are provided adequate drainage to preclude the accumulation of water.</p> <p>The storage configuration of the new fuel precludes criticality for water density that might occur during fire protection water application.</p> <p>Standpipes, hose stations and portable fire extinguishers are provided in the area.</p>	<p>Detection is not provided in the spent fuel pool area. Refer to Part VII, Section 4.5 of the FPR.</p> <p>Radwaste areas are part of the Auxiliary Building (Rooms 729.0-A3 and -A4). This area is separated from the Railroad Bay by 2-hour barriers. Detection (which annunciates in the main control room) and suppression are provided.</p>	<p>The area containing the spent fuel pool pumps, coolers, and heat exchangers is provided with automatic detection and suppression. Refer to Part VII of the FPR.</p> <p>There is no Radwaste Building.</p>

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>During a fire, the ventilation system in these areas should be capable of being isolated. Water should drain to liquid Radwaste Building sumps.</p> <p>Acceptable alternative fire protection is an automatic fire detection to alarm and annunciate in the control room, in addition to manual hose stations and portable extinguishers consisting of hand-held and large wheeled units.</p> <p>F.15 <u>Decontamination Areas</u></p> <p>The decontamination areas should be protected by automatic sprinklers if flammable liquids are stored. Automatic fire detection should be provided to annunciate and alarm in the control room and alarm locally. The ventilation system should be capable of being isolated. Local hose stations and hand portable extinguishers should be provided as backup to the sprinkler system.</p>	<p>Rooms 729.0-A3 & A4 have fire dampers with fusible links in the ventilation system ducts at each point the ducts enters the rooms. The drains for these rooms go to either the Tritiated Drain Collector Tank or the Floor Drain Collector Tank, both of which are in the Auxiliary Building.</p> <p>The decontamination room (713.0-A27) is provided with automatic suppression and detection that provides alarms at a constantly attended location and locally. In addition, hose stations (in adjacent room) and portable fire extinguishers are available.</p>	<p>Manual hose stations (located in room 729.0-A5) and hand held portable extinguishers are available.</p> <p>The cask decontamination room (728.0-A7) has hose station and portable extinguishers available in the area. The ventilation system can be isolated. Flammable liquids are not stored in this room.</p>	

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

<u>Appendix A Guidelines</u>	<u>Plant Conformance</u>	<u>Alternatives</u>	<u>Remarks</u>
<p>F.16 <u>Safety-Related Water Tanks</u></p> <p>Storage tanks that supply water for safe shutdown should be protected from the effects of fire. Local hose stations and portable extinguishers should be provided. Portable extinguishers should be located in nearby hose houses. Combustible materials should not be stored next to outdoor tanks. A minimum of 50 feet of separation should be provided between outdoor tanks and combustible materials where feasible.</p>	<p>The refueling water storage tanks are located outdoors. Combustible materials are controlled within 50 feet of outdoor tanks per the administrative control program. The volume control tanks are located inside the Auxiliary Building in rooms that have a 2-hour rating and are provided with automatic preaction sprinkler system actuated by cross-zoned detection system.</p>	<p>Yard hydrants are strategically located for providing protection to the refueling water storage tanks. Portable extinguishers and adequate lengths of hose are maintained on mobile apparatus.</p>	<p>Mobile apparatus can be used in lieu of hose houses.</p>
<p>F.17 <u>Cooling Towers</u></p> <p>Cooling towers should be of noncombustible construction or so located that a fire will not adversely affect any safety-related systems or equipment. Cooling towers should be of noncombustible construction when the basins are used for the ultimate heat sink or for the fire protection water supply.</p> <p>Cooling towers of combustible construction, so located that a fire in them could adversely affect safety-related systems or equipment should be protected with an open head deluge system installation with hydrants and hose houses strategically located.</p>	<p>The cooling towers are of noncombustible construction (except for the drift eliminators and replacement fills) and are located so that a fire will not affect safety-related systems or equipment.</p> <p>Yard hydrants are available to support manual fire suppression activities around the cooling towers.</p>		

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>F.18 <u>Miscellaneous Areas</u></p> <p>Miscellaneous areas such as records storage areas, shops, warehouses, and auxiliary boiler rooms should be so located that a fire or effects of a fire, including smoke, will not adversely affect any safety-related systems or equipment</p> <p>Fuel oil tanks for auxiliary boilers should be buried or provided with dikes to contain the entire tank contents.</p> <p>G. <u>Special Protection Guidelines</u></p> <p>G.1 <u>Welding and Cutting, Acetylene Oxygen Fuel Gas Systems</u></p> <p>This equipment is issued in various areas throughout the plant. Storage locations should be chosen to permit fire protection by automatic sprinkler systems. Local hose stations and portable equipment should be provided as backup. The requirements of NFPA 51 and 51B are applicable to these hazards. A permit system should be required to utilize this equipment. (Also refer to 2f herein.)</p>	<p>Miscellaneous areas are located or protected such that the effects of fire or smoke will not adversely affect safety-related systems or equipment.</p> <p>The auxiliary boilers are fed from the fuel oil tanks that are located in the yard. These tanks are in a diked area. The diked area will contain the contents of one tank.</p>	<p>Oxygen and acetylene are controlled by administrative procedures in safety-related areas of the plant. Welding and cutting operations are controlled by operational procedures. Portable extinguishers and yard hydrants are strategically located for use. WBN adequately addresses the functional requirements of NFPA 51B-1976. Refer to Part X of the FPR.</p>	

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

Appendix A Guidelines	Plant Conformance	Alternatives	Remarks
<p>G.2 <u>Storage Areas for Dry Ion Exchange Resins</u></p> <p>Dry ion exchange resins should not be stored near essential safety-related systems. Dry unused resins should be protected by automatic wet pipe sprinkler installations. Detection by smoke and heat detectors should alarm and annunciate in the control room and alarm locally.</p> <p>Local hose stations and portable extinguishers should provide backup for these areas. Storage areas of dry resin should have curbs and drains. (Refer to NFPA 92M, "Waterproofing and Draining of Floors.")</p>	<p>Extinguishers and hose stations are available. See the response to D.1.i regarding NFPA 92M.</p>	<p>The ion exchange resins at WBN have an entrained moisture content of 50-60 percent and are therefore not considered a fire hazard.</p>	
<p>G.3 <u>Hazardous Chemicals</u></p> <p>Hazardous chemicals should be stored and protected in accordance with the recommendations of NFPA 49, "Hazardous Chemicals Data." Chemical storage areas should be well ventilated and protected against flooding conditions since some chemicals may react with water to produce ignition.</p>		<p>Hazardous chemicals are controlled in accordance with administrative procedures in safety-related buildings or structures, or in areas that will expose safety-related equipment. The ammonia and hydrazine storage is in the Turbine Building. The Turbine Building ventilation system provides adequate ventilation. The acid and caustic storage tanks are located in a remote building and are provided with adequate ventilation. NFPA 49-1975 is only applicable to chemistry lab work at WBN. Refer to Part X of the FPR.</p>	

PART VIII – CONFORMANCE TO APPENDIX A TO BTP 9.5-1 GUIDELINES

<u>Appendix A Guidelines</u>	<u>Plant Conformance</u>	<u>Alternatives</u>	<u>Remarks</u>
<p>G.4 <u>Materials Containing Radioactivity</u></p> <p>Materials that collect and contain radioactivity such as spent ion exchange resins, charcoal filters, and HEPA filters should be stored in closed metal tanks or containers that are located in areas free from ignition sources or combustibles. These materials should be protected from exposure to fires in adjacent areas as well. Consideration should be given to requirements for removal of isotopic decay heat from entrained radioactive materials.</p>	<p>Materials containing or collecting radioactivity are stored in closed metal containers in the radwaste area. Rated fire barriers are provided to preclude exposure to fire in adjacent areas. Requirements for control of decay heat are developed for specific storage materials.</p>		

PART IX – APPENDIX R COMPLIANCE MATRIX

PART IX - APPENDIX R COMPLIANCE MATRIX

Based on the criteria established in 10 CFR Part 50.48, WBN's licensing commitment requires compliance with Sections III-G, -J, and -O of Appendix R, and Section III.L where necessary. The information which follows is a lineup of the Watts Bar Nuclear Plant (WBN) designs against the requirements of Appendix R to 10 CFR Part 50.

Appendix R requirements are given in the first (left-hand) column of the following tabulations, retaining the numbering sequence of Appendix R. Information on various aspects of the WBN Fire Protection Program's compliance is given in the second column, with details provided in other Parts of the FPR or other plant documentation, to demonstrate conformance with Appendix R requirements. The third column describes alternative approaches and references deviation requests/engineering evaluations. The fourth column provides supplemental information as appropriate.

PART IX – APPENDIX R COMPLIANCE MATRIX

Appendix R Requirements	Plant Conformance	Alternatives	Remarks
<p>I. INTRODUCTION AND SCOPE (Details deleted)</p> <p>II. GENERAL REQUIREMENTS</p> <p>II.A Fire Protection Program</p> <p>A fire protection program shall be established at each nuclear power plant which shall establish the fire protection policy for the protection of structures, systems and components important to safety at each plant, and the procedures, equipment, and personnel required to implement the program at the plant site.</p> <p>The fire protection program shall be under the direction of an individual who has been delegated authority commensurate with the responsibilities of the position and who has available staff personnel knowledgeable in both fire protection and nuclear safety.</p>			<p>The Fire Protection Program at WBN is formulated to: a) prevent fires from occurring through plant design and administrative control, b) detect fires quickly, control, and extinguish promptly those fires that do occur, and c) to ensure through separation of essential components that a single fire that is not promptly extinguished could not jeopardize plant safe shutdown. This is described in the Fire Protection Plan.</p> <p>Plant procedures delineate the individuals who have been delegated authority over the fire protection program.</p>

PART IX – APPENDIX R COMPLIANCE MATRIX

Appendix R Requirements	Plant Conformance	Alternatives	Remarks
<p>The fire protection program shall extend the concept of defense-in-depth to fire protection in fire areas important to safety, with the following objectives:</p> <ul style="list-style-type: none">• To prevent fires from starting;• To detect rapidly, control, and extinguish promptly, those fires that do occur; and• To provide protection for structures, systems, and components important to safety so that a fire that is not promptly extinguished by the fire suppression activities will not prevent the safe shutdown of the plant.			

PART IX – APPENDIX R COMPLIANCE MATRIX

Appendix R Requirements	Plant Conformance	Alternatives	Remarks
<p>II.B Fire Hazards Analysis</p> <p>A fire hazards analysis shall be performed by qualified fire protection and reactor systems engineers to (1) consider potential in situ and transient fire hazards; (2) determine the consequences of fire in any location in the plant on the ability to safely shut down the reactor or on the ability to minimize and control the release of radioactivity to the environment; and (3) specify measures for fire prevention, fire detection, fire suppression, and fire containment and alternative shutdown capability as required for each fire area containing structures, systems, and components important to safety in accordance with NRC guidelines and regulations.</p> <p>II.C Fire Prevention Features</p> <p>C.1 In situ fire hazards shall be identified and suitable protection provided.</p>			<p>A fire hazard analysis was performed for WBN which considered potential fire hazards and their possible effect on safe shutdown capability (see Fire Hazards Analysis, Part VI of the FPR).</p> <p>In situ fire hazards are identified in the combustible loading summary and suitable protection provided (see Part VI of the FPR).</p>

PART IX – APPENDIX R COMPLIANCE MATRIX

Appendix R Requirements	Plant Conformance	Alternatives	Remarks
<p>C.2 Transient fire hazards associated with normal operation, maintenance, repair, or modification activities shall be identified and eliminated where possible. Those transient fire hazards that cannot be eliminated shall be controlled and suitable protection provided.</p>			<p>A combustibles control program is utilized to minimize transient combustibles. Refer to Section 10.0, "Control of Combustibles," of Part II, "Fire Protection Plan."</p>
<p>C.3 Fire detection systems, portable extinguishers, and standpipe and hose stations shall be installed.</p>			<p>Fire detection and suppression systems are installed as described in Part II, Fire Protection Plan, and Part VI, Fire Hazards Analysis, of the FPR.</p>
<p>C.4 Fire barriers or automatic suppression systems or both shall be installed as necessary to protect redundant systems or components necessary for safe shutdown.</p>			<p>The suppression systems and fire barriers are described in Part II, Fire Protection Plan, and Part VI, Fire Hazards Analysis, of the FPR.</p>
<p>C.5 A site fire brigade shall be established, trained, and equipped and shall be onsite at all times.</p>			<p>See the Fire Protection Plan described in Part II of the FPR for details of the site fire brigade</p>
<p>C.6 Fire detection and suppression systems shall be designed, installed, maintained, and tested by personnel properly qualified by experience and training in fire protection systems.</p>			<p>Fire detection and suppression systems are described in Part II, Fire Protection Plan, and Part VI, Fire Hazards Analysis, of the FPR.</p>

PART IX – APPENDIX R COMPLIANCE MATRIX

Appendix R Requirements	Plant Conformance	Alternatives	Remarks
<p>C.7 Surveillance procedures shall be established to ensure that fire barriers are in place and that fire suppression systems and components are operable.</p> <p>II.D Alternative or Dedicated Shutdown Capability</p> <p>In areas where the fire protection features cannot ensure safe shutdown capability in the event of a fire in that area, alternative or dedicated safe shutdown capability shall be provided.</p> <p>III. Specific Requirements</p> <p>III.A Water Supplies for Fire Suppression Systems (Details deleted)</p> <p>III.B Sectional Isolation Valves</p> <p>III.C Hydrant Isolation Valves (Details Deleted)</p> <p>III.D Manual Fire Suppression (Details Deleted)</p> <p>III.E Hydrostatic Hose Tests (Details Deleted)</p>			<p>Surveillance procedures have been established to ensure that fire barriers are in place and that fire suppression systems and components are operable.</p> <p>Alternative shutdown is provided for those Control Building fires that could result in abandonment of the main control room.</p> <p>Section 12 of Part II, Fire Protection Plan, of the FPR describes the water supplies for the fire suppression systems.</p>

PART IX – APPENDIX R COMPLIANCE MATRIX

Appendix R Requirements	Plant Conformance	Alternatives	Remarks
<p>III.F Automatic Fire Detection (Details Deleted)</p> <p>III.G Fire Protection of Safe Shutdown Capability</p> <p>G.1 Fire protection features shall be provided for structures, systems, and components important to safe shutdown. These features shall be capable of limiting fire damage so that:</p> <p>a. One train of systems necessary to achieve and maintain hot shutdown conditions from either the control room or emergency control station(s) is free of fire damage; and</p> <p>b. Systems necessary to achieve and maintain cold shutdown from either the control room or emergency control station(s) can be repaired within 72 hours.</p>	<p>The WBN fire protection program is designed to ensure that one train of systems necessary to achieve and maintain hot shutdown conditions from either the main control room or alternate shutdown panels is kept free of fire damage provided manual actions are also credited.</p> <p>Cold shutdown system repairs can be accomplished within 72 hours. Refer to Part V of the FPR. Selected manual actions (e.g., valve operation) may be required.</p>		<p>Part II, Section 12.5 of the FPR describes the fire detection systems.</p> <p><u>See Part VII, Section 2.9 for details on compliance using FHA.</u></p> <p>Free of fire damage means that the system or component is capable of performing its intended function. Manual actions such as valve operation by a handwheel are allowed when within minimum staffing and system safety limits. Portable ventilation is available if normal HVAC is lost.</p>

PART IX – APPENDIX R COMPLIANCE MATRIX

Appendix R Requirements	Plant Conformance	Alternatives	Remarks
<p>G.2 Except as provided for in paragraph G.3 of this section, where cables or equipment including associated nonsafety circuits that could prevent operation or cause maloperation due to hot shorts, open circuits or shorts to ground, or redundant trains of systems necessary to achieve and maintain hot shutdown conditions are located within the same fire area outside of primary containment, one of the following means of ensuring that one of the redundant trains is free of fire damage shall be provided:</p> <p>a. Separation of cables and equipment and associated nonsafety circuits of redundant trains by a fire barrier having a three-hour rating. Structural steel forming a part of or supporting such fire barriers shall be protected to provide fire resistance equivalent to that required of the barrier.</p>	<p>Safe shutdown capability is assured by separation or protection of equipment performing functions necessary for safe shutdown. The type of protection provided varies from area to area.</p> <p>Separation of redundant cables and equipment and associated nonsafety circuits in the same fire area by fire barriers having a three-hour rating are provided in certain areas. Structural steel supporting electrical raceways protected with ERFBS is protected to provide fire resistance equivalent to the ERFBS in accordance with the requirements of G-Spec G-98.</p>	<p>In certain areas, deviations from the separation criteria of Appendix R are identified. In these cases, alternate or equivalent fire protection is provided. Refer to Parts VI and VII of the FPR.</p>	<p>Refer to Part VI of the FPR for more information on separation and fire protection provided in individual areas.</p> <p>Refer to Part VI of the FPR for more information on separation and fire protection provided in individual areas.</p>

PART IX – APPENDIX R COMPLIANCE MATRIX

Appendix R Requirements	Plant Conformance	Alternatives	Remarks
<p>b. Separation of cables and equipment associated nonsafety circuits of redundant trains by a horizontal distance of more than 20 feet with no intervening combustible or fire hazards. In addition, fire detectors and an automatic fire suppression system shall be installed in the fire area.</p> <p>c. Enclosure of cable and equipment and associated nonsafety circuits of one redundant train in a fire barrier having a one-hour rating. In addition, fire detectors and an automatic fire suppression system shall be installed in the fire area; or</p> <p>Inside noninerted containments one of the fire protection means specified above or one of the following fire protection means shall be provided:</p>	<p>Separation of redundant cables equipment and associated nonsafety circuits is provided by a horizontal distance greater than 20 feet with no intervening combustibles or fire hazards in certain areas. Fire detectors and automatic fire suppression systems are installed in areas indicated in Part VI of the FPR.</p> <p>Redundant cables and equipment and associated nonsafety circuits are enclosed in a fire barrier having a one-hour rating in certain areas. Fire detectors and automatic suppression are installed as indicated in Part VI of the FPR.</p>	<p>In certain areas, deviations from the separation criteria of Appendix R are identified. In these cases, alternate or equivalent fire protection is provided. In other areas, engineering evaluations are used to document the adequacy of less than full detection and/or suppression coverage. Refer to Part VI and Part VII of the FPR.</p> <p>In some areas, engineering evaluations are used to document the adequacy of less than full detection and/or suppression coverage. Refer to Part VII of the FPR.</p>	<p>Since the containments at WBN are noninerted, fire protection is provided by one or more of the means as indicated below.</p>

PART IX – APPENDIX R COMPLIANCE MATRIX

Appendix R Requirements	Plant Conformance	Alternatives	Remarks
<p>d. Separation of cables and equipment and associated nonsafety circuits of redundant trains by a horizontal distance of more than 20 feet with no intervening combustibles or fire hazards;</p> <p>e. Installation of fire detectors and an automatic fire suppression system in the fire area; or</p> <p>f. Separation of cables and equipment and associated nonsafety circuits of redundant trains by a noncombustible radiant energy shield.</p>	<p>Detection and automatic suppression are used in selected areas of the Annulus to protect redundant safe shutdown cables.</p> <p>Radiant energy shields are used in selected areas to protect redundant safe shutdown cables.</p>		<p>Redundant cables and equipment inside containment are addressed by Sections III.G.2d, 2e, and/or 2f as appropriate or by FHA. Refer to Part VI and Part VII, Section 2.9 of the FPR.</p>

PART IX – APPENDIX R COMPLIANCE MATRIX

Appendix R Requirements	Plant Conformance	Alternatives	Remarks
<p>G.3 Alternative or dedicated shutdown capability and its associated circuits, independent of cables, systems, or components in the area, room, or zone under consideration shall be provided:</p> <p>a. Where the protection of systems whose function is required for hot shutdown does not satisfy the requirement of paragraph G.2 of this section; or</p> <p>b. Where redundant trains of systems required for hot shutdown located in the same fire area may be subject to damage from fire suppression activities or from the rupture or inadvertent operation of fire suppression systems.</p>	<p>An alternate shutdown capability is provided for those Control Building fires that could cause abandonment of the main control room, such as fires in the main control room, cable spreading room, and auxiliary instrument rooms. Alternate shutdown panels are located in the auxiliary control room located in the Auxiliary Building. Cables, systems, and components necessary to achieve safe shutdown using the auxiliary control room are independent (physically and electrically) of the main control room and auxiliary instrument rooms.</p>		

PART IX – APPENDIX R COMPLIANCE MATRIX

Appendix R Requirements	Plant Conformance	Alternatives	Remarks
<p>In addition, fire detection and a fixed fire suppression system shall be installed in the area, room, or zone under consideration.</p> <p>III.H Fire Brigade</p> <p>III.I Fire Brigade Training</p> <p>III.J Emergency Lighting</p> <p>Emergency lighting units with at least an eight-hour battery power supply shall be provided in all areas needed for operation of safe shutdown equipment and in access and egress routes thereto.</p> <p>III.K Administrative Controls</p>	<p>The main control room has installed fire detection. The cable spreading room and auxiliary instrument rooms are provided with detection and automatic suppression. Other portions of the Control Building are provided with detection and suppression as identified in Part VI of the FPR.</p> <p>Emergency lighting units with minimum eight-hour capabilities are provided in areas required for the operation of safe shutdown equipment and in access and egress routes.</p>	<p>The main control room is not provided with a fixed suppression system, but has portable extinguishers located inside and hose stations available for use in the area. Other areas of the Control Building with less than full detection and suppression systems have low fire loadings.</p> <p>Diesel generator backed standby lighting is used in Turbine Building and Yard and portable lanterns are used in the Reactor Building in lieu of 8-hour battery power lights. Refer to Part VII of the FPR.</p>	<p>Refer to Part VI of the FPR for details in individual areas.</p> <p>Refer to Part VII of the FPR for the III.G.3 fixed suppression deviation request in the Control Building.</p> <p>Fire Brigade and their training are discussed in Part II, section 9.0 of the FPR.</p> <p>Not applicable.</p>

PART IX – APPENDIX R COMPLIANCE MATRIX

Appendix R Requirements	Plant Conformance	Alternatives	Remarks
<p>III.L Alternative and Dedicated Shutdown Capability</p> <p>L.1 Alternative or dedicated shutdown capability provided for a specific fire area shall be able to:</p> <ul style="list-style-type: none"> a. Achieve and maintain subcritical reactivity conditions in the reactor; b. Maintain reactor coolant inventory; c. Achieve and maintain hot standby conditions for PWR (hot shutdown for a BWR); d. Achieve cold shutdown conditions within 72 hours; e. Maintain cold shutdown conditions thereafter. 	<p>The alternate shutdown capability (provided for Control Building fires that require main control room abandonment) is able to achieve and maintain subcritical reactivity conditions in the reactor, maintain reactor coolant inventory, achieve and maintain hot standby conditions and achieve cold shutdown conditions within 72 hours, and maintain cold shutdown conditions thereafter.</p>		

PART IX – APPENDIX R COMPLIANCE MATRIX

Appendix R Requirements	Plant Conformance	Alternatives	Remarks
<p>During the post fire shutdown, the reactor coolant system process variables shall be maintained within those predicted for a loss of normal AC power, and the fission product boundary integrity shall not be affected; i.e., there shall be no fuel clad damage, rupture of any primary coolant boundary, or rupture of the containment boundary.</p> <p>L.2 The performance goals for the shutdown functions shall be:</p> <ul style="list-style-type: none"> a. The reactivity control function shall be capable of achieving and maintaining cold shutdown reactivity conditions. b. The reactor coolant makeup function shall be capable of maintaining the reactor coolant level above the top of the core for BWRs and be within the level indication in the pressurizer for PWRs. 	<p>The process variables can be maintained within those predicted for loss of normal AC power. No fuel clad damage, rupture of any primary coolant boundary, or rupture of the containment boundary will occur because these conditions are prevented from occurring following a fire in the Control Building.</p> <p>Performance goals of the alternate shutdown capability are achieved according to Section III.L.2, items a through e.</p>		

PART IX – APPENDIX R COMPLIANCE MATRIX

Appendix R Requirements	Plant Conformance	Alternatives	Remarks
<p>c. The reactor heat removal function shall be capable of achieving and maintaining decay heat removal.</p> <p>d. The process monitoring function shall be capable of providing direct readings of the process variable necessary to perform and control the above functions.</p> <p>e. The supporting functions shall be capable of providing the process cooling, lubrication, etc., necessary to permit the operation of the equipment used for safe shutdown functions.</p> <p>L.3 The shutdown capability for specific fire areas may be unique for each such area, or it may be one unique combination of systems for all such areas. In either case, the alternative shutdown capability shall be independent of the specific fire area(s) and shall accommodate postfire conditions where offsite power is available and where offsite power is not available for 72 hours.</p>	<p>The alternate shutdown capability is independent of the Control Building. Post fire conditions can be accommodated with or without offsite power available for 72 hours.</p>	<p>Refer to Part VII of the FPR for Tc indication deviation request.</p>	

PART IX – APPENDIX R COMPLIANCE MATRIX

Appendix R Requirements	Plant Conformance	Alternatives	Remarks
<p>Procedures shall be in effect to implement this capability.</p> <p>L.4 If the capability to achieve and maintain cold shutdown will not be available because of fire damage, the equipment and systems comprising the means to achieve and maintain the hot standby or hot shutdown condition shall be capable of maintaining such conditions until cold shutdown can be achieved. If such equipment and systems will not be capable of being powered by both onsite and offsite electric power systems because of fire damage, an independent onsite power system shall be provided. The number of operating shift personnel exclusive of fire brigade members, required to operate such equipment and systems shall be onsite at all times.</p>	<p>Plant procedures address alternate shutdown capability.</p> <p>The systems used during alternate shutdown are capable of being powered by both onsite and offsite power. There are sufficient operating shift personnel, independent of the Fire Brigade, onsite to accomplish safe shutdown simultaneously.</p>		

PART IX – APPENDIX R COMPLIANCE MATRIX

Appendix R Requirements	Plant Conformance	Alternatives	Remarks
<p>L.5 Equipment and systems comprising the means to achieve and maintain cold shutdown conditions shall not be damaged by fire; or the fire damage to such equipment and systems shall be limited so that the systems can be made operable and cold shutdown can be achieved within 72 hours. Materials for such repairs shall be readily available onsite and procedures shall be in effect to implement such repairs. If such equipment and systems used prior to 72 hours after the fire will not be capable of being powered by both onsite and offsite electric power systems because of fire damage, an independent onsite power system shall be provided. Equipment and systems used after 72 hours may be powered by offsite power only.</p> <p>L.6 Shutdown systems installed to ensure post fire shutdown capability need not be designed to meet seismic Category I criteria, single failure criteria, or other design basis accident criteria, except where required for other reasons, e.g., because of interface with or impact on existing safety systems, or because of adverse valve actions due to fire damage.</p>	<p>Repair of cold shutdown components can be accomplished and cold shutdown achieved within 72 hours. Materials required for this repair are readily available onsite and procedures are in effect to implement these repairs. Local operation of selected equipment is required.</p> <p>An adequate inventory of fuses is available onsite.</p>		<p>Portable ventilation is available if normal HVAC is lost.</p> <p>No systems were installed for alternate or dedicated safe shutdown.</p>

PART IX – APPENDIX R COMPLIANCE MATRIX

Appendix R Requirements	Plant Conformance	Alternatives	Remarks
<p>L.7 The safe shutdown equipment and systems for each fire area shall be known to be isolated from associated nonsafety circuits in the fire area so that hot shorts, open circuits, or shorts to ground in the associated circuits will not prevent operation of the safe shutdown equipment. The separation and barriers between trays and conduits containing associated circuits of one safe shutdown division and trays and conduits containing associated circuits or safe shutdown cables from the redundant division, or the isolation of these associated circuits from the safe shutdown equipment, shall be such that a postulated fire involving associated circuits will not prevent safe shutdown.</p> <p>III.M Fire Barrier Cable Penetration Seal Qualification</p> <p>III.N Fire Doors</p>	<p>The safe shutdown equipment and systems are protected from hot shorts, shorts to ground, or open circuits in associated circuits such that a postulated fire involving associated circuits will not adversely affect safe shutdown capability.</p>		<p>Penetration seals are discussed in Part II, Section 12.10.6 of the FPR.</p> <p>Fire doors are discussed in Part II, Section 12.10.4 of the FPR.</p>

PART IX – APPENDIX R COMPLIANCE MATRIX

Appendix R Requirements	Plant Conformance	Alternatives	Remarks
<p>III.O Oil Collection System for Reactor Coolant Pump</p> <p>The reactor coolant pump shall be equipped with an oil collection system if the containment is not inerted during normal operation. The oil collection system shall be so designed, engineered, and installed that failure will not lead to fire during normal or design basis accident conditions and that there is reasonable assurance that the system will withstand the safe shutdown earthquake.</p> <p>Such collection systems shall be capable of collecting lube oil from all potential pressurized and unpressurized leakage sites in the reactor coolant pump lube oil systems. Leakage shall be collected and drained to a vented closed container that can hold the entire lube oil system inventory. A flame arrestor is required in the vent if the flash point characteristics of the oil present the hazard of fire flashback.</p>	<p>The RCPs are equipped with an oil collection system. The pumps, lube oil systems, oil spray shields, oil collection, and containment sump are all designed to seismic Category I requirements. The oil collection system is designed, engineered, and installed such that failure will not lead to fire during normal or design basis accident conditions and that there is reasonable assurance that the system will withstand the safe shutdown earthquake.</p> <p>The collection system is designed to collect oil from all pressurized and unpressurized leakage sites in the RCP lube oil system. No flame arrestors are needed because the tank is located away from the heat source of the reactor coolant system and because the flash point of the oil is over 450°F, while the maximum normal operating temperature of the oil is 200°F. Containment operating temperature is approximately 120°F, which is well below the flash point of the oil.</p>	<p>Refer to Part VII of the FPR for deviation to allow minor oil leakage outside the lube oil collection system.</p>	<p>Leakage is drained to each reactor's building floor and equipment sump which is a closed vented container of adequate size to hold the entire lube oil system inventory.</p>

PART IX – APPENDIX R COMPLIANCE MATRIX

Appendix R Requirements	Plant Conformance	Alternatives	Remarks
<p>Leakage points to be protected shall include lift pump and piping, overflow lines, lube oil cooler, oil fill, drain lines and plugs, flanged connections on oil lines, and lube oil reservoirs where such features exist on the reactor coolant pumps.</p> <p>The drain line shall be large enough to accommodate the largest potential oil leak.</p>	<p>The drain line will accommodate the largest potential oil leak.</p>		

PART X – NFPA CODE EVALUATION

1.0 INTRODUCTION

Part X determines the level of compliance with applicable National Fire Protection Association (NFPA) codes at Watts Bar Nuclear Plant (WBN). The objective is achieved by:

- (1) identifying the NFPA codes and standards to which WBN is committed for the installation of passive and active fire protection features;
- (2) reviewing plant documentation and procedures to determine the location of passive and active fire protection features; and
- (3) comparing the existing levels and configurations of passive and active fire protection features at WBN against the criteria contained within each applicable NFPA code and standard.

Where deviations from the code criteria are identified, justifications for existing configurations to demonstrate equivalent levels of protection are required. Those code deviations that have a potential impact on the operational capabilities of the specific fire protection feature are identified and justified in Part VII, Section 5.0 of the Fire Protection Report (FPR). The compliance status of WBN fire protection features against the applicable code and section is identified in this Part.

2.0 SCOPE

The scope of this evaluation is limited to those fire protection features that are provided for those buildings and areas that contain systems, cables, or components relied on for safety related and fire safe shutdown (FSSD) purposes at WBN. This evaluation addresses fire protection features in both Reactor Buildings, the common Auxiliary Building (includes Unit 1 and Unit 2 Additional Equipment Buildings, fuel handling areas and main steam valve vaults) and Control Building, Diesel Generator Buildings, and intake pumping station at WBN.

Other buildings that do not contain systems, components, or cables relied on for safety related and FSSD purposes are not included in the scope of this review.

The scope of the review was to identify the passive and active fire protection features as installed at WBN and evaluate the level of compliance with the applicable sections of the NFPA codes. This scope was achieved by an article-by-article or section-by-section review of the applicable code articles. Included in this review were automatic detection systems, manual and automatic fixed suppression systems (water-based and CO₂ suppression systems), fire doors, fire dampers, manual hose stations, portable extinguishers, exterior hydrants, and fire pumps.

The scope of this evaluation was accomplished through a combination of field walkdowns and a review of documentation for references to passive and active fire protection features. Those codes which are referenced in Appendix A to BTP 9.5-1 are covered in this Part, with documentation reviewed and/or field walkdowns performed to evaluate those fire protection features that are relied on for compliance with Appendix A to BTP 9.5-1 and Appendix R to 10CFR50. Documentation reviews and/or field walkdowns were not performed for all applicable codes referenced in Appendix A to BTP 9.5-1. Section 3.3 provides the bases for the level of review and methods of documentation for each applicable NFPA code addressed in this Part.

PART X – NFPA CODE EVALUATION

To establish the level of compliance with the NFPA codes addressed in this Part, plant documentation dealing with fire protection related issues was reviewed. Information on the fire protection features existing at WBN was then reviewed to determine the level of compliance with the NFPA codes. As a general rule, the appendix of each NFPA code states that it is not a portion of the code and is included for information purposes only. As such, appendices to the codes were not included in the scope of the evaluation. However, where appropriate, the guidance contained in the appendices was utilized to either justify existing configurations or identify additional fire protection features that should be provided.

The code conformance evaluation was conducted by experienced fire protection engineers familiar with the application of NFPA codes and standards to nuclear power plants. Personnel holding Member Grade status in the Society of Fire Protection Engineers were responsible for review of the level of code compliance and preparation of the bases for justification of deviations identified in this Part. The code conformance evaluation was developed and/or reviewed by both engineering and fire operations personnel.

3.0 APPLICABLE NFPA CODES

A total of 30 NFPA codes are specifically identified in Appendix A to BTP 9.5-1; however not all them are directly applicable to WBN. Codes not applicable to WBN were identified, along with the bases for non-applicability.

3.1 NFPA Codes Not Applicable to WBN

Some of the codes address fire protection features that are not installed at WBN. These codes have not been addressed. In addition, some of the codes address requirements that are not applicable to the multi-story, noncombustible construction buildings of WBN. Other codes provide general guidance on training and organization of fire brigades and guidance on fire loss prevention, some of which have been superseded by new codes. The NFPA codes identified in Appendix A to BTP 9.5-1 that fall into these categories have been identified and are listed below.

3.1.1 Not Applicable Codes - Apply to Single Story and/or Combustible Structures

The following NFPA codes are not applicable because the code requirements are not directly applicable to the multi-story, noncombustible construction structures at WBN:

NFPA 92M-1972	Waterproofing and Draining of Floors (Waterproofing of floors is not required at WBN. Adequate drainage exists as documented in suppression effects calculations.)
NFPA 204-1968	Smoke and Heat Venting (Smoke and heat venting is covered by pre-fire plans and implemented by the fire brigade. NFPA 204 was applicable to single story structures and has been superseded by NFPA 204M.)

3.1.2 Not Applicable Codes - Fire Brigade and Fire Loss Prevention

The following NFPA codes are not applicable to WBN because the codes provide general guidance on training and organization of fire brigades and guidance on fire loss prevention, some of which have also been superseded by new codes:

- NFPA 4-1977 Organization for Fire Services

PART X – NFPA CODE EVALUATION

- NFPA 4A-1969 Organization for Fire Department
- NFPA 6-1974 Recommendations for Organization of Industrial Fire Loss Prevention
- NFPA 7-1974 Recommendations for Management Control of Fire Emergencies
- NFPA 8-1974 Recommendations for Management Responsibility for Effects of Fire on Operations
- NFPA 27-1975 Private Fire Brigades
- NFPA 197-1966 Training Standard on Initial Fire Attack
- NFPA 601-1975 Guard Service in Fire Loss Prevention

The training and organization of the WBN fire brigade is identified in detail in Part II of the FPR, thereby demonstrating proper training and organization of onsite firefighting capabilities.

3.2 Not Applicable Codes - WBN Site-Specific Fire Protection Features

A number of NFPA codes that are typically applicable to nuclear power plants are not applicable to WBN based on site-specific methods for implementation of fire protection features. In most cases, existing fire protection features were identified and evaluated for the level of protection afforded by the fire protection feature. This approach was applicable to specific features with code requirements that did not readily lend themselves to an in-depth code evaluation at WBN. Compliance with code criteria is only provided to the extent identified below for the existing fire protection features.

3.2.1 NFPA 10-1975: Portable Fire Extinguishers

Portable extinguishers are not installed in accordance with the spacing and location criteria nor inspected at the specified frequency of NFPA 10. Portable extinguishers are provided at WBN solely for the use by personnel trained in the use and application of portable fire extinguishers. Fire brigade members and fire watches receive training in hands-on use of portable extinguishers. Fire brigade members are also trained on the location of extinguishers for firefighting purposes through the extinguishers inspection program. The experience history of other TVA nuclear plants was used as a base for an inspection frequency of quarterly.

3.2.2 NFPA 11B-1977: Foam-Water Sprinkler Systems

NFPA 11B is not applicable because the only foam-water sprinkler systems are located in plant buildings that do not contain systems, components, or cables relied on for fire safe shutdown. The systems covered by this code are provided in the Security Power and Additional Diesel Generator Buildings (some system 67 piping and valves are located in the Additional Diesel Generator Buildings, but they are not required for fire safe shutdown). Therefore, the systems covered by this code are outside of the scope of this review.

3.2.3 NFPA 12A and 12B-1973: Halon 1301 and 1211 Extinguishing Systems

NFPA 12A and NFPA 12B are not applicable because there are no Halon extinguishing systems installed to protect structures, components, or cables relied on for fire safe shutdown. Therefore, the systems covered by this code are outside of the scope of this review.

PART X – NFPA CODE EVALUATION

3.2.4 NFPA 25-1992: Water System Tests

NFPA 25 is not a code of record at WBN for any specific fire protection feature test and inspection requirement. This code is only referenced for the bases of the surveillance frequency and criteria that is applied to WBN in Part II, Section 14 of the FPR, as documented in the 7/1/94 WBN response to NRC Requests for Additional Information.

3.2.5 NFPA 26-1958: Valve Supervision

WBN's method of ensuring valve position is identified in Part II of the FPR. Valve positions are inspected quarterly in accordance with plant procedures.

3.2.6 NFPA 49-1975: Hazardous Chemical Reactions

Hazardous chemical reaction code criteria are only applicable to the storage and handling of chemicals by the chemistry department. Administrative procedures govern hazardous chemical use at WBN. The criteria of NFPA 49 have no impact on the fire safe shutdown conformance program at WBN and were therefore not reviewed.

3.2.7 NFPA 50A-1973: Gaseous Hydrogen Systems

Hydrogen is supplied to the volume control tanks (VCTs) through 1-inch seismically qualified piping from the exterior east wall of the Auxiliary Building through elevation 713 to the VCTs. The piping is seismically designed for pressure boundary retention between the VCTs and the isolation valves adjacent to the tanks. The remainder of the piping in the Auxiliary Building is seismically supported but not designed for pressure boundary retention. Two isolation valves, installed on the hydrogen supply line on the exterior wall of the auxiliary building, are designed to close automatically if the hydrogen flow in the downstream piping exceeds 50 scfm. Leakage less than 50 scfm should be diffused and carried away by the building ventilation system, thereby keeping the hydrogen concentration below the explosive limit of 4% by volume.

3.2.8 NFPA 51-1975: Oxygen Fuel Gas Systems for Welding and Cutting

NFPA 51 is applicable to large manifolded oxygen fuel gas systems and the use of oxy-acetylene cylinders for cutting and welding activities. Large manifolded systems are not used at WBN. The use of oxy-acetylene cylinders is controlled through the approval and issuance of an ignition source permit and is covered under NFPA 51B.

3.2.9 NFPA 90A-1975: Air Conditioning and Ventilation Systems

The heating, ventilating and air conditioning (HVAC) systems at Watts Bar are not designed to NFPA 90A. The HVAC systems are designed as described in FSAR chapters 3, 6 and 9 and the following evaluations of systems have been performed:

- The required locations for fire dampers were reviewed by a comparison of HVAC duct locations and the locations of regulatory fire barriers.
- Specific HVAC penetrations through regulatory fire barriers without fire dampers are addressed in Part VII of the FPR.
- Closure of dampers under flow conditions has been demonstrated via testing except for two large dampers as evaluated in FPR Part VII, Section 3.4. Large damper closure under air flow conditions is addressed by shutting off HVAC fans.
- Justification for sealing thermal expansion gaps between the ductwork and the barrier is provided by fire test documentation.

PART X – NFPA CODE EVALUATION

- Access to fire dampers is usually provided by access doors. However, in some cases, bolted connection duct sections require removal for access to fire dampers.

3.2.10 **NFPA 251-1985: Fire Tests of Building Materials**

The fire rating of walls and floor/ceiling assemblies is based on a comparison with typical UL listed designs as documented in Part II of the FPR. The fire rating of electrical raceway fire barrier materials is addressed under a separate program that has been reviewed in detail by the NRC. There are no other claims regarding WBN's level of compliance with NFPA 251.

3.2.11 **Inspection, Testing, and Maintenance of Fire Protection Features**

The inspection, testing, and maintenance of fire protection features within each code were not reviewed for compliance. Part II of the FPR identifies the scope of testing, inspection, and maintenance of fire protection features to be performed at WBN. The information in Part II of the FPR contains the testing, inspection, and maintenance requirements for regulatory fire protection features.

3.3 **Applicable NFPA Codes Reviewed in Detail for Compliance**

The remaining NFPA codes referenced in Appendix A to BTP 9.5-1 are both applicable to WBN and relied on to establish compliance with fire safe shutdown regulations and guidance documents. Detailed code evaluations were conducted as appropriate of the applicable sections of these codes to identify code requirements. Documentation was reviewed and field investigations were conducted in order to establish the level of compliance with code requirements.

The following list identifies the codes, along with the year of the edition, which were used to evaluate the adequacy of existing fire protection features against code requirements:

- | | |
|------------------|---|
| • NFPA-12-1973 | Carbon Dioxide Systems |
| • NFPA-13-1975 | Automatic Sprinkler Systems |
| • NFPA-14-1974 | Standpipe and Hose Systems |
| • NFPA-15-1973* | Water Spray Fixed Systems for Fire Protection |
| • NFPA-20-1973* | Centrifugal Fire Pumps |
| • NFPA-20-1993 | Centrifugal Fire Pumps |
| • NFPA-24-1973 | Outside Protection |
| • NFPA-30-1973 | Flammable and Combustible Liquids Code |
| • NFPA-51B-1976* | Cutting and Welding Processes |
| • NFPA-69-1973* | Explosion Prevention Systems |
| • NFPA-72D-1975 | Proprietary Protective Signaling Systems |
| • NFPA-72E-1974 | Automatic Fire Detectors |
| • NFPA-80-1975* | Fire Doors and Windows |
| • NFPA-194-1974* | Fire Hose Connectors |
| • NFPA-196-1974* | Fire Hose |

Detailed checklists were used to document the results of the code conformance evaluations for some, but not all, of the above identified codes. Where detailed code checklists were developed, a summary compliance matrix was developed that identifies the code article, the compliance status, and the topic of the code article and relevant remarks. Section 4.0 presents a discussion of the summary compliance matrices, with the matrices developed for each code immediately following Section 4.0. Detailed

PART X – NFPA CODE EVALUATION

checklists and summary compliance matrices were not developed for those codes identified with an asterisk (*). Where detailed checklists were not used, a summary description of code compliance is provided in Subsections 3.3.1 through 3.3.6.

3.3.1 NFPA 15-1973: Water Spray Fixed Systems for Fire Protection

Three distinct types of water spray fixed systems for fire protection are used to protect special hazards in safety related areas. The hazards protected are unique to a nuclear power plant and therefore direct code application and compliance is beyond the scope of NFPA 15 in respect to the overall goals of the National Fire Code. However, NFPA 15-1973 forms the design basis of the water spray systems. Listed below is a synopsis of each system and the key application of NFPA 15.

3.3.1.1 Reactor Coolant Pumps (RCP)

Each of the RCPs is protected by a closed head, automatic pre-action water spray fixed system. Listed nozzles are located around the top of the RCP motor along a ring header. The systems are hydraulically designed in accordance with NFPA 13 & 15 and produce a minimum design density of 0.25 gpm/ft². This density corresponds to NFPA 15 requirement for transformer protection (oil hazard). The pre-action system is automatically actuated upon initiation of cross zoned thermal detectors located above the motor.

3.3.1.2 Charcoal Filters

Closed head, automatic pre-action, water spray fixed systems are provided for the Control Building Emergency Air Supply Unit (CBEASU), Containment Purge Air Exhaust System (CPAES), Post Accident Sampling Filter (PASF), Emergency Gas Treatment System (EGTS), and the Auxiliary Building Gas Treatment System (ABGTS). The use of water spray fixed systems for protection of charcoal filters is the only type of suppression system recognized by NFPA 803-1983 (Table 10-1.2). The systems are hydraulically designed in accordance with NFPA 13 & 15 and produce a minimum design density of 0.25 gpm/ft² across the surface of the exposed filters.

The flow density of 0.25 gpm/ft² corresponds to the flow density specified in Section 5-4.6.1 of NFPA 850, "Recommended Practice for Fire Protection for Fossil Fueled Steam Electric Generating Plants" for sprinklers provided for coal handling structures subject to accumulations of coal or coal dust. Charcoal filters have a lower heat energy value (i.e., Btu/volume) than coal (based on lesser density and chemistry of the material). The flow density of 0.20 gpm/ft² over the plan area for bag-type dust collectors (in coal handling facilities) is adequate for the hazard. Therefore the use of 0.25 gpm/ft² for the charcoal filters is conservative.

The temperatures for the fusible elements in the spray nozzles was determined by correlating the maximum temperature expected in the filter units to the recommendations of NFPA 13, Table 3-15.6.1, "Temperature Ratings, Classifications and Color Codings".

In the event of a charcoal fire in an ABGTS, EGTS, CBEASU or CPAES filter unit, the smoke detectors will annunciate the alarm and trip the spray system's deluge valve, allowing water up to the closed nozzles. After shutdown of the fan and closure of the downstream damper, the heat will build inside the unit. Because the unit is constructed of heavy gauge metal, it will essentially act as an oven. This will ensure operation of the thermal elements in the nozzles if they have not previously been activated by the fire. The PASF unit's suppression system is similar to the other units but is not provided with a dedicated flow control valve (FCV). The system is supplied by the general area pre-

PART X – NFPA CODE EVALUATION

action sprinkler system. A manual isolation valve located at the unit must be opened upon confirmation of a fire to allow water into the unit.

3.3.1.3 Annulus Cable Interactions

An automatic, pre-action sprinkler system, utilizing standard upright sprinkler heads, provides a unique application of a water spray fixed system in the annulus. Section III.G.2.e of 10CFR50 Appendix R, allows the use of "fire detectors and an automatic fire suppression system in the fire area" as one of the means of providing fire protection of safe shutdown capability inside a non-inerted containment. In order to meet this requirement a unique application of the suppression system was developed. The sprinkler heads were strategically located, by a fire hazard analysis, to prevent a single fire from damaging redundant trains of equipment. The design basis utilized a density of 0.15 gpm/ft² across a 20-foot design area. This density corresponds to NFPA 15 requirements for cable tray systems which are the principle combustible inside the Annulus. The pre-action system is automatically actuated upon initiation of cross-zoned smoke detectors located adjacent and above the sprinkler heads.

3.3.2 NFPA 20-1973: Centrifugal Fire Pumps

The electric motor driven High Pressure Fire Protection (HPFP) pumps fulfill the safety function of supplying emergency cooling water during a flood mode condition. Therefore, the design and installation of the four electric motor driven HPFP pumps are based on ASME codes. The electric motor driven HPFP pumps are not designed in accordance with NFPA 20 requirements. Refer to Part II, Section 12.1 for a description of the HPFP pumps.

3.3.3 NFPA 51B-1976: Cutting and Welding Processes

The use of ignition sources such as welding, flame cutting, thermite welding, thawing pipe, brazing, grinding, arc gouging, torch applied roofing, and open flame soldering within safety-related areas are controlled through the approval and issuance of an ignition source permit. Permits are reviewed and approved by appropriate plant personnel. The ignition source permit is valid for one job. Job area inspections are performed and documented at the start of each shift that ignition source activities are being performed. If no ignition sources activities are performed, then re-inspection is not required.

Designated ignition source activity areas are located and approved by the fire protection organization. A fire watch system is established for ignition source work activities that are performed in safety-related areas of the plant. Ignition source fire watches are established and will remain for 30 minutes following the elimination of the ignition source, unless other durations are approved by the fire protection organization. Non-smoking areas have been established at WBN in accordance with TVA policy and, when necessary, in areas which may create a fire hazard concern. TVA adequately addresses the primary functional requirements of NFPA 51B via the implementation of administrative controls, ignition source permits that are reviewed and approved by appropriate plant personnel, and the use of fire watches for ignition source work activities in safety-related areas of the plant.

PART X – NFPA CODE EVALUATION

3.3.4 NFPA 69-1973: Explosion Prevention Systems

NFPA 69 is applicable only to the battery rooms. The exhaust air system for these areas is designed to limit the potential build-up of hydrogen gas to less than 2%. The systems as installed meet the intent of the code; however, there are no means to control and monitor the effectiveness of the combustible gas concentration.

3.3.5 NFPA 80-1975: Fire Doors and Windows

A summary door evaluation list was utilized to review fire doors per NFPA 80. As noted on the compartmentation drawings and in Part VI of the FPR, evaluations have been performed by TVA or nationally recognized laboratories on those fire door assemblies that are not listed or labeled as fire rated door assemblies. TVA has ensured that the hardware and other components of fire door assemblies comply with NFPA 80 requirements or are appropriately evaluated. Security hardware additions and repairs to fire doors are controlled by General Engineering Specification G-73 to ensure the required fire resistive capability of the fire doors are maintained and are within the guidelines identified in Generic Letter 86-10.

3.3.6 NFPA 194-1974: Fire Hose Connectors; NFPA 196-1974: Fire Hose

Fire Hose Connectors (NFPA 194) and Fire Hose (NFPA 196) address the acceptable connectors and materials for fire hose assemblies. The information did not require a checklist. Instead, fire hoses and their connectors were visually inspected at WBN and found to be acceptable. Fire hose and connectors are considered to be consumable items and replacement parts are purchased to the current standards at the time of purchase.

4.0 NFPA Code Conformance Summary Compliance List

The following lists summarize the results of the NFPA code evaluation for the applicable NFPA codes identified in Section 3.3. The summary compliance lists address those code articles which may impact on the performance of the fire protection feature. The lists contain three columns which document each NFPA code section or article included in the code review. The first column identifies the code section or article by the numbering system that exists in the code of record. The second column identifies the level of compliance with the particular code section or article. The third column provides a brief description of the topic covered by the code section or article, along with the bases for the level of compliance when appropriate.

The code sections or articles are not all individually listed. If a particular section or article (such as Article 230) of a particular code contains ten subsections or subarticles (such as Articles 2301 through 2310) that address general information about the code without any reviewable criteria, the level of compliance with the entirety of the section or article would be identified as not applicable, or N/A. In the case of Article 230 with its ten subarticles, only Article 230 would be listed, and the level of compliance would be identified as N/A. Where only the main code article is listed, the level of compliance for all subarticles within the main code article is the same. Where differences exist in the level of compliance between subarticles of the same article, then each subarticle is listed and summarized separately.

The level of compliance for each listed section or article is identified and defined as follows:

PART X – NFPA CODE EVALUATION

<u>N/A</u>	The code section has been identified as not applicable to WBN, or the section provides only general information with no specific code requirements.
<u>Alternative</u>	This particular feature/requirement is in general compliance with the identified code section, but is not in literal compliance. For example, Section 15 of NFPA 24-1973 requires the plans of the completed piping system be "framed and conspicuously posted". The system 26 (high pressure fire protection system) flow diagrams are under configuration control and maintained in the Main Control Room. This clearly complies with the intent of the code (as applicable to a nuclear plant) but does not meet literal compliance.
<u>Comply</u>	The particular feature is in compliance with the identified code section.
<u>Deviation</u>	<p>Compliance with the particular code section is not achieved, but is adequate.</p> <p>Deviations from the criteria of applicable NFPA codes, as determined by field verification walkdowns and document review during the course of this code evaluation, are identified and justified in either Part VII of the FPR, or in the applicable WBN system description. The summary compliance matrices provide a brief description of the identified deviations.</p>

The following pages contain the summary code compliance lists for the applicable NFPA codes identified in Section 3.3 of this Part.

PART X – NFPA CODE EVALUATION

NFPA 12-1973, "Carbon Dioxide Systems" TVA System 39 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
Introduction		General information on purpose, scope, arrangement of the standard, and definitions.
Chapter 1		General Information and Requirements
11 through 115	N/A	General information on scope, definitions, effects of CO ₂ on fire, use and limitations, examples of protected and not protected hazards, and types of systems.
116	N/A	Package Systems. Package systems are not used at WBN.
12 through 1212	N/A	Personnel Safety. General information on personnel safety and hazards, hazards of CO ₂ , and visibility in CO ₂ .
122	Comply	Safety Requirements
123	Comply	Electrical Clearances
13	N/A	Title, Specifications, Plans and Approvals
131	Comply	Design, analysis, review, purchasing, and installation are per TVA standards and procedures. TVA is the authority having jurisdiction.
132 through 134	Comply	Plans, including level of details on plans, are per TVA standards and procedures. TVA is the authority having jurisdiction.
14	N/A	Title, Operation and Control of Systems
141	Comply	Methods of Actuation - System Classification
142	Comply	Detection of Fires
1421	Comply	Reliance on visual detection
1422	Comply	Automatic detection is by listed or approved methods or devices.

PART X – NFPA CODE EVALUATION

NFPA 12-1973, "Carbon Dioxide Systems" TVA System 39 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
1423	Comply	The detection systems have backup power supply from the emergency diesel generators.
143	N/A	Title, Operating Devices - General Information - Definition
1431	Comply	Operation by listed or approved mechanical, electrical, or pneumatic means in compliance with code.
1432	Comply	Devices are designed for the service they will encounter and will function properly at -20° F to 150° F.
1433	Comply	Protection from damage
1434	Comply	Location of local manual control
1435	Comply	Emergency manual control of valves is accessible; however, a key and a confined space access permit are required to access the power house tank in the CO ₂ tank pit located in the Yard.
1436	Comply	Manual controls do not require a pull of more than 40 lbs. (force) nor a movement of more than 14 inches to secure operation.
1437	N/A	Slave cylinders are not used at WBN.
1438	Comply	Shut down devices
1439	Comply	Operating devices identify the hazard they protect.
144	Comply	Supervision of the automatic detection system is provided.
145	Comply	General information with regards to alarms and indicators.

PART X – NFPA CODE EVALUATION

NFPA 12-1973, "Carbon Dioxide Systems" TVA System 39 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
1451	Comply	Alarm/Indicator on Discharge
1452	Comply	Alarm on Discharge
1453	Comply	Alarm for Warning Personnel
1454	Comply	Alarms Indicating Device Failure
15	N/A	Title, Carbon Dioxide Supply
151	Comply, See Note 1	Quantities
1511	N/A	Hand hose lines are not used at WBN.
1512	Comply	Continuous protection reserved quantity.
1513	N/A	Primary and reserve supplies for high pressure systems.
152	Comply	Quality
1521	Comply	Vapor phase is not less than 99.5 percent carbon dioxide with no detectable off taste or odor.
1522	Comply	The water content of the liquid phase is not more than 0.01 percent by weight (-30° F dew point) to comply.
1523	Comply	Oil content is not more than 10 ppm by weight to comply.
153	Comply	Replenishment
154	Comply	Storage Containers
1541	Comply	Location of Storage Containers
1542	Comply	Storage containers not subject to severe weather conditions.

PART X – NFPA CODE EVALUATION

NFPA 12-1973, "Carbon Dioxide Systems" TVA System 39 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
1543	Comply	Excessive climatic or mechanical exposures not expected.
155	N/A	High pressure storage containers not used at WBN.
156	Comply	Low pressure storage containers
1561	Comply	Pressure container per ASME Code for unfired pressure vessels, with DOT information on tank.
1562	Comply	Liquid level and pressure gages, and hi/lo pressure supervisory alarms set at 315 and 250 psi, respectively, for pressure containers.
1563 and 1564	Comply	Refrigeration system of pressure container
1565	N/A	Heating system for pressure container is not used at WBN.
16	N/A	Standard for the Installation of Foam-Water Sprinkler and Foam-Water Spray Systems.
161	Comply	Piping
1611	N/A	Flexible piping is not used at WBN.
1612	Comply	Ordinary cast iron pipe and fittings shall not be used.
1613	Comply	Joints
1614	N/A	High pressure supply is not used at WBN.
1615	Comply	Low pressure supply pipe and fittings have a minimum bursting pressure of 1800 psi to comply.
162	Comply	Arrangement and Installation of Piping
1621	Comply	Piping system layouts

PART X – NFPA CODE EVALUATION

NFPA 12-1973, "Carbon Dioxide Systems" TVA System 39 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
1622	Comply	Piping system supports
1623	Comply	Pipe shall be reamed and cleaned before assembly, and after assembly the entire piping system shall be blown out before nozzles or discharge devices are installed.
1624	N/A	Pressure relief devices where valve arrangements introduce sections of closed piping - no closed sections.
1625	Comply	Suppression system pressure relief devices are designed to discharge to the outside or to non-objectionable area.
163	Comply	Valves
1631	N/A	High pressure systems are not used at WBN.
1632	Comply	Low pressure system valves can withstand a hydrostatic test to 1800 psi without permanent distortion.
1633	Comply	Valves are not subject to mechanical, chemical or other damage.
1634	Comply	Equivalent length of valves
164	Comply	Discharge Nozzles
1641	Comply	Discharge nozzle criteria
1642	Comply	Discharge orifice criteria
1643	N/A	Local application systems are not used at WBN.
1644	Comply	Marking of discharge nozzles
1645	N/A	Discharge nozzles are not subject to clogging and are not provided with blow out caps.

PART X – NFPA CODE EVALUATION

NFPA 12-1973, "Carbon Dioxide Systems" TVA System 39 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
165	Comply	Pipe and Orifice Size Determination
1651	Comply	Pressure drop in a pipe line determination.
1652	Comply	Calculation of flow for low pressure systems.
1653	N/A	High pressure storage is not used at WBN.
17	N/A	Title, Inspection, Maintenance and Instruction
171	Comply See 3.2.11 of Part X	CO ₂ systems shall be thoroughly inspected and tested for proper operation at least annually by competent personnel.
1711	Comply See 3.2.11 of Part X	Inspection goals
1712	Comply See 3.2.11 of Part X	Suitable discharge tests
1713	Comply See 3.2.11 of Part X	An inspection report with recommendations shall be filed with the owner.
1714	Comply See 3.2.11 of Part X	Visual inspection requirements
1715	N/A	High pressure cylinders are not used at WBN.
1716	Comply See 3.2.11 of Part X	Weekly liquid level inspection
172	Comply	System maintenance
1721	Comply	Correction of trouble and impairments
173	Comply See 3.2.11 of Part X	All personnel who may be expected to inspect, test, maintain, or operate the systems shall be trained in the functions they are expected to perform.

PART X – NFPA CODE EVALUATION

NFPA 12-1973, "Carbon Dioxide Systems" TVA System 39 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
1731	Comply	Training programs approved by the authority having jurisdiction shall be established. TVA is the authority having jurisdiction.
Chapter 2		Total Flooding Systems
21	N/A	Title, General Information
211	Comply	Description of total flooding systems
212	Comply	Concentration is achieved and maintained for the surface fires and rotating electrical equipment in diesel engine rooms to ensure complete fire extinguishment.
2121	Comply	Examples of hazards protected by total flooding systems
213	N/A	General requirements and identifying that Chapter 1 requirements to be met in addition to those of Chapter 2.
22	N/A	Title, Hazard Specifications - General Information
221	N/A	Enclosure description
2211	Comply	Unclosable opening area for flash or surface-type fires exceed either 3% of the cubic foot volume or 10% of the square foot room surface area. If exceeded, the system shall be tested to assure proper performance.
2212	Comply	Unclosable opening area for deep seated fires exceeds small openings in or near the ceiling unless the system is tested to assure proper performance.
2213	Comply	Prevention of fire spread
2214	N/A	Process and storage tank with flammable vapors are not applicable to WBN.
222	Comply See Note 1	Leakage and ventilation is not compensated by extended discharge of CO ₂ agent.

PART X – NFPA CODE EVALUATION

NFPA 12-1973, "Carbon Dioxide Systems" TVA System 39 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
2221	Comply	Automatic closure of openings (see 2351 for diesel engine rooms)
2222	Comply	Shut down of ventilation
223	N/A	Types of fires - general information
2231	N/A	Surface fire extinguishment - General Information
2232	Comply	Deep seated fire extinguishment does not specify the required concentration and the required time for extinguishment. The Fire Brigade will respond to any CO ₂ discharge and verify extinguishment as appropriate.
23	N/A	Title, CO ₂ Requirements for Surface Fires
231	N/A	General information
232	Comply	Flammable material design concentration
2321	Comply	Table 4 carbon dioxide concentrations
2322	N/A	Calculation of design concentration if not on Table 4.
233	Comply	Volume factor
2331	Comply	Calculating volume to protect
2332	Comply	Table 5 Volume Factors
2333	Comply	Comment on Column B Table 5
2334	Comply	Interconnected volumes
234	N/A	Material conversion factor
235	N/A	Special conditions require additional agent

PART X – NFPA CODE EVALUATION

NFPA 12-1973, "Carbon Dioxide Systems" TVA System 39 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
2351	Comply See Note 1	Compensating for openings that cannot close (i.e., ceiling grills in diesel engine rooms) by addition of 1 pound of agent per square foot of opening.
2352	Comply See Note 1	Ventilation fans are shut off or taken into account.
2353	N/A	Elevated temperature of the enclosure is not anticipated.
2354	N/A	Low temperature of the enclosure is not anticipated.
2355	Comply	Surface fire extinguishment
24	N/A	Title, CO ₂ Requirements for Deep Seated Fires
241	Comply See Note 1	General - The carbon dioxide concentration is maintained for a substantial period of time to assure complete extinguishment.
242	Comply	Combustible materials
2421	Comply	Flooding factors for specific hazards (50% for deep seated fire locations such as board rooms, instrument rooms, etc.).
2422	N/A	Flooding factors for other deep seated fires
243	Comply	Volume of space protected
244	N/A	The discharge timers are adjusted for the hazard protected.
2441	Comply See Note 1	Compensating for openings that cannot close
25	N/A	Title, Distribution Systems
251	Comply	General

PART X – NFPA CODE EVALUATION

NFPA 12-1973, "Carbon Dioxide Systems" TVA System 39 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
252	Comply See Note 1	Rate of Application
2521	Comply See Note 1	Time to reach design concentration for surface fires
2522	N/A	High pressure systems are not used at WBN.
2523	Comply See Note 1	Time to reach design concentration for deep-seated fires
253	N/A	Extended rate of application is not used at WBN.
254	Comply	Piping Systems
2541	N/A	High pressure storage is not used at WBN.
255	Comply	Nozzle sizing and distribution
2551	Comply	Requirements of nozzles
26	N/A	Title, Venting Considerations
261	Comply	General
262	N/A	Relief venting - General Information
2621	Comply	Relief venting provided in auxiliary instrument rooms but not required elsewhere.
2622	N/A	Relief venting when hazardous materials involved
2623	N/A	Table 7, Strength and allowable pressures for average enclosures by general construction practices
Chapter 3	N/A	Local application systems are not used at WBN.
Chapter 4	N/A	Hand hose line systems are not used at WBN.

PART X – NFPA CODE EVALUATION

NFPA 12-1973, "Carbon Dioxide Systems" TVA System 39 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
Chapter 5	N/A	Standpipe systems and mobile supply are not used at WBN.

Note 1: WBN has verified the compliance with these code criteria based on system dump tests to ensure agent concentration, agent reserve, and operability of the distribution system.

PART X – NFPA CODE EVALUATION

NFPA 13-1975, "Automatic Sprinkler Systems" TVA System 26 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
1-1 through 1-4	N/A	General Information on scope, purpose, definitions, and related publications
1-5	N/A	Title, Maintenance
1-5.1	Alternative	Sprinkler systems shall be properly maintained. Sprinkler system installation is performed in accordance with plant operating and maintenance procedures.
1-5.2	N/A	Instruction charts describing operation and maintenance of sprinkler devices - in accordance with TVA procedures.
1-6 through 1-6.1	N/A	Title, Classification of Sprinkler Systems, and general information
1-7	N/A	Classification of occupancies - general information
1-8	N/A	Title, Design and Installation
1-8.1.1 and 1-8.1.2	Comply	TVA approved materials and devices (including regulatory and associated devices on pre-action system air supervision) used based on review of bill of materials for system installation.
1-9	N/A	Title, Working plans
1-9.1 and 1-9.2	Comply	Working plans are prepared, reviewed, and approved in accordance with TVA design, construction and modification procedures.
1-10	Comply	Approval of sprinkler systems. Approval of the systems are in accordance with TVA design, construction and modification procedures.
1-11	N/A	Title, Acceptance tests

PART X – NFPA CODE EVALUATION

NFPA 13-1975, "Automatic Sprinkler Systems" TVA System 26 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
1-11.1 thru 1-11.4	Comply	Performance of acceptance tests (but not with identical paper to contractor's material and test certificate, but TVA's paper meets/exceeds intent), flushing of underground connections, hydrostatic tests, and dry pipe system tests. System tests are performed in accordance with TVA design, construction and modification procedures.
1-11.5	Deviation	The 2-inch drain design prevents meaningful results from a test, and operational controls with the installed equipment lessen the need for this test.
1-12	Comply	Material and test documentation via pre-op and system turnover tests. Material and test documentation is prepared in accordance with TVA design, construction, and modification procedures.
2-1	Comply	Each system shall have at least one automatic water supply.
2-2	Comply	Guide Tables - General Information
2-3	N/A	Connections to water works systems
2-4	N/A	Gravity tanks
2-5	Deviation	Fire pumps as source of water (i.e., the four electric driven pumps are ASME rated due to their safety function. Diesel driven fire pump is UL/FM as required by NFPA 20.
2-6	N/A	Pressure tanks
2-7	Deviation	Fire Department (FD) connections are desirable unless omission approved by authority having jurisdiction (TVA).
2-8	N/A	Arrangement of water supply connections unobservable, underground
2-9	Comply	Water supply test pipes and gages

PART X – NFPA CODE EVALUATION

NFPA 13-1975, "Automatic Sprinkler Systems" TVA System 26 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
3-1	Comply	Piping shall be at least equivalent to listed standards
3-2	N/A	Definitions
3-3 through 3-7.1	N/A	Pipe schedule sprinkler installations
3-7.2	N/A	Sprinklers in storage racks
3-7.3	Deviation	Provision for flushing system
3-7.4	N/A	Enclosed stair towers are not provided with sprinklers.
3-7.5	Comply	Return bends with 1/2 or 3/4 inch close nipples used or dry pendant sprinklers, unless different configuration documented and justified in sprinkler modification DCNs..
3-7.6	N/A	Dry pipe not provided underground
3-7.7	N/A	Hand hose connections to sprinkler pipes not used.
3-7.8	N/A	Hose connections for FD use provided on separate hose station risers, not connected directly to sprinkler systems.
3-8	N/A	Title, System test pipes
3-8.1	N/A	Wet systems not used. Pre-action sprinkler systems are wet only up to the FCV, systems are dry to the protected areas
3-8.2	N/A	Dry pipe system test pipes - no dry systems in safety-related areas.
3-9	N/A	Title, Protection of piping

PART X – NFPA CODE EVALUATION

NFPA 13-1975, "Automatic Sprinkler Systems" TVA System 26 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
3-9.1	Comply	Heat tracing has been added to piping subject to freezing in the intake pumping station.
3-9.2	N/A	Corrosive exposure conditions to external surface of pipe
3-9.3	Alternative	Piping and supports are designed in accordance with WBN seismic requirements.
3-10	N/A	Title, Drainage
3-10.1.1	Comply	Pitching of piping for drainage
3-10.1.2, 3-10.1.3	N/A	No wet or dry pipe sprinkler systems in safety related areas.
3-10.2.1 thru 2.3	Comply	System or main drain connections and drain valves
3-10.2.4, 3-10.2.5	N/A	No sprinkler risers less than 2-1/2 inches and no sprinkler system sectional control valves.
3-10.3.1	Comply	Auxiliary drains are provided.
3-10.3.2, 3-10.3.3	N/A	No wet pipe sprinkler systems in safety related areas.
3-10.3.4.1	Comply	Small capacity segments are provided with auxiliary drains, some are provided with caps.
3-10.3.4.2	Deviation	Not all large capacity systems are provided with (2) 1 inch valves and a 2 inch condensate nipple with a cap or plug.
3-10.3.5	N/A	Tie-in drains minimum 1 inch in size
3-10.4.1	Comply	Sprinkler drains are not interconnected with sewers.
3-10.4.2, 3-10.4.3	N/A	Drain pipes not buried or in blind spaces.

PART X – NFPA CODE EVALUATION

NFPA 13-1975, "Automatic Sprinkler Systems" TVA System 26 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
3-10.4.4	Alternative	Drain pipes are fitted with hose connection to facilitate drainage as opposed to turned down elbow.
3-10.4.5	Comply	Drain pipes are arranged so as not to be exposed to freezing conditions.
3-11	N/A	Title, Joining of pipe and fittings
3-11.1	N/A	Title, Threaded pipe and fittings
3-11.1.1 thru 1.3	Comply	Joint compounds, threaded pipe, and standard fittings are properly used in installation of sprinkler systems.
3-11.2.1, 3-11.2.2	Comply	Welded piping welded onsite and, where appropriate, welded pipe is joined by screwed flange fittings.
3-11.2.3 thru 2.6	Alternative	Torch cutting may be used to access pipe, welding performed per TVA procedures, welders are trained per TVA procedures, and welding is done per drawings but done in field not shop.
3-11.2.7	Comply	Welded outlets are attached by work plans which include procedures.
3-11.3	N/A	Rolled groove fittings not used.
3-11.4	N/A	Brazed joints not used.
3-12.1.1	Comply	Fittings shall be at least equivalent to materials listed.
3-12.1.2	N/A	Other type fittings not used.
3-12.1.3	Comply	Approved fittings are used.
3-12.1.4	Comply	Types of pipes and valves where operating water pressures of 175 to 300 psi reached (only reached by pressure spike at WBN).

PART X – NFPA CODE EVALUATION

NFPA 13-1975, "Automatic Sprinkler Systems" TVA System 26 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
3-12.1.5	Deviation	Flange joints on risers are not provided on each floor. The piping design and installation are in accordance with WBN procedures.
3-12.2	Comply	Coupling and/or unions are used on pipes 2 inches or smaller.
3-12.3	Alternative	Square shoulder bushings were used in lieu of one piece reducers in portions of the original installation. This was due in part to the sprinkler industry generic misinterpretation to the code statement "not available". After NFPA formal interpretation 83-12, controls were established in TVA General Engineering Specification G-73 to stop the use of bushings. Existing bushings were evaluated for acceptance as a part of the sprinkler upgrade program and accounted for in the hydraulic calculations for the systems.
3-13	N/A	Title, Valves (See NFPA 24 also)
3-13.1.1	Comply	Valves on connections to water supplies shall be of approved indicating type unless underground gate valve with approved roadway box accepted by the authority having jurisdiction.
3-13.1.2	Comply	Drain and test valves are of the approved type.
3-13.1.3	Comply	Check valves are of the approved type and are properly installed.
3-13.2.1	Comply	Each system is provided with an approved indicating valve.
3-13.2.2	Comply	At least one approved indicating valve is installed in each source of water supply, except the fire department connection.
3-13.2.3	Deviation	Valves are locked or sealed open and inspected once every 92 days instead of once per week.

PART X – NFPA CODE EVALUATION

NFPA 13-1975, "Automatic Sprinkler Systems" TVA System 26 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
3-13.2.4	Alternative, See NFPA 24	Each sprinkler riser (except inside containment) receives water from two directions, with sectional isolation valves used in lieu of check valves.
3-13.2.5	N/A	Check valves in conjunction with fire department connections - no FDCs protecting safety-related areas.
3-13.2.6	N/A	There are no wet pipe systems in safety related areas.
3-13.2.7	N/A	No city connections are used.
3-13.3	Alternative	Identification of valves. System valves are identified in accordance with TVA procedures.
3-14	N/A	Title, Hangers
3-14.1.1	Comply	Adequate hangers are provided.
3-14.1.2	Alternative	Hangers are installed to resist earthquake loads in accordance with WBN seismic design criteria.
3-14.1.3	Comply	There are no ceiling sheathing
3-14.1.4	Comply	Hangers are qualified in accordance with WBN seismic criteria.
3-14.1.5 thru 1.8	Alternative	Sprinkler systems are supported by WBN qualified seismic hangers/supports.
3-14.2.1 thru 3.4	Deviation	Hangers in concrete are in accordance with WBN structural analysis and procedures.
3-14.4.1	Comply	Hanger assemblies, including rods, are approved.
3-14.4.2 thru 4.8	N/A	"U" hooks, screws, bolts or lag screws on the side of beams, drive screws, wood screws, nails, timber, joist, nailing strips, and planking are not used.

PART X – NFPA CODE EVALUATION

NFPA 13-1975, "Automatic Sprinkler Systems" TVA System 26 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
3-14.5	Alternative	Distance between hangers is per WBN seismic requirements.
3-14.6.1	Alternative	Spacing of hangers on branch lines is per WBN seismic requirements.
3-14.6.2	Comply	The spacing between sprinklers and hangers are addressed as acceptable in sprinkler DCN packages.
3-14.6.3	Comply	The 36 inch maximum distance is not exceeded.
3-14.6.4 thru -14.6.6	Alternative	Spacing of hangers on branch lines is per WBN seismic requirements.
3-14.7 thru 3-14.9.3	Alternative	Spacing of hangers on cross mains, feed mains, and risers is per WBN seismic requirements.
3-14.9.4	Comply	Set screws are not used on hangers.
3-15	N/A	Title, Sprinklers
3-15.1	N/A	Standard and Old Style Sprinklers
3-15.2	Comply	Types of sprinklers are addressed as acceptable in sprinkler DCN packages.
3-15.3	N/A	Corrosion resistant sprinklers
3-15.4	Comply	Types of sprinklers are addressed as acceptable in sprinkler DCN packages.
3-15.5	Comply	Types of sprinklers are addressed as acceptable in sprinkler DCN packages.
3-15.6	Comply	Types of sprinklers are addressed as acceptable in sprinkler DCN packages.
3-15.7	Alternative	Stock of spare sprinklers. Procurement and storage of spare sprinkler heads is in accordance with applicable WBN procedures and G-73 requirements.

PART X – NFPA CODE EVALUATION

NFPA 13-1975, "Automatic Sprinkler Systems" TVA System 26 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
3-15.8	Comply	Types of sprinklers are addressed as acceptable in sprinkler DCN packages.
3-15.9	Comply	Painting and Ornamental finishes
3-16.1 thru 3-16.5	Comply	Sprinkler alarms, waterflow detection devices, and attachments
3-16.6.1, 3-16.6.2	Comply	Sprinkler alarms are provided per NFPA 72D-1975, not 1974, which meets intent of code articles.
3-16.6.3	Comply See 3.2.11 of Part X	Testing of waterflow detection devices by actual waterflow through a test connection
3-16.6.4	Comply	Outdoor electric alarm devices
3-16.7	Alternative	Drain pipes are fitted with hose connection to facilitate drainage.
Chapter 4	Alternative	Literal code conformance for the exact location and spacing of sprinkler heads is not always achievable due to congestion (e.g., tray, conduit, and pipe supports). The sprinkler heads have been located by qualified Fire Protection Engineers to provide adequate protection in the areas.
4-4.8.2.3	Comply	Unenclosed or unprotected elevators, stairs, and shafts are provided with water curtains and draft stops except between elevations 676 and 692 in Auxiliary Building. See VII of the FPR.
4-4.11	Deviation	Sprinklers are not installed in some plant locations under decks, galleries, and open gratings over 4 feet wide.
4-4.13	Comply	Sprinklers under HVAC ducts over 4 feet wide are provided.

PART X – NFPA CODE EVALUATION

NFPA 13-1975, "Automatic Sprinkler Systems" TVA System 26 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
4-4.20	Deviation	Sprinklers not provided in the Telephone Room (755.0-C17).
5-1	N/A	Wet Pipe Systems
5-2	N/A	Dry Pipe Systems
5-3 through 5-3.4	N/A	General Information
5-3.5	N/A	Title, Pre-Action Systems
5-3.5.1 and 5-3.5.2	Comply	Number of sprinklers per pre-action valve, piping and detection supervision
5-3.5.3	N/A	Pipe schedule systems
5-3.5.4	N/A	Use of dry pendent sprinklers in pre-action systems if subject to freezing.
5-3.6	N/A	Deluge systems only in nonsafety related locations.
5-3.7.1	N/A	Test devices are accessible.
5-3.7.2	Comply	Test apparatus are provided.
5-3.7.3	Comply	Pressure gages are installed above and below pre-action valves and on air supply to pre-action system supervision.
5-4	N/A	Combined Dry-Pipe and Pre-Action Systems
5-5	N/A	Anti-Freeze Systems
Chapter 6	N/A	Outside Sprinklers for Protection against Exposure Fires

PART X – NFPA CODE EVALUATION

NFPA 13-1975, "Automatic Sprinkler Systems" TVA System 26 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
Chapter 7	Comply	Hydraulically designed sprinkler system calculations are performed in accordance with TVA Nuclear Engineering calculation procedures. Information is documented on a combination of drawings (flow, isometric and pipe layout) and calculations. Calculation methodology is per TVA hydraulic calculation using the QA software HYPERCALC.
Chapter 8	N/A	High-Rise Buildings

Section 1-11.5 Deviation

The 2 inch main drain test was not performed at Watts Bar because the design did not account for how to move the water from inside the safety related structures. The main purpose of the 2-inch main drain test is to ensure valves in the supply line are not closed due to mis-positioning or valve failure. At Watts Bar the mis-positioning is addressed by the rigid controls placed on configuration control and procedure use and adherence. The valve failure is generally a dropped disk on a gate valve and at Watts Bar the majority of the valves in the safety-related buildings are butterfly valves. There are gate valves in the system but they are generally in the yard. The design will not allow for a meaningful 2 inch main drain test and the operational controls are greater than normal industry practice and the installed equipment is less susceptible to blockage failure.

Section 2-5 Deviation

Refer to Part VII, Section 5.1.

Section 2-7 Deviation

FD pumper connections are provided to buildings with only one connection to the underground fire main. Buildings with two or more connections to the fire main need not have FD pumper connections.

Section 3-7.3 Deviation

Strainers are provided in the supply to each pre-action sprinkler system in lieu of flushing connections.

Section 3-10.3.4.2 Deviation

Auxiliary drains for trapped piping are provided.

Section 3-12.1.5 Deviation

Flange joints on risers are not provided on each floor. The piping design and installation are in accordance with TVA seismic criteria that exceed the intent of this section.

Section 3-13.2.3 Deviation

Valves are locked or sealed open and inspected once every 92 days instead of once per week (see Part II of this report).

PART X – NFPA CODE EVALUATION

NFPA 13-1975, "Automatic Sprinkler Systems" TVA System 26 Compliance Summary Matrix

Section 3-14.2.1 through 3.4 Deviation

Hangers in concrete are in accordance with TVA structural criteria that exceed the intent of this section.

Section 4-4.11 Deviation

The plant locations listed below do not have sprinklers installed under gratings/platforms. These locations have been evaluated and determined to be acceptable since the gratings/platforms do not significantly impede the sprinkler coverage.

- Room 692.0-A7 - grating located above four HPFP FCVs in the U1 penetration room.
- Room 692.0-A25 – grating located above four HPFP FCVs in the U2 penetration room.
- Room 757.0-A10 - grating located south of column line A4/W.
- Room 737.0-A9 - grating located northeast of column A11/W.
- Room 737.0-A12 - grating located between the exterior wall and the first bank of filters.
- Room 737.0-A3 - grating located between the exterior wall and the first bank of filters.
- Room 757.0-A2 - under stairs.
- Room 757.0-A24 - under stairs.
- Room 772.0-A9 - platform over the HEPA filters.

PART X – NFPA CODE EVALUATION

NFPA 13-1975, "Automatic Sprinkler Systems" TVA System 26 Compliance Summary Matrix

The plant locations listed below do not have sprinklers installed under equipment spray shields. Other vital electrical equipment such as shutdown boards, motor control centers, vital inverters, logic cabinets, etc. are also provided with spray shields, but are not listed. The spray shields were installed to prevent damage to water-sensitive equipment in the event of an inadvertent actuation of the area sprinklers.

- Room 692.0-C10 - equipment spray shield over the chillers.
- Room 737.0-A1 - equipment spray shields over the following chillers and radiation monitors:
 - CHR-31-36/2
 - 0-CHR-31-96
 - 0-CHR-31-80
 - 1-RE-90-112
 - 1-RE-90-106

Section 4-4.20 Deviation

The Telephone Closet in the Technical Support Center (TSC) Conference Room houses communications cables. The closet is approximately 5-feet wide by 2-feet deep. A sprinkler is located approximately 2-feet outside the door to the closet. The cables are not required for fire safe shutdown and are protected by adequately sized circuit protective devices. The lack of a sprinkler in this room (closet) does not present a significant fire hazard and is therefore acceptable.

PART X – NFPA CODE EVALUATION

NFPA 14-1974, "Standpipe and Hose Stations" TVA System 26 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
11 thru 14	N/A	General information on efficiency, classes of service, types of systems, and combined systems
151	Comply	Approved devices and materials used.
161	Comply	Closets and cabinets in the Reactor Buildings, on elevation 741 of the IPS (Class III), lower containment access (Class II), and on top of diesel generator and Auxiliary Buildings (Class I) meet the criteria.
171	Comply	Plans and specifications
181	Comply	Installation by experienced workmen
21 and 211	N/A	Design basis title and general information
212	Deviation	Size and flow requirements
213	N/A	Standpipe heights exceeding 275 feet
214 thru 218	N/A	Combined systems, standpipes on individual zones, and pumps for individual zones of standpipes
219	Comply	Sizing for Class II service
31	N/A	Title, Factors Governing, and general information
32	Deviation	Number of standpipes (length of hose)
33 and 331	N/A	Title, Location of Standpipes
331	N/A	No major building exposure within 60 feet.
332	Comply	Standpipe protection from mechanical and fire damage
333	N/A	Dry standpipe location requirements
334	Comply	Location of standpipes to protect rooms in buildings with many partitions

PART X – NFPA CODE EVALUATION

NFPA 14-1974, "Standpipe and Hose Stations" TVA System 26 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
335	N/A	Standpipes located at exterior columns in large areas.
34	N/A	Title, Hose Connections
341	Comply	2½ inch hose connections at each floor for Class I service, only located on roofs of safety-related buildings.
342	Alternative	WBN configuration lends itself more toward a "Hose System" rather than a "Standpipe System". An adequate number of hose stations are provided to ensure area coverage.
343	Comply	1½ and 2½ inch hose connections at each floor for Class III service in lower containment and in the Control Building.
41	N/A	Title, Location of Hose
411	Comply	Hose outlets within easy reach.
412	Alternative	Hose outlets only located in or near enclosed stairways in the Control Building (only building with enclosed stairways).
413	Deviation	Valves of approved indicating type provided at main riser provided in most cases. Two hose stations (valves 0-26-677 and -690) are fed directly from the header with no header isolation valves..
414	N/A	Wall outlets connected to standpipes not utilized
42 and 421	Deviation	No more than 100 feet of hose at Class II and III outlets.
43 and 431	Comply	Hose racks

PART X – NFPA CODE EVALUATION

NFPA 14-1974, "Standpipe and Hose Stations" TVA System 26 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
432	Alternative	WBN provides hose stations for the dedicated fire brigade as discussed in Part II, Section 9.0 and not for occupant use. Plant personnel are instructed in General Employee Training to not use such equipment unless they are trained in its use. The fire brigade members are routinely trained in the use of the hose stations.
44	N/A	Title, Hose Valves
441	Comply	Approved hose valves at each outlet.
442	Alternative	The hose stations are for use by the fire brigade. The fire brigade is trained in the use of fire hose where pressures in excess of 100 psi can be experienced. The fire hose is maintained to accommodate these higher pressures. Therefore, the pressure reducing devices are not needed to provide for personnel or equipment safety.
443	N/A	Automatic drip connections where linen hose used.
444	Comply	Hose valve threads
45	Comply	Nozzles approved and have discharge coefficient not exceeding 7.5.
46	N/A	Dry standpipe identification
51 and 511	N/A	Factors Governing Water Supplies - General Information
52	N/A	Title, Character of Water Supplies
521 and 522	Comply	Approved water supplies
523	Alternative	The diesel fire pump will automatically start on low system pressure.
524 and 525	Comply	Water supply quantity and duration

PART X – NFPA CODE EVALUATION

NFPA 14-1974, "Standpipe and Hose Stations" TVA System 26 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
526	N/A	Water supply connections from public waterworks
53, 54, and 55	Comply	Minimum supply for Class I, II, and III service
56	N/A	Fire department connections not used within Q* boundaries at WBN- used at MDB.
61	N/A	Title, Connections to Systems
611 and 612	N/A	Gravity tanks
613	Comply	Connections from fire pumps
614	Alternative	Standpipes in Auxiliary and Control Buildings are interconnected to the buildings internal HPFP loop, but not necessarily at the lowest elevation.
62	N/A	Title, Isolation and Check Valves
621	Alternative	Indicating and check valves at connections to water supplies are not provided, but standpipes can be isolated by system 26 (HPFP system) in the piping network. The HPFP system is a dedicated raw water system and check valves to prevent back flow (as in the case of a "water works" system) is not warranted.
622	Deviation	Isolation of standpipe
623	N/A	Pressure indicating valves (PIVs) in connections to public works system.
624	Deviation	Water supply control valves of approved indicating type at a safe distance from building or header.
625	Alternative	High pressure valves not used, even though system spikes of up to 190 psi can occur due to pump start surges before relief devices compensate. This is acceptable and in accordance with ANSI B31.1 requirements.

PART X – NFPA CODE EVALUATION

NFPA 14-1974, "Standpipe and Hose Stations" TVA System 26 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
63	N/A	Title, Piping
631	Alternative	Listed materials are used and the piping can withstand working pressure of system.
632 and 633	N/A	Other types of pipe and brazed joints not used.
64	N/A	Title, Fittings
641	Alternative	The piping is in accordance with ANSI B31.1 material requirements.
642 and 643	Comply	Approved fittings and expansion joints
65	Comply	Pipe hangers
66	Deviation	Pressure gages
67	Deviation	Water flow alarm
Chapter 7	N/A	Tests and maintenance (See Section 3.2.11 of Part X).
Chapter 8	N/A	Buildings Under Construction

Section 212 Deviation

The standpipes located on elevations 676, 692, 713, 729, 757, 772, and 782 of the Auxiliary Building are supplied with 3 inch supply piping rather than the 4 inch required by NFPA 14-1974 and BTP 9.5-1; and elevation 755 of the Control Building is provided with 2-1/2 inch supply piping. The pipe sizes were verified as adequate by hydraulic calculations.

Section 32, 42, and 421 Deviation

Some standpipes have more than 100 feet of hose attached. Adequate nozzle pressure is available with the additional hose length (refer to Part VII of the FPR).

Sections 413 and 622 Deviation

Valves of approved indicating type provided at main riser provided, except for hose stations at valves 0-26-677 and -690; however, systems can be isolated and not preclude ability to provide hose stream coverage in same locations.

PART X – NFPA CODE EVALUATION

NFPA 14-1974, "Standpipe and Hose Stations" TVA System 26 Compliance Summary Matrix

Section 624 Deviation

Water supply control valve to standpipes in Diesel Generator Building not a PIV. The supply is provided with a wrench operated curb box (non-self indicating) valve. Administrative controls (e.g., second party verification, locking or sealing the valve in position, and strict control of work) for valve manipulation and the access restriction to trained and qualified personnel provide adequate assurance that the valve is in the proper position.

Section 66 Deviation

The tops of each standpipe do not have a 3½ inch dial spring pressure gage.

Section 67 Deviation

Push button stations at standpipes inside the Reactor Buildings will alarm in the Main Control Room. Flow alarms are not provided on other standpipes. The hose stations are provided primarily for the fire brigade members. Other site personnel are trained to report fires. After reporting a fire an individual may attempt to extinguish it if he has been trained in the use of firefighting equipment (see Part II, Section 7.8 and 9.0). Adequate notification of standpipe use will therefore be provided to the Main Control Room.

PART X – NFPA CODE EVALUATION

NFPA 20-1993, “Centrifugal Fire Pumps” Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
1		Introduction and Definitions
2-1	Comply	Water supply is from the Unit 1 Cooling Tower basin, which can supply the fire pump for at least 2 hours at 150% capacity.
2-2	Comply	The pump is a listed pump.
2-3	Comply	Pump is rated for 2500 gpm at 125 psi.
2-4	Comply	Nameplate is provided.
2-5	Comply	Pressure gages are provided.
2-6	Comply	Cooling water is taken from the discharge side of the pump.
2-7	Comply	Pump is mounted on adequately designed concrete slab and inside a pump house that is provided with adequate lighting and heat.
2-8	Comply	Piping is appropriate.
2-9	Alternative	Water level required in the cooling tower basin to ensure no vortexing and provide 2-hours of continuous operation determined by calculation.
2-10	Comply	Discharge piping and fittings meet pressure requirements and are listed as required.
2-11	Comply	The valves are locked open.
2-12	Comply	Adequate clearances are provided.
2-13	Comply	Relief valve and piping are adequately sized.
2-14	Comply	Water metering device (listed flow meter) is provided.
2-15	Comply	Dependable electric power is available.
2-16	Alternative	The pump manufacturer tested the pump at the factory.
2-17	Comply	Pump rotation correctly specified.

PART X – NFPA CODE EVALUATION

NFPA 20-1993, “Centrifugal Fire Pumps” Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
2-18	Comply	Appropriate alarms are provided.
2-19	Alternative	System pressure is maintained by the Raw Cooling Water pumps (a jockey pump has been provided as part of the fire pump package, but is not used).
2-20	N/A	Summary of Fire Pump Data
3-1	N/A	General
3-2	Comply	Factory and field performance
3-3	Comply	Fittings
3-4	Comply	Foundation and setting
4	N/A	Vertical Shaft Turbine-Type Pumps
5	N/A	Fire Pumps for High-Rise Buildings
6	N/A	Electric Drive for Pumps
7	N/A	Electric Drive Controllers and Accessories
8	N/A	Diesel Engine Drive
8-1	N/A	General
8-2.1	Comply	Engine is listed for fire pump service.
8-2.2	Comply	Engine ratings
8-2.3	Comply	Engine connection to pump
8-2.4	Comply	Instrumentation and Control
8-2.5	Comply	Engine is equipped with reliable electric starting device.
8-2.6	Comply	Two storage battery units are provided with chargers.
8-2.7	Comply	Engine cooling

PART X – NFPA CODE EVALUATION

NFPA 20-1993, "Centrifugal Fire Pumps Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
8-3	Comply	Pump and Engine Protection
8-4	Comply	Fuel Supply and Arrangement
8-5	Comply	Engine Exhaust
8-6	Title	Driver System Operations
8-6.1	Alternative	Pump is started every 31 days and run for 30 minutes. Consistent with Standard Technical Specifications.
8-6.2	Comply	Engines shall be kept clean, dry, and well lubricated.
8-6.3	Alternative	See Part II, Section 14.2.
8-6.4	Alternative	See Part II, Section 14.2.
8-6.5	Comply	Temperature maintenance
8-6.6	Comply	Emergency starting and stopping
8-7	N/A	Air starting
9	Title	Engine Drive Controllers
9-1	Comply	General
9-2	Comply	Location
9-3	Comply	Construction
9-4	Comply	Components
9-5	Title	Starting and control
9-5.1	Comply	Automatic and nonautomatic
9-5.2	N/A	Automatic Operation of Controllers

PART X – NFPA CODE EVALUATION

NFPA 20-1993, "Centrifugal Fire Pumps Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
9-5.2.1	Alternative	Jockey Pump - Pressure is maintained using the RCW System
	Comply	DFP Controller Circuit
9-5.2.2	N/A	Pump supplies the fire protection system loop.
9-5.2.3	Comply	Manual electric control at remote station.
9-5.2.4	N/A	Sequence starting of pumps operating in parallel.
9-5.2.5	Comply	External circuits connected to controllers.
9-5.2.6	N/A	Sole supply pumps
9-5.2.7	Alternative	The weekly timer is provided, but will be locked out so personnel can be available for the performance testing.
9-5.3	Comply	Nonautomatic operation of controller
9-5.4	Comply	Methods of stopping
9-5.5	Comply	Emergency control
9-6	N/A	Air Starting Engine Controllers
10	N/A	Steam Turbine Drive
11	Title	Acceptance Testing, Performance, and Maintenance
11-1	Comply Alternative	Hydrostatic tests Flushing per TVA Engineering Specification.
11-2	Comply	Field acceptance tests are performed by pump vendor.
11-3	Comply	Manuals, special tools, and spare parts
11-4	Alternative	Periodic inspections, testing, and maintenance is done in accordance with Part II, section B.14.2 of the FPR and is consistent with standard Technical Specification requirements.

PART X – NFPA CODE EVALUATION

**NFPA 20-1993, "Centrifugal Fire Pumps
Compliance Summary Matrix**

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
11-5	N/A	Impeller replacement
12	N/A	Referenced Publications

PART X – NFPA CODE EVALUATION

NFPA 24-1973, "Outside Protection" TVA System 26 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
11	Comply	Layout plans of new yard piping
12	Comply	Plan drawings showing size and location of water supplies, piping, valves, hydrants, sprinkler and standpipe risers, and fire department connections.
13	N/A	Piping layout general information
14	Comply	Installation by experienced and responsible workers.
15	Alternative	The system 26 (HPFP system) flow diagrams are under configuration control and maintained in the Main Control Room. This clearly complies with the intent of the code (as applicable to a nuclear plant) but does not meet literal compliance.
21	Comply	Choice of water supplies
22	N/A	Title, Public Water Systems
2200	N/A	WBN does not rely on the public water system
2201	Comply	Adequate water supply - Tennessee River
2202	Comply	Street mains are of ample size
2203	Comply	No pressure regulating valves used in water supply.
2204	N/A	No connection to public waterworks.
2205	Alternative	The HPFP system is a dedicated raw water system and does not interface with a public water works system.
2206	Comply	Connections for domestic or standpipe use to meet Code Section 2205.
23	N/A	Title, Pumps

PART X – NFPA CODE EVALUATION

NFPA 24-1973, "Outside Protection" TVA System 26 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
2300	N/A	Pumps - general information
2301	Comply	Pump supervisory service, see NFPA 72D, pumps operated monthly by operations personnel.
24	N/A	No tanks used.
25	N/A	Title, Penstocks or Flumes, Rivers or Lakes
2501	Comply	Approved (by AHJ which is TVA) double removable screens and strainers used.
26	N/A	Fire department connections not used within Q* boundaries at WBN- used at MDB.
31	N/A	Title, Types of Valves
3101	Alternative	Both indicating and non-indicating valves are used in the HPFP system.
3102	Alternative	Check valves are in accordance with WBN approved material (e.g., ANSI B31.1).
32	N/A	Title, Valves Controlling Water Supply
3201	Comply	Use of approved OS&Y or other indicating control valves.
3202	Alternative	There is only one source of water supply for the four electric motor driven fire pumps (if multiple supplies, then a check valve is required in each connection), but there are two trained headers and a common header. The diesel driven fire pump takes suction from a separate source of water not interconnected with the river.
3203	Comply	Installation of control valves at check valves
3204	N/A	No gravity tank.
3205	N/A	Pump house noncombustible and no tanks used.
3206	N/A	Check valve placement - general information

PART X – NFPA CODE EVALUATION

NFPA 24-1973, "Outside Protection" TVA System 26 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
3207	Comply	Control valves are readily accessible.
33	N/A	Title, Post Indicator Valves
3301	Comply	Post indicator and curb box valves used.
3302	Comply	Post indicator valve location (PIV 0-26-1969 located on the north side of EQ Building is closer than recommended and it is not within the Q* boundaries and is therefore out of scope)
3303	Alternative	Post Indicating Valves are not all 36" above the ground level (grade), but are accessible for proper operation.
3304	Comply	Post indicating valve protection
34	N/A	Valves in pits not used within Q* boundaries (only MDB valve is in a pit, which is of appropriate size and readily accessible, but outside of scope).
35	N/A	Title, Sectional Valves
3501	Comply	Use of sectional controlling valves at appropriate points.
3502	N/A	Main does not cross water.
36	N/A	Title, Identifying and Securing

PART X – NFPA CODE EVALUATION

NFPA 24-1973, "Outside Protection" TVA System 26 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
3601	Alternative	Break-away locks or the red seals are used on fire protection system valves to administratively control their position. Inspections of valve positions are done quarterly, not weekly. The quarterly inspection is based on the administrative controls (e.g., second party verification of position, locking or sealing the valve in position, and strict control of work) for valve manipulation and the site access restriction to trained and qualified personnel. The frequency is more conservative than the inspection criteria established for primary system valves that are locked or sealed. This provides adequate assurance that the valve is in the proper position.
41	Comply	Type of Hydrants
42	N/A	Title Number and Location of Hydrants
4201	Comply	Quantity and placement of hydrants
4202	Comply	Placement with respect to buildings
43	N/A	Title, Setting of Hydrants
4301 and 4302	Comply	Hydrant setting and drainage considerations in accordance with TVA design, construction, and modification procedures.
4303	Comply	Height of Hose Outlet Above Grade
4304	Comply	Fastening of hydrants to piping in accordance with TVA design, construction, and modification procedures.
4305	Comply	Protection of hydrants
51 through 56	N/A	Hose houses and equipment criteria met by mobile apparatus.

PART X – NFPA CODE EVALUATION

NFPA 24-1973, "Outside Protection" TVA System 26 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
57	Comply	Couplings of same size and thread, and are interchangeable with those of local fire department.
58	Comply	Nozzles are of the approved type.
59	Comply	Technical specification hydrants used only for fire protection purposes when plant operating.
61	N/A	Title, General, information on hose care per NFPA 198
6100	Comply	Proper storage of hose (Note: WBN does not use rubber lined hose referenced in 6100, which addresses hose storage issues. WBN uses lined hose procured to current standards.).
6101	N/A	Hose not stored at hose houses.
6102 through 6402	Comply	Usage, storage, testing, cleaning, and drying of hose
71	N/A	Heavy caliber hose stream available via portable monitor nozzles; hazards do not require permanent installations.
81 through 85	Alternative	Selection, coating and lining, and fitting of joints for piping is per TVA design, construction, and modification procedures. These procedures provide guidance that meets or exceeds the code. Corrosion is monitored per Part II of the FPR.
86	N/A	Title, Sizing of Pipe

PART X – NFPA CODE EVALUATION

NFPA 24-1973, "Outside Protection" TVA System 26 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
8601 thru 8603	Comply	Minimum size of pipe underground not less than 6 inches, loop system provided, and pipe sizes to systems approved by authority having jurisdiction.
91 through 99	Alternative	Laying of pipe is per TVA design, construction, and modification procedures.

PART X – NFPA CODE EVALUATION

NFPA 30-1973, "Flammable and Combustible Liquids Code" Compliance Summary Matrix

Note: NFPA 30 was only evaluated for storage and transport of transient combustible materials.

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
Chapter I	N/A	General Provisions
Chapter II	N/A	Tank Storage
Chapter III	N/A	Piping, Valves, and Fittings
40	N/A	Title, Scope, and general information
41	N/A	Title, Design, Construction, and Capacity of Containers
4110	Comply	Approved containers
4120	N/A	Portable tanks
4130	Comply	Maximum size
4131	N/A	Medicines, beverages, and foodstuffs
4132	Comply	Glass containers
42	N/A	Title, Design, Construction, and Capacity of Storage Cabinets
4210	Comply	Storage cabinet limitations
4220	Comply	Storage cabinet design
4221	Comply	Metal cabinet construction
4222	N/A	Wooden cabinets
43	N/A	Design and construction of inside storage rooms
44	N/A	Storage inside buildings
45	N/A	Storage outside buildings
46	N/A	Title, Fire Control
4610	Comply	Hose and extinguishers

PART X – NFPA CODE EVALUATION

NFPA 30-1973, "Flammable and Combustible Liquids Code" Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
4611	N/A	Portable extinguishers (See Section 3.2.1 of Part X)
4612	N/A	Portable extinguishers (See Section 3.2.1 of Part X)
4620	N/A	Sprinklers
4630	Comply	No open flames or smoking.
4640	Comply	Materials that react with water
4650	N/A	Tanks bonded or grounded
50	N/A	Scope - General Information
51 and 5110	N/A	Title, Incidental Storage or Use of Flammable and Combustible Liquids, and general information
5120 through 5122	Comply	Storage in tanks or closed containers - requirements
5123	N/A	Large quantities in tanks
5130	N/A	Separation of transfer areas
5140	N/A	Title, Handling Liquids at Point of Final Use
5141	Comply	Covered containers
5142	Comply	Closed containers used for transport to work areas.
5143 and 5144	Comply	No open flames and transfer requirements
52	N/A	Unit physical operations - general information
5210 through 5230	N/A	Applicability, location of plants, and unstable liquids
5240	N/A	Title, Drainage
5241 and 5242	N/A	Emergency drainage systems

PART X – NFPA CODE EVALUATION

NFPA 30-1973, "Flammable and Combustible Liquids Code" Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
5243	Comply	Preventing discharge
5250	N/A	Ventilation
5260	N/A	Processing plants
53	N/A	Tank vehicle and tank car loading and unloading
54	N/A	Title, Fire Control
5410 through 5430	Comply	Fire extinguishment and control equipment
5440	N/A	Special hazards
5450 and 5460	Comply	Fire alarm system and inspections
55	N/A	Title, Sources of Ignition
5510	Comply	Preventing ignition
5520	N/A	Class I liquids dispensed into metal containers.
56	N/A	Electrical equipment
57	Comply	Repairs to equipment
58	Comply	Housekeeping
Chapter VI	N/A	Bulk Plants
Chapter VII	N/A	Service Stations
Chapter VIII	N/A	Processing Plants
Chapter IX	N/A	Refineries, Chemical Plants and Distilleries

PART X – NFPA CODE EVALUATION

NFPA 72D-1975, "Installation, Maintenance and Use of Proprietary Signaling Systems" TVA System 13 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
100	N/A	Definitions
1110	N/A	Application - Title
1111	Comply	"Class A" system
1112 through 1113	N/A	Emergency operation of Class A systems for manual fire alarm stations and guard tour signals
1120	N/A	Title, Central Supervising Structure
1121	Deviation	Location of the central supervising station in the Main Control Room, but is not in a room that is separated from the rest of the Main Control Room.
1210	N/A	Title, System Operation
1211	Comply	System arranged to receive and record all signals, and direct supervised circuit to local fire department not deemed necessary
1212	Comply	Recording requirements
1213	Alternative	The fire alarm console in the Main Control Room is a UL listed device designed by Pyrotronics, Inc. Pyrotronics, Inc. is a UL listed manufacturer of fire service equipment. TVA has modified the fire alarm console by adding a A-B switchover panel which allows a quick change over to the installed spare control system. This option is not commercially available and does not degrade the system. The audible alarm levels have been adjusted to meet the requirements of the human factors analysis for the Main Control Room. These changes were performed in accordance with General Engineering Specification G-73.
1220	N/A	Title, Operating Personnel

PART X – NFPA CODE EVALUATION

NFPA 72D-1975, "Installation, Maintenance and Use of Proprietary Signaling Systems" TVA System 13 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
1221	Alternative	Access to the "control supervising station" (Main Control Room) is not limited to only those personnel required to operate the system. Site security procedures ensures strict access control for personnel who can be on site much less in the Main Control Room. Areas in the Main Control Room that involve control functions of the plant, have additional access restrictions applied. The combination of these controls ensure the proper operation of and response to the "control supervising station".
1222	Comply	Reserve operators
1223	Alternative	Operation and supervision of fire alarm not primary function of the Main Control Room operators. They are responsible for all Main Control Room alarm response functions.
1224	Comply	Maintenance, inspection, and repair personnel availability
1230	N/A	Title, Tests
1231	Comply	Daily tests
1232	Deviation See 3.2.11 of Part X	Water flow actuated devices
1233	Deviation See 3.2.11 of Part X	Water flow test
1234	Deviation See 3.2.11 of Part X	Drain tests
1235	Comply	Test and operation records
1240	N/A	Title, Signals and Reports
1241	Comply	Reports of signals required by AHJ.

PART X – NFPA CODE EVALUATION

NFPA 72D-1975, "Installation, Maintenance and Use of Proprietary Signaling Systems" TVA System 13 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
1242	Comply	Signal designation
1243	N/A	Sprinkler supervisory signals, See 3423 and 3442.
1244	N/A	Transmission over common signaling circuit for fire alarm boxes and supervisory signals.
1250	N/A	Title, Disposition of Signals
1251	Deviation	Actions upon receipt of selected low threshold fire alarm signal - fire brigade not immediately activated, basis for alarm investigated first.
1252	N/A	No guard tours.
1253	Comply	Actions upon receipt of supervisory signal.
1254	Comply	Actions upon receipt of trouble signal.
1310 through 1322	Comply	Circuit arrangement
2010 through 2013	N/A	Title, Scope, and general information
2020 through 2021	N/A	Title, Approval, and general information
2022	Alternative	The system is UL listed except as noted in 1213.
2023	Comply	Acceptance tests
2024	N/A	Maintenance agreement
2030 and 2031	N/A	Title, Installation and Design, and general information
2032 and 2033	Comply	Vibration and grounding requirements
2034	N/A	Multiple alarm feature
2035	Comply	System restricted for fire protection use only.

PART X – NFPA CODE EVALUATION

NFPA 72D-1975, "Installation, Maintenance and Use of Proprietary Signaling Systems" TVA System 13 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
2036	Alternative	System is not rated to operate at 85% and 100% of rated voltage, system is rated at 105V to 115V, and nominal is 115V. (85% of 115V is 97.75V. 85% of 120V is 102V.)
2037	N/A	System does not use devices that require rewinding or resetting.
2038	N/A	Coded alarm signals
2110	N/A	Even though criteria of NFPA 70 Article 760 followed, NFPA 70 is not applicable to electric generating stations.
2210 and 2211	N/A	Title, Power Supply Sources, and general information
2212	Comply	Use of approved equipment
2213	N/A	Even though criteria of NFPA 70 for wiring and power supply equipment is followed, NFPA 70 is not applicable to electric generating stations.
2220	N/A	Title, Power Supply, Central Supervising Station
2221	Alternative	Primary and secondary power supply not within the Main Control Room; they are provided for the fire alarm console from offsite and onsite power sources.
2222	Comply	Primary power supply requirements
2223	Alternative	The fire alarm system has the emergency diesel generators as the automatic secondary power supply. The UPS backup and batteries within the fire alarm console supply selected devices in the fire alarm console.
2224	Deviation	Separate power supply for trouble signals
2230	N/A	Title, Power Supply for Remotely Located Control Equipment

PART X – NFPA CODE EVALUATION

NFPA 72D-1975, "Installation, Maintenance and Use of Proprietary Signaling Systems" TVA System 13 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
2231	Deviation	Power supply for remotely located control equipment - requirements
2240	N/A	Title, Light and Power Services
2241	Comply	Three-wire power supply
2242 and 2243	Deviation	Limiting access to power service connection (0-DPL-13-1) and overcurrent protective devices (not in locked panels).
2250 through 2252	N/A	Rectifier power supplies
2260	Alternative	Emergency diesel generators (DG) are not reviewed against NFPA 37, and the DGs are not operated weekly (they are designed, tested, and operated based on FSAR and Technical Specification requirements with the intent of ensuring the supply is met).
2270	N/A	Storage batteries not used to operate system.
2280	N/A	Cycle-charged batteries not used to operate system.
2290	N/A	Primary (dry cell) batteries not used to operate system.
230	N/A	Title, Overcurrent Protection
2310 and 2311	N/A	Batteries, see 2270 - 2290
2321	N/A	Although the criteria of NFPA 70 for wiring is followed, NFPA 70 is not applicable to electric power generating stations.
2330	Comply	System control unit protection to 150% of rating.
2340	Comply	Transformer protection
240	N/A	Title, Electrical Supervision

PART X – NFPA CODE EVALUATION

NFPA 72D-1975, "Installation, Maintenance and Use of Proprietary Signaling Systems" TVA System 13 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
2410	Comply	Electronic supervision for breaks, faults, and failures provide alarms in the Main Control Room.
2420	Comply	Power supply circuit supervision
2430	Comply	Signal initiating circuits supervision
2440	Comply	Alarm signal sounding circuits supervision
2450	N/A	Exceptions to electrical supervision
2460	N/A	Title, Trouble Signals
2461	N/A	Distinctive signals for trouble, alarm, and supervisory signals or comply with 2462.
2462	Comply	Distinctive audible signals for trouble, alarm, and supervisory signals, or supplementary visual indication.
2463 through 2465	Comply	Trouble signal silencing and reflash
2470	N/A	Speaker amplifier and tone generating equipment requirements not on system 13.
2510	Comply	Audible signal appliances
2520	Comply	Listing and protection requirements
2530	N/A	Requirements for speakers (see 2470)
2540	N/A	Distribution and adequacy of evacuation signals (see 2470)
2550	Deviation	Distinctive signals, but fire alarm signals do not take priority over all other Main Control Room signals. Priority is left to discretion of Operations Shift Manager.
2610 and 2611	N/A	Signal capacity of circuits and number of code wheels

PART X – NFPA CODE EVALUATION

NFPA 72D-1975, "Installation, Maintenance and Use of Proprietary Signaling Systems" TVA System 13 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
2612	Comply	Number of waterflow and supervisory switches
2620	N/A	Separate alarm signal circuits (multiplex circuits used)
2630	Comply	Combined alarm and supervisory signal circuits requirements (multiplex circuits used).
2640	Comply	Loading capacity of signaling line circuits
2650	Comply	Loading capacity of sprinkler supervisory signaling line circuits
2660	N/A	Loading capacity of guard supervisory signaling line circuits
3010	N/A	Types of signaling systems general information
310	N/A	Fire alarm boxes
320	N/A	Guard tour supervisory service
3310 and 3311	N/A	Title, Automatic Fire Detection And Alarm Service, and general information
3321	Comply	Supplementary manual alarm signal operation
3330	Comply	Detectors installed per NFPA 72E (see NFPA 72E review).
3410 and 3411	N/A	Title, Sprinkler System Waterflow Alarm and Supervisory Signal Service, and general information
3420	N/A	Title, General
3421	N/A	Dry pipe systems not used in safety related buildings.
3422	Comply	See 2462 (distinctive audible signals for trouble, alarm, and supervisory signals).

PART X – NFPA CODE EVALUATION

NFPA 72D-1975, "Installation, Maintenance and Use of Proprietary Signaling Systems" TVA System 13 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
3423	Deviation	Signal attachments and circuits (pressure switches) can be removed or tampered with and not cause an alarm.
3430	N/A	Title, Waterflow Alarm Service
3441	Comply	Supervising sprinkler systems
3442	Deviation	Control valve supervision (locked or sealed instead).
3443b and 3443d	Comply	Pressure source supervision for pipe integrity
3444 and 3445	N/A	Water storage container supervision
3446	Comply	Fire pump supervision (Fire Pump "Running" signal)
3510	N/A	Title, Signal Indication
3511	Comply	Signal indication for automatic smoke alarms
3520	Comply	Detectors installed per NFPA 72E (see NFPA 72E review).
3530	Comply See 3.2.11 of Part X	Maintenance servicing
3540	N/A	Title, Circuit Arrangement
3541	Comply	Circuit arrangement (Class A)
3542	N/A	(3541 Applies)
3543	N/A	Blowers in smoke detectors
3544	Comply	Electrical supervision
3545	Comply	Trouble signal upon failure of supervised circuits (audible and printed out on fire alarm console as required by 2462).

PART X – NFPA CODE EVALUATION

NFPA 72D-1975, "Installation, Maintenance and Use of Proprietary Signaling Systems" TVA System 13 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
4010	N/A	Multiplex alarm systems introduction
4110	N/A	Title, System Operation
4111	Alternative	Both visual and recorded displays in compliance, but records not preserved.
4112	Deviation	The transmission of an alarm signal to the fire alarm console, because of a wire to wire short circuit, cannot be recorded.
4113	Comply	Fault(s) on trunk/leg facilities
4114	N/A	Private radio facilities
4120	N/A	Satellite station facilities
4210 thru 4214	Comply	Circuit Arrangement
4220	N/A	Power supplies for repeater and satellite stations
4310	N/A	Title, Systems Equipment and Trunk Capacities
4311	Deviation	Operability under fault conditions (see 4112)
4312	N/A	System equipment and trunk capacities - general information
4313	Comply	System equipment and trunk capacities

Section 1121 Deviation

The central supervising station is located in the Main Control Room which is a security area with strict access control.

Section 1232 Deviation

Water flow actuated devices and transmitters are not being tested every two months. See Section 3.2.11 of Part X.

Section 1233 Deviation

Water flow through the test connection is not performed. See Section 3.2.11 of Part X.

Section 1234 Deviation

A main drain test is not performed after operation of a system isolation control valve. See Section 3.2.11 of Part X.

PART X – NFPA CODE EVALUATION

NFPA 72D-1975, "Installation, Maintenance and Use of Proprietary Signaling Systems" TVA System 13 Compliance Summary Matrix

Section 1251 Deviation

Upon receipt of an alarm from a cross zoned detection system, an individual is dispatched to the area to determine cause of alarm. If a fire exists, the individual notifies the Main Control Room and they notify the site fire brigade. If both zones of a cross zoned detection system alarm, the site fire brigade is notified immediately. This allows false alarms to be addressed at a proper level while still maintaining a rapid response by the site fire brigade to actual fires.

Sections 2224 and 2231 Deviation

The alarm power and trouble power for the local panels come from the same power panel, but from different circuit breakers. The same primary and secondary power supplies power to both alarm and trouble circuits.

Section 2242 and 2243 Deviation

Limited access to power service connection (0-DPL-13-1) and overcurrent protective devices (not in locked panels); however, access to panels is under operations control so intent is met.

Section 2550 Deviation

Distinctive signals, but fire alarm signals do not take priority over all other Main Control Room signals. Priority is determined by the Operations Shift Manager.

Section 3423 Deviation

Signal attachments and circuits (pressure switches) can be removed or tampered with and not cause an alarm. However, site personnel access control and the work control system provide adequate assurance that work on such devices are properly controlled and documented. Therefore, there is not a need for such alarms as would be in areas accessible to the general public where tampering is a concern.

Section 3442 Deviation

Sprinkler system control valves are not electrically supervised. They are locked or sealed open and periodically inspected instead. Administrative controls (e.g., second party verification of position, locking or sealing the valve in position, and strict site access and work control) for valve manipulation assure that the valve has not been tampered with and is in the proper position.

Section 4111 Alternative

Both visual and recorded displays are in compliance, but records are not preserved for later inspection. Plant procedures have reporting requirements for conditions adverse to quality. These procedures require that an adverse condition report be initiated by the end of the shift on which the problem was identified. The printouts from the fire alarm console are periodically retrieved and retained by the site Fire Protection staff; therefore, documentation from the fire alarm console would be available to support an adverse condition report. This retention is adequate to aid in the reconstruction of a sequence of events and meets the intent of the code.

Sections 4112 and 4311 Deviation

The transmission of an alarm signal to the fire alarm console, because of a wire to wire short circuit, cannot be recorded. A wire to wire short will generate a trouble signal which requires action to correct. See Part II, Section 14.1 for disposition of trouble signals.

PART X – NFPA CODE EVALUATION

NFPA 72E-1974, "Automatic Fire Detectors" TVA System 13 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
Chapter 1	N/A	General information
2-1 thru 2-4	N/A	Classification of detectors, definitions, shape of ceilings, and ceiling surfaces - general information
2-5 and 2-5.1	N/A	Titles, Common Requirements and Approval
2-5.1.1	Comply	Approved detection devices used.
2-5.1.2	Comply	Specifications and floor plans for detectors
2-5.1.3	Comply	Contractor statement (TVA is installer and AHJ)
2-5.2.1	Comply	Acceptance tests
2-6	N/A	Title, Installation
2-6.1	Comply	Protection from mechanical damage
2-6.2	Comply	Detector support
2-6.3	Comply	Detectors not recessed into the mounting surface.
2-6.4	Comply	Installation on solid joist construction.
2-6.5	Deviation	Required installation areas
2-6.6	N/A	Installation under loading docks, platforms, and crawl spaces
2-6.7	Comply	Protection of selected areas
3-1	N/A	Heat detectors - general information
3-2	N/A	Heat detector operating principles - general information
3-3	Comply	Temperature classification of heat detectors
3-4	Comply	Location of heat detectors
3-5	N/A	Title, Spacing

PART X – NFPA CODE EVALUATION

NFPA 72E-1974, "Automatic Fire Detectors" TVA System 13 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
3-5.1	Comply	Smooth ceiling spacing
3-5.1.1	Comply	Irregular area spacing
3-5.2	N/A	Open joist construction spacing
3-5.3	Deviation	Beam construction spacing
3-5.4	N/A	Sloped ceiling spacing
4-1	N/A	Smoke detector - general information
4-2	N/A	Smoke detector operating principles - general information
4-3	Comply	Location of smoke detectors
4-4 and 4-4.1	N/A	Title, Detector Spacing, and general information
4-4.2	Deviation	Smooth ceiling spacing
4-4.3	N/A	Joisted ceiling spacing
4-4.4	Comply	Sloped Ceiling Spacing
4-4.5 and 4-4.5.1	N/A	Title, High Ceiling Spacing, and general information
4-4.5.2	Alternative	High ceiling spacing

PART X – NFPA CODE EVALUATION

NFPA 72E-1974, "Automatic Fire Detectors" TVA System 13 Compliance Summary Matrix

<u>Code Section</u>	<u>Summary</u>	<u>Topic/Remarks</u>
Chapter 7	Comply See 3.2.11 of Part X	Maintenance and testing
8-1.1.1	N/A	Duct detector general information
8-1.1.2	Deviation	Use of duct detectors in lieu of area detectors done in Reactor Building upper and lower compartment coolers.
8-1.1.3 thru 8-1.1.5	Comply	Location of duct detectors, listed or approved devices, suitability for maximum temperatures.
8-1.2.1	Deviation	Duct detectors not provided per NFPA 90A requirements.
8-1.2.2	N/A	Duct detectors connected to signalling system.
8-1.2.3	Comply	Listed or approved detectors when connected to signalling system.
8-1.3	Comply See 3.2.11 of Part X	Testing and maintenance of duct detectors
8-2	N/A	Smoke detectors for door release service
8-3	N/A	Automatic data processing facilities

Section 2-6.5 Deviation

The following areas in the Diesel Generator Building do not have detection: Stairs D1, Bathroom and CO2 Storage Room on elevation 742, and the Corridor and Radiation Shelter Room on elevation 760. A fire in these rooms would not impact the plant's ability to achieve and maintain safe shutdown (i.e., would not cause an entry into the Appendix R shutdown procedures).

The airlocks do not have detection. Specific Auxiliary Building pump room entrance labyrinths do not have detection. The Auxiliary Building elevator shaft and elevator equipment do not have detection. See Part VI, Fire Hazards Analysis for Fire Area 10, and Part VII, Deviations for Lack of full area detection for justification.

PART X – NFPA CODE EVALUATION

NFPA 72E-1974, "Automatic Fire Detectors" TVA System 13 Compliance Summary Matrix

Sections 3-5.3 and 4-4.2 Deviation

Note: The code allows for locating smoke detectors based on each detector covering a square with each side of the square equal to the recommended spacing. TVA has reduced this coverage to be more consistent with how fire effects spread along a ceiling by locating smoke detectors based on a circle with a radius equal to 1/2 of the recommended spacing. This is more conservative than the code of record and will result in additional detectors to cover the area; however, this spacing is more representative of later code editions.

The following locations exceed these spacing requirements:

- Auxiliary instrument room #2 (708.0-C4) - One detector exceeds the spacing requirement from the south wall at column C8 (18' vs 15').
- Elevations 776 and 786 of the Unit 1 Additional Equipment Building do not have a detector on the stairway side of the two foot deep beam nor on the ceiling over the hoist area, respectively. These areas do not comply with the spacing requirements. In addition, the beam construction criteria of Section 3-5.3 of NFPA 72E is not met.
- The following areas on elevation 676 of the Auxiliary Building do not meet the spacing requirements in the entrance corridors to the nearest detector:

ROOM NAME	ROOM NUMBER
• Containment Spray Pump 1B-B	676.0-A8
• Containment Spray Pump 1A-A	676.0-A9
• RHR Pump 1B-B	676.0-A10
• RHR Pump 1A-A	676.0-A11
• RHR Pump 2A-A	676.0-A12
• RHR Pump 2B-B.	676.0-A13
• Containment Spray Pump 2A-A	676.0-A14
• Containment Spray Pump 2B-B	676.0-A15

- The following areas on elevation 692 of the Auxiliary Building do not meet the spacing requirements in the entrance labyrinth to the nearest detector:

ROOM NAME	ROOM NUMBER
• Charging Pump 1B-B	692.0-A10
• Charging Pump 1C	692.0-A11
• Cask Decon Collector Tank	(east 692.0-A14 corridor only)
• Charging Pump 2C	692.0-A21
• Charging Pump 2B-B	692.0-A22

- The Post Accident Sampling Rooms (729.0-A8 and 729.0-A9) do not have detectors in the entrance corridor.

PART X – NFPA CODE EVALUATION

NFPA 72E-1974, "Automatic Fire Detectors" TVA System 13 Compliance Summary Matrix

Section 4-4.5.2 Alternative

Smoke detectors in the high ceiling areas are not installed alternately on two levels. In general, high ceilings are addressed by reduced spacing of detectors at ceiling level as opposed to two levels of detectors. This is acceptable because stratification is not a concern as it would be in a warehouse and because of the HVAC mixing of the air.

Section 8-1.1.2 Deviation

Use of duct detectors in lieu of area detectors done in Reactor Building upper and lower compartment coolers; however, regulatory requirements for detectors met in Reactor Building. Duct detectors are used to address the hazard which is the coolers.

Section 8-1.2.1 Deviation

Duct detectors not provided per NFPA 90A requirements; fans that service area of the fire are manually shut down to ensure that air flow will not prevent fire dampers from closing.

Enclosure 2
Fire Protection Report (FPR) Sections Updated

Enclosure 1 to TVA's letter to NRC dated June 30, 2014 (Reference 1) provided a listing of changes made to Parts II, III, IV, VIII, IX and X. Enclosure 2 to this letter dated September 18, 2014 reflects the same information but has been modified to also reflect additional changes to Parts II, III, IV, VIII, IX and X made since TVA submitted the June 30, 2014 letter (Reference 1). The changes to the FPR made after TVA submitted Reference 1 are marked in the enclosed listing with an asterisk (*). Enclosure 2 to this letter dated September 18, 2014 also reflects changes which were made to Parts I, V, VI and VII.

Enclosure 2
Fire Protection Report (FPR) Sections Updated

General

1. The as-constructed version of the Unit /Unit 2 Fire Protection Report (FPR) incorporates changes which are based on Revisions 40 through 47 of the Unit 1 FPR. These revisions were incorporated into the Unit 1 FPR after the dual unit FPR was originally submitted. These Unit 1 changes were made under the Generic Letter 86-10 process as allowed by the WBN License Condition 2.F.
2. For Parts I, VI and VII, the combustible loading was revised to refer only to the fire severity rating. Combustible loadings were updated to reflect the as-constructed configuration.
3. For Parts VI and VII, corrected equipment unique identifiers.

Part I

1. Part 1, Table I-1, "Summary Compliance Fire Protection"
Table I-1 was updated to be consistent with the other parts of the FPR and to reflect the latest design basis information.
2. Part I, Section 4.0, "Summary Compliance Table"
Removed references to Supplemental Safety Evaluation Report (SSER) 19. This action was taken based on TVA's understanding that only Section 3.5, "Manual Operator Actions," of SSER 18, SSER 26 and a future SSER (assumed 27) remain applicable to the fire protection program for the licensing of WBN Unit 1 and Unit 2.

Enclosure 2
Fire Protection Report (FPR) Sections Updated

Part II

1. Part II, Reference 4.1.28
Added Reference 4.1.28 for Regulatory Guide 8.15.
2. Part II, Reference 4.2.8
Revised the number of calculation EDQ00099920090012 to be WBN-OSG4-031 for consistency with the Unit 1 FPR. Replaced reference to WBN drawing series 45A897-1 with calculation EDQ00099920090016.
3. Part II, Reference 4.2.82
Added a reference to:
MDQ0010002012000074, "Design Basis of Radiant Energy Shields (RES) Protecting Electrical Circuits in the Reactor Building (3M Type E54C)"
4. *Part II, Reference 4.2.87
Added a reference to DCN 59675 that installed the 225kVA FLEX diesel generators.
5. Part II, References 4.3.9 and 4.3.10
Updated the references to reflect Section 3.5 of SSER 18 along with SSERs 26 and 27.
6. *Part II, Section 4.4, "NFPA Codes and Standards"
To be consistent with TVA Engineering Specification G-73, "Installation, Modifications, and Maintenance of Fire Protection Systems and Features," a statement regarding the use of later versions of the NFPA code was added.
7. *Part II, Section 5.0, "Definitions"
Updated the definition for Authority Having Jurisdiction. Updated the listing of "Inaccessible Areas" to include 729.0, Unit 2 South Main Steam Valve Room. Added a definition for Operator Manual Action. Added a definition for Operator Actions. Definition of Operable-Operability, clarified when the CPU for 0-M-29 is Operable.
8. *Part II, Section 7.0, "Fire Protection Organization/Programs"
Updated the organizational information to align with the current TVA fleet procedure for the organization of the Fire Protection organization.
9. Part II, Section 8.1, "Program Changes and Associated Review and Approval"
Deleted the following words from Item b; "and fire protection administrative procedures." Revised Item c to read as follows; WBN may make changes to the approved Fire Protection Report without prior approval of the NRC in accordance with the Appendix R License Condition in each unit's Operating License.
10. Part II, Section 9.1, "Fire Brigade Staffing"
Updated the first and second paragraphs to clarify that the Incident Commander position is separate from the Shift Manager or Unit Supervisor position.
11. Part II, Section 9.3, "Training and Qualification"
Clarified the wording of the last sentence of the paragraph labeled "Recurrent Training" to read as follows; Any individual who misses or fails to complete recurrent training is placed in an ineligible status when the current training expires until the training is completed in accordance with site procedure (Ref. 4.2.80).
12. Part II, Section 10.0, "Control of Combustibles"
Figure II-41A was deleted as part of the removing of the Additional Diesel Generator Building (ADGB) from the FPR. The references to figures were updated due to the deletion of the figure.

Enclosure 2
Fire Protection Report (FPR) Sections Updated

Part II

13. *Part II, Section 11.0, "Control of Ignition Sources"
Text of the second paragraph of Section 11.0 was updated to address the following statement from Section 2.4.2.2, "Control of Ignition Sources," of Appendix FF of SSER 26:

"Before the start of work, the work area is made "fire safe." In addition; TVA's program will establish a hot work fire watch for all ignition source work activities that are performed in safety-related and safe-shutdown areas of the plant."

The change made to Part II clarifies that a fire watch is not required for certain ignition source work in safety-related areas.
14. *Part II, Section 12.3.1, "Preaction Sprinkler Systems"
Part II, Section 12.3.2, "Fire Suppression Systems with Closed Water Spray Heads"
Clarified that actuation of the sprinkler/fire suppression system will start two electric fire pumps and that manual initiation will not start the electric fire pumps.
15. *Part II, Section 12.3.3, "Carbon Dioxide Suppression Systems"
The listing of rooms protected by the CO2 system was deleted as part of TVA's letter dated June 30, 2014. The room information was placed back in Section 12.3.3 as part of this submittal.
16. *Part II, Section 12.8, "Communication"
Revised the description of the radio systems to address the changes made by DCN 60384 which removed the cell phone system from the plant.
17. *Part II, Section 12.10.2, "Raceway Protection"
Regarding radiant energy shields (RESs), clarified that Minnesota Mining and Manufacturing (3M) M20A and M20C material was installed in Unit 1. Also clarified that 3M E54 has been used for some recent RES installations in Unit 1 and will be used for the Unit 2 RES installations.
18. *Part II, Section 13.1.E, "Closed Circuit Television - CCTV (Alternative)"
In the following sentence, revised the words "trained personnel" to be "fire watch personnel."
CCTV monitors are monitored by trained personnel at a frequency consistent with standard compensatory actions identified in Section 14, "Fire Protection Systems and Features Operating Requirements (OR)."
19. Part II, Bases for OR 14.1.4.a
Clarified when the CPU for 0-M-29 is Operable.
20. Part II, Section 14.8, "Fire-Rated Assemblies"
Figure II-41A was deleted as part of the removing of the ADGB from the FPR. The references to figures were updated due to the deletion of the figure.
21. *Part II, OR 14.2.1 and Bases
Statements were added to 14.2.1(a) to clarify fire watch requirements. The plant areas addressed by the fire watch requirements for 14.2.1(b) were updated.
22. Part II, Bases for OR 14.2.4
Updated the wording of the second paragraph to be consistent with the associated Operating Requirement.
23. Part II, Bases for OR 14.2.5
Updated the wording of Steps a.3 and a.4 to be consistent with the associated Operating Requirement.
24. Part II, Bases for OR 14.2.7
Deleted a reference to "cellular radio."
25. *Part II, OR 14.3.1 and Bases

Enclosure 2

Fire Protection Report (FPR) Sections Updated

Part II	
	Statements were added to 14.3.1(b) to clarify fire watch and compensatory action requirements.
26.	*Part II, Section B.14.8 Removed a reference to doors A64 and A77.
27.	*Part II, Section B.14.8.c Replaced reference to WBN Preventative Maintenance Program with reference to WBN Fire Operations Requirements procedure.
28.	Part II, Bases for OR 14.9.c Updated the Bases to address the use of sealed maintenance-free battery UPG UB6420 as a replacement Appendix R Emergency Battery Light (EBL) batteries.
29.	Part II, Bases for Testing and Inspection Requirement (TIR) 14.10.I Clarified that the testing requirements of TIR 14.10.I are fulfilled by the performance of Technical Surveillance Requirement 3.8.3.1.
30.	Part II, OR 14.10.4 and Bases This section was updated to address an NRC violation cited at Sequoyah Nuclear Plant regarding the impact upon the Fire Safe Shutdown (FSSD) analysis whenever a Pressurizer PORV is isolated by closing its block valve in accordance with Technical Specifications 3.4.11.
31.	Part II, Bases for OR 14.10.4 Revise the first sentence of the second paragraph to read: "For a fire in these rooms, the Reactor Head Vent valves are not available..."
32.	*Part II, Table 14.6 In accordance with EDCR 53587, hose station 2-SPV-026-1203 was deleted from Table 14.6.
33.	Part II, Table 14.8.1, "Fire Doors" Added door A217. Deleted doors A64 and A77.
34.	Part II, Table 14.8.2 Added 2-ISD-31-1001.
35.	Part II, Table 14.6, "Fire Hose Stations" Updated the hose rack number associated with valves 2-26-671 & 672 to ABH-4. Updated the hose rack number associated with valves 2-26-674 & 675 to ABH-6.
36.	*Part II, Table 14.10, "Fire Safe Shutdown Equipment" Added valves 1, 2-FSV-77-2561 and 1, 2-FSV-77-2562 to Table 14.10. Updated the local panel numbers for the Nitrogen Operating Station. Added 0-Tank-77-2701. Updates were made to add; HS-70-81BA-B, HS-70-81EA-A, MTR-70-131-A and MTR-70-130-B.
37.	Part II, TIR 14.1.d and Bases Deleted the TIR because the required testing is performed in accordance with 14.1.b.
38.	Part II, Bases for TIR 14.10.c Deleted the following from the first sentence of the Bases; or locally by manual operation of the valve.
39.	*Part II, TIRs Added TIR 14.10.o, 14.10.p, 14.10.q and 14.10.r and Bases to reflect as-constructed Design Change Notices (DCNs) and Engineering Document Construction Releases (EDCRs).

Enclosure 2
Fire Protection Report (FPR) Sections Updated

Part III

1. *Part III, Section 1.1, "Design Basis Evaluation"
 This section contained the following sentence:
 Loss of offsite power has been assumed for control building fires, for which alternative shutdown is provided.
 This sentence was revised to read as follows:
 Cases for only on-site power available and for off-site power available are evaluated for control building fires, for which alternative shutdown is provided.
2. Part III, Section 3.2, "Initial Assumptions"
 Clarified Item (2) and Item (3).
3. Part III, Section 4.14, "Auxiliary Control Air System (ACAS) Key 13"
 Replaced the third paragraph of this section to update the description of the ACAS.
4. Part III, Section 4.2.1, "Pressurizer Heater"
 Revised the number of calculation EDQ00099920090012 to be WBN-OSG4-031 for consistency with Unit 1 FPR.
5. *Part III, Section 6.0, "Identification of Safe Shutdown Circuits and Cables"
 Updates were made to address the Distributed Control System.
6. Part III, Section 10.3.1, "Analysis Volume Types and Appendix R Compliance"
 Figure II-41A was deleted as part of the removing of the ADGB from the FPR. The references to figures were updated due to the deletion of the figure.
7. Part III, Figures III-1 and III-2
 Revised the number of calculation EDQ00099920090012 to be WBN-OSG4-031 for consistency with Unit 1 FPR.
8. Part III, Table 3-2, "Safe-Shutdown Equipment List"
 Updated information related to the nitrogen supply to PCV-1-5, -12, -23 & -30 and to LCV-3-172, -173, -174 & -175.
9. Part III, Table 3-2, "Safe Shutdown Equipment List,"
 Part III, Table 3-3, "Analysis Volume by Fire Area List,"
 Various updates were made based on the incorporation of DCNs into the FPR.
10. Part III, Table 3-3
 Deleted the listing for the ADGB.

Enclosure 2
Fire Protection Report (FPR) Sections Updated

Part IV

1. *Part IV, Section 3.0, "Alternate Control Room Capabilities"
 Updates were made to address the Distributed Control System.

2. Part IV, Section 3.0, "Alternate Control Room Capabilities"
 Added the following sentence to the third paragraph; The post fire alternate safe shutdown analysis is conducted for both the case with offsite power available as well as the case with only onsite power available for 72 hours.

3. Part IV, Section 3.3, "Instruments and Controls Required for Alternative Shutdown Not in the ACR"
 Updated the number of Component Cooling System (CCS) pumps to five.

Enclosure 2
Fire Protection Report (FPR) Sections Updated

Part V

1. Part V, Section 2.0, "Operator Manual Actions"
Reworded the first paragraph to read as follows. The text that was added is bolded:
Operator Manual Actions (OMAs) are those actions performed by operators to manipulate components and equipment from outside the main control room to achieve and maintain post fire hot shutdown, but do not include "repairs". OMAs comprise an integrated set of actions needed to help ensure that hot shutdown can be accomplished, given that a fire has occurred in a particular plant area. **Operator Actions (OAs) are actions taken by an Operator while in the Main Control Room (MCR).** Actions performed inside the main control room are not included in the definition of operator manual actions. **Additionally, actions performed at auxiliary control system stations (e.g., Auxiliary Control Room) in response to a main control room abandonment event are considered OAs but are evaluated against the guidance for OMAs.** OMAs are identified in calculation EDQ00099920090016, "Appendix R – Units 1 & 2 Manual Action Requirements," (Part II, Reference 4.2.59) which also establishes the allowable time to complete each action. **Operator actions performed inside the main control room are also identified in a separate appendix within this calculation.**
2. Part V, Sections 2.1, "OMA Feasibility and Reliability," 2.1.2, "Acceptance Criteria" and 2.2.2, "Operator Locations Prior to Initiating Operator Manual Actions and t=0 Definition"
Clarified Operator Manual Action requirements for Unit 1.
3. Part V, Section 2.1.2, "Acceptance Criteria"
Added general information regarding compliance with NUREG 1852 including information regarding main control room abandonment. Updated the assumptions used to establish an Operator Manual Action is feasible and reliable. This included a statement regarding a 15 percent penalty for the use of an SCBA as defined in Regulatory Guide 8.15.
4. Part V, Section 2.2, "Safe Shutdown Procedures"
Updated the table that list the number of Senior Reactor Operators, Reactor Operators and Assistant Unit Operators required for two unit operation. Updated the wording of Items 3 and 4 under the first paragraph. Revised the number of calculation EDQ00099920090012 to be WBN-OSG4-031 for consistency with Unit 1 FPR.
5. Part V, Section 2.2.1, "Plant Walkdowns"
Clarified that both Main Control Room operator actions (OAs) and local Operator Manual Actions (OMAs) were timed.
6. Part V, Section 2.2.2
Clarified the definition of t=0 and addressed small fires and rapid developing fires.
7. Part V, Section 3.0, "Cold Shutdown Repairs"
Revised the rooms for which cold shutdown (CSD) repairs are required.
8. *Part V, Section 3.1, "Loading Two ERCW Pumps on 6.9kV Board 1-BD-211-A-A"
Deleted Section 3.1 based on changes made under Design Change Notice 53785 (PIC 59730).
9. Part V, Section 3.1, "RHR Room Cooler Repair Section"
Part V, Section 3.2 "RHR/RCS High-Low Pressure Boundary Valve Repair,"
Updated the plant locations where a fire could require cold shutdown repairs
10. Part V, Section 4.1, "Adequacy of Emergency Lighting Locations and Illumination Levels"
Revised the first sentence to clarify that plant walkdowns were performed under blackout conditions for the licensing of WBN Unit 1.

Enclosure 2
Fire Protection Report (FPR) Sections Updated

Part V

11. Part V, Section 4.2, "Function Testing and Periodic Replacement of Emergency Lighting Units"
Deleted Section 4.2. The information in this section was redundant to the information provided in Part II, Section 12.7, "Emergency Lighting," and Section 14.9, "Emergency Battery Lighting Units." Added the following sentence to Section 4.0, "Emergency Lighting;" Refer to Sections 12.7, "Emergency Lighting," and 14.9, "Emergency Battery Lighting Units," of Part II, "Fire Protection Plan," for additional requirements.

Enclosure 2
Fire Protection Report (FPR) Sections Updated

Part VI

1. Part VI, Section 2.2, "Summary of Safe Shutdown Analyses for the Fire Area"
Removed a reference to Table 6-3.
2. Part VI, Section 3.15.1, "Auxiliary Building Elevation 729.0"
Updated the Fire Rated Wrap column to indicate the use of a 1 hour wrap in Fire Area 10, Room 729.0-A8. Due to the use of the wrap, the fire severity of the room was changed from insignificant to low.

The following sentence was in the Evaluations sub-section; The lack of total area suppression and detection room 729.0-A6 is documented in Part VII, Section 3.1. This sentence was updated to read as follows; The lack of total area suppression in room 729.0-A6 is documented in Part VII, Section 3.1.
3. Part VI, Sections 3.15.2 and 3.15.3
The Barriers table in the listed sections was updated to add information regarding Room 741.5.
4. Part VI, Section 3.31.1, "Rooms 782.0 A1 and A2, 757.0 A10"
Added the following sentence to the Deviations section:
The justification for the heavy sheet metal ducts is documented in Part VII, Section 2.6.3.2.b.
5. Part VI, Section 3.38.1, "Room 772.0-A1"
Added the following sentence to the Evaluations section:
The justification for the in situ combustible load in Room 772.0-A1 is provided in Part VII, Section 3.6.
6. Part VI, Section 3.39.1, "Room 772.0 A2"
Added the following sentence to the Evaluations section:
The justification for the in situ combustible load in room 772.0-A2 is provided in Part VII, Section 3.6.
7. Part VI, Section 3.46.1, "Room 772.0 A10"
Added the following sentence to the Evaluations sub-section:
The justification for the in situ combustible load in room 772.0-A10 is provided in Part VII, Section 3.6.
8. Part VI, Section 3.51.1, "Room 772.0 A15"
Deleted the following sentence to the Deviations sub-section:
The justification for fire doors is documented in Part VII, Section 4.1.
9. Part VI, Section 3.53.2.1, "AV-075"
Revised the first paragraph to read as follows:
A fire in Analysis Volume 75 does not impact major equipment required to maintain safe shutdown functions. However, offsite power may be lost. Shutdown can be achieved by utilizing both train A and B systems and components without mitigating actions. Onsite power is available. Equipment credited to achieve shutdown is identified below:
10. Part VI, Section 3.54.21, "Fire Area 48 Safe Shutdown Analysis by Analysis Volume"
Updated AV-076 and added AV-076A.
11. Part VI, Section 3.54.14, "Stairwell C1"
Updated the Barriers table to include an entry for the West Wall, Elevation 755.
12. Part VI, Section 3.60.3, "Rooms 742.0 D1, Stairwell D1, 760.5 D1 and 760.5-D2"
Removed the following sentence from the "Deviations" section; "The justification for the sliding fire doors only having fusible links on one side of the opening is documented in Part VII, Section 5.2 (room 742.0-D1)."

Enclosure 2
Fire Protection Report (FPR) Sections Updated

Part VI

13. Part VI, Section 3.63, "Fire Area 57"
Deleted the listing for the ADGB.
14. Section 3.77.1, "Room 713.0-A19 and -A21"
Deleted door A77 from the "Doors" table.
15. Part VI, Section 3.80.4, "Unit 2 Additional Equipment Building"
Updated the fire severity classification for rooms 729.0-A15, 737.0-A14 and 763.5-A2.
16. Part VI, Section 3.84.1, "Unit 2 Reactor Building Annulus"
Added the following sentence to the Evaluations sub-section:
The feasibility and reliability evaluation for Unit 2 operator manual actions is documented in Part VII, Section 8.3.7.
17. Part VI, Section 3.84.2, "Unit 2 Reactor Building Primary Containment"
Updated the "Fire Loading" paragraph to address the use of wood in an ice condenser door. The "Fire Loading" section was updated to reflect a fire severity classification of moderate.
18. Part VI, Table 6-1
A complete update was made to Table 6-1.
19. Part VI, Tables 6.2 and 6-3
Deleted Table 6-2 and Table 6-3.
20. Part VI, Table of Contents
Deleted the listing for the ADGB.
21. Part VI, Various Sections
Various sections of Part VI were updated to include as-constructed information and a review was performed to ensure Part VI was consistent with the information contained in the other parts of the FPR.
22. Part VI, Various Sections
Several sections of Part VI contained statements similar to the following:
Specifically, safe shutdown for Unit 1 is achieved through the use of the A RHR pump, B Auxiliary Feedwater and Charging pumps, and associated flow paths. Safe shutdown for Unit 2 is achieved through the use of the A RHR pump, B Auxiliary Feedwater pumps, B Charging pump, and associated flow paths. These statements were replaced with the following statement:
Safe shutdown for Units 1 and/or 2 is achieved through the use of the equipment and associated flowpaths shown below, as credited.

Enclosure 2
Fire Protection Report (FPR) Sections Updated

Part VII

1. Part VII, Section 2.3 "Fixed Suppression for Alternate Shutdown Locations"
Updated the table in the Justification subsection.
2. Part VII, Section 2.4, "Intervening Combustibles"
Clarified that the discussion of fluid filled transformers in the Deviation section only applies to the Intake Pumping Station (IPS). Also clarified that the discussion of transformer silicone liquid only applies to the IPS.
3. Part VII, Section 2.9
Updated to reflect as-constructed information and dimensions.
4. Part VII, Section 2.9.4.1, "Description of Condition"
Deleted Item "a" in this section.
5. Part VII, Section 2.9.9.1, "Description of Condition"
This section contained the following sentence:
Fire area 73 is considered a III.G.2 area; however, 729.0-A15 and 763.5-A2 do not contain equipment or cables associated with both redundant shutdown paths.

The sentence was updated to read as follows:
Fire area 73 is considered a III.G.2 area; however, 729.0-A15 and 763.5-A2 contains cables associated with both redundant shutdown paths.
6. Part VII, Sections 2.9.17.2.b, "Fire Load"
Part VII, Section 2.9.18.2.d, "Adjacent Rooms"
Part VII, Section 2.9.20.2.d, "Adjacent Rooms"
Part VII, Section 2.9.21.2.d, "Adjacent Rooms"
These sections were revised to remove expansion joint material from combustible loads for Accumulator Room 4 since the expansion joint is not present in this room.
7. Part VII, 2.9.17.3.a, "Redundant FSSD Components in the Room"
Updated the number of feet the cables are separated in the second sentence.
8. Part VII, 2.9.18.3.a, "Redundant FSSD Components in the Room"
Updated the number of feet the cables are separated in a sentence in the second paragraph.
9. Part VII, Section 3.1.1, "Fire Area 1," Sub-Section Titled "Room 676.0-A1 Corridor"
Revised the first sentence of the third paragraph to read:
The in situ combustible loading of the corridor is low.
10. Part VII, Section 3.1.1, "Fire Area 1," Sub-section Titled "Room 692.0-A18: Hot Tool Room"
Revised the second sentence of the first paragraph to read as follows:
The room contains one cable required for fire safe shutdown and it is routed in a conduit with no other cables.
11. Part VII, Section 3.1.1, "Fire Area 1"
For Room 692.0-A18 listed in the table under Section 3.1.1, revised the FFSD column from "None" to "Yes."
12. Part VII, Section 3.1.7, "Fire Area 14"
Updated the FSSD column in the table in Section 3.1.7 and the paragraph below the table.
13. Part VII, Section 3.1.8, "Fire Areas 33 and 45: 480V Board Rooms 1B and 2B"
Updated the fire severity classification to Severe in the third sentence of the second paragraph.

Enclosure 2
Fire Protection Report (FPR) Sections Updated

Part VII

14. Part VII, Section 3.2, "Containment Purge Air System Return and Exhaust Air Duct Openings Protection Between 713.0-A6 Pipe Gallery and the Unit 1 Annulus and the Unit 2 Pipe Gallery (713.0-A19) and Unit 2 Annulus"
The following was added to the Evaluation sub-section:
The flexible connection in room 713.0-A19 is protected with 3M E54C (M20A is no longer available and E54C is a superior fire rated replacement for M20A) fire barrier mat to give a 3-hour rating to the connection.
15. Part VII, Section 3.3, Sub-Section Labeled "HPFP Hydraulic Calculation Results"
Updated the last sentence of the first paragraph to clarify that the calculation addresses unlined steel pipe.
16. Part VII, Sections 3.4 and 3.5
Updated the format of the evaluations to clarify that these sections are engineering evaluations.
17. Part VII, Section 3.5, "Fire Damper in VCT Room Fire Door"
Updated the Evaluation section to clarify that the entrance labyrinth to the VCT room does not have automatic detection or suppression.
18. Part VII, Section 3.6, "Fire Barrier Rating"
Section 3.6 is a new section that was added to Part VII.
19. Part VII, Section 4.4
Clarified the configuration of the Diesel Generator fuel oil tanks.
20. Part VII, Section 5.1, "Non-Listed, Non-Approved Fire Pumps and Fire Pump Controllers"
Item 5 of Section 5.1 was revised to read as follows:
The electric fire pumps can only be manually stopped from the main control room, which is constantly manned by operations personnel, or the shutdown board rooms. The diesel fire pump can only be stopped locally at the pump. These features provide adequate controls over when the fire pumps can be stopped.
21. Part VII, Section 5.2, "Sliding Fire Doors with Fusible Links on One Side of Door Only"
Clarified the location of the fusible links associated with Door D8A.
22. Part VII, Section 7.0
Replaced reference to WBN drawing series 45A897-1 with calculation EDQ00099920090016.
23. Part VII, Section 8.0, "Feasibility and Reliability Evaluations for Unit 2 Operator Manual Actions"
Revised Section 8.0 to include Unit 1 OMAs added after SSER 18.
24. Part VII, Section 8.2.b
Clarified the method for the calculation of time margins.
25. Part VII, Section 8.2.f
Updated to reflect the elimination of the use of cell phones.
26. Part VII, Section 8.2, Item i, Procedures and Training,
This section was revised to delete the date when the last Fire Safe Shutdown training was conducted.
27. Part VII, Section 8.2.h
Revised this section to clarify the personal protective equipment such as SCBAs is picked up by the AUO on their way to the control room.

Enclosure 2
Fire Protection Report (FPR) Sections Updated

Part VII

28. Part VII, Section 8.3, "Fire Area Evaluations"
Updated the Communications sections to reference Section 12.8 of Part II. The following additional updates were made: 1) Updated to reflect as-constructed configuration of Unit 2. 2) Adding bounding times from dual unit OMA walkdowns. 3) Updated staffing according to the 0-AOI 30.2 procedure series and removed unnecessary details. 4) Updated rooms with actions in room of fire origin. 5) Added five new Unit 1 OMAs to the feasibility and reliability evaluation (1397, 1398, 1598, 1599, 1411, 1447, & 1614).
29. Part VII, Section 8.3.11.3, "OMA 1016 - Operate Steam Generator Relief Valves to Control Secondary Pressure"
In the first paragraph, revised cable number 2PV6752 to 2PV6756.
30. Part VII, Section 8.3.25.1, "Fire Prevention" and Section 8.3.51.1, "Fire Prevention"
Deleted from the listed sections, the following sentence from the second paragraph:
The justification for a manual hose station having more than 100 feet of hose is documented in Section 4.3 of this Part.
31. Part VII, Section 8.3.27.2, "Detection, Control, and Extinguishment"
Deleted the following sentence from the second paragraph:
In addition, a water curtain is provided for the equipment hatch.
32. Part VII, Section 8.3.31.2, "Detection, Control, and Extinguishment"
Added the following sentence to the first paragraph:
In addition, a water curtain is provided for the stairwell.
33. Part VII, Section 8.3.36.1, "Fire Prevention"
Updated the fire severity classification to Severe in the first sentence of the second paragraph.
34. Part VII, Section 8.3.37.1, "Fire Prevention"
Updated the fire severity classification to Severe in the first sentence of the second paragraph.
35. Part VII, Section 8.3.37.2, "Detection, Control, and Extinguishment"
In the last paragraph, replaced the reference to room 729.0-A15 with a reference to 757.0-A24.
36. Part VII, Section 8.3.37.3, "OMA 1022 Operate Steam Generator Relief Valves to Control Secondary Pressure"
In the second sentence of the first paragraph, corrected Room Number 722.0-A2 to read 772.0-A2.
37. Part VII, Section 8.3.37.4, "OMA 1023 – Operate Steam Generator Relief Valves to Control Secondary Pressure"
In the second sentence of the first paragraph, corrected Room Number 722.0-A2 to read 772.0-A2.
38. Part VII, Section 8.3.41.3
Clarified when room 772.0-A8 is required for the operation of WBN.
39. Part VII, Section 8.3.63, "Bounding Evaluation for OMA 1022 – Operate Steam Generator Relief Valves to Control Secondary Pressure"
In the second paragraph and in Sub-section b, "Adequate Time Available to Ensure Reliability," replaced the reference to room 729.0-A15 with a reference to 757.0-A24.
40. Part VII, Sections 8.3.5.3, 8.3.5.4, 8.3.8.3, 8.3.8.4, 8.3.9.3, 8.3.9.4, 8.3.11.3, 8.3.11.4, 8.3.19.3, 8.3.19.4, 8.3.20.4, 8.3.23.3, 8.3.23.4, 8.3.24.3 and 8.3.24.4
Added the following sentence to Item g, Portable Equipment:
No portable equipment is necessary to perform these OMAs.

Enclosure 2
Fire Protection Report (FPR) Sections Updated

Part VII

41. Part VII, Sections 8.3.62, 8.3.63, 8.3.64 and 8.3.65
Added the following sentence to Item g, Portable Equipment:
The reliability of the N2 station is assured by the Operational Requirements and Testing and Inspection program as described in Part II, Section 14.10.
42. Part VII, Sections 8.3.66, 8.3.67 and 8.3.68
Added sections to address Unit 1 OMAs added after issuance of SSER 18.
43. Part VII, Section 8.4, "Re-Entry into Room of Fire Origin for Unit 2 Important to Safe Shutdown Operator Manual Actions"
Updated the Communications sections to reference Section 12.8 of Part II.
44. Part VII, Section 8.4.2.2
Clarified that there is no suppression in room 713.0-A20.

Enclosure 2
Fire Protection Report (FPR) Sections Updated

Part VIII

1. Part VIII, Section A.5, "Fire Suppression Systems"
Deleted the following from the Plant Conformance column of Section A.5; In addition, some dampers in the diesel generator building do not close automatically upon CO2 discharge to preclude a spurious CO2 system operation from adversely impacting safety-related components.
2. *Part VIII, Section D.1.j, "Building Design"
Clarified WBN's compliance with NFPA 90-1975.
3. *Part VIII, F.2.b
Clarified in the Plant Conformance column that cables are not routed through the main control room (MCR).
4. Part VIII, Section D.1.g
Revised the "high fire point" from 650 degrees F to >600 degrees F in the Plant Conformance column.
5. Part VIII, Sections D.2.a
Addressed the installation of 225 kVA diesel generators on the roof of the Auxiliary Building.
6. Part VIII, Sections D.2.b
Updated the wording of the Remarks column to address the storage of compressed gas bottles.
7. Part VIII, D.5.a
Removed the term "sealed beams."
8. *Part VIII, Section D.5.d
Updated the Alternatives column to reflect the radio system installed under DCN 60384.
9. Part VIII, Section E.3.a
Added the following to the Remarks column; The automatic fire suppression systems for charcoal type filter units and associated standpipe systems can be impaired by a single failure but the area sprinkler systems are not affected by the same failure. Added the following to the Alternatives column; At the IPS separate connections are also provided for the sprinkler system and the standpipes.
10. Part VIII, Section F.2
Deleted the following from the Alternatives column; The control room is separated from adjacent rooms on the same elevation in the Control Building by 1 hour (minimum) fire barriers.
11. *Part VIII, Section F.2, "Control Room"
Revised a paragraph under the Plant Conformance column to read as follows:
Ionization smoke detectors are provided in selected cabinets in the MCR. General area fire alarms in the MCR and other areas of the plant alarm and annunciate in the constantly attended MCR to alert the operators of a fire.
12. Part VIII, Section F.2.b
Deleted the following from the Alternatives column; The control room is separated from adjacent rooms on the same elevation in the Control Building by 1-hour (minimum) fire barriers. Also, clarified in the Plant Conformance column that cables are not routed through the main control room (MCR).
13. Part VIII, Sections F.9 and F.10
Added to the Remarks column, information regarding the 225 kVA Diesel Generators. For Section F.9, the following was also added to the Remarks column; The diesel generator electrical board rooms do not have drains for manual fire fighting water. The only fire fighting water would be from standpipe systems and personnel would be in the area at the time to ensure equipment was not adversely affected.

Enclosure 2
Fire Protection Report (FPR) Sections Updated

Part VIII

14. Part VIII, Section F.15
Updated the wording in the Plant Conformance column to read as follows; The decontamination room (713.0-A27) is provided with automatic suppression and detection that provides alarms at a constantly attended location and locally. In addition, hose stations (in adjacent room) and portable fire extinguishers are available.
15. Part VIII, Section F.8
In the second sentence added "and door" to make the sentence read as follows; Cable tray and door penetrations through the wall that separates the Turbine Building from the Control Building are sealed with equivalent 3-hour seals and are provided with water curtain protection on the Turbine Building side.
16. *Part VIII, Section F.10
Added the following statement to the Remarks column:
The 225 kVA Diesel Generator Rooms A and B have detection and automatic closed head suppression installed to the original NFPA code of record (Reference 4.2.87).

Enclosure 2
Fire Protection Report (FPR) Sections Updated

Part IX

1. Part IX, Section G.2.a
In the Plant Conformance column, clarified the use of Electrical Raceway Fire Barrier System (ERFBS) to protect structural steel.

Enclosure 2
Fire Protection Report (FPR) Sections Updated

Part X

1. *Part X, Section 3.2.9, "NFPA 90A-1975: Air Conditioning and Ventilation Systems"
Clarified WBN's compliance with NFPA 90-1975.

2. Part X, NFPA 12-1973, Code Section 241
Updated the Remarks to read; The carbon dioxide concentration is maintained for a substantial period of time to assure complete extinguishment.

3. Part X, NFPA 12-1973, Code Section 212
Updated the Remarks to read; Concentration is achieved and maintained for the surface fires and rotating electrical equipment in diesel engine rooms to ensure complete fire extinguishment.

4. Part X, NFPA 12-1973, Code Section 2232
Updated the Remarks to read; Deep seated fire extinguishment does not specify the required concentration and the required time for extinguishment. The Fire Brigade will respond to any CO2 discharge and verify extinguishment as appropriate.

Enclosure 3
Fire Protection Commitment Update

Enclosure 3
Fire Protection Commitment Update

Commitment Number	Date of TVA Letter that Made Commitment & NRC Accession Number*	Commitment Description	Status of Commitment (Refer to the Notes at the end of this table)
NCO080008020	September 7, 2007 ML072570676	Generic Letter 06-03 - Potentially Nonconforming Hemyc and MT Fire Barrier Configurations The Fire Protection Corrective Action Program will ensure Watts Bar Unit 2 conforms with NRC requirements and applicable guidelines prior to fuel load. The fire barrier configurations are documented in facility design basis documentation that are controlled and maintained in accordance with TVA's Design Control and Quality Assurance Programs. Item 18 of Enclosure 23 of letter T90 070911 002	WBN does not utilize Hemyc or MT fire barrier configurations as documented in the referenced letter and in TVA's June 7, 2006 letter, the WBN dual unit Fire Protection Report (FPR), Part II, Section 12.10.2 and TVA's General Engineering Specification G-98, "Installation, Modification and Maintenance of electrical Raceway Fire Barrier Systems (ERFBS)". Engineering Document Construction Release (EDCR) 55523 is installing Thermolag material where fire wrap is required.
111905993	August 20, 2010 ML102360283	The resolutions contained in Appendix B of the Multiple Spurious Operation (MSO) Evaluation Report shall be implemented prior to Unit 2 fuel load.	An as-constructed update to the MSO evaluation report is provided in Enclosure 4 to TVA's letter dated September 18, 2014. These resolutions have been incorporated into the design output documents and the Unit 1/Unit 2 Fire Protection Report.
111905994	August 20, 2010 ML102360283	PWROG Scenario 13a: "Charging Pump Runout" shall be confirmed to be within the bounds of CCP operation during the large break LOCA analysis prior to Unit 2 fuel load.	The as-constructed update of the MSO evaluation report is provided in Enclosure 4 to TVA's letter dated September 18, 2014. The updated evaluation of PWROWG Scenario 13a shows that flow remains within the bounds of centrifugal charging pump (CCP) operation since the possibility of CCP runout is prevented by ensuring that RCS depressurization is prevented for all fire scenarios.
112068531	March 16, 2011	Figures representing the as-constructed plant configuration will be provided after construction completion. [RAI FPR General - 4]	TVA plans to submit the as-constructed fire protection figures around the time it submits the letter that documents the Unit 2 construction work is substantially complete.

Enclosure 3
Fire Protection Commitment Update

Commitment Number	Date of TVA Letter that Made Commitment & NRC Accession Number*	Commitment Description	Status of Commitment (Refer to the Notes at the end of this table)
112068578	March 16, 2011	Upon performing the final plant walkdowns as prescribed in FPR Sections 2.1.1, 2.4.3, and 2.3, TVA will review the information and submit the results for NRC approval if they differ from the assumptions and details provided in Part V or the other parts of the FPR. Otherwise, TVA will inform the NRC when the walkdowns are complete and that no revisions to the FPR were required. [RAI FPR V-3]	Walkdowns/demonstrations of the operator manual actions (OMAs) have been completed. The timing data has been incorporated into the as constructed Fire Safe Shutdown (FSSD) analysis in Part VI and the Feasibility and Reliability Evaluations in Part VII. Revisions to previous time durations are marked as revisions in the as constructed version of the FPR Part VI and VII.
112068748	March 16, 2011	The barriers separating the Unit 2 Reactor Building from the Refueling Floor will be configured and controlled the same as the Unit 1 Reactor Building Equipment Hatch. [RAI FPR VII-1]	The design change to return the Unit 2 equipment hatch to its original as designed configuration is issued and will be implemented prior to initial fuel load.
112294554	May 18, 2011	The operator manual action timelines shall include the time required for getting the lantern. Enclosure 4, Question 12. NRC Question (RAI FPR V-10)	WBN's fire response is contained within the procedures 0-AOI-30.1, "Plant Fires" and 0-AOI-30.2, "Fire Safe Shutdown". The plant enters 0-AOI-30.1 when indications of a fire are detected. This procedure directs the Operators to notify the Appendix R assistant unit operators (AUOs) to report with their Appendix R related gear.
112331325	May 26, 2011 ML111520119	Additionally, it has been determined that the RES M-20A & M-20C materials are no longer available and Unit 2 will be replaced with a compatible material, such as 3M E54, that will provide equal or greater protection than the M-20A & M-20C. Enclosure 1, Letter Item 2. NRC Question (RAI FPR II-42)	Information was provided in the following sections of the as-constructed FPR which states that new cable protection installations for both units will be constructed using 3M-E54, 1) Part II, Section 12.10.2, Part VII, Section 2.2, Part VII, Section 3.2.

Enclosure 3
Fire Protection Commitment Update

Commitment Number	Date of TVA Letter that Made Commitment & NRC Accession Number*	Commitment Description	Status of Commitment (Refer to the Notes at the end of this table)
112331447	May 26, 2011 ML111520119	WBN design criteria WB-DC-30-13, "10CFR50, Appendix R, Type I, II, and III Circuits – Unit 1 / Unit 2" will be revised to define the evaluation methodology and specify the applicable circuit failure criteria in accordance with NEI-00-01 Revision 2 and RG 1.189, Revision 2. Enclosure 1, Letter Item 29. NRC Question (RAI FPR MSO-1)	WBN design criteria WB-DC-30-13, "10CFR50, Appendix R, Type I, II, and III Circuits – Unit 1 / Unit 2" was revised (Revision 10, dated March 26, 2014) to define the evaluation methodology and specify the applicable circuit failure criteria in accordance with NEI-00-01 Revision 2 and RG 1.189, Revision 2.
112331509	May 26, 2011 ML111520119	The term "backup control stations" should have been "auxiliary control system" and the WBN Unit 2 MSO Report Revision 1 will be revised to state "auxiliary control system." Enclosure 1, Letter Item 33. NRC Question (RAI FPR MSO-6)]	The term "backup control stations" has been replaced with "auxiliary control system" in the as-constructed MSO report: This revision affected Appendix A sections: 22.3.1, 23.3.1, 32.3.5, 33.3.1, 54.3.1, 54a.3.1, 54b.3.1, 54c.3.1, 54d.3.1, 54f.3.1 and Appendix B)
112345687	June 7, 2011	As resolution of this RAI, TVA commits to completing prior to Unit 2 fuel load the modifications and document revisions required to resolve the common MSOs identified in Appendix C submitted in TVA letter to NRC dated August 20, 2010 (Reference 3).	An as-constructed update to the MSO evaluation report is provided in Enclosure 4 to TVA's letter dated September 18, 2014. These resolutions have been incorporated into the design output documents and the Unit 1/Unit 2 Fire Protection Report.
112384234	June 17, 2011	TVA will complete the resolution actions for the MSO scenarios affecting Unit 2 prior to the Unit 2 fuel load. Letter Item # 15, [NRC RAI FPR MSO-10]	
112384277	June 17, 2011	The statement in FPR Part IV, Section 1.0, "fires in the building that could result in abandonment of the main control room (MCR)," is correct. There are fires in the control building that will not result in MCR abandonment. The WBN Unit 2 MSO Report, Revision 1, will be revised to eliminate this apparent contradiction. Letter Item # 16, [NRC RAI FPR MSO-11]	The as-constructed MSO report clarifies the statements crediting the Auxiliary Control System for control building fires "resulting in MCR abandonment" which noted that some control building fires would not result in MCR abandonment. This revision affected Appendix A sections 4.3.1, 22.3.1, 23.3.1, 32.3.5, 33.3.1, 35.3.1, 38.3.3, 48.3.1, and Appendix B.

Enclosure 3
Fire Protection Commitment Update

Commitment Number	Date of TVA Letter that Made Commitment & NRC Accession Number*	Commitment Description	Status of Commitment (Refer to the Notes at the end of this table)
112444565	July 1, 2011	Validation of the Unit 2 Operator Manual Action (OMA) performance times will be demonstrated prior to Unit 2 fuel load.	Walkdowns/demonstrations of the operator manual actions (OMAs) have been completed. The timing data has been incorporated into the as constructed Fire Safe Shutdown (FSSD) analysis in Part VI and the Feasibility and Reliability Evaluations in Part VII. Revisions to previous time durations are marked as revisions in the as constructed version of the FPR Part VI and VII.
112444572	July 1, 2011	Emergency lighting and communications for the Unit 2 OMAs will be demonstrated during the Unit 2 OMA validation walkdowns.	Due to the status of the modifications to the emergency lighting and communications, these capabilities will be demonstrated separately from the OMA walkdowns but will be completed prior to Unit 2 initial fuel load. Completion of the walkdowns with acceptable results will be confirmed via TVA's Substantially Complete letter to be issued prior to initial fuel load.
112444575	July 1, 2011	The post fire safe shutdown procedures [Abnormal Operating Instruction (AOI) 30.2] will be revised for dual unit operation prior to Unit 2 fuel load.	The dual unit 0-AI-30.2 procedure series have been prepared, reviewed and timing successfully demonstrated for both the main control room actions and the operator manual actions outside the control room. The procedures will be placed on Administrative Hold in TVA's electronic document control library and made effective when WBN transitions from the current single unit fire protection program to the new dual unit fire protection program. Completion of this activity will be confirmed via TVA's Substantially Complete letter to be issued prior to initial fuel load.

Enclosure 3
Fire Protection Commitment Update

Commitment Number	Date of TVA Letter that Made Commitment & NRC Accession Number*	Commitment Description	Status of Commitment (Refer to the Notes at the end of this table)
112444581	July 1, 2011	The feasibility and reliability evaluation will be reviewed and modifications, as needed, incorporated when the combustible loadings are finalized. These actions will be completed prior to Unit 2 fuel load.	The feasibility and reliability evaluations contained in FPR Part VII, Section 8, have been updated to reflect the design output and resultant combustible loading.
112488301	July 22, 2011	Piping and hose stations will be added in the following areas for Unit 2 operation: a. Two sprinkler systems in the Unit 2 Reactor Building. These are pre-action sprinkler systems, normally dry with an air supervision of the piping. b. Two sets of hose stations in the Unit 2 Reactor Building. These hose stations are fed from a sprinkler system type deluge valve thus they will normally be dry also but will not have air supervision. c. Sprinkler system for the protection of the charcoal beds in the Unit 2 Containment Purge Air filter housing. This will be a pre-action sprinkler system but will not have air supervision. [Letter # 2. NRC Question (RAI FPR VII-2.2)]	These modifications are contained in EDCRs 54655 and 53587 and are in the process of being installed. Completion of the implementation will be confirmed via TVA's Substantially Complete letter to be issued prior to initial fuel load.
112550136	August 5, 2011 ML11227A257		
112488384	July 22, 2011	Existing Unit 1 hose stations that presently are not required by the FPR to provide protection to operating equipment will be re-classified to providing protection for operating equipment when Unit 2 goes on line. Letter # 2. NRC Question (RAI FPR VII-2.2)	The scope of this commitment is limited to the following four hose stations (refer to Table 14.6 in Part II of the FPR); 2-26-671, 2-26-672, 2-26-674 and 2-26-675. The hose stations will be confirmed to be Operable as part of the implementation of the Unit 1/Unit 2 FPR for Unit 2 operation.
112549702	August 5, 2011 ML11227A257	The following design changes will be implemented prior to Unit 2 fuel load or startup, as applicable: EDCR 53217; EDCR 53287; EDCR 53288; EDCR 53290; EDCR 53291; EDCR 53292; EDCR 53293; EDCR 53296; EDCR 54103; DCN 52606; EDCR 54795; EDCR 54796; EDCR 54797; EDCR 54798; EDCR 54799; and EDCR 54819 Letter Item # 15, NRC Question RAI FPR III-17	These modifications have been incorporated into the Unit 1/Unit 2 Fire Protection Report.

Enclosure 3
Fire Protection Commitment Update

Commitment Number	Date of TVA Letter that Made Commitment & NRC Accession Number*	Commitment Description	Status of Commitment (Refer to the Notes at the end of this table)
112783894	September 30, 2011 ML13060A225	TVA confirms there will be procedures for each affected room that address each OMA. The OMAs identified in the FPR are to be verified by walkdowns and documented in AOI 30.2 prior to fuel load. The statement that a room does not have dedicated procedures for fire safe shutdown will be deleted for the evaluations. These revised evaluations will be included in the next FPR submittal. Letter item # 16. NRC Question (RAI FPR VII-22)” Item 14 of Enclosure 2 of letter T02 110930 001	The 0-AI-30.2 procedure for each fire area has been prepared and walkdowns conducted to demonstrate that the OMAs meet the feasibility and reliability criteria of NUREG 1852. Certain rooms as documented in the deviation in FPR Part VII, Section 2.9 and accepted by NRC in SSER 26, Section 6.1.10 do not require fire response procedures and thus the statement.
112868246	October 28, 2011 ML11306A090	Performance demonstration walkdowns described in Section 2.2.1 of part V will be performed for alternate shutdown operator manual actions, and the timing of those walkdowns for Unit 2 will consider that the control room operators will need to travel from the Main Control Room to the Auxiliary Control Room or other Auxiliary Control System (ACS) locations, as applicable. These performance demonstration walkdowns will be performed prior to Unit 2 fuel load. Letter Item # 2. [2] (RAI FPR IV-5) Item 2 of Enclosure 2 of letter T02 111028 001	The 0-AI-30.2-C.69 procedure for a fire in the main control room and thus requires alternate shutdown has been prepared and walkdowns conducted to demonstrate that the OMAs meet the feasibility and reliability criteria of NUREG 1852. The procedure includes the travel from the Main Control Room to the Auxiliary Control Room or other Auxiliary Control System (ACS) locations.
113461862	April 26, 2012	TVA will ensure that the as-constructed FPR conforms to the as-constructed configuration of the plant. Based on the current completion schedule for WBN Unit 2, the as-constructed FPR will be submitted to NRC no later than October 15, 2014.	The as constructed version of the FPR was provided in Enclosure 1 of TVA’s letter dated September 18, 2014.
113950905	September 13, 2012	In order to prevent this condition, bypass switches will be added on the 6.9 kv shutdown boards to be used during Appendix R events which will allow a second ERCW pump to be loaded on one of the Train B diesels. Item 1. of Enclosure 7 of letter T02 120913 002	The switches have been included in the as constructed FPR provided in Enclosure 1 of TVA’s letter dated September 18, 2014.

Enclosure 3
Fire Protection Commitment Update

Commitment Number	Date of TVA Letter that Made Commitment & NRC Accession Number*	Commitment Description	Status of Commitment (Refer to the Notes at the end of this table)
113950915	September 13, 2012	Plant modifications will be made to provide spent fuel pool cooling pump kill switches in the main control room. Item 2. of Enclosure 7 of letter T02 120913 002	The switches have been included in the as constructed FPR provided in Enclosure 1 of TVA's letter dated September 18, 2014.
114303784	December 20, 2012	The review of the building information identified that only the use of the name Temporary Storage Office Building (TSOB) in Section 10.1, "Overview of Evaluation Methodology," of Part III, "Safe Shutdown Capabilities," needed to be updated to the current name of Modification Building. For non-technical issues, such as a building name that does not affect the fire safe shutdown (FSSD) analysis, TVA intends to collect these changes and submit them as part of the as-constructed dual unit FPR. Item 1. of Enclosure 7 of letter T02 121220 001	The building nomenclature change was included in FPR Part III submitted via TVA's letter dated September 18, 2014.
114303791	December 20, 2012	The schedule for the implementation of the organizational corrective actions has not been finalized. Since this is a non-technical change, the required updates for Part II will be provided in the as-constructed dual unit FPR. Item 2. of Enclosure 7 of letter T02 121220 001	Based on a meeting with NRC on July 16, 2014, the organizational information has been updated in FPR Part II, Sections 5.0 and 7.0. The revision that incorporated these changes in provided in Enclosure 1 of TVA's letter dated September 18, 2014.
114303801	December 20, 2012	The Deviation statement will be removed from Section 3.60.3 as part of the submittal of the as-constructed FPR. Item 3. of Enclosure 7 of letter T02 121220 001	The required revision has been made and is reflected in the version of FPR Part VI provide in Enclosure 1 of TVA's letter dated September 18, 2014.

Notes:

1. The commitments shaded grey were resolved by the submittal of the as-constructed Unit1/Unit 2 Fire Protection Report (TVA's letter dated September 18, 2014), Revision 3 of the MSO report (Enclosure 4 of TVA's letter dated September 18, 2014) or the required actions have been completed.
2. The status of the other commitments (white background) will be updated in TVA's Substantially Complete letter.

Executive Summary

This report evaluates multiple fire induced spurious failures at Watts Bar Nuclear Plant – Unit 2 as required by Nuclear Regulatory Commission (NRC) Regulatory Guide 1.189, Rev. 2. Based on the results of the Multiple Spurious Operations Expert Panel conducted at the plant for Unit 1, various scenarios were identified and were reviewed for WBN Unit 2. Most of these scenarios were resolved by the existing baseline Fire Safe Shutdown (FSSD) analysis. Resolutions have been incorporated for the previously unresolved scenarios identified in Appendices B and C.

APPENDIX A: MSO EVALUATIONS

APPENDIX B: UNIT 2 RESOLUTIONS

APPENDIX C: UNIT 1/COMMON RESOLUTIONS

1.0 PURPOSE

This report provides the result of the evaluation of Watts Bar (WBN) Unit 2 for issues resulting from the publication of Nuclear Regulatory Commission (NRC) Regulatory Guide 1.189 Rev. 2 (RG 1.189) (Ref. 7.1). Specifically, Section 5.3 of RG 1.189 discusses an allowable approach to address multiple fire induced circuit failures. This report identifies scenarios that may be caused by multiple circuit failures and evaluates each scenario to determine if, in fact, it is a concern. For any concern identified, resolutions are provided to address the concern.

2.0 RESULTS

Appendices B and C summarize the resolutions resulting from the review of Regulatory Guide 1.189 Multiple Spurious Operation (MSO) requirements at WBN-2. Concerns were identified in a few plant areas and for different post-fire scenarios. Where concerns were identified, resolutions were provided to eliminate the concern. Many of the resolutions were identified by the baseline post fire safe shutdown analysis (FSSD). The resulting plant modifications have been completed, but the resolutions are included in this report for completeness.

The review of the MSO scenarios is attached as Appendix A. The scenarios selected for review are the same set of scenarios that were determined to be applicable to WBN unit 1 by the MSO Expert Panel. This list was based on the Pressurized Water Reactor Owner's Group (PWROG) generic list of multiple spurious operations. The Sequoyah (dual unit) MSO list was compared to the WBN Unit 1 list and no additional scenarios were identified due to dual unit operation.

3.0 BACKGROUND

RG 1.189 Revision 2 (Reference 7.1) was issued by the Nuclear Regulatory Commission (NRC) in October 2009. RG 1.189 provides guidance for nuclear power plants that are not transitioning their fire protection licensing basis to a performance-based standard under 10CFR50.48(c) and National Fire Protection Association (NFPA) standard 805.

RG 1.189 formalized the requirements for addressing multiple fire induced circuit failures, or MSOs and multiple concurrent hot shorts. RG 1.189 endorsed portions of NEI 00-01 Rev. 2 (Ref. 7.3) as an acceptable approach to address these issues. NEI 00-01 allows the use of an expert panel to identify plant specific scenarios that might be caused by MSOs.

TVA reviewed MSOs in accordance with RG 1.189 for Watts Bar Unit 1 and its sister plant, Sequoyah Units 1 and 2. Construction of Watts Bar Unit 2 is nearing completion and is proceeding through the licensing process. Most of the multiple spurious operation scenarios were previously addressed in the baseline post fire safe shutdown analysis of WBN-2. Those that were not in the baseline analysis have been incorporated into the as-designed post fire safe shutdown analysis as applicable.

4.0 SCOPE

This report evaluates the MSO scenarios selected for SQN Units 1 and 2 and for WBN Unit 1. The evaluation determines whether the scenario is applicable to WBN Unit 2 and how WBN-2 complies with each scenario.

5.0 METHODOLOGY

Starting from the WBN Unit 1 MSO information, the WBN-2 MSO evaluation used following the general process in the evaluation of each scenario.

1. For each scenario or issue, components were identified whose failure would cause the particular scenario or issue to occur.
2. These components were arranged in a logical relationship.
3. For components already included in the FSSD analysis, the associated cables already identified and located by fire zone/analysis volume. The MSO functional requirement for the component was compared to the FSSD functional requirement to ensure the appropriate cables were included in the evaluation.
4. For newly identified components (not included in the FSSD), or components with new functional requirements associated cables were identified and located by fire zone/analysis volume.
5. Cable and cable location information is maintained in the System Assurance & Fire Protection Engineering (SAFE) database (FSSD analysis).
6. For each Fire Area where MSO components could fail due to cable fire damage, an evaluation was performed to determine the impact of multiple fire induced faults.

6.0 OPERATOR MANUAL ACTIONS

Operator Manual Actions (OMA) identified in the Post Fire Safe Shutdown (FSSD) analysis were identified and credited where applicable to resolve the MSO scenarios. Operator manual actions credited in the Unit 2 MSO evaluations have been evaluated for feasibility and reliability in accordance with the criteria described in the dual unit Fire Protection Report, Part V, Section 2.1.

8.0 RECORD OF REVISIONS

Revision	Description of Change
1	<p>Noted that previously identified plant design changes are included and credited in this report. (see section 2.0 and scenarios 22, 32, 54, 54a, 54b, 54c, & 54d)</p> <p>Noted that operator actions credited for MSO resolutions were the same as OMA's previously approved for Unit 1. (see section 6.0 and scenarios 2, 10, 12, 20, 27, 28, 30, 31, 35a, 54, 54a, 54b, 54c, & 54d)</p> <p>Removed reference to Unit 1 Problem Evaluation Reports that are not applicable to Unit 2. (see scenarios 27 & 28)</p> <p>Appendix B – Added resolutions for scenarios 13a, 22, 32, 54, 54a, 54b, 54c, & 54d</p> <p>Appendix C – Added resolution for scenario 15a.</p>

2	<p>Updated MSO evaluations based on the As-Designed FSSD analysis and unit 1 and unit 2 MSO design changes.</p> <p>Updated and added references.</p> <p>Replaced “backup control” with “Auxiliary Control System” per NRC commitment tracking item 112331509. (affected Appendix A sections: 22.3.1, 23.3.1, 32.3.5, 33.3.1, 54.3.1, 54a.3.1, 54b.3.1, 54c.3.1, 54d.3.1, 54f.3.1, Appendix B)</p> <p>Clarified statements crediting the Auxiliary Control System for control building fires “resulting in MCR abandonment” per NRC commitment tracking item 112384277 which noted that some control building fires would not result in MCR abandonment (affected Appendix A sections 4.3.1, 22.3.1, 23.3.1, 32.3.5, 33.3.1, 35.3.1, 38.3.3, 48.3.1, and Appendix B).</p> <p>Added references 7.5 thru 7.8 as support information for scenario 21.</p> <p>Updated MSO scenarios descriptions as needed based on NEI-00-01 Revision 3, Table G-2 (Ref. 7.10) while maintaining original scenario numbering to match WBN Unit 1 MSO evaluation. Added scenario 48a (49.1) and expanded scenarios 50 and 51 to include Table G-2 scenarios 52 and 53.</p> <p>Replaced reference to White Paper on Westinghouse Reactor Coolant Pump Seal Behavior for Fire Scenarios with Revision 2 (Westinghouse Letter LTR-RAM-I-10-053) See Reference 7.11.</p> <p>Removed comparison of Unit 2 and Unit 1 compliance strategies</p> <p>Other changes to specific Appendix A Sections:</p> <ul style="list-style-type: none"> • 1.3.2, 4.3.1, 5.3.1, 9.3.1, 10.3.1, 39.3.2 -- Identified AV where TBC is credited. • 2.3.1, 20.3.2 – Credited MCR closure of 2-FCV-62-89 rather than local manual valve. • 2.3.2, 20.3.3, 37.3.1 – Credited closure of 2-FCV-63-39-A and 2-FCV-63-40-B from MCC rather than local manual valve operations. • 5.3.2, 6.3.1, 7.3.1, 13.3.1 – Credit reactor building non-essential control air header isolation and venting to fail valves open/closed. • 8.3.1, 9.3.1, 12.3.1, 13.3.2, 14.3.1, 14.3.2, 19.3.1, 22.3.1, 24.3.1, 29.3.2, 32.3.2; 32.3.5, 37.3.1, 39.3.2, 48.3.1 – Expanded compliance evaluation for clarity. • 13a.3.1 – Revised CCP run out evaluation. • 27.3.1, 27.3.2, 28.3.3, 28.3.3, 29.3.4, 30.3.2 – Credited backup motive air supply (nitrogen) for MCR operation of SG level and AFWP pressure control rather than local valve operation (both units). • 42.3.3, 47.3.1 – Changed EDG cooling water valves from normally open

	<p>with power removed to normally closed, automatic opening on EDG start.</p> <ul style="list-style-type: none">• 46.3.1 – Credited revised EDG loading calculation methodology.• 48.3.1 – Expanded evaluation of potential paralleling EDG with offsite sources through spurious breaker operation.• 53.3.2 – Updated to include results of MOV stall analysis. <p>Updated Appendices B and C resolutions to reflect those that have been incorporated or are no longer needed.</p>
3	<p>Updated report to reflect the as-constructed FSSD analysis and plant configuration. Sections 2.0, 6.0, 10.3.1, 32.3.1</p> <p>Revised reference 7.4 from calculation EDQ00099920090012 to WBN-OSG4-031 which will be the Safe Shutdown Analysis after unit 2 startup.</p> <p>Added new reference 7.9, Dual Unit Fire Protection Report, Part VI.</p> <p>Replaced specific OMA allowable time with reference to the dual unit FPR, Part VI (ref. 7.9) to minimize possible errors due to future changes; affects Sections 2.3.1, 2.3.2, 20.3.2, 20.3.3, and 37.3.1.</p> <p>Corrected condensate storage tank availability time (section 31.3.1).</p> <p>Updated Appendices B and C.</p>

Appendix A

UNIT 2 MSO EVALUATION

1.0 PWROG Scenario 1: Primary Inventory Control - Loss of all reactor coolant pump (RCP) seal cooling due to spurious closure of RCP seal injection header valve(s) concurrent with spurious isolation of component cooling water (CCW) to the thermal barrier heat exchanger.

1.1. Description: Spurious isolation of reactor coolant pumps seal injection header flow AND spurious isolation of component cooling water (CCW) to the thermal barrier heat exchanger

1.2. Notes:

- Scenario causes loss of all RCP seal cooling and subsequent increase in RCP seal leakage, challenging the reactor coolant system (RCS) Inventory Control Function.
- Westinghouse Tech Bulletin 04-22 Rev. 1 provides a summary of the issue. Tech Bulletin references provide additional detail. B&W plants with Westinghouse designed seals may have similar concerns.
- Seal injection flow isolation can occur at main header or at supply to each individual pump. In addition, scenarios that cause loss of all charging (i.e., multiple pump failure due to loss of suction, non-spurious pump failures such as loss of power, etc.) can also cause loss of seal injection.
- Loss of all seal cooling to any individual RCP is a problem (i.e., does not have to occur on all RCPs to be a problem)
- Westinghouse plants refer to Letter LTR-RAM-I-10-053 Revision 2 of White Paper on Westinghouse Reactor Coolant Pump Seal Behavior for Fire Scenarios
- * CE plants generally do not have seal injection and can lose seal cooling for an extended period of time without increased seal leakage. These plants can lose all seal cooling due to spurious isolation of CCW.
- Refer to WCAP-16175.

1.3. WBN Unit 2 Safe Shutdown Compliance:

- 1.3.1. Seal Injection Header Isolation can only be accomplished by closing flow control valve (FCV) 2-FCV-062-093. 2-FCV-062-093 is an air operated valve which is normally open and fails full open on loss of control air or electrical power. The valve has a pneumatic stop to ensure valve will allow a minimum seal injection flow. For analysis volume AV-104 (fire on the valve) or AV-005 (fire on panel 2-L-112 where pneumatic stop is located) fire

damage could possibly cause 2-FCV-62-93 closure. For these AVs thermal barrier cooling (TBC) is available and provides RCP seal cooling. Both centrifugal charging pumps (CCPs) are stopped while manual valves are aligned to bypass 2-FCV-62-93 and CCP suction is aligned to the RWST. One of the CCPs is restarted within 75 minutes to resume RCP seal injection.

- 1.3.2. Loss of suction to the centrifugal charging pump (CCP) has been reviewed and determined that one CCP will always survive considering multiple spurious closure of either volume control tank (VCT) suction valve, loss of refueling water storage tank (RWST) suction valves, loss of or multiple spurious start of CCPs, spurious safety injection (SI), and loss of CCP heating ventilation and cooling (HVAC). For analysis volume (AV)-106, fire on the RWST suction valves, TBC is credited for 75 minutes for RCP seal cooling. During this time both charging pumps are stopped from MCR within 23 minutes, a RWST suction valve is manually opened within 75 minutes, and a charging pump is started after RWST suction valve is opened to resume normal seal injection.

2.0 PWROG Scenario 2: Primary Inventory Control - Loss of all reactor coolant pump (RCP) seal cooling due to charging flow diversion concurrent with spurious isolation of component cooling water (CCW) to the thermal barrier heat exchanger.

2.1. Description:

Spurious opening of charging injection valve(s) causing diversion flow away from seals

AND

Spurious isolation of component cooling water (CCW) to the thermal barrier heat exchanger

2.2. Notes:

- Flow diversion away from seal injection could be caused by spurious opening of charging injection valves. Note, spurious opening of #1 seal bypass valve is judged to not fail seal injection function due to orifice restricting bypass flow to ~1gpm (Reference Letter #OG-09-156)
- Scenario causes loss of all RCP seal cooling and subsequent increase in RCP seal leakage, challenging the RCS Inventory Control Function.
- Westinghouse Tech Bulletin 04-22 Rev. 1 provides a summary of the issue. Tech Bulletin references provide additional detail. B&W plants with Westinghouse designed seals may have similar concerns.

- Seal injection flow isolation can occur at main header or at supply to each individual pump. In addition, scenarios that cause loss of all charging (i.e., multiple pump failure due to loss of suction, non-spurious pump failures such as loss of power, etc.) can also cause loss of seal injection.
- Loss of all seal cooling to any individual RCP is a problem (i.e., does not have to occur on all RCPs to be a problem)
- Westinghouse plants refer to Letter LTR-RAM-I-10-053 Revision 2 of White Paper on Westinghouse Reactor Coolant Pump Seal Behavior for Fire Scenarios.
- * CE plants generally do not have seal injection and can lose seal cooling for an extended period of time without increased seal leakage. These plants can lose all seal cooling due to spurious isolation of CCW.
- Refer to WCAP-16175.

2.3. WBN Unit 2 Safe Shutdown Compliance:

- 2.3.1. Cable separation ensures closure of at least one of the Injection Header Isolation valves (2-FCV-62-90-A or 2-FCV-62-91-B) except for a fire where the valves are located (AV-099). For AV-099, the Charging Flow Control valve (2-FCV-62-89) in series with the injection header isolation valves but located in a different fire zone will be closed from the main control room within the allowable time shown in the Dual Unit Fire Protection Report, Part VI (ref.7.9).
- 2.3.2. The only fires that could cause the boron injection tank (BIT) outlet isolation valves 2-FCV-63-25-A or 2-FCV-63-26-B to spuriously open is a fire in their respective Reactor Motor Operated Valve (RMOV) board rooms (AV-072, -073, -074). The BIT path will be isolated by closing the BIT inlet isolation valves 2-FCV-63-39-A and 2-FCV-63-40-B from their respective Control & Auxiliary Building Vent Boards located in AV-054 and AV-057. The time requirement for these actions is shown in the Dual Unit FPR Part VI (ref. 7.9).

3.0 **PWROG Scenario 3: Primary Inventory Control - Spurious re-initiation of reactor coolant pump seal injection / thermal barrier cooling results in failure of the RCP seals due to thermal shock.**

3.1. Description:

Loss of all seal cooling to reactor coolant pump(s) (see PWR Owners Group scenarios #1 and #2)

AND

(Spurious re-initiation of seal injection OR spurious re-initiation of component cooling water (CCW) to the thermal barrier heat exchanger)

3.2. Notes:

- Scenario is assumed to cause RCP seal failure and a subsequent RCP seal loss of cooling accident (LOCA), challenging the RCS Inventory Control Function.
- Westinghouse Tech Bulletin 04-22 Rev. 1 (Reference 11) provides summary of issue. Tech Bulletin references provide additional detail.
- Westinghouse plants please refer to Letter LTR-RAM-I-10-053 Revision 2 of White Paper on Westinghouse Reactor Coolant Pump Seal Behavior for Fire Scenarios.
- * CE plants generally do not have seal injection and can lose seal cooling for an extended period of time without increased seal leakage. These plants can lose all seal cooling due to spurious isolation of CCW. Refer to WCAP-16175.

3.3. WBN Unit 2 Safe Shutdown Compliance:

3.3.1. Based on Scenario 1 & 2 discussions, there will not be a sustained loss of seal injection, so this scenario is not applicable.

4.0 PWROG Scenario 4: Primary Inventory Control - Catastrophic RCP Seal Failure

4.1. Description:

Loss of all seal cooling to reactor coolant pump(s) (see PWR Owners Group scenarios #1 and #2)

AND

Fire prevents tripping the reactor coolant pumps OR spurious start of a reactor coolant pump(s)

4.2. Notes:

- Scenario causes catastrophic RCP seal failure and subsequent RCP seal LOCA, challenging the RCS Inventory Control Function.
- Westinghouse Tech Bulletin 04-22, Rev. 1 provides summary of issue. Tech Bulletin references provide additional detail. Additionally refer to Letter LTR-

RAM-I-10-053, Revision 2 of White Paper on Westinghouse Reactor Coolant Pump Seal Behavior for Fire Scenarios.

- Refer to WCAP-16175 for RCP seal behavior on loss of seal cooling at CE plants.

4.3. WBN Unit 2 Safe Shutdown Compliance:

- 4.3.1. As discussed in Scenarios 1 & 2, RCP seal flow is always credited except for AV-005, -104, -106 where TBC is credited for 75 minutes until RCP seal cooling can be reestablished. The cables associated with the RCPs which can cause a spurious start of the pump or prevent the pump from being tripped are entirely contained inside the Control or Turbine Building. For all AVs except Control Building the RCPs are tripped from the main control room (MCR) panels. For a Control Building fires resulting in MCR abandonment, the RCPs and the normal and alternate supply breakers feeding the 6.9kv RCP board would be tripped prior to evacuating the control room. Additionally local action at the 6.9kv RCPs board ensures that the RCP breakers remain tripped.

5.0 **PWROG Scenario 5: Primary Inventory Control - Loss of all reactor coolant pump (RCP) seal cooling concurrent with spurious operation of the number 1 seal leakoff valve results in failure of RCP seal number 2**

5.1. Description:

Loss of all seal cooling to any RCP(s). See Scenarios 1 & 2.

AND

Spurious isolation of No.1 seal leakoff valve(s).

5.2. Notes:

- Isolation of the No. 1 seal leakoff line during a loss of all seal cooling event would force the No. 2 RCP seal into a high pressure mode of operation at high temperature, which is beyond the design bases of the No. 2 seal. This could cause failure of the No. 2 seal and increase RCP seal leakage.
- Westinghouse Tech Bulletin 04-22, Rev. 1 provides summary of issue. Tech Bulletin references provide additional detail.
- Also reference Letter WOG-05-163 DW-04-004 "Isolation RCP#1 Seal Leakoff" and Letter LTR-RAM-I-10-053 Revision 2 of White Paper on Westinghouse Reactor Coolant Pump Seal Behavior for Fire Scenarios.
- This scenario would apply to B&W plants with Westinghouse designed RCP seals.

5.3. WBN Unit 2 Safe Shutdown Compliance:

- 5.3.1. As discussed in Scenarios 1 & 2, RCP seal flow is always credited except for AV-005, -104, and -106 where TBC is credited for 75 minutes until RCP seal cooling can be reestablished.
- 5.3.2. The No. 1 seal leakoff valves (2-FCV-62-9, -22, -35, and -48) are normally open and fail open on loss of air or electric power. For areas where valve circuits could be fire damaged the valves can be maintained open by main control room operator actions to close the Reactor Building non-essential control air header isolation valve (2-FCV-32-111-B) and open valve (2-XSV-32-112A1, A2, B1, B2) to vent the downstream header. This will depressurize the control air header and ensure the No. 1 seal leakoff valves fail open. For AV-057 a postulated fire could cause the seal leakoff valves for RCPs 2 and 4 to fail closed and also prevent isolation of the non-essential control air header.
- 5.3.3. Resolution: Relocate the cables for 2-FCV-62-22 and 2-FCV-62-48 out of AV-057.
- 5.3.4. WBN Unit 1 identified this condition in PER 227833.

6.0 PWROG Scenario 6: Primary Inventory Control - Failure to isolate / spurious opening of normal letdown active isolation valves

6.1. Description:

Spurious opening of (or failure to close) letdown isolation valve(s)

AND

Spurious opening of (or failure to close) letdown orifice valve(s)

6.2. Notes:

- Scenario causes loss of RCS inventory, challenging the RCS Inventory Control Function.
- In a typical Post-Fire Safe Shutdown (PFSS) Analysis, the Chemical and Volume Control System (CVCS) downstream of the letdown isolation valve(s) and upstream of the Volume Control Tank (VCT) isolation valve(s) is not evaluated, and the RCS inventory (letdown) is conservatively assumed lost and unavailable for makeup. In reality, additional failures downstream of the letdown isolation valves would have to occur for this RCS inventory to be unavailable for makeup.

- Also note that the letdown isolation valves and letdown orifice valves are often interlocked such that the isolation valves will not open without the orifice valves being open. Letdown failure to isolate can be a single spurious operation with interlocked valves.
- Note B&W plants do not have letdown orifice valves. Scenario applicable to B&W is spurious operation of multiple letdown isolation valves.

6.3. WBN Unit 2 Safe Shutdown Compliance:

- 6.3.1. Normal Letdown is isolated by closure of series valves 2-FCV-62-69-A or 2-FCV-62-70-A from the control room. For areas where valve circuit fire damage could prevent closure of one of the valves (AV-036, -037, -037C, -038, -042(D,E,F,G), -045, -048, -056, -058, -067, -74, -115, and -117) letdown isolation is achieved by main control room actions to isolate and vent the reactor building non-essential control air header (2-FCV-32-111-B and 2-XSV-32-112A1, A2, B1, B2) causing 2-FCV-62-69-A and 2-FCV-62-70-A to fail closed.

7.0 PWROG Scenario 7: Primary Inventory Control - Normal letdown fails to isolate and inventory is lost to the pressurizer relief tank (PRT)

7.1. Description:

Letdown fails to isolate (see scenario #6)

AND

Spurious closure of downstream containment isolation valve.

7.2. Notes:

- Scenario causes letdown flow to Pressurizer Relief Tank (PRT) through relief valve. This letdown flow is assumed unavailable for RCS makeup.

7.3. WBN Unit 2 Safe Shutdown Compliance:

- 7.3.1. Normal Letdown is isolated by closure of series valves 2-FCV-62-69-A or 2-FCV-62-70-A from the control room. To ensure valve closure for areas where valve circuits could be fire damaged (AV-036, -037, -037C, -038, -042(D,E,F,G), -045, -048, -056, -058, -067, -074, -115, and -117) main control room operator actions will isolate and vent the reactor building non-essential control air header (2-FCV-32-111-B and 2-XSV-32-112A1, B1, A2, B2) causing 2-FCV-62-69-A and 2-FCV-62-70-A to fail closed due to loss of control air.

8.0 PWROG Scenario 8 Primary Inventory Control - Excess letdown fails to isolate

8.1. Description:

Spurious opening of (or failure to close) of multiple in-series excess letdown isolation valves

8.2. Notes:

- Scenario causes loss of RCS inventory to the CVCS system, challenging the RCS Inventory Control Function. The RCS inventory (letdown) is conservatively assumed lost and unavailable for makeup. In reality, additional failures downstream of the excess letdown isolation valves would have to occur for this RCS inventory to be unavailable for makeup.
- This scenario often requires three spurious operations.

8.3. WBN Unit 2 Safe Shutdown Compliance:

8.3.1. The excess letdown isolation valves 2-FCV-62-55 and 2-FCV-62-56 are normally closed and fail closed on loss of air. Valve 2-FCV-62-55 is a solenoid controlled, air operated valve and fails closed on loss of power. Hand indicating controller 2-HIC-62-56A opens/closes valve 2-FCV-62-56 from the MCR. Other than in the Control Building cables for 2-FCV-62-56 are routed in dedicated conduit with no energized circuits to prevent spurious opening due to hot shorts. Auxiliary Control System transfer switches isolate the Control building portion of the letdown isolation valves' circuits when the MCR is abandoned.

9.0 PWROG Scenario 9: Primary Inventory Control - Spurious valve operation results in loss of all high head RCS makeup flow paths

9.1. Description:

Spurious isolation of reactor coolant pump (RCP) seal injection flow path AND / OR
Spurious isolation of normal charging flow path AND / OR Spurious isolation of
charging injection flow path

9.2. Notes:

- Scenario isolates all high head RCS makeup flow paths, challenging the RCS Inventory Control Function.
- Each flow path contains a number of series and/or parallel valves. P&ID review is required to identify each relevant combination of valves.

- Note that isolation of all RCS makeup may also involve non-spurious failures. For example, the charging injection valves are normally closed, and a fire-induced loss of valve power (not a spurious operation) would cause these valves to fail closed. On the other hand, these valves could spuriously close after they have been opened.
- *Note CE plants generally do not have seal injection.

9.3. WBN Unit 2 Safe Shutdown Compliance:

9.3.1. Seal Injection Header Isolation can only be accomplished by closing FCV-062-093. FCV-062-093 is an air operated valve which is normally open and fails full open on loss of control air or electrical power. The valve has a pneumatic stop to ensure valve will always allow a minimum seal injection flow. For a fire on valve 2-FCV-62-93 (AV-104), or for a fire on panel 2-L-112 that contains the pneumatic stop for valve 2-FCV-62-93 (AV-005); TBC is available and provides RCP seal cooling for 75 minutes while an alternate injection path is established by manipulating manual valves that are not located in either AV-005 or AV-104. During this time both charging pumps are stopped from the MCR and one is re-started from the MCR within 75 minutes.

9.3.2. No credit is taken for charging through the BIT flow path or normal charging flow path in the FSSD analysis.

10.0 PWROG Scenario 10: Primary Inventory Control - Spurious isolation of Makeup Tank (MUT) / Volume Control Tank (VCT) outlet valve(s) concurrent with spurious isolation of suction valves to the refueling water storage tank (RWST) results in damage to charging pump(s) when they are in normal operation (aligned to the MUT / VCT)

10.1. Description:

Initial condition is charging pump running with suction from VCT.

Spurious isolation of suction from the MUT / VCT to running charging pump(s) when the charging pump(s) is aligned to the VCT

AND

Spurious isolation of (or failure to open) suction from the RWST to the running charging pump(s)

10.2. Notes:

- Scenario causes charging pump failure, challenging the RCS Inventory Control Function. This is especially challenging if the credited charging pump is running at the time of the fire.
- Can be a single spurious scenario if the RWST valves are normally closed motor operated valves (MOVs) and they are not interlocked with the VCT outlet valves.
- Note that valve interlocks may prevent scenario if they prevent VCT and RWST outlets from both being in closed position simultaneously.

10.3. WBN Unit 2 Safe Shutdown Compliance:

10.3.1. Spurious closure of either VCT isolation valve will automatically open the both RWST suction valves. This automatic interlock has been evaluated in the FSSD analysis and is operable except for AV-106.

10.3.2. For AV-106, where the RWST suction valves are located, TBC is available and provides RCP seal cooling for 75 minutes. During this time both charging pumps are stopped from MCR, a RWST suction valve is manually opened within 75 minutes, and a charging pump is re-started to resume normal seal injection. This OMA was previously approved for Unit 1.

10.3.3. This SCENARIO is only addressing spurious valve closure resulting in CCP suction isolation. Gas ingestion into CCP's is addressed in section 12.3.

11.0 PWROG Scenario 11: Primary Inventory Control - Spurious isolation of two parallel refueling water storage tank (RWST) suction valves results in failure of running charging pump(s) when the charging pump(s) is aligned to the RWST

11.1. Description:

Initial condition is charging pump running and drawing suction from the RWST. Spurious isolation of two parallel RWST outlet valves.

11.2. Notes:

- Scenario causes loss of charging pump suction, causing subsequent pump cavitation and failure. This challenges the RCS Inventory Control Function.

11.3. WBN Unit 2 Safe Shutdown Compliance:

11.3.1. See Scenario 10 for discussion.

- 11.3.2. For AV-106, fire on the RWST suction valves, both CCPs are available. A fire on the RWST valves (open per scenario initial condition) would not cause spurious closure.

12.0 PWROG Scenario 12: Primary Inventory Control - Spurious opening (or failure to close) of multiple series VCT outlet valves

12.1. Description:

Spurious opening (or failure to close) of multiple in-series volume control tank (VCT) outlet valves

12.2. Notes:

- Scenario causes VCT drain down and hydrogen cover gas entrainment into charging pump suction, ultimately causing charging pump failure and challenging the RCS Inventory Control Function. This is especially challenging if the credited charging pump is running at the time of the fire. Note this scenario assumes that VCT makeup has been isolated (i.e., letdown isolated).
- Note that spurious starting of idle charging pump(s) may cause failure of additional pumps. Spurious pump starting can occur for several reasons, including fire damage to control circuitry or an inadvertent ESFAS signal.
- Potential resolution is comparison of charging pump suction header pressure provided by the RWST versus the VCT. Specifically, the RWST may provide sufficient pressure such that the check valve to the VCT remains seated and hydrogen is not entrained into the pump suction.

12.3. WBN Unit 2 Safe Shutdown Compliance:

- 12.3.1. For AV-111, fire on the VCT isolation valves (2-FCV-62-132-A, -133-B), or for AV-110, fire on the VCT vent valves (2-FCV-62-1228-A and 2-FCV-62-1229-B), one each of the VCT isolation and vent valves must be closed within 70 minutes. The closure of the VCT vent valves is to ensure the line going to the charging suction is water solid. One RWST suction valve is available to be opened from the main control room to provide suction to the CCP.
- 12.3.2. Manual closure of one of the VCT isolation valves is credited for some analysis volumes due to potential cable damage, but AV-111 is the most time limiting. This OMA was previously approved for Unit 1.

13.0 PWROG Scenario 13: Primary Inventory Control - Failure to isolate / spurious opening of normal letdown active isolation valves concurrent with spurious isolation of component cooling water (CCW) to the letdown heat exchanger results in failure of charging pump(s)

13.1. Description:

Letdown fails to isolate (see PWR Owners Group scenario #6)

AND

Spurious isolation of component cooling water (CCW) to the letdown heat exchanger

13.2. Notes:

- Scenario causes elevated charging pump suction temperature and subsequent pump failure. Charging pump failure challenges the RCS Inventory Control Function. This is especially challenging if the credited charging pump is running at the time of the fire.
- Starting of additional charging pumps can cause failure of additional pumps. Spurious pump starting can occur for several reasons, including fire damage to control circuitry or an inadvertent ESFAS signal

13.3. WBN Unit 2 Safe Shutdown Compliance:

13.3.1. Normal Letdown is isolated by closure of series valves 2-FCV-62-69-A or 2-FCV-62-70-A from the control room. To ensure valve closure for areas where valve circuits could be fire damaged (AV-036, -037, -037C, -038, -042(D,E,F,G), -045, -048, -056, -058, -067, -74, -115, and -117) main control room operator actions will isolate and vent the reactor building non-essential control air header (2-FCV-32-111-B and 2-XSV-32-112A1, A2, B1, B2) causing 2-FCV-62-69-A and 2-FCV-62-70-A to fail closed due to loss of control air.

13.3.2. In addition, 2-TCV-70-192 (CCS discharge from the non-regenerative letdown heat exchanger) is included in the FSSD analysis to ensure CCS flow to the letdown heat exchanger and prevent CCS suction heatup. For AV-038 either 2-TCV-70-192 is available to provide cooling to the heat exchanger or valves 2-FCV-62-69-A or 2-FCV-62-70-A can be closed promptly from the MCR to isolate letdown flow and avoid CCP suction heatup.

13a.0 PWROG Scenario 13a: Charging Pump Runout

Note: PWROG Rev. 1 (6/5/09) Scenario No. 14 and 52 (partial)

13a.1 Description:

Scenario causes charging pump runout and failure. Pump(s) must be running when RCS is at a depressurized condition. Unintentional RCS depressurization could occur due to spurious opening of pressurizer power operated relief valves (PORVs), for example. Charging pump(s) can spuriously start if they are not already running. Scenario may also require failure of other components (e.g., charging flow control valve, etc.).

13a.2 Notes:

- Scenario causes charging pump runout and failure. Pump(s) must be running when RCS is at a depressurized condition. Unintentional RCS depressurization could occur due to spurious opening of pressurizer PORV(s), for example. Charging pump(s) can spuriously start if they are not already running. Scenario may also require failure of other components (e.g., charging flow control valve, etc.).

13a.3 WBN Unit 2 Safe Shutdown Compliance:

13a.3.1 This scenario would cause CCP run out when the RCS is depressurized concurrent with fire induced failure of charging path flow control valves. For WBN Unit 2 CCP run out cannot occur because the FSSD analysis shows that the RCS will remain pressurized for a fire in any analysis volume. The normal charging path can be isolated by MCR operator actions. In AV-117 (Annulus), a MCR operator action will close the pressurizer PORV block valve to prevent the pressurizer from flashing and depressurizing the RCS.

14.0 PWROG Scenario 14: Primary Inventory Control - Spurious opening of Containment sump motor operated isolation valves (including residual heat removal (RHR) and containment spray (CS) suction valves) results in gravity draining of refueling water (borated water) storage tank (RWST / BWST) inventory to the Containment sump

Note: PWROG Rev. 1 (6/5/09) Scenario No. 15

14.1. Description: Spurious opening of multiple in-series containment sump valves

14.2. Notes:

- Scenario causes a pumped RWST draindown via the containment spray ring. The RWST inventory ultimately settles to the containment sump. Since typical PFSS analyses do not credit alignment of the containment sump, the RWST inventory is assumed unavailable for RCS makeup, challenging the RCS Inventory Control Function.
- Note that either the RHR pumps or the containment spray pumps could cause this RWST pumped diversion to the spray ring.
- Note that the spurious pump starting can occur for several reasons, including fire damage to control circuitry or inadvertent ESFAS signal.

14.3. WBN Unit 2 Safe Shutdown Compliance:

14.3.1. CS/RHR containment sump valves have been evaluated with the in-series CS/RHR Pump Suction valves to ensure RWST drain down does not occur. The CS/RHR containment sump valves 2-FCV-72-44-A, -45-B and 2-FCV-63-72-A, -73-B are normally closed. Their control circuits have been modified such that fire initiated spurious opening is only a concern in the AV where the MCC is located. The CS/RHR containment sump valves and the CS/RHR pump suction valves are powered from different MCCs to ensure availability of at least one valve. For AV-072 and AV-073, 2-FCV-63-73-B and 2-FCV-72-45-B could spuriously open, but 2-FCV-74-21-B and 2-FCV-72-21-B closure isolate the sump via MCR operator action. For AV-074, 2-FCV-63-72-A and 2-FCV-72-44-A could spuriously open, but 2-FCV-74-3-A and 2-FCV-72-22-A are available to isolate the sump via MCR operator action.

15.0 PWROG Scenario 15: Primary Inventory Control - Spurious start of containment spray pump(s) concurrent with spurious opening of associated pump discharge valve results in transferring refueling water (borated water) storage tank (RWST / BWST) inventory to the Containment sump

Note: PWROG Rev. 1 (6/5/09) Scenario No. 16

15.1. Description:

Spurious starting of containment spray pump(s)

AND

Spurious opening of the associate pump discharge valve(s) AND / OR containment spray header valve(s)

15.2. Notes:

- Scenario causes a pumped RWST draindown via the containment spray ring. The RWST inventory ultimately settles to the containment sump. Since typical PFSS analyses do not credit alignment of the containment sump, the RWST inventory is assumed unavailable for RCS makeup, challenging the RCS Inventory Control Function.
- Note that either the RHR pumps or the containment spray pumps could cause this RWST pumped diversion to the spray ring.
- Note that the spurious pump starting can occur for several reasons, including fire damage to control circuitry or inadvertent ESFAS signal.

15.3. WBN Unit 2 Safe Shutdown Compliance:

15.3.1. For all AVs except AV-042 and AV-057, either the containment spray pump trip circuits are available and the pumps can be tripped from the control room or the containment spray header isolation valves are closed which will prevent RWST drain-down via containment spray ring. For a fire inside the applicable pumps board room A (AV-042) and B (AV-057), the board supplies are tripped at their upstream boards feeder breakers (normal, auxiliary, maintenance) within 10 minutes and the emergency diesel generator (EDG) for that board is shutdown. The diesel kill switches on both 0-M-26 and 0-L-4 were cabled thru and selected from the associated board rooms and as such could not assure functionality. Modification DCN 58383 added a switch to L-11A and/or L-11B that will select between main control room and auxiliary control room and the circuit is powered from a 125V Vital Battery Board feed whose cable is not be routed in the board room. Associated cables to the MCR and DG building have been routed outside the board room. This modification has been done for each of the four EDGs.

15.3.2. WBN Unit 1 identified this condition in PER 227839.

15a.0 SCENARIO 15a : Primary Inventory Control - Spurious start of residual heat removal (RHR / shutdown cooling (SDC) / low pressure safety injection (LPSI) pump(s) concurrent with spurious opening of containment spray header valve(s) results in transferring refueling water (borated water) storage tank (RWST / BWST) inventory to the Containment sump. Note: PWOG Rev.1 (6/5/09) Scenario No. 16.

15a.1 Description:

Spurious starting of residual heat removal (RHR / shutdown cooling (SDC) / low pressure safety injection (LPSI) pump(s)

AND

Spurious opening of the associate pump discharge valve(s)

AND / OR

Containment spray header valve(s)

15a.2 Notes:

- Scenario causes a pumped RWST draindown via the containment spray ring. The RWST inventory ultimately settles to the containment sump. Since typical PFSS analyses do not credit alignment of the containment sump, the RWST inventory is assumed unavailable for RCS makeup, challenging the RCS Inventory Control Function.
- Note that either the RHR pumps or the containment spray pumps could cause this RWST pumped diversion to the spray ring.
- Note that the spurious pump starting can occur for several reasons, including fire damage to control circuitry or inadvertent ESFAS signal.

15a.3 WBN Unit 2 Safe Shutdown Compliance:

15a.3.1 For all AVs except AV-042 and AV-057, either the RHR pumps are available and can be tripped from the MCR or the containment spray header isolation valves are closed which will prevent RWST drain down via the containment spray ring. For a fire inside pump board room A (AV-042) or B (AV-057), the board's supplies are tripped at their upstream board's feeder breakers (normal, auxiliary, maintenance) within 10 minutes and the emergency diesel generator is shutdown. The diesel kill switches on both 0-M-26 and 0-L-4 were cabled thru and selected from the associated board rooms and as such could not assure functionality. Modification DCN 58383 added a switch to L-11A and/or L-11B that selects between main control room and auxiliary control room. The circuit is powered from a 125V Vital Battery Board feed whose cable is not routed in the board room. Associated cables to the MCR and DG building are routed outside the board room. This modification has been done for each of the four EDGs.

16.0 PWROG Scenario 16: Primary Inventory Control - Spurious opening of shutdown cooling suction line isolation valves (interfacing systems LOCA)

Note: PWROG Rev. 1 (6/5/09) Scenario No. 17.

16.1. Description:

Spurious opening of multiple in-series RHR suction valves from the RCS

16.2. Notes:

- Scenario causes interfacing system LOCA, challenging the RCS Inventory Control Function.
- The valve operators are typically maintained de-energized during normal plant operation. If so, spurious operation of each valve would generally require three proper phase hot shorts.
- Note B&W plants have three series valves.
- From a Fire PRA perspective, this interfacing system LOCA scenario generally screens out if at least two series valves are normally de-energized.
- From a PFSS analysis perspective, this is classified as a high/low pressure interface and maintaining the valves de-energized generally complies with fire protection regulatory requirements.

16.3. WBN Unit 2 Safe Shutdown Compliance:

16.3.1. RHR suction valves (interface with RCS) 2-FCV-74-1-A and 2-FCV-74-9-B are in-parallel and in-series with valves 2-FCV-74-8-A and 2-FCV-74-2-B. These valves are administratively locked in the closed position with the power removed during normal operation. The power will not be restored until the valves are required for RHR. The power cable for valves 2-FCV-74-1-A and 2-FCV-74-9-B are routed in separate dedicated conduit with no other cables such that spurious operation due to hot shorts is not possible.

17.0 PWROG Scenario 17: Primary Inventory Control - Spurious operation of pressurizer PORV(s) / PORV block valve(s) given that the associated PORV block valve is open

Note: PWROG Rev. 1 (6/5/09) Scenario No. 18

17.1. Description:

Spurious opening of multiple (two or three) pressurizer PORVs with corresponding block valves in their normal, open position

17.2. Notes:

- Scenario causes loss of RCS inventory through the pressurizer PORVs, challenging the RCS Inventory Control Function. Scenario also causes pressurizer depressurization, challenging the RCS Pressure Control Function.
- Note some CE plants do not have any PORVs. Scenario would not be applicable to these plants.
- Note B&W plants only have one PORV. Scenario would not be applicable to these plants.

17.3. WBN Unit 2 Safe Shutdown Compliance:

17.3.1. PORVs 2-PCV-68-334-B and 2-PCV-68-340A-A are in series with Block valves 2-FCV-68-332-B and 2-FCV-68-333-A respectively. Cables for PORVs 2-PCV-68-334-B and 2-PCV-68-340A-A are routed in dedicated conduit, thus spurious operation is not possible. The PORVs and their associated Block valves are routed through primary containment penetrations which are separated such that a fire on one penetration will not spuriously open the PORV and prevent closure of the associated Block valve. In AV-117 (Unit 2 annulus), a MCR operator action can close the PORV Block valve to prevent pressurizer from flashing and depressurizing the RCS.

18.0 PWROG Scenario 18: Primary Inventory Control - Spurious operation of pressurizer PORV(s) / PORV block valve(s) given that the associated PORV block valve is closed.

Note: PWROG Rev. 1 (6/5/09) Scenario No. 19

18.1. Description:

Spurious opening of pressurizer PORV(s)

AND

Spurious opening of pressurizer PORV block valve(s) after the block valve(s) has been closed

18.2. Notes:

- Scenario causes loss of RCS inventory through the pressurizer PORV(s), challenging the RCS Inventory Control Function. Scenario also causes pressurizer depressurization, challenging the RCS Pressure Control Function.
- In this scenario, operators may have closed the block valve either to 1) mitigate a fire-induced PORV LOCA or as a 2) pre-emptive action to prevent PORV LOCA from occurring. The first spurious operation is the PORV and the second is the block valve that has been closed.
- Note that the initial PORV LOCA, caused by spurious operation of PORV alone, is a single spurious since block valve is normally open.

18.3. WBN Unit 2 Safe Shutdown Compliance:

18.3.1. See Scenario 17.3.1 discussion.

19.0 PWROG Scenario 19: Primary Inventory Control - Spurious operation of reactor vessel head vent valves

Note: PWROG Rev. 1 (6/5/09) Scenario No. 20

19.1. Description:

Spurious opening of multiple reactor head vent valves

Note: PWROG Rev. 1 (6/5/09) Scenario No. 20

19.2. Notes:

- Scenario causes loss of RCS inventory through open reactor head vent flowpath(s), challenging the RCS Inventory Control Function.
- Spurious operation of one head vent flowpath generally requires two spurious operations. Likewise, spurious operation of two head vent flowpaths generally requires four spurious operations.
- Note B&W plants only have one head vent flowpath. Hot leg vents should be also be evaluated for B&W plants.
- From a PRA perspective, note that this scenario may screen out due to the low RCS inventory loss rate through these flowpaths. The scenario may also screen if the head vent valves are normally de-energized.

- From a PFSS analysis perspective, a head vent LOCA may be acceptable if the available makeup mass flow rate exceeds the LOCA mass flow rate.

19.3. WBN Unit 2 Safe Shutdown Compliance:

19.3.1. Reactor Upper Head Vent valves 2-FSV-68-394-A and 2-FSV-68-395-B are in parallel and in series with in-parallel valves 2-FSV-68-396-B and 2-FSV-68-397-A. These valves are all administratively closed (Modes 1 through 4) with control circuits disabled (switch 2-SW-68-394, -395 are in "off" position). In addition, the power cables for 2-FSV-68-396, -397 are routed in dedicated conduits with no energized circuits and the cables are protected at penetrations with radiant energy shields if needed). This will preclude these valves spuriously opening and causing loss of RCS inventory through open reactor head vent flow paths.

20.0 PWROG Scenario 20: Primary Inventory Control - Spurious operation of high head charging pumps challenges pressurizer safety valves

Note: PWROG Rev. 1 (6/5/09) Scenario No. 21

20.1. Description:

Spurious starting of additional high head charging pump(s)

AND

Spurious opening of additional RCS makeup flow paths (i.e., charging injection)

20.2. Notes:

- Scenario causes increasing RCS inventory, leading to a water solid pressurizer and PORV or safety valve opening. This scenario challenges both RCS Inventory and RCS Pressure Control Functions.
- Similar to inadvertent SI.
- Note that the spurious pump starting can occur for several reasons, including fire damage to control circuitry or an inadvertent ESFAS signal.
- Also note that other failures (spurious or non-spurious) in the makeup control system could contribute to this scenario.

20.2.1. See Scenario 2 for BIT isolation.

20.3. WBN Unit 2 Safe Shutdown Compliance:

20.3.1. Either CCP 2-MTR-62-104-B or 2-MTR-62-108-A is credited in all fire areas for makeup and seal injection (cooling). The normal charging path and BIT injection path are closed to prevent pressurizer overfill. Spurious start of the non-credited charging pump is not explicitly modeled in the FSSD analysis. However, operating both pumps would not have a detrimental effect on seal injection flow since this would result in a slight increase in both flow and pressure.

20.3.2. The normal charging path can be isolated by closing either 2-FCV-62-90-A or 2-FCV-62-91-B. At least one of these valves is available in all AVs except AV-099 where both valves are located. For AV-099, 2-FCV-62-89 (in-series with the injection header isolation valves but located in a different fire zone) will be closed from the MCR to isolate the Injection Header within the allowable time shown in the Dual Unit FPR Part VI (ref. 7.9).

20.3.3. The only fires that could cause the BIT outlet isolation valves 2-FCV-63-25-A or 2-FCV-63-26-B to open is a fire in their respective board rooms (AV-072, -073, -074). The BIT path will be isolated by closing BIT inlet valves 2-FCV-63-39-A and 2-FCV-63-40-B from their respective board rooms. These valves are powered by the respective Train A and Train B 480 VAC Control & Auxiliary Building Vent Boards located in AV-054 and AV-057. The allowable time requirement for these actions is shown in the Dual Unit FPR Part VI (ref. 7.9).

20.3.4. In summary, two charging pumps running with only the seal injection flow path available would result in a slight increase in both flows and pressure; but would not challenge pump minimum flow.

21.0 PWROG Scenario 21: Primary Inventory Control - Spurious opening of active valves in primary sample lines

Note: PWROG Rev. 1 (6/5/09) Scenario No. 22

21.1. Description:

Spurious opening of RCS sample valve(s) (i.e., hot leg, pressurizer liquid space, pressurizer steam space, etc.)

AND

Spurious opening of inside containment isolation valve

AND

Spurious opening of outside containment isolation valve

AND

Spurious opening of downstream sample valve(s)

21.2. Notes:

- Scenario causes loss of reactor coolant through the primary sample system, challenging the RCS Inventory Control Function.
- From a PRA perspective, scenario will generally screen due to requirement of 3+ spurious operations and the small magnitude of the leak. Also note that existing thermal hydraulic evaluation of loss of coolant through head vents may bound loss of coolant via the primary sample system.
- Scenario can be screened from consideration if a manual isolation valve prevents the flow. Scenario may also screen if it is within a closed loop capable of withstanding expected pressure.

21.3. WBN Unit 2 Safe Shutdown Compliance:

21.3.1. The RCS Hot Leg Loops 1 and 3, Pressurizer Liquid, and Pressurizer Gas primary sample isolation valves are not included in FSSD analysis. Each sample line consists of three in-series normally closed valves (fail close on loss of power or control air) and a manual isolation valve that could be closed in the Hot Sample room. The sample inlet valves 2-SMV-43-1153 (RCS hot leg sample), 2-SMV-43-1167 (Pressurizer liquid sample) and 2-SMV-43-1180 (Pressurizer gas sample) are closed during normal operation and are only open when taking a sample (Ref. 7.5 through 7.8). The sample lines are closed loop design with the liquid samples return to the volume control tank and the gas sample to the gas analyzer vent header except when a local sample is taken in the hot sample room. Therefore, a failure would require spurious operation of three in-series normally closed valves and a break in the sample line. In addition, a manual isolation valve for each sample line can be closed in Hot Sample Room. Also, the sample lines are 3/8 inch OD, thus the magnitude of the leak is small and need not be considered.

22.0 PWROG Scenario 22: Decay Heat Removal - Spurious opening of atmospheric relief valve(s) upstream of the main steam isolation valves (MSIVs)

Note: PWROG Rev. 1 (6/5/09) Scenario No. 23

22.1. Description:

Spurious opening of atmospheric relief valve(s) (also sometimes called atmospheric dump valves) upstream of the main steam isolation valves (MSIVs)

22.2. Notes:

- Scenario causes RCS over-cooling. Also, the overcooling can cause RCS shrinkage, causing low pressurizer level, and challenging the RCS Inventory Control Function.
- Note that spurious operation of each individual steam dump valve may require multiple hot shorts.
- Note some B&W designs do not have MSIVs.

22.3. WBN Unit 2 Safe Shutdown Compliance:

22.3.1. The FSSD Analysis includes the ability to close all 4 steam generator power operated relief valves (PORVs) in the event of spurious opening. A Unit 2 design change has been incorporated to add a third "C" solenoid of opposite train from the existing "A & B" solenoid valves for each PORV. It is located in a separate fire zone and its cables are routed separately from the "A & B" solenoid valves for each PORV. For all AVs except the Control Building, a MCR operator action will close the PORV's via either the "B" or "C" solenoid valve. For Control Building fires resulting in MCR abandonment the PORV's are closed by pressure indicating controllers in the auxiliary control system panel.

23.0 PWROG Scenario 23: Decay Heat Removal - Failure to close or spurious opening of main steam isolation valves with concurrent failure of downstream steam relief valve(s) to close

Note: PWROG Rev. 1 (6/5/09) Scenario No. 24

23.1. Description:

Main steam isolation valve(s) (MSIV(s)) spuriously open OR fail to close

AND

Valve(s) for downstream steam load(s) (e.g., condenser steam dumps, turbine inlet valves, some atmospheric relief / dump valves, etc.) spuriously open OR fail to close

23.2. Notes:

- Scenario causes RCS over-cooling. Also, the overcooling can cause RCS shrinkage, causing low pressurizer level, and challenging the RCS Inventory Control Function.
- Note that spurious opening, or failure to close, each individual MSIV may require multiple hot shorts. In addition, re-opening an MSIV once it has been closed may be very difficult due to differential pressure across valve.
- Note some B&W designs do not have MSIVs.

23.3. WBN Unit 2 Safe Shutdown Compliance:

23.3.1. The MSIVs can be closed from the main control room except for AV-032, -037, 037C.-038, -112, -114S, -115. As an alternate the steam load valves (MS Cool Down, MS Dump, Main FW Pump Turb HP Stop & Control, Main Turb Stop & Control, MSR Control & Low Power Bypass Control) (TBISOL) are available and can be closed by MCR operator action for these AV's. For Control Building fires resulting in MCR abandonment the MSIV can be operated from the auxiliary control room.

24.0 PWROG Scenario 24: Decay Heat Removal - Failure to close or spurious opening of main steam isolation Bypass valves with concurrent failure of downstream steam relief valve(s) to close

Note: PWROG Rev. 1 (6/5/09) Scenario No. 25

24.1. Description:

Main steam isolation valve(s) (MSIV(s)) bypass valves spuriously open OR fail to close

AND

Valve(s) for downstream steam load(s) (e.g., condenser steam dumps, turbine inlet valves, some atmospheric relief / dump valves, etc.) spuriously open OR fail to close

24.2. Notes:

- Scenario may cause RCS over-cooling. Also, the overcooling can cause RCS shrinkage, causing low pressurizer level, and challenging the RCS Inventory Control Function

- Note, depending on size and number of bypass lines failing open, scenario may not cause overcooling.
- Note some B&W designs do not have MSIVs.

24.3. WBN Unit 2 Safe Shutdown Compliance:

24.3.1. Electric power is removed from the steam line warming valves (main steam isolation valve bypass valves) 2-FCV-1-147-A, -148-B, -149-A, -150-B by administrative control of local control switches (2-HS-1-147B, -148B, -149B, -150B) during normal power operation to prevent spurious opening due to Appendix R fire. In addition, as an alternate the steam load valves (MS Cool Down, MS Dump, Main FW Pump Turbine HP Stop & Control, Main Turbine Stop & Control, MSR Control & Low Power Bypass Control) (TBISOL) are available for all auxiliary and reactor building fires and can be closed by MCR operator action.

25.0 PWROG Scenario 25: Decay Heat Removal - Spurious operation of main steam header drain valve(s)

Note: PWROG Rev. 1 (6/5/09) Scenario No. 26

25.1. Description:

Spurious operation of main steam header drain valve(s)

25.2. Notes:

- Scenario may cause RCS over-cooling. Also, the overcooling can cause RCS shrinkage, causing low pressurizer level, and challenging the RCS Inventory Control Function.
- Thermal hydraulic analysis may show that the drain valve flowpath is not large enough to be a problem.

25.3. WBN Unit 2 Safe Shutdown Compliance:

25.3.1. Not Applicable. WBN has no solenoid valves associated with the Main Steam Drains (in Aux. Bldg.), these are manual valves that are locked closed, and the DRVs and ISVs are not Appendix R equipment.

26.0 PWROG Scenario 26: Decay Heat Removal - Spurious operation / failure to operate of active steam supply valves fails the turbine driven auxiliary (emergency) feedwater pump (AFW / EFW)

Note: PWROG Rev. 1 (6/5/09) Scenario No. 27

26.1. Description:

Spurious isolation of redundant steam supply valves to turbine driven AFW pump.

26.2. Notes:

- Scenario causes turbine driven AFW pump loss of function, which challenges the Decay Heat Removal Function.

26.3. WBN Unit 2 Safe Shutdown Compliance:

26.3.1. The turbine driven auxiliary feedwater pump (TDAFWP) is credited in AV-026, and AV-038. The steam supply valves are operational for AV-026 and AV-38. For AV-026, 2-FCV-1-51-S requires local operator action within 20 minutes. For AV-038 cables have been relocated out of AV-038 to prevent spurious isolation of the steam supply to the TDAFWP.

26a PWROG Scenario 26a: Decay Heat Removal - Spurious operation / failure to isolate steam to non-credited TDAFW pump

Note: PWROG Rev. 1 (6/5/09) Scenario No. 26 (partial)

26a.1 Description:

Failure to isolate steam to non-credited TDAFW pump.

26a.2 Notes:

- Scenario may cause RCS over-cooling. Also, the overcooling can cause RCS shrinkage, causing low pressurizer level, and challenging the RCS Inventory Control Function.
- Thermal hydraulic analysis may show that the drain valve flowpath is not large enough to be a problem..

26a.3 WBN Unit 2 Safe Shutdown Compliance:

26a.3.1 The motor driven auxiliary feedwater pumps (MDAFWPs) are credited in all AV's except AV-026 and AV-038. For all other analysis volumes, at least one of the TDAFWP steam supply valves 2-FCV-1-17-A, 2-FCV-1-18-B, or 2-FCV-1-52 can be closed from the MCR to isolate steam to the non-credited TDAFWP. Although the TDAFWP can be driven by steam from either SG1 or SG4 the FSSD analysis only credits SG1. Spurious opening of 2-FCV-1-16-B (SG4) is not of concern because the steam

supply valves listed above are down stream of the SG selection valves (2-FCV-1-15-A & 2-FCV-1-16-B).

- 26a.3.2 The baseline FSSD Analysis did not specifically evaluate shutting the non-credited TDAFWP steam supply valves; however, as described above that capability does exist and is included in the FSSD analysis. This problem is identified in WBN Unit 1 PER 227804.

27.0 PWROG Scenario 27: Decay Heat Removal - Spurious closure of auxiliary (emergency) feedwater pump (AFW / EFW) active discharge valve(s)

Note: PWROG Rev. 1 (6/5/09) Scenario No. 28

27.1. Description:

Spurious closure of multiple valves in AFW pump discharge flow path(s)

27.2. Notes:

- Scenario isolates AFW flow to the steam generator(s), challenging the Decay Heat Removal Function.
- AFW flow isolation can occur due to several combinations of valve closures in the pump discharge and/or discharge cross-connect flow paths. Review P&IDs to identify specific valves.

27.3. WBN Unit 2 Safe Shutdown Compliance:

27.3.1. WBN auxiliary feedwater (AFW) system consists of 1 TDAFWP feeding all four SGs and 2 MDAFWPs feeding 2 SGs each. The TDAFWP is credited in AV-026 and AV-038. The MDAFWPs are credited for the remaining AVs. Local operator manual actions previously credited to operate the steam generator level control valves have been eliminated by EDCR 58210 which provided a nitrogen supply as a backup to the control air for the level control valves and the MDAFW pump back pressure control valves. These valves are now operable from the main control room. There are no other valves between the AFW pumps and the credited steam generators.

27.3.2. WBN Unit 1 identified the control air problem in PER 226948. DCN 58387 installed a nitrogen backup to the control air for the unit 1 steam generator level control valves just like unit 2.

27.3.3. Compliance strategy for both units is the same.

28.0 PWROG Scenario 28: Decay Heat Removal - Spurious operation / failure to operate of active steam supply valves fails the turbine driven auxiliary (emergency) feedwater pump (AFW / EFW) concurrent with spurious isolation of the AFW / EFW discharge flow path

Note: PWROG Rev. 1 (6/5/09) Scenario No. 29

28.1. Description:

Spurious closure of steam supply valve(s) to turbine driven AFW / EFW pump

AND

Spurious isolation of AFW / EFW pump discharge flow path(s)

28.2. Notes:

- Scenario isolates AFW flow to the steam generator(s) and causes turbine driven AFW pump loss of function, challenging the Decay Heat Removal Function.

28.3. WBN Unit 2 Safe Shutdown Compliance:

28.3.1. As discussed in scenarios 26 and 26a the TDAFW pump and associated FCVs and level control valves (LCVs) are credited in AV-026 and AV-038. For all AVs except AV-026 and AV-038, the MDAFW pumps are available.

28.3.2. The TDAFWP and MDAFWPs LCV's are discussed in scenario 27.

28.3.3. WBN Unit 1 identified the loss of control air problem in PER 226948.

28.3.4. Unit 1 and Unit 2 compliance strategies are the same.

29.0 PWROG Scenario 29: Decay Heat Removal - Auxiliary (emergency) feedwater (AFW / EFW) flow diversion to non-credited steam generator(s)

Note: PWROG Rev. 1 (6/5/09) Scenario No. 30

29.1. Description:

Combination of spurious valve operations in the AFW / EFW pump discharge flowpaths to the steam generators

29.2. Notes:

- Scenario causes AFW flow diversion to a non-credited steam generator(s), challenging the Decay Heat Removal Function. A steam generator may be "non-credited" by the FSSD analysis for a number of reasons including unavailability of instrumentation, failure of steam dumps on that loop, etc.
- Scenario may be a single spurious event in some cases.
- Also note that plants with unit-crossties may be subject to flow diversion to steam generators for another unit.

29.3. WBN Unit 2 Safe Shutdown Compliance:

29.3.1. The FSSD analysis ensured that two credited SGs had AFW flow either from the MDAFWP or TDAFWP.

29.3.2. As discussed in scenarios 26 and 26a, the TDAFWP is credited in AV-026 and AV-038. The steam supply valves are operational for these AVs. For AV-026, 2-FCV-1-51-S requires local operator action within 20 minutes. In addition, the MDAFWPs are stopped from the MCR, thus preventing flow diversion to the non-credited SGs. For AV-026 the pumps are stopped from the MCR. For AV-038 MDAFW pump A is stopped from the MCR and MDAFW pump B is stopped via the auxiliary control transfer and control switches on 6.9kv Shutdown board 2B (2-BD-211-B-B).

29.3.3. The MDAFWPs are credited with the remaining AVs. The non-credited MDAFWP can be stopped either in the MCR or in the associated shutdown board room. The non-credited TDAFWP can be stopped from the MCR by closing one of the TDAFWP steam supply valves 2-FCV-1-17-A, 2-FCV-1-18-B, or 2-FCV-1-52, thus preventing flow diversion to the non-credited SGs.

29.3.4. Pressure control valves (PCVs) 2-PCV-3-122 and 2-PCV-3-132 are modeled in the FSSD analysis and are designed to prevent MDAFW pump runout. Unit 2 EDCR 58210 and Unit 1 DCN 58387 added a nitrogen supply to provide motive power to the MDAFW pump pressure control valves upon loss of control air. The valves (PCVs) can be controlled from the MCR.

30.0 PWROG Scenario 30: Decay Heat Removal - Auxiliary (emergency) feedwater (AFW / EFW) pump failure due to runout following spurious full opening of multiple AFW / EFW flow control and / or isolation valves

Note: PWROG Rev. 1 (6/5/09) Scenario No. 31

30.1. Description:

Spurious full opening of multiple EFW / AFW flow control and / or isolation valves

30.2. Notes:

- Scenario may cause AFW pump runout and failure, challenging the Decay Heat Removal Function.
- Note that this scenario may occur even without spurious operations if the fail-safe position of relevant valves is full open.

30.3. WBN Unit 2 Safe Shutdown Compliance:

30.3.1. The TDAFWP and MDAFWP mini-flow lines contain breakdown orifices.

30.3.2. For the TDAFWP the credited SGs LCVs are modulated from the MCR as discussed in 27.3.1 within 20 minutes. Speed control of the TDAFWP is included as part of the FSSD analysis. Local control of the TDAFWP (credited for AV-026.) prevents turbine overspeed.

30.3.3. For the MDAFWPs, the credited pump discharge PCV and SG LCVs are modulated from the MCR as discussed in section 27.3.1 within 20 minutes. MDAFWP A is credited in AV-037 and AV-037C and its associated discharge PCV could fail open due to fire damage to the differential pressure transmitter cable. The PCV can still be modulated from the MCR via 2-PDIC-3-122A (manual mode) with the operator using the AFW flow indicators for SG 1 and 2.

31.0 PWROG Scenario 31: Decay Heat Removal - Spurious opening of condenser hotwell makeup control valve results in gravity draining condensate storage tank (CST) inventory to the hotwell

Note: PWROG Rev. 1 (6/5/09) Scenario No. 32

31.1. Description:

Spurious opening of valves between the Condensate Storage Tank (CST) and condenser hotwell.

31.2. Notes:

- Scenario causes inadvertent draining of CST inventory to the condenser. This CST inventory becomes unavailable as an AFW source, challenging the Decay Heat Removal Function.

- In some plants, this requires spurious operation of multiple valves. In other plants, this only requires spurious operation of one valve. And in other plants, this may occur due to loss of instrument air or a non-spurious valve failure (e.g., loss of air / power).
- Other CST draindown paths may exist. P&ID review required.
- Some plants may have a standpipe that prevents the CST from draining below a certain level.

31.3. WBN Unit 2 Safe Shutdown Compliance:

31.3.1. Valve 2-LCV-2-9 is not part of the FSSD analysis. The Hotwell makeup can not lower the CST level below the minimum volume required for supply to AFW (standpipe protected volume). The valve is normally shut and fails closed on loss of air and power. AFW pump suction can be aligned to the ERCW discharge header from the MCR within 120 minutes for all analysis volumes except AV-026, AV-069, AV-037, AV-037C, AV-038, and AV-072 which credit local operator manual actions for pump suction alignment. Per technical specification bases the CST standpipe protected volume is sufficient for more than 420 minutes. This OMA was previously approved for Unit 1.

32.0 PWROG Scenario 32: Decay Heat Removal - Spurious pump(s) operation / failure to trip pump(s) results in steam generator(s) overfill / overcooling

Note: PWROG Rev. 1 (6/5/09) Scenario No. 33

32.1. Description:

Scenario can occur due to various combinations of spurious AFW / EFW pump starts, spurious opening (or failure to close) of valves in AFW / EFW pump discharge flowpaths and spurious opening of main feedwater (MFW) isolation valves with MFW pump(s) running.

32.2. Notes:

- Scenario causes RCS over-cooling and/or steam generator overfill, both challenging the Decay Heat Removal Function. RCS over-cooling can cause RCS shrinkage and low pressurizer level. Steam generator overfill can affect operability of turbine-driven AFW pump.
- Note that the spurious pump starting can occur for several reasons, including fire damage to control circuitry or an inadvertent ESFAS signal.

32.3. WBN Unit 2 Safe Shutdown Compliance:

32.3.1. As discussed in scenario 29, the TDAFWP is credited in AV-026 and AV-038. The steam supply valves are operational for these AVs. For AV-026, 2-FCV-1-51-S requires local operator action within 20 minutes. In addition, the MDAFWPs can be stopped, thus preventing steam generator overfill. For AV-038 MDAFW pump A is stopped from the MCR and MDAFW pump B is stopped from 6.9kv shutdown board B (2-BD-211-B-B) via the auxiliary control system (ACS) transfer and control switches.

32.3.2. The MDAFWPs are credited with the remaining AVs. The non-credited MDAFWP can be stopped either from the MCR or the associated 6.9KV shutdown board room. Steam flow to the non-credited TDAFWP can be isolated from the MCR by closing either of the TDAFWP steam supply valves 2-FCV-1-17-A, or 2-FCV-1-18-B, or 2-FCV-1-52 within 19 minutes.

32.3.3. As noted above, the non-credited MDAFWP or TDAFWP can be stopped within 20 minutes.

32.3.4. The MFW isolation and control valves for both the main and bypass lines are included in FSSD analysis. For Control Building fires resulting in MCR abandonment, MFW main line isolation is ensured by operator action at the ACS stations and bypass line isolation is ensured by operator action in Vital Battery Board rooms III and IV. The bypass feedwater line isolation and regulating valve control circuits have been modified to ensure main and bypass line isolation for all postulated fire locations.

32.3.5. WBN Unit 1 identified this condition in PER 227804.

33.0 PWROG Scenario 33: Decay Heat Removal - Spurious operation of steam generator blowdown valves with subsequent loss of steam generator(s) inventory

Note: PWROG Rev. 1 (6/5/09) Scenario No. 34

33.1. Description:

Spurious opening of, or failure to close, multiple series steam generator blowdown valves

33.2. Notes:

- Scenario causes drain down of steam generator inventory through the blowdown system, challenging the Decay Heat Removal Function.
- The number of valves required to spuriously open varies by plant design.
- B&W plants generally do not have a steam generator blowdown system. However, some B&W plants with replacement steam generators may have this system.
- Potential Resolution: Scenario may screen if available AFW mass flow rate exceeds steam generator inventory mass loss rate through blowdown.

33.3. WBN Unit 2 Safe Shutdown Compliance:

- 33.3.1. Each pair of Steam Generator Blowdown Containment Isolation Valves was evaluated in the FSSD analysis to ensure closure of at least one SGBD valve in each flow path. MCR operator actions will close the SGBD CIVs within 71 minutes. For Control Building fires resulting in MCR abandonment, the valve controls will be transferred to and closed from the Auxiliary Control System stations.

34.0 PWROG Scenario 34: Decay Heat Removal - Spurious opening of active valves in secondary sampling system(s) causes loss of steam generator(s) inventory

Note: PWROG Rev. 1 (6/5/09) Scenario No. 35

34.1. Description:

Spurious opening of steam generator sample valve(s) inside containment

AND

Spurious opening of isolation valve(s) outside containment

AND

Spurious opening of downstream sample valve(s)

34.2. Notes:

- Scenario causes drain down of steam generator inventory through the sample system, challenging the Decay Heat Removal Function.

- From a PRA perspective, scenario will generally screen due to requirement of 3+ spurious operations and the small magnitude of leak.
- Scenario can be screened from consideration if a manual isolation valve prevents the flow or if the system is closed loop capable of withstanding expected pressure.
- Scenario may also screen if available AFW mass flow rate exceeds steam generator inventory mass loss rate through the sample system.
- B&W plants sample directly from the steam generator (i.e., not through blowdown system).

34.3. WBN Unit 2 Safe Shutdown Compliance:

34.3.1. The Steam Generator Drum and Blowdown Sampling Isolation Valves are required to be closed to complete Secondary Side Isolation to ensure that the AFW system can maintain steam generator level and remove decay heat. However, these valves were removed from the FSSD analysis since the steam generator blowdown sample flow (maximum of 0-6 gpm) is considered negligible and would not compromise the auxiliary feed water makeup flow.

35.0 PWROG Scenario 35: Primary Pressure Control - Spurious operation of active normal pressurizer spray valves concurrent with inability to trip operating reactor coolant pump(s) (RCPs) from the Control Room

Note: PWROG Rev. 1 (6/5/09) Scenario No. 36

35.1. Description:

Spurious opening of normal pressurizer spray valve(s)

AND

Inability to trip / failure to trip, or spurious operation of, RCP(s)

AND

Inoperability of pressurizer heater(s)

35.2. Notes:

- Scenario causes a RCS pressure transient, challenging the RCS Pressure Control Function. Typical PFSS analyses address this issue; PRAs often consider scenario negligible since there is no real threat of core uncover.

- Potential candidate for generic analysis to evaluate various spray / heater combinations and show no adverse impact on safe shutdown capability.
- Note that spurious opening or failure to isolate pressurizer auxiliary spray would have similar consequence; however this is typically a single spurious scenario.

35.3. WBN Unit 2 Safe Shutdown Compliance:

- 35.3.1. The cables associated with the RCPs which can cause a spurious start of the pump or prevent the pump from being tripped are entirely contained inside the Control or Turbine Building. For all AVs requiring the RCP's to be tripped except Control Building, the RCPs are tripped from MCR panels. For Control Building fires resulting in MCR abandonment, the RCPs are tripped by control room switches, the RCP board normal and alternate supply breakers are also tripped at the Electrical Control Board (in the control room), and a local action at the 6.9KV RCP Board ensures the RCP's do not restart. (Reference Scenario 4)
- 35.3.2. The PZR Spray valves 2-PCV-68-340B, and 2-PCV-68-340D could spuriously open in AV-025, -025C, -026, -037, -037C, -38, -115, and -117. For each of these analysis volumes the RCPs are tripped via MCR operator action to prevent pressurizer spray.
- 35.3.3. The PZR Heaters are not credited to mitigate spurious opening of the pressurizer spray valves. However, as described in scenario 36, they could spuriously operate due to fire in the control building and in AV-036, AV-037, AV-037C, AV-038, , AV-045, AV-048, AV-049, AV-050, AV-053, AV-055, AV-056, AV-066, AV-070, AV-071, and AV-117. They can be tripped from the MCR or from the 6.9kv shutdown boards (AV-042, AV-057) within 25 minutes. For fires in the 6.9KV shutdown board rooms (AV-042, AV-057) the board will be de-energized by tripping the supply breakers and the EDG.

35a.0 PWROG Scenario 35a: Primary Pressure Control - Spurious operation of auxiliary pressurizer spray valves with charging pumps in operations

Note: PWROG Rev. 1 (6/5/09) Scenario No. 36

35a.1 Description:

Spurious opening of auxiliary pressurizer spray valve(s)

AND

Inoperability of pressurizer heater(s).

35a.2 Notes:

- Scenario causes a RCS pressure transient, challenging the RCS Pressure Control Function. Typical PFSS analyses address this issue; PRAs often consider scenario negligible since there is no real threat of core uncover.
- Potential candidate for generic analysis to evaluate various spray / heater combinations and show no adverse impact on safe shutdown capability.
- Note that spurious opening of failure to isolate pressurizer auxiliary spray would have similar consequence; however this is typically a single spurious scenario.

35a.3 WBN Unit 2 Safe Shutdown Compliance:

35a.3.1 The charging header isolation valves 2-FCV-62-90-A, -91-B can be closed from MCR in all AVs except AV-099 to isolate the auxiliary pressurizer spray line. The auxiliary spray valve, 2-FCV-62-84-A, will not spuriously open due to fire damage in AV-099. Therefore the auxiliary pressurizer spray line can be isolated for all AVs and the pressurizer heaters are not needed to mitigate spurious operation of the auxiliary spray valve.

35a.3.2 Unit 2 compliance strategy is the same as Unit 1.

36.0 PWROG Scenario 36: Primary Pressure Control - Spurious operation of multiple pressurizer heater banks

Note: PWROG Rev. 1 (6/5/09) Scenario No. 37

36.1. Description:

Spurious operation of multiple pressurizer heaters

AND

Inoperability of pressurizer spray and auxiliary spray

36.2. Notes:

- Scenario causes a RCS pressure transient, challenging the RCS Pressure Control Function. RCS pressure increase could cause PORV(s) and/or safety valve(s) to open.

36.3. WBN Unit 2 Safe Shutdown Compliance:

36.3.1. The PZR Heaters could spuriously operate due to fire damage in AV-036, -037, -037C, -038, -045, -048, -049, -050, -053, -055, -056, -066, -070, 0-71, and -117. The heaters can be tripped from the MCR or the 6.9kv shutdown board rooms (AV-042 and AV-057). For fires in the 6.9kv shutdown board rooms (AV-042, Av-057) the boards are de-energized by tripping all of the supply breakers (normal, alternate, maintenance) and the EDG. EDG kill switches are located on both MCR panel 0-M-26 and ACS panel 0-L-4. Each EDG has a transfer switch located on 1,2-L-11A or 1,2-L-11B to select between MCR and ACS. DCN 58383 relocated the transfer switches from the 6.9kv board rooms to the ACS transfer panels. The heaters can be disabled within 25 minutes.

36.3.2. WBN Unit 1 identified this condition in PER 227839.

37.0 PWROG Scenario 37: Reactivity Control - Inadvertent injection of undiluted makeup water / inadvertent injection of makeup water with very low boron concentration

Note: PWROG Rev. 1 (6/5/09) Scenario No. 38

37.1. Description:

Unborated water supply to the RCS can occur due to combinations of the following:

- Spurious start of reactor makeup pump(s) (supplies unborated water to the VCT),
- Spurious opening of valves between reactor makeup pump(s) and VCT,
- Spurious full opening of the reactor makeup flow control valve,
- Spurious closure of the boric acid flow control valve.

37.2. Notes:

- Scenario decreases RCS boron concentration, potentially causing reactivity increase, and challenging the Reactivity Control Function.
- The reactor makeup flow control valve would normally provide the setpoint flowrate instead of being fully open.
- Potential Solution: The maximum flow from the reactor makeup pump may be limited due to the plant specific design (e.g., installation of a flow orifice to limit the pump's maximum flow, boron dilution protection system, etc.).
- Potential Solution: The reactivity increase may occur at a very slow rate, allowing operators sufficient time to mitigate.

37.3. WBN Unit 2 Safe Shutdown Compliance:

37.3.1. If the primary makeup pumps (2-MTR-81-3 and 2-MTR-81-7) spuriously start they can be tripped within the allowable time shown in the Dual Unit FPR Part VI (ref 7.9) from the main control room or from their 480vac MCC to ensure the reactor coolant system boron concentration is maintained. Main control room trip capability is available for all fires except analysis volumes AV-005, AV-026, AV-038, and AV-057.

For AV-005, -026, -038, and -057 the allowable time is conservative since the normal makeup path can be isolated from the MCR and the BIT outlet isolation valves (2-FCV-63-25-A and 2-FCV-63-26-B) are normally closed and their control circuits have been modified such that they cannot spuriously open except for a fire where their MCCs are located (AV-072, -073, & -074). Therefore a boron dilution event will not occur for these analysis volumes and the primary makeup pumps can be stopped at their MCCs in a timely manner.

For AV-072, -073, & -074 the normal makeup path can be isolated and the primary makeup pumps stopped from the MCR. Therefore, a boron dilution event will not occur for these analysis volumes. The BIT injection path can be isolated by closing the BIT inlet isolation valves (2-FCV-63-39-A and 2-FCV-63-40-B) from their MCCs (reference Section 2.3).

For the remaining analysis volumes the normal makeup path can be isolated and the primary makeup pumps stopped from the MCR and the BIT outlet isolation valves remain closed. Therefore, boron dilution event will not occur.

38.0 PWROG Scenario 38: Reactivity Control - Fire prevents reactor trip

Note: PWROG Rev. 1 (6/5/09) Scenario No. 39

38.1. Description:

Fire damage to the reactor protection system (RPS) may prevent reactor trip. For example, hot shorts may prevent tripping of the RPS motor generator (MG) sets.

38.2. Notes:

- BWRs have identified scenarios where fire-induced hot shorts could prevent all control rod groups from inserting when required. Reference NRC Information Notice 2007-07.
- No cases at PWRs were identified by the survey results that supported this MSO list. However, each plant should consider performing a review to determine if scenario is plausible at their plant. Note that this review may have already been performed for the disposition of Information Notice 2007-07.

38.3. WBN Unit 2 Safe Shutdown Compliance:

38.3.1. The post fire safe shutdown analysis demonstrates that at least one train of the reactor trip switchgear can be tripped from the main control room for all AVs with the possible exception of AV-115 where the reactor trip switchgear is located.

38.3.2. For AV-115 reactor trip is confirmed by tripping the normal and alternate supplies to the control rod MG sets, 2-MTR-85-1A and 2-MTR-85-1B, at the 480vac unit boards in the turbine building within 15 minutes.

38.3.3. For Control Building fires resulting in MCR abandonment reactor trip is initiated and confirmed prior to evacuating the control room.

39.0 PWROG Scenario 39: Support Systems - Spurious loss of component cooling water (CCW) either as an entire system or to individual headers (including potential water hammer events)

Note: PWROG Rev. 1 (6/5/09) Scenario No. 40

39.1. Description:

CCW flow can be isolated via several combinations of spurious valve closures. Pertinent valves include:

- CCW pump discharge valves,
- CCW pump crosstie valves,
- CCW heat exchanger inlet valves,
- CCW heat exchanger outlet valves,
- CCW heat exchanger crosstie valves,
- Etc.

39.2. Notes:

- Scenarios cause failure of CCW function to provide cooling to safe shutdown loads.
- Review P&IDs to identify relevant valve combinations.

39.3. WBN Unit 2 Safe Shutdown Compliance:

39.3.1. Spurious loss of Component Cooling System (CCS) is prevented by removing power from the motor operated valves that could isolate CCS flow or provide flow diversion. The CCS pump supply (inlet) and discharge are open with power removed. CCS heat exchanger inlet and outlet valves are open with power removed. Cross tie valves between units and heat exchangers are closed with power removed. Isolation valves in supply lines serving the charging pumps, safety injection pumps, RHR pumps and Containment Spray pumps are open with power removed.

39.3.2. The following individual load valves are powered and are evaluated for spurious operation in the post fire safe shutdown analysis:

CCS Heat Exchanger B (Unit 2 train A loads):

0-FCV-70-194-B, normally open supply to spent fuel pool heat exchanger B. The valve control circuit has been modified such that only fire damage in the electrical board room (AV-072 or AV-073) could cause spurious closure. Spurious valve closure would not prevent the CCS pump from providing the needed flow to safe shutdown equipment.

2-FCV-70-156-A, normally closed RHR heat exchanger 2A outlet valve. The valve control circuit has been modified to minimize spurious opening of the valve. For a fire in the electrical board room (AV-074) the valve could open and divert CCS flow through the RHR heat exchanger, but normally open valve 0-FCV-70-194-B can be closed from the MCR to ensure adequate CCS flow is available for the fire safe shutdown equipment.

2-FCV-70-87-B, 2-FCV-70-90-A, 2-FCV-70-133-A & 2-FCV-70-134-B, normally open thermal barrier cooling isolation valves. Thermal Barrier Cooling (TBC) is only credited for AV-005, AV-104, and AV-106 (See section 1.3). The valves will not spuriously close due to fire damage in these AVs except for AV-106 where the TBC differential flow transmitters are located. MCR operator actions are credited to bypass the differential flow signal and re-open the valves that may have spuriously closed.

CCS Heat Exchanger C (both units train B loads):

2-FCV-70-153-B, normally closed RHR heat exchanger 2B outlet valve. Valve control circuit has been modified to prevent spurious opening except for a fire in the Unit 2 train B RMOV board room. If the valve spuriously opens the Unit 1 valve can be closed from the MCR.

1-FCV-70-153-B, RHR normally open heat exchanger 1B outlet valve.

Valve control circuit has been modified to prevent spurious closing except for a fire in the Unit 1 Train B RMOV board room. If the valve spuriously closes, the Unit 2 valve can be opened from the MCR.

40.0 PWROG Scenario 40: Support Systems - Spurious loss of component cooling water (CCW) to individual critical loads (including potential water hammer events)

Note: PWROG Rev. 1 (6/5/09) Scenario No. 41

40.1. Description:

Spurious isolation of CCW cooling to individual redundant loads including lube oil coolers, RHR heat exchangers, etc.

40.2. Notes:

- Scenario isolates CCW cooling to credited loads causing safe shutdown equipment inoperability of credited trains.
- For example, a plant may have two redundant charging pumps. Each charging pump may have a lube oil system that is cooled by the corresponding train of CCW. If CCW flow to both lube oil coolers spuriously isolates, then both charging pumps would become inoperable.
- All credited CCW loads should be reviewed.

40.3. WBN Unit 2 Safe Shutdown Compliance:

40.3.1. See scenario 39.

41.0 PWROG Scenario 41: Support Systems - Component cooling water (CCW) flow diversion to non-credited loop(s)

Note: PWROG Rev. 1 (6/5/09) Scenario No. 42

41.1. Description:

Flow diversion can occur via several combinations of spurious valve operations in the CCW pump discharge and CCW loop crosstie flowpaths. Review P&IDs to identify relevant combinations.

41.2. Notes:

- Scenario causes CCW flow to be diverted to the non-credited loop. This ultimately prevents CCW cooling of credited safe shutdown loads.

- Review P&IDs to identify relevant valve combinations.

41.3. WBN Unit 2 Safe Shutdown Compliance:

41.3.1. Spurious loss of Component Cooling System (CCS) is prevented by removing power from the motor operated valves that could isolate CCS flow or provide flow diversion. The CCS pump supply (inlet) and discharge are open with power removed. CCS heat exchanger inlet and outlet valves are open with power removed. Cross tie valves between units and heat exchangers are closed with power removed. Isolation valves in supply lines serving the charging pumps, safety injection pumps, RHR pumps and Containment Spray pumps are open with power removed.

41.3.2. The following individual load valves are powered and are evaluated for spurious operation in the safe shutdown analysis (See Scenario 39):

CCS Heat Exchanger B (Unit 2 train A loads):

0-FCV-70-194-A, normally open supply to spent fuel pool heat exchanger B.

2-FCV-70-156-A, normally closed RHR heat exchanger 2A outlet valve.

2-FCV-70-133-A, 2-FCV-70-134-B, 2-FCV-70-87-B, & 2-FCV-70-90-A normally open thermal barrier cooling valves

CCS Heat Exchanger C (both units train B loads):

2-FCV-70-153-B, normally closed RHR heat exchanger 2B outlet valve.

1-FCV-70-153-B, RHR normally open heat exchanger 1B outlet valve.

41.3.3. CCS normally closed valves 1-FCV-70-143-A, -85-B (Excess Letdown Heat Exchanger Containment Isolation Valves) are not included in FSSD analysis because the additional 232 gpm load would not impact the CCS pumps.

42.0 PWROG Scenario 42: Support Systems - Spurious loss of safety-related service water (SW) either as an entire system or to individual headers (including potential water hammer events)

Note: PWROG Rev. 1 (6/5/09) Scenario No. 43

42.1. Description:

Safety related service water (sometimes called, "essential," service water) flow to credited loads can be isolated via several combinations of spurious valve closures.

Pertinent valves include:

- SW pump discharge valves,
- SW pump crosstie valves,
- SW heat exchanger inlet valves,
- SW heat exchanger outlet valves,
- SW heat exchanger crosstie valves,

Review P&IDs to identify relevant combinations.

42.2. Notes:

- Scenario causes isolation of ESW, which can fail cooling to the CCW system and other safe shutdown components directly cooled by ESW (e.g., EDG cooling).
- All credited ESW loads should be reviewed for spurious isolation.

42.3. WBN Unit 2 Safe Shutdown Compliance:

- 42.3.1. ERCW pump availability is evaluated in the FSSD analysis to ensure that at least 2 of the 4 pumps of the credited train are available for all fire scenarios. Note: when ERCW header 1B is supplying header 2A (1-FCV-67-458-A open) 3 train B pumps are credited to ensure adequate flow for both headers.
- 42.3.2. Pump discharge (strainer inlet) and header isolation valves are open with power removed to prevent spurious closure and ensure ERCW flowpath.
- 42.3.3. FCV-67-66-A and FCV-67-67-B, emergency diesel generator heat exchanger supply valves from ERCW headers, for both units are normally closed and open upon emergency diesel generator start. The valves, their control and power circuits, and power sources are included in the FSSD analysis to ensure ERCW flow to emergency diesel generators when needed.
- 42.3.4. FCV-67-127-A and FCV-67-128-B for both units are open with power removed to ensure ERCW flow to critical air conditioning equipment.
- 42.3.5. Potential flow diversion to Containment Spray heat exchangers due to spurious opening of in-series valves FCV-67-123-B and -124-B or FCV-67-125-A and -126-A for both units is evaluated in FSSD analysis.

- 42.3.6. Supply and discharge valves for each of the three CCS heat exchangers are evaluated in the FSSD analysis to ensure ERCW flow is available for the credited safe shutdown components. Valve control circuits are modified to minimize spurious operation potential.

43.0 PWROG Scenario 43: Support Systems - Spurious loss of safety-related service water (SW) to individual critical loads (including potential water hammer events)

Note: PWROG Rev. 1 (6/5/09) Scenario No. 44

43.1. Description:

Spurious isolation of safety related service water (SW) cooling to redundant loads including component cooling water (CCW) heat exchangers and emergency diesel generator cooling (EDG) cooling.

43.2. Notes:

- Scenario isolates ESW cooling to redundant loads causing safe shutdown equipment failure on redundant trains.
- For example, redundant EDGs may be cooled by ESW. If ESW flow to both EDGs spuriously isolates, then both EDGs could fail.
- All credited ESW loads should be reviewed.

43.3. WBN Unit 2 Safe Shutdown Compliance:

43.3.1. See Scenario 42.

44.0 PWROG Scenario 44: Support Systems - Safety related service water (SW) flow diversion to non-credited loops / loads

Note: PWROG Rev. 1 (6/5/09) Scenario No. 45

44.1. Description:

Flow diversion can occur via several combinations of spurious valve operations in the service water pump discharge and loop crosstie flowpaths. Review P&IDs to identify relevant combinations.

44.2. Notes:

- Scenario causes ESW flow to be diverted to a non-credited loop or system. This ultimately prevents ESW cooling of credited loads.

- Review P&IDs to identify relevant valve combinations.

44.3. WBN Unit 2 Safe Shutdown Compliance:

44.3.1. The only significant potential flow diversion are the Containment Spray heat exchangers each of which is isolated by 2 normally closed motor operated valves. These valves are included in the FSSD analysis and evaluated for spurious opening. If both valves for a heat exchanger could spuriously open additional ERCW flow capacity is ensured. The Unit 2 valves are modified to minimize spurious opening potential.

45.0 PWROG Scenario 45: Support Systems - Non-critical components inadvertently loaded onto credited emergency diesel generator(s) (EDGs)

Note: PWROG Rev. 1 (6/5/09) Scenario No. 46

45.1. Description:

Additional components load onto credited diesel generator

45.2. Notes:

- Scenario causes diesel generator overloading and failure.
- Scenario very site specific. Interlocks may prevent this from occurring.

45.3. WBN Unit 2 Safe Shutdown Compliance:

45.3.1. See scenario 46.

46.0 PWROG Scenario 46: Support Systems - Emergency diesel generator(s) (EDGs) overloading

Note: PWROG Rev. 1 (6/5/09) Scenario No. 47

46.1. Description:

Emergency diesel generator (EDG) overloading

46.2. Notes:

- Scenarios cause diesel generator overloading and failure.
- Scenarios very site specific. Interlocks may prevent these from occurring.

- In addition to Scenario 45, overloading may also occur if proper load sequencing is bypassed via hot shorts, causing simultaneous loading of multiple components onto the EDG.

46.3. WBN Unit 2 Safe Shutdown Compliance:

- 46.3.1 An investigation was initiated to determine the effects of MSOs on each EDG with respect to overloading the EDG. This was accomplished by revising calculation WBPEVAR9503001, *Appendix R – Diesel Generator Load Study* to change the methodology from an evaluation of a worst-case steady state loading applied to EDG 1A-A to an evaluation of each EDG during each Appendix R fire that credits the EDG. All cables that could cause any load to spuriously connect to its EDG or prevent required load shedding was included in the Appendix R Analysis. Failure of any of these cables resulted in the associated loading addition being evaluated in WBPEVAR9503001. This evaluation considers both steady state loading and load pickup capability. Steady state loading is evaluated for the short time rating (<2 hours) and at the continuous rating (>2 hours) of the EDG. Load pickup capability is evaluated for the worst case loading for each EDG for three conditions: (1) Maximum starting plus running (transient) loading, 0 to 180 sec, compared to cold engine capability, (2) Maximum starting plus running (transient) loading, 180 sec to end, compared to hot engine capability, and (3) Maximum step load increase (excitation), 0 sec to end, compared to generator step load capability. Spurious loading that resulted in an overloaded EDG resulted in cable reroutes that were necessary to bring the EDG within its ratings.

Results for each EDG requiring reroutes are as follows:

2A-A For fire in 737-A7, 737-A8, 737-A1AN, 737-A1BN and 737-A1CN (AV-37C)

Relocating cable 2PL5145 out of these fire zones was accomplished by PIC 56638 as part of DCN 54912.

1B-B For fire in 772-A2A1, 772-A2A2 and 772-A2A3 (AV-059)

Relocating cables 1B27G, 1B32G, 1PL5396B and 1PL5398B out of these fire zones was accomplished by DCN 58383 which also changed their cable numbers to 1B20G, 1B21G, 1PL1191B, and 1PL1192B.

- 46.3.2 Overall long term resolution has been accomplished by including in the FSSD analysis all cables that could spuriously start or prevent removing loads to/from an EDG. These cables are analyzed with the specific EDG for which they are associated as described in 46.3.1 above.

46.3.3 WBN Unit 1 identified this condition in PER 227839.

47.0 PWROG Scenario 47: Support Systems - Spurious start of an emergency diesel generator(s) (EDGs) with concurrent failure to provide required cooling

Note: PWROG Rev. 1 (6/5/09) Scenario No. 48

47.1. Description:

Fire spuriously starts an emergency diesel generator(s)

AND

MOVs providing required cooling water to the emergency diesel generator(s) either fail to open or spuriously close

47.2. Notes:

- The fire causes startup of the Emergency Diesel Generator and spurious isolation of ESW cooling (See Scenarios 43 & 45). Running the Emergency Diesel Generator with a loss of cooling water could trip and/or damage the diesel on high temperature.

47.3. WBN Unit 2 Safe Shutdown Compliance:

47.3.1. The ERCW valves supplying the EDGs (1/2-FCV-67-66-A and 1/2-FCV-67-67-B) are normally closed and automatically open upon EDG start. The valves, their power supplies, and associated cables are included in the FSSD analysis to ensure that cooling water is available for each fire zone where the EDGs are credited.

48.0 PWROG Scenario 48: Support Systems - Non-synchronous paralleling of emergency diesel generator(s) (EDGs) with on-site and off-site sources through spurious circuit breaker operations

Note: PWROG Rev. 1 (6/5/09) Scenario No. 49

48.1. Description:

Non-synchronous paralleling of emergency diesel generator(s) (EDGs) with on-site and off-site sources through spurious circuit breaker operations.

48.2. Notes:

- Non-synchronous paralleling of EDG with on-site and off-site sources through spurious breaker operations

48.3. WBN Unit 2 Safe Shutdown Compliance:

48.3.1. EDGs cannot be connected to other on-site EDGs except through multiple spurious offsite feeder breaker closures. The EDG breaker cannot be closed spuriously to parallel a running DG with offsite power for the credited boards for all fire zones. Cables associated with the EDG breaker CLOSE circuit that could spuriously close the breaker are routed outside all fire zones that credit the associated board. Similarly, neither the normal feeder breaker, alternate feeder breaker, nor maintenance feeder breaker can be closed spuriously to connect offsite power to a board that is receiving power from a running EDG. Cables associated with these offsite breakers' CLOSE circuits that could spuriously close the breaker are routed outside all fire zones that credit the associated board. All of the 6.9kV shutdown board feeder breaker control circuit cables that could spuriously close a board feeder breaker are modeled in the FSSD analysis.

The following specific cables, wires, fire zones, and Analysis Volumes are used to demonstrate the above statements for board 1-BD-211-A-A; the other boards are similar:

To spuriously close Emergency Feeder Breaker (1912)(Onsite source) with a running EDG while operating on Offsite Power, wire SA6C3 in cable 1PP475A must experience a hot short (positive battery) AND wire SA6GA in cables 1PP478A OR PP1715A OR wire SA6GA1 in cable 1PP474A must experience a hot short (negative battery). The latter energizes permissive relay AX allowing the positive short on SA6C3 to close the breaker. Cable 1PP475A is located in fire zones 737-A1A, 757-A2, and control building. The control building is eliminated by the operation of the Norm/Auxiliary transfer switch 1-XS-57-46 in the event of a control building fire resulting in MCR abandonment. Other affected analysis volumes are AV-036, AV-042, AV-042D AV-042E, AV-042F, and AV-042G. None of these analysis volumes takes credit for board 1-BD-211-A-A. Cable damage on 1PP478A, PP1715A and 1PP474A alone cannot spuriously close the EDG breaker.

To spuriously close the Normal Feeder Breaker (1713)(Offsite source) while operating on Onsite Power, wire SA16T6 (energizes relay R716) and wire SA16C5 (completes close circuit through R716 contact) must experience a hot short (positive battery). Both wires are in cable 1PP462A. Cable 1PP463A contains wire SA16C4 which could complete the close circuit if R716 were energized by hot short on cable

1PP462A wire SA16T6. However, cable 1PP463A is routed entirely in the control building and is eliminated by Norm/Auxiliary transfer switch 1-XS-57-41 in the event of a control building fire resulting in MCR abandonment. Cable 1PP462A is located in fire zones 737-A1A, 757-A2 and control building. The control building is eliminated by the operation of the Norm/Auxiliary transfer switch 1-XS-57-41 in the event of a control building fire resulting in MCR abandonment. Other affected analysis volumes are AV-036, AV-042, AV-042D AV-042E, AV-042F, and AV-042G. None of these analysis volumes takes credit for board 1-BD-211-A-A.

To spuriously close the Alternate Feeder Breaker (1932)(Offsite source) while operating on Onsite Power, wire SA1T6 (energizes relay R932) and wire SA1C5 (completes close circuit through R932 contact) must experience a hot short (positive battery). Both wires are in cable 1PP440A. Cable 1PP442A contains wire SA1C4 which could complete the close circuit if R932 were energized by hot short on cable 1PP440A wire SA1T6. However, cable 1PP442A is routed entirely in the control building and is eliminated by Norm/Auxiliary transfer switch 1-XS-57-97 in the event of a control building fire resulting in MCR abandonment. Cable 1PP440A is located in fire zones 737-A1A, 757-A2 and control building. The control building is eliminated by the operation of the Norm/Auxiliary transfer switch 1-XS-57-97 in the event of a control building fire resulting in MCR abandonment. Other affected analysis volumes are AV-036, AV-042, AV-042D AV-042E, AV-042F, and AV-042G. None of these analysis volumes takes credit for board 1-BD-211-A-A.

To spuriously close the Maintenance Feeder Breaker (1718)(Offsite source) while operating on Onsite Power, wire SA11T6 (energizes relay R718) and wire SA11C4 (completes close circuit through R718 contact) must experience a hot short (positive battery). Both wires are in cable 1PP450A. Cable 1PP451A contains wire SA1C3 which could complete the close circuit if R718 were energized by hot short on cable 1PP450A wire SA11T6. However, cable 1PP451A is routed entirely in the control building and is eliminated by Norm/Auxiliary transfer switch 1-XS-57-44 in the event of a control building fire resulting in MCR abandonment. Cable 1PP450A is located in fire zones 737-A1A, 757-A2 and control building. The control building is eliminated by the operation of the Norm/Auxiliary transfer switch 1-XS-57-44 in the event of a control building fire resulting in MCR abandonment. Other affected analysis volumes are AV-036, AV-042, AV-042D AV-042E, AV-042F, and AV-042G. None of these analysis volumes takes credit for board 1-BD-211-A-A.

48a.0 PWROG Scenario 48a: Emergency Power – Inadvertent paralleling of normal and alternate offsite power sources through the onsite busses and breakers

Note: PWROG Rev. 1 (6/3/09) Scenario 49.1

48a.1 Description:

Similar to non-synchronous paralleling-inadvertent crosstie breaker operation between opposite divisions or non-synchronous paralleling-inadvertent cross tying the offsite power sources through the onsite busses and breakers, with synchronous faults. Spurious closure on alt feeder and failure of normal to open (i.e. parallel supply) + circuit fault could result in short circuit currents above withstand/interrupt ratings.

48a.2 Notes:

- May apply to Electrical Boards with normal and alternate feeder breakers without physical mechanical interlocks.

48a.3 WBN Unit 2 Safe Shutdown Compliance:

48a.3.1 Normal and alternate offsite power sources cannot be connected in parallel through any onsite busses and breakers by multiple spurious operations. Each 6.9 kV shutdown board can be connected to an offsite source through a Normal, Alternate, or Maintenance feeder breaker. Each of these feeder breakers close circuits are interlocked with the other two breakers through series 52b switches (52b is closed when its associated breaker is open). This arrangement will only allow a close signal (close coil energized) for a given breaker if both of the other breakers are open. (Anticipatory trip fast transfer scheme is not utilized on these boards.) All wiring for these interlocks is contained within the board, thus not subject to fire damage external to the board. All other busses can only be fed from either one offsite source or through mechanically interlocked breakers.

49.0 PWROG Scenario 49: Other Scenarios - Spurious isolation of various combinations of pump(s) suction valve(s)

Note: PWROG Rev. 1 (6/5/09) Scenario No. 50

49.1. Description:

Note: Spurious operation of powered (i.e., MOVs, AOVs, SOVs) pump(s) suction valve(s) is most likely already included in the PRA logic and the safe shutdown cable analysis.

49.2. Notes:

- Suction flow paths for all credited pumps should be reviewed for MSO scenarios causing loss of suction and pump failure. An example of a pump suction MSO was previously identified in which both the VCT outlet valve(s) and RWST outlet valve(s) spuriously close.
- Another example involves pump suction cross-connect valves. Three pumps may be supplied from a common suction header that includes several cross connect valves. If two valves spuriously isolate, the pump drawing suction from the common header between the two isolated valves can lose suction and fail.
- The spurious operation of idle pumps after suction has been spuriously isolated should also be considered. Spurious pump starting can occur for several reasons, including fire damage to control circuitry or an inadvertent ESFAS signal.

49.3. WBN Unit 2 Safe Shutdown Compliance:

49.3.1. The primary pumps including associated suction and cross-connect valves that should be evaluated are the CCPs, CCS Pumps, and TDAFW/MDAFW Pumps, and ERCW Pumps. The CCPs are addressed in scenarios 10 (1, 3, 11, 12); the CCS pumps are addressed in scenarios 39, 42; the ERCW Pumps are addressed in scenario 42, and TDAFW/MDAFW are addressed in scenarios 26, 28, 31.

50.0 PWROG Scenario 50: Other Scenarios - Spurious isolation of various combinations of pump(s) discharge valve(s)

Note: PWROG Rev. 1 (6/5/09) Scenario No. 51 and PWROG Rev. 3 (10/11) Scenario No. 53

50.1. Description:

Spurious isolation of pump discharge flow

OR

Spurious operation of various valves causing flow diversion

Note: Spurious operation of powered (i.e., MOVs, AOVs, SOVs) pump(s) discharge valve(s) are most likely already included in the PRA logic and the safe shutdown cable analysis.

50.2. Notes:

- Scenario causes pump operation at shutoff head and subsequent inoperability. All credited pumps should be reviewed for this scenario.
- Note that spurious starting of idle pump(s), in combination with isolation of discharge flow and recirculation, may cause inoperability of additional pumps. Spurious pump starting can occur for several reasons, including fire damage to control circuitry or a spurious ESFAS signal.
- All credited flow paths should be reviewed for MSO scenarios that can divert flow away from desired location. An example is AFW pump flow diversion through the recirculation flow path back to the emergency Feed water storage tank failing the AFW makeup to steam generator function.

50.3. WBN Unit 2 Safe Shutdown Compliance:

50.3.1. The primary pumps including associated discharge and cross-connect valves that should be evaluated are the CCPs, CCS Pumps, ERCW Pumps, and TDAFW/MDAFW Pumps. The CCPs are addressed in scenario 9; the CCS pumps are addressed in scenario 39; the ERCW Pumps are addressed in scenario 42, and TDAFW/MDAFW are addressed in scenario 27.

50.3.2. The primary pumps associated with valves causing flow diversion that should be evaluated are the CCPs, CCS pumps, ERCW pumps and TDAFW/MDAFW pumps. The CCPs are addressed in scenarios 2, 35a; the CCS pumps are addressed in scenario 41; the ERCW pumps are addressed in scenario 44; and the TDAFW/MDAFW pumps are addressed in scenarios 29, 31.

51.0 PWROG Scenario 51: Other Scenarios - Pump failure due to spurious closure of discharge valve(s) concurrent with failure to open or spurious closure of required minimum recirculation flow path(s)

Note: PWROG Rev. 1 (6/5/09) Scenario No. 51 and PWROG Rev.3 (10/11) Scenario 52.

51.1. Description:

Spurious isolation of pump discharge flow path

AND

Spurious isolation of recirculation valve(s)

Spurious operation of various valves causing flow diversion

51.2. Notes:

- Scenario causes pump failure. All credited pumps should be reviewed for this scenario.
- Operation at shutoff head can occur, for example, if pump discharge flow spuriously isolates with the recirculation valves closed. Run-out can occur, for example, if the discharge header is at reduced pressure conditions.
- Note that spurious starting of idle pump(s), in combination with isolation of discharge flow and recirculation, may cause failure of additional pumps. Spurious pump starting can occur for several reasons, including fire damage to control circuitry or an inadvertent ESFAS signal.

51.3. WBN Unit 2 Safe Shutdown Compliance:

51.3.1. The primary pumps including associated discharge and recirculation valves that should be evaluated are the CCPs, CCS Pumps, ERCW pumps, and TDAFW/MDAFW Pumps. The discharge valves for CCPs are addressed in scenario 9; CCS pump discharge valves are addressed in scenario 39; the ERCW pump discharge valves are addressed in scenario 42; and the auxiliary feedwater pump discharge valves are addressed in scenario 27. The CCPs recirculation valves 1-FCV-62-98-A, -99-B are Locked Open. The CCS pumps and the TDAFW/MDAFW recirculation lines contain only normally open manual valves.

51.3.2. RHR pump spurious start concurrent with closure of the recirculation valves is evaluated in the FSSD analysis.

51.3.3. CCP run out is addressed in scenario 13a and MDAFW pump run out is addressed in scenario 30.

51a.0 PWROG Scenario xx: Other Scenarios - Spurious start of high head charging pump(s) concurrent with closing of required minimum flow path valve(s) results in failure of the pump(s)

51a.1 Description:

High head charging pump(s) spuriously starts

AND

Recirculation flow path valve(s) fails to open OR transfers closed

51a.2 Notes:

This scenario results in failure of the high head charging pump(s).

51a.3 WBN Unit 2 Safe Shutdown Compliance:

51a.3.1 The centrifugal charging pump recirculation valves, 2-FCV-62-98-A and -99-B are open with power removed.

51a.3.2 Overheating of the charging pump suction due to loss of component cooling system (CCS) flow to the seal water return heat exchanger has been addressed in the FSSD analysis.

51a.3.3 Loss of suction to the CCP has been reviewed and determined that one CCP will always survive considering multiple spurious of either VCT suction valve, loss of either RWST suction valves, loss of or multiple spurious start of CCPs, spurious SI, and loss of CCP HVAC. For AV-106, fire on the RWST suction valves, VCT must be isolated and RWST established by opening either suction valve within 75 minutes.

51b.0 PWROG Scenario 51b: Other Scenarios - Spurious start of high pressure safety injection pump(s) concurrent with closing of required minimum flow path valve(s) results in failure of the pump(s)

51b.1 Description:

High pressure safety injection pump(s) spuriously starts

AND

Recirculation flow path valve(s) fails to open OR transfers closed

51b.2 Notes:

This scenario results in failure of the high head injection pump(s).

51b.3 WBN Unit 2 Safe Shutdown Compliance:

51b.3.1 The safety injection pumps are intermediate head injection pumps and are not actively credited in the FSSD analysis. The FSSD analysis ensures that the pumps are stopped prior to decreasing RCS pressure below the SI pump injection pressure (60 minutes).

51c.0 PWROG Scenario 51c: Other Scenarios - Spurious operation of residual heat removal (RHR) shutdown cooling (SDC) / low pressure safety injection pump(s) concurrent with failure of associated minimum flow path valve(s) to open results in failure of the pump(s)

51c.1 Description:

Residual heat removal (RHR) / shutdown cooling (SDC) / low pressure safety injection pump(s) spuriously starts

AND

Recirculation flow path valve(s) fails to open OR transfers closed

51c.2 Notes:

None

51c.3 WBN Unit 2 Safe Shutdown Compliance:

51c.3.1 RHR pump spurious start concurrent with closure of the recirculation valves is evaluated in the FSSD analysis.

52.0 PWROG Scenario 52: Other Scenarios - Loss of credited heating, ventilation and air conditioning (HVAC) to component(s)

Note: PWROG Rev. 1 (6/5/09) Scenario No. 54

52.1. Description:

Spurious isolation of HVAC to credited loads

52.2. Notes:

- Perform review to identify spurious failures that could cause isolation of HVAC to credited loads. Credited loads may include pump rooms, switchgear rooms and rooms containing solid state control systems. Examples of spurious failures include spurious damper isolation and spurious isolation of cooling flow to chillers.
- One should expect to find disconnects between PRA and safe shutdown success criteria with respect to HVAC requirements. While one might expect to find instances where the safe shutdown analysis requires HVAC and the PRA does not (i.e., where the safe shutdown analysis is more conservative), we have encountered at least one instance where the opposite was true (i.e.,

the PRA was more conservative and required pump room HVAC that the safe shutdown analysis did not require).

52.3. WBN Unit 2 Safe Shutdown Compliance:

52.3.1. The HVAC systems (including ERCW supply, temperature control valves and dampers) listed below are included in the FSSD analysis to ensure adequate cooling for credited equipment for each fire scenario:

Lower Compartment coolers

Control Rod Drive Mechanism coolers

Main Control Room coolers

RHR Pump Room coolers

Centrifugal Charging Pump Room coolers

TDAFW Pump Room Exhaust Fan

CCS & MDAFW area coolers

Diesel Generator Building exhaust fans

Shutdown Board Transformer Rm exhaust fans

53.0 PWROG Scenario 53: Other Scenarios - Spurious motor operated valve (MOV) operation concurrent with fire-induced failure of torque and / or limit switches

Note: PWROG Rev. 1 (6/5/09) Scenario No. 55

53.1. Description:

Spurious motor-operated valve operation

AND

Wire-to-wire short(s) bypass torque and limit switches

53.2. Notes:

- General scenario is that fire damage to motor-operated valve circuitry causes spurious operation. If the same fire causes wire-to-wire short(s) such that the valve torque and limit switches are bypassed, then the valve motor may stall at the end of the valve cycle. This can cause excess current in the valve motor windings

as well as valve mechanical damage. This mechanical damage may be sufficient to prevent manual operation of the valve.

- This scenario only applies to motor-operated valves.
- This generic issue may have already been addressed during disposition of NRC Information Notice 92-18. This disposition should be reviewed in the context of multiple spurious operations and multiple hot shorts.

53.3. WBN Unit 2 Safe Shutdown Compliance:

53.3.1. WBN's standard MOV control circuit design provides full compliance with IN 92-18. Damage from a control building fire cannot bypass the valve end of travel limit/torque switch.

53.3.2. For all MOV's required to be manually operated to achieve cold shutdown following a fire outside the control building, a review has been performed to ensure that, if fire damage could cause spurious valve operation and the limit/torque switch could be bypassed, the MOV motor stall torque could not damage the valve operator such that the valve could not be manually operated. Modifications have been incorporated as needed to prevent valve stalling and ensure that the valve can be manually operated.

53.3.3. WBN Unit 1 identified this condition in PER 227808.

54.0 **PWROG Scenario 54: Other Scenarios - Spurious engineered safeguards actuation signal (ESFAS)**

Note: PWROG Rev. 1 (6/5/09) Scenario No. 56

54.1. Description:

Fire induced spurious ESFAS signal

54.2. Notes:

- Fire-induced spurious ESFAS signals (e.g., safety injection, containment isolation, etc), combined with other fire-induced failures, can adversely affect safe shutdown capability. An example of a fire-induced ESFAS signal is a fire causing open circuits on 2/3 main steam pressure instruments on one loop resulting in a spurious safety injection signal. ESFAS signals can result from open circuits, shorts to ground, and/or hot shorts. Fire-induced failure of instrument inverters may also cause spurious ESFAS signals. The plant should perform a systematic review to assess the potential for fire-induced spurious ESFAS to adversely affect safe shutdown capability. Some

examples are shown in PWR Owners Group scenarios 54a, 54b, 54c, 54d and 54e.

54.3. WBN Unit 2 Safe Shutdown Compliance:

54.3.1. FSSD design changes have been incorporated to provide adequate physical separation between redundant sensing instruments and cables such that fire damage cannot cause a spurious ESFAS except for a control building fire. The control building is an alternative shutdown area. For control building fires that could cause a spurious ESFAS the control room will be abandoned and safe shutdown achieved from the auxiliary control system stations.

54a.0 PWROG Scenario 54a: Other Scenarios - Spurious start of makeup / injection pump(s) due to a spurious safety injection signal with concurrent spurious isolation of pump suction valve(s)

Note: PWROG Rev. 1 (6/5/09) Scenario No. 56a

54a.1 Description:

Spurious safety injection signal

AND

Spurious isolation of makeup pump suction

54a.2 Notes:

Safety injection signal starts multiple RCS makeup pumps. Fire causes makeup pump suction valves to fail closed. Scenario results in cavitation / inoperability of multiple RCS makeup pumps.

54a.3 WBN Unit 2 Safe Shutdown Compliance:

54a.3.1 FSSD design changes have been incorporated to provide adequate physical separation between redundant sensing instruments and cables such that fire damage cannot cause a spurious ESFAS except for a control building fire. The control building is an alternative shutdown area. For control building fires that could cause a spurious ESFAS the control room will be abandoned and safe shutdown achieved from the auxiliary control system stations.

54b.0 PWROG Scenario 54b: Other Scenarios - Spurious isolation of reactor coolant pump(s) thermal barrier cooling due to a spurious containment isolation signal with a concurrent isolation of seal injection

Note: PWROG Rev. 1 (6/5/09) Scenario No. 56c (similar)

54b.1 Description:

Spurious containment isolation signal isolates component cooling water (CCW) to the thermal barrier heat exchangers for all reactor coolant pumps (RCPs)

AND

Spurious isolation of seal injection header flow

54b.2 Notes:

Scenario causes loss of all RCP seal cooling and subsequent RCP Seal LOCA.

54b.3 WBN Unit 2 Safe Shutdown Compliance:

54b.3.1 FSSD design changes have been incorporated to provide adequate physical separation between redundant sensing instruments and cables such that fire damage cannot cause a spurious ESFAS except for a control building fire. The control building is an alternative shutdown area. For control building fires that could cause a spurious ESFAS the control room will be abandoned and safe shutdown achieved from the auxiliary control system stations.

54c.0 PWROG Scenario 54c: Other Scenarios - Spurious isolation of reactor coolant pump(s) thermal barrier cooling due to a spurious containment isolation signal with a concurrent isolation of charging

Note: PWROG Rev. 1 (6/5/09) Scenario No. 56c

54c.1 Description:

Spurious containment isolation signal isolates CCW to the thermal barrier heat exchangers for all RCPs

AND

Spurious opening of charging injection valve(s) causing insufficient flow to seals

54c.2 Notes:

Scenario causes loss of all RCP seal cooling and subsequent RCP Seal LOCA.

54c.3 WBN Unit 2 Safe Shutdown Compliance:

54c.3.1 FSSD design changes have been incorporated to provide adequate physical separation between redundant sensing instruments and cables such that fire damage cannot cause a spurious ESFAS except for a control building fire. The control building is an alternative shutdown area. For control building fires that could cause a spurious ESFAS the control room will be abandoned and safe shutdown achieved from the auxiliary control system stations.

54d.0 PWROG Scenario 54d: Other Scenarios - Spurious start of containment spray pump(s) due to a spurious containment spray signal

Note: PWROG Rev. 1 (6/5/09) Scenario No. 56d

54d.1 Description:

Spurious high containment pressure on multiple channels causing spurious containment spray signal

54d.2 Notes:

Scenario causes a pumped RWST drain down via the containment spray pumps and containment spray ring.

54d.3 WBN Unit 2 Safe Shutdown Compliance:

54d.3.1 FSSD design changes have been incorporated to provide adequate physical separation between redundant sensing instruments and cables such that fire damage cannot cause a spurious ESFAS except for a control building fire. The control building is an alternative shutdown area. For control building fires that could cause a spurious ESFAS the control room will be abandoned and safe shutdown achieved from the auxiliary control system stations.

54d.3.2 For all AVs except AV-042 and AV-057, either the containment spray pumps can be tripped from the main control room or the containment spray header isolation valves are closed which will prevent RWST drain down via the containment spray ring. For a fire inside the 6.9kv shutdown board room A (AV-042) and B (AV-057), the board is de-energized by tripping the feeder breakers (normal, auxiliary,

maintenance) and the EDG within 10 minutes. De-energizing the board stops the containment spray pump.

54e.0 PWROG Scenario 54e: Other Scenarios - Spurious opening of PORV(s) due to spurious high pressurizer pressure signals on multiple channels

Note: PWROG Rev. 1 (6/5/09) Scenario No. 56e

54e.1 Description:

Spurious high pressurizer pressure on multiple channels causes high pressurizer pressure signal

54e.2 Notes:

Spurious high pressurizer pressure on multiple channels causes high pressurizer pressure signal

54e.3 WBN Unit 2 Safe Shutdown Compliance:

54e.3.1 Spurious opening of the PORVs is evaluated in the FSSD analysis. The pressure sensing instrumentation and cables are included in the analysis. For every fire scenario either the PORV or its in-line block valve is credited for maintaining RCS pressure. See scenarios 17 and 18 for additional details.

54f.0 PWROG Scenario 54f: Other Scenarios - Spurious Recirculation Actuation Signal (RAS) starting and aligning pumps to a dry containment sump.

Added on 6/5/09 NEI 00-01 Rev 2 list (Item 56f)

54f.1 Description:

Spurious Recirculation Actuation Signal (RAS) starting and aligning pumps to a dry containment sump.

54f.2 Notes:

- None

54f.3 WBN Unit 2 Safe Shutdown Compliance:

54f.3.1 WBN design, upon a high containment sump level, in conjunction with a low RWST level and SI signal, will initiate closure of the RHR pump suction valve and open the containment sump valves (concurrently). There are no AVs where a high containment sump level will occur. In

addition, a Unit 2 spurious SI signal can only occur with a fire in the Control Building. For a control building fire that could cause a spurious ESFAS control of the containment sump level and RHR pump suction valves will be transferred to the auxiliary control system stations.

- 54f.3.2 There are no AVs where a spurious start of RHR pump occurs concurrently with a spurious closure of the respective suction valve (2-FCV-74-3-A, -21-B). The common suction valve from the RWST (2-FCV-63-1) is open with power removed.

Appendix B

UNIT 2 RESOLUTIONS

MSO#	Resolutions	Comment
5 Section 5.3.2	<u>Resolution</u> RCP Seal Leakoff valves have been added to the FSSD analysis. Plant modifications have been incorporated to ensure MCR operator actions for reactor building non-essential control air header isolation (2-FCV-32-111-B) and venting (2-XSV-32-112A1, -112A2, -112B1, & -112B2) to fail open the seal leakoff valves on loss of control air.	Unit 1 PER 227833 EDCR 57938 DCN 58390
5 5.3.3	<u>Resolution</u> Relocated the cables for 2-FCV-62-22 and 2-FCV-62-48 out of AV-057.	EDCR 53421 FCR 60953 Complete
22 Section 22.3.1	A third "C" solenoid of opposite train from the existing "A & B" solenoid valves has been added to Unit 2. It is located in a separate fire zone and its cables are routed separately from the "A & B" solenoid valves for each PORV.	Previously identified design change EDCR 53178
26 Section 26.3.1	For AV-038 the cables listed below have been relocated out of AV-038 to prevent spurious isolation of the steam supply to the TDAFW pump. Cables 2V2635B, 2V2633B, 2V2623A, 2V1831A, 2PV83A, 2V1832A, 2V1833A, 2V2625A, 2V2621A.	EDCRs 54631, 54636, 55494, 56638, 57938

MSO#	Resolutions	Comment
15 Section 15.3.1 15a Section 15a.3.1 36 Section 36.3.1	Modification DCN 58383 added a switch to L-11A and/or L-11B that will select between main control room and auxiliary control room and the EDG trip circuit is powered from a 125V Vital Battery Board feed whose cable is not be routed in the board room. Associated cables to the MCR and DG building kill switches are routed outside the board room. This modification has been done for each of the four EDGs.	Unit 1 PER 227839 Complete
46 Section 46.3.1	Implementation of DCN 58383 renamed cables 1B27G, 1B32G, 1PL5396B, and 1PL5398B to 1B20G, 1B21G, 1PL1191B, and 1PL1192B and relocated them out of AV-059 to ensure that EDG-1B-B could not be overloaded due to fire damage in AV-059.	Unit 1 PER 227839 Complete

Enclosure 5
TVA Comments on
Supplemental Safety Evaluation Report 26

Enclosure 5
Tennessee Valley Authority's (TVA's)
Comments on Supplemental Safety Evaluation Report (SSER) 26

The following represents sections of SSER 26 for which suggested SSER revisions are noted. Most of the revisions are provided to align the SSER with the actual configuration of WBN and/or the Fire Protection Report (FPR). Suggested revisions are shown in **bold**.

1. SSER 26, Section 3.1.4 - third paragraph states:

TVA stated that in areas protected by automatic CO2 suppression systems, fire doors close upon the CO2 system actuation. The thermal link on the fire doors actuates and closes prior to CO2 fire suppression system discharge.

Suggested SSER revision:

TVA stated that in areas protected by automatic CO2 suppression systems, **sliding** fire doors close upon the CO2 system actuation. **The sliding fire doors will also close when heat melts the fusible link. The swinging doors are normally closed and thus are closed prior to actuation of the CO2 system.**

Basis: Part II, Sections 12.3.3 and 12.10.4 and Part VII, Section 5.2

2. SSER 26, Section 3.1.5 and SSER 26, Section 4.2.1.2 - Paragraph 2 of Section 3.1.5 (below), does not address that some dampers are closed by the HVAC controls. A suggested SSER revision for Section 3.1.5 is provided below:

In **selected** areas protected by automatic CO2 suppression systems, these dampers also close during the CO2 system discharge. ~~The~~**When** fire dampers ~~that~~**provide CO2 suppression system isolation capability, the fire dampers** are actuated by a release mechanism when the CO2 system activates, if not actuated by a thermal link prior to CO2 system discharge.

Paragraph 4 of Section 4.2.1.2 (below) should be clarified as shown below:

In addition, TVA stated that the actuation of these systems causes selected ~~fire~~**fire** dampers and doors to the protected area to close and ~~these~~**selected HVAC** fans to the area to shut down, ensuring that the minimum concentration of CO2 is maintained and preventing fire spread from the area of fire origin. TVA also stated that it has performed full discharge tests for representative rooms in conjunction with door fan pressurization tests to validate CO2 concentration and soak times.

Basis: Part II, Section 12.5, 6th paragraph and Part II, Section 12.3.3, 5th paragraph.

3. SSER 26, Section 4.1, page FF-35 - 2nd full paragraph from the bottom, suggested SSER revision:

“TVA stated that the HPFP system is interconnected to the raw cooling water (RCW) ~~system and raw service water (RSW) systems~~. Automatic isolation valves are provided to isolate the RCW system and selected ~~RCW~~**RCW RSW** loads from the HPFP system when any fire pump is started to reduce the ~~RCW RSW~~**RCW RSW** load on the HPFP system to ensure adequate flow and pressure are available.

Enclosure 5
Tennessee Valley Authority's (TVA's)
Comments on Supplemental Safety Evaluation Report (SSER) 26

During normal operation, HPFP system pressure is maintained by the RCW pumps.”

Basis: Part II, Section 12.1, 6th and 7th paragraphs

4. SSER 26. Section 4.1, page FF-35 - last full paragraph, suggested SSER revision:

“The buried steel piping has an exterior coating to prevent corrosion. The electric fire pumps feed the steel headers **and the iron yard main** and the diesel pump feeds the iron yard main. The two loops (iron and steel) are connected at the IPS (via normally open valve 0-FCV-26-17) and at two remote points in the auxiliary building (via normally open valves 0-FCV-26-15 and 0-FCV-26-16). TVA stated that pressure control is provided by a pressure control valve downstream of the four electric pumps **and downstream of the diesel fire pump.**”

Basis: TVA Letter dated May 26, 2011, RAI FPR VII-2

5. SSER 26. Section 4.1, page FF-36 - in first, partial paragraph, suggested SSER revision:

“Because the two headers are redundant and because they are also connected to the iron yard main through valves in the **turbine auxiliary** building and Intake Pumping Station, the plant could isolate either main and would still have two sources of fire water available.”

Basis: WBN Drawing series 47W850

6. SSER 26. Section 4.1, page FF-36 - in 2nd, full paragraph, suggested SSER revision:

In the FPR, TVA stated that the WBN fire water supply system as being able to provide the designed fire-fighting capacity either with one electric pump and the diesel pump unavailable or with the hydraulically least demanding portion of any loop main out of service. TVA further stated that the design flow demand consists of design flow to the largest sprinkler or water spray system plus design flow to non-isolated **RCW RSW** loads and 500 gpm for hose streams.

Basis: Part VII, Section 3.3, “HPFP Hydraulic Calculation Results”, 1st paragraph

7. SSER 26. Section 4.1, page FF-36 - in 5th, full paragraph, suggested SSER revision:

TVA’s design calculation reduces the actual **unlined steel** pipe inside diameter by 0.8 inches and uses a Hazen-Williams C factor of 55 for the sections of piping that are normally wetted.

Basis: Suggested revision for clarity since the diameter of the cement lined pipe is not treated in this manner because it will not corrode. TVA has revised the corresponding sentence in Part VII, Section 3.3 for clarity.

Enclosure 5
Tennessee Valley Authority's (TVA's)
Comments on Supplemental Safety Evaluation Report (SSER) 26

8. SSER 26, Section 4.1 - paragraph 6 (Page FF-34) states:

Supervised (emphasis added by TVA) alarm circuits, indicating fire pump motor running condition and loss of line power on the line side of the switchgear, are provided in the MCR for each electric pump.

Suggested SSER revision:

~~Supervised alarm circuits, indicating~~ Indications of fire pump motor running condition and loss of line power on the line side of the switchgear are provided in the MCR for each electric pump.

Basis: The above states that the condition of the electric fire pump motor running and loss of line power annunciation circuits are supervised when in reality they are not supervised. A supervised circuit has features that alarm if something occurs to disable the alarm circuit. These circuits do not have this feature. The fire pump motor running status and loss of line power on the line side have indications in the MCR but the circuits are not supervised. This is consistent with the wording in FPR Part II, Section 12.1, 4th paragraph.

9. SSER 26, Section 4.2.1.1, page FF-38 - 2nd full paragraph after the bullets states:

TVA used the guidance of NFPA 13 to design the directional fusible nozzle water spray systems used to protect certain charcoal filters and the RCPs.

Suggested SSER revision:

TVA used the guidance of NFPA 13 **and 15** to design the directional fusible nozzle water spray systems used to protect certain charcoal filters and the RCPs.

Basis: These features are addressed by Part X, Section 3.3.1.2

10. SSER 26, Sec 5.1 - 5th full paragraph suggested SSER revision:

"TVA stated that areas of divisional interaction within the annulus areas are protected by automatic fixed water-spray systems and **ionization photoelectric** smoke detectors. ~~Additionally, fixed waterspray systems are provided for the charcoal and HEPA filters in the lower containment air cleanup units.~~ Thermal detectors are provided for the charcoal filters and HEPA filters. Ionization duct detectors are provided for each lower containment cooling unit and each upper compartment cooling unit. In addition, ionization smoke detectors are provided for the exhaust ducts serving the containment purge and air exhaust systems and the emergency gas treatment system."

Basis: The detectors in this area are photoelectric rather than ionization. Part X, Section 3.3.1.2 states there are no fixed waterspray systems provided for the charcoal and HEPA filters in the lower containment air cleanup units.

Enclosure 5
Tennessee Valley Authority's (TVA's)
Comments on Supplemental Safety Evaluation Report (SSER) 26

11. SSER 26, Section 5.2.1 - 3rd full paragraph, suggested SSER revision:

"FPR Part VIII summarizes the fire barriers that separate the MCR from the balance of the control building. The MCR is separated from most adjacent rooms on the same elevation in the control building by **non-regulatory** 1-hour rated fire barriers. Doors between the control room and the turbine building and the control room and auxiliary building are 3-hour fire-rated doors. The MCR and the cable spreading room are not separated by a rated fire barrier."

Basis: FPR Figure II-34, WBN Drawing 2-47W240-7

12. SSER 26, Section 5.4 - the last line of the first paragraph, suggested SSER revision:

"...are **provided for** ~~provided in~~ each of the switchgear rooms.

Basis: Some of the standpipe and hose stations are outside the switchgear rooms but are provided for use in that room.

13. SSER 26. Sec, 5.6 - the first paragraph, 6th line, states

TVA stated in FPR Part VIII that turbine building oil hazards are protected by fixed water spray systems.

Suggested SSER revision:

TVA stated in FPR Part VIII that turbine building oil **tank** hazards are protected by fixed water spray systems.

Basis: This is consistent with Part VIII, Section F.8. Not all the oil hazards such as piping and turbine bearings are protected but the oil tank hazards are protected.

14. SSER 26, Section 6.2.3, fifth paragraph, second line - Clarify the stairwell wall to the Mechanical Equipment room is a non-regulatory barrier.

Suggested SSER revision:

The chiller packages are located in the Unit 2 mechanical equipment room, which is not part of Stairwells C1 or C2 or the corridor. However, the room is separated from Stairwell C2 by a 2-hour **rated non-regulatory** reinforced concrete wall.

Basis: FPR Figure II-34, WBN Drawing 2-47W240-7

15. SSER 26, Section 6.2.7.2.1, second paragraph, starting at - There is only one traveling screen room.

Suggested SSER revision:

Remove the "s" in several places as shown below in bold:

Enclosure 5
Tennessee Valley Authority's (TVA's)
Comments on Supplemental Safety Evaluation Report (SSER) 26

In FPR Part VII, Section 2.6.2.1, TVA stated that, contrary to Position D.1.j, on elevation 741.0 feet of the IPS, there are four scupper openings penetrating the fire wall between the ERCW pump rooms and traveling screen rooms.

The wall separating the redundant ERCW pumps and the wall separating the ERCW pumps from the traveling screen pumps are 3-hour fire-rated barriers with the exception of the four scupper openings. These scupper openings are located at the floor and provide drainage of rainwater from the ERCW pump rooms to the traveling screen wells. The floor slopes away from the ERCW pumps toward the scuppers so that a fire in one ERCW pump room will not propagate through the scuppers and jeopardize a redundant train of ERCW pumps.

The wall separating the ERCW pump rooms and traveling screen rooms is intended to protect the rooms from the radiant heat of an exposure fire. The roof is designed as a missile shield and has beams that will allow free air flow from a fire to dissipate heat to the outside environment. ERCW Pump Rooms A and B have heat detectors installed over the ERCW pumps and standpipe and hose stations are accessible for manual fire-fighting activities. TVA stated that even though these rooms are not provided with suppression and full area detection, the fire area barrier ratings are sufficient given the combustible loadings in the area...

...Based on its review of the information submitted by TVA, the NRC staff concludes that the scupper configuration for the wall separating the ERCW pump rooms from the adjacent traveling screen rooms is an acceptable deviation from the guidance in Position D.1.j of Appendix A to BTP (APCSB) 9.5.1.

Basis: WBN FPR Figure II-36, WBN Drawing 2-47W240-9

16. SSER 26, Section 6.2.11 - As discussed in FPR Part VIII, Section D.1.d, the control point is for Radiation Protection and not Security.

Suggested SSER revision:

6.2.11 Evaluation – Plexiglass Windows in the **Radiation Protection** Control Point Building on the Refueling Floor

TVA committed to the guidance in Position D.1.d in Appendix A to BTP (APCSB) 9.5-1, which states, in part, that interior finishes should be noncombustible or have a flame spread rating of 25 or less.

In FPR Part VIII, TVA stated that, contrary to the guidance, the windows in a **Radiation Protection** control point building (on the 757.0 feet elevation on the Refueling Floor) was built with plexiglass windows, which do not meet the flame spread criteria. TVA stated the following concerning the plexiglass windows:

- Based on operating experience at Sequoyah Nuclear Plant, (i.e., a near-miss incident), glass windows pose a safety concern.
- Available alternatives either do not meet the flame spread criteria, or are not sufficiently transparent.
- The plexiglass windows add an insignificant amount of combustibles to a large room.

Enclosure 5
Tennessee Valley Authority's (TVA's)
Comments on Supplemental Safety Evaluation Report (SSER) 26

- The plexiglass windows have no effect on the safe shutdown analysis.
- The building is not used for safe shutdown.

Based on its review of the information submitted by TVA, the NRC staff concludes that, because of the minimal amount of combustibles involved and the lack of an effect on safe shutdown, the presence of the plexiglass windows in the **Radiation Protection** control point building on the Refueling Floor is an acceptable deviation from the guidance in Position D.1.d of Appendix A to BTP (APCSB) 9.5-1.

Basis: The control point on the Refuel floor is for the Radiation Protection staff.

17. SSER 26, Section 6.3.4.3 states:

TVA stated that Rooms 676.0-A2 and 676.0-A3 are separated from adjacent non-high radiation area rooms by 2-and 3-hour fire rated barriers of reinforced concrete construction. Clarify that the barriers are 2 hour non-regulatory.

Suggested SSER revision:

TVA stated that Rooms 676.0-A2 and 676.0-A3 are separated from adjacent non-high radiation area rooms by **2-hour non-regulatory** fire rated barriers of reinforced concrete construction.

Basis: FPR Figure II-27, WBN Drawing 2-47W240-11

18. SSER 26, Sec 6.3.4.4 states:

TVA stated that Rooms 692.0-A3 and 692.0-A5 are separated from adjacent non-high radiation area rooms by 2-and 3-hour fire rated barriers of reinforced concrete construction. Clarify that some of the barriers are 2 hour non-regulatory.

Suggested SSER revision:

TVA stated that Rooms 692.0-A3 and 692.0-A5 are separated from adjacent non-high radiation area rooms by ~~2-and~~ 3-hour **regulatory and 2-hour non-regulatory** fire rated barriers of reinforced concrete construction.

Basis: FPR Figure II-28, WBN Drawing 2-47W240-1

19. SSER 26, Section 6.3.4.5 states:

TVA stated that the barriers between Rooms 676.0-A2 and 676.0-A3, Rooms 676.0-A2 and 692.0-A3, and Rooms 692.0-A3 and 692.0-A5 are not accessible because of the high levels of radiation present in these rooms. Clarify these are non-regulatory barriers

Enclosure 5
Tennessee Valley Authority's (TVA's)
Comments on Supplemental Safety Evaluation Report (SSER) 26

Suggested SSER revision:

TVA stated that the **non-regulatory** barriers between Rooms 676.0-A2 and 676.0-A3, Rooms 676.0-A2 and 692.0-A3, and Rooms 692.0-A3 and 692.0-A5 are not accessible because of the high levels of radiation present in these rooms. Basis: FPR Figure II-27, WBN Drawing 2-47W240-11

20. SSER 26, Section 6.1.2 states:

TVA evaluated this deviation in FPR Part VII, Section 2.2. The RESs installed inside the reactor buildings at WBN are Minnesota Mining and Manufacturing (3M) M20A in the annulus, and M20C in the Unit 1 primary containment.

The use of the term "reactor buildings" implies that the M20 material is used in both the Unit 1 and the Unit 2 reactor buildings. The M20 material is not used in the Unit 2 reactor building.

Suggested SSER revision:

TVA evaluated this deviation in FPR Part VII, Section 2.2. The RESs installed inside the reactor ~~buildingbuildings~~ at WBN are Minnesota Mining and Manufacturing (3M) M20A in the annulus, and M20C in the Unit 1 primary containment.

Comments needing FPR correction and possible SSER revision.

1. SSER 26, Section 2.4.2.2 - The present WBN fire protection procedures do not require fire watch for all hot work in the safety related areas. Work such as underwater welding, outside areas and electric soldering are excluded. This appears to conflict with the second half of the first paragraph of the SSER.

FPR Part II, Section 11.0, 2nd paragraph was revised for clarity as:

Designated ignition source activity areas are reviewed and approved by the fire protection organization. A fire watch system shall be established for all ignition source work activities that are performed in safety-related areas of the plant except for specific non-risk ignition source activities of underwater welding, outside areas (fences, light poles, etc.), and electric soldering. These fire watches remain with the work activity in accordance with the requirements stated in NPG-SPP-18.4.8 (Ref. 4.2.65).

NRC SSER 26, Section 2.4.2.2 suggested SSER revision for the end of the first paragraph:

In addition, TVA's program has established a hot work fire watch for all ignition source work activities that are performed in safety-related and safe-shutdown areas of the plant except for specific non-risk ignition source activities of underwater welding, outside areas (fences, light poles, etc.), and electric soldering.

Enclosure 5
Tennessee Valley Authority's (TVA's)
Comments on Supplemental Safety Evaluation Report (SSER) 26

2. SSER 26, Section 2.5.2, page FF-10 - The second full paragraph needs to be clarified that eligibility status is not removed until tolerance has expired.

The SSER states:

TVA stated that if a brigade member misses or does not complete a training session, either annual or quarterly; the member is placed in an ineligible status until the training is completed.

TVA revised Part II, Section 9.3.b as:

Any individual who misses or fails to complete recurrent training is placed in an ineligible status **when the current training expires** until the training is **completed** in accordance with site procedure (Ref. 4.2.80)

NRC SSER 26, section 2.5.2 suggested SSER revision:

TVA stated that **any individual who misses or fails to complete recurrent training is placed in an ineligible status when the current training (including the 25 percent extension) expires. The individual is ineligible until the missed training is made-up in accordance with the site procedure.**

3. SSER 26, Section 4.1 (4), page FF-35 - states:

"The fire pumps can only be manually stopped from the MCR or in the IPS (where the pumps are located)."

In reality, the electric fire pumps cannot be shut down from the IPS but can be in the MCR and at the applicable switchgear in the shutdown board rooms and the diesel pump can only be shut down locally at the pump.

FPR Part VII, section 5.1 currently states:

Outside of the Intake Pumping Station itself where the pumps are located, the fire pumps can only be manually stopped from the main control room, which is constantly manned by operations personnel, thereby providing adequate controls over when the fire pumps can be stopped.

This section was revised as follows:

The electric fire pumps can only be manually stopped from the main control room, which is constantly manned by operations personnel, or the shutdown board rooms. The diesel fire pump can only be stopped locally at the pump. These features provide adequate controls over when the fire pumps can be stopped.

NRC SSER 26, Section 4.1 (4) suggested SSER revision:

The electric fire pumps can only be manually stopped from the main control room, which is constantly manned by operations personnel, or the

Enclosure 5
Tennessee Valley Authority's (TVA's)
Comments on Supplemental Safety Evaluation Report (SSER) 26

shutdown board rooms. The diesel fire pump can only be stopped locally at the pump.

4. SSER 26, Section 5.2.1 - 4th full paragraph, states:

"FPR Part VIII describes the use of cables in the MCR. TVA stated that (1) wiring for lighting terminates in the lighting fixtures, (2) instrumentation and control wiring enters through the bottom of cabinets and runs only inside the panels or control boards in which the wires are terminated, and (3) cable are not routed through the control room from one area to another area."

Revise FPR Part VIII, Section F.2 "Plant Conformance" as follows:

Lighting wiring terminates in the lighting fixtures. Instrumentation and control wiring terminates inside the panels or control boards. Cable is not routed through the control room from one area to another.

NRC SSER 26, Section 5.2.1 suggested SSER revision:

"FPR Part VIII describes the use of cables in the MCR. TVA stated 1) lighting wiring terminates in the lighting fixtures, 2) instrumentation and control cables terminate inside the panels or control boards, and 3) all cables that enter the control room terminate in the control room (cable is not routed through the control room from one area to another).

5. Revised FPR Part VIII, Section F.2, "Plant Conformance" column to state:

Ionization smoke detectors are provided in selected cabinets in the MCR. General area fire alarms in the MCR and other areas of the plant will alarm and annunciate in the constantly attended MCR to alert the operators of a fire.

NRC SSER 26, Section 5.2.1, paragraph 6 - suggested SSER revision:

"TVA stated that ionization smoke detectors are provided in selected cabinets. TVA further stated that fire alarms in other parts of the plant, as well as the MCR, alarm and annunciate in a constantly attended location in the MCR."

6. SSER 26, Section 5.5 - The last sentence of the first paragraph is inaccurate in that some rooms in auxiliary building have combustible loading that exceeds the rating of the surrounding barriers.

WBN added Evaluation 3.6 to FPR Part VII:

WBN requests NRC approval of this deviation and associated revision to SSER 26, Section 5.5

7. SSER 26, Section 6.1.4 - Third paragraph, the statement of transformer silicon liquid in the Auxiliary Building conflicts with the statement in Section 5.11.2, 4th paragraph on buffer areas.

Enclosure 5
Tennessee Valley Authority's (TVA's)
Comments on Supplemental Safety Evaluation Report (SSER) 26

SSER 26, Section 5.11.2 states:

In its response dated September 30, 2011, to RAI VIII-21.1, TVA provided additional information regarding the installation of transformers containing "high fire point" silicone fluid. The NRC staff questioned the location of these transformers in plant areas that constitute buffer zones between analysis volumes, since the transformers were not described as being located in the buffer zones. TVA confirmed, in its RAI response that the transformers are not located in buffer zones for large fire areas, except for in the electrical equipment room in the IPS.

SSER 26, Section 6.1.4 states:

The intervening combustibles in the auxiliary building are mainly in the form of insulation on cables in open ladder type cable trays and Thermo-Lag fire barrier material. The remaining in situ combustible loading consists of lubricating oil in pumps, motors, and valves; transformer silicon liquid; and plastics in electrical panels, junction boxes, etc. The intervening combustibles in the IPS electric equipment room are mainly in the form of insulation on cables in open ladder type cable trays and transformer silicone liquid. The remaining in situ combustible loading consists of lubricating oil in small pumps, plastics associated with electrical panels, junction boxes, etc. Discussion of the nature of the transformer silicon liquid can be found in Section 5.11.2 of this evaluation.

TVA's 9/30/11 submittal states that the IPS is the only place where the silicon liquid is in the buffer zone. Part VII, Section 2.4 is not clear on this issue and seems to imply the Auxiliary Building is also involved.

FPR Part VII, Section 2.4 was revised to include the words in **bold** below:

DEVIATION - Safe shutdown components in the auxiliary building and Electrical Equipment room in the Intake Pumping Station (IPS) are in compliance with III.G.2.b requirements except that intervening combustibles, in the form of fluid filled transformers (**IPS only**), insulation on cables in open ladder type cable trays and Thermo-Lag fire barrier material, are located between the redundant components.

JUSTIFICATION - The combustible loading in the areas of the auxiliary building where redundant safe shutdown components are spatially separated is primarily the insulation on the cables in the cable trays and the Thermo-Lag fire barrier material (90% to 96%). The remaining in situ combustible loading consists of lubricating oil in pumps, motors, and valves; transformer silicone liquid (**IPS only**); plastics in electrical panels and junction boxes, etc. The combustible loading in the Electrical Equipment room in the IPS

consists primarily of transformer silicone liquid (approximately 13% of the load) and cables in cable trays (approximately 83% of the load) and the remainder is due to lubricating oil in small pumps and plastics associated with electrical panels and junction boxes, etc.

Suggested NRC SSER Section 6.1.4, third paragraph as shown in **bold**:

Enclosure 5
Tennessee Valley Authority's (TVA's)
Comments on Supplemental Safety Evaluation Report (SSER) 26

The intervening combustibles in the auxiliary building are mainly in the form of insulation on cables in open ladder type cable trays and Thermo-Lag fire barrier material. The remaining in situ combustible loading consists of lubricating oil in pumps, motors, and valves; transformer silicon liquid (**Intake Pumping Station only**); and plastics in electrical panels, junction boxes, etc. The intervening combustibles in the IPS electric equipment room are mainly in the form of insulation on cables in open ladder type cable trays and transformer silicone liquid. The remaining in situ combustible loading consists of lubricating oil in small pumps, plastics associated with electrical panels, junction boxes, etc. Discussion of the nature of the transformer silicon liquid can be found in Section 5.11.2 of this evaluation.

8. SSER 26, Section 6.2.10 regarding the VCT room states:

The rooms on both sides of the doors are provided with automatic fire detection and suppression.

FPR Part VII, Section 3.5 states:

"Both the pipe gallery and the VCT room are provided with automatic detection and suppression."

This statement is in conflict with the actual plant configuration and the information in Table I-1 (which states the VCT room has partial suppression)

Revised FPR Part VII, Section 3.5 as:

Both the pipe gallery and the VCT room (except the entrance labyrinth) are provided with automatic detection and suppression.

NRC SSER 26, Section 6.2.10, second paragraph, third bullet - suggested revision:

The rooms on both sides of the doors (**except VCT room entrance labyrinth**) are provided with automatic fire detection and suppression.

9. SSER 26, Section 6.3.5 - The SSER states that the Diesel Generator Building Lube Oil Storage room is a 3-hour rated compartment. In actuality the room only has one regulatory 3-hr rated fire wall, two walls are non-regulatory, and one wall is not rated. The floor and ceiling are not rated. There is only one fire rated door (D8A) and that door is not described correctly in either SSER 18 or 26. This error (one regulatory door versus two regulatory doors) was identified to the NRC in TVA's letter dated June 27, 2012.

FPR Part VII, Section 5.2 incorrectly describes the fusible link arrangement.

The FPR wording has been revised in in TVA's September 18, 2014 letter to clarify the location of the fusible links. The last sentence of the second paragraph now reads as follows:

Enclosure 5
Tennessee Valley Authority's (TVA's)
Comments on Supplemental Safety Evaluation Report (SSER) 26

“Door D8A, located in the Diesel Generator Building Lube Oil Storage Room, is provided with two fusible links (one directly above the center line of the door and the other higher up) and the door has a CO₂ actuated door release.”

NRC SSER 26, Section 6.3.5, entire section - suggested revision:

The lube oil storage room (Room 742.0-D2) has a regulatory 3-hour fire-rated barrier between Room 742.0-D2 and the adjacent rooms 742.0-D4 and 742.0-D9 and non-regulatory 2-hour fire rated barriers to Room 742.0-D10 and Room 742.0-D1. The other wall for the room and the floor/ceiling are not fire rated.

The configuration at Watts Bar is provided with a swinging hollow metal door in the opening and a sliding fire door. The 3-hour fire rated self closing sliding door (D8A) is in the open position and closes only when the thermal link above the door melts or the CO₂ suppression system for the room discharges. Door D8A, located in the Diesel Generator Building Lube Oil Storage Room, is provided with two fusible links (one just above the door and the other higher up), but only on one side. To conform to the guidelines of NFPA 30 and 80, this door should be self-closing. In addition to the sliding door, TVA installed a normally closed hollow metal side-hinged swinging door. TVA stated that this swinging door is similar to rated fire doors and is expected to prevent smoke and hot gases from a fire from passing through the opening until the fusible links melt and the fire rated sliding door closes or the fire suppression system actuates.

10. SSER 26, Section 3.1.5, “Fire Dampers,” states:

“TVA stated that fire dampers have been evaluated per the requirements of NFPA 90A-1975, Standard for the Installation of Air Conditioning and Ventilating Systems.”

The above statement implies WBN is committed to NFPA 90A-1975; however, WBN is not committed to NFPA 90A-1975 and therefore, TVA has clarified the Alternatives column of Item D.1.j of Part VIII, to state:

“...Even though WBN is not committed to NFPA 90A-1975, fire dampers have been evaluated per the requirements of NFPA 90A-1975. Refer to Part X of the FPR. Penetrations for ventilation systems have been designed/evaluated as described in Part X of the FPR.”

TVA has also clarified Section 3.2.9, “NFPA 90A-1975: Air Conditioning and Ventilation Systems,” of Part X to state:

“Closure of dampers under flow conditions has been demonstrated via testing except for two large dampers as evaluated in FPR Part VII, Section 3.4. Large damper closure under air flow conditions is addressed by shutting off HVAC fans.”

Below is a suggested revision to SSER 26, Section 3.1.5, last sentence of first paragraph:

Enclosure 5
Tennessee Valley Authority's (TVA's)
Comments on Supplemental Safety Evaluation Report (SSER) 26

“Even though WBN is not committed to NFPA 90A-1975, TVA stated that fire dampers have been evaluated per the requirements of NFPA 90A-1975, Standard for the Installation of Air Conditioning and Ventilating Systems.

11. SSER 26 Section 6.2.6, second paragraph, second bullet, states:

As described in TVA's letter dated October 28, 2011 (ADAMS Accession No. ML11306A090), in response to NRC question RAI FPR VII-32, the connection between the duct and the purge air system is protected by 3M M20A wrap.

FPR Part VII, Section 3.2, was revised to clarify the fire wrap configuration for Unit 1 and Unit 2 as:

A flexible connection in Room 713.0-A6 is provided between the purge air duct and the embedded containment duct penetration. The flexible connection is protected with 3M M20A fire barrier mat to give a 3-hour rating to the connection. The flexible connection in room 713.0-A19 is protected with 3M E54C (M20A is no longer available and E54C is a superior fire rated replacement for M20A) fire barrier mat to give a 3-hour rating to the connection.

Suggested SSER revision:

As described in **Part VII, Section 3.2, the connection between the duct and the Unit 1 purge air system is protected by 3M M20A wrap and the Unit 2 purge air system is protected by 3M E54 wrap.**

Enclosure 6
Commitment List

1. Once the calculations are issued and the construction is substantially complete, TVA will verify whether completion of these calculations and construction required any further changes to the FPR or resolution in TVA's corrective action program.
2. After the completion of hot functional testing, TVA will notify the NRC that the supporting construction is substantially complete and whether the completion of the construction of Unit 2 impacted the enclosed version of the FPR.
