Abstract: This *Final Site-Wide Environmental Impact Statement for the Continued Operation of the Department of Energy/National Nuclear Security Administration Nevada National Security Site and Off-Site Locations in the State of Nevada (NNSS SWEIS)* analyzes the potential environmental impacts of proposed alternatives for continued management and operation of the Nevada National Security Site (NNSS) (formerly known as the Nevada Test Site) and other U.S. Department of Energy/National Nuclear Security Administration (DOE/NNSA)-managed sites in Nevada, including the Remote Sensing Laboratory (RSL) on Nellis Air Force Base in North Las Vegas, the North Las Vegas Facility (NLVF), the Tonopah Test Range (TTR), and environmental restoration areas on the U.S. Air Force Nevada Test and Training Range. The purpose and need for agency action is to provide support for meeting NNSA's core missions established by Congress and the President and to satisfy the requirements of Executive Orders and comply with Congressional mandates to promote, expedite, and advance the production of environmentally sound energy resources, including renewable energy resources such as solar and geothermal energy systems.

The NNSS has a long history of supporting national security objectives by conducting underground nuclear tests and other nuclear and nonnuclear activities. Since the October 1992 moratorium on nuclear testing, NNSA's mission at the NNSS has evolved from one that focuses on active nuclear weapons tests to one that maintains readiness and the capability to conduct underground nuclear weapons tests; such a test would be conducted only if so directed by the President in the interest of national security. Resources have been reallocated to introduce and expand other mission activities/programs at the NNSS, RSL, NLVF, and TTR to support three DOE/NNSA core missions: National Security/Defense, Environmental Management, and Nondefense. The National Security/Defense Mission includes the Stockpile Stewardship and Management,

Nuclear Emergency Response, Nonproliferation and Counterterrorism, and Work for Others Programs. The Work for Others Program supports other DOE programs and Federal agencies such as the U.S. Department of Defense, U.S. Department of Justice, and U.S. Department of Homeland Security. The Environmental Management Mission includes the Waste Management and Environmental Restoration Programs. The Nondefense Mission includes the General Site Support and Infrastructure, Conservation and Renewable Energy, and Other Research and Development Programs.

The NNSS, RSL, NLVF, and TTR support DOE/NNSA's core missions by providing the capabilities to process and dispose of a damaged nuclear weapon or improvised nuclear device and to conduct high-hazard experiments involving special nuclear material and high explosives, nonnuclear experiments, and hydrodynamic testing. Nuclear stockpile stewardship activities at the NNSS include dynamic plutonium experiments that provide technical information to maintain the safety and reliability of the U.S. nuclear weapons stockpile and research and training in areas such as nuclear safeguards, criticality safety, and emergency response. Special nuclear materials are also stored at the NNSS. In addition, in accordance with the amended Record of Decision (ROD) (DOE/EIS-0243) for the *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada (1996 NTS EIS*), DOE/NNSA receives low-level and mixed low-level radioactive waste for disposal at the NNSS.

This *NNSS SWEIS* analyzes the potential environmental impacts of three reasonable alternatives for continued operations at the NNSS, RSL, NLVF, and TTR. These alternatives include a No Action Alternative and two action alternatives: Expanded Operations and Reduced Operations. The No Action Alternative, which is analyzed as a baseline for evaluating the two action alternatives, would continue implementation of the *1996 NTS EIS* ROD (DOE/EIS-0243) and subsequent amendments (61 FR 65551and 65 FR 10061), as well as other decisions supported by separate NEPA analyses completed since issuance of the final *1996 NTS EIS*. The No Action Alternative reflects activity levels consistent with those seen since 1996. The Expanded Operations Alternative considers adding new work at the NNSS in the areas of nonproliferation and counterterrorism, high-hazard and other experiments, research and development, and testing. Such expanded operations could include developing test beds for concept testing of sensors, mitigation strategies, and weapons effectiveness. The Reduced Operations Alternative would reduce the overall level of operations and close specific buildings and structures. NNSA would also consider allowing the development of solar power generation facilities under each alternative.

Public Comments: In preparing this *Final NNSS SWEIS*, NNSA considered comments received during the scoping period (July 24, 2009, to October 16, 2009) and during the public comment period on the *Draft NNSS SWEIS* (July 29, 2011, to December 2, 2011), as well as those received after the close of the public comment period on the *Draft NNSS SWEIS*. Five public hearings on the *Draft NNSS SWEIS* were held to provide interested members of the public with opportunities to learn more about NNSA missions, programs, and activities and the content of the *Draft NNSS SWEIS* from exhibits, factsheets, and discussion with NNSA subject matter experts. From September 20 through 28, 2011, public hearings were held in Las Vegas, Pahrump, Tonopah, and Carson City, Nevada, and St. George, Utah. An additional hearing was conducted for the Consolidated Group of Tribes and Organizations on October 6, 2011. All comments received were considered during preparation of this *Final NNSS SWEIS*.

This *Final NNSS SWEIS* contains revisions and new information based in part on comments received on the *Draft NNSS SWEIS*. Vertical change bars in the margins indicate the locations of these revisions and new information. Volume 3 contains the comments received on the *Draft NNSS SWEIS* and DOE/NNSA's responses to those comments. DOE/NNSA will use the analysis presented in this *Final NNSS SWEIS*, as well as other information, in preparing a ROD regarding the continued operation of the NNSS and offsite locations in Nevada. DOE/NNSA will issue a ROD no sooner than 30 days after the U.S. Environmental Protection Agency publishes a Notice of Availability of this *Final NNSS SWEIS* in the *Federal Register*.

FOREWORD

This Foreword to the *Final Site-Wide Environmental Impact Statement for the Continued Operation of the Department of Energy/National Nuclear Security Administration Nevada National Security Site and Off-Site Locations in the State of Nevada (NNSS SWEIS)* focuses on the nature of the changes to the *Draft NNSS SWEIS* that resulted from public comments, as well as changes in environmental baseline information and the analyses of potential environmental impacts. The Foreword also discusses the role the National Environmental Policy Act (NEPA) review process and this *Final NNSS SWEIS* play in the DOE/NNSA decisionmaking process.

PUBLIC COMMENT ON THE *NNSS SWEIS*

This *Final NNSS SWEIS* analyzes potential environmental impacts of continued management and operation of the Nevada National Security Site (NNSS) (formerly known as the Nevada Test Site) and other sites managed by the U.S. Department of Energy/National Nuclear Security Administration (DOE/NNSA) in Nevada. During development of an environmental impact statement (EIS), there are two required opportunities for public involvement: during public scoping and during the public comment period after the draft EIS is issued. The *NNSS SWEIS* public scoping process began on July 24, 2009, and concluded on October 16, 2009. DOE/NNSA received approximately 150 comment documents, each of which was evaluated to determine the scope of issues to be evaluated in this site-wide environmental impact statement (SWEIS).

On July 29, 2011, DOE/NNSA published a notice in the *Federal Register* (FR) announcing the availability of the *Draft NNSS SWEIS*, the duration of the comment period, the location and timing of the public hearings, and methods for submitting comments. DOE/NNSA announced a 90-day public comment period, from July 29 to October 27, 2011, to provide time for interested parties to review the *Draft NNSS SWEIS*. In response to requests for additional review time, DOE/NNSA extended the comment period by 36 days, through December 2, 2011, giving commentors a total review and comment period of 126 days. DOE/NNSA received more than 240 comment documents containing almost 800 comments.

WHAT WAS THE NATURE OF PUBLIC COMMENTS?

In reviewing the comments on the *Draft NNSS SWEIS*, DOE/NNSA identified several topics that were of heightened interest or concern to stakeholders, or resulted in generally substantive changes to relevant information and analyses in this *NNSS SWEIS*. These topics included:

- ***Transportation Routing***. Commentors were concerned that DOE/NNSA was considering changing routes for shipping radioactive waste to allow shipment of waste through Las Vegas, and indicated the analysis should address site-specific conditions along the routes in the vicinity of Las Vegas. Additionally, commentors stated that the analysis of rail transfer stations was incomplete because specific operations and accidents that could occur at the analyzed rail transfer stations were not addressed.

- ***Groundwater Quality and Use***. Commentors stated that groundwater contamination from historic nuclear weapons testing continued to pose an unacceptable risk to human health and that the *Draft NNSS SWEIS* did not characterize this risk adequately. Commentors alleged that this groundwater contamination and restrictions on public access to other groundwater on the NNSS constituted a loss of a valuable resource, which contributed to a lack of economic development.

- ***Former Yucca Mountain Site***. Commentors believed that DOE/NNSA should analyze, as a reasonably foreseeable future action, either the construction and operation of a high-level radioactive waste repository at Yucca Mountain or the remediation and reclamation of the former Yucca Mountain Site.

- ***American Indian Rights***. Commentors expressed concern that the U.S. Government is not abiding by the terms of the Treaty of Ruby Valley, and stated that the lands encompassing the NNSS rightfully belong to the Western Shoshone people.

- ***Use of the NNSS***. Commentors contended that ongoing and proposed activities at the NNSS were not consistent with the purposes for which the land was originally withdrawn from public use and stated that DOE/NNSA should consider returning some or all of the lands to public use.

- ***Nuclear Weapons Testing***. Commentors were opposed to resumption of nuclear weapons testing and were concerned that resumption of testing was possible, despite the current moratorium on such tests.

- ***Renewable Energy***. Commentors were generally supportive of using the NNSS for research and commercial-scale renewable energy projects, but expressed concerns that such projects, particularly commercial-scale projects, have the potential to cause adverse environmental impacts on many resources.

DOE/NNSA has responded to each public comment in the Comment Response Document (Volume 3) of this *Final NNSS SWEIS*.

HOW WAS THE DRAFT *NNSS SWEIS* CHANGED?

DOE/NNSA revised the *Draft NNSS SWEIS* in response to public comments and provided additional environmental baseline information and new and revised analyses including, but not limited to, the following:

- DOE/NNSA added information (figures and supporting text) regarding current and projected levels of surface soil and groundwater contamination.

- DOE/NNSA enhanced its cumulative effects analysis by including the remediation of the former Yucca Mountain Site as a reasonably foreseeable future action.

- DOE/NNSA added a human health impacts analysis for an alternate maximally exposed individual based upon a “subsistence consumer” lifestyle pattern.

- DOE/NNSA added an analysis of potential impacts associated with wildland fire events.

- DOE/NNSA included new information regarding existing environmental conditions based upon more-recent, routine sampling and field data collection (e.g., groundwater contaminant sampling).

DOE/NNSA also corrected inaccuracies, made editorial corrections, and clarified text. Substantive changes to the text are identified through the use of margin bars on the edges of the affected pages.

WHAT HAPPENS NEXT?

DOE/NNSA will announce its decision regarding the selected alternative or alternatives in a Record of Decision (ROD) no sooner than 30 days after the U.S. Environmental Protection Agency Notice of Availability for this *Final NNSS SWEIS* is published in the *Federal Register*. The ROD will be published in the *Federal Register* and explain all factors, including the potential environmental impacts, considered by DOE/NNSA in reaching its decision. The ROD will identify the environmentally Preferred Alternative or Alternatives. If mitigation measures, monitoring, or other conditions are adopted as part of DOE/NNSA's decision, these will be summarized in the ROD, as applicable, and included in a mitigation action plan that will be prepared following issuance of the ROD. The mitigation action plan will explain how and when mitigation measures would be implemented and how DOE/NNSA would monitor the mitigation measures over time to judge their effectiveness.

After DOE/NNSA issues its ROD, both the ROD and the mitigation action plan will be posted on DOE's NEPA website (http://nepa.energy.gov), and copies will be placed in the DOE/NNSA Reading Room in Las Vegas, Nevada, and in public libraries in southern Nevada and southwestern Utah; they also will be made available to interested parties upon request.

This page left blank intentionally.

SUMMARY

S.1 Introduction and Purpose and Need

S.1.1 Introduction

The U.S. Department of Energy's (DOE's) "National Environmental Policy Act Implementing Procedures" (10 *Code of Federal Regulations* [CFR] 1021.330(c)) require preparation of a site-wide environmental impact statement (SWEIS), a broad-scope document that identifies and assesses the potential individual and cumulative impacts of ongoing and reasonably foreseeable future actions for certain large multiple-facility DOE sites, such as the Nevada National Security Site (NNSS) (formerly the Nevada Test Site). An evaluation of an existing SWEIS is required every 5 years. DOE determines whether an existing SWEIS remains adequate or whether a new SWEIS or supplement to the existing SWEIS is needed.

In 1996, DOE issued the *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada (1996 NTS EIS)* (DOE 1996) and an associated Record of Decision (ROD) (61 *Federal Register* [FR] 65551). In the ROD, DOE selected the Expanded Use Alternative for most activities, but decided to manage low-level radioactive waste and mixed low-level radioactive waste at levels described under the No Action Alternative, pending decisions resulting from the *Final Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste (WM PEIS)* (DOE 1997). In the February 2000 *WM PEIS* ROD (65 FR 10061), DOE announced that the NNSS would be one of two regional sites to be used for disposal of low-level radioactive waste and mixed low-level radioactive waste. At the same time, DOE amended the *1996 NTS EIS* ROD to select the Expanded Use Alternative for waste management activities at the NNSS.

Subsequently, as required by DOE regulations (10 CFR 1021.330(d)), the National Nuclear Security Administration (NNSA), a separately organized semiautonomous agency within DOE, conducted the first 5-year review of the *1996 NTS EIS*, as documented in the 2002 *Supplement Analysis for the Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (DOE 2002). Based on this review, DOE/NNSA concluded there were no substantial changes to the actions proposed in the *1996 NTS EIS* and no significant new circumstances or information relevant to environmental concerns. Thus, DOE/NNSA determined that no further National Environmental Policy Act (NEPA) analysis was required.

In 2007, DOE/NNSA initiated its second 5-year review of the *1996 NTS EIS* and, in April 2008, issued the *Draft Supplement Analysis for the Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (DOE 2008). Based on consideration of comments received on the draft supplement analysis, potential changes to the NNSS program work scope, and changes to the environmental baseline, DOE/NNSA decided to prepare this *Final Site-Wide Environmental Impact Statement for the Continued Operation of the Department of Energy/National Nuclear Security Administration Nevada National Security Site and Off-Site Locations in the State of Nevada (NNSS SWEIS)* (DOE/EIS-0426). DOE/NNSA has prepared this *NNSS SWEIS* in compliance with Council on Environmental Quality regulations that implement NEPA (40 CFR Parts 1500–1508) and DOE NEPA implementing procedures (10 CFR Part 1021).

The U.S. Air Force, U.S. Bureau of Land Management, and Nye County, Nevada, are cooperating agencies in the preparation of this *NNSS SWEIS*. In addition, the Consolidated Group of Tribes and Organizations, which includes representatives from 17 tribes and organizations, participated in the preparation of this SWEIS; their assessments and recommendations appear in text boxes in this Summary and throughout this SWEIS.

Consolidated Group of Tribes and Organizations

Southern Paiute
- Kaibab Paiute Tribe, Arizona
- Paiute Indian Tribes of Utah
- Moapa Band of Paiutes, Nevada
- Las Vegas Paiute Tribe, Nevada
- Pahrump Paiute Tribe, Nevada
- Chemehuevi Paiute Tribe, California
- Colorado River Indian Tribes, Arizona

Western Shoshone
- Duckwater Shoshone Tribe, Nevada
- Ely Shoshone Tribe, Nevada
- Yomba Shoshone Tribe, Nevada
- Timbisha Shoshone Tribe, California

Owens Valley Paiute and Shoshone
- Benton Paiute Tribe, California
- Bishop Paiute Tribe, California
- Big Pine Paiute Tribe, California
- Lone Pine Paiute Tribe, California
- Fort Independence Paiute Tribe, California

Other Official Native American Indian Organizations
- Las Vegas Indian Center, Nevada

S.1.2 Purpose and Need for Agency Action

The purpose and need for agency action is to support DOE/NNSA's core missions established by the U.S. Congress and the President. These include meeting its obligations to ensure a safe and reliable nuclear weapons stockpile, support other national security programs, characterize and remediate areas of the NNSS and offsite locations previously contaminated as a result of the Nation's nuclear weapons testing program, and provide for the disposal of low-level and mixed low-level radioactive waste from across the DOE complex.

DOE/NNSA also must meet the mandates of Executive Orders 13212, *Actions to Expedite Energy-Related Projects*, and 13514, *Federal Leadership in Environmental, Energy, and Economic Performance*, as well as the *Energy Independence and Security Act of 2007* (Public Law 109-58). Accordingly, DOE/NNSA's purpose and need is also to satisfy the requirements of these Executive Orders and comply with Congressional mandates to promote, expedite, and advance the production of environmentally sound energy resources, including renewable energy resources such as solar and geothermal energy systems.

Summary—American Indian Perspective

CGTO

Since the beginning of time, the area encompassing the Nevada National Security Site (NNSS) and the offsite locations has been essential to the lives of American Indian tribes. These lands contain traditional gathering, ceremonial, and recreational areas for the American Indian people. They contain ecological resources and power places that are crucial for the continuation of American Indian culture, religion, and society.

The Consolidated Group of Tribes and Organizations (CGTO) knows American Indian people are charged by the Creator to interact with the environment and its resources in culturally appropriate ways to maintain balance, regardless of the U.S. Department of Energy's stated purpose and need for agency action. American Indians further believe these lands and their resources contain life-sustaining characteristics that must be properly respected and cared for to ensure harmony. The CGTO does not support harmful land-disturbing activities currently conducted and proposed within the NNSS area and offsite locations.

The NNSS has a long history of supporting national security objectives by conducting underground nuclear tests and other nuclear and nonnuclear activities. Since October 1992, there has been a moratorium on underground nuclear testing. Thus, DOE/NNSA's mission at the NNSS has evolved from one that focused on active nuclear weapons tests to one that maintain readiness and the capability to conduct underground nuclear weapons tests; such a test would be conducted only if so directed by the President in the interest of national security. DOE/NNSA's primary mission at the NNSS is to support nuclear stockpile reliability through subcritical experiments. Changes in national security priorities have resulted in resource reallocation and the introduction and expansion of other national security missions, programs, and activities at the NNSS and offsite locations in Nevada. In addition, the NNSS supports DOE waste management activities, including disposal; environmental restoration activities; and research, development, and testing programs related to national security. The NNSS also provides opportunities for various environmental research projects and development of commercial-scale solar energy projects, as well as development of innovative solar and other renewable energy technologies.

S.2 Alternatives

S.2.1 Background

This *NNSS SWEIS* analyzes the potential environmental impacts of continued management and operation of the NNSS and other DOE/NNSA-managed sites in Nevada, including the Remote Sensing Laboratory (RSL), North Las Vegas Facility (NLVF), and Tonopah Test Range (TTR) (see **Figure S–1**). This *NNSS SWEIS* also analyzes the impacts of other DOE program activities, as well as those of other Federal agencies, such as the U.S. Department of Defense and U.S. Department of Homeland Security, that occur or are proposed to occur on these DOE/NNSA-managed sites.

The NNSS occupies approximately 1,360 square miles of desert and mountain terrain in southern Nevada. About 6,500 square miles of the U.S. Air Force's Nevada Test and Training Range and the Desert National Wildlife Refuge surround the NNSS on the northern, western, and eastern sides. The NNSS is a multi-disciplinary, multi-purpose facility primarily engaged in work that supports national security, homeland security initiatives, waste management, environmental restoration, and defense and nondefense research and development programs for DOE/NNSA, and other government entities.

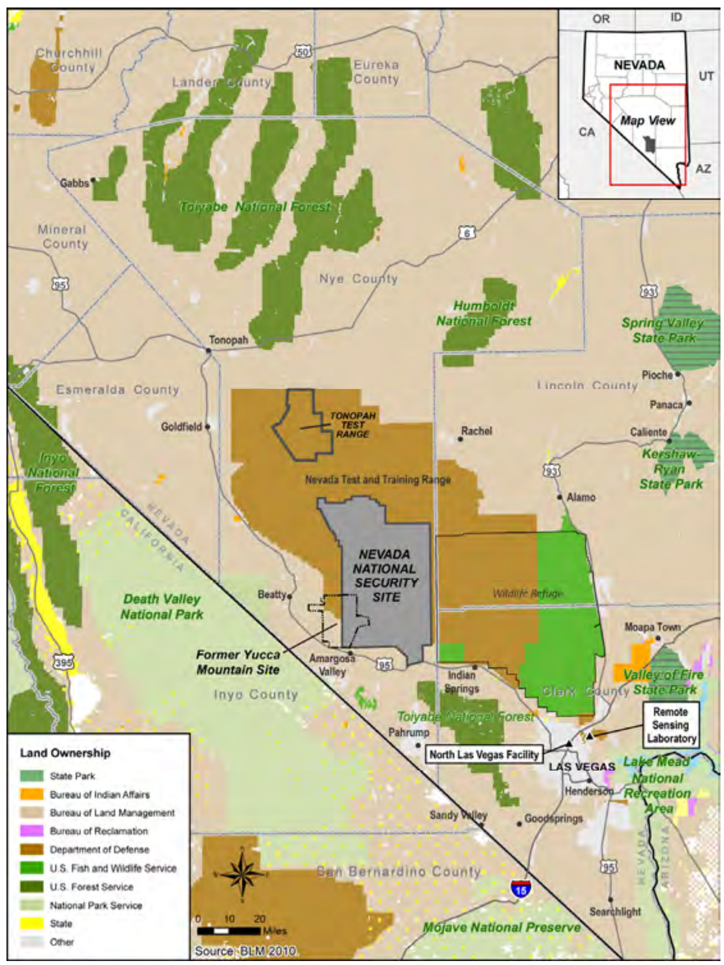

Figure S–1 Location of Nevada National Security Site and Offsite Locations in the State of Nevada

RSL is located on 35 acres at Nellis Air Force Base in North Las Vegas, Nevada, approximately 59 miles southeast of the nearest NNSS boundary. RSL is adjacent to the Nellis Air Force Base runway and has seven buildings. Radiological emergency response, the Aerial Measuring System, radiological sensor development and testing, Secure Systems Technologies, nuclear nonproliferation capabilities, and information and communication technologies are supported at RSL.

NLVF, located on 78 acres approximately 55 miles southeast of the nearest NNSS boundary in Las Vegas, comprises 29 buildings that support ongoing NNSS missions. The facility includes office buildings, a high bay, machine shop, laboratories, experimental facilities, and various other mission-support facilities. Among the NLVF buildings is the Nevada Support Facility, the location of most of the DOE/NNSA Nevada Site Office (NSO) personnel offices.

The TTR, located approximately 12 miles north of the nearest NNSS boundary, is a U.S. Air Force facility. It consists of a 280-square-mile area north of the NNSS on the Nevada Test and Training Range. DOE/NNSA operations at the TTR are conducted pursuant to a land use permit from the U.S. Air Force under the direction of Sandia National Laboratories and the DOE/NNSA Sandia Site Office (other DOE/NNSA sites in Nevada are under the direction of the DOE/NNSA NSO). DOE/NNSA operations at the TTR include flight-testing of gravity weapons (bombs) and research, development, and evaluation of nuclear weapons components and delivery systems.

In this *NNSS SWEIS*, DOE/NNSA analyzes the potential environmental impacts of three alternatives: (1) No Action, (2) Expanded Operations, and (3) Reduced Operations. Each alternative comprises current and reasonably foreseeable missions, programs, capabilities, and projects at the NNSS and the three offsite locations during a 10-year period. This SWEIS considers ongoing and proposed programs, capabilities, and projects (i.e., activities) at DOE/NNSA facilities in Nevada over the next 10 years.

The nature of ongoing activities and their associated environmental impacts are well understood. In contrast, however, the nature of some proposed activities is less well known. In the interest of disclosing potential environmental impacts that could occur at the NNSS and offsite locations, this SWEIS includes ongoing activities, as well as activities that are more conceptual in nature. DOE/NNSA understands that the level of NEPA analysis conducted for some proposed future activities may not be sufficient to permit implementation, and such activities could require additional NEPA analysis.

Terminology Used in this *Final Site-Wide Environmental Impact Statement for the Continued Operation of the Department of Energy/National Nuclear Security Administration Nevada National Security Site and Off-Site Locations in the State of Nevada*

Missions. This term refers to the major responsibilities assigned to the U.S. Department of Energy (DOE) and the National Nuclear Security Administration (NNSA) and comprises the National Security/Defense Mission, Environmental Management Mission, and Nondefense Mission.

Programs. DOE and NNSA are organized into program offices, each of which has primary responsibilities within the set of missions. Funding and direction for activities at DOE and NNSA facilities are provided through these program offices, and similarly coordinated sets of activities to meet program office responsibilities are often referred to as "programs." Programs are usually long-term efforts with broad goals or requirements.

Capabilities. This term refers to the combination of facilities, equipment, infrastructure, and expertise necessary to undertake types or groups of activities and to implement mission assignments. Capabilities at the Nevada National Security Site and offsite locations have been established over time, principally through mission assignments and activities directed by program offices.

Projects. This term is used to describe activities with a clear beginning and end that are undertaken to meet a specific goal or need. Projects can vary in scale from very small (such as a project to undertake one experiment or a series of small experiments) to major (such as a project to construct and start up a new nuclear facility).

Activities. In this site-wide environmental impact statement, activities are those physical actions used to implement missions, programs, capabilities, or projects.

Alternative descriptions are organized under three missions, each with two or more associated programs. The DOE/NNSA missions and associated programs in Nevada are (1) the National Security/Defense Mission, which includes the Stockpile Stewardship and Management, Nuclear Emergency Response, Nonproliferation, Counterterrorism, and Work for Others Programs; (2) the Environmental Management Mission, which includes the Waste Management and Environmental Restoration Programs; and (3) the Nondefense Mission, which includes the General Site Support and Infrastructure, Conservation and Renewable Energy, and Other Research and Development Programs. Mission-related capabilities, projects, and activities are identified for each of the alternatives. The three alternatives include similar types of capabilities, projects, and activities, but differ primarily in their levels of operations and facility requirements. The No Action Alternative reflects the use of existing facilities and ongoing projects to maintain operations at levels consistent with those experienced since 1996. The Expanded Operations Alternative differs from the No Action Alternative in that the levels of operations would be enhanced or accelerated, and new facilities would be constructed to support increased levels of operations. In addition, under the Expanded Operations Alternative, DOE/NNSA would modify (resize) land use zones at the NNSS to better reflect the kinds of activities that would be undertaken in those zones. Under the Reduced Operations Alternative, DOE/NNSA would conduct some activities at levels similar to those under the No Action Alternative, but for other activities, the levels of operations would be reduced or would cease altogether. DOE/NNSA also would modify land use zones on the NNSS, and limit most activities in the northwestern portion of the NNSS.

Levels of Operations – An Example

In the 1996 Record of Decision, the U.S. Department of Energy (DOE) selected the Expanded Use Alternative. Under this alternative, DOE proposed to undertake as many as 110 annual experiments to improve its knowledge of the properties of plutonium, and assess the performance and safety of nuclear weapons. Since then, however, only about 10 such experiments have occurred annually.

The historic levels of operations form the underlying basis for the No Action Alternative in this site-wide environmental impact statement.

Sections S.2.2 through S.2.4 describe the three alternatives in greater detail. **Table S–1** (at the end of Section S.2.4) summarizes the mission-based programmatic similarities and differences among the three alternatives.

Description of Alternatives—American Indian Perspective

CGTO

The Consolidated Group of Tribes and Organizations (CGTO) recommends that the U.S. Department of Energy and the CGTO develop co-management strategies to avert or minimize further impacts before continuing with current or proposed activities. Strategies include:

- Identify those areas that have been disrespected and culturally damaged, so that balance can once again be restored.
- Avoid further harmful ground-disturbing activities.
- Make mitigation of restorable areas a top priority.
- Avert or minimize damage to geological formations important to the cultural and ecological landscape, songscapes, and storyscapes.
- Implement collaborative environmental restoration techniques that require minimal ground-disturbing activities.
- Continue to pursue systematic consultations with American Indians so potentially impacted resources can be readily identified, alternative solutions discussed, and adverse impacts averted.
- Provide American Indian people increased access to culturally significant areas so we can use our knowledge, prayers, and traditions to effectively restore balance to the natural and spiritual harmony of the Nevada National Security Site area and offsite locations.

S.2.2 No Action Alternative

The No Action Alternative reflects the use of existing facilities and ongoing projects to maintain the levels of operations (activities) consistent with those experienced in recent years at the NNSS and offsite locations. For each of the three mission areas and their supporting programs, the levels of operations for associated capabilities, projects, and activities were determined by analyzing operational levels realized since 1996.

Under the No Action Alternative, Stockpile Stewardship and Management Program activities would continue at DOE/NNSA facilities in Nevada under the conditions of the ongoing nuclear testing moratorium. These activities would include science-based stockpile stewardship tests, experiments, and projects to maintain the safety and reliability of the Nation's nuclear weapons stockpile without underground nuclear testing.

Under Presidential Decision Directive 15, DOE/NNSA must be able to resume underground nuclear weapons tests within 24 to 36 months if so directed by the President. Although DOE/NNSA would maintain the capability to conduct an underground nuclear test, conducting such a test is neither included nor analyzed under this, or any, of the alternatives.

In support of the Nuclear Emergency Response, Nonproliferation, and Counterterrorism Programs, under the No Action Alternative, DOE/NNSA would continue to (1) provide support to the Nuclear Emergency Support Team, the Federal Radiological Monitoring and Assessment Center, the Accident Response Group, and the Radiological Assistance Program; (2) undertake Aerial Measuring System activities; (3) provide emergency responder training for emergencies involving weapons of mass destruction; (4) disposition improvised nuclear devices; (5) support DOE/NNSA's Emergency Communications Network; and (6) integrate existing activities and facilities to support national efforts to control the spread of weapons of mass destruction.

Under the No Action Alternative, the Work for Others Program hosted by DOE/NNSA would entail the shared use of certain facilities, such as the Big Explosives Experimental Facility, Nonproliferation Test and Evaluation Complex, and the T-1 Training Area, by other agencies such as the U.S. Department of Defense, as well as the shared use of resources at the NNSS, RSL, NLVF, and the TTR. DOE/NNSA also would continue to host projects of other Federal agencies, such as the U.S. Departments of Defense and Homeland Security, as well as state and local government agencies and nongovernmental organizations.

As part of the Environmental Management Mission, Waste Management Program, the NNSS would continue accepting and disposing of wastes, such as low-level radioactive waste and mixed low-level radioactive waste. The Environmental Restoration Program would continue to ensure compliance with the Federal Facility Agreement and Consent Order to characterize, monitor, and, if necessary, remediate contaminated areas, facilities, soils, and groundwater that have sustained adverse environmental impacts (NDEP 1996).

Federal Facility Agreement and Consent Order

The Nevada National Security Site Environmental Restoration Program includes activities to comply with the Federal Facility Agreement and Consent Order, which was entered into in 1996 by the U.S. Department of Energy, the U.S. Department of Defense, and the State of Nevada. The Federal Facility Agreement and Consent Order provides a process for identifying sites having potential historic contamination, implementing state-approved corrective actions, and instituting closure actions for remediated sites.

Under the No Action Alternative, the Nondefense Mission would include those activities that are necessary to support mission-related programs, such as construction and maintenance of facilities, provision of supplies and services, and warehousing. Activities related to supply and conservation of energy, including renewable energy and other research and development projects, would also continue to be conducted under the Nondefense Mission. For example, DOE/NNSA would continue to identify and implement energy conservation measures and renewable energy projects related to energy efficiency, renewable energy, water, and transportation/fleet management. DOE/NNSA would also support development of a 240-megawatt commercial solar power generation facility and an associated transmission line in the southwest corner of the NNSS. If a commercial solar power generation facility were proposed at the NNSS, additional project-specific NEPA review would be required.

At the NNSS, the missions, programs, capabilities, and projects under the No Action Alternative would be undertaken in one or more of seven land use zones. The land use zones, which are used to manage activities at the NNSS and prevent interference among the various projects and activities, are not considered absolute descriptors of the range of activities that may occur in a particular zone. In addition, the NNSS is divided into numbered operational areas to facilitate management; communications; and distribution, use, and control of resources. **Figure S–2** provides the locations and sizes of these zones and operational areas, as well as the locations of major facilities within these zones and areas.

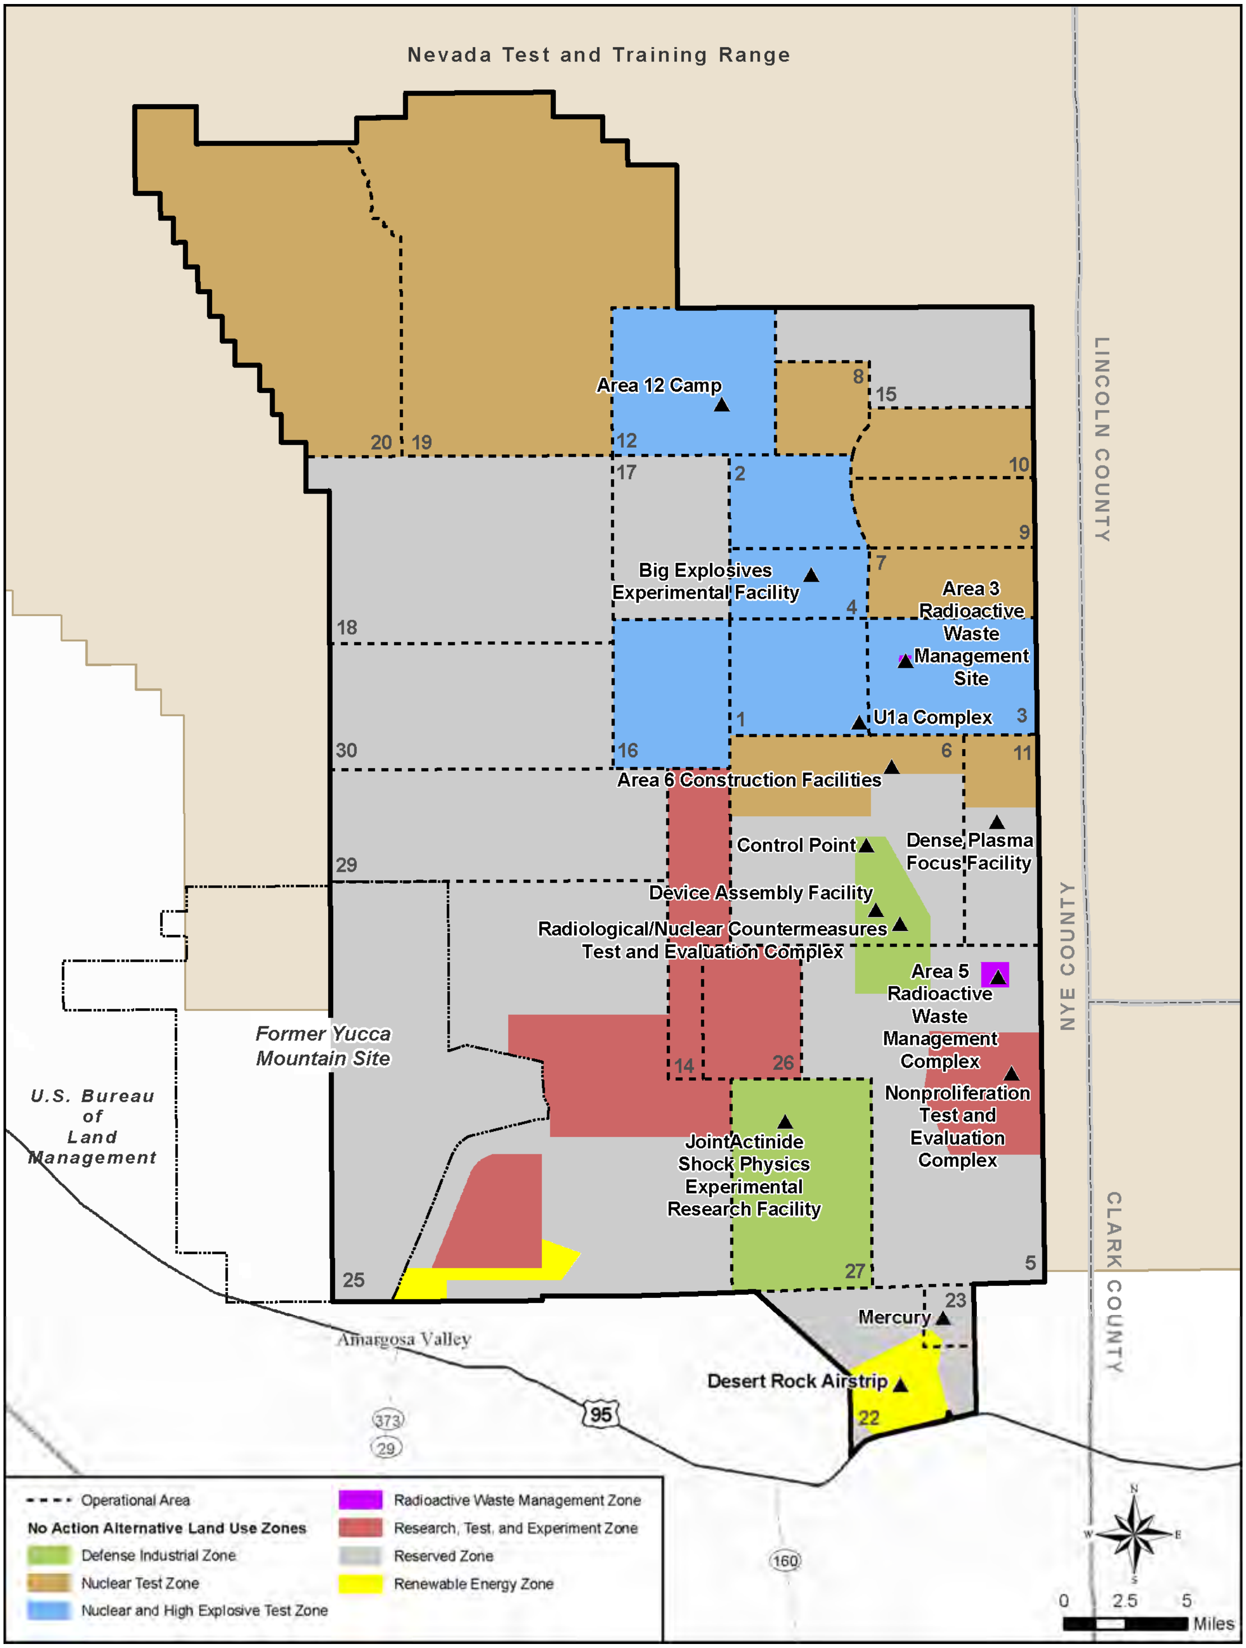

Figure S–2 No Action Alternative Land Use Zones

S.2.3 Expanded Operations Alternative

The Expanded Operations Alternative includes the levels of operations, capabilities, and projects described under the No Action Alternative, as well as additional proposed capabilities and projects. These additional capabilities and projects include modification and/or expansion of existing facilities and construction of new facilities. In addition, some ongoing activities would be conducted more frequently than under the No Action Alternative.

To illustrate, under the Expanded Operations Alternative, the annual number of stockpile stewardship tests and experiments and the yearly number of nuclear weapons that would be dispositioned would increase relative to the No Action Alternative. DOE/NNSA would construct new facilities to support enhanced training for the Office of Secure Transportation, to enhance efforts to control the spread of weapons of mass destruction, and to advance counterterrorism training, research, and development. Although the pace of environmental restoration activities would remain unchanged from that under the No Action Alternative, DOE/NNSA would accelerate the pace and amount of low-level radioactive waste that would be disposed on the NNSS.

Under the Expanded Operations Alternative, there would be two changes in NNSS land use zones: (1) the designated use for Area 15 would be changed from "Reserved" to "Research, Test, and Experiment," and (2) approximately 39,600 acres within Area 25 would be designated as a Renewable Energy Zone (an expansion of the 4,100-acre area under the No Action Alternative). In the Renewable Energy Zone, DOE/NNSA would support development of several commercial solar power generation facilities with a maximum combined generating capacity of 1,000 megawatts in Area 25. Elsewhere, DOE/NNSA would construct a 5-megawatt photovoltaic solar power generation facility (in Area 6), and a Geothermal Demonstration Project and Geothermal Research Center (location to be determined). The locations and sizes of the land use zones and operational areas, as well as the locations of major facilities within these zones and areas, are shown in **Figure S–3**.

S.2.4 Reduced Operations Alternative

The Reduced Operations Alternative includes all of the types of activities conducted at the NNSS and offsite locations since 1996. The activity level under the Reduced Operations Alternative would vary across programs; however, the levels of operations for many programs would be reduced (relative to the No Action Alternative). Furthermore, under the Reduced Operations Alternative, activities would cease in the northwestern portion of the NNSS (Areas 18, 19, 20, 29, and 30), with the exception of environmental restoration and monitoring, site security operations, military training and exercises, and maintenance of Well 8 and critical communications and electrical transmission systems. Maintenance of roads on Pahute Mesa, Stockade Wash, and Buckboard Mesa would also be reduced to provide access only for maintaining necessary infrastructure and conducting environmental restoration activities. Operation of the Pahute Mesa Airstrip would be limited to those operations necessary to provide access for activities that would continue in these areas. In addition, the electrical transmission and distribution system beyond the Echo Peak Substation in Areas 19 and 20 would be de-energized.

The pace of environmental restoration activities and most waste generation and disposal rates would remain unchanged from that under the No Action Alternative. However, the amount of transuranic waste generated, as well as the amount of sanitary waste generated and disposed of on site, would be reduced.

Under the Reduced Operations Alternative, activities related to supply and conservation of energy, including renewable energy and other research and development projects, would continue to be conducted. For example, DOE/NNSA would support development of a 100-megawatt commercial solar power generation facility in Area 25.

At the NNSS, the Area 18, 19, 20, 29, and 30 land use designations would change to a Limited Use Zone. **Figure S–4** provides the locations and sizes of these zones and operational areas, as well as the locations of major facilities within these zones and areas.

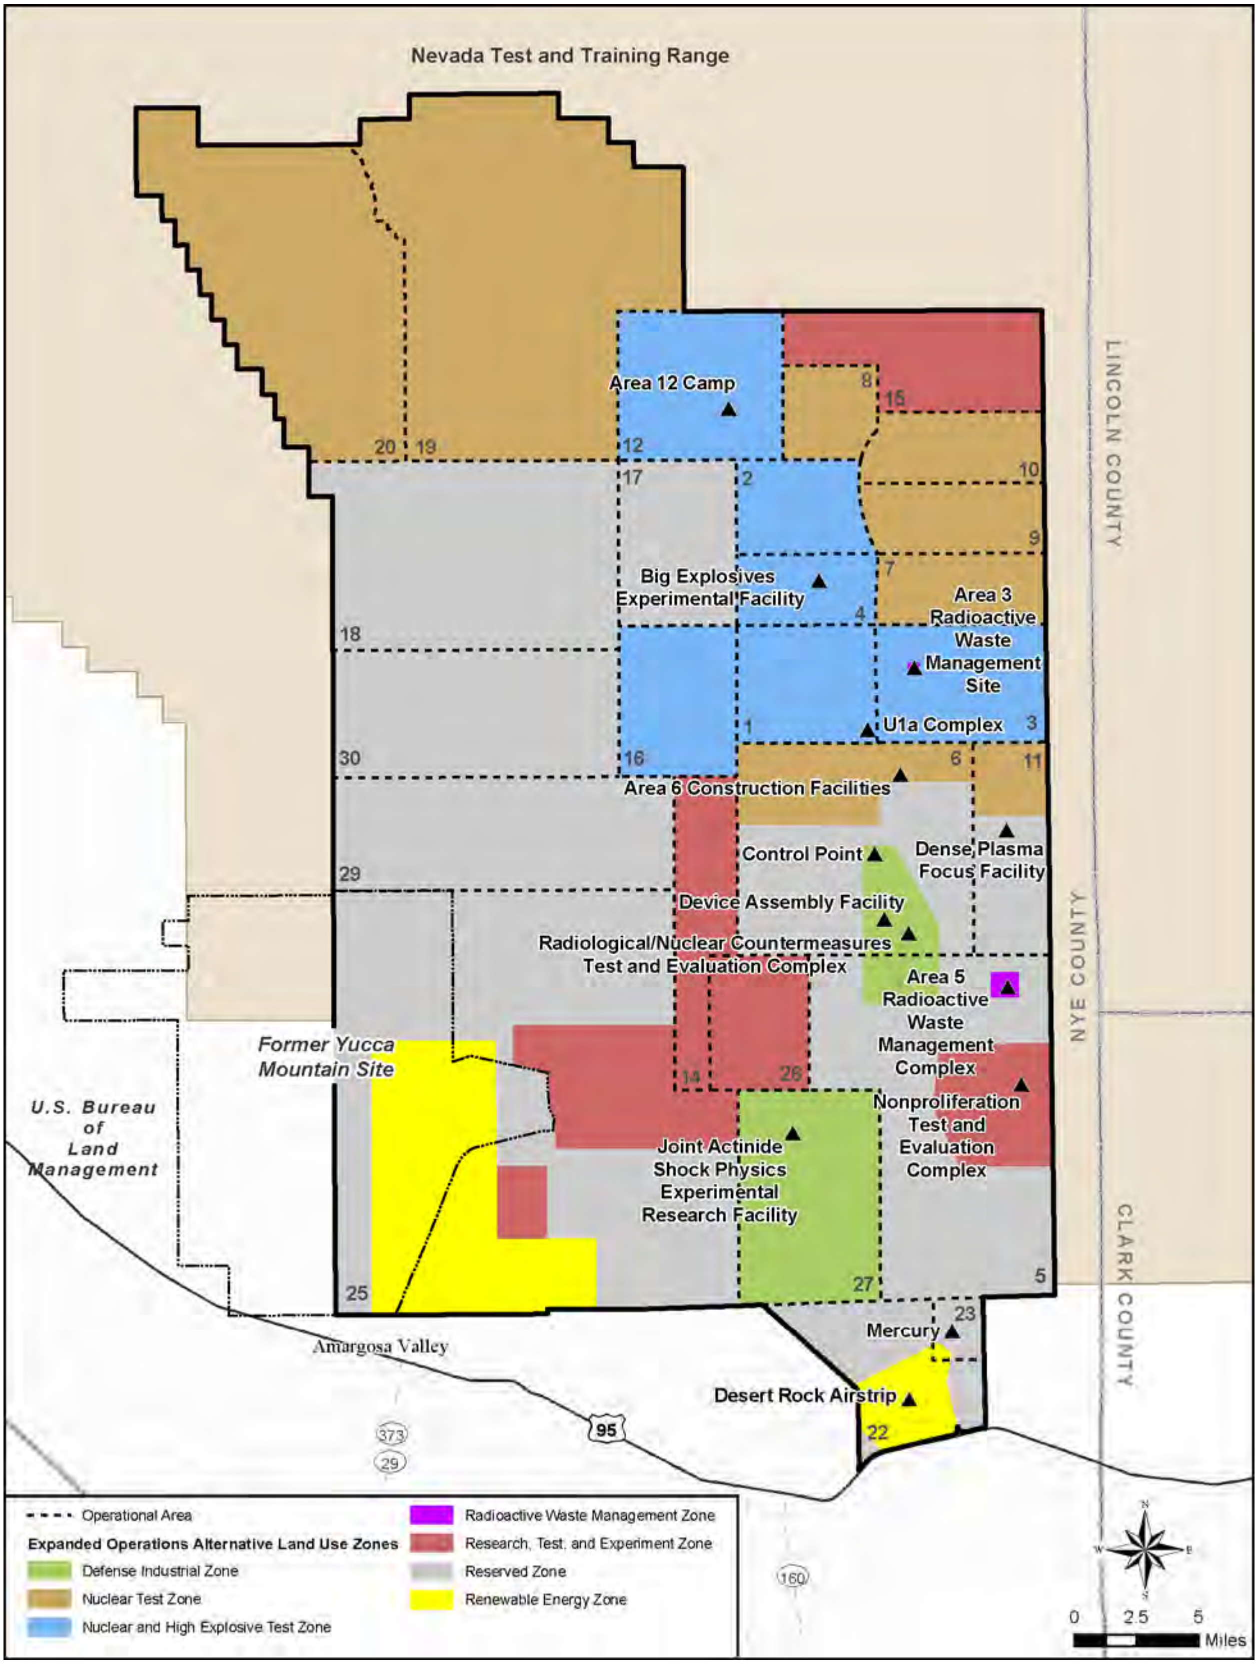

Figure S–3 Expanded Operations Alternative Land Use Zones

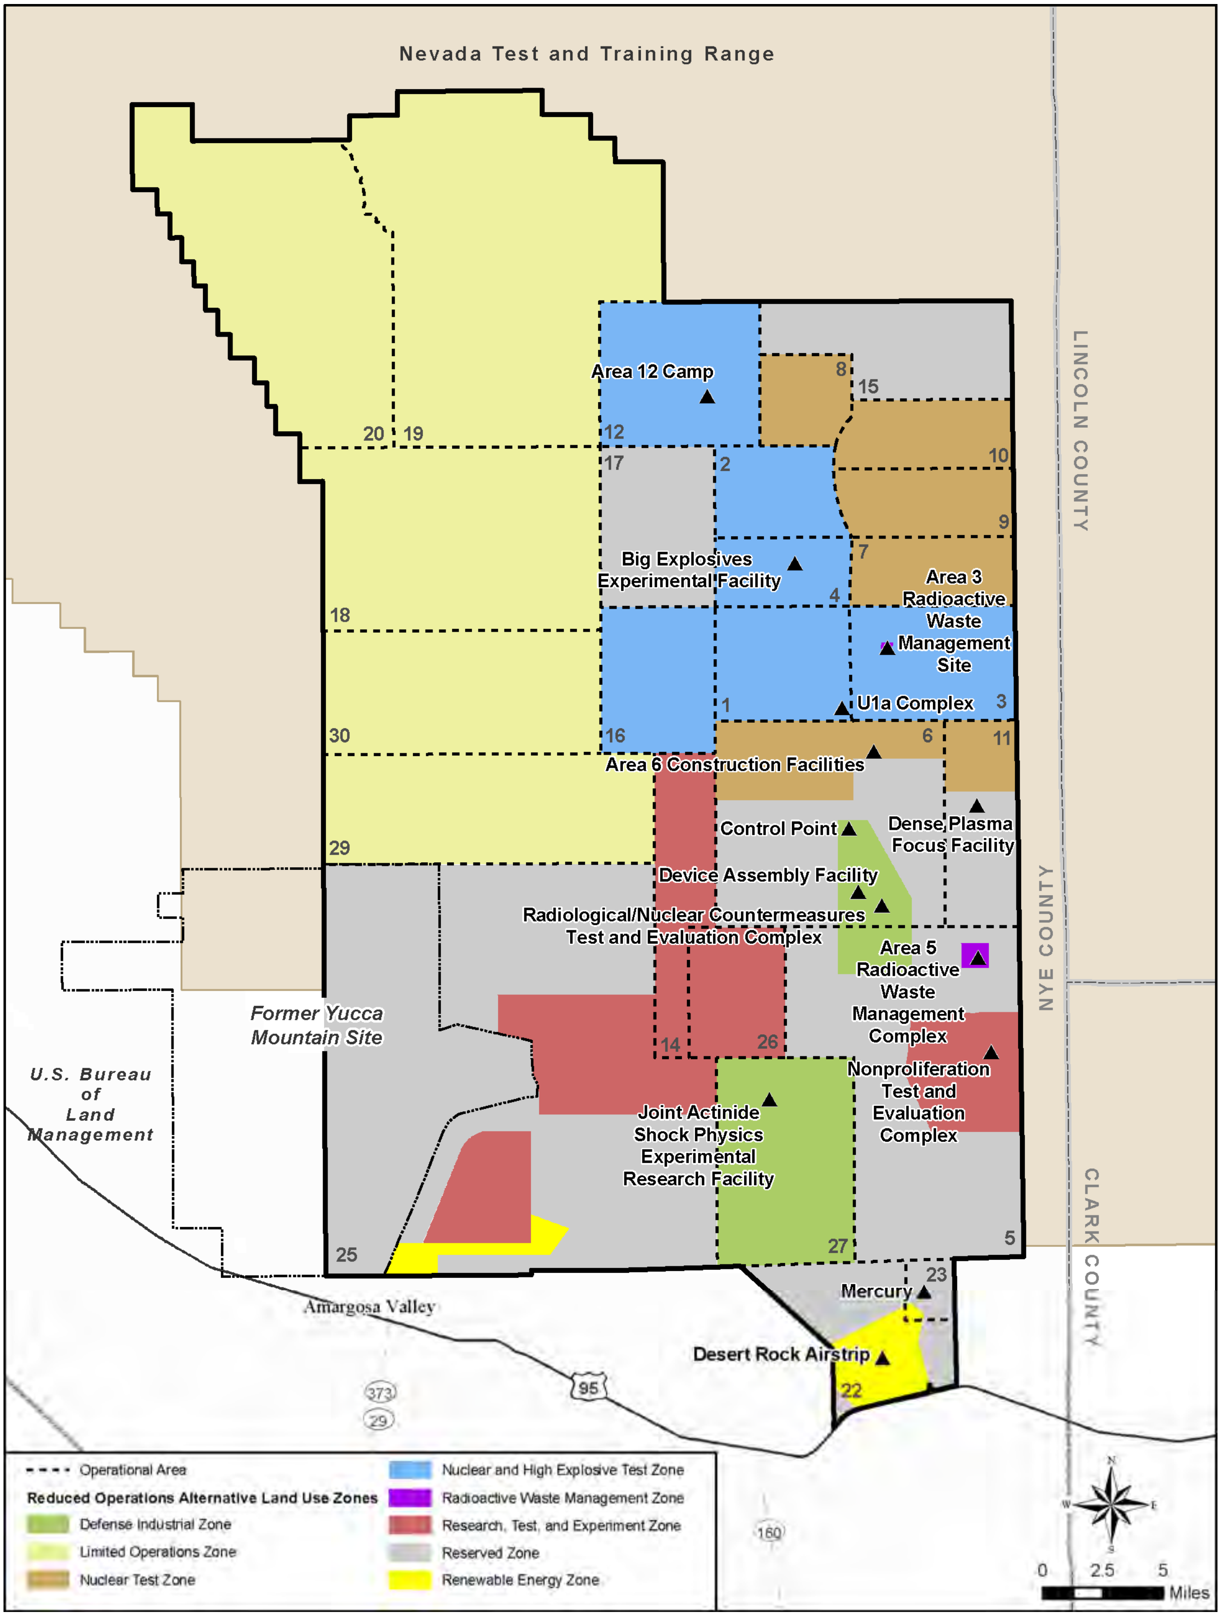

Figure S–4 Reduced Operations Alternative Land Use Zones

Table S–1 Comparison of Mission-Based Program Activities Under the Proposed Alternatives and Identification of the Preferred Alternative (blue shading)

NO ACTION ALTERNATIVE	*EXPANDED OPERATIONS ALTERNATIVE*	*REDUCED OPERATIONS ALTERNATIVE*
National Security/Defense Mission		
Stockpile Stewardship and Management Program		
Maintain readiness to conduct underground nuclear tests.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Conduct up to 10 dynamic experiments per year within NNSS Areas 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 16, 19, or 20.	Conduct up to 20 dynamic experiments per year within NNSS Areas 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 16, 19, or 20.	Conduct up to 6 dynamic experiments per year at the NNSS; no dynamic experiments would be conducted in Areas 19 or 20.
Conduct up to 20 conventional explosives experiments per year at the Big Explosives Experimental Facility and up to 10 per year within NNSS Areas 1, 2, 3, 4, 12, or 16 using up to 70,000 pounds TNT-equivalent of explosives charges; would also support Work for Others Program.	• Conduct up to 100 conventional explosives experiments per year within NNSS Areas 1, 2, 3, 4, 12, or 16 using up to 120,000 pounds TNT-equivalent of explosives charges (50 of these would be at the Big Explosives Experimental Facility with a TNT-equivalent limitation of 70,000 pounds); would also support Work for Others Program. • Add second firing table and high-energy x-ray capability at Big Explosives Experimental Facility. • Establish up to three areas at the NNSS for conducting explosives experiments with depleted uranium and conduct up to 20 experiments per year.	Conduct up to 10 conventional explosives experiments per year at the Big Explosives Experimental Facility using up to 70,000 pounds TNT-equivalent of explosives charges per year to directly support the Stockpile Stewardship and Management Program; no other explosives experiments would be conducted.
Conduct up to 12 shock physics experiments per year at the NNSS using actinide targets at the Joint Actinide Shock Physics Experimental Research Facility in Area 27 and up to 10 experiments per year using the Large-Bore Powder Gun in Area 1.	Conduct up to 36 shock physics experiments per year at the NNSS using actinide targets at the Joint Actinide Shock Physics Experimental Research Facility in Area 27 and up to 24 experiments per year using the Large-Bore Powder Gun in Area 1.	Conduct up to 6 shock physics experiments per year at the NNSS using actinide targets at the Joint Actinide Shock Physics Experimental Research Facility in Area 27 and up to 8 experiments per year using the Large-Bore Powder Gun in Area 1.
Conduct up to 500 criticality operations, training, and other operations per year at the National Criticality Experiments Research Center at the Device Assembly Facility in Area 6.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Maintain the Atlas Facility in standby with the capability to conduct up to 12 pulsed-power experiments per year.	Activate the Atlas Facility and conduct up to 24 pulsed-power experiments per year.	Decommission and disposition the Atlas Facility.
Conduct up to 600 plasma physics and fusion experiments each year at NLVF and 50 per year in NNSS Area 11.	Conduct up to 1,000 plasma physics and fusion experiments each year at NLVF and 650 per year in NNSS Area 11, increasing the size and complexity of such experiments.	Conduct up to 350 plasma physics and fusion experiments each year at NLVF and 25 per year in NNSS Area 11.
Conduct five drillback operations at the NNSS over an approximate 10-year period.	Same as under the No Action Alternative.	Same as under the No Action Alternative.

NO ACTION ALTERNATIVE	EXPANDED OPERATIONS ALTERNATIVE	REDUCED OPERATIONS ALTERNATIVE
Conduct Stockpile Stewardship and Management Program activities in NNSS Areas 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 16, 19, or 20, including the following:	Same as under the No Action Alternative:	Same as under the No Action Alternative, except Stockpile Stewardship and Management Program activities would not be conducted in Areas 19 and 20.
• Disposition damaged U.S. nuclear weapons on an as-needed basis.	• Stage nuclear devices pending dismantlement, modification/maintenance, and/or transportation to another location. • Dismantle up to 100 nuclear weapons per year • Replace limited-life components of up to 360 nuclear devices per year and conduct associated maintenance activities. • Test weapons components for quality assurance under the Limited Life Component Exchange Program.	
• Stage special nuclear material, including nuclear weapon pits.	• Transfer special nuclear material, including nuclear weapon pits, to and from other locations in the DOE complex for staging and use in experiments at the NNSS.	
Conduct training for the Office of Secure Transportation up to six times per year at various locations on NNSS roads.	Same as under the No Action Alternative, plus: • Develop facilities in Area 17 and upgrade or construct new facilities in Area 6, 12, or 23 to support training for the Office of Secure Transportation.	Conduct training for the Office of Secure Transportation up to four times per year at various locations on NNSS roads.
Conduct the following stockpile stewardship operations at the TTR: • Conduct tests and experiments, including flight test operations for gravity weapons (i.e., bombs). • Conduct ground/air-launched rocket and missile operations. • Conduct impact testing. • Conduct passive testing of joint test assemblies and conventional weapons. • Conduct fuel-air explosives testing.	Same as under the No Action Alternative, except: • Certain safeguards and security functions and other administrative functions would be turned over to the U.S. Air Force.	Same as under the No Action Alternative, except: • Discontinue ground/air-launched rocket and missile operations. • Discontinue fuel-air explosives testing.
Nuclear Emergency Response, Nonproliferation, and Counterterrorism Programs		
Provide support for the Nuclear Emergency Support Team, the Federal Radiological Monitoring and Assessment Center, the Accident Response Group, and the Radiological Assistance Program (most of this support is provided by RSL at Nellis Air Force Base).	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Conduct Aerial Measuring System activities from RSL at Nellis Air Force Base.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Conduct weapon of mass destruction emergency responder training at various DOE/NNSA NSO locations.	Same as under the No Action Alternative.	Same as under the No Action Alternative.

NO ACTION ALTERNATIVE	*EXPANDED OPERATIONS ALTERNATIVE*	*REDUCED OPERATIONS ALTERNATIVE*
Support DOE Emergency Communications Network.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Disposition improvised nuclear dispersion devices and deploy the DOE/NNSA Disposition Program and Federal Bureau of Investigation Disposition and Disposition Forensics Program to the NNSS for training and exercises or for an actual event, as needed.	Same as under the No Action Alternative, plus: • Disposition radiological dispersion devices, as needed	Same as under the No Action Alternative.
Integrate existing activities and primarily NNSS facilities to support United States efforts to control the spread of weapons of mass destruction, particularly nuclear weapons of mass destruction, including arms control, nonproliferation activities, nuclear forensics, and counterterrorism capabilities.	Same as under the No Action Alternative, plus: At the NNSS: • Construct laboratory space and other facilities for design and certification of treaty verification technology, training of inspectors, and development of arms control confidence-building measures as part of the Arms Control Treaty Verification Test Bed. [a] • Develop and construct new facilities to support a Nonproliferation Test Bed to simulate chemical and radiological processes that an adversary would clandestinely conduct. [a] • Construct an Urban Warfare Complex to support counterterrorism training. [a]	Same as under the No Action Alternative.
Work for Others Program		
Work for Others Program activities would continue to be conducted in all appropriate zones on the NNSS, and at RSL and NLVF.	Same as under the No Action Alternative, except the NNSS land use zone designation for Area 15 would be changed from "Reserved Zone" to "Research, Test, and Experiment Zone."	Same as under the No Action Alternative, except Work for Others Program activities, with the exception of military training and exercises, would not be conducted in Areas 18, 19, 20, 29, and 30 of the NNSS.
Host treaty verification activities.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Conduct nonproliferation projects and counterproliferation research and development at the NNSS, including:	Same as under the No Action Alternative.	Same as under the No Action Alternative, except:
• Conduct conventional weapons effects and other explosives experiments within parameters established for conducting conventional high-explosives experiments.		• Discontinue Work for Others Program conventional weapons effects and other high-explosives experiments.
• Support development of capabilities to hold at-risk and defeat military assets in deeply buried hardened targets. • Conduct up to 20 controlled chemical and biological simulant release experiments per year (each experiment would include multiple releases by a variety of means, including explosives).		• Discontinue development of capabilities to hold at-risk and defeat military assets in deeply buried hardened targets. • Discontinue projects requiring explosive releases of chemical or biological simulants.

NO ACTION ALTERNATIVE	***EXPANDED OPERATIONS ALTERNATIVE***	***REDUCED OPERATIONS ALTERNATIVE***
• Support training, research, and development of equipment, specialized munitions, and tactics related to counterterrorism.		
Support the U.S. Department of Defense and other Federal agencies in developing counterterrorism capabilities.	Develop and construct new facilities to support counterterrorism training, research, and development activities.	Same as under the No Action Alternative.
Conduct criticality experiments to support National Aeronautics and Space Administration deep space power source development within the parameters for criticality experiments established under the Stockpile Stewardship and Management Program.	Same as under the No Action Alternative, plus: • Conduct experiments using existing boreholes at the NNSS to sequester emissions such as radionuclides.	Same as under the No Action Alternative.
Host the use of various aerial platforms, such as airplanes, unmanned aerial systems, and helicopters, at various locations at the NNSS for research and development, training, and exercises.	• Increase use of various aerial platforms, such as airplanes, unmanned aerial systems, and helicopters, for research and development, training, and exercises, including constructing additional hangars, shops, and buildings at existing airports at the NNSS. • Conduct up to 3 underground and 12 open-air radioactive tracer experiments per year. • Host treaty verification activities, including development of a facility for simulating nuclear fuel cycle-related radionuclide release detection and characterization. [a] • Develop a facility for specialized explosive experiments and simulated manufacture to support high-explosives experiments. [a] • Support increased research and development of active interrogation equipment, methods, and training. • Develop new facilities to support research and development in radio frequency generation and infrasonic observations. [a] • Develop new facilities, including simulated clandestine laboratories, to support chemical and biological simulant experiments. [a]	Same as under the No Action Alternative.
Conduct Work for Others Program activities at the TTR, including robotics testing, smart transportation-related testing, smoke obscuration operations, infrared tests, and rocket development.	Same as under the No Action Alternative, except: • Certain safeguards and security functions and other administrative functions would be turned over to the U.S. Air Force.	Same as under the No Action Alternative.

NO ACTION ALTERNATIVE	EXPANDED OPERATIONS ALTERNATIVE	REDUCED OPERATIONS ALTERNATIVE
Environmental Management Mission		
Waste Management Program		
Dispose up to 15 million cubic feet of low-level radioactive waste and 900,000 cubic feet of mixed low-level radioactive waste in the Area 5 Radioactive Waste Management Complex.	Dispose up to 48 million cubic feet of low-level radioactive waste and 4 million cubic feet of mixed low-level radioactive waste at the Area 5 Radioactive Waste Management Complex and Area 3 Radioactive Waste Management Site.[b]	Same as under the No Action Alternative.
Maintain the Area 3 Radioactive Waste Management Site on standby.	Open the Area 3 Radioactive Waste Management Site for disposal of authorized and/or permitted waste.	Same as under the No Action Alternative.
Treat onsite-generated mixed low-level radioactive waste.	Same as under the No Action Alternative, plus: • At the Area 5 Radioactive Waste Management Complex, store mixed low-level radioactive waste received from on- and offsite generators pending treatment via macroencapsulation and microencapsulation (i.e., repackaging), sorting/segregating, and bench-scale mercury amalgamation, as appropriate, and/or disposal.	Same as under the No Action Alternative.
Store onsite-generated transuranic waste (up to 9,600 cubic feet over the next 10 years) pending offsite disposal.	Same as under the No Action Alternative, except a larger volume of transuranic waste (up to 19,000 cubic feet over the next 10 years) would be generated by increased activities at NNSS facilities, such as the Joint Actinide Shock Physics Experimental Research Facility.	Same as under the No Action Alternative, except a smaller volume of transuranic waste (up to 7,100 cubic feet over the next 10 years) would be generated by increased activities at NNSS facilities, such as the Joint Actinide Shock Physics Experimental Research Facility.
Store onsite-generated hazardous waste as needed at the Area 5 Hazardous Waste Storage Unit pending offsite treatment or disposal. Up to 170,000 cubic feet would be generated over the next 10 years.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Operate the Area 11 Explosives Ordnance Disposal Unit. No more than 41,000 pounds of explosives would be treated over the next 10 years.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Operate the Area 6 Hydrocarbon Landfill.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Operate the Area 23 Solid Waste Disposal Site and the U10c Solid Waste Disposal Site. Up to 3,400,000 cubic feet would be disposed over the next 10 years.	Same as under the No Action Alternative, except larger volumes of solid sanitary waste (up to 8,500,000 cubic feet) would be generated by increased activity levels at the NNSS over the next 10 years. Construct new sanitary solid waste disposal facilities as needed in Area 23 and develop a new solid waste disposal site in Area 25 to support environmental restoration activities.	Same as under the No Action Alternative, except smaller volumes of solid sanitary waste (up to 3,300,000 cubic feet) would be generated by reduced activity levels at the NNSS over the next 10 years).

NO ACTION ALTERNATIVE	*EXPANDED OPERATIONS ALTERNATIVE*	*REDUCED OPERATIONS ALTERNATIVE*
Environmental Restoration Program		
Underground Test Area Project – Comply with the Federal Facility Agreement and Consent Order; monitor groundwater from existing wells; drill new characterization and monitoring wells; develop groundwater flow and transport models; and continue to evaluate closure strategies.	Same as under the No Action Alternative, except: • Characterization and monitoring wells would be developed more quickly.	Same as under the No Action Alternative.
Soils Project – Identify and characterize areas with contaminated soils and perform corrective actions in compliance with the Federal Facility Agreement and Consent Order.	Same as under the No Action Alternative, except: • If stricter cleanup standards were implemented, larger volumes of radioactive waste would be generated and disposed.	Same as under the No Action Alternative.
Industrial Sites Project – Identify, characterize, and remediate industrial sites under the Federal Facility Agreement and Consent Order and continue decontaminating and decommissioning facilities.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Defense Threat Reduction Agency Sites – In accordance with the Federal Facility Agreement and Consent Order, perform remediation activities at sites that are the responsibility of the Defense Threat Reduction Agency.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Execute the Borehole Management Program.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Nondefense Mission		
General Site Support and Infrastructure Program		
Conduct small projects to maintain the present capabilities of DOE/NNSA NSO facilities in all areas of the NNSS and at NLVF, RSL, and the TTR. Maintain existing infrastructure, manage various permits and agreements, and provide security for the former Yucca Mountain Repository site.	Same as under the No Action Alternative, plus: • Construct a new 85,000-square-foot multistory security building in Area 23. • Replace the NNSS 138-kilovolt electrical transmission system. • Expand cellular telecommunication system on the NNSS. • Reconfigure Mercury.[a]	Same as under the No Action Alternative, except: Only critical infrastructure would be maintained within Areas 18, 19, 20, 29, and 30 of the NNSS, including certain communications facilities, electrical transmission lines and substations, and Well 8. Roads within these areas would only be maintained to provide access to the infrastructure and environmental restoration sites.

NO ACTION ALTERNATIVE	EXPANDED OPERATIONS ALTERNATIVE	REDUCED OPERATIONS ALTERNATIVE
Conservation and Renewable Energy Program		
Continue to identify and implement energy conservation measures and renewable energy projects in compliance with applicable Executive Orders and DOE Orders. • Reduce energy intensity by 3 percent annually and a total of 30 percent by the end of fiscal year 2015. • Reduce greenhouse gas emissions by 28 percent by fiscal year 2020. • Install advanced electric metering systems. • Obtain at least 7.5 percent of the NNSS annual electricity and thermal consumption from renewable energy sources. • Support development of a 240-megawatt commercial solar power generation facility in NNSS Area 25. [a] • Reduce water use by 16 percent by 2015. • Maximize use of alternative fuels (e.g., E85 and biodiesel). • Ensure all new construction and renovation projects implement high-performance building goals.	Same as under the No Action Alternative, plus: • Support development of 1,000 megawatts of commercial solar power generation facilities in NNSS Area 25. [a] • Modify NNSS land use zones to establish a 39,600-acre Renewable Energy Zone in Area 25. • Construct a 5-megawatt photovoltaic solar power generation facility near the Area 6 Construction Facilities. • Support a Geothermal Energy Demonstration Project and Geothermal Research Center at the NNSS. [a]	Same as under the No Action Alternative, except: • Support development of a 100-megawatt commercial solar power generation facility in NNSS Area 25. [a]
Other Research and Development Programs		
Support the DOE National Environmental Research Park Program and other non-DOE/NNSA research and development activities in all areas of the NNSS.	Same as under the No Action Alternative.	Same as under the No Action Alternative, except: Activities would be conducted in all areas of the NNSS, except Areas 18, 19, 20, 29, and 30.

NLVF = North Las Vegas Facility; NSO = Nevada Site Office; RSL = Remote Sensing Laboratory; TNT = 2,4,6-trinitrotoluene; TTR = Tonopah Test Range.

[a] These potential projects have not reached a point of development that allows full analysis in this *NNSS SWEIS*, and would be subject to additional NEPA review before DOE/NNSA would make any decision regarding implementation. At this point, DOE/NNSA has not received or solicited proposals for any commercial solar power generation projects.

[b] Reopening of the Area 3 Radioactive Waste Management Site would only occur based upon mission need and as stated in Chapter 4, Section 4.1.11.1.1.1, of the *NNSS SWEIS*, including detailed consultation with the state of Nevada.

S.2.5 Preferred Alternative

Council on Environmental Quality regulations for implementing NEPA (40 CFR 1502.14(e)) require an agency to identify its preferred alternative or alternatives, if one or more exists, in the draft EIS. At the time the *Draft NNSS SWEIS* was published, DOE/NNSA had not selected a preferred alternative. Since publication of the *Draft NNSS SWEIS*, DOE/NNSA has identified its Preferred Alternative (see the blue-shaded cells in Table S–1).

In identifying its Preferred Alternative, NNSA considered the current and future needs of DOE/NNSA and other users of the NNSS and offsite locations. In doing so, DOE/NNSA balanced mission requirements established by the U.S. Congress with contemporary goals and objectives identified in planning documents such as the *10 Year Site Plan Fiscal Year 2012* for the NNSS (DOE 2011), as well as anticipated funding levels for DOE/NNSA and other users of the NNSS and offsite locations, such as the Department of Homeland Security. DOE/NNSA also considered the preferences expressed by commentors on the *Draft NNSS SWEIS* and sought to balance those preferences with the needs of the agency and other users of the NNSS and offsite locations in Nevada. Moreover, NNSA analyzed and considered the potential environmental impacts that could accrue from the implementation of any alternative.

Based on these considerations, DOE/NNSA identified a Preferred Alternative for continued operation of the NNSS and offsite locations in the state of Nevada. DOE/NNSA's Preferred Alternative is a "hybrid" alternative comprising various programs, capabilities, projects, and activities selected from among the three alternatives. Table S–1 provides a comparison of mission-based program activities under the three alternatives and the Preferred Alternative (identified by blue-shaded cells).

Under the Stockpile Stewardship and Management Program, activities would largely reflect the No Action Alternative, but with an increased frequency of conventional explosives and shock physics experiments, and the Expanded Operations Alternative, under which certain functions at the TTR would be transferred to the U.S. Air Force. As identified under the Reduced Operations Alternative, the Atlas facility (designed for pulsed power experiments) would be decommissioned. Within the Nuclear Emergency Response, Nonproliferation, and Counterterrorism Programs, activities would also align with the No Action Alternative, except that the capability for disposition of radiological dispersion devices would be added, as well as some additional laboratory and test bed facilities. The Work for Others Program, as an emerging mission, would implement the Expanded Operations Alternative in most areas.

Under the Waste Management Program, activities would generally conform to the Expanded Operations Alternative, with the exception of hazardous waste, explosive ordnance wastes, and hydrocarbon waste management activities, which would remain at current levels. Under the Environmental Restoration Program, activities would resemble those described under the No Action Alternative, but could proceed at a faster pace and/or meet stricter cleanup standards as described under the Expanded Operations Alternative.

The preferred alternative for the General Site Support and Infrastructure Program would be Expanded Operations, which would entail developing new facilities and upgrading existing infrastructure elements (e.g., electrical and cellular communications) on much of the NNSS. Only critical infrastructure would be retained in Areas 18, 19, 20, 29, and 30 of the NNSS, as described under the Reduced Operations Alternative. For the Conservation and Renewable Energy Program, activities would closely conform to the No Action Alternative, except that a 5-megawatt photovoltaic solar power facility and a Geothermal Demonstration Project and Geothermal Research Center could be constructed at the NNSS as identified

under the Expanded Operations Alternative. For the Other Research and Development Programs, activities would continue as described under the No Action Alternative.

S.2.6 Potential Decisions Resulting from this Site-Wide Environmental Impact Statement

The information, analyses, and potential environmental impacts of this *NNSS SWEIS* will provide the basis, in part, for DOE/NNSA to determine the nature of capabilities and projects, as well as their associated levels of operations, over the next 10-year period at the NNSS and offsite locations in Nevada. Accordingly, DOE/NNSA may choose to implement, either wholly or in part, any of the three alternatives, or may choose to implement a "hybrid" alternative, comprising various capabilities, projects, and activities selected from among the three alternatives. Implementation of any of the alternatives could result in changes to the names, sizes, or locations of the land use zones, or in the locations of ongoing or proposed capabilities and projects within these zones.

Although DOE/NNSA analyzed various radioactive waste shipping routes through and around metropolitan Las Vegas, Nevada, decisions on routing would not be made as part of this NEPA process. DOE/NNSA undertook this analysis to inform any highway-routing-related revisions to its waste acceptance criteria; such revisions are developed in accordance with DOE/NNSA's standard practices, which include consultation with the State of Nevada; and, when finalized, become publicly available through publication on the NNSS website. As discussed in Section S.3.1.2, DOE/NNSA determined that it would retain the highway routing restrictions for shipments of low-level radioactive waste; therefore, there would be no need to revise the waste acceptance criteria in this regard (DOE 2012).

DOE/NNSA also would not make any decisions regarding environmental restoration activities that are not consistent with the Federal Facility Agreement and Consent Order unless agreed to by the Nevada Division of Environmental Protection.

S.3 Summary of Environmental Impacts

S.3.1 Nevada National Security Site

This section summarizes the potential environmental impacts at the NNSS from continuing and proposed projects and capabilities, including their associated levels of operations (activities), under each of three alternatives analyzed in this SWEIS. The text focuses on those resource areas for which the impacts are sufficiently different to permit the reader to distinguish among the alternatives in a meaningful manner or those resource areas that may be controversial, i.e., infrastructure and energy, transportation and traffic, socioeconomics, groundwater hydrology, biological resources, air quality, visual resources, and cultural resources, waste management, human health, and cumulative impacts.

Table S–14 (at the end of Section S.3.1.10) summarizes the potential environmental impacts for all 13 resource areas for each alternative. As discussed above in Section S.2.5, DOE/NNSA's Preferred Alternative is a "hybrid" alternative comprising various programs, capabilities, projects, and activities selected from among the three alternatives. Although the text of this Summary does not discuss the potential environmental impacts from implementing the Preferred Alternative, consistent with the approach used in Chapter 3 of the *NNSS SWEIS*, Table S–14 summarizes those impacts to enable a comparison to the three alternatives.

S.3.1.1 Energy

DOE/NNSA compared projections of utility resource requirements, such as the demand for electricity and liquid fuels, under each alternative to local and regional capabilities to supply these resources. Implementing the Expanded Operations Alternative would result in the highest energy demands of the three alternatives.

Under the Expanded Operations Alternative, continuing and newly proposed projects and capabilities would require an increase of up to 25 percent or about 1.4 million gallons per year of various fuel types, such as unleaded gasoline, ethanol-gasoline blended fuel, and biodiesel fuel. DOE/NNSA does not foresee difficulty in obtaining this amount of liquid fuels from regional suppliers. The projected annual demand for most fuel types constitutes a small proportion of current fuel use in Nevada. For example, the estimate of unleaded gasoline needed annually (534,000 gallons) would be approximately 0.05 percent of the total unleaded gasoline used in Nevada (NSOE 2009). However, the NNSS is a major consumer of biodiesel fuel in Nevada, making up approximately 60 percent of the current, annual statewide demand of 575,000 gallons (NSOE 2009); under the Expanded Operations Alternative, DOE/NNSA would increase consumption of biodiesel fuel to about 75 percent (429,000 gallons). Although not anticipated, if demand for biodiesel fuel were to exceed regional supply, the NNSS could temporarily switch to petroleum-based diesel fuel for most applications.

Implementing the Expanded Operations Alternative also would result in increased demand for electricity during construction and, later, operation of proposed projects and capabilities. DOE/NNSA estimates that the average power demand would increase up to approximately 25 percent (from 22 to 28 megawatts) over current demand, and up to approximately 35 percent (from 30 to 41 megawatts) under peak power demand. Peak demand would exceed existing system capacity (40 megawatts) (NNSA/NSO 2010a), which could result in voltage fluctuations or blackouts. However, as part of implementing the Expanded Operations Alternative, DOE/NNSA would upgrade the existing electrical distribution system to accommodate projected electrical demand, increase service reliability, and provide additional capacity to support future growth on the NNSS.

A 35 percent increase over the 2009 average electrical demand of 84,600 megawatt-hours at the NNSS (DOE 2008) would amount to approximately 105,700 megawatt-hours. During 2009, NV Energy and Valley Electric Association provided about 21,675,000 megawatt-hours collectively to their customers. Under the Expanded Operations Alternative, electricity demand would represent only about 0.49 percent of the regional electrical supply (NSOE 2009). In addition, the construction of commercial solar power generation facilities in Area 25 would increase regional electricity supplies.

S.3.1.2 Transportation and Traffic

Transportation. Radiological and nonradiological impacts on workers and the public would result from the shipments to the NNSS of radioactive waste (such as low-level radioactive waste) and radioactive materials (such as special nuclear material) from locations outside the State of Nevada, as well as from locations within Nevada, such as the TTR, to the NNSS. Radiological impacts are those associated with the effects of radiation emitted during incident-free transportation (normal operations) and from accidents resulting in a release of radioactive materials; radiological impacts are expressed as additional latent cancer fatalities. Nonradiological impacts are independent of the nature of the cargo being transported and are expressed as number of traffic accident fatalities.

Radioactive waste shipments would be by truck or by a combination of rail and truck. There is no rail line to the NNSS; therefore, rail cargo must be transferred to trucks at a transfer station. DOE/NNSA is not proposing, however, to construct or cause to be constructed any new rail-to-truck transfer facilities. Some shipments, such as radioactive materials shipments, would only be by truck. **Table S–2** provides the estimated number of shipments of radioactive waste and radioactive materials to the NNSS under each alternative.

Special Nuclear Material

Special nuclear material is (1) plutonium, uranium-233, uranium enriched in isotopes of uranium-233 or -235, or any other material that the U.S. Nuclear Regulatory Commission determines to be special nuclear material, or (2) any material artificially enriched by any of these radioactive materials.

Table S–2 Estimated Number of Shipments of Radioactive Waste and Materials

Mode of Shipment to the Nevada National Security Site	*No Action Alternative*	*Expanded Operations Alternative*	*Reduced Operations Alternative*
Truck			
In-state radioactive waste shipments	2,300	15,000	2,300
Out-of-state radioactive waste shipments	25,000	80,000	25,000
Out-of-state radioactive material shipments	240	11,000	180
Rail-to-Truck			
In-state radioactive waste shipments (truck only)	2,300	15,000	2,300
Out-of-state radioactive waste shipments (rail and truck)	38,000	92,000	38,000
Out-of-state radioactive material shipments (truck only)	240	11,000	180

This *Final NNSS SWEIS* includes analyses of incident-free transportation for two cases: a Constrained Case and an Unconstrained Case. The Constrained Case retains current routing of shipments of low-level and mixed low-level radioactive waste to avoid crossing the Colorado River near Hoover Dam and the interstate system in Las Vegas, Nevada. The Unconstrained Case, in which shipments of this waste would travel over the bypass bridge near the Hoover Dam and on the interstate system through the greater metropolitan area, was analyzed to provide information relevant to consideration of potential highway routing-related revisions to NNSS's waste acceptance criteria. After consultation with the Nevada Department of Environmental Protection as part of the waste acceptance criteria revision process, DOE/NNSA determined that it would retain the highway routing restrictions for shipments of low-level radioactive waste; therefore, there will be no need to revise the waste acceptance criteria in this regard (DOE 2012). For this reason, the Summary no longer includes the results of the Unconstrained Case analysis; those results, however, may be found in Volume 2, Chapter 5, Section 5.1.3.1.2, of the *NNSS SWEIS*.

Incident-Free Transportation (Constrained Case). For incident-free truck transportation, under all three alternatives (No Action, Expanded Operations, and Reduced Operations), DOE/NNSA estimated (numerically calculated) that approximately 1 (1.3), 3 (3.3), and 1 (1.3) latent cancer fatality(ies), respectively, would occur in the population of transportation workers exposed to radiation from shipments of low-level and mixed low-level radioactive waste (see **Figure S–5**). Because many workers would be involved, the risk to an individual worker would be small. Similarly, DOE/NNSA estimated that less than 1 (0.2, 0.8, and 0.2, respectively) latent cancer fatality would occur among members of the public exposed to these same truck shipments under the three alternatives.

For incident-free rail-to-truck transportation, under all three alternatives (No Action, Expanded Operations, and Reduced Operations), DOE/NNSA estimated (numerically calculated) that less than 1 (0.5), 2 (1.5), and less than 1 (0.5) latent cancer fatality(ies), respectively, would occur in the population of transportation workers exposed to radiation from shipments of low-level and mixed low-level radioactive waste. Similarly, DOE/NNSA estimated that less than 1 (0.1 for No Action and Reduced Operations and 0.3 for Expanded Operations) latent cancer fatality would occur among members of the public exposed to these same truck and rail shipments under the three alternatives (see Figure S–5).

What is a Latent Cancer Fatality?

A latent cancer fatality is a death from cancer resulting from, and occurring sometime after, exposure to ionizing radiation or other carcinogens. This site-wide environmental impact statement focuses on latent cancer fatalities as the primary means of evaluating health risk from radiation exposure. The values reported for latent cancer fatalities are the increased risk of a fatal cancer for a maximally exposed individual or noninvolved worker, or the increased risk of a single fatal cancer occurring in an identified population.

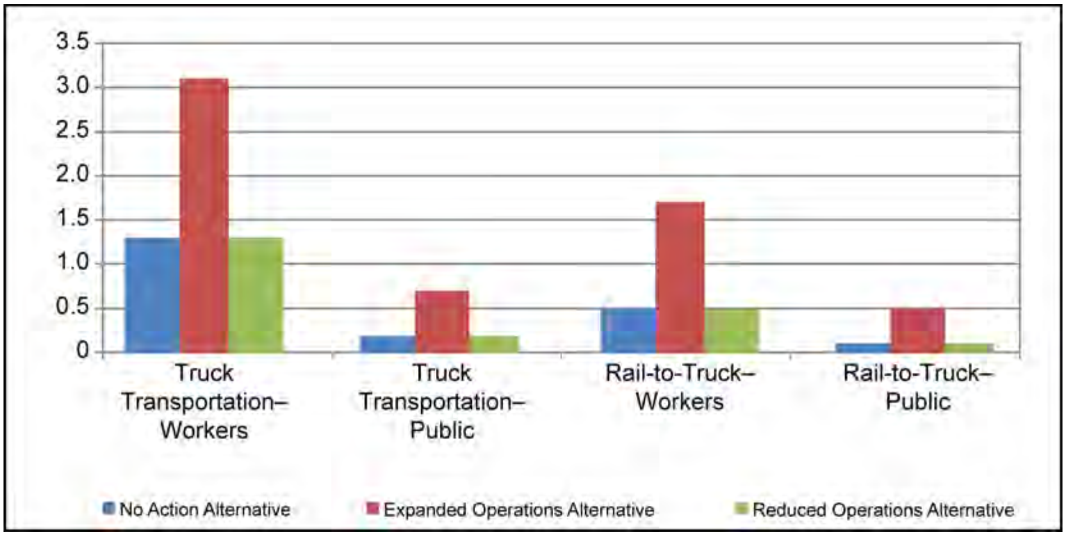

Figure S–5 Latent Cancer Fatalities from Incident-Free Transportation (Constrained Case)

Under the No Action Alternative or Reduced Operations Alternative, if an individual member of the public were exposed to every truck shipment of radioactive waste and materials, an unlikely event, this maximally exposed individual would receive an estimated dose of about 10 millirem, resulting in a risk of contracting a fatal cancer of 5×10^{-5} (1 chance in 200,000). Under the Expanded Operations Alternative, this individual would receive an estimated dose of about 20 millirem, resulting in a risk of contracting a fatal cancer of 1×10^{-5} (1 chance in 100,000). An individual exposed to every rail shipment would receive an estimated dose of about 10 millirem under the No Action and Reduced Operations Alternatives, and about 20 millirem under the Expanded Operations Alternative.

Transportation Accidents. Two types of accident analyses were performed: an assessment of consequences associated with a maximum reasonably foreseeable accident and a risk analysis that accounted for all types of accidents. The maximum reasonably foreseeable transportation truck accident involving the release of radiation was estimated to occur at an annual frequency of about 3.2×10^{-7} (about 1 chance in 3.1 million) under the No Action and Reduced Operations Alternatives and about 6.1×10^{-7} (about 1 chance in 1.6 million) under the Expanded Operations Alternative. This accident would involve the release of radiation from a truck carrying low-level radioactive waste or mixed low-level radioactive waste that is involved in a severe collision and an ensuing fire. If the accident were to occur in an urban area, DOE/NNSA estimates that the consequences for the population within 50 miles of the accident would be a collective dose of approximately 180 person-rem, which would result in less than 1 (0.1) additional fatal cancer in that population. The consequences for the maximally exposed individual, a hypothetical individual assumed to be located downwind of the event and exposed to the entire plume of radioactive release, would be an estimated dose of 34 millirem, resulting in a risk to that individual of contracting a fatal cancer of 2×10^{-5} (1 chance in 50,000). The corresponding rail accident was estimated to occur at an annual frequency of about 8.4×10^{-8}

Units of Radiation

A rem is a unit of radiation dose used to measure the biological effects of different types of radiation on humans. The dose in rem is estimated by a formula that accounts for the type of radiation, the total absorbed dose, and the tissues involved. One thousandth of a rem is a millirem. The average dose to an individual in the United States, primarily from natural background sources of radiation, is about 310 millirem per year; the national average including medical sources is about 620 millirem.

A person-rem is a unit of collective dose applied to a population or group of individuals. It is calculated as the sum of the estimated doses, in rem, received by each individual of the specific population. For example, if 1,000 people each received a dose of 1 millirem, the collective dose would be 1 person-rem (1,000 persons × 0.001 rem = 1.0 person-rem).

(about 1 chance in 10 million); this accident was not analyzed because the probability of the event is so remote.

For the risk analysis, under the No Action and Reduced Operations Alternatives, the total transportation accident risk for all projected accidents involving radioactive waste and radioactive materials would result in an estimated collective dose to the general population of 0.33 person-rem (truck) and 0.13 person-rem (rail-to-truck), resulting in less than 1 (0.0002) latent cancer fatality for truck transport and less than 1 (0.00008) latent cancer fatality for rail-to-truck transport. The nonradiological accident risks were estimated to be 2 and 6 traffic accident fatalities in the general population for truck transport and rail-to-truck transport, respectively. Under the Expanded Operations Alternative, the total transportation accident risk for all projected accidents would result in an estimated collective dose to the population of about 17 person-rem (truck) and 8 person-rem (rail-to-truck), resulting in less than 1 (0.01) latent cancer fatality for truck transport, and less than 1 (0.005) latent cancer fatality for rail-to-truck transport. The nonradiological accident risks were estimated to be 7 and 16 fatal traffic accident fatalities in the general population for truck transport and rail-to-truck transport, respectively.

Transportation Accident Risk

In a shipping campaign, risk is defined as the sum of the probability of each accident involving a release of radioactive material multiplied by the consequence of that event (i.e., the product of these two factors summed for all accidents).

Traffic. Traffic impacts would result from personnel (worker) trips, and trucks transporting radioactive waste and radioactive and nonradioactive materials. Traffic impacts are expressed as the relative change in the number of onsite and offsite daily vehicle trips and the degree to which traffic on nearby Federal and state highways would be affected, collectively referred to as the "level of service." The level of service provides a means to gauge the degree of congestion on transportation networks. The six levels, designated "A" through "F," represent a range of traffic conditions; the best operating conditions are characterized by free flow and little delay (level of service A) and the worst operating conditions, by poor progression and long delays (level of service F) (TRB 2000).

Level of Service C

The number of vehicles stopping is significant, although many still pass through the affected intersection without being required to stop.

Under the No Action Alternative, traffic on Mercury Highway (onsite traffic) would continue to operate at level of service A during peak traffic hours, as there would be an increase of only 16 daily vehicle trips (relative to a baseline of 1,748 trips) (see **Figure S–6**). Implementing the Expanded Operations Alternative would result in additional congestion on Mercury Highway during peak traffic hours (level of service B), as there would be an increase of about 832 daily vehicle trips. Under the Reduced Operations Alternative, traffic on Mercury Highway would continue to flow freely (level of service A), as daily vehicle trips would decrease by about 153.

Construction of one or more commercial solar power generation facilities in Area 25 would result in increased traffic on Lathrop Wells Road north of U.S. Route 95 and on site (level of service information is unavailable). Under the No Action, Expanded Operations, and Reduced Operations Alternatives, DOE/NNSA estimates that average daily vehicle trips (worker vehicles) during peak hours would increase by 250, 375, and 200, respectively. The increase in traffic from workers and construction equipment would require increased road maintenance or fundamental improvements. Although traffic during operations of solar power generation facilities would be less than traffic during construction, road maintenance or fundamental improvements would continue to be needed.

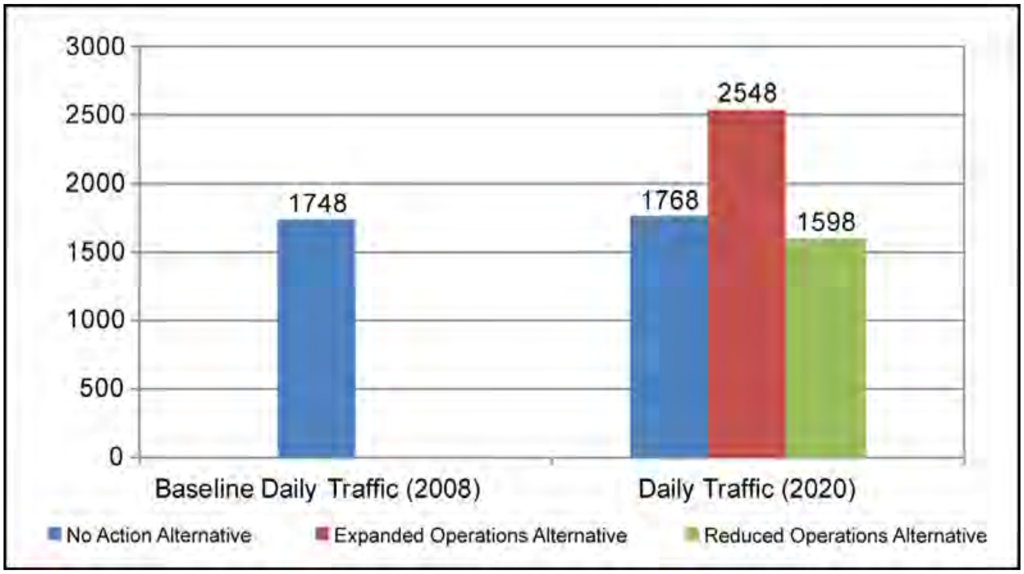

Figure S–6 Daily Vehicle Trips Between U.S. Route 95 and Mercury Highway

To estimate offsite traffic impacts after complete implementation of the alternatives, DOE/NNSA estimated baseline traffic levels and corresponding levels of service for the year 2020 for highways nearby the NNSS. The additional traffic associated with any alternative generally would not change future levels of service; for instance, the levels of service along U.S. Route 95 just west of Nevada State Route 373 in Amargosa Valley would remain at level of service C, and along Nevada State Route 373 south of U.S. Route 95 would remain at level of service A.

S.3.1.3 Socioeconomics

The continued operation and proposed projects and capabilities at the NNSS would result in changes to the current (baseline) workforce under each of the three alternatives. Accordingly, DOE/NNSA evaluated how these changes in workforce could affect economic activity; population; and the demand on housing, public finance, and public services, such as police and fire protection, in Clark and Nye Counties (the counties in which the principal direct and indirect socioeconomic impacts are likely to occur).

DOE/NNSA estimates that implementing the No Action Alternative would result in the creation of up to 1,000 temporary and 150 permanent jobs (direct employment), in addition to the current (baseline) workforce of about 1,700. Most of the additional workforce would be due to the construction and operation of a 240-megawatt commercial solar power generation facility in Area 25, as construction would require an average of approximately 500 individuals during the 35-month construction period (temporary workforce), and operation would require approximately 150 individuals (permanent workforce).

An increase in direct employment under the No Action Alternative also would result in an increase in the demand for goods (for example, fuel for personal vehicles) and services (for example, vehicle repair), which, in turn, would create additional employment opportunities (indirect jobs). DOE/NNSA used the Regional Input-Output Modeling System II (RIMS II 2010), which was developed for the U.S. Department of Commerce, to evaluate the indirect economic impact of employment. Based on this analysis, approximately 930 to 1,860 indirect temporary and approximately 394 indirect permanent jobs would be created.

The addition of 544 direct and indirect permanent jobs (150 direct and 394 indirect) was estimated to reduce unemployment by 0.3 percent in Clark County and 3.9 percent in Nye County. DOE/NNSA estimates there would be adequate housing and public services available for this additional workforce. For example, housing vacancies in Clark and Nye Counties would decrease by only 0.01 percent and 0.1 percent, respectively, and the person-to-hospital-bed ratio would remain unchanged.

Implementing the Expanded Operations Alternative would result in the creation of up to 1,500 temporary and 625 permanent jobs, in addition to the current (baseline) workforce of about 1,700. Most of the additional workforce would be a result of the construction and operation of 1,000 megawatts of commercial solar power generation facilities in Area 25, as construction would require an average of approximately 750 individuals (1,500 workers at peak) during the 42-month construction period (temporary workforce), and operation would require approximately 200 individuals (permanent workforce). DOE/NNSA estimates that this workforce would result in approximately 1,866 to 3,256 indirect temporary and approximately 920 indirect permanent jobs.

The addition of 1,545 direct and indirect permanent jobs (625 direct and 920 indirect) under the Expanded Operations Alternative would reduce unemployment in Clark and Nye Counties by 0.8 and 11.0 percent, respectively. The increased temporary and permanent workforce would not result in undue demand on housing (vacancies would decrease by only 0.02 percent in Clark County and 0.4 percent in Nye County) and most public services, although there could be a need to hire five new teachers (four in Clark County and one in Nye County) to maintain the current student-to-teacher ratio, and a need to expand the medical clinic in Mercury to maintain the person-to-hospital-bed ratio.

Implementing the Reduced Operations Alternative would result in the need for an average of 400 individuals (800 workers at peak) during the 32-month period to construct a 100-megawatt commercial solar power generation facility in Area 25. The permanent workforce needed to operate a solar power generation facility (125 individuals), however, would not offset the loss of employment due to the reduction in the levels of operation at the NNSS; the NNSS workforce would be reduced by approximately 45 individuals (from about 1,700 to 1,655 individuals). The longer-term workforce reduction also would reduce the demand for goods and services and thus indirect employment in Clark and Nye Counties. Housing vacancies would increase and demand for public services would decrease because of the reduction in the permanent workforce.

S.3.1.4 Groundwater Hydrology

Groundwater Quality. Drinking water quality is monitored to assess compliance with primary and secondary drinking water standards according to a schedule set in Federal and state laws, and requirements set by the Nevada Division of Environmental Protection. The three public water systems on site and permitted water hauling trucks meet primary and secondary drinking water standards. Implementing any of the three alternatives is not expected to result in a degradation of groundwater quality because projects and activities would be undertaken within confinement barriers, such as tests in the Joint Actinide Shock Physics Experimental Research Facility, or would be above ground, where depth to groundwater is on the order of several hundred feet. In addition, the use of operational controls and other administrative measures would remove and remediate any surface spills well before contaminants could migrate to the water table (the zone beneath the surface that is saturated with water).

There have been 828 underground nuclear tests at the NNSS. Of these, approximately one-third were detonated near, below, or within the water table. These detonations have contaminated groundwater with 43 radionuclides; tritium (a radioactive form of hydrogen) is believed to be the most mobile

Corrective Action

Corrective action unit means one or more corrective action sites grouped geographically, by technical similarity or agency responsibility, or for other appropriate reasons, for purposes of determining corrective actions.

Corrective action site refers to the sites potentially requiring corrective action.

(Bowen et al. 2001). The Federal Facility Agreement and Consent Order established five corrective action units that delineate and define areas of concern for groundwater contamination (see **Figure S–7**).

In response, and to satisfy DOE Orders and other program requirements, DOE/NNSA has monitored tritium (and other radionuclides) in wells on the NNSS and nearby offsite areas. Other organizations, such as Nye County, also monitor tritium and other radionuclides in groundwater. Tritium has been detected in two offsite wells. In 2009, DOE/NNSA detected tritium in Well ER-EC-11, which is less than half a mile off the northwestern boundary of the NNSS on the Nevada Test and Training Range and about 14 miles from the nearest public water source, a private well (see Figure S–7). The tritium concentration was 13,180 picocuries per liter, which is below the U.S. Environmental Protection Agency's (EPA's) Safe Drinking Water Act standard of 20,000 picocuries per liter. Later, in 2010, DOE/NNSA found detectable levels of tritium (48.3 picocuries per liter) in Well PM-3, which is located about 11,000 feet west of the NNSS boundary on the Nevada Test and Training Range (see Figure S–7). **Figure S–8** displays the locations of these and other wells on the NNSS and nearby offsite areas, as well as associated tritium concentrations.

In compliance with the Federal Facility Agreement and Consent Order, DOE/NNSA continues to develop groundwater flow and transport models for each of the corrective action units to identify contaminant boundaries where waters inside the boundaries exceed the radiological protection requirements of the Safe Drinking Water Act. Contaminant boundaries provide the basis for establishing use-restriction areas and identifying regulatory boundaries for protection of the health and safety of the public.

Groundwater modeling development requires two steps. First, a regional three-dimensional groundwater flow model was developed for the Death Valley regional flow system to identify risks to the public, workers, and the environment (DOE/NV 1997). Second, groundwater flow (boundary conditions) from this regional model was used to develop groundwater flow and transport models for each underground corrective action unit. These smaller-scale groundwater models will be used to identify contaminant boundaries based on the maximum extent of contaminant migration over a 1,000-year period.

Although groundwater flow and transport models are under development, they have been completed only for the Frenchman Flat corrective action unit (see Figure S–7) (Navarro Nevada Environmental Services 2010). **Figure S–9** shows the model-based estimation of the extent of groundwater contamination where there is a 95 percent certainty that contamination will exceed the Safe Drinking Water Act standards for radionuclides in the Frenchman Flat area over the next 1,000 years.

Groundwater Use. In this *NNSS SWEIS*, DOE/NNSA examined the extent to which each of the alternatives would have an adverse impact on the capacity of aquifers (sustainable yield) within a hydrographic basin. Potential impacts were estimated by comparing current (baseline) groundwater demand for each basin, modified by the demand from continuing and proposed projects and capabilities under each alternative, to the sustainable yield of each basin. **Figure S–10** shows the basins underlying the NNSS.

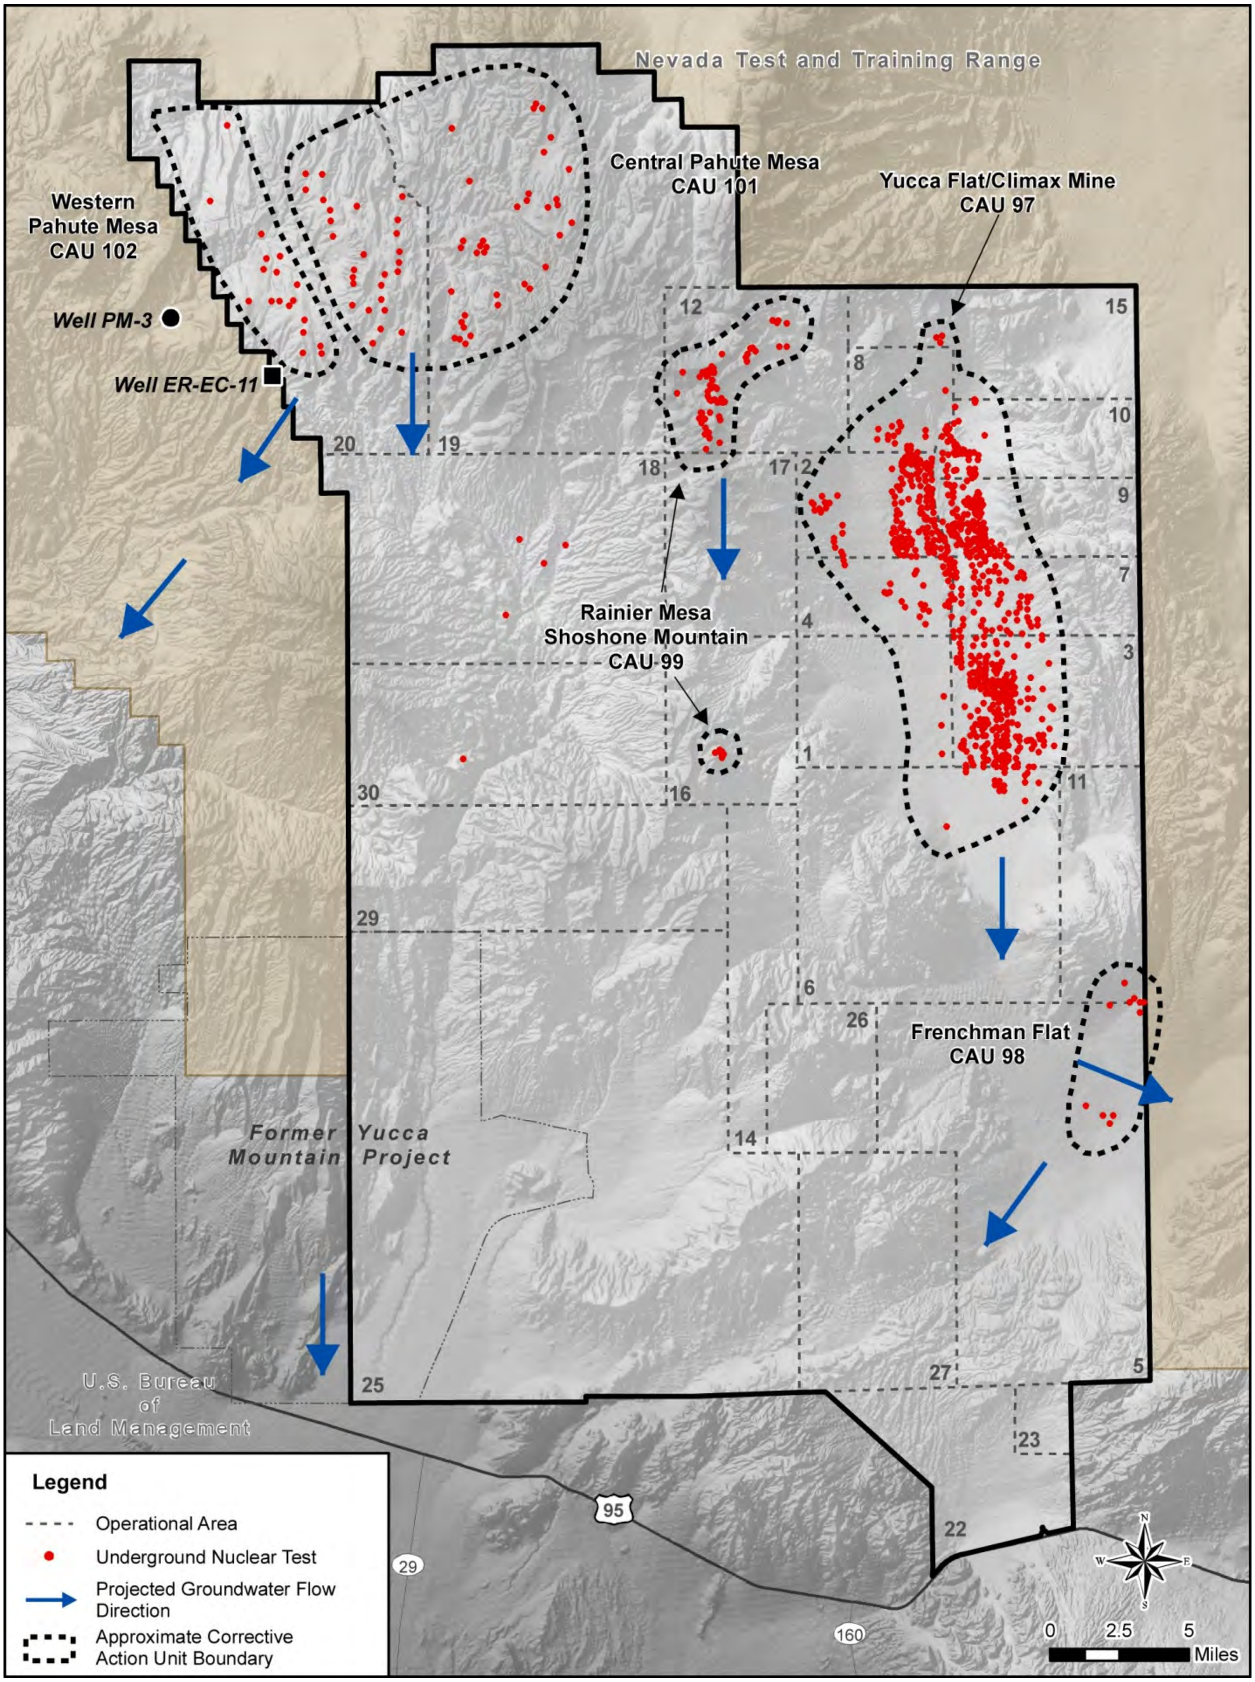

Figure S–7 Underground Test Area Corrective Action Units at the Nevada National Security Site

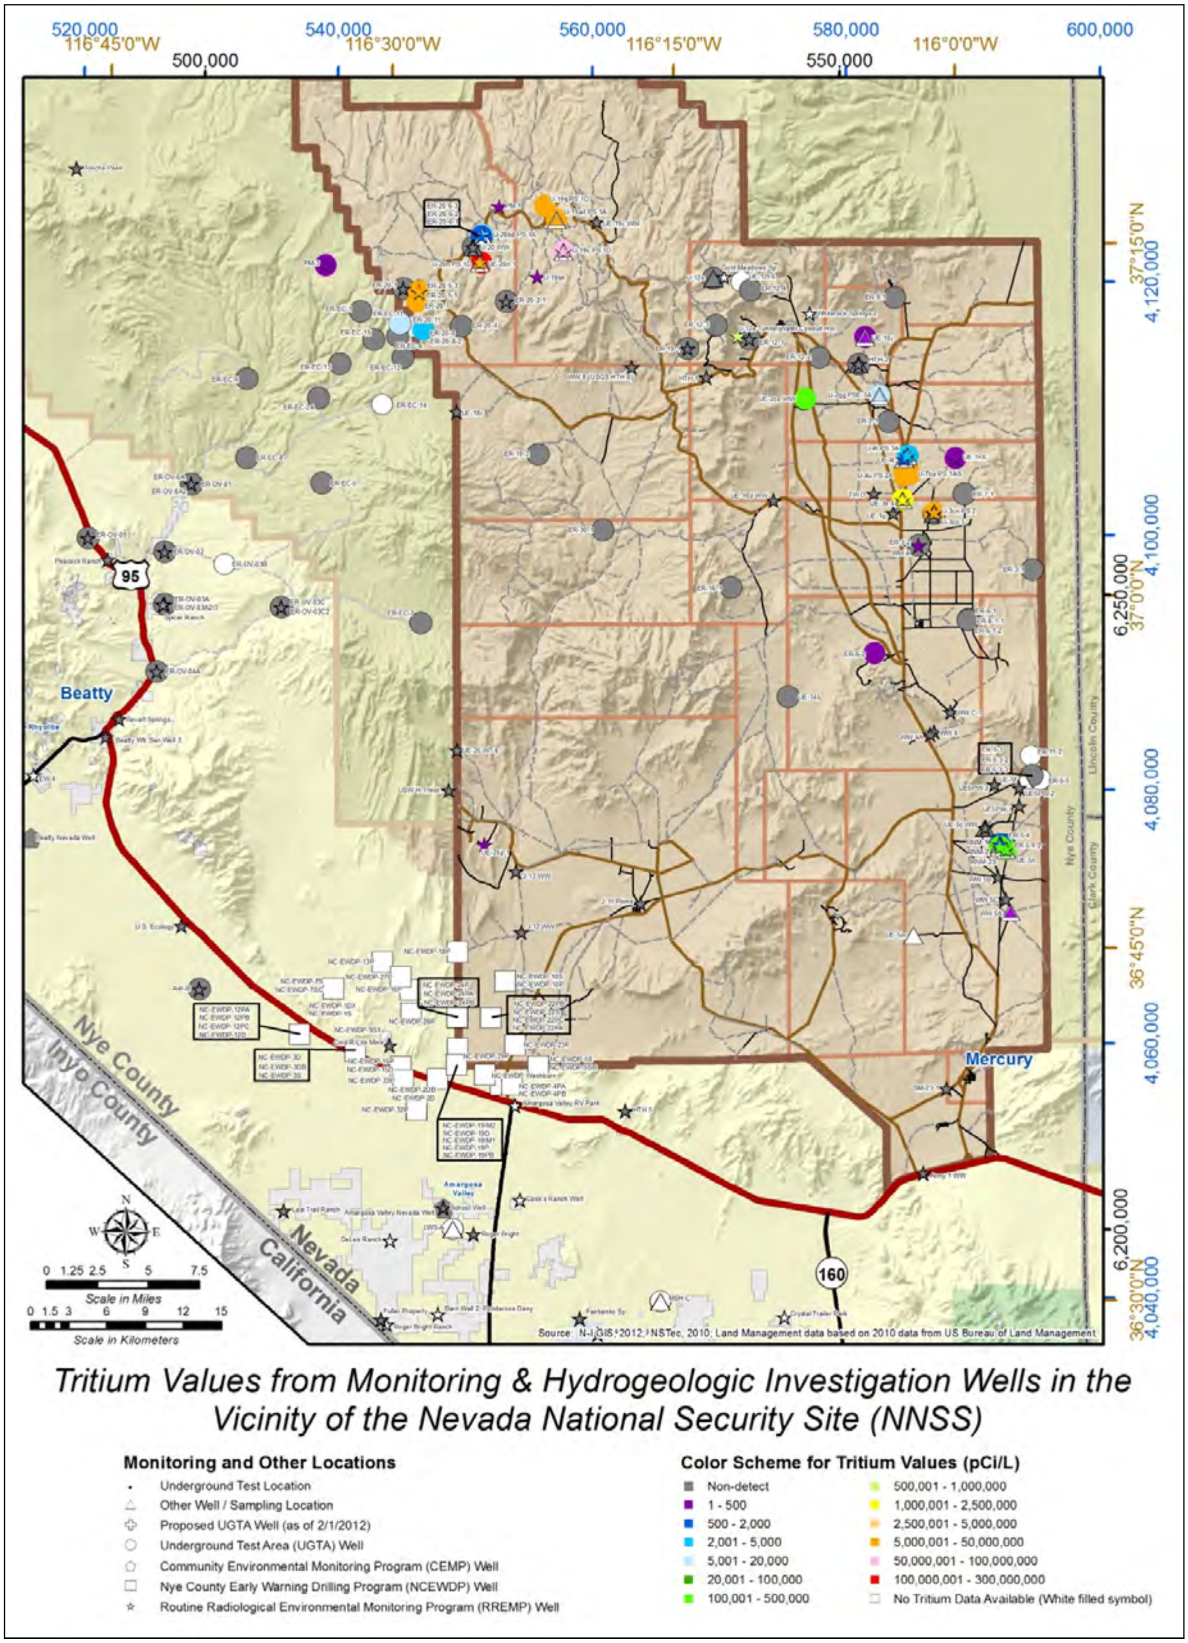

Figure S–8 Concentration of Tritium Detected in Monitoring and Hydrogeologic Investigation Wells and Springs of the Nevada National Security Site

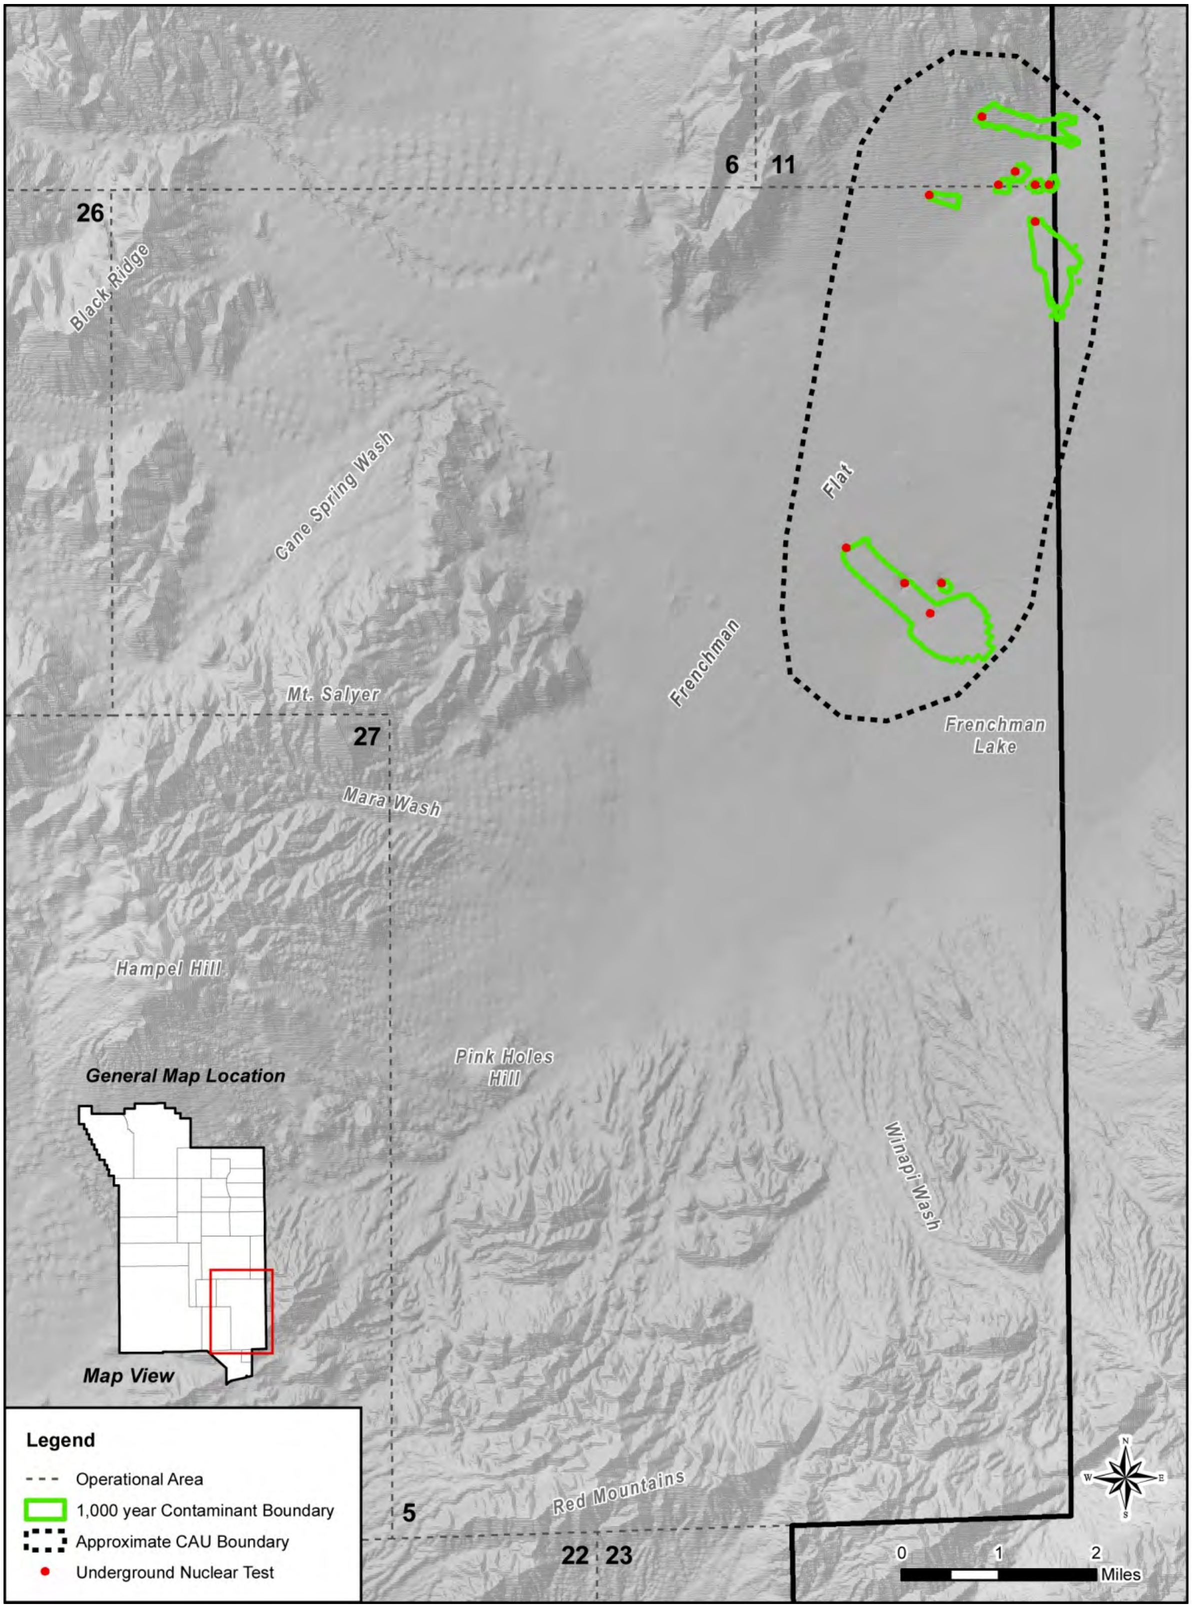

Figure S–9 Modeled Extent of the Contaminant Boundary in the Frenchman Flat Corrective Action Unit in 1,000 Years

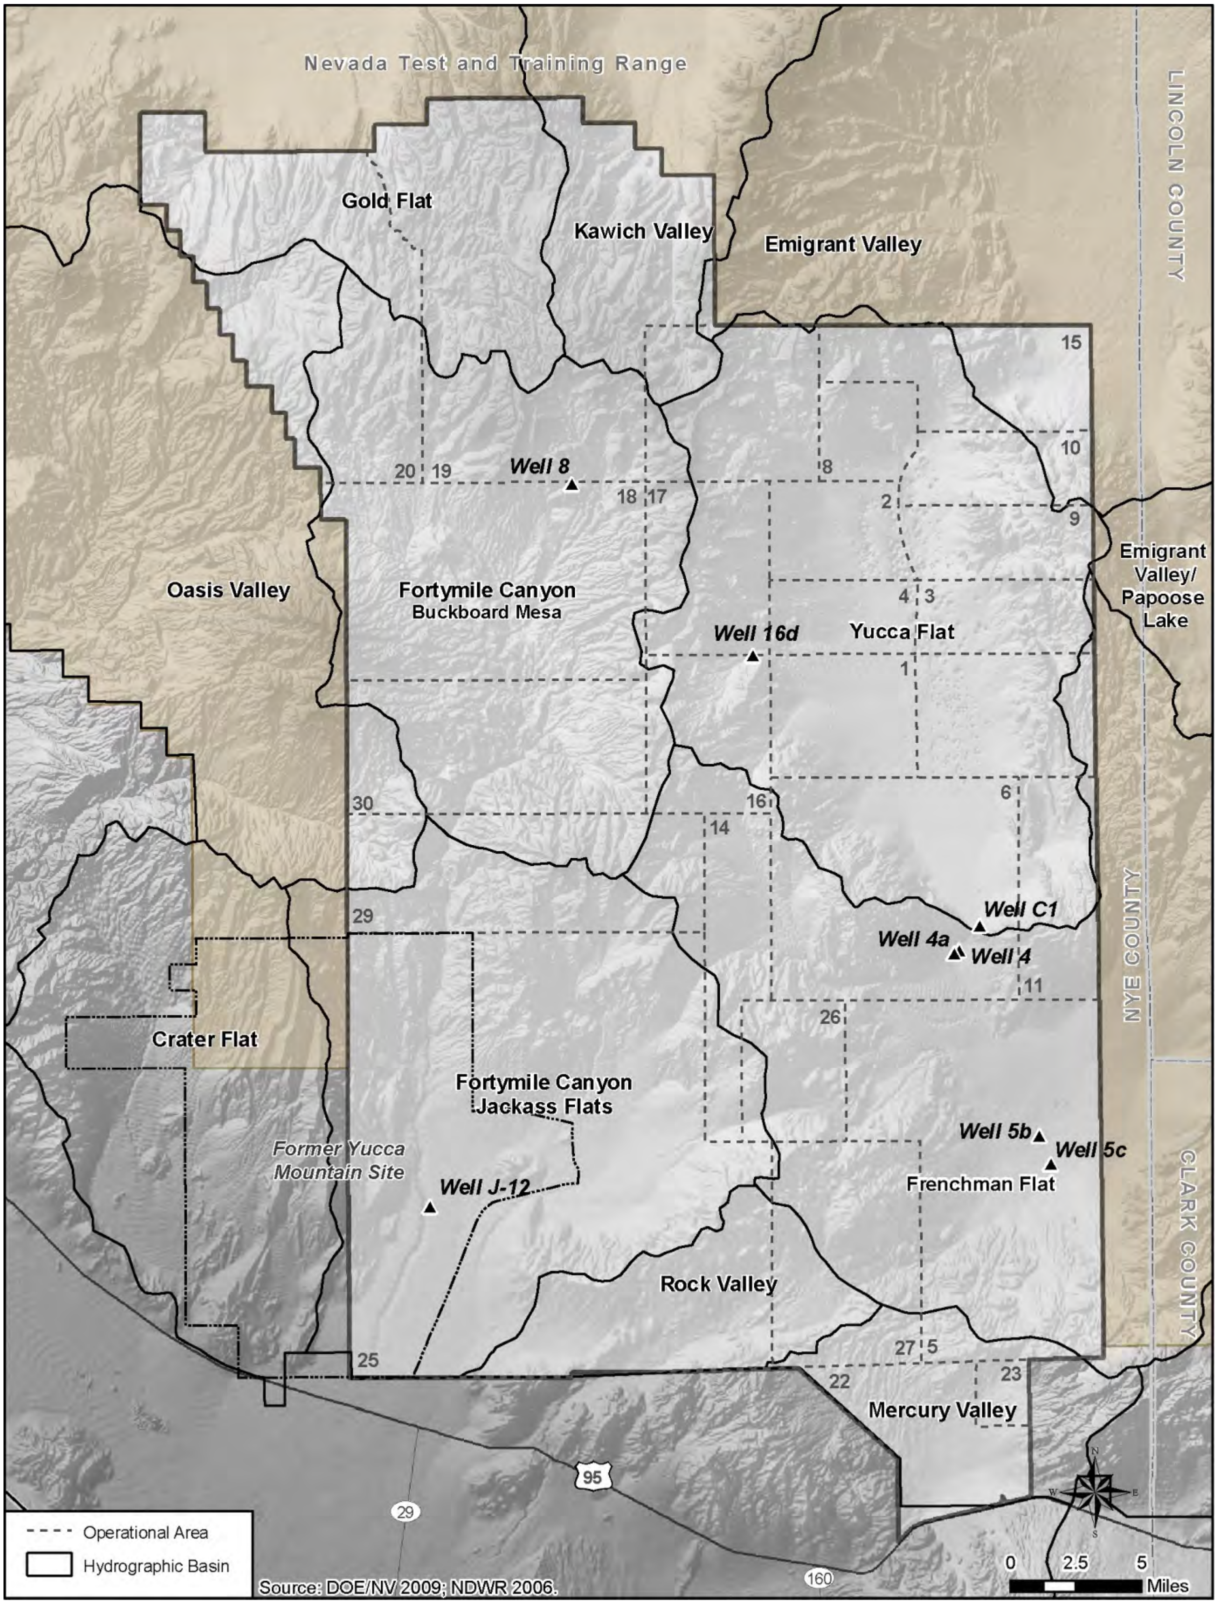

Figure S–10 Hydrographic Basins at the Nevada National Security Site

Annual water usage at the NNSS from 2005 through 2011 ranged from 530 to 691 acre-feet (NSTec 2010; Rudolph 2012). DOE/NNSA has established goals to reduce the use of potable water by 2015 by at least 16 percent from the 2007 total water use level of about 691 acre-feet per year (NSTec 2008) (potable water accounts for up to 90 percent of the current groundwater use). However, the analysis in this *NNSS SWEIS* did not account for this reduction in demand, and, instead, conservatively assumed a continued annual (baseline) water usage of 691 acre-feet.

Tables S–3 through **S–5** illustrate the estimated groundwater demand and the extent to which demand would affect sustainable yield of the affected basins (sustainable yields are from the Nevada State Engineer [NDWR 2010]). Under the three alternatives, withdrawals from each basin would be below the sustainable yield of each basin, with the exception of Frenchman Flat, where approximately 427 (Reduced Operations Alternative) to 591 percent (Expanded Operations Alternative) of the basin's sustainable yield would be withdrawn annually. The Nevada State Engineer estimates a perennial yield of 100 acre-feet per year for Frenchman Flat (NDWR 2010), which is based on assumptions that little or no groundwater recharge from precipitation occurs in the basin. Studies by DOE/NNSA and others suggest that in-basin recharge does occur and that perennial yield values are much higher than 100 acre-feet per year. Groundwater flow and transport models from underground corrective action unit activities (SNJV 2004), two U.S. Geological Survey models (Hevesi et al. 2003), and two Desert Research Institute models (Russell and Minor 2002) suggest greater estimates of precipitation-driven recharge (and thus perennial yield) to the Frenchman Flat basin. As an example, the underground corrective action unit model yields an estimate of 1,070 acre-feet per year, and the Desert Research Institute models provide perennial yield estimates of 1,920 acre-feet per year. Although DOE/NNSA appears to be overdrawing water from Frenchman Flat by a large percentage, water levels in wells have remained static and have not declined, even during peak water usage of 3,375 acre-feet in 1989. This suggests that the perennial yield of Frenchman Flat is far higher than 100 acre-feet per year and more likely in the range of yields estimated by DOE/NNSA and other models.

Groundwater Use Terms

Perennial yield is an estimate of the quantity of groundwater that can be withdrawn from a basin on an annual basis without depleting the basin (Scott et al. 1971).

Sustainable yield is the perennial yield of the basin minus any rights already committed by the Nevada State Engineer to other users.

Hydrographic basins are mapped on the basis of topographic divides and are used by the State of Nevada for the purposes of water appropriation and management.

Construction and operation of one or more commercial solar power generation facilities would result in a marked increase in water consumption in Jackass Flats basin (and the single largest use of water on the NNSS), with the resulting long-term demand ranging from 5 (Reduced Operations Alternative) to 19 percent (Expanded Operations Alternative) of sustainable yield of the basin. While the Nevada State Engineer lists the perennial yield of the Fortymile Canyon, Jackass Flats Subdivision as 4,000 acre-feet per year, this value represents an aggregation of yield values for several basins adjacent to Jackass Flats (i.e., a regional yield value). Studies conducted by DOE show a range of values as low as 880 acre-feet per year (DOE 2008). These demands would be unlikely to reduce groundwater recharge to another downgradient aquifer to the degree that the aquifer's sustainable yield is reduced or current uses of that aquifer are adversely affected. Regardless, DOE/NNSA would continue to monitor groundwater levels and flow patterns across the NNSS, employ site-specific modeling to estimate specific impacts of future projects, and modify the points of diversion and pumping rates as needed to avoid adversely impacting any single aquifer.

Table S–3 No Action Alternative Impacts on Groundwater Supply

Basin	***Water Demand, excluding solar power generation facility(ies) (acre-feet per year)***	***Water Demand, including construction demand from solar power generation facility(ies) (acre-feet per year)***	***Water Demand, including operational demand from solar power generation facility(ies) (acre-feet per year)***	***Nevada State Engineer Sustainable Yield of Basin (acre-feet per year)***	***Maximum Percentage of Sustainable Yield Consumed during Construction***	***Maximum Percentage of Sustainable Yield Consumed during Operation***
Frenchman Flat (160)	474	474	474	100	474 [a]	474 [a]
Fortymile Canyon, Buckboard Mesa Subdivision (227b)	42	42	42	3,600	1	1
Fortymile Canyon, Jackass Flats Subdivision (227a)	47	397	297	4,000	10	7
Yucca Flat (159)	128	128	128	350	37	37
Total	691	1,041	941			

[a] Analysis is based on Nevada State Engineer estimates of perennial yield (100 acre-feet per year), which results in the appearance of an overutilization of the resource. To the contrary, several groundwater flow and transport models demonstrate higher estimates of precipitation-driven recharge (and thus perennial yield), and water levels in wells have not declined suggesting that perennial yield is far higher than 100 acre-feet per year.

Table S–4 Expanded Operations Alternative Impacts on Groundwater Supply

Basin	***Water Demand, excluding solar power generation facility(ies) (acre-feet per year)***	***Water Demand, including construction demand from solar power generation facility(ies) (acre-feet per year)***	***Water Demand, including operational demand from solar power generation facility(ies) (acre-feet per year)***	***Nevada State Engineer Sustainable Yield of Basin (acre-feet per year)***	***Maximum Percentage of Sustainable Yield Consumed during Construction***	***Maximum Percentage of Sustainable Yield Consumed during Operation***
Frenchman Flat (160)	591	591	591	100	591 [a]	591 [a]
Fortymile Canyon, Buckboard Mesa Subdivision (227b)	53	53	53	3,600	1	1
Fortymile Canyon, Jackass Flats Subdivision (227a)	59	1,059	759	4,000	27	19
Yucca Flat (159)	159	159	159	350	46	46
Total	862	1,862	1,562			

[a] Analysis is based on Nevada State Engineer estimates of perennial yield (100 acre-feet per year), which results in the appearance of an overutilization of the resource. To the contrary, several groundwater flow and transport models demonstrate higher estimates of precipitation-driven recharge (and thus perennial yield), and water levels in wells have not declined suggesting that perennial yield is far higher than 100 acre-feet per year.

Table S–5 Reduced Operations Alternative Impacts on Groundwater Supply

Basin	Water Demand, excluding solar power generation facility(ies) (acre-feet per year)	Water Demand, including construction demand from solar power generation facility(ies) (acre-feet per year)	Water Demand, including operational demand from solar power generation facility(ies) (acre-feet per year)	Nevada State Engineer Sustainable Yield of Basin (acre-feet per year)	Maximum Percentage of Sustainable Yield Consumed during Construction	Maximum Percentage of Sustainable Yield Consumed during Operation

Yucca Flat (159)	115	115	115	350	33	33
Total	622	822	797			

[a] Analysis is based on Nevada State Engineer estimates of perennial yield (100 acre-feet per year), which results in the appearance of an overutilization of the resource. To the contrary, several groundwater flow and transport models demonstrate higher estimates of precipitation-driven recharge (and thus perennial yield), and water levels in wells have not declined suggesting that perennial yield is far higher than 100 acre-feet per year.

S.3.1.5 Biological Resources

Implementing the alternatives would result in the permanent loss of native and nonnative vegetation of varying types, distribution and abundance, which would adversely impact wildlife that inhabit or otherwise use the NNSS. Vegetation would be lost through actions such as the drilling of new wells, grading and excavation for new facilities, detonations of high explosives, remediation of contaminated soils, and modification or construction of infrastructure such as roads and water lines.

In general, DOE/NNSA assessed the impacts on biological resources by considering the amount of land that would be disturbed under each alternative as a means to represent the permanent loss of vegetation and animal habitat. **Table S–6** provides an estimate of the amount of newly disturbed lands, and thus vegetation and habitat that would be lost, under each alternative.

Table S–6 Land Disturbance

Source of Disturbance	*No Action Alternative (acres)*	*Expanded Operations Alternative (acres)*	*Reduced Operations Alternative (acres)*
Total Land Disturbance	4,460	25,877	2,740
Commercial Solar Power Generation Facilities	2,650	10,300	1,200

The NNSS occupies approximately 870,000 acres of land, about 790,400 (91 percent) of which are undisturbed (DOE 2008). Of the undisturbed land, implementing the No Action, Expanded Operations, and Reduced Operations Alternatives would require an additional 4,460 (0.6 percent), 25,877 (3.3 percent), and 2,740 (0.4 percent) acres, respectively.

Vegetation. Under the Expanded Operations Alternative, which would result in the highest land disturbance among the alternatives, the primary vegetation alliances that would be impacted are Creosote Bush/White Bursage Shrubland, Nevada Jointfir Shrubland, Saltbush Shrubland, Blackbrush Shrubland, and Burrobush/Wolfberry Shrubland. In total, these vegetation alliances cover about 483,200 acres, or about 61 percent of the undisturbed lands on the NNSS. Because of the prevalence of these vegetation types on the NNSS as well as regionally, the amount of additional habitat loss (25,877 acres) would not reduce the viability of any of the vegetation alliances or result in substantial adverse impacts on biodiversity. However, some areas of creosote bush/white bursage vegetation in Jackass Flats and Frenchman Flat, as well as blackbrush vegetation in Yucca Flat, are considered sensitive habitat (BN 1999; DOE/NV 1998a) because soils are particularly vulnerable to wind erosion and require longer periods of time to recover if disturbed. To the extent possible, DOE/NNSA would avoid activities that would disturb soils in these areas.

Implementing the No Action and Reduced Operations Alternatives would result in lesser amounts of land disturbance (see Table S–6) in the same vegetation alliances, with the exception of Blackbrush Shrubland, which is not prevalent in the areas that would be affected by these alternatives. The additional habitat loss under either of these alternatives would not reduce the viability of any of the vegetation alliances or result in substantial adverse impacts on biodiversity because of the prevalence of these vegetation types on the NNSS and regionally. However, although less than under the Expanded Operations Alternative, activities under the No Action and Reduced Operations Alternatives would also occur in some areas of Jackass Flats and Frenchman Flat that have creosote bush/white bursage vegetation. To the extent possible, DOE/NNSA would avoid activities that would disturb soils in these areas.

Sensitive and Protected Species. The desert tortoise, a "threatened" species, is the only plant or animal species on the NNSS that has been determined by the U.S. Fish and Wildlife Service (USFWS) to be threatened or endangered. DOE/NNSA focused its analysis of direct and indirect impacts on the desert tortoise because data are available to delineate desert tortoise habitat on the NNSS, and these data allow quantitative estimates of the potential impacts on desert tortoises from ongoing and proposed activities at the NNSS.

On the NNSS, the northern extent of the desert tortoise occurs between elevations of approximately 3,900 and 4,880 feet above mean sea level, and its distribution and population densities are shown in **Figure S–11**. In its 2009 *Final Programmatic Biological Opinion for Implementation of Actions Proposed on the Nevada Test Site, Nye County, Nevada (2009 Biological Opinion*), USFWS concluded that activities on the NNSS would not jeopardize the continued existence of the Mojave population of desert tortoises, and no critical habitat would be destroyed or adversely modified (USFWS 2009). The *2009 Biological Opinion* also identified terms and conditions applicable to activities on the NNSS. Under these terms and conditions, USFWS determined that up to 2,710 acres of land could be disturbed, and up to 216 tortoises could be "taken" incidentally, that is, 22 could be killed or injured, and 194 could be harassed (captured, displaced, relocated, have their behavior disrupted, or intentionally removed and relocated) without the need to reinitiate consultation.

Based on the distribution and a density range of 10 to 45 tortoises per square mile (DOE/NV 1998b), DOE/NNSA estimated the amount of desert tortoise habitat disturbed and the range of the number of tortoises that could be taken under each alternative (see **Table S–7**). Implementing any alternative would result in disturbing desert tortoise habitat; however, only the No Action and Expanded Operations Alternatives would result in disturbance in excess of that permitted by USFWS. Under the Expanded Operations Alternative, the estimated number of tortoises taken (163 to 346) could exceed that permitted by USFWS (216), whereas under the No Action and Reduced Operations Alternatives, the estimated number of tortoises taken (133 to 213 and 131 to 181, respectively) would be less than that permitted by USFWS.

DOE/NNSA anticipates that the take of desert tortoises would be due primarily to harassment, rather than injury or death, because DOE/NNSA would continue to implement its Desert Tortoise Compliance Program, which requires, in part, (1) conducting clearance surveys at project sites within 1 day of the start of project construction, (2) ensuring that environmental monitors are on site during heavy equipment operations, and (3) ensuring personnel are trained in the requirements of the *2009 Biological Opinion*. Based on the annual average of takes due to injury or death on NNSS roadways since 1992 (0.75 tortoises), only a single (1) tortoise would be expected to be taken by injury or mortality each year, and the remainder would be taken by harassment by being moved off roadways or from areas of proposed land disturbance to prevent their injury or death. Nonetheless, if either the permitted disturbance of tortoise habitat or take of tortoises were reached and anticipated to be exceeded during implementation of the alternatives, DOE/NNSA would reinitiate consultation with USFWS in accordance with the *2009 Biological Opinion*.

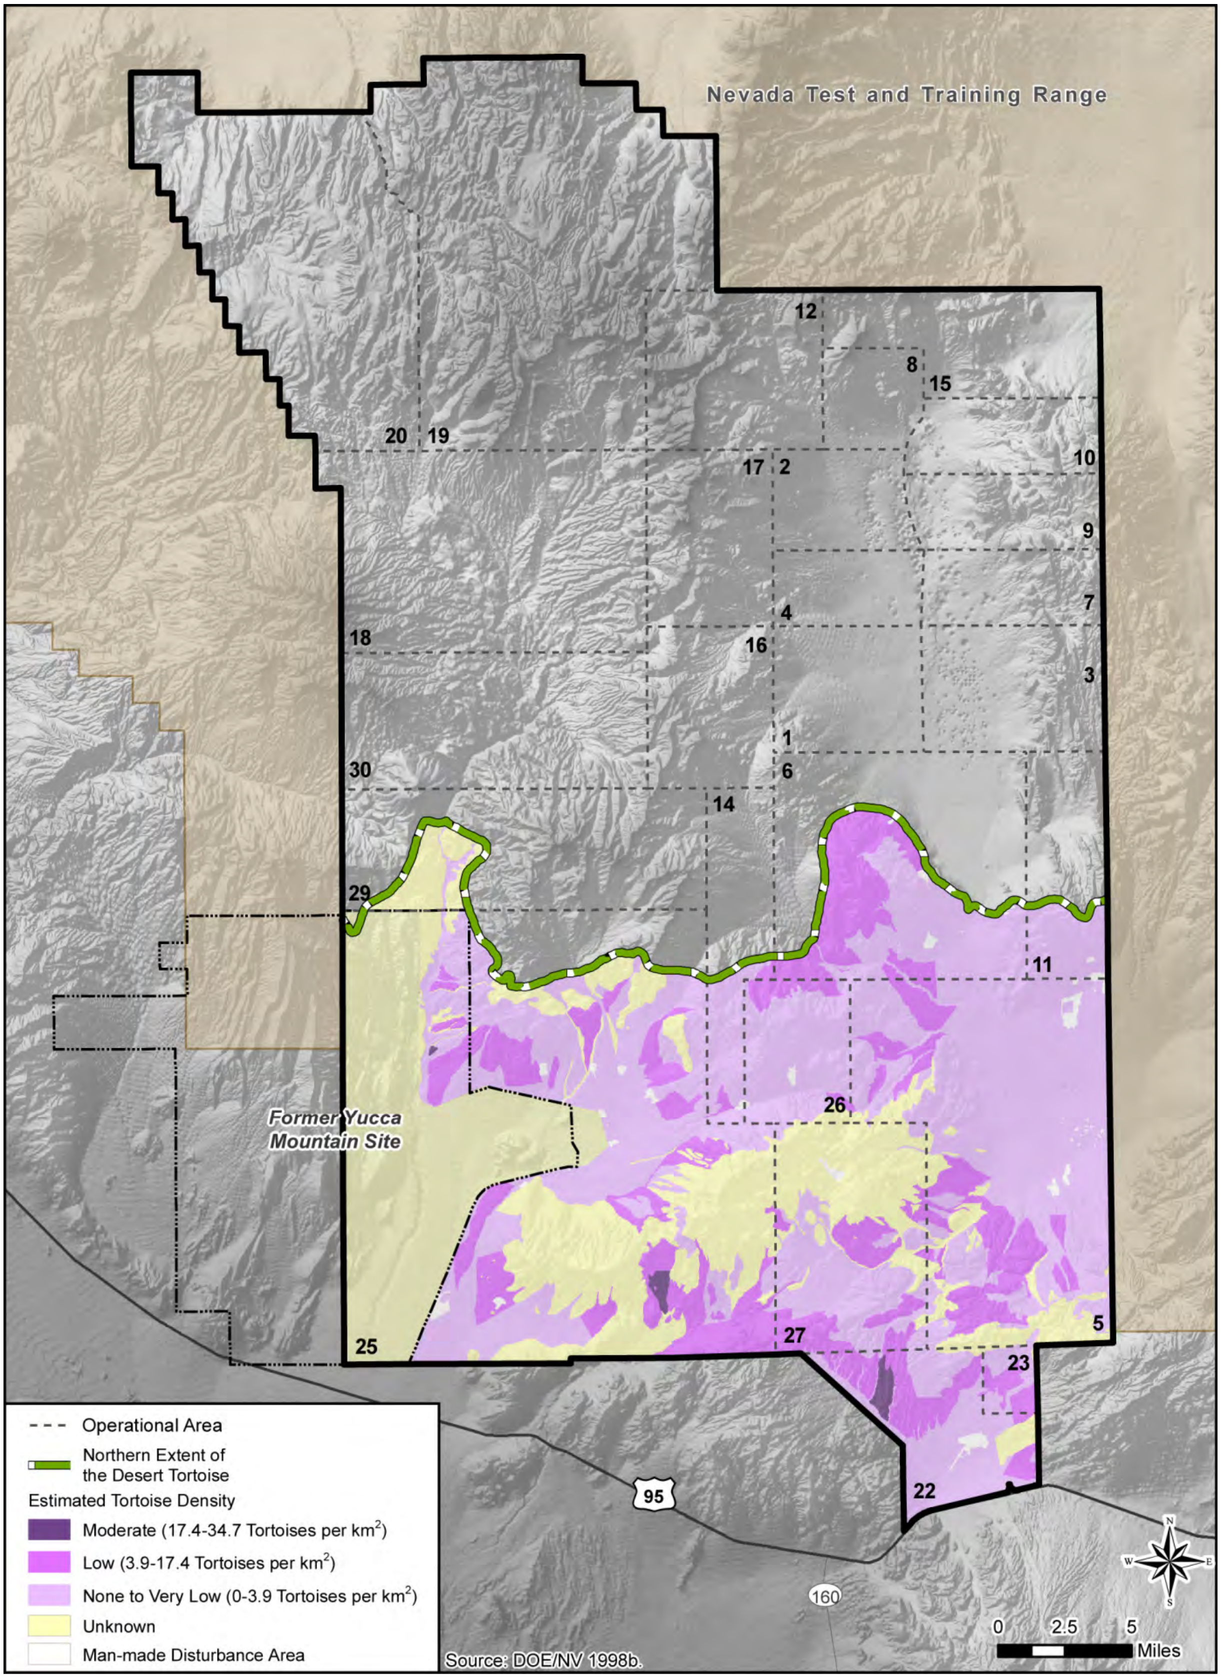

Figure S–11 Desert Tortoise Range and Abundance on the Nevada National Security Site

Commercial Solar Power Generation Facility(ies)	0–41	0–161	0–19	

S.3.1.6 Air Quality

Ambient air quality in Clark and Nye Counties would be adversely impacted because of releases of air pollutants from stationary, mobile, and fugitive sources, with the magnitude of the impact variable by alternative. Greenhouse gases, also released from these sources, would contribute to global climate change.

Air quality is determined, in part, by measuring concentrations of certain pollutants (referred to as "criteria pollutants") in the atmosphere. The EPA designates an area as "in attainment" for a particular pollutant if ambient air concentrations of that pollutant are below the National Ambient Air Quality Standards. Criteria pollutants regulated under these standards by both EPA and the State of Nevada include ozone, carbon monoxide, nitrogen dioxide, sulfur dioxide, lead, and particulate matter (two different sizes of particulates are regulated).

Air quality also is determined, in part, by estimating emissions of hazardous air pollutants; these pollutants are known or suspected to cause cancer or other serious health effects, such as birth defects. EPA, under the Clean Air Act, established emission standards (the National Emission Standards for Hazardous Air Pollutants) for 188 such pollutants, most of which originate from manmade sources. Benzene, for example, is found in gasoline. In establishing the standards, EPA identified various industries and corresponding emission limits that, if exceeded, would require the use of additional control technologies to reduce such emissions to the maximum extent achievable.

Greenhouse gases are emitted from a wide variety of sources, including energy production, industrial processes, waste, agriculture, and forestry. Carbon dioxide is by far the primary greenhouse gas emitted in the United States (EPA 2009); other gases include methane, nitrous oxide, and a variety of fluorinated gases. Effects of these emissions on the climate involve very complex processes, although recent advances in the state of the science regarding these processes suggest a very high likelihood that greenhouse gases produced by humans are affecting climate in detectable and quantifiable ways (IPCC 2008).

Greenhouse Gases

Greenhouse gases are gaseous constituents of the atmosphere, both natural and anthropogenic (resulting from or produced by human beings), that absorb and emit thermal infrared radiation (heat) emitted by the Earth's surface, the atmosphere itself, and clouds. Water vapor, carbon dioxide, nitrous oxide, methane, and ozone are the primary greenhouse gases in the Earth's atmosphere. Greenhouse gases trap heat between the Earth's surface and the lower part of the atmosphere; this phenomenon is called the greenhouse effect.

For each alternative, DOE/NNSA estimated the amount of nonradiological and hazardous air pollutants, and greenhouse gases (expressed as carbon dioxide-equivalents) that would be released during the construction of proposed projects and the operation of ongoing and proposed projects (see **Table S–8**).

Table S–8 Emissions of Air Pollutants and Greenhouse Gases at the Nevada National Security Site (tons per year)

		No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*
	Estimated 2008 Emissions	***Annual Average Operational Emissions in 2015***		
Particulate Matter$_{10}$	3.3	6.8	20.1	4.4
Particulate Matter$_{2.5}$	2.7	3.4	8.1	2.6
Carbon Monoxide	181.3	123.3	160.9	109.8
Nitrogen Oxides	64.2	39.7	56.6	36.3
Sulfur Dioxide	0.41	0.55	1.1	0.41
Volatile Organic Compounds	4.0	5.9	11.0	4.8
Lead	0.0024	0.030	~0.010	0.0024
Hazardous Air Pollutants	0.56	0.41	~0.53	0.40
Carbon Dioxide-equivalent	50,478	39,690	49,303	38,045
	Estimated 2008 Emissions	***Peak Year Construction Emissions*** [a]		
Particulate Matter$_{10}$	3.3	20.0	129.1	8.4
Particulate Matter$_{2.5}$	2.7	6.0	35.6	2.6
Carbon Monoxide	181.3	44.8	296.5	24.4
Nitrogen Oxides	64.2	56.0	388.6	24.4
Sulfur Dioxide	0.41	0.14	0.68	0.08
Volatile Organic Compounds	4.0	6.2	41.6	2.8
Lead	0.0024	0.0000089	0.000013	0.0000071
Hazardous Air Pollutants	0.56	0.038	0.058	0.030
Carbon Dioxide-equivalent	50,478	5,686	21,158	2,774

Particulate Matter$_{10}$ = particulate matter with an aerodynamic diameter less than or equal to 10 micrometers; Particulate Matter$_{2.5}$ = particulate matter with an aerodynamic diameter less than or equal to 2.5 micrometers.

[a] Represents emissions for first year of construction, as construction activity would be linearly distributed over multiple years; however, mobile source emissions would be highest in the first construction year.

In general, emission-generating activities under any alternative would be widely dispersed over the 1,360-square-mile area of the NNSS, as well as along the U.S. Route 95 corridor between Las Vegas and the NNSS. Thus, at the boundaries of the NNSS, ambient air concentrations are expected to be below the National Ambient Air Quality Standards. Nye County would continue to be in attainment for all criteria pollutants, while in Clark County, these emissions would not cause or contribute to any new violations of the standards or increases in the frequency or severity of any violations of the standards. DOE/NNSA also estimates that emissions of hazardous air pollutants would continue to remain low under any alternative and would not require additional emission control technologies; and, therefore, such emissions would not pose an undue health risk to workers or the public. Greenhouse gas emissions, while estimated to decrease relative to baseline levels, would still contribute to global climate change.

More specifically, emissions of carbon monoxide, nitrogen oxides, and greenhouse gases attributable to the levels of operations would decrease relative to existing levels under any alternative. These reductions would be due primarily to the introduction over time of newer DOE/NNSA fleet and worker vehicles with improved fuel economy, as well as improved combustion and emissions treatment efficiencies for electric power generation sources on the NNSS.

In contrast, relative to 2008 levels, emissions of volatile organic compounds, sulfur dioxide, and particulate matter would increase under the No Action and Expanded Operations Alternatives. The

higher emissions of volatile organic compounds would result from the increased use of ethanol-blended fuels in vehicles. Sulfur dioxide and particulate matter emissions would increase primarily because of new projects and an increase in the levels of operations on the NNSS. Corresponding emissions under the Reduced Operations Alternative would tend to remain similar to existing emissions levels.

S.3.1.7 Visual Resources

The evaluation of visual impacts requires an understanding and identification of the visual resources (features) of the landscape, an assessment of the character and quality of those resources relative to the overall regional visual character, and a determination of the importance to people, or sensitivity, of views of visual resources in the landscape. DOE/NNSA evaluated the impact on visual resources in consideration of scenic quality classes, which are defined as follows:

- Class A – The visual environment is made up of outstanding natural and manmade physical features.
- Class B – The visual environment is made up of a combination of outstanding natural and manmade physical features and those that are common to the region.
- Class C – The visual environment is made up of natural and manmade physical features that are common to the region.

Under the No Action Alternative, only the construction of a commercial solar power generation facility and associated transmission lines in Area 25 would affect the existing visual resources of the NNSS. However, with projected traffic volumes along U.S. Route 95 of about 3,000 average daily trips, viewer sensitivity (i.e., the importance of a particular viewshed to the public) would remain moderate. A solar power generation facility and associated transmission line, which would occupy about 2,650 acres, would introduce a source of glare, alter the visual character of a landscape that is largely undeveloped, be visible to highly sensitive viewers, and reduce the existing visual quality from Class B to Class C.

Under the Expanded Operations Alternative, new facilities would be constructed or reconfigured, an existing electric transmission line would be upgraded, and geothermal and solar energy projects would be constructed. With the projected traffic volumes along U.S. Route 95, viewer sensitivity would change from moderate to high near Mercury (approximately 5,310 average daily trips) and near Area 25 (approximately 3,030 average daily trips). For most such facilities, impacts on visual resources would not be adverse. However, the addition of approximately 200,000 square feet of facilities to the Desert Rock Airport would be visible from U.S. Route 95 and would have an adverse visual impact, as would the construction of commercial solar power generation facilities and associated transmission lines on approximately 10,350 acres in Area 25, which would reduce the visual quality from Class B to Class C. The Geothermal Demonstration Project could also alter the visual character and reduce visual quality if its facilities are visible from U.S. Route 95.

Under the Reduced Operations Alternative, only the construction of a commercial solar power generation facility in Area 25 would affect existing visual resources. A solar power generation facility, which would occupy about 1,200 acres, would reduce the existing visual quality of this area of Area 25 from Class B to Class C, even though viewer sensitivity would remain moderate (2,980 average daily trips).

S.3.1.8 Cultural Resources

Cultural resources include prehistoric and historic archaeological districts, sites, buildings, structures, or objects created or modified by human activity. Cultural resources also include traditional cultural

properties—properties that are eligible for inclusion in the National Register of Historic Places (the Register) because of their association with the cultural practices or beliefs of a living community that are (a) rooted in that community's history and (b) important in maintaining the continuing cultural identity of the community (Parker and King 1998).

National Register of Historic Places

The National Register of Historic Places is the official list of the Nation's historic places worthy of preservation. Authorized by the National Historic Preservation Act of 1966, the National Park Service's National Register of Historic Places is part of a national program to coordinate and support public and private efforts to identify, evaluate, and protect America's historic and archeological resources.

An area's potential for containing cultural resources sites is site specific and influenced by factors such as the presence of water, food sources, shelter (e.g., caves or rock alcoves), sources of materials for building shelters, and less-tangible but equally important factors such as features that may have spiritual value to a culture. While all areas of the NNSS have the potential to possess cultural resources, the areas with the highest number of recorded cultural resources are Rainier and Pahute Mesas in the northwest, Jackass Flats in the southwest, and Yucca Flat in the east. Although it is not possible to predict with a high degree of certainty the number of cultural resources sites in a given area, the record provided by cultural resources surveys conducted at the NNSS provides a means to estimate site densities and, therefore, the likelihood of encountering a cultural resources site within a given area.

Cultural Resources Management

As part of compliance with Section 106 of the National Historic Preservation Act, the National Nuclear Security Administration (NNSA) conducts cultural resource surveys and identifies cultural resources within the area of potential effect for all proposed projects and activities (undertakings) that may affect cultural resources. If possible, NNSA avoids significant cultural resources impacts by adjusting the location of a proposed undertaking. When avoidance is not practicable, NNSA consults with the Nevada State Historic Preservation Officer, and possibly the Advisory Council on Historic Preservation, to identify measures to mitigate adverse impacts on those resources.

Under the No Action Alternative, the disturbance of approximately 4,460 acres of land would affect an estimated 1,855 cultural resources sites, 575 of which would be eligible for inclusion in the Register. DOE/NNSA estimates that implementing the Expanded Operations Alternative would disturb approximately 25,877 acres of land and thereby directly affect about 7,688 cultural resources sites, about 2,447 of which would be eligible for inclusion in the Register. Under the Reduced Operations Alternatives, approximately 2,170 acres of land would be disturbed, directly affecting about 861 cultural resources sites; about 266 of these sites would be eligible for inclusion in the Register.

One or more commercial solar power generation facilities, including an associated transmission line, would be developed in Area 25. Solar power generation facilities would vary in size; under the No Action, Expanded Operations, and Reduced Operations Alternatives, the facilities would disturb approximately 2,650, 10,300, and 1,200 acres, respectively. **Table S–9** presents the estimated number of cultural resources sites that would be impacted by solar power generation facilities under the three alternatives, including a subset of those eligible for listing in the Register.

Table S–9 Cultural Resources Sites Impacted by Solar Power Generation Facilities

Alternative	*Cultural Resources Sites*	*National Register of Historic Places – Eligible Sites*
No Action	1,802	557
Expanded Operations	7,004	2,163
Reduced Operations	816	252

S.3.1.9 Waste Management

At the NNSS, DOE/NNSA operations, environmental restoration, and decontamination and decommissioning activities would generate low-level radioactive waste; mixed low-level radioactive waste; transuranic waste; hazardous waste; explosive waste; and nonhazardous wastes, including sanitary solid waste, hydrocarbon-contaminated soil and debris, and construction and demolition debris. DOE/NNSA also accepts waste for disposal at the NNSS, including low-level and mixed low-level radioactive waste and selected nonradioactive classified wastes, from other in-state locations such as the TTR, as well as from authorized out-of-state DOE and U.S. Department of Defense generators.

DOE/NNSA assessed waste management impacts by comparing the projected waste volumes generated or disposed under each alternative to current waste management practices and/or the availability of onsite or offsite waste management capacity. **Table S–10** summarizes the types and volumes of wastes generated and disposed at the NNSS under the three alternatives. The estimates of low-level radioactive waste and mixed low-level radioactive waste volumes to be disposed of at the NNSS under the Expanded Operations Alternative are based upon conservative estimates from waste-generating facilities, and the aggregated totals reflect this conservatism (i.e., likely overestimates quantities). Appendix A, Section A.2.2.1, Table A–6, of this SWEIS provides additional details regarding generators and their associated waste volumes; Chapter 6, Table 6–13, of this SWEIS shows historical and projected disposal volumes.

Table S–10 Waste Generated and Disposed at the Nevada National Security Site

Waste Stream	*Alternatives*		
	No Action (cubic feet)	*Expanded Operations (cubic feet)*	*Reduced Operations (cubic feet)*
Waste Volumes Generated at the Nevada National Security Site			
Low-level radioactive waste	1,000,000	1,300,000	1,000,000
Mixed low-level radioactive waste	520,000	520,000	520,000
Transuranic waste	9,600	19,000	7,100
Hazardous waste	210,000	340,000	190,000
Sanitary solid waste and construction and demolition debris	3,800,000	10,000,000	3,700,000
Waste Volumes Disposed at the Nevada National Security Site			
Low-level radioactive waste	15,000,000	48,000,000	15,000,000
Mixed low-level radioactive waste	900,000	4,000,000	900,000
Sanitary solid waste and construction and demolition debris	3,500,000	9,200,000	3,400,000

Construction and operation of one or more solar power generation facilities in Area 25 at the NNSS under each of the three alternatives also would generate hazardous waste, sanitary solid waste, and construction debris. **Table S–11** describes the estimated volumes of these wastes.

Table S–11 Waste Generated by Construction and Operation of Commercial Solar Power Generation Facilities

Waste Stream	*Alternatives*		
	No Action (cubic feet)	*Expanded Operations (cubic feet)*	*Reduced Operations (cubic feet)*
Waste Volumes Generated During Construction			
Hazardous waste	6,500	27,000	2,700
Sanitary solid waste and construction debris	140,000	600,000	60,000
Waste Volumes Generated During Operations (per year)			
Hazardous waste	7,100	30,000	3,000
Sanitary solid waste and construction and demolition debris	41,000	5,400	3,400

Waste Definitions

Radioactive Waste – Solid, liquid, or gaseous material that contains radionuclides regulated under the Atomic Energy Act of 1954, as amended, and is of negligible economic value considering costs of recovery.

Transuranic Waste – Radioactive waste containing alpha particle-emitting radionuclides having an atomic number greater than 92 (the atomic number of uranium) and half-lives greater than 20 years, in concentrations greater than 100 nanocuries per gram.

Low-Level Radioactive Waste – Radioactive waste not classified as high-level radioactive waste, transuranic waste, spent fuel, or byproduct material as defined by Section 11e(2) of the Atomic Energy Act of 1954, as amended. Test specimens of fissionable material irradiated for research and development only, and not for the production of power or plutonium, may be classified as low-level radioactive waste, provided the concentration of transuranic elements is less than 100 nanocuries per gram.

Greater-than-Class C Waste -- The U.S. Nuclear Regulatory Commission (NRC) classification system for the four classes of low-level radioactive waste (A, B, C, and greater-than-Class C) is established in Title 10 of the *Code of Federal Regulations*, Section 61.55, (10 CFR 61.55) and is based on the concentrations of specific short- and long-lived radionuclides given in two tables. Section 3(b)(1)(D) of the Low-Level Radioactive Waste Policy Amendments Act of 1985 specifies that the Federal Government is responsible for disposal of greater-than-Class C low-level radioactive waste generated by NRC and agreement state licensees. The U.S. Department of Energy is the Federal Agency responsible for disposal of greater-than-Class C low-level radioactive waste.

Hazardous Waste – A category of waste regulated under the Resource Conservation and Recovery Act. To be considered hazardous, a waste must be a solid waste under the Resource Conservation and Recovery Act and must exhibit at least one of four characteristics described in 40 CFR 261.20-24 (ignitability, corrosivity, reactivity, and toxicity) or be specifically listed by the U.S. Environmental Protection Agency in 40 CFR 261.31-33.

Mixed Waste – Waste containing both radioactive and hazardous components, as defined by the Atomic Energy Act and the Resource Conservation and Recovery Act, respectively. Mixed waste intended for disposal must meet the Land Disposal Restrictions as listed in 40 CFR Part 268. Mixed waste is a generic term for specific types of mixed waste, such as mixed low-level radioactive waste and mixed transuranic waste.

Under the No Action and Reduced Operations Alternatives, sufficient capacity would be available at the NNSS to dispose the projected volume of low-level radioactive waste and mixed low-level radioactive waste at the Area 5 Radioactive Waste Management Complex. The Waste Isolation Pilot Plant near Carlsbad, New Mexico, maintains adequate capacity to enable the disposal of transuranic waste generated at the NNSS. In addition, adequate capacity is expected to exist in Nevada and elsewhere in the United States to recycle or treat, store, and dispose hazardous waste generated at the NNSS, including waste generated by a solar power generation facility. For instance, four treatment, storage, and disposal facilities were permitted to receive hazardous waste in Nevada as of 2009 (NDEP 2009). There is also existing capacity at the NNSS to dispose nonhazardous waste (including such waste from a solar power generation facility). As of 2008, DOE/NNSA estimated that the three NNSS landfills have the following waste capacities: the Area 6 Hydrocarbon Solid Waste Disposal Site, 2.8 million cubic feet; the Area 9 U10c Solid Waste Disposal Site, 15 million cubic feet; and the Area 23 Solid Waste Disposal Site, 13 million cubic feet.

Under the Expanded Operations Alternative, the Area 3 Radioactive Waste Management Site could be reopened to receive low-level radioactive waste generated from environmental restoration and other activities at DOE/NNSA sites in the State of Nevada. Specifically, this action could be triggered by a need for additional disposal space beyond that available in the Area 5 Radioactive Waste Management Complex for the disposal of large onsite remediation debris, or soils from cleanup activities on the Nevada Test and Training Range. There is no near-term need to use the Area 3 Radioactive Waste Management Site; however, should DOE/NNSA identify a need to reopen the Area 3 Radioactive Waste Management Site in the future, it would first undertake detailed consultation with the State of Nevada and would limit disposal to in-state-generated, nonhazardous low-level radioactive waste. The Waste Isolation Pilot Plant maintains adequate capacity to enable the disposal of transuranic waste generated at

the NNSS. In addition, for the reasons described immediately above, adequate capacity is expected to exist in Nevada and elsewhere in the United States to recycle or treat, store, and dispose hazardous waste generated at the NNSS, including the waste from solar power generation facilities, and to dispose nonhazardous solid waste in NNSS or offsite landfills.

S.3.1.10 Human Health

Surface-disturbing activities, tests, and experiments (operations) at various facilities on the NNSS could result in health impacts on workers and the public from exposure to radioactive waste and materials and hazardous chemicals. Workers could also be exposed to hazardous chemicals and would be subject to industrial accidents.

Radiological impacts were estimated (numerically calculated) for three public receptors: the general population living within 50 miles of a location at which radiation is released; a maximally exposed individual, which is a hypothetical individual assumed to be at the offsite location that would receive the maximum radiological exposure; and a subsistence consumer who derives all of his or her sustenance from the land and receives the same exposures as the maximally exposed individual. General population impacts were estimated for a residential scenario whereby people are exposed to radiation emitted from operational facilities, other locations where experiments are to be performed, environmental restoration activities, or legacy weapons testing areas that emit tritium or are contaminated with particulate radioactive materials. DOE/NNSA also considered potential impacts on the public from exposure to hazardous chemicals.

Impacts on the maximally exposed individual were estimated for a scenario that included the same exposure pathways assumed for the general population, but assumed an increased amount of time spent outdoors and a higher rate of contaminated food consumption. Impacts on the subsistence consumer were estimated for a scenario in which the maximally exposed individual was assumed to live near the NNSS at a location where the soil has been contaminated with radionuclides, and a portion of the individual's diet was assumed to be derived from crops raised on this soil, with the balance of the diet coming from wildlife that also has become contaminated on the NNSS.

Potential radiological and chemical impacts also were considered for two categories of workers: (1) those directly involved in activities associated with assigned missions (involved workers) and (2) nearby, noninvolved workers. An involved worker is defined as a person who is exposed to radioactive or chemical emissions during normal operations. A noninvolved worker is defined as a person who is incidentally exposed to radioactive or chemical emissions, either during normal operations or as a result of an accident.

Radiological impacts were estimated (numerically calculated) for involved workers routinely exposed to radioactive emissions, but were not estimated for these workers under accident conditions. In the event of an accident, although involved workers could receive a radiation dose, the impacts were not estimated because it is recognized that an accident could lead to extensive physical injuries or high radiological exposures and, ultimately, to worker deaths.

Impacts also were estimated (numerically calculated) for noninvolved workers incidentally exposed to radiological emissions under accident conditions. Noninvolved workers generally were assumed to be 110 yards downwind of the emission source, except in those instances where the presence of a noninvolved worker would not be logical (for example, inside the exclusion zone of a high-explosives experiment).

In addition, DOE/NNSA estimated impacts on the entire workforce (involved and noninvolved) from industrial accidents.

Normal Operations. Under the No Action Alternative, the public and workers would be exposed to radiation primarily from widespread diffuse sources, such as residual radioactive contamination, and from

releases from activities associated with the Stockpile Stewardship and Management Program at the Dense Plasma Focus Facility in Area 11 and the Environmental Restoration Program. DOE/NNSA estimates that the offsite population would receive 0.50 person-rem, resulting in an estimated risk of 0.0003 latent cancer fatalities to that population (an annual risk of 1 chance in 3,300 of a single latent cancer fatality in the population). The maximally exposed individual would receive an estimated dose of 2.8 millirem, resulting in a risk of 1 chance in 500,000 (0.000002) of contracting a fatal cancer, and the subsistence consumer would receive an estimated dose of 13 millirem, resulting in a risk of 1 chance in 130,000 (0.000008) of contracting a fatal cancer. The involved worker population would receive an estimated collective dose of 5.2 person-rem, resulting in a risk of 0.003 latent cancer fatalities to that population (an annual risk of 1 chance in 330 of a single latent cancer fatality in the population). The estimated latent cancer fatalities to the public and worker populations under the Reduced Operations Alternative would be the same as or less than those under the No Action Alternative.

Under the Expanded Operations Alternative, the public and workers would be exposed to radiation primarily from widespread diffuse sources, such as residual radioactive contamination, and from releases from activities associated with the Stockpile Stewardship and Management Program at the Dense Plasma Focus Facility in Area 11 and the Big Explosives Experimental Facility in Area 4, tracer experiments under the Work for Others Program, and the Environmental Restoration Program activities. DOE/NNSA estimates that the offsite population would receive a dose of 0.89 person-rem, resulting in a risk of 0.0005 latent cancer fatalities to that population (an annual risk of 1 chance in 2,000 of a single latent cancer fatality in the population). The maximally exposed individual would receive an estimated dose of 4.8 millirem, resulting in an annual risk of 1 chance in 330,000 (0.000003) of contracting a fatal cancer, and the subsistence consumer would receive an estimated dose of 15 millirem, resulting in a risk of 1 chance in 110,000 (0.000009) of contracting a fatal cancer. The involved worker population would receive an estimated collective dose of 6.6 person-rem, resulting in a risk of 0.004 latent cancer fatalities to that population (an annual risk of 1 chance in 250 of a single latent cancer fatality in the population).

Radiological and Chemical Accidents. DOE/NNSA considered a range of potential accidents, including the maximum reasonably foreseeable accident, associated with ongoing and proposed projects and activities at various facilities on the NNSS. The same types of operations involving radioactive waste and materials, and hazardous chemicals would occur at the facilities under each of the alternatives, but the levels of operations would vary by alternative. Nonetheless, the accident scenarios and consequences analyzed were the same for each alternative because the differences in accident frequencies (probabilities of occurrence) due to the levels of operations were within the uncertainty range of the accident frequencies.

Maximum reasonably foreseeable accidents involving a release of radioactivity would involve a beyond-design basis earthquake at the Device Assembly Facility in Area 6 followed by the release of 5 kilograms of plutonium, or an explosion followed by the release of 1 kilogram of plutonium to the atmosphere. The estimated probabilities of these events occurring are 1×10^{-6} and 8×10^{-4} per year of operation, respectively (1 chance in 1,000,000 and 1 chance in 1,250).

Maximum Reasonably Foreseeable Accident

A maximum reasonably foreseeable accident is an accident with the most severe consequences that can reasonably be expected to occur.

The severe earthquake accident would result in the highest consequences for the public and workers. If it were to occur, the maximally exposed individual would receive an estimated dose of 860 millirem, corresponding to a latent cancer fatality risk of 0.0005 (1 chance in 2,000). The offsite population within 50 miles would receive a collective dose estimated to be 113 person-rem; the calculated number of latent cancer fatalities associated with this dose is 0.07, implying that the most likely outcome would be no additional latent cancer fatalities in the exposed population. An involved worker within the Device Assembly Facility could be fatally injured in the explosion, and a noninvolved worker (located 110 yards downwind of the release) would receive an estimated dose of 2,800 rem, resulting in a lethal dose.

The above consequences would be reduced by a factor of 1 million if the probability of the accident occurring were taken into account. Because the probability of this accident is 1 chance in 1 million, the Device Assembly Facility accident involving an explosion followed by release of plutonium presents a higher risk (consequence times probability) to the public. The explosion followed by a plutonium release accident represents an estimated latent cancer fatality risk to the maximally exposed individual of 9×10^{-8} (1 chance in 11 million), the risk of a single latent cancer fatality in the population of 1×10^{-5} (1 chance in 100,000), and a latent cancer fatality risk to a noninvolved worker of 3×10^{-6} (1 chance in 300,000).

The maximum reasonably foreseeable accident involving a chemical release would involve an accidental chlorine gas release from a railcar at the Nonproliferation Test and Evaluation Complex. This hypothetical accident is expected to be in the "extremely unlikely" to "beyond extremely unlikely" frequency category, in other words, in the 10^{-4} (1 chance in 10,000) to 10^{-6} (1 chance in 1,000,000) per year or lower frequency range.

DOE/NNSA estimates that fatal concentrations of chlorine would extend downwind a few miles under typical daytime conditions and for 5 to 6 miles, or greater under more-stable (reduced windspeeds and limited vertical mixing) nighttime conditions. Chlorine concentrations that could lead to irreversible and long-lasting health effects would extend further downwind. DOE/NNSA considers these health impacts to be conservative in that the analysis was based on a 1-hour chlorine release; during actual accidents, however, releases occurred over many hours, which resulted in lower concentrations than estimated here.

Members of the public likely would not be affected by a chlorine release because the remote location of the Nonproliferation Test and Evaluation Complex on the NNSS and the additional buffer provided by the Nevada Test and Training Range would keep members of the public at least 8 miles away.

Industrial Accidents. DOE/NNSA estimated the injuries and fatalities that could arise in the workforce from industrial accidents based upon accident rates from DOE and the U.S. Department of Labor (DOE 2010; DOL 2010a, 2010b). Total recordable cases, as well as those cases that result in lost workdays, restricted duty, or require a transfer, were estimated for construction activities and facility operations (see **Table S–12**). Industrial accidents that could result in fatalities are more likely to occur during construction activities than during facility operations and include, for example, electrocution and equipment mishaps. DOE/NNSA estimates that less than one fatality would occur during construction activities at the NNSS (see **Table S–13**).

Table S–12 Estimated Incidence of Nonfatal Accidents at the Nevada National Security Site

Location/Activity	*No Action Alternative*		*Expanded Operations Alternative*		*Reduced Operations Alternative*	
	Total Recordable Cases	*Lost Workdays, Restrictions, Transfer*	*Total Recordable Cases*	*Lost Workdays, Restrictions, Transfer*	*Total Recordable Cases*	*Lost Workdays, Restrictions, Transfer*
All Operations (annual total)	32	14	44	20	28	13

Commercial Solar Power Generation Facilities Construction (during construction)	0.019	0.029	0.015

Table S–14 Summary of Potential Direct and Indirect Impacts at the Nevada National Security Site

	No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*	*Preferred Alternative*
Land Use				
National Security/ Defense Mission	No impacts were identified from the continuation of activities at the current levels of operations or foreseeable actions because activities under this alternative would continue to be compatible with existing land use designations on the NNSS and primary land uses adjacent to the site.	No impacts were identified from the increased activities and change in land use designations under this alternative because activities would be compatible with the proposed land use designations and primary land uses adjacent to the NNSS. The Reserved Zone would decrease in area by 5.5 percent; the Research, Test, and Experiment Zone would increase by 21 percent.	No impacts were identified from the decreased activities and change in land use designations under this alternative because activities would be compatible with the proposed land use designations and primary land uses adjacent to the NNSS. The Reserved Zone would decrease in area by 71 percent, and Areas 18, 19, 20, and 30 would change from Reserved to Limited Use, which is a new land use zone designation.	No impacts were identified from the increased activities and change in land use designations under this alternative because activities would be compatible with the proposed land use designations and primary land uses adjacent to the NNSS. Area 15 would change from the Reserved to the Research, Test, and Experiment zone designation. Areas 18, 19, 20, and 30 would change from Reserved to Limited Operations, which is a new land use zone designation.
	Airspace No new impacts were identified from airspace activities because these activities would be maintained at the current levels of air traffic, navigational aid services, and airspace structure, and would be coordinated and scheduled by the controlling entity responsible for NNSS airspace, the Nellis Air Traffic Control Facility.	*Airspace* Minimal impacts would result from increased usage of aerial platforms and airspace usage, as these activities would continue to be coordinated with the Nellis Air Traffic Control Facility.	*Airspace* Same as under the No Action Alternative.	*Airspace* Minimal impacts would result from increased usage of aerial platforms and airspace usage, as these activities would continue to be coordinated with the Nellis Air Traffic Control Facility.
Environmental Management Mission	No impacts were identified from the continuation of activities at the current levels of operations because activities under this alternative would not change.	No impacts were identified from the increased activities under this alternative as these activities would be compatible with land use designations and primary land uses adjacent to the site.	Same as under the No Action Alternative.	No impacts were identified from the increased activities under this alternative, as these activities would be compatible with land use designations and primary land uses adjacent to the site.
Nondefense Mission	No impacts were identified from the continuation of activities at the current levels of operations or foreseeable actions because activities under this alternative would continue to be compatible with existing land use designations on the NNSS and primary land uses adjacent to the site. The Solar Enterprise Zone would be renamed the Renewable Energy Zone.	Same as under the No Action Alternative, plus: • Area 15 would be changed from a Reserved Zone to a Research Test and Experiment Zone and the Solar Enterprise Zone would be renamed the Renewable Energy Zone and increase in area by 276 percent.	Same as under the No Action Alternative.	Same as under the No Action Alternative, plus: • Area 15 would be changed from a Reserved Zone to a Research Test and Experiment Zone.

	No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*	*Preferred Alternative*
Infrastructure and Energy				
Infrastructure	Buildings, transportation, water supply, and services are adequate to handle temporary increases in demands during construction and long-term demands during operations. Infrastructure would be maintained as needed to accommodate ongoing activities. In addition, new low-level radioactive waste cells would be developed to accommodate disposal of those waste types. Up to 50 new wells would be developed by the Underground Test Area Project. A commercial 240-megawatt solar power generation facility would be developed in Area 25 of the NNSS. Up to 10 miles of new 230-kilovolt transmission lines would be required to interconnect the new generation facility with the main power grid. The commercial facility would provide a portion of the electrical power at the NNSS. Sanitary needs of construction and operational employees would be provided by the commercial entity and are not expected to affect the NNSS solid waste or wastewater infrastructure.	Same as under the No Action Alternative, plus: • New buildings (about 479,000 square feet), ranges and training facilities (13,455 acres), water distribution lines, wastewater treatment systems (septic tanks), power lines, and communication systems would be added and improvements would be made to existing infrastructure. In addition, new low-level and mixed low-level radioactive waste cells would be developed to accommodate disposal of increased volumes of those waste types and new sanitary and construction, decontamination and decommissioning waste landfills in Areas 23 and 25. • An upgrade to the NNSS electrical transmission system would increase capacity from 40 to 100 megawatts. • A 5-megawatt photovoltaic solar power generation facility would be developed in Area 6. Up to 1,000 megawatts of commercial solar power generating capacity would be developed in Area 25 of the NNSS. Up to 10 miles of new 500-kilovolt transmission lines would be required to interconnect the new generation facilities with the main power grid. The commercial facilities would provide a portion of the electrical power at the NNSS. Sanitary needs of construction and operational employees would be provided by the commercial entity and are not expected to affect the NNSS solid waste or wastewater infrastructure.	Same as under the No Action Alternative, except: • Buildings, transportation, water supply, and services would experience reduced demands. Because most operations in the northwestern portion of the NNSS (within Areas 18, 19, 20, 29, and 30) would be discontinued, non-essential infrastructure in those areas would be shut down or removed. A commercial 100-megawatt solar power generation facility would be developed in Area 25 of the NNSS. No new transmission lines would be required to interconnect the new generating facility with the main power grid. The commercial facility would provide a portion of the electrical power at the NNSS. Sanitary needs of construction and operational employees would be provided by the commercial entity and are not expected to affect the NNSS solid waste or wastewater infrastructure.	Same as under the No Action Alternative, plus: • New buildings (about 350,000 square feet), ranges and training facilities (approximately 3,455 acres), water distribution lines, wastewater treatment systems (septic tanks), power lines, and communication systems would be added and improvements would be made to existing infrastructure. In addition, new low-level and mixed low-level radioactive waste cells would be developed to accommodate disposal of increased volumes of those waste types and new sanitary and construction, decontamination, and decommissioning waste landfills in Areas 23 and 25. • An upgrade to the NNSS electrical transmission system would increase capacity from 40 to 100 megawatts. • A 5-megawatt photovoltaic solar power generation facility would be developed in Area 6. • Because most operations in the northwestern portion of the NNSS (within Areas 18, 19, 20, 29, and 30) would be discontinued, non-essential infrastructure in those areas would be shut down or removed. A commercial 240-megawatt solar power generation plant would be developed in Area 25 of the NNSS. Up to 10 miles of new 230-kilovolt transmission lines would be required to interconnect the new generation facility with the main power grid. The commercial facility would provide a portion of the electrical power at the NNSS. Sanitary needs of construction and operational employees would be provided by the commercial entity and are not expected to affect the NNSS solid waste or wastewater infrastructure.

	No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*	*Preferred Alternative*
Energy	Average electric power demand would be 22 megawatts, with a peak demand of 30 megawatts.	Average electrical power demand would be 28 megawatts, with a peak demand of 41 megawatts. As noted under Infrastructure, DOE/NNSA would rebuild the 138-kilovolt transmission system on the NNSS to accommodate increased loads.	Average electrical power demand would be 20 megawatts, with a peak demand of 27 megawatts.	Average electrical power demand would be 28 megawatts, with a peak demand of 41 megawatts. As noted under Infrastructure, NNSA would rebuild the 138-kilovolt transmission system on the NNSS to accommodate increased loads.
	Annual usage of various liquid fuels was estimated as follows: Fuel oil for heating – 66,000 gallons Unleaded gasoline – 427,000 gallons Ethanol/E85 – 217,000 gallons #2 Diesel fuel – 65,000 gallons Biodiesel fuel – 343,000 gallons DOE/NNSA would maintain and repair energy infrastructure.	Annual usage of various liquid fuels was estimated as follows: Fuel oil for heating – 83,000 gallons Unleaded gasoline – 534,000 gallons Ethanol/E85 – 271,000 gallons #2 Diesel fuel – 81,000 Biodiesel fuel – 429,000 gallons DOE/NNSA would maintain and repair energy infrastructure.	Annual usage of various liquid fuels was estimated as follows: Fuel oil for heating – 59,000 gallons Unleaded gasoline – 384,000 gallons Ethanol/E85 – 195,000 gallons #2 Diesel fuel – 59,000 gallons Biodiesel fuel – 309,000 gallons DOE/NNSA would maintain and repair energy infrastructure.	Annual usage of various liquid fuels was estimated as follows: Fuel oil for heating – 83,000 gallons Unleaded gasoline – 534,000 gallons Ethanol/E85 – 271,000 gallons #2 Diesel – 81,000 gallons Biodiesel – 429,000 gallons DOE/NNSA would maintain and repair energy infrastructure.

	No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*	*Preferred Alternative*
Traffic				
Onsite traffic impacts	There would be about 20 additional vehicle trips per day on Mercury Highway, which would operate at a level of service A during peak traffic hours. Construction of a 240-megawatt commercial solar power generation facility would result in 500 (average over the period of construction) and 1,000 (during the peak of the construction period) additional vehicle trips on a daily basis during the peak commute hours on Lathrop Wells Road; increased roadway maintenance or improvements may be required.	There would be about 800 additional vehicle trips per day on Mercury Highway, which would operate at a level of service B or better during peak traffic hours. Construction of 1,000 megawatts of commercial solar power generation facilities would result in 750 (average over the period of construction) and 1,500 (during the peak of the construction period) additional vehicle trips on a daily basis during the peak commute hours on Lathrop Wells Road; increased roadway maintenance or improvements may be required.	There would be about 150 fewer vehicle trips per day on Mercury Highway, which would operate at a level of service A during peak traffic hours. Construction of a 100-megawatt commercial solar power generation facility would result in 400 (average over the period of construction) and 800 (during the peak of the construction period) additional vehicle trips on a daily basis during the peak commute hours on Lathrop Wells Road; increased roadway maintenance or improvements may be required.	There would be about 800 additional vehicle trips per day on Mercury Highway, which would operate at a level of service B or better during peak traffic hours. Construction of a 240-megawatt commercial solar power generation facility would result in 250 (average over the period of construction) and 500 (during the peak of the construction period) additional vehicle trips on a daily basis during the peak commute hours on Lathrop Wells Road; increased roadway maintenance or improvements may be required.
Regional traffic impacts	U.S. Route 95, State Route 160, and State Route 372 would experience the greatest increases in daily traffic volumes in the area around the NNSS; however, these would be relatively minor and would not affect the levels of service on regional roadways. Overall traffic volumes would increase during peak hours because of additional traffic volumes attributable to construction and operation of a solar power generation facility.	Segments of State Route 372, State Route 160, U.S. Route 95, and State Route 164 would experience moderately high percent increases in daily traffic compared to the No Action Alternative. Most of the increase in daily traffic volumes during the peak hours would be attributable to workers commuting to the NNSS; any detectable changes in traffic volumes would primarily occur during the main commuting hours and at the entry gates of the NNSS (the main entrance gate for regular NNSS employees and Gate 510 for those associated with the construction and operation of the commercial solar power generation facilities in Area 25). However, the levels of service on public roadways in the region would not change.	Although the number of commuter trips for the reduced NNSS workforce would decrease, overall traffic volumes would increase slightly during peak hours because of additional traffic volumes attributable to construction and operation of the solar power generation facility. Impacts on regional traffic under this alternative would, therefore, be slightly less or similar to those described under the No Action Alternative; volume-to-capacity ratios and levels of service would not change.	Segments of Nevada State Route 372, State Route 160, U.S. Route 95, and State Route 164 would experience moderately high percent increases in daily traffic compared to the No Action Alternative. Most of the increase in daily traffic volumes during the peak hours would be attributable to workers commuting to the NNSS; any detectable changes in traffic volumes would primarily occur during the main commuting hours and at the entry gates of the NNSS (the main entrance gate for regular NNSS employees and Gate 510 for those associated with the construction and operation of the commercial solar power generation facilities in Area 25). However, the levels of service on public roadways in the region would not change.

	No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*	*Preferred Alternative*
Socioeconomics				
	Operation of a 240-megawatt commercial solar power generation facility would increase employment by 150 full-time equivalents, of which about 15 solar power generation facility employees would relocate from outside of the region. Sufficient housing exists to support the increased population. A total of 22 new students relocating to Clark County would create a need for 1 additional teacher to maintain the student-to-teacher ratio. An increase of 6 new students in Nye County would not result in a need for additional teachers. Direct jobs would reduce unemployment by 0.07 and 0.99 percent, respectively, in Clark and Nye Counties.	Site employment would increase by 625 full-time equivalents; about 63 employees would relocate from outside of the region. Sufficient housing exists in the area to support the increased population. A total of 92 new students relocating to Clark County would create a need for 4 new teachers to maintain the student-to-teacher ratio. An increase of 27 new students in Nye County would create a need for 1 new teacher to maintain the student-to-teacher ratio. Direct jobs would reduce unemployment by 0.31 and 4.2 percent, respectively, in Clark and Nye Counties.	Site employment would decrease by 45 full-time equivalents, increasing unemployment in Clark County by about 0.03 percent and in Nye County by about 0.39 percent. Additional employees would not relocate to Clark or Nye County and there would be no need for new housing or teachers.	Site employment would increase by approximately 575 full-time equivalents; about 60 employees would relocate from outside of the region. Sufficient housing exists in the area to support the increased population. Approximately 90 new students relocating to Clark County would create a need for 4 new teachers to maintain the student-to-teacher ratio. An increase of approximately 25 new students in Nye County would create the need for 1 new teacher to maintain the student-to-teacher ratio. Direct jobs would reduce unemployment by 0.3 and 4.0 percent, respectively, in Clark and Nye Counties.
	Approximately 500 full-time equivalents over 35 months, with a peak of 1,000 full-time equivalents, would need to be hired for construction of the solar power generation facility.	Approximately 750 full-time equivalents over 42 months, with a peak of 1,500 full-time equivalents, would need to be hired for construction of the solar power generation facilities. Other construction projects at the NNSS would require approximately 250 full-time equivalents over the 10-year period.	Approximately 400 full-time equivalents over 32 months, with a peak of 800 full-time equivalents, would need to be hired for construction of the solar power generation facility.	Approximately 500 full-time equivalents over 35 months, with a peak of 1,000 full-time equivalents, would need to be hired for construction of the solar power generation facility. Other construction projects at the NNSS would require approximately 250 full-time equivalents over the 10-year period.
	Direct jobs, indirect jobs, and construction materials purchases would reduce unemployment and have a beneficial effect on local government revenues.	Direct jobs, indirect jobs, and construction materials purchases would reduce unemployment and have a beneficial effect on the local economy and government revenues.	Direct construction jobs and indirect jobs would reduce the unemployment rate in the region and would have a beneficial impact on the economy in the region. Job loss would have a small negative impact on the local economy; construction material purchases for the solar power generation facility would have a small positive economic impact, including generating additional revenues for local governments.	Direct jobs, indirect jobs, and construction materials purchases would reduce unemployment and have a beneficial effect on local government revenues.
	Buildings associated with construction and operation of a solar power generation facility and increased site personnel would create an increased demand for onsite security and fire and rescue services.	Buildings associated with construction and operation of solar power generation facilities and other facilities on site and increased personnel would create a greater demand for onsite security and fire and rescue services.	Buildings associated with construction and operation of a solar power generation facility would create an increased demand for onsite security and fire and rescue services.	Buildings associated with construction and operation of a solar power generation facility and increased site personnel would create a modest increase in demand for onsite security and fire and rescue services.

	No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*	*Preferred Alternative*
Geology and Soils				
National Security/ Defense Mission	About 700 acres of soil would be disturbed by dynamic experiments in boreholes, explosives experiments, drillback operations, Office of Secure Transportation training and exercises, experiments involving biological simulants, and counterterrorism training.	About 13,455 acres of soil would be disturbed by the same kinds of activities as under the No Action Alternative, including: Up to 10,000 acres of soil would be disturbed for an Office of Secure Transportation training facility; 120 acres for depleted uranium experiment sites; and 3,335 acres for additional explosives experiments, new test beds and training facilities, drillback operations, and additions to existing aviation facilities at the NNSS.	About 430 acres of soil would be disturbed by many of the same kinds of activities as under the No Action Alternative, except: There would be 50 percent fewer explosive experiments and 33 percent fewer Office of Secure Transportation training and exercises.	About 3,455 acres of soil would be disturbed by activities including dynamic experiments, explosives experiments, drillback operations, Office of Secure Transportation training and exercises, experiments involving biological simulants, counterterrorism training, depleted uranium experiments, new test beds and training facilities, and additions to existing aviation facilities at the NNSS.
Environmental Management Mission	About 190 acres of soil would be disturbed for construction of new waste cells at the Area 5 Radioactive Waste Management Complex. Up to 420 acres of soil would be disturbed as part of the Environmental Restoration Program, Soils Project cleanup. Up to 500 acres of soil would be disturbed for development of Underground Test Area Project monitoring wells.	About 600 acres of soil would be disturbed for construction of new waste cells at the Area 5 Radioactive Waste Management Complex. About 35 acres of soil would be disturbed for new sanitary, decontamination, decommissioning, and construction waste landfills in Areas 23 and 25. Environmental Restoration Program impacts would be the same as under the No Action Alternative.	Same as under the No Action Alternative.	About 600 acres of soil would be disturbed for construction of new waste cells at the Area 5 Radioactive Waste Management Complex. About 35 acres of soil would be disturbed for new sanitary, decontamination, decommissioning, and construction waste landfills in Areas 23 and 25. Up to 420 acres of soil would be disturbed as part of the Environmental Restoration Program, Soils Project cleanup. Up to 500 acres of soil would be disturbed for development of Underground Test Area Project monitoring wells.
Nondefense Mission	Construction of a 240-megawatt commercial solar power generation facility and associated transmission lines would disturb approximately 2,650 acres.	Construction of 1,000 megawatts of commercial solar power generation facilities and associated transmission lines would disturb up to 10,300 acres. Replacing the existing 138-kilovolt NNSS electrical transmission line would disturb, temporarily, about 467 acres of soil. Construction of a DOE photovoltaic solar power generation facility would disturb about 50 acres of land. Minor soil disturbance is expected from several additional research projects. Development of a Geothermal Demonstration Project would disturb up to 50 acres of soil.	Construction of a 100-megawatt commercial solar power generation facility could disturb up to 1,200 acres.	Construction of a 240-megawatt commercial solar power generation facility and associated transmission lines would disturb approximately 2,650 acres. Replacing the existing 138-kilovolt NNSS electrical transmission line would temporarily disturb about 467 acres of soil. Construction of a DOE photovoltaic solar power generation facility would disturb about 50 acres of land. Minor soil disturbance is expected from several additional research projects. Development of a Geothermal Demonstration Project would disturb up to 50 acres of soil.

Hydrology				
Surface Water Resources				
National Security/ Defense Mission	Disturbance of about 700 acres of land by dynamic experiments in boreholes, explosives experiments, drillback operations, Office of Secure Transportation training and exercises, experiments involving releases of chemicals and biological simulants, and counterterrorism training would cause alterations of natural drainage pathways, contamination of ephemeral surface waters via chemical agents, and sedimentation to ephemeral surface waters.	About 13,455 acres of soil and near-surface geologic media would activities similar to those as under the No Action Alternative, plus: • Up to 10,000 acres of disturbance for Office of Secure Transportation training facilities, 120 acres for depleted uranium experiment sites, and 3,335 acres for additional explosives experiments, new test beds and training facilities, drillback operations and additions to existing aviation facilities at the NNSS. This would result in proportionately larger impacts on ephemeral waters compared to the No Action Alternative.	About 430 acres of soil and near-surface geologic media would be disturbed by many of the same kinds of activities as under the No Action Alternative, except: There would be 50 percent fewer explosives experiments and 33 percent less Office of Secure Transportation training and exercises. This would result in proportionately smaller impacts on ephemeral waters compared to the No Action Alternative.	Disturbance of about 3,455 acres of land would cause alterations of natural drainage pathways, contamination of ephemeral surface waters via chemical agents, and sedimentation to ephemeral surface waters. This includes dynamic experiments in boreholes, explosives experiments, drillback operations, depleted uranium experiment sites, Office of Secure Transportation training exercises, new test beds and training facilities, and additions to existing aviation facilities at the NNSS.
Environmental Management Mission	Disturbance of up to 190 acres of soil to construct, use, cover, and close disposal units within the existing Area 5 Radioactive Waste Management Complex would result in impacts on ephemeral waters due to alteration of natural drainage pathways, increased erosion, and subsequent sedimentation. The Soils Project would reduce or stabilize legacy contamination in soil and could result in disturbance of up to 420 acres. Soil disturbance on about 500 acres of land from drilling additional wells for the Underground Test Area Project could cause localized erosion, as could decontamination and decommissioning of industrial sites, remediation of Defense Threat Reduction Agency sites, and the Borehole Management Program. These activities would affect ephemeral waters by altering natural drainage pathways and increasing sedimentation. Stabilization and/or removal of contaminated facilities and soils would reduce the potential for contamination of ephemeral waters.	Disturbance of up to 600 acres of soil to construct, use, cover, and close disposal units within the existing Area 5 Radioactive Waste Management Complex, plus up to 35 acres of disturbance for new sanitary, decontamination, decommissioning, and construction waste landfills would result in impacts on ephemeral waters due to alteration of natural drainage pathways, increased erosion, and subsequent sedimentation. Environmental Restoration Program impacts would be the same as under the No Action Alternative.	Same as under the No Action Alternative for both Waste Management and Environmental Restoration Programs.	Disturbance of up to 600 acres of soil to construct, use, cover, and close disposal units within the existing Area 5 Radioactive Waste Management Complex, plus up to 35 acres of disturbance for new sanitary, decontamination, decommissioning, and construction waste landfills, would result in impacts on ephemeral waters due to alteration of natural drainage pathways, increased erosion, and subsequent sedimentation. The Soils Project would reduce or stabilize legacy contamination in soil and could result in disturbance of up to 420 acres. Soil disturbance on about 500 acres of land from drilling additional wells for the Underground Test Area Project could cause localized erosion, as could decontamination and decommissioning of industrial sites, remediation of Defense Threat Reduction Agency sites, and the Borehole Management Program. These activities would affect ephemeral waters by altering natural drainage pathways and increasing sedimentation. Stabilization and/or removal of contaminated facilities and soils would reduce the potential for contamination of ephemeral waters.

	No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*	*Preferred Alternative*
Nondefense Mission	No new land disturbances would occur during infrastructure-related activities under the No Action Alternative. Development of a 240-megawatt commercial solar power generation facility and associated transmission lines would alter natural drainage pathways over 2,650 acres in Area 25, though it is expected that larger ephemeral waters (e.g., Fortymile Wash) would be avoided; however, there would be a potential for chemical contamination and sedimentation to ephemeral waters during construction-related land preparation.	Up to 517 acres of land would be disturbed by rebuilding the existing 138-kilovolt transmission line on the NNSS and constructing a 5-megawatt photovoltaic solar power generation facility. These disturbances would result in alterations of natural drainage pathways and increased sedimentation of ephemeral waterways. Development of up to 1,000 megawatts of commercial solar power generation facilities and associated transmission lines would disturb drainage pathways over 10,300 acres and increased erosion and construction/operational activities would potentially increase sedimentation and chemical contamination in ephemeral waterways. Development of a Geothermal Demonstration Project would disturb up to 50 acres and cause sedimentation to ephemeral waters, as well as long-term alteration of natural drainage pathways.	Same as under the No Action Alternative, except: • The land area associated with the development of a 100-megawatt solar power generation facility would be 1,200 acres.	Up to 517 acres of land would be disturbed by rebuilding the existing 138-kilovolt transmission line on the NNSS and construction of a 5-megawatt photovoltaic solar generating facility. Development of a Geothermal Demonstration Project would disturb up to 50 acres. These disturbances would result in alterations of natural drainage pathways and increased sedimentation of ephemeral waterways. Development of a 240-megawatt commercial solar power generation facility and associated transmission lines would alter natural drainage pathways over 2,650 acres in Area 25, though it is expected that larger ephemeral waters (e.g., Fortymile Wash) would be avoided; however, there would be a potential for chemical contamination of and sedimentation to ephemeral waters during construction-related land preparation.

	No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*	*Preferred Alternative*
Groundwater Resources				
Total water use (excluding solar power generation facility[ies])	Total water use for DOE/NNSA activities would not exceed 691 acre-feet per year. This water demand would exceed published estimates of the sustainable yield for Basin 160 (Frenchman Flat) , although other yield estimates suggest that adverse impacts to water supply may not occur.	Total water use for DOE/NNSA activities would increase by 25 percent from the No Action Alternative to 862 acre-feet per year. This water demand would exceed published estimates of the sustainable yield for Basin 160 (Frenchman Flat) , although other yield estimates suggest that adverse impacts to water supply may not occur.	Total water use for DOE/NNSA activities would decrease by 10 percent from the No Action Alternative to 622 acre-feet per year. This water demand would exceed published estimates of the sustainable yield for Basin 160 (Frenchman Flat) , although other yield estimates suggest that adverse impacts to water supply may not occur.	Total water use for DOE/NNSA activities would total as much as 862 acre-feet per year. This water demand would exceed published estimates of the sustainable yield for Basin 160 (Frenchman Flat), although other yield estimates suggest that adverse impacts to water supply may not occur.
National Security/ Defense Mission	No new or additional impacts on groundwater resources.	The following would be impacts on groundwater resources, in addition to impacts under the No Action Alternative: • 5.5 acre-feet per year of potable water for construction workers. • Water use for construction of facilities included in the overall 25 percent increase in all water uses.	Same as under the No Action Alternative.	The following would be additional impacts on the groundwater resource, compared to the No Action Alternative: • 5.5 acre-feet per year of potable water for construction workers. Water use for new construction of facilities is included in the 862 acre-feet per year.
Environmental Management Mission	Through 2020, 30 acre-feet per year of nonpotable water for the drilling of new wells under the Underground Test Area Project. Less than 7 acre-feet of total water use for dust suppression during decontamination and decommissioning of facilities.	Same as under the No Action Alternative.	Same as under the No Action Alternative.	Through 2020, 30 acre-feet per year of nonpotable water would be required for the drilling of new wells under the Underground Test Area Project. Less than 7 acre-feet of total water use for dust suppression during decontamination and decommissioning of facilities.
Nondefense Mission	Positive impact of reducing potable water production 16 percent by 2015 utilizing water conservation measures.	Same as under the No Action Alternative, plus: • A 5-megawatt photovoltaic solar power system near Area 6 would use 0.5 acre-feet per year of nonpotable water. • A one-time nonpotable water demand of 20 acre-feet to prime a geothermal power plant. Once operational, the geothermal power plant would use 50 acre-feet of water per year.	Same as under the No Action Alternative.	The positive impact of reducing potable water production 16 percent by 2015 would be partially offset by: • A 5-megawatt photovoltaic solar power system near Area 6, which would use 0.5 acre-feet per year of nonpotable water. • A one-time nonpotable water demand of 20 acre-feet, which would be required to prime a geothermal power plant. Once operational, the geothermal power plant would use 50 acre-feet of water per year.

	No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*	*Preferred Alternative*
Commercial Solar Power Generation Facility(ies)				
Construction Operation	350 acre-feet per year from Fortymile Canyon, Jackass Flats Subdivision 250 acre-feet per year from Fortymile Canyon, Jackass Flats Subdivision These water demands would be below the sustainable yield of the Fortymile Canyon, Jackass Flats Subdivision Basin (4,000 acre-feet per year).	1,000 acre-feet per year from Fortymile Canyon, Jackass Flats Subdivision 700 acre-feet per year from Fortymile Canyon, Jackass Flats Subdivision These water demands would be below the sustainable yield of the Fortymile Canyon, Jackass Flats Subdivision Basin (4,000 acre-feet per year).	200 acre-feet per year from Fortymile Canyon, Jackass Flats Subdivision 175 acre-feet per year from Fortymile Canyon, Jackass Flats Subdivision These water demands would be below the sustainable yield of the Fortymile Canyon, Jackass Flats Subdivision Basin (4,000 acre-feet per year).	350 acre-feet per year from Fortymile Canyon, Jackass Flats Subdivision 250 acre-feet per year from Fortymile Canyon, Jackass Flats Subdivision These water demands are below the sustainable yield of the Fortymile Canyon, Jackass Flats Subdivision Basin (4,000 acre-feet per year).
Biological Resources				
National Security/ Defense Mission	Approximately 295 acres of currently undisturbed desert tortoise habitat would be affected by activities in Frenchman Flat, Yucca Flat, and Jackass Flats; Mercury Valley; and Fortymile Canyon. The estimated number of desert tortoises affected ranges from 4 to 21, all by harassment. Total new disturbed area (about 700 acres) would be 0.09 percent of undisturbed land on the NNSS.	Approximately 1,930 acres of currently undisturbed desert tortoise habitat would be affected in the same areas as under the No Action Alternative. The estimated number of desert tortoises affected ranges from 30 to 136, all by harassment. Total new disturbed area (about 13,455 acres) would be 1.70 percent of undisturbed land on the NNSS.	Approximately 160 acres of currently undisturbed desert tortoise habitat would be affected in the same areas as under the No Action Alternative. The estimated number of desert tortoises affected ranges from 2 to 11, all by harassment. Total new disturbed area (about 430 acres) would be 0.05 percent of undisturbed land on the NNSS.	Approximately 1,910 acres of currently undisturbed desert tortoise habitat would be affected in the same areas as under the No Action Alternative. The estimated number of desert tortoises affected ranges from 30 to 136; all by harassment. Total new disturbed area (about 3,455 acres) would be 0.47 percent of undisturbed land on the NNSS.
Environmental Management Mission	Approximately 760 acres of currently undisturbed desert tortoise habitat would be affected, primarily by environmental restoration activities in Frenchman, Yucca, and Jackass Flats, and Mercury Valley. The estimated number of desert tortoises affected ranges from 4 to 26, all by harassment. Total new disturbed area (about 1,110 acres) would be 0.14 percent of undisturbed land on the NNSS.	Approximately 1,205 acres of currently undisturbed desert tortoise habitat would be affected in the same areas as under the No Action Alternative because of additional waste management activities. The estimated number of desert tortoises affected ranges from 4 to 33, all by harassment. Total new disturbed area (about 1,555 acres) would be 0.2 percent of undisturbed land on the NNSS.	Same as under the No Action Alternative.	Approximately 1,205 acres of currently undisturbed desert tortoise habitat would be affected because of additional waste management activities. The estimated number of desert tortoises affected ranges from 4 to 33; all by harassment. Total new disturbed area (about 1,555 acres) would be 0.2 percent of undisturbed land on the NNSS.
Nondefense Mission	Over the next 10 years, up to 125 desert tortoises would be taken on NNSS roadways due to non-project vehicle travel. Fewer than 20 of these desert tortoises are expected to be taken by injury or mortality. Approximately 2,650 acres of currently undisturbed desert tortoise habitat in Jackass Flats, Mercury Valley, and Frenchman Flat would be affected by DOE/NNSA activities, including a 240-megawatt commercial solar power	Over the next 10 years, up to 125 desert tortoises would be taken on NNSS roadways due to non-project vehicle travel. Fewer than 20 of these desert tortoises are expected to be taken by injury or mortality. Approximately 10,535 acres of currently undisturbed desert tortoise habitat in Jackass Flats, Mercury Valley, and Frenchman Flat would be affected by DOE/NNSA activities, including 1,000 megawatts of commercial solar power	Over the next 10 years, up to 125 desert tortoises would be taken on NNSS roadways due to non-project vehicle travel. Fewer than 20 of these desert tortoises are expected to be taken by injury or mortality. Approximately 1,200 acres of currently undisturbed desert tortoise habitat in Jackass Flats, Mercury Valley, and Frenchman Flat would be affected by DOE/NNSA activities, including a 100-megawatt commercial solar power	Over the next 10 years, up to 125 desert tortoises would be taken on NNSS roadways due to non-project vehicle travel. Fewer than 20 of these desert tortoises are expected to be taken by injury or mortality. Approximately 2,885 acres of currently undisturbed desert tortoise habitat in Jackass Flats, Mercury Valley, and Frenchman Flat would be affected by DOE/NNSA activities, including 240 megawatts of commercial solar power

	No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*	*Preferred Alternative*
	generation facility and associated transmission lines in Jackass Flats. The estimated number of desert tortoises affected ranges from 0 to 41, all by harassment. Total new disturbed area (about 2,650 acres) would be 0.34 percent of undisturbed land on the NNSS.	generation facilities and associated transmission lines in Jackass Flats. The estimated number of desert tortoises affected ranges from 4 to 178, all by harassment. Total new disturbed area (about 10,867 acres) would be 1.37 percent of undisturbed land on the NNSS.	generation facility in Jackass Flats. The estimated number of desert tortoises affected ranges from 0 to 19, all by harassment. Total new disturbed area (about 1,200 acres) would be 0.15 percent of undisturbed land on the NNSS.	generation facilities and associated transmission lines in Jackass Flats. The estimated number of desert tortoises affected ranges from 4 to 62; all by harassment. Total new disturbed area (about 3,167 acres) would be 0.40 percent of undisturbed land on the NNSS.

Visual Resources				
National Security/ Defense Mission	No impacts on visual resources.	No impacts on visual resources.	No impacts on visual resources.	No impacts on visual resources.
Environmental Management Mission	No impacts on visual resources.	No impacts on visual resources.	No impacts on visual resources.	No impacts on visual resources.
Nondefense Mission	Construction and operation of a commercial solar power generation facility and associated transmission lines over about 2,400 acres of land would reduce the visual quality from a Class B to a Class C rating in portions of Area 25 visible to viewers on U.S. Route 95.	Construction of approximately 200,000 square feet of additional facilities would be added to Desert Rock Airport that would have an adverse effect on visual resources visible from U.S. Route 95. Construction and operation of commercial solar power generation facilities and associated transmission lines over about 10,300 acres of land would reduce the visual quality from a Class B to a Class C rating in portions of Area 25 visible to viewers on U.S. Route 95. A Geothermal Demonstration Project could alter the visual character and reduce visual quality if facilities are built along U.S. Route 95.	Construction and operation of a commercial solar power generation facility over 1,200 acres of land would reduce the visual quality from a Class B to a Class C rating in portions of Area 25 visible to viewers on U.S. Route 95.	Construction and operation of a solar power generation facility and associated transmission lines would disturb about 2,650 acres of land and would reduce the visual quality from a Class B to a Class C rating in portions of Area 25 visible to viewers on U.S. Route 95. Construction of approximately 200,000 square feet of additional facilities would be added to Desert Rock Airport, which would have an adverse effect on visual resources visible from U.S. Route 95. A Geothermal Power Project could alter the visual character and reduce visual quality if facilities are built along U.S. Route 95.
Cultural Resources				
National Security/ Defense Mission	Approximately 700 acres of undisturbed land would be affected by activities in Frenchman Flat, Yucca Flat, and Jackass Flats; Mercury Valley; and Fortymile Canyon. An estimated 24 cultural resources sites would be involved, of which an estimated 10 may be eligible for the National Register of Historic Places.	Approximately 13,455 acres of undisturbed land would be affected in the same areas as under the No Action Alternative. An estimated 624 cultural resources sites would be involved, of which an estimated 265 may be eligible for the National Register of Historic Places.	Approximately 430 acres of undisturbed land would be affected in the same areas as under the No Action Alternative. An estimated 16 cultural resources sites would be involved, of which an estimated 6 may be eligible for the National Register of Historic Places.	Approximately 3,335 acres of undisturbed land would be affected in the same areas as under the No Action Alternative. An estimated 180 cultural resources sites would be involved, of which an estimated 63 may eligible for the National Register of Historic Places.
Environmental Management Mission	Approximately 1,110 acres of undisturbed land would be affected, primarily by environmental restoration activities in Frenchman Flat, Yucca Flat, and Jackass Flats; Emigrant and Mercury Valleys; and Fortymile Canyon. An estimated 29 cultural resource sites would be involved, of which an estimated 7 may be eligible for the National Register of Historic Places.	Approximately 1,555 acres of undisturbed land would be affected in the same areas as under the No Action Alternative because of additional waste management activities. An estimated 43 cultural resources sites would be involved, of which an estimated 12 may be eligible for the National Register of Historic Places.	Same as under the No Action Alternative.	Approximately 1,555 acres of undisturbed land would be affected because of additional waste management activities. An estimated 43 cultural resources sites would be involved, of which an estimated 12 may be eligible for the National Register of Historic Places.

	No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*	*Preferred Alternative*
Nondefense Mission	No impacts on cultural resources from DOE/NNSA infrastructure and energy conservation activities.	Approximately 517 acres of undisturbed land would be affected by DOE/NNSA infrastructure and renewable energy projects. An estimated 15 cultural resource sites may be involved, of which an estimated 6 would be eligible for the National Register of Historic Places.	Same as under the No Action Alternative.	Approximately 517 acres of undisturbed land would be affected by DOE/NNSA infrastructure and renewable energy projects. An estimated 15 cultural resource sites may be involved, of which an estimated 6 would be eligible for the National Register of Historic Places.
	Approximately 2,650 acres of undisturbed land in the Jackass Flats area would be affected by development of a 240-megawatt commercial solar power generation facility and associated transmission lines. An estimated 1,802 cultural resources sites would be involved, of which an estimated 557 would be eligible for the National Register of Historic Places.	Approximately 10,300 acres of undisturbed land in the Jackass Flats area would be affected by development of commercial solar power generation facilities and associated transmission lines. An estimated 7,004 cultural resources sites would be involved, of which an estimated 2,163 would be eligible for the National Register of Historic Places. Approximately 50 acres of undisturbed land would be affected by development of a Geothermal Demonstration Project in the Yucca Flat area. An estimated 2 cultural resources sites may be involved, of which 1 would be eligible for the National Register of Historic Places.	Approximately 1,200 acres of undisturbed land in the Jackass Flats area would be affected by development of a 100-megawatt commercial solar power generation facility. An estimated 816 cultural resources sites would be involved, of which an estimated 252 may be eligible for the National Register of Historic Places.	Approximately 2,650 acres of undisturbed land in the Jackass Flats area would be affected by development of a commercial solar power generation facility and associated transmission lines. An estimated 1,802 cultural resources sites would be involved, of which an estimated 557 would be eligible for the National Register of Historic Places.
Waste Management (10-year volumes)				
Low-level radioactive waste	15,000,000 cubic feet of low-level radioactive waste is within the disposal capacity of the Area 5 Radioactive Waste Management Complex.	48,000,000 cubic feet of low-level radioactive waste is within the disposal capacity of the Area 3 Radioactive Waste Management Site and the Area 5 Radioactive Waste Management Complex.[b]	Same as under the No Action Alternative.	48,000,000 cubic feet of low-level radioactive waste is within the disposal capacity of the Area 3 Radioactive Waste Management Site and the Area 5 Radioactive Waste Management Complex.
Mixed low-level radioactive waste	900,000 cubic feet of mixed low-level radioactive waste is within the permitted disposal capacity of Cell 18 in the Area 5 Radioactive Waste Management Complex.	Disposal of 4,000,000 cubic feet of mixed low-level radioactive waste would require additional permitted mixed low-level radioactive waste disposal capacity at the Area 5 Radioactive Waste Management Complex.	Same as under the No Action Alternative.	Disposal of 4,000,000 cubic feet of mixed low-level radioactive waste would require additional permitted mixed low-level radioactive waste disposal capacity at the Area 5 Radioactive Waste Management Complex.
Transuranic waste	9,600 cubic feet would be generated by DOE/NNSA activities in Nevada. All transuranic waste would be disposed within available capacity at the Waste Isolation Pilot Plant.	19,000 cubic feet would be generated by DOE/NNSA activities in Nevada. All transuranic waste would be disposed within available capacity at the Waste Isolation Pilot Plant.	7,100 cubic feet would be generated by DOE/NNSA activities in Nevada. All transuranic waste would be disposed within available capacity at the Waste Isolation Pilot Plant.	19,000 cubic feet would be generated by DOE/NNSA activities in Nevada. All transuranic waste disposed within available capacity at the Waste Isolation Pilot Plant.

	No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*	*Preferred Alternative*
Hazardous waste	Total of 210,000 cubic feet would be generated, including 42,000 cubic feet generated by a commercial solar power generation facility. All would be recycled, treated, and/or disposed within available offsite capacity. Disposal of hazardous solid waste generated by a commercial solar power generation facility would be the responsibility of that project. NNSS hazardous waste management capabilities would not be impacted under current permit conditions.	Total of 340,000 cubic feet would be generated, including 170,000 cubic feet generated by commercial solar power generation facilities. All would be recycled, treated, and/or disposed within available offsite capacity. Disposal of hazardous solid waste generated by a commercial solar power generation facility would be the responsibility of that project. NNSS hazardous waste management capabilities would not be impacted under current permit conditions.	Total of 190,000 cubic feet would be generated, including 17,000 cubic feet generated by a commercial solar power generation facility. All would be recycled, treated, and/or disposed within available offsite capacity. Disposal of hazardous solid waste generated by a commercial solar power generation facility would be the responsibility of that project. NNSS hazardous waste management capabilities would not be impacted under current permit conditions.	Total of 212,000 cubic feet would be generated, including 42,000 cubic feet generated by commercial solar power generation facilities. All would be recycled, treated, and/or disposed within available offsite capacity. Disposal of hazardous solid waste generated by a commercial solar power generation facility would be the responsibility of that project. NNSS hazardous waste management capabilities would not be impacted under current permit conditions.
Solid waste	Total of 3,800,000 cubic feet would be generated, including 3,700,000 cubic feet generated by DOE/NNSA activities in Nevada and 160,000 cubic feet generated by construction and operation of a 240-megawatt commercial solar power generation facility. DOE/NNSA solid waste disposed at the NNSS would not exceed the disposal capacity at NNSS landfills. Included in the DOE/NNSA volume are 370,000 cubic feet that would be transported off site for recycling within available offsite capacity.	Total of 10,000,000 cubic feet would be generated, including 9,400,000 cubic feet generated by DOE/NNSA activities in Nevada and 630,000 cubic feet generated by construction and operation of 1,000 megawatts of commercial solar power generation facilities. DOE/NNSA solid waste disposed at the NNSS would not exceed the disposal capacity at NNSS landfills. Included in the DOE/NNSA volume are 970,000 cubic feet that would be transported off site to be recycled within available offsite capacity.	Total of 3,700,000 cubic feet would be generated, including 3,600,000 cubic feet generated by DOE/NNSA activities in Nevada and 77,000 cubic feet generated by construction and operation of a 100-megawatt commercial solar power generation facility. DOE/NNSA solid waste disposed at the NNSS would not exceed the available capacity at NNSS landfills. Included in the DOE/NNSA volume are 360,000 cubic feet that would be transported off site to be recycled within available offsite capacity.	Total of 9,560,000 cubic feet would be generated, including 9,400,000 cubic feet generated by DOE/NNSA activities in Nevada and 160,000 cubic feet generated by operation of 240 megawatts of commercial solar power generation facilities. DOE/NNSA solid waste disposed at the NNSS would not exceed the disposal capacity at NNSS landfills. Included in the DOE/NNSA volume are 970,000 cubic feet that would be transported off site to be recycled within available offsite capacity.
	Disposal of nonhazardous solid waste generated by a commercial solar power generation facility would be the responsibility of that project. NNSS disposal capacity would not be impacted under current permit conditions.	Disposal of nonhazardous solid waste generated by a commercial solar power generation facility would be the responsibility of that project. NNSS disposal capacity would not be impacted under current permit conditions.	Disposal of nonhazardous solid waste generated by a commercial solar power generation facility would be the responsibility of that project. NNSS disposal capacity would not be impacted under current permit conditions.	Disposal of nonhazardous solid waste generated by a commercial solar power generation facility would be the responsibility of that project. NNSS disposal capacity would not be impacted under current permit conditions.

	Impacts on low-income and minority populations would be identical to those of the general population. Therefore, no disproportionately high and adverse impacts on minority and low-income populations are expected. An increase in construction jobs for the solar power generation facility could provide jobs for unemployed individuals, which would have a beneficial impact on low-income individuals.	Same as under the No Action Alternative, except there would be a larger number of construction jobs created.	Same as under the No Action Alternative, except there would be fewer construction jobs created.	Impacts on low-income and minority populations would be identical to those of the general population. Therefore, no disproportionately high and adverse impacts on minority and low-income populations are expected. An increase in construction jobs for the solar power generation facility could provide jobs for unemployed individuals, which would have a beneficial impact on low-income individuals.

NNSA = National Nuclear Security Administration; NNSS = Nevada National Security Site; Particulate $Matter_{10}$ = particulate matter with an aerodynamic diameter less than or equal to 10 micrometers; Particulate $Matter_{2.5}$ = particulate matter with an aerodynamic diameter less than or equal to 2.5 micrometers; rem = roentgen equivalent man.

[a] The reported radiological risks are the projected number of latent cancer fatalities in the population and are, therefore, presented as whole numbers. The calculated value is shown in parentheses. Both radiological impacts and nonradiological traffic impacts are based upon shipment of the entire inventory of low-level radioactive waste over a 10-year period.

[b] Reopening of the Area 3 Radioactive Waste Management Site would only occur based upon mission need and as stated in 4.1.11.1.1.1, including detailed consultation with the state of Nevada.

[c] The risk is the annual increased likelihood of a latent cancer fatality in the maximally exposed individual or the noninvolved worker, or the increased likelihood of a single latent cancer fatality occurring in the offsite population, accounting for the estimated probability (frequency) of the accident occurring.

S.3.1.11 Cumulative Impacts

Council on Environmental Quality regulations define a cumulative impact as the "impact on the environment which results from the incremental impact of the action when added to past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor, but collectively significant, actions taking place over a period of time." Thus, the cumulative impacts of an action are the total effects on a resource, ecosystem, or human community of that action and all other activities affecting that resource, no matter which entity is acting.

Most of the land in the vicinity of the NNSS is managed by Federal agencies, including the U.S. Bureau of Land Management, U.S. Air Force, USFWS, U.S. Forest Service, and U.S. National Park Service. In addition, there are lands and facilities under the jurisdiction of agencies of the State of Nevada; Nye, Clark, Esmeralda, and Lincoln Counties in Nevada; the State of California; Inyo County, California; various municipal governments; and private landowners. DOE/NNSA identified reasonably foreseeable future actions of others by conducting a review of publicly available documents prepared by these Federal, state, tribal, and local government agencies and organizations. In addition, DOE/NNSA requested information regarding potential future actions that may not yet have been addressed in publicly available documents.

For DOE/NNSA contributions to cumulative impacts, the analysis primarily used the Expanded Operations Alternative, as it tends to result in the highest estimates of potential cumulative impacts associated with alternatives analyzed in this *NNSS SWEIS*. To provide a comparison of the cumulative impacts associated with each of the three alternatives considered in this *NNSS SWEIS*, **Table S–15** summarizes cumulative impacts by alternative.

S.3.2 Remote Sensing Laboratory

No new project or capabilities or changes in the levels of operations (activities) are proposed at RSL. For this reason, among the 13 resource areas, either there would be no impacts or the impacts associated with ongoing operations would continue unchanged from baseline conditions. **Table S–16** summarizes the potential environmental impacts for all 13 resource areas under each alternative. As discussed above in Section S.2.5, DOE/NNSA's Preferred Alternative is a "hybrid" alternative comprising various programs, capabilities, projects, and activities selected from among the three alternatives. Although the text of this Summary does not discuss the potential environmental impacts from implementing the Preferred Alternative, consistent with the approach used in Chapter 3 of the *NNSS SWEIS*, Table S–16 summarizes those impacts to enable a comparison to the three alternatives.

S.3.3 North Las Vegas Facility

This section summarizes the potential environmental impacts at NLVF from continuing and proposed projects and capabilities, including their associated levels of operations (activities), under each of three alternatives. The text focuses on those resource areas for which the impacts would be sufficiently different to permit distinguishing among the alternatives in a meaningful manner or would tend to be controversial, i.e., energy, traffic, socioeconomics, air quality, waste management, and human health.

Table S–19 (at the end of Section S.3.3.6) summarizes the potential environmental impacts for all 13 resource areas. As discussed above in Section S.2.5, DOE/NNSA's Preferred Alternative is a "hybrid" alternative comprising various programs, capabilities, projects, and activities selected from among the three alternatives. Although the text of this Summary does not discuss the potential environmental impacts from implementing the Preferred Alternative, consistent with the approach used in Chapter 3 of the *NNSS SWEIS*, Table S–19 summarizes those impacts to enable a comparison to the three alternatives.

Table S–15 Potential Cumulative Impacts

Resource Area	*DOE/NNSA Contribution to Cumulative Impacts*	*Non-DOE/NNSA Contribution to Cumulative Impacts*	*Cumulative Impacts*
Land Use	The following land use changes would occur under the noted *NNSS SWEIS* alternatives: **No Action** • There would be no changes to NNSS Land Use Zones. • Construction of a commercial solar power generation facility would affect land use patterns outside of the NNSS due to construction of a 230-kilovolt transmission line. **Expanded Operations** • Area 15 – Change from Reserved Zone to Research, Test and Experiment Zone. • Area 25 – Designate about 39,600 acres as a Renewable Energy Zone. • Construction of commercial solar power generation facilities would affect land use patterns outside of the NNSS due to construction of a 500-kilovolt transmission line. **Reduced Operations** • Areas 19 and 20 – Change from Nuclear Test Zone to Limited Use Zone. • Areas 18, 29, and 30 – Change from Reserved Zone to Limited Use Zone. • Construction of a commercial solar power generation facility would not affect land use patterns outside of the NNSS.	In Nye County, approximately 149,000 acres of public land managed by the U.S. Bureau of Land Management would be committed to use for renewable energy facilities or commercial/industrial uses. In Clark County, the U.S. Bureau of Land Management would dispose up to about 36,000 acres of public land. Use of this land would be changed from its current public uses to private and/or municipal uses.	Regardless of the implementation of any alternative in this *NNSS SWEIS*, changes in NNSS land use zone designations or functions are not expected to affect land use patterns in areas outside of the NNSS, except for the potential construction of interconnecting transmission lines for commercial solar power generation facilities under the No Action (250 acres) and Expanded Operations (300 acres) Alternatives. Land uses at RSL, NLVF, and the TTR are expected to remain unchanged and would not affect land uses in other areas. Over 185,000 acres of public land managed by the U.S. Bureau of Land Management would be either disposed or withdrawn for non-public uses within Clark and Nye Counties.

Resource Area	***DOE/NNSA Contribution to Cumulative Impacts***	***Non-DOE/NNSA Contribution to Cumulative Impacts***	***Cumulative Impacts***
Infrastructure and Energy	<u>Infrastructure</u> Construction of new facilities at the NNSS, particularly one or more solar power generation facilities with a capacity of 240 megawatts under the No Action Alternative, a combined capacity of 1,000 megawatts under the Expanded Operations Alternative, and 100 megawatts under the Reduced Operations Alternative, would cause a demand for construction materials and skilled labor, in proportion to their size, similar to those of other large construction projects.	<u>Infrastructure</u> Construction of new facilities, particularly large projects, would place cumulative demands on goods and services. The proposed renewable energy projects in Amargosa Valley and Area 25 of the NNSS would all have similar needs for large tracts of undeveloped land and water; use earthmoving/grading equipment, cranes, and other construction equipment; require similar materials, such as concrete, steel, wood, wiring and cables, etc.; and require the services of both general and specialized construction workers.	<u>Infrastructure</u> Large-scale construction projects, particularly renewable energy facilities in the Jackass Flats area of the NNSS and in Amargosa Valley and construction of new high-voltage transmission lines would create an increase in demand for and cumulatively affect availability of construction materials, supplies, and labor. Because of the relative number and/or size of new facility construction considered in this *NNSS SWEIS*, the noted cumulative impact would be substantially greater for the Expanded Operations Alternative than for the No Action Alternative. The Reduced Operations Alternative would create the least demand on construction materials, supplies, and labor and would contribute the least to cumulative impacts.
	<u>Energy</u> The 2020 projected cumulative annual electrical energy demand for DOE/NNSA activities in Nevada under the No Action Alternative is about 113,000 megawatt-hours; under the Expanded Operations Alternative, about 127,000 megawatt-hours; and under the Reduced Operations Alternative, about 96,000 megawatt-hours. A portion of the electrical energy demand under the Expanded Operations Alternative would be offset by development of a 5-megawatt photovoltaic solar power generation facility in Area 6 of the NNSS.	<u>Energy</u> In 2009, NV Energy (southern division) and Valley Electric Association provided a total of about 21,670,000 megawatt-hours of electricity to their customers (NSOE 2010). The Nevada Public Utilities Commission forecasts a 1.5 percent growth rate in electricity sales through 2020 (NDEP 2008). Based on that growth rate, by 2020, total electricity sales in southern Nevada would be about 25,500,000 megawatt-hours, an increase of almost 4,000,000 megawatt-hours. There are proposals for renewable energy projects in southern Nevada that would produce a total of about 5,800 megawatts of new generating capacity.	<u>Energy</u> Cumulatively, the projected increase in electrical energy demand, regardless of the demand under any of the alternatives, would be offset by development of up to 5,800 megawatts of new generating capacity from proposed renewable energy facilities. In addition, construction of new high-voltage transmission lines, such as the Solar Express Transmission Line Project and the Transwest Express Transmission Project, would provide a stronger connection with other regions to support electrical demand in southern Nevada.

Resource Area	*DOE/NNSA Contribution to Cumulative Impacts*	*Non-DOE/NNSA Contribution to Cumulative Impacts*	*Cumulative Impacts*
Transportation and Traffic	Traffic Personnel and trucks associated with one or more commercial solar power generation facilities in Area 25 would increase daily vehicle trips on local roadways by 500 to 1,000 through the 36-month construction period under the No Action Alternative; by 750 to 1,500 through the 42-month construction period under the Expanded Operations Alternative; and by 400 to 800 under the Reduced Operations Alternative. The addition of these vehicles and associated construction trucks on a daily basis would increase the rate of pavement deterioration, degrade levels of service, and could require increased road maintenance and upgrades for roads in the project area.	Traffic During construction of proposed renewable energy projects in Amargosa Valley and the Yucca Mountain Project Gateway Area development, roads in Nye County could experience increases in daily traffic ranging from a two- to a fivefold increase on primary roads such as U.S. Route 95 and Nevada State Route 160, which could degrade levels of service from A to D during peak commuting hours. Personnel and trucks associated with one or more commercial solar power generation facilities in Area 25 would increase daily vehicle trips on local roadways by 500 to 1,000 through the 35-month construction period. During operations, primary roadways could experience increases in daily traffic, and levels of service could degrade one level during peak commuting hours. The degradation in levels of service caused by increased traffic volumes on these roads could generate the need for additional travel lanes and other improvements.	Traffic The cumulative impact of increased traffic on local roadways in southern Nye County, nearby the NNSS, associated with NNSS operations and construction and operation of one or more commercial solar power generation facilities in Area 25 would be a reduction in level of service on U.S. Route 95 from B to C, relative to the 2008 baseline, regardless of the traffic increases resulting from implementation of any of the alternatives. When combined with increased traffic from other large construction projects in Amargosa Valley, the level of service would degrade to D, causing accelerated deterioration and associated increased need for maintenance and repair. Some roadways and traffic control measures would need to be upgraded.
	Radiological Transportation **No Action Alternative** • Worker dose = 2,100 person-rem, equivalent to 1.3 latent cancer fatalities. • Population dose = 400 person-rem, equivalent to 0.2 latent cancer fatalities. **Expanded Operations Alternative** • Worker dose = 5,600 person-rem, equivalent to 3 latent cancer fatalities. • Population dose = 1,400 person-rem, equivalent to 1 latent cancer fatality. **Reduced Operations Alternative** • Worker dose = 2,100 person-rem, equivalent to 1.3 latent cancer fatalities. • Population dose = 400 person-rem, equivalent to 0.2 latent cancer fatalities.	Radiological Transportation Collective worker dose (1943 to 2073) = 399,000 person-rem, equivalent to 240 latent cancer fatalities over 130 years. Collective general population dose (1943 to 2073) = 373,000 person-rem, equivalent to 224 latent cancer fatalities over 130 years.	Radiological Transportation **No Action Alternative** • Worker dose = 401,000 person-rem, equivalent to 241 latent cancer fatalities over 130 years. • Population dose = 373,000 person-rem, equivalent to 224 latent cancer fatalities over 130 years. **Expanded Operations Alternative** • Worker dose = 405,000 person rem, equivalent to 243 latent cancer fatalities over 130 years. • Population dose = 374,000 person-rem, equivalent to 225 latent cancer fatalities over 130 years. **Reduced Operations Alternative** • Worker dose = 401,000 person-rem, equivalent to 241 latent cancer fatalities over 130 years. • Population dose = 373,000 person-rem, equivalent to 224 latent cancer fatalities over 130 years.

Resource Area	*DOE/NNSA Contribution to Cumulative Impacts*	*Non-DOE/NNSA Contribution to Cumulative Impacts*	*Cumulative Impacts*
Geology and Soils	An unknown but substantial amount of deep subsurface geologic media has been affected by underground nuclear tests conducted on the NNSS. Approximately 80,000 acres of land on the NNSS has been disturbed by previous DOE/NNSA activities. Overall, new disturbance of soils and near-surface geological media resulting from proposed DOE/NNSA actions at the NNSS would be as follows: **No Action**: About 1,800 acres plus an additional 2,650 acres for a commercial solar power generation facility. **Expanded Operations**: About 15,500 acres, plus an additional 10,350 acres for commercial solar power generation facilities and a Geothermal Demonstration Project. **Reduced Operations**: About 1,540 acres plus an additional 1,200 acres for a commercial solar power generation facility.	Within the cumulative impacts region of influence, about 215,000 acres of Clark County and 51,000 acres of Nye County have been disturbed by previous development. A total of about 509,750 acres of additional soil and near-surface geologic media would be affected by reasonably foreseeable land development activities in Nye and Clark Counties. This would result in a total of about 775,750 acres of soil and near-surface geologic media being disturbed.	Previous combined actions within the cumulative impacts region of influence have disturbed about 346,000 acres. Reasonably foreseeable actions would disturb additional soil and near-surface geological media within the region of influence, as follows: **No Action:** About 514,250 acres **Expanded Operations:** About 535,750 acres **Reduced Operations:** About 512,450 The total potential cumulative area of land disturbance would range from about 858,450 to 881,750 acres, which represents about 5.5 to 5.6 percent of the total area of the region of influence (15,737,760 acres).
Hydrology	<u>Surface Water</u> Within areas that drain off the NNSS, under the No Action, Expanded Operations, and Reduced Operations Alternatives, a total of 2,650, 10,300, and 1,200 acres, respectively, of land could be disturbed for construction of one or more commercial solar power generation facilities. During construction of these facilities, the potential for soil erosion affecting surface waters would be greater due to removal of vegetation and other earth-disturbing activities. If such erosion were to occur it would likely result in increased sediments being transported into Fortymile Wash and eventually into the Amargosa River. However, implementation of erosion control measures would reduce the likelihood of such erosion.	<u>Surface Water</u> Disturbing about 94,300 acres in Amargosa Valley for constructing one or more solar power generation facilities and developing the Yucca Mountain Project Gateway Area could result in erosion and slightly increase sedimentation in the Amargosa River during the construction period. However, U.S. Bureau of Land Management-prescribed and enforced erosion control measures would reduce the likelihood of such an impact.	<u>Surface Water</u> Although the potential for increased sedimentation in the Amargosa River drainage is a potential cumulative impact regardless of alternative considered in this *NNSS SWEIS*, implementation of recognized measures to prevent erosion would reduce the likelihood of such impacts occurring.

Resource Area	DOE/NNSA Contribution to Cumulative Impacts	Non-DOE/NNSA Contribution to Cumulative Impacts	Cumulative Impacts
Hydrology *(cont'd)*	Groundwater Past underground nuclear testing has contaminated an unknown volume of groundwater beneath the NNSS. That contamination is not expected to impact publicly available water supplies within the next 100 years, based on estimated groundwater travel times between the NNSS and Oasis Valley that range from 337 to over 6,191 years (95 percent confidence limits) (Rose et al 2002). DOE/NNSA proposed activities under this *NNSS SWEIS* would not cause new or additional groundwater contamination. DOE/NNSA activities at the NNSS and the TTR, as well as operation of one or more solar power generation facilities in Area 25 of the NNSS, under all three alternatives addressed in this *NNSS SWEIS*, would require withdrawal of groundwater, as follows: **No Action:** 959 acre-feet **Expanded Operations:** 1,580 acre-feet **Reduced Operations:** 815 acre-feet This volume of groundwater represents about 16 percent, 27 percent, and 14 percent, respectively, of the cumulative sustainable yield for all of the affected hydrographic basins. DOE/NNSA would not withdraw groundwater from the Oasis Valley, Crater Flats, or Amargosa Valley Hydrographic Basins.	Groundwater The town of Beatty, Nevada, uses just under 500 acre-feet of water per year obtained from the Oasis Valley Hydrographic Basin. Operational water requirements for one or more solar power generation facilities proposed in Amargosa Valley would require almost 6,000 acre-feet of groundwater each year, primarily from the Amargosa Desert, Oasis Valley, and Crater Flats Hydrographic Basins. Nevada State Engineer Order 1197 requires that water for new uses in the Amargosa Desert Hydrographic Basin be obtained by acquisition of existing water rights.	Groundwater Regardless of alternative considered in this *NNSS SWEIS*, groundwater monitoring programs conducted by DOE/NNSA and other organizations, such as the U.S. Geological Survey and Desert Research Institute, would ensure that there would be sufficient lead-time for DOE/NNSA to identify and implement appropriate protective and mitigative measures if contamination associated with underground nuclear testing were to affect any water supply located off Federal land. Due to the implementation of Nevada State Engineer Order 1197, there would be no new cumulative impacts associated with groundwater availability resulting from DOE/NNSA proposed actions and reasonably foreseeable projects in the Amargosa Desert Hydrographic Basin.

Resource Area	***DOE/NNSA Contribution to Cumulative Impacts***	***Non-DOE/NNSA Contribution to Cumulative Impacts***	***Cumulative Impacts***
Biological Resources	Currently, approximately 80,000 acres of the NNSS are considered disturbed. Overall, new wildlife habitat disturbed by DOE/NNSA actions would be as follows: **No Action**: About 1,810 acres, plus an additional 2,650 acres for a commercial solar power generation facility. **Expanded Operations**: About 15,500 acres, plus an additional 10,350 acres for commercial solar power generation facilities and a Geothermal Demonstration Project. **Reduced Operations**: About 1,540 acres, plus an additional 1,200 acres for a commercial solar power generation facility. Impacts on the threatened desert tortoise under all alternatives would be the result of harassment. **No Action**: DOE/NNSA activities at the NNSS would affect about 1,055 acres of desert tortoise habitat and impact up to 47 tortoises; a commercial solar power generation facility would affect an additional 2,650 acres of tortoise habitat and up to 41 tortoises. **Expanded Operations**: DOE/NNSA activities at the NNSS would affect about 3,370 acres of desert tortoise habitat and impact up to 60 tortoises; commercial solar power generation facilities would disturb about 10,300 acres of tortoise habitat and up to 161 desert tortoises. **Reduced Operations**: DOE/NNSA activities at the NNSS would disturb about 920 acres of desert tortoise habitat and impact up to 37 tortoises; a commercial solar power generation facility would affect an additional 1,200 acres of tortoise habitat and up to 19 tortoises. An additional 125 tortoises may experience impacts due to harassment on NNSS roads under all three alternatives. Overall, wildlife habitat disturbed by DOE/NNSA actions would total about 26,000 acres.	Reasonably foreseeable actions by the U.S. Fish and Wildlife Service would result in a total of about 360,000 acres of desert tortoise habitat in Clark County, Nevada, being permitted under the Endangered Species Act for incidental take of desert tortoises (USFWS 2000; 74 FR 50239). This represents about 9 percent of the estimated 4,000,000 acres of tortoise habitat in Clark County. Within Nye County, desert tortoise habitat would be affected by a number of reasonably foreseeable actions. The development of solar energy projects in Nye County would remove up to about 131,500 acres of desert tortoise habitat; development of the Nye County Yucca Mountain Project Gateway Area would remove up to 5,800 acres. The development of over 509,000 acres of open land in the region would cumulatively affect wildlife and wildlife habitat. The loss of large areas of habitat would reduce the available habitat for native wildlife, including federally listed species and other special status species. Development of undisturbed land would contribute to loss, fragmentation, and degradation of habitat and encourage nonnative invasive species, thereby eliminating or degrading natural plant communities on which wildlife depend.	The development of from about 512,000 (Reduced Operations Alternative) to 535,750 acres (Expanded Operations Alternative) of currently open land in the region would cumulatively affect wildlife and wildlife habitat. The loss of large areas of habitat would reduce the available habitat for native wildlife, including federally listed species and other special status species. Development of undisturbed land would contribute to loss, fragmentation, and degradation of habitat and encourage nonnative invasive species, thereby eliminating or degrading natural plant communities on which wildlife depend. DOE/NNSA proposed actions and reasonably foreseeable actions by others within the cumulative impacts region of influence would result in the loss of over 522,000 acres of tortoise habitat under the Expanded Operations Alternative or about 508,000 acres under the No Action and Reduced Operations Alternatives. However, because a large portion of that habitat loss would be permitted by USFWS under the Endangered Species Act, pursuant to Section 10(a)(1)(B) for non-Federal entities and Section 7 for Federal agencies, this habitat loss would not threaten the continued existence of the desert tortoise.

Resource Area	*DOE/NNSA Contribution to Cumulative Impacts*	*Non-DOE/NNSA Contribution to Cumulative Impacts*	*Cumulative Impacts*
Air Quality and Climate	Nye County Annual DOE/NNSA air emissions in Nye County from all sources in 2015: **No Action Alternative:** Particulate $Matter_{10}$ = 9.8 tons Particulate $Matter_{2.5}$ = 6.8 tons Carbon Monoxide = 66 tons Nitrogen Oxides = 40 tons Sulfur Dioxide = 1.3 tons Volatile Organic Compounds = 5.2 tons Lead = 0.04 tons Hazardous Air Pollutants = 1.4 tons **Expanded Operations Alternative:** Particulate $Matter_{10}$ = 22.6 tons Particulate $Matter_{2.5}$ = 11 tons Carbon Monoxide = 82 tons Nitrogen Oxides = 50 tons Sulfur Dioxide = 2 tons Volatile Organic Compounds = 10 tons Lead = 0.2 tons Hazardous Air Pollutants = 1.4 tons **Reduced Operations Alternative:** Particulate $Matter_{10}$ = 7.2 tons Particulate $Matter_{2.5}$ = 5.8 tons Carbon Monoxide = 55 tons Nitrogen Oxides = 36 tons Sulfur Dioxides = 1.2 tons Volatile Organic Compounds = 4.1 tons Lead = 0.01 tons Hazardous Air Pollutants = 1.3 tons	Nye County Because Nye County is considered an attainment/nondesignated area for purposes of compliance with National Ambient Air Quality Standards, no countywide air monitoring data are available.	Nye County Cumulatively, the annual air emissions from Federal and non-Federal activities in Nye County from all sources in 2015, regardless of the level of projected emissions under any of the alternatives considered in this *NNSS SWEIS*, are not expected to cause a nonattainment condition with respect to National Ambient Air Quality Standards.

Resource Area	***DOE/NNSA Contribution to Cumulative Impacts***	***Non-DOE/NNSA Contribution to Cumulative Impacts***	***Cumulative Impacts***
Air Quality and Climate *(cont'd)*	Clark County Estimated annual mobile source emissions related to DOE/NNSA activities in Clark County, including worker commuting, for the criteria pollutants that are in nonattainment in the Las Vegas Valley are: **No Action Alternative:** Particulate $Matter_{10}$ = 1.5 tons Carbon Monoxide = 97 tons Nitrogen Oxides = 24 tons Volatile Organic Compounds = 3.1 tons **Expanded Operations Alternative:** Particulate $Matter_{10}$ = 2 tons Carbon Monoxide = 119 tons Nitrogen Oxides = 29 tons Volatile Organic Compounds = 3.9 tons **Reduced Operations Alternative:** Particulate $Matter_{10}$ = 2 tons Carbon Monoxide = 86 tons Nitrogen Oxides = 22 tons Volatile Organic Compounds = 3 tons	Clark County Clark County, principally the Las Vegas Valley, is classed as a nonattainment area for some air pollutants, i.e., not in compliance with National Ambient Air Quality Standards. Criteria pollutants for which the Las Vegas Valley have been out of attainment and the projected (2013) annual mobile source emissions are: Particulate $Matter_{10}$ = 28,744 tons Carbon Monoxide = 140,160 tons Nitrogen Oxides = 11,625 tons Volatile Organic Compounds = 12,399	Clark County The estimated 2015 cumulative total of annual mobile source emissions of criteria pollutants that are currently in nonattainment in the Las Vegas Valley are: **No Action Alternative:** Particulate $Matter_{10}$ = 28,746 tons Carbon Monoxide = 140,257 tons Nitrogen Oxides = 11,649 tons Volatile Organic Compounds = 12,402 tons **Expanded Operations Alternative:** Particulate $Matter_{10}$ = 28,746 tons Carbon Monoxide = 140,279 tons Nitrogen Oxides = 11,654 tons Volatile Organic Compounds = 12,403 tons **Reduced Operations Alternative:** Particulate $Matter_{10}$ = 28,746 tons Carbon Monoxide = 140,246 tons Nitrogen Oxides = 11,647 tons Volatile Organic Compounds = 12,402 tons
	Greenhouse Gas Emissions DOE/NNSA activities in Nye and Clark County were estimated to annually generate the following estimated amounts of greenhouse gas emissions in 2015: **No Action Alternative:** 60,555 tons **Expanded Operations Alternative:** 88,679 tons **Reduced Operations Alternative:** 53,755 tons	Greenhouse Gas Emissions Annual greenhouse gas emissions in Nye, Clark, Lincoln, and Esmeralda Counties in 2015 were estimated to be about 54.6 million tons.	Greenhouse Gas Emissions Annual cumulative greenhouse gas emissions in Nye, Clark, Lincoln, and Esmeralda Counties are projected to be as follows: **No Action:** 54,661,000 tons **Expanded Operations:** 54,689,000 tons **Reduced Operations:** 54,654,000 tons
Visual Resources	Under all three alternatives addressed in this *NNSS SWEIS*, the development of one or more solar power generation facilities with generating capacities ranging from 100 to 1,000 megawatts in Area 25 of the NNSS would reduce the visual quality rating of that viewshed from Class B to Class C due to intrusion of manmade elements. Under the Expanded Operations Alternative, construction of additional facilities at Desert Rock Airport would adversely impact the viewshed along U.S. Route 95 in Mercury Valley.	In Nye County, in the vicinity of the NNSS, development of one or more solar power generation facilities would substantially alter the visual character along U.S. Route 95 in Amargosa Valley.	Regardless of the alternative considered in this *NNSS SWEIS*, development of one or more solar power generation facilities, the Yucca Mountain Gateway Project, and new facilities at Desert Rock Airport (only under the Expanded Operations Alternative) would substantially alter the visual character along U.S. Route 95 in Amargosa and Mercury Valleys, reducing the visual quality rating from Class B to Class C.

Resource Area	DOE/NNSA Contribution to Cumulative Impacts	Non-DOE/NNSA Contribution to Cumulative Impacts	Cumulative Impacts
Cultural Resources	The estimated number of cultural resources sites potentially affected by DOE/NNSA activities and development of one or more commercial solar power generation facilities under each alternative are as follows: **No Action Alternative:** DOE/NNSA activities would potentially affect up to 53 sites; 18 could be considered eligible for inclusion in the National Register of Historic Places. Development of a 100-megawatt commercial solar power generation facility would potentially affect up to 802 sites; 557 could be considered eligible for inclusion in the National Register of Historic Places. **Expanded Operations Alternative:** DOE/NNSA activities would potentially affect up to 682 sites; 283 could be considered eligible for inclusion in the National Register of Historic Places. Development of up to 1,000 megawatts of commercial solar power generation facilities and a Geothermal Demonstration Project would potentially affect up to 7,006 sites; 2,163 could be considered eligible for inclusion in the National Register of Historic Places. **Reduced Operations Alternative:** DOE/NNSA activities would potentially affect up to 45 sites; 14 could be considered eligible for inclusion in the National Register of Historic Places. Development of a 100-megawatt commercial solar power generation facility would potentially affect up to 816 sites; 252 could be eligible for inclusion in the National Register of Historic Places.	An estimated 26,000 cultural resources sites would be affected by land-disturbing activities within the cumulative impacts region of influence, with about 13,000 of those sites being considered eligible for inclusion in the National Register of Historic Places.	The estimated cumulative total of potentially affected cultural resources sites, including both proposed and reasonably foreseeable future actions under each alternative, are as follows: **No Action Alternative:** Total sites—26,855 National Register of Historic Places-eligible sites—13,565 **Expanded Operations Alternative:** Total sites—33,688 National Register of Historic Places-eligible sites—15,446 **Reduced Operations Alternative:** Total sites—26,861 National Register of Historic Places-eligible sites—13,266

Resource Area	***DOE/NNSA Contribution to Cumulative Impacts***	***Non-DOE/NNSA Contribution to Cumulative Impacts***	***Cumulative Impacts***
Waste Management	Radioactive Waste Historic disposal of low-level and mixed low-level radioactive waste, and some transuranic waste at the NNSS totaled about 40,000,000 cubic feet through 2010. During the next 10 years, the following estimated volumes of radioactive waste would potentially be disposed at the NNSS: **No Action and Reduced Operations Alternatives:** • Low-level radioactive waste = 15,000,000 cubic feet • Mixed low-level radioactive waste = 900,000 cubic feet **Expanded Operations Alternative:** • Low-level radioactive waste = 48,000,000 cubic feet • Mixed low-level radioactive waste = 4,000,000 cubic feet	Radioactive Waste The NNSS is the only active disposal facility for low-level radioactive waste and mixed low-level radioactive waste in Nevada. It accepts for disposal only low-level radioactive waste and mixed low-level radioactive waste that meet the NNSS waste acceptance criteria. A commercial low-level radioactive waste disposal facility operated from 1962 to the end of 1992 in Beatty, Nevada, about 45 miles west of Mercury on the NNSS. Because of a lack of a groundwater pathway from NNSS radioactive waste management facilities, the large distances between this facility and DOE/NNSA waste management operations, depth to groundwater, the high evaporation rate in the region, and monitoring by the Nevada Division of Environmental Protection to ensure continued proper function of closure/containment measures, this closed disposal facility is not expected to have any cumulative impacts with DOE/NNSA waste management activities.	Radioactive Waste Because the NNSS operates the only low-level radioactive waste/mixed low-level radioactive waste disposal facilities in Nevada, there would be no cumulative impacts from management of such wastes outside of the NNSS.

Resource Area	*DOE/NNSA Contribution to Cumulative Impacts*	*Non-DOE/NNSA Contribution to Cumulative Impacts*	*Cumulative Impacts*
Waste Management *(cont'd)*	Nonradioactive Waste The following estimated volumes of hazardous waste would be generated by DOE/NNSA activities and one or more commercial solar power generation facilities over the next 10 years: **No Action Alternative:** • DOE/NNSA activities—170,000 cubic feet • Commercial solar power generation facility—42,000 cubic feet **Expanded Operations Alternative:** • DOE/NNSA activities—170,000 cubic feet • Commercial solar power generation facilities—170,000 cubic feet **Reduced Operations Alternative**: • DOE/NNSA activities—170,000 cubic feet • Commercial solar power generation facility—17,000 cubic feet All hazardous waste generated by DOE/NNSA activities would be transported to commercial treatment, storage, and disposal facilities for treatment and/or disposal. Hazardous waste generated by one or more commercial solar power generation facilities would be managed by the operator in accordance with applicable statutes and regulations.	Nonradioactive Waste There are a number of hazardous waste treatment, storage, and disposal facilities in Nevada and neighboring states that treat and dispose such wastes from many generators.	Nonradioactive Waste The volume of hazardous waste that DOE/NNSA and one or more commercial solar power generation facilities would dispose at commercial treatment, storage, and disposal facilities would not exceed the capacity of such facilities and would represent a very small portion of the overall volume of such waste disposal, regardless of the alternative considered.

Resource Area	DOE/NNSA Contribution to Cumulative Impacts	Non-DOE/NNSA Contribution to Cumulative Impacts	Cumulative Impacts
Human Health	<u>Radiological</u> The dose to the offsite population resulting from DOE/NNSA activities in southern Nevada under each alternative addressed in this *NNSS SWEIS* would be: **No Action Alternative:** • Dose = 5.0 person-rem over 10 years • Consequences = No (0.003) latent cancer fatality **Expanded Operations Alternative:** • Dose = 8.9 person-rem over 10 years • Consequences = No (0.005) latent cancer fatality **Reduced Operations Alternative:** • Dose = 4.8 person-rem over 10 years • Consequences = No (0.003) latent cancer fatality	<u>Radiological</u> There are no other non-background sources of potential radiological exposure for an offsite member of the public within the cumulative impacts region of influence.	<u>Radiological</u> Because there is no other source for above-background level of exposure to radioactivity in the cumulative impacts region of influence, DOE/NNSA is the sole contributor to the cumulative dose analyzed in this *NNSS SWEIS*. Cumulatively, the impacts would then be as follows: **No Action Alternative:** • Dose = 5.0 person-rem over 10 years • Consequences = No (0.003) latent cancer fatality **Expanded Operations Alternative:** • Dose = 8.9 person-rem over 10 years • Consequences = No (0.005) latent cancer fatality **Reduced Operations Alternative:** • Dose = 4.8 person-rem over 10 years • Consequences = No (0.003) latent cancer fatality

Resource Area	DOE/NNSA Contribution to Cumulative Impacts	Non-DOE/NNSA Contribution to Cumulative Impacts	Cumulative Impacts
Human Health *(cont'd)*	Nonradiological The following estimated nonradiological consequences would occur over a 10-year period from DOE/NNSA activities at the NNSS, RSL, NLVF, and the TTR and construction of one or more commercial solar power generation facilities at the NNSS under each alternative addressed in this *NNSS SWEIS*: **No Action Alternative:** Operations Total recordable cases = 578 Days away, restricted, or transferred = 253 Construction Total recordable cases = 60 Days away, restricted, or transferred = 31 TOTAL for Alternative Total recordable cases = 638 Days away, restricted, or transferred = 314 **Expanded Operations Alternative:** Operations Total recordable cases = 700 Days away, restricted, or transferred = 314 Construction Total recordable cases = 148 Days away, restricted, or transferred = 48 TOTAL for Alternative Total recordable cases = 848 Days away, restricted, or transferred = 362 **Reduced Operations Alternative:** Operations Total recordable cases = 508 Days away, restricted, or transferred = 225 Construction Total recordable cases = 44 Days away, restricted, or transferred = 23 TOTAL for Alternative Total recordable cases = 552 Days away, restricted, or transferred = 248	Nonradiological During construction of proposed renewable energy projects in Amargosa Valley, industrial accidents could result in an estimated fatality to one worker in 750 total recordable cases and 380 days away, restricted, or transferred.	Nonradiological Industrial accidents from all activities at DOE/NNSA sites over a 10-year period, and construction of renewable energy projects in Amargosa Valley could result in the following total recordable cases and days away, restricted or transferred for each alternative: **No Action Alternative:** Total recordable cases = 1,328 Days away, restricted, or transferred = 633 **Expanded Operations Alternative:** Total recordable cases = 1,598 Days away, restricted, or transferred = 742 **Reduced Operations Alternative:** Total recordable cases = 1,302 Days away, restricted, or transferred = 628

Resource Area	DOE/NNSA Contribution to Cumulative Impacts	Non-DOE/NNSA Contribution to Cumulative Impacts	Cumulative Impacts
Environmental Justice	Potential new land disturbances on the NNSS for both DOE/NNSA activities and development of one or more commercial solar power generation facilities would result in new land disturbance on up to about 4,500 acres, 26,000 acres, and 2,700 acres, respectively under the No Action, Expanded Operations, and Reduced Operations Alternatives. Previously undisturbed lands may be important to American Indians. Land disturbances on the NNSS could affect traditional cultural properties of concern for various American Indian tribes with a cultural affiliation with the NNSS.	Non-DOE/NNSA actions would account for approximately 509,750 acres of new land disturbances within the cumulative impacts region of influence. Land disturbance of this magnitude would likely have adverse impacts on American Indian traditional cultural properties by destroying places important to the continuation of those cultures.	The potential disturbance of up to 514,250 acres (No Action Alternative), 535,750 acres (Expanded Operations Alternative), or 512,450 acres (Reduced Operations Alternative) of currently undisturbed land within the cumulative impacts region of influence would likely have adverse impacts on American Indian traditional cultural properties by affecting places important to the continuation of those cultures.

NLVF = North Las Vegas Facility; Particulate Matter$_{10}$ = particulate matter with an aerodynamic diameter less than or equal to 10 micrometers; Particulate Matter$_{2.5}$ = particulate matter with an aerodynamic diameter less than or equal to 2.5 micrometers; rem = roentgen equivalent man; RSL = Remote Sensing Laboratory; TTR = Tonopah Test Range.

Note: Chapter 6, Section 6.2, of the *NNSS SWEIS* provides additional qualitative discussions of other potentially cumulative actions (including the proposed Greater-Than-Class C Low-Level Waste Disposal Facility and the formerly proposed Yucca Mountain Repository Projects) located within the region of influence.

Table S–16 Summary of Potential Direct and Indirect Impacts at the Remote Sensing Laboratory

	No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*	*Preferred Alternative*
Land Use				
	No impacts were identified from the continuation of activities at the current levels of operations or foreseeable actions because activities under this alternative would continue to be compatible with existing land use designations on Nellis Air Force Base.	Same as under the No Action Alternative.	Same as under the No Action Alternative.	No impacts were identified from the continuation of activities at the current levels of operations or foreseeable actions because activities under this alternative would continue to be compatible with existing land use designations on Nellis Air Force Base.
Infrastructure and Energy				
	Infrastructure would be maintained as needed to accommodate ongoing activities. No new buildings or facilities are planned. Energy demand is expected to continue at about 4,850 megawatt-hours per year and the existing electrical distribution is adequate to support this demand. Natural gas use is expected to continue to be about 33,673 therms per year. There is adequate capacity to serve this demand and the condition of the gas lines is satisfactory. Approximately 11,000 gallons of JP-8 jet fuel are used each year for aircraft operations. An adequate supply of JP-8 fuel is available directly through Nellis Air Force Base.	Same as under the No Action Alternative.	Same as under the No Action Alternative.	Infrastructure would be maintained as needed to accommodate ongoing activities. Environmental Justice				
	Impacts on low-income and minority populations would be identical to those of the general population. Therefore, no disproportionately high and adverse impacts on minority and low-income populations are expected.	Same as under the No Action Alternative.	Same as under the No Action Alternative.	Impacts on low-income and minority populations would be identical to those of the general population. Therefore, no disproportionately high and adverse impacts on minority and low-income populations are expected.

Particulate $Matter_{10}$ = particulate matter with an aerodynamic diameter less than or equal to 10 micrometers; Particulate $Matter_{2.5}$ = particulate matter with an aerodynamic diameter less than or equal to 2.5 micrometers.

S.3.3.1 Energy

DOE/NNSA assessed potential impacts on energy resources by comparing projections of utility resource requirements, such as the demand for electricity, natural gas, and liquid fuels at NLVF, to local and regional capabilities to supply these resources. The baseline or current energy demand is the same as that under the No Action Alternative. For instance, recent peak electrical demand was about 3.2 megawatts, and approximately 48,000 therms of natural gas (equivalent to about 495,000 cubic feet) were used for heating and in boilers (NNSA/NSO 2010b). Under the Expanded Operations Alternative, continuing and newly proposed projects and capabilities would require an increase of up to 10 percent in the use of electricity, natural gas, and liquid fuels such as gasoline and diesel fuel. Energy demand under the Reduced Operations Alternative would be no more than that under the No Action Alternative. DOE/NNSA does not foresee difficulty in obtaining electricity and fuels from regional suppliers under any alternative.

What is a Therm?

A therm equals 100,000 British thermal units. A British thermal unit is the heat required to raise the temperature of one pound of water by one degree Fahrenheit.

On average, 1,000 cubic feet of natural gas equals 10.31 therms.

S.3.3.2 Traffic

Traffic impacts would result primarily from changes in the workforce. DOE/NNSA estimates that the current workforce would not change under the No Action Alternative, would increase by approximately 25 percent (from 1,442 to 1,803) under the Expanded Operations Alternative, and would decrease by about 10 percent (from 1,442 to 1,298) under the Reduced Operations Alternative.

Traffic conditions of roadways near NLVF are represented by Losee Road. Under the No Action and Reduced Operations Alternatives, minimal changes in daily traffic volumes would affect Losee Road as a result of NNSS personnel. DOE/NNSA estimates that implementing the Expanded Operations Alternative would result in an approximately 3 percent increase in traffic volumes during the peak hour; the level of service, however, would remain at a level of service C.

Level of Service C

The number of vehicles stopping is significant, although many still pass through the affected intersection without being required to stop.

S.3.3.3 Socioeconomics

The continued operation and proposed activities at NLVF would result in changes to the current (baseline) workforce only under the Expanded Operations and Reduced Operations Alternatives. Accordingly, DOE/NNSA evaluated how these workforce changes could affect economic activity; population; housing; public finance; and public services, such as police and fire protection, in Clark and Nye Counties.

Under the Expanded Operations Alternative, the workforce would increase by 361 (from about 1,442 to 1,803). DOE/NNSA estimates that approximately 10 percent, or 36 individuals, would relocate to Clark and Nye Counties (the remaining 325 individuals would already live in Clark and Nye Counties). Of the total employment increase, DOE/NNSA estimates that 99 percent of the workers would live in Clark County and 1 percent in Nye County.

Under the Expanded Operations Alternative, in Clark County, a total of 322 direct jobs could be added, which would decrease the unemployment rate by about 0.23 percent. In Nye County, up to 3 jobs would be added, decreasing unemployment by about 0.10 percent.

An increase in direct employment also would result in an increase in the demand for goods (for example, fuel for personal vehicles) and services (for example, vehicle repair), which in turn would create

additional employment opportunities (indirect jobs). The combined effect of direct (361) and indirect (699) jobs would result in a decrease in the unemployment rate in Clark County by about 0.5 percent and in Nye County by about 0.22 percent.

The increased workforce due to relocating workers (36 individuals) is not expected to result in undue demand on housing (vacancies would decrease by about 0.2 percent) and most public services. There could be a need, however, to hire three new teachers in Clark County to maintain the current student-to-teacher ratio.

Under the Reduced Operations Alternative, the workforce would decrease by about 144; the unemployment rate in Clark County would, in turn, increase by about 0.10 percent and the rate in Nye County would increase by about 0.03 percent. There would be no impact on housing or public services in either county.

S.3.3.4 Air Quality

For each alternative, DOE/NNSA estimated the amount of nonradiological and hazardous air pollutants and greenhouse gases that would be released from activities at NLVF (see **Table S–17**).

Table S–17 Emissions of Air Pollutants and Greenhouse Gases at the North Las Vegas Facility (tons per year)

		No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*
	Estimated 2008 Emissions	*Annual Average Operational Emissions in 2015*		
Particulate Matter$_{10}$	0.48	0.36	0.44	0.33
Particulate Matter$_{2.5}$	0.34	0.24	0.28	0.21
Carbon Monoxide	26.6	24.4	30.5	22.0
Nitrogen Oxides	8.8	5.9	7.2	5.4
Sulfur Dioxide	0.090	0.079	0.095	0.072
Volatile Organic Compounds	0.80	0.77	0.96	0.70
Lead	~0.060	Less than 0.01	Less than 0.01	Less than 0.01
Hazardous Air Pollutants	0.076	0.062	0.078	0.056
Carbon Dioxide-equivalent	13,355	8,379	9,031	8,118

Particulate Matter$_{10}$ = particulate matter with an aerodynamic diameter less than or equal to 10 micrometers; Particulate Matter$_{2.5}$ = particulate matter with an aerodynamic diameter less than or equal to 2.5 micrometers.

Under the No Action and Reduced Operations Alternatives, the NLVF contribution to Clark County emissions of nonradiological (criteria) pollutants would continue to be small and would decrease relative to 2008 emission levels. Most of the emission reductions at NLVF would be associated with the phasing in of newer worker vehicles with emission reduction technology. Thus, neither alternative would contribute to or cause additional violations of the criteria pollutant standards.

Implementing the Expanded Operations Alternative would result in increases (relative to the 2008 baseline) in emissions of carbon monoxide, sulfur dioxide, and volatile organic compounds, principally from mobile sources. Because the increases in emissions would be small and would come from mobile sources dispersed throughout the Las Vegas Valley, the additional pollutant burden would not produce additional violations of pollutant standards.

DOE/NNSA estimates that emissions of hazardous air pollutants would continue to remain low under any alternative and would not require additional emission control technologies; and, therefore, such emissions would not pose an undue health risk to workers or the public. Greenhouse gas emissions, although estimated to decrease relative to baseline levels under all alternatives, would continue to contribute to global climate change.

S.3.3.5 Waste Management

At NLVF, DOE/NNSA operations would generate low-level radioactive waste, hazardous waste, sanitary solid waste, and demolition debris. Under all alternatives, about 150 cubic feet of low-level radioactive waste and small amounts of water containing tritium would be generated. The low-level radioactive waste would be shipped to the NNSS for disposal where adequate capacity exists; water containing tritium either would be evaporated by introducing it to evaporative coolers at NLVF or by shipping it to the NNSS for evaporation.

About 1,100 cubic feet of hazardous waste would be generated over 10 years under all alternatives. This waste would be transferred off site to permitted facilities to be recycled or treated, stored, and disposed. Adequate capacity is expected to exist in Nevada and elsewhere in the United States to recycle or treat, store, and dispose hazardous waste generated at NLVF. For instance, four treatment, storage, and disposal facilities were permitted to receive hazardous waste in Nevada as of 2009 (NDEP 2009).

About 390,000, 490,000, and 350,000 cubic feet of sanitary solid waste would be generated under the No Action, Expanded Operations, and Reduced Operations Alternatives over 10 years, respectively. DOE/NNSA anticipates that the local municipal waste service would have sufficient capacity to accommodate disposal of this waste.

Decommissioning and demolition of certain structures at NLVF were estimated to generate up to about 110,000 cubic feet of demolition debris under each alternative. Sufficient capacity is expected to exist at landfills in Clark County to accommodate disposal of these amounts of demolition debris (otherwise, this waste would be disposed at landfills on the NNSS, which have adequate disposal capacity).

S.3.3.6 Human Health

Tritium is the only radionuclide that could result in an exposure to a noninvolved worker or a member of the public. In 1995, an accident resulted in the release of more than 1 curie of tritium in the basement of Building A-1. The tritium release was cleaned up, but residual tritium continues to emanate from the basement floor. The small amount of tritium released was estimated (numerically calculated) to result in a dose of about 0.00035 millirem per year to the maximally exposed individual member of the public located at the facility boundary or to a noninvolved worker. This dose represents an annual risk of a latent cancer fatality of about 1 chance in 5 billion. Applying this dose to the entire population of approximately 2,390,000 persons within 50 miles of NLVF results in an estimated collective dose of 4.1×10^{-5} person-rem per year, with a corresponding estimate of 2×10^{-8} latent cancer fatalities, resulting in an annual risk of 1 in 50 million of a single latent cancer fatality in the exposed population. The amount of tritium released, and thus the dose and latent cancer fatalities, would be the same among all alternatives.

DOE/NNSA estimated the injuries that could arise in the workforce from industrial accidents based upon accident rates from DOE and the U.S. Department of Labor (DOE 2010; DOL 2010a, 2010b). Total recordable cases, and those cases that result in lost workdays, restricted duty, or require a transfer are shown in **Table S–18**.

Table S–18 Annual Estimated Incidence of Nonfatal Accidents at the North Las Vegas Facility

Facility Operations	22	9.5	27	12	20	8.6

Table S–19 Summary of Potential Direct and Indirect Impacts at the North Las Vegas Facility

	No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*	*Preferred Alternative*
Land Use				
	No impacts were identified from the continuation of activities at the current levels of operations or foreseeable actions because activities under this alternative would continue to be compatible with existing land use designations.	Same as under the No Action Alternative.	Same as under the No Action Alternative.	No impacts were identified from the continuation of activities at the current levels of operations or foreseeable actions because activities under this alternative would continue to be compatible with existing land use designations.
Infrastructure and Energy				
	Infrastructure would be maintained as needed to accommodate ongoing activities. No new buildings or facilities are planned. Electric energy demand is expected to continue at about 15,000 megawatt-hours per year and the existing electrical distribution is adequate to support this demand. Natural gas use is expected to continue to be about 48,000 therms per year. There is adequate capacity to serve this demand.	Same as under the No Action Alternative for infrastructure. Electric energy demand would increase by no more than 10 percent to a total of 16,500 megawatt-hours per year. The capacity of the electrical distribution system and the capability of commercial providers are adequate to supply the needed electrical energy.	Same as under the No Action Alternative for infrastructure. Electrical energy demand is expected to be the same as under the No Action Alternative or slightly lower.	Infrastructure would be maintained as needed to accommodate ongoing activities. No new buildings or facilities are planned. Electric energy demand would increase by no more than 10 percent to a total of 16,500 megawatt-hours per year. The existing electrical distribution is adequate to support this demand. Natural gas use is expected to continue to be about 48,000 therms per year. There is adequate capacity to serve this demand.
Transportation and Traffic				
Transportation	No radioactive materials were analyzed. Nonradioactive material transports are included in the NNSS impacts.	Same as under the No Action Alternative.	Same as under the No Action Alternative.	No radioactive materials were analyzed. Nonradioactive material transports are included in NNSS impacts.
Traffic	No increase in traffic volume due to NLVF-related traffic compared to the projected baseline; levels of service would remain the same.	Approximately a 3 percent increase in daily traffic volumes during peak hours on local roads, when compared to the projected baseline; levels of service would remain the same.	Less than a 1 percent decrease in daily traffic volumes during peak hours on local roads; levels of service would remain the same.	Approximately a 2 percent increase in daily traffic volumes would occur during peak hours on local roads, when compared to the projected baseline; levels of service would remain the same.

	No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*	*Preferred Alternative*
Socioeconomics				
	There would be no change in employment; therefore, there would be no change in socioeconomic impacts.	Employment would increase by 361 full-time equivalents; about 36 employees would relocate from outside the region. Up to 3 new teaching jobs would need to be filled to maintain the current student-to-teacher ratio. Sufficient housing exists in the region to support the increased population. Direct jobs would reduce unemployment by 0.27 and 0.12 percent in Clark and Nye Counties, respectively. Direct jobs and indirect jobs would have a beneficial effect on the local economy and government revenues. The addition of 361 employees would result in an increase in the number of service calls, but would have a negligible impact on area hospitals and hospital personnel.	Employment would decrease by 45 full-time equivalents, increasing unemployment in Clark County by about 0.12 percent and in Nye County by about 0.04 percent. Additional employees would not relocate to Clark or Nye County and there would be no impact on student-to-teacher ratios. Job loss would have a small negative impact on the local economy and government revenues. There would be no impact on public services.	Employment would increase by 361 full-time equivalents; about 36 employees would relocate from outside the region. Up to 3 new teaching jobs would need to be filled to maintain the current student-to-teacher ratio. Sufficient housing exists in the region to support the increased population. Direct jobs would reduce unemployment by 0.27 and 0.12 percent in Clark and Nye Counties, respectively. Direct jobs and indirect jobs would have a beneficial effect on the local economy and government revenues. The addition of 361 employees would result in an increase in the number of service calls, but would have a negligible impact on area hospitals and hospital personnel.
Geology and Soils				
	Proposed activities would not affect geological and soil resources.	Same as under the No Action Alternative.	Same as under the No Action Alternative.	Proposed activities would not affect geological and soil resources.
Hydrology				
Surface Water Resources	Proposed activities would not affect surface hydrology.	Same as under the No Action Alternative.	Same as under the No Action Alternative.	Proposed activities would not affect surface hydrology.
Groundwater Resources	Proposed activities would not adversely affect groundwater quality or supply.	Same as under the No Action Alternative.	Same as under the No Action Alternative.	Proposed activities would not adversely affect groundwater quality or supply.
Biological Resources				
	All activities would occur in previously disturbed, developed areas and would not affect native biological resources.	Same as under the No Action Alternative.	Same as under the No Action Alternative.	All activities would occur in previously disturbed, developed areas and would not affect native biological resources.

	No Action Alternative	***Expanded Operations Alternative***	***Reduced Operations Alternative***	***Preferred Alternative***
Air Quality				
Annual Average Operational Emission in 2015 (tons per year)				
Particulate Matter$_{10}$	0.36	0.44	0.33	0.44
Particulate Matter$_{2.5}$	0.24	0.28	0.21	0.28

NLVF = North Las Vegas Facility; Particulate $Matter_{10}$ = particulate matter with an aerodynamic diameter less than or equal to 10 micrometers; Particulate $Matter_{2.5}$ = particulate matter with an aerodynamic diameter less than or equal to 2.5 micrometers; rem = roentgen equivalent man.

[a] Does not include tritiated liquids shipped from NLVF to the NNSS for treatment.

S.3.4 Tonopah Test Range

This section summarizes the potential environmental impacts at the TTR from continuing and proposed projects and capabilities, including their associated levels of operations (activities), under each of three alternatives. The text focuses on those resource areas for which the impacts would be sufficiently different to permit distinguishing among the alternatives in a meaningful manner or would tend to be controversial, i.e., transportation, socioeconomics, air quality, waste management, and human health.

Table S–22 (at the end of Section S.3.4.5) summarizes the potential environmental impacts for all 13 resource areas. As discussed above in Section S.2.5, DOE/NNSA's Preferred Alternative is a "hybrid" alternative comprising various programs, capabilities, projects, and activities selected from among the three alternatives. Although the text of this Summary does not discuss the potential environmental impacts from implementing the Preferred Alternative, consistent with the approach used in Chapter 3 of the *NNSS SWEIS*, Table S–22 summarizes those impacts to enable a comparison to the three alternatives.

S.3.4.1 Transportation

Radiological impacts on workers and the public would result from the shipment of low-level radioactive waste from the Nevada Test and Training Range, including the TTR, to the NNSS. This waste would be generated from environmental restoration activities. DOE/NNSA estimates there would be approximately 230 truck shipments to the NNSS under the No Action and Reduced Operations Alternatives, and about 13,100 truck shipments under the Expanded Operations Alternative.

For incident-free truck transportation, DOE/NNSA estimated that less than 1 latent cancer fatality would occur in the population of transportation workers exposed to radiation from shipments of low-level radioactive waste under the No Action Alternative (9×10^{-6}), Expanded Operations Alternative (0.0005), and Reduced Operations Alternative (9×10^{-6}). Because many workers would be involved, the risk to an individual worker would be small. Similarly, DOE/NNSA estimated that less than 1 (1×10^{-6}, 0.0002, and 1×10^{-6}, respectively) latent cancer fatality would occur among members of the public exposed to these same truck shipments under the three alternatives.

S.3.4.2 Socioeconomics

Continued operations and proposed activities at the TTR would result in changes to the current (baseline) workforce only under the Expanded Operations and Reduced Operations Alternatives. Accordingly, DOE/NNSA evaluated how this change in workforce would affect economic activity, population, housing, public finance, and public services, such as police and fire protection, in Clark and Nye Counties.

Under the Expanded Operations Alternative, the workforce would decrease from about 106 to 43 (a decrease of 63 employees); the unemployment rate in Clark County would, in turn, increase by about 0.01 percent and the rate in Nye County would increase by about 1.34 percent. There would be no impact on housing or public services in either county.

Implementing the Reduced Operations Alternative would have essentially the same impacts as those under the Expanded Operations Alternative, as the workforce would decrease by 67 employees.

S.3.4.3 Air Quality

For each alternative, DOE/NNSA estimated the amount of nonradiological and hazardous air pollutants and greenhouse gases that would be released from ongoing and proposed activities at the TTR (see **Table S–20**). In general, emission-generating activities under any alternative would be widely dispersed over the 280-square-mile area of the TTR, and mobile sources of emissions would occur mostly outside of the TTR.

Table S–20 Emissions of Air Pollutants and Greenhouse Gases at the Tonopah Test Range (tons per year)

		No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*
	Estimated 2008 Emissions	*Annual Average Operational Emissions in 2015*		
Particulate Matter$_{10}$	Less than 4.5	Less than 4.0	Less than 3.8	Less than 3.8
Particulate Matter$_{2.5}$	Less than 4.4	Less than 4.0	Less than 3.8	Less than 3.8
Carbon Monoxide	Less than 14.3	Less than 10.8	Less than 6.1	Less than 5.8
Nitrogen Oxides	Less than 21.4	Less than 17.1	Less than 14.8	Less than 14.7
Sulfur Dioxide	Less than 0.94	Less than 0.93	Less than 0.92	Less than 0.92
Volatile Organic Compounds	Less than 2.0	Less than 1.4	Less than 1.1	Less than 1.1
Lead	Less than 0.05	Less than 0.010	Less than 0.01	Less than 0.01
Hazardous Air Pollutants	Less than 1.2	Less than 1.1	Less than 1.1	Less than 1.1
Carbon Dioxide-Equivalent	4,166	3,653	1,791	1,671

Particulate Matter$_{10}$ = particulate matter with an aerodynamic diameter less than or equal to 10 micrometers; Particulate Matter$_{2.5}$ = particulate matter with an aerodynamic diameter less than or equal to 2.5 micrometers.

Under all alternatives, emissions of criteria pollutants (hazardous air pollutants) would decrease relative to baseline (2008) levels, and, therefore, would not contribute to or cause additional violations of the criteria pollutant standards. Nye County would continue to be in attainment for all criteria pollutants, while in Clark County, these emissions would not cause or contribute to any new violations of the standards or increases in the frequency or severity of any existing violation of any standard.

DOE/NNSA estimates that emissions of hazardous air pollutants would continue to remain low under any alternative and would not require additional emission control technologies; therefore, such emissions would not pose an undue health risk to workers or the public. Greenhouse gas emissions, although also estimated to decrease relative to baseline levels under all alternatives, would continue to contribute to global climate change.

S.3.4.4 Waste Management

At the TTR, DOE/NNSA actions would generate low-level radioactive waste, hazardous waste, solid waste, and construction debris. Environmental restoration activities at the Nevada Test and Training Range, including the TTR, also would generate low-level radioactive waste and possibly some transuranic waste.

Under the No Action and Reduced Operations Alternatives, about 2.9 million cubic feet of low-level radioactive waste would be generated over 10 years; this waste would be shipped by truck to the NNSS for disposal at the Area 5 Radioactive Waste Management Complex. Under the Expanded Operations Alternative, environmental restoration would generate about 11 million cubic feet of low-level radioactive waste. Although this waste would be shipped to the NNSS for disposal at the Area 5 Radioactive Waste Management Complex, because of the volume of low-level radioactive waste from the TTR and from other in-state and out-of-state sources (see Section S.3.1.10), DOE/NNSA also would need to reactivate the Area 3 Radioactive Waste Management Site to accommodate the disposal of this waste.

About 8 tons of hazardous waste would be generated annually under all alternatives. This waste would be shipped from the TTR to permitted facilities to be recycled or treated, stored, and disposed. Adequate capacity is expected to exist in Nevada and elsewhere in the United States to recycle or treat, store, and dispose hazardous waste generated at the TTR. For instance, four treatment, storage, and disposal facilities were permitted to receive hazardous waste in Nevada as of 2009 (NDEP 2009).

TTR site operations also would generate solid waste, including sanitary waste and construction debris. Under the No Action, Expanded Operations, and Reduced Operations Alternatives, about 9,400; 7,700; and 6,600 cubic feet, respectively, of solid waste would be generated annually. The volume of solid

waste would be lower under the Expanded Operations Alternative because the projection for sanitary solid waste was based on the estimated number of employees and there would be a decrease of about 63 employees at the TTR. Sufficient capacity exists for DOE/NNSA to dispose this waste in solid waste landfills on the TTR, the solid waste landfills on the NNSS, or in local municipal landfills.

S.3.4.5 Human Health

Normal Operations. Environmental restoration activities on the TTR would result in the resuspension of legacy radioactive materials that are transported in the air. DOE/NNSA numerically estimated, for the alternatives, that the annual dose to a maximally exposed individual and the population within 50 miles of the TTR would be 0.024 millirem and much less than 1 person-rem, respectively. The maximally exposed individual would incur an increased risk of contracting a latent cancer fatality of 1×10^{-8} (1 chance in 100 million). The estimated number of latent cancer fatalities associated with the annual population dose of 1 person-rem is 0.0006, which results in an annual risk of a single latent cancer fatality in the population of much less than 1 in 1,700.

Workers also would be exposed to legacy radioactive materials. Under the No Action Alternative, the estimated collective worker dose would be 1.3 person-rem per year (workforce of 106 workers), resulting in an estimated annual latent cancer fatality risk of 0.0008. The workforces under the Expanded Operations and Reduced Operations Alternatives would decrease to 43 and 39 workers, respectively; and, therefore, the collective dose and risk of contracting a latent cancer fatality would be less than estimated for the No Action Alternative.

Accidents. The maximum reasonably foreseeable accident (a beyond-design-basis event), which is the same for all alternatives, would involve an aircraft crash and ensuing fire involving multiple low-level radioactive waste containers. The estimated probability of this event occurring was estimated to be 1.7×10^{-6} per year of operation (1 chance in 590,000).

If the accident were to occur, the maximally exposed individual would receive a dose of 0.34 millirem, corresponding to a latent cancer fatality risk of 2×10^{-7} (1 chance in 5,000,000). The offsite population within 50 miles would receive a collective dose estimated to be 0.012 person-rem; the calculated number of latent cancer fatalities associated with this dose is 7×10^{-6}, implying that the most likely outcome would be no additional latent cancer fatalities in the exposed population. A noninvolved worker outside the immediate area of the crash would receive an estimated dose of 1.5 rem, with an associated risk of contracting a fatal cancer of 9×10^{-4} (1 chance in 1,100). When the frequency of this accident was considered, the annual risk of a latent cancer fatality was estimated to be 3×10^{-13} for the maximally exposed individual, 1×10^{-11} for the population, and 2×10^{-9} for the noninvolved worker.

DOE/NNSA estimated the injuries that could arise in the workforce from industrial accidents based upon accident rates from DOE and the U.S. Department of Labor (DOE 2010; DOL 2010a, 2010b). Total recordable cases and those cases that could result in lost workdays, restricted duty, or a transfer are shown in **Table S–21**.

Table S–22 Summary of Potential Direct and Indirect Impacts at the Tonopah Test Range

	No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*	*Preferred Alternative*
Land Use				
	There would be no impact on land use from the continuation of activities at the current levels of operations because activities would continue to be compatible with existing land use designations on the TTR and primary land uses on the Nevada Test and Training Range.	Same as under the No Action Alternative.	Same as under the No Action Alternative.	There would be no impact on land use from the continuation of activities at the current levels of operations because activities would continue to be compatible with existing land use designations on the TTR and primary land uses on the Nevada Test and Training Range.
	Airspace No new impacts were identified for airspace activities because these activities would be maintained at the current levels of air traffic, navigational aid services, and airspace structure, and would continue to be coordinated and scheduled by the Nellis Air Traffic Control Facility.	*Airspace* Same as under the No Action Alternative.	*Airspace* Impacts would be slightly reduced compared to the No Action Alternative because of the discontinuation of fixed rocket and missile launches, cruise missile operations, and detonation of fuel-air explosives at the TTR, which would increase the restricted airspace availability for other military uses as coordinated and scheduled by the Nellis Air Traffic Control Facility.	*Airspace* No new impacts were identified for airspace activities because these activities would be maintained at the current level of air traffic, navigational aid services, and airspace structure and would be coordinated and scheduled by the Nellis Air Traffic Control Facility.
Infrastructure and Energy				
	Infrastructure would be maintained as needed to accommodate ongoing activities. No new buildings or facilities are planned.	Same as under the No Action Alternative.	Same as under the No Action Alternative.	Infrastructure would be maintained as needed to accommodate ongoing activities. No new buildings or facilities are planned.

	No Action Alternative	Expanded Operations Alternative	Reduced Operations Alternative	Preferred Alternative
Transportation [a] and Traffic				
Low-Level and Mixed Low-Level Radioactive Waste				
Incident-free truck transport				
Worker risk (latent cancer fatality)	0 (9×10^{-6})	0 (0.0005)	0 (9×10^{-6})	0 (0.0005)
Population risk (latent cancer fatality)	0 (1×10^{-6})	0 (0.0002)	0 (1×10^{-6})	0 (0.0002)
Transport accidents				
Radiological risk (latent cancer fatality)	0 (1×10^{-12})	0 (6×10^{-11})	0 (1×10^{-12})	0 (6×10^{-11})
Nonradiological fatalities	0 (0.002)	0 (0.1)	0 (0.002)	0 (0.1)
Nonradiological waste transport fatalities	Nonradioactive material transports included in Nevada National Security Site impacts.	Same as under the No Action Alternative.	Same as under the No Action Alternative.	Nonradioactive material transports included in Nevada National Security Site impacts.
Traffic	Up to 4 additional truck trips per day from Environmental Restoration Program radioactive waste transport; minimal impacts on onsite and regional traffic conditions.	Up to 14 additional truck trips per day from Environmental Restoration Program radioactive waste transport; minimal impacts on onsite and regional traffic conditions.	Same as under the No Action Alternative.	Up to 10 additional truck trips per day from Environmental Restoration Program radioactive waste transport; minimal impacts on onsite and regional traffic conditions.
Socioeconomics				
	There would be no change in employment; therefore, there would be no change in socioeconomic impacts.	Employment would decrease by 63 full-time equivalents, which would increase the unemployment rate by about 0.01 percent in Clark County and about 1.64 percent in Nye County. Local spending would decrease and revenues for Clark and Nye Counties could decrease. This small decrease would have a negligible adverse impact on local economies. There would be no impact on public services.	Employment would decrease by 67 full-time equivalents, which would increase the unemployment rate by about 0.01 percent in Clark County and about 1.76 percent in Nye County. Local spending would decrease and revenues for Clark and Nye Counties could decrease. This small decrease would have a negligible adverse impact on local economies. There would be no impact on public services.	Employment would decrease by 63 full-time equivalents, which would increase the unemployment rate by about 0.01 percent in Clark County and about 1.64 percent in Nye County. Local spending would decrease and revenues for Clark and Nye Counties could decrease. This small decrease would have a negligible adverse impact on local economies. There would be no impact on public services.

Impacts on low-income and minority populations would be identical to those of the general population. Therefore, no disproportionately high and adverse impacts on minority and low-income populations are expected.

Particulate $Matter_{10}$ = particulate matter with an aerodynamic diameter less than or equal to 10 micrometers; Particulate $Matter_{2.5}$ = particulate matter with an aerodynamic diameter less than or equal to 2.5 micrometers; rem = roentgen equivalent man; TTR = Tonopah Test Range.

[a] The reported radiological risks are the projected number of latent cancer fatalities in the population and are, therefore, presented as whole numbers. The calculated value is shown in parentheses.

[b] The emissions under the Expanded Operations Alternative would be less than the levels projected under the No Action Alternative, as the Record of Decision for the *Complex Transformation Supplemental Programmatic Environmental Impact Statement* would occur under the Expanded Operations Alternative because certain site support functions would be transferred from DOE/NNSA to the U.S. Air Force, resulting in fewer DOE/NNSA and DOE/NNSA-contractor employees at the TTR.

[c] The risk is the annual increased likelihood of a latent cancer fatality in the maximally exposed individual or the noninvolved worker or the increased likelihood of a single latent cancer fatality occurring in the offsite population, accounting for the estimated probability (frequency) of the accident occurring.

S.4 Conclusions

S.4.1 Major Conclusions

DOE/NNSA evaluated the potential direct, indirect, and cumulative impacts on 13 environmental resource areas that include features of the natural environment and matters of social, cultural, and economic concern. Each resource area is evaluated under each of three alternatives and the Preferred Alternative, and the potential environmental consequences are summarized in Section S.3.

In general, the potential environmental impacts would be greatest under the Expanded Operations Alternative, and lowest under the Reduced Operations Alternative. For most resource areas, the potential environmental impacts of the Preferred Alternative would be the same as those under the Expanded Operations Alternative. However, for a few resource areas at the NNSS, such as biological and cultural resources and air quality, the potential impacts under the Preferred Alternative would be less than those under the Expanded Operations Alternative, but greater than those under the No Action Alternative.

The continuation and enhancement of current levels of operations, specifically the rate of radioactive waste disposal, quantities of radioactive material used in tests and experiments, and transportation of radioactive wastes and materials at the NNSS, as well as the pace of environmental restoration at the Nevada Test and Training Range, including the TTR, are the primary factors that would contribute to the radiological dose and estimated health impacts on the public and workers. The vast majority of the public dose would be due to transportation of radioactive materials and waste. If all of the transportation activities evaluated under this alternative were to occur, the public would receive a collective dose of 1,400 person-rem, resulting in an estimated 1 (0.8) latent cancer fatality in that population.

Under each alternative, construction and operation of one or more solar power generation facilities at the NNSS would result in the following: an increase in employment relative to the current workforce, loss of desert tortoise habitat and the taking of tortoises, direct impacts on cultural resources, and increases in demand for groundwater. At present, DOE/NNSA has neither sought nor received proposals for specific solar facilities. Prior to authorizing the development of such facilities, DOE/NNSA would conduct a project-specific NEPA review, and undertake actions necessary to demonstrate compliance with applicable regulations.

At RSL, DOE/NNSA would maintain the current levels of operations, as no new projects or enhanced capabilities are proposed. Among the 13 resource areas, either there would be no impacts or the impacts associated with ongoing operations would remain small and continue unchanged from baseline conditions. Although the levels of operations could increase and proposed projects could be implemented at NLVF and the TTR, DOE/NNSA concluded that environmental impacts on all resource areas would remain small.

S.4.2 Areas of Controversy

American Indian tribes and organizations believe that activities at the NNSS and offsite locations, regardless of the magnitude of potential environmental impacts under any of the alternatives, would result in an adverse and unacceptable disturbance of the natural and cultural environment. In recognition of Federal laws and policies, DOE/NNSA maintains an ongoing consultation program with the Consolidated Group of Tribes and Organizations to address American Indian concerns about the environment, and, in particular, archaeological sites, plant and animal resources, traditional cultural properties, and sacred sites of cultural value.

The public in general, and Nye County residents in particular, remain concerned about the quality of groundwater from the NNSS, which flows into southern Nye County along multiple flow paths.

Groundwater contaminated by past underground nuclear weapons testing has the potential to affect the quality of water available to communities, residents, and commercial enterprises in the future. In 2009, tritium was detected in a well located on the Nevada Test and Training Range adjacent to the Western Pahute Mesa region of the NNSS. This well is about 14 miles from the nearest public water source, a private well. In 2010, tritium also was detected in a second well on the Nevada Test and Training Range. The tritium concentrations were well below the Safe Drinking Water Act standards established by the EPA. Based on early computer model predictions, DOE/NNSA does not expect contamination to reach the private well for at least 100 years; and furthermore, contamination may never reach the well.

Summary of the Consolidated Group of Tribes and Organizations' Areas of Interest

- Increased access to the Nevada National Security Site (NNSS) and Off-Site Locations to conduct traditional ceremonies and activities to promote balance and sustainability to the land.
- Expanded ethnographic studies focusing on traditional and religious use areas culminating in a Traditional Cultural Property nomination on the NNSS.
- Identify and establish co-management strategies with the National Nuclear Security Administration Nevada Site Office (NNSA/NSO) for protection of American Indian cultural resources on the NNSS and Off-Site Locations.
- Expanded studies of impacts derived from the transportation of radioactive waste and materials through ancestral lands and to the overall Indian culture.

Water use and water rights will continue to be a major concern, regardless of the water demands associated with the NNSS. Growth in water demand in Nevada, particularly in Nye County, has been rapid, and water use and Federal water rights at the NNSS remain a controversial issue when considered against the backdrop of regional water transfer plans.

The State of Nevada continues to believe that disparities exist between the original NNSS land withdrawals and DOE/NNSA activities.

The public remains concerned about possible health effects that could occur from the resuspension of radioactively contaminated soils on the NNSS. DOE/NNSA continues to monitor the releases of radionuclides to the environment from all sources, such as soils and air, and used these data to estimate the dose to a maximally exposed individual. Since 2004, this dose is estimated to have ranged from 2.0 to 2.9 millirem per year, a small fraction of the average annual dose of about 310 millirem that a member of the public receives from natural background sources of radiation.

Maximally Exposed Individual

A hypothetical individual whose location and habits result in the highest total radiological exposure, (and thus dose), from a particular source for all relevant exposure routes (e.g., inhalation, ingestion, direct exposure).

The State of Nevada and others continue to promote the current DOE/NNSA commitment of avoiding shipments of low-level and mixed low-level radioactive waste through Las Vegas, Nevada. This commitment, as expressed in the waste acceptance criteria for the NNSS, avoided Hoover Dam and Las Vegas. DOE/NNSA committed to avoid these areas at a time when major highways, specifically Interstate 15 and U.S. Route 95, were

Routing of Low-Level Radioactive Waste Shipments

While the U.S. Department of Energy/National Nuclear Security Administration's (DOE/NNSA's) environmental analyses showed no meaningful differences in potential environmental effects between the constrained and unconstrained cases, the preponderance of stakeholder comments recommended that DOE/NNSA retain highway routing restrictions to avoid shipments of low-level radioactive waste through greater metropolitan Las Vegas (constrained case). In consideration of the environmental analyses and stakeholder comments, and after consultation with the Nevada Department of Environmental Protection as part of the waste acceptance criteria revision process, DOE/NNSA determined that it would retain the highway routing restrictions for shipments of low-level radioactive waste and therefore there would be no need to revise the waste acceptance criteria in this regard (DOE 2012).

unable to accommodate the growing traffic volume. Since then, these highways have been widened and otherwise improved, the Bruce Woodward Beltway (Interstate 215 and Clark County Route 215) around Las Vegas has been expanded, and the bypass bridge has been constructed near Hoover Dam. DOE/NNSA, in this *NNSS SWEIS*, has analyzed two transportation cases; a Constrained Case and an Unconstrained Case. The Constrained Case retains current routing of shipments of low-level and mixed low-level radioactive waste and avoids crossing the Colorado River near Hoover Dam, as well as the interstate system in Las Vegas. The Unconstrained Case analyzes shipments on highways through the greater metropolitan area. This analysis was undertaken to develop a greater understanding of the potential environmental consequences of shipping such waste through and around metropolitan Las Vegas, as well as to inform any potential highway routing-related revisions to DOE/NNSA's waste acceptance criteria. Such revisions are developed in accordance with DOE/NNSA's standard practices, which include consultation with the State of Nevada; when finalized, they will be made publicly available through publication on the NNSS website. DOE/NNSA determined that it would retain the highway routing restrictions for shipments of low-level radioactive waste; therefore, there would be no need to revise the waste acceptance criteria in this regard (DOE 2012). As discussed above in Section S.3.1.2, the Summary no longer includes the results of the Unconstrained Case analysis; they may be found in Volume 1, Chapter 5, Section 5.1.3.1.2.

S.4.3 Issues to be Resolved

Implementing any of the alternatives may trigger other regulatory actions that DOE/NNSA would need to undertake prior to proceeding, such as reinitiating consultation under Section 7 of the Endangered Species Act with USFWS regarding the desert tortoise, consultations with the Nevada State Historic Preservation Officer under Section 106 of the National Historic Preservation Act, or consultations with the State of Nevada regarding reactivation of the Area 3 Radioactive Waste Management Site. DOE/NNSA has in the past undertaken such consultations, and continues to do so. As an example, DOE/NNSA, in consultation with USFWS, submitted a biological assessment of projects and activities anticipated to occur on the NNSS, and in 2009, USFWS issued its *2009 Biological Opinion* (USFWS 2009). This SWEIS addresses a range of reasonably foreseeable projects and activities that would be developed or undertaken over the next 10 years, although several such projects and activities are in the early phases of development. For these proposals, conservative assumptions regarding the location and scale of these projects and activities were made to provide a basis for programmatic analysis. Accordingly, when the planning processes for future projects and activities are refined and more-detailed information becomes available, and subsequent to any decisions in a Record of Decision, DOE/NNSA would identify regulatory requirements applicable to newly proposed projects and to changes in ongoing operations (activities), and then initiate actions leading to compliance with those requirements.

Groundwater contaminated from past weapons testing continues to migrate, and tritium has been found in a well outside the NNSS, but within the secure boundaries of the Nevada Test and Training Range. Developing an improved understanding of where radiological contamination exists in the groundwater, predicting where the contamination is moving, and defining how far it will migrate will require DOE/NNSA to continue the development of a regional three-dimensional groundwater computer model. This model also formed the basis for individualized models for each major area where underground testing was conducted. Individualized models continue to evolve as additional data are collected, and further analysis and model calibration are conducted.

DOE/NNSA could not proceed with the development of utility-scale solar power generation facilities in Area 25 of the NNSS in the absence of a commercial developer. If a developer were to propose such a facility, additional NEPA review would be required to identify and analyze potential project-specific environmental impacts. In addition, DOE/NNSA would need to identify and resolve any conflicts between the proposed facility and ongoing operations at the NNSS before the facility could be constructed.

Abstract: This *Final Site-Wide Environmental Impact Statement for the Continued Operation of the Department of Energy/National Nuclear Security Administration Nevada National Security Site and Off-Site Locations in the State of Nevada (NNSS SWEIS)* analyzes the potential environmental impacts of proposed alternatives for continued management and operation of the Nevada National Security Site (NNSS) (formerly known as the Nevada Test Site) and other U.S. Department of Energy/National Nuclear Security Administration (DOE/NNSA)-managed sites in Nevada, including the Remote Sensing Laboratory (RSL) on Nellis Air Force Base in North Las Vegas, the North Las Vegas Facility (NLVF), the Tonopah Test Range (TTR), and environmental restoration areas on the U.S. Air Force Nevada Test and Training Range. The purpose and need for agency action is to provide support for meeting NNSA's core missions established by Congress and the President and to satisfy the requirements of Executive Orders and comply with Congressional mandates to promote, expedite, and advance the production of environmentally sound energy resources, including renewable energy resources such as solar and geothermal energy systems.

The NNSS has a long history of supporting national security objectives by conducting underground nuclear tests and other nuclear and nonnuclear activities. Since the October 1992 moratorium on nuclear testing, NNSA's mission at the NNSS has evolved from one that focuses on active nuclear weapons tests to one that maintains readiness and the capability to conduct underground nuclear weapons tests; such a test would be conducted only if so directed by the President in the interest of national security. Resources have been reallocated to introduce and expand other mission activities/programs at the NNSS, RSL, NLVF, and TTR to support three DOE/NNSA core missions: National Security/Defense, Environmental Management, and Nondefense. The National Security/Defense Mission includes the Stockpile Stewardship and Management,

Nuclear Emergency Response, Nonproliferation and Counterterrorism, and Work for Others Programs. The Work for Others Program supports other DOE programs and Federal agencies such as the U.S. Department of Defense, U.S. Department of Justice, and U.S. Department of Homeland Security. The Environmental Management Mission includes the Waste Management and Environmental Restoration Programs. The Nondefense Mission includes the General Site Support and Infrastructure, Conservation and Renewable Energy, and Other Research and Development Programs.

The NNSS, RSL, NLVF, and TTR support DOE/NNSA's core missions by providing the capabilities to process and dispose of a damaged nuclear weapon or improvised nuclear device and to conduct high-hazard experiments involving special nuclear material and high explosives, nonnuclear experiments, and hydrodynamic testing. Nuclear stockpile stewardship activities at the NNSS include dynamic plutonium experiments that provide technical information to maintain the safety and reliability of the U.S. nuclear weapons stockpile and research and training in areas such as nuclear safeguards, criticality safety, and emergency response. Special nuclear materials are also stored at the NNSS. In addition, in accordance with the amended Record of Decision (ROD) (DOE/EIS-0243) for the *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada (1996 NTS EIS*), DOE/NNSA receives low-level and mixed low-level radioactive waste for disposal at the NNSS.

This *NNSS SWEIS* analyzes the potential environmental impacts of three reasonable alternatives for continued operations at the NNSS, RSL, NLVF, and TTR. These alternatives include a No Action Alternative and two action alternatives: Expanded Operations and Reduced Operations. The No Action Alternative, which is analyzed as a baseline for evaluating the two action alternatives, would continue implementation of the *1996 NTS EIS* ROD (DOE/EIS-0243) and subsequent amendments (61 FR 65551and 65 FR 10061), as well as other decisions supported by separate NEPA analyses completed since issuance of the final *1996 NTS EIS*. The No Action Alternative reflects activity levels consistent with those seen since 1996. The Expanded Operations Alternative considers adding new work at the NNSS in the areas of nonproliferation and counterterrorism, high-hazard and other experiments, research and development, and testing. Such expanded operations could include developing test beds for concept testing of sensors, mitigation strategies, and weapons effectiveness. The Reduced Operations Alternative would reduce the overall level of operations and close specific buildings and structures. NNSA would also consider allowing the development of solar power generation facilities under each alternative.

Public Comments: In preparing this *Final NNSS SWEIS*, NNSA considered comments received during the scoping period (July 24, 2009, to October 16, 2009) and during the public comment period on the *Draft NNSS SWEIS* (July 29, 2011, to December 2, 2011), as well as those received after the close of the public comment period on the *Draft NNSS SWEIS*. Five public hearings on the *Draft NNSS SWEIS* were held to provide interested members of the public with opportunities to learn more about NNSA missions, programs, and activities and the content of the *Draft NNSS SWEIS* from exhibits, factsheets, and discussion with NNSA subject matter experts. From September 20 through 28, 2011, public hearings were held in Las Vegas, Pahrump, Tonopah, and Carson City, Nevada, and St. George, Utah. An additional hearing was conducted for the Consolidated Group of Tribes and Organizations on October 6, 2011. All comments received were considered during preparation of this *Final NNSS SWEIS*.

This *Final NNSS SWEIS* contains revisions and new information based in part on comments received on the *Draft NNSS SWEIS*. Vertical change bars in the margins indicate the locations of these revisions and new information. Volume 3 contains the comments received on the *Draft NNSS SWEIS* and DOE/NNSA's responses to those comments. DOE/NNSA will use the analysis presented in this *Final NNSS SWEIS*, as well as other information, in preparing a ROD regarding the continued operation of the NNSS and offsite locations in Nevada. DOE/NNSA will issue a ROD no sooner than 30 days after the U.S. Environmental Protection Agency publishes a Notice of Availability of this *Final NNSS SWEIS* in the *Federal Register*.

CHAPTER 1
INTRODUCTION AND PURPOSE AND NEED FOR AGENCY ACTION

1.0 INTRODUCTION AND PURPOSE AND NEED FOR AGENCY ACTION

1.1 Introduction

This *Site-Wide Environmental Impact Statement for the Continued Operation of the Department of Energy/National Nuclear Security Administration Nevada National Security Site and Off-Site Locations in the State of Nevada (NNSS SWEIS)* analyzes potential environmental impacts of continued management and operation of the Nevada National Security Site (NNSS) (formerly known as the Nevada Test Site) and other sites managed by the U.S. Department of Energy/National Nuclear Security Administration (DOE/NNSA) in Nevada. The primary purpose of continuing operation of the NNSS is to provide support for DOE/NNSA's nuclear weapons stockpile stewardship missions. DOE/NNSA also supports other DOE programs and Federal agencies such as the U.S. Department of Defense (DoD), U.S. Department of Justice, and U.S. Department of Homeland Security. This site-wide environmental impact statement (SWEIS) analyzes the potential environmental impacts of reasonable alternatives for current and reasonably foreseeable missions, programs, capabilities, and projects at the NNSS and offsite locations in Nevada during a 10-year period.

Established by Congress through the National Nuclear Security Administration Act (Title XXXII of the National Defense Authorization Act for Fiscal Year 2000, Public Law [P.L.] 106-65), DOE/NNSA is a separately organized, semiautonomous agency within DOE. The DOE/NNSA Nevada Site Office (NSO) operates programs at the NNSS and at offsite locations in Nevada, including the North Las Vegas Facility (NLVF), the Remote Sensing Laboratory (RSL) on Nellis Air Force Base in North Las Vegas, the Tonopah Test Range (TTR), and environmental remediation areas on the U.S. Air Force Nevada Test and Training Range (formerly the Nellis Air Force Range). These facilities and sites are shown in **Figure 1–1**. The NNSS and the TTR are located in Nye County; NLVF and RSL are located in Clark County; and the Nevada Test and Training Range is located in Nye, Lincoln, and Clark Counties in southern Nevada.

DOE's "National Environmental Policy Act Implementing Procedures" (10 *Code of Federal Regulations* [CFR] Part 1021) require preparation of a SWEIS, a broad-scope document that identifies and assesses the individual and cumulative impacts of ongoing and reasonably foreseeable future actions for certain large multiple-facility DOE sites such as the NNSS (10 CFR 1021.330c). In accordance with 10 CFR Part 1021, an evaluation of a SWEIS is required every 5 years. DOE/NNSA determines whether an existing SWEIS remains adequate or a new SWEIS or supplement to the existing SWEIS is needed. DOE/NNSA prepared this SWEIS to comply with National Environmental Policy Act (NEPA) and Council on Environmental Quality (CEQ) regulations (40 CFR Parts 1500–1508) and DOE NEPA Implementing Procedures (10 CFR Part 1021).

In 1996, DOE issued the *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada (1996 NTS EIS)* (DOE 1996c) and an associated Record of Decision (ROD) (61 *Federal Register* [FR] 65551). DOE selected the *1996 NTS EIS* Expanded Use Alternative for most activities, but decided to manage low-level radioactive waste (LLW) and mixed low-level radioactive waste (MLLW) at levels described under the No Action Alternative, pending decisions on the *Final Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste (WM PEIS)* (DOE 1997). In the February 2000 *WM PEIS* ROD (65 FR 10061), DOE announced that the NNSS would be one of two regional sites to be used for LLW and MLLW disposal. At the same time, DOE amended the *1996 NTS EIS* ROD to select the Expanded Use Alternative for waste management activities at the NNSS (65 FR 10061).

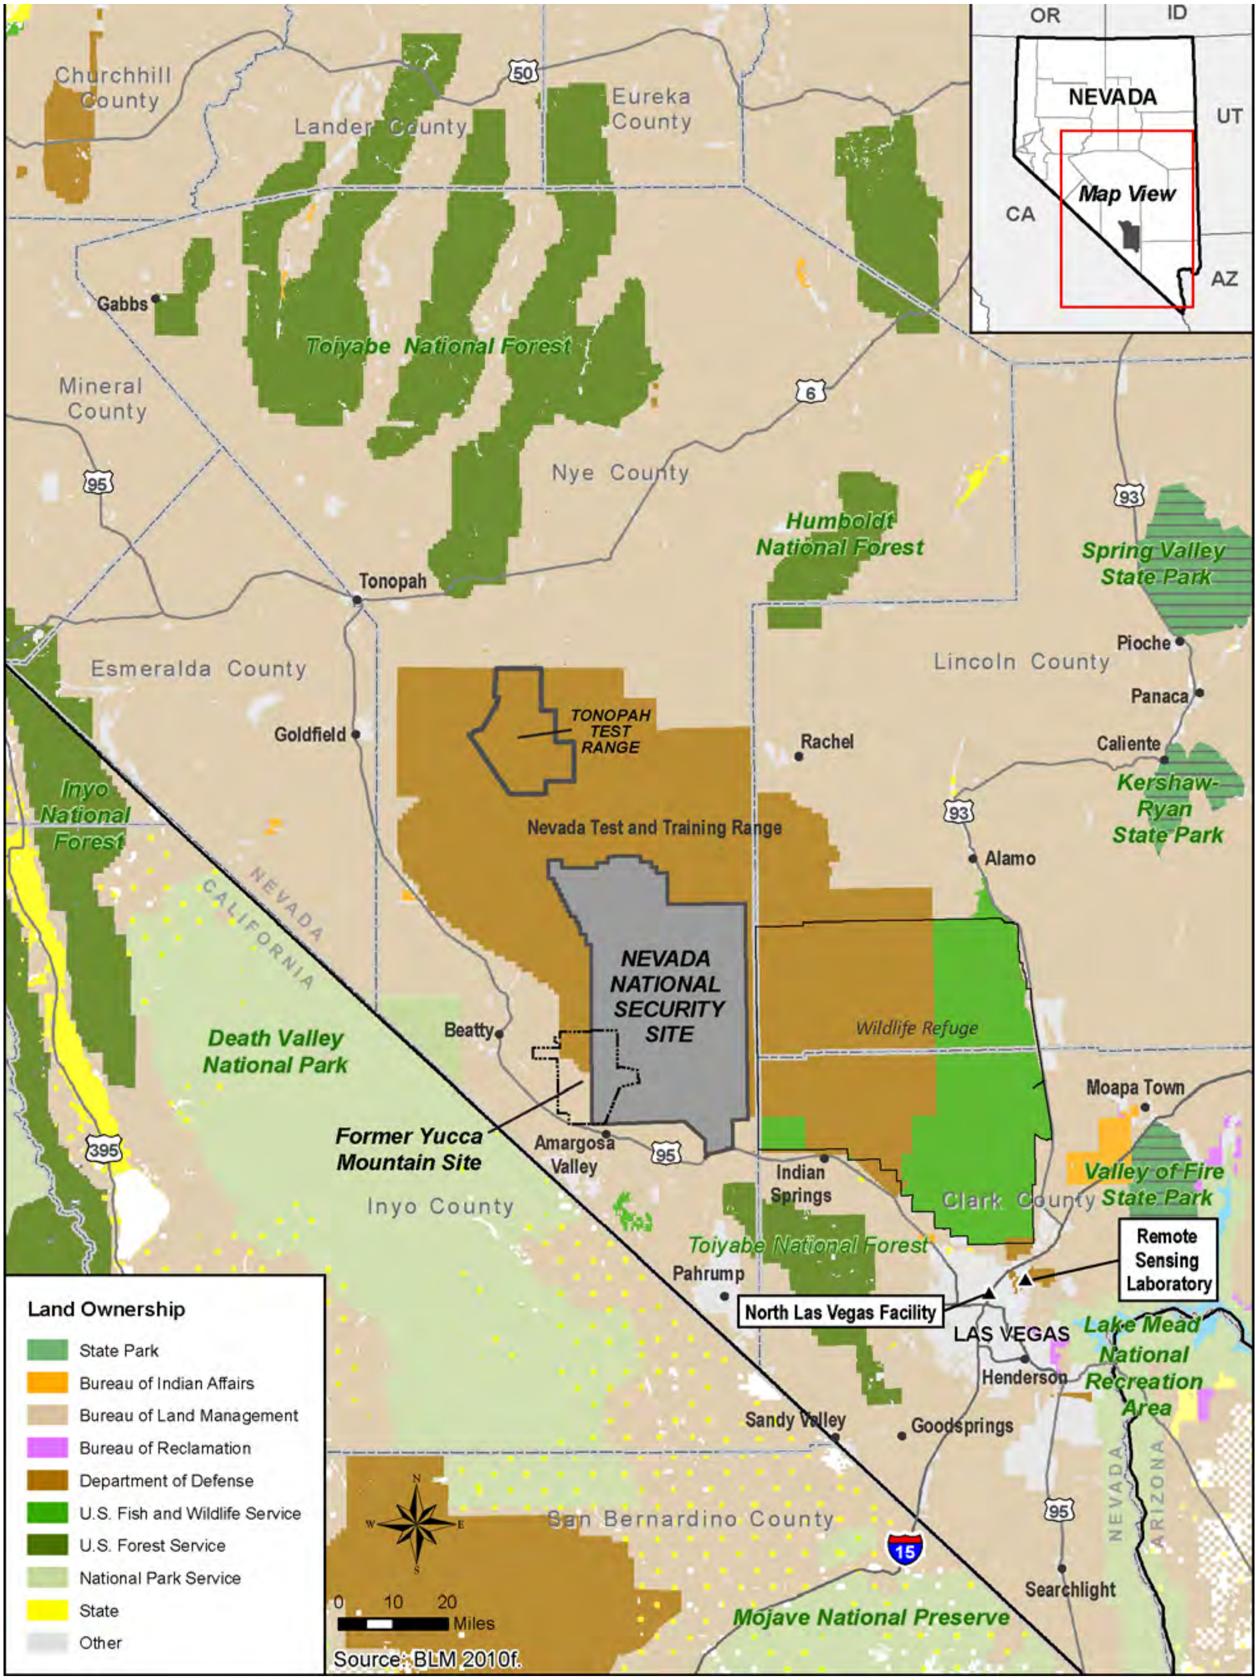

Figure 1–1 Location of the Nevada National Security Site and Offsite Locations

Subsequently, as required by DOE regulations (10 CFR 1021.330(d)), DOE/NNSA conducted the first 5-year review of the *1996 NTS EIS*, as documented in the 2002 *Supplement Analysis for the Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada (2002 NTS SA)* (DOE 2002g). The review found that there were no substantial changes to the actions proposed in the *1996 NTS EIS* and no significant new circumstances or information relevant to environmental concerns. Thus, DOE/NNSA determined that no further NEPA analysis was required (i.e., the existing *1996 NTS EIS* remained adequate based on the supplement analysis [SA], in accordance with 10 CFR 1021.330(d)).

In 2007, DOE/NNSA initiated its second 5-year review of the *1996 NTS EIS* and, in April 2008, issued the *Draft Supplement Analysis for the Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada (2008 Draft NTS SA)* (DOE 2008f). Based on consideration of comments received on the *2008 Draft NTS SA*, potential changes to the NNSS program work scope, and changes to the environmental baseline, DOE/NNSA decided to prepare this SWEIS to update its analysis of the NNSS and offsite location operations in Nevada.

This chapter provides information on the purpose and need for agency action and introduces the alternatives analyzed for DOE/NNSA operations in Nevada and potential decisions to be supported by this SWEIS. This chapter also includes descriptions of related NEPA reviews and a summary of the public involvement process and stakeholder scoping comments, as well as American Indian perspectives prepared by the American Indian Writers Subgroup (AIWS). The AIWS input is in text boxes identified with a Consolidated Group of Tribes and Organizations (CGTO) feather icon.

Introduction—American Indian Perspective

Information provided by the Consolidated Group of Tribes and Organizations (CGTO) for inclusion in the chapters of this site-wide environmental impact statement (SWEIS) is presented in text boxes such as this to distinguish it from U.S. Department of Energy (DOE) text. The full text of American Indian perspective and concerns related to the resources and alternatives evaluated in this SWEIS is presented in Appendix C.

Since the beginning of time, the area encompassing the Nevada National Security Site (NNSS) and the offsite locations has been essential to the lives of American Indian tribes. These lands contain traditional gathering, ceremonial, and recreational areas for the American Indian people. They contain ecological resources and power places that are crucial for the continuation of American Indian culture, religion, and society.

In consideration of our ties to these lands and their resources, and to comply with DOE Order 144.1 and Executive Order 13127, DOE invited the CGTO to contribute to the development of this SWEIS. Specifically, DOE provided the CGTO with the opportunity to develop text summarizing our perspective and concerns regarding the resources and alternatives presented in this SWEIS.

The CGTO has had a long-standing relationship with DOE since 1987. We are comprised of 17 tribes and organizations, representing the Southern Paiute, Western Shoshone, and Owens Valley Paiute and Shoshone people. Each of these groups has substantiated cultural and historic ties to the NNSS and the surrounding areas.

1.2 Purpose and Need for Agency Action

The purpose and need for agency action is to support DOE/NNSA's core missions established by Congress and the President. These include meeting its obligations to ensure a safe and reliable nuclear weapons stockpile, support other national security programs, characterize and/or remediate areas of the NNSS and offsite locations previously contaminated as a result of the Nation's nuclear weapons testing program, and provide for the disposal of LLW and MLLW from across the DOE complex.

DOE/NNSA also must meet the mandates of Executive Orders 13212, *Actions to Expedite Energy-Related Projects*, and 13514, *Federal Leadership in Environmental, Energy, and Economic Performance*, as well as the Energy Independence and Security Act of 2007 (P.L. 109-58). Accordingly, DOE/NNSA's purpose and need also is to satisfy the requirements of these Executive Orders and comply with congressional mandates to promote, expedite, and advance the production of environmentally sound energy resources, including renewable energy resources such as solar and geothermal energy systems.

The NNSS has a long history of supporting national security objectives by conducting underground nuclear tests and other nuclear and nonnuclear activities. Since October 1992, there has been a moratorium on underground nuclear testing (a brief description of underground nuclear testing is provided in Appendix H). Thus, NNSS's role has evolved from an active nuclear testing program to maintaining readiness and the capability to conduct underground nuclear weapons tests; such a test would be conducted only if so directed by the President in the interest of national security. DOE/NNSA's primary mission at the NNSS is supporting nuclear weapons stockpile reliability through subcritical experiments. Changes in national security priorities have resulted in resource reallocation and the introduction and expansion of other national security missions, programs, and activities at the NNSS and offsite locations in Nevada. In addition, the NNSS supports DOE/NNSA waste management activities, including disposal; environmental restoration activities; and research, development, and testing programs related to national security. The NNSS also provides opportunities for various environmental research projects and the development of commercial-scale solar energy projects, as well as development of innovative solar and other renewable energy technologies.

Purpose and Need for Agency Action—American Indian Perspective

The Consolidated Group of Tribes and Organizations (CGTO) knows American Indian people are charged by the Creator to interact with the environment and its resources in culturally appropriate ways to maintain balance, regardless of the U.S. Department of Energy's (DOE's) stated purpose and need for agency action. American Indians further believe these lands and their resources contain life-sustaining characteristics that must be properly respected and cared for to ensure harmony.

The CGTO does not support harmful land-disturbing activities currently conducted and proposed within the Nevada National Security Site (NNSS) area and offsite locations. These lands are part of the traditional holy lands of the Southern Paiute, Western Shoshone, and Owens Valley Paiute and Shoshone people. Harmful land disturbing activities threaten the health and welfare of Indian people through possible contamination and resource destruction.

As Indian people, we are obligated to manage the land and its resources for seven generations. This means we evaluate and guide our actions in terms of what they could do for or to the next seven generations. The CGTO takes this obligation very seriously and has provided information throughout the site-wide environmental impact statement (SWEIS) so we can continue to fulfill our purpose and need to care for these lands.

See Appendix C for more details.

1.3 Alternatives Analyzed

The proposed action in this SWEIS is the continued operation of the NNSS, other DOE/NNSA sites in Nevada, and environmental restoration sites in Nevada. The alternatives in this SWEIS are structured to provide information regarding current and future use of DOE/NNSA facilities in Nevada. The following three alternatives are analyzed: (1) No Action, (2) Expanded Operations, and (3) Reduced Operations. These alternatives were developed to reflect current operations and reasonably foreseeable future operations and to allow DOE/NNSA to analyze and compare the potential environmental effects of a wide range of use options. Chapter 3, Table 3–1, provides a summary of the alternatives analyzed in this SWEIS. In addition, in this *Final NNSS SWEIS*, DOE/NNSA has identified a Preferred Alternative. The Preferred Alternative is discussed briefly in Section 1.3.4 and is fully presented in Chapter 3, Section 3.6, of this SWEIS.

DOE NEPA Implementing Procedures (10 CFR Part 1021) define site-wide NEPA documents as broad-scope environmental impact statements (EISs) or environmental assessments (EAs) that are programmatic in nature and identify and assess the individual and cumulative impacts of ongoing and reasonably foreseeable future actions at a DOE site. This SWEIS considers ongoing and proposed programs, capabilities, and projects (i.e., activities) at DOE/NNSA facilities in Nevada over the next 10 years.

The nature of ongoing activities and their relationship to associated environmental impacts are well-understood. In contrast, however, the nature of some proposed activities is less well known. In the interest of disclosing potential environmental impacts that could occur at the NNSS and offsite locations

over the next 10 years, this SWEIS includes ongoing activities as well as activities that are more conceptual in nature. Some examples are commercial solar power development, etc.

To assess potential environmental impacts from all such activities, it was necessary for DOE/NNSA to estimate at a programmatic level certain aspects of the more conceptual proposed activities, such as potential area of land disturbance or amount of groundwater that may be required. DOE/NNSA incorporated these programmatic-level estimates along with more detailed information on ongoing and better-understood proposed activities into the analysis of impacts. For instance, estimated areas of land disturbance, for both potential future activities and well-defined activities, were used in estimating impacts on resources such as soils (area of disturbance and erosion), cultural resources (number of sites potentially affected), and biology (vegetation/habitat loss, number of desert tortoises affected).

DOE/NNSA understands that the level of NEPA analysis conducted for some proposed future activities may not be sufficient to permit implementation, and such activities could require additional NEPA analysis. These activities are identified in Chapter 3. DOE/NNSA will conduct NEPA review for these activities, as appropriate, in the future. DOE/NNSA'S NEPA review procedures are described in Section 9.1.1.

The alternative descriptions are organized under the three NNSS missions. Each mission includes two or more associated programs. The missions and associated programs are (1) the National Security/Defense Mission, which includes the Stockpile Stewardship and Management, Nuclear Emergency Response, Nonproliferation, Counterterrorism, and Work for Others Programs; (2) the Environmental Management Mission, which includes the Waste Management and Environmental Restoration Programs; and (3) the Nondefense Mission, which includes the General Site Support and Infrastructure, Conservation and Renewable Energy, and Other Research and Development Programs. More information about the NNSS missions and programs; their associated capabilities, projects, and facilities; and the levels of operations under each alternative can be found in Chapter 3 of this SWEIS.

Terminology Used in this *NNSS SWEIS*

Missions. In this site-wide environmental impact statement (SWEIS), the term "missions" refers to the major responsibilities assigned to the U.S. Department of Energy/National Nuclear Security Administration (DOE/NNSA) (described in Section 1.1). DOE/NNSA accomplishes these major responsibilities by assigning groups or types of activities to DOE's system of security laboratories, production facilities, and other sites.

Programs. DOE and NNSA are organized into program offices, each of which has primary responsibilities within the set of DOE and NNSA missions. Funding and direction for activities at DOE/NNSA facilities are provided through these program offices, and similarly coordinated sets of activities to meet program office responsibilities are often referred to as "programs." Programs are usually long-term efforts with broad goals or requirements.

Capabilities. This term refers to the combination of facilities, equipment, infrastructure, and expertise necessary to undertake types or groups of activities and implement mission assignments. Capabilities at the Nevada National Security Site (NNSS) have been established over time, principally through mission assignments and activities directed by program offices.

Projects. This term is used to describe activities with a clear beginning and end that are undertaken to meet a specific goal or need. Projects can vary in scale from very small (such as a project to undertake one experiment or a series of small experiments) to major (such as a project to construct and start up a new nuclear facility). Projects are usually relatively short-term efforts and can cross multiple programs and missions, although they are usually "sponsored" by a primary program office. In this SWEIS, "project" is usually used more narrowly to describe construction activities, including facility modifications (such as a project to build a new office building or to establish and demonstrate a new capability). Construction projects considered reasonably foreseeable at the NNSS over about a 10-year period are discussed and analyzed in this SWEIS.

Activities. In this SWEIS, activities are those physical actions used to implement missions, programs, capabilities, or projects.

1.3.1 No Action Alternative

As defined in this *NNSS SWEIS*, the No Action Alternative reflects the use of existing facilities and ongoing projects to maintain operations consistent with those experienced in recent years at the NNSS and offsite locations in Nevada. For each of the three mission areas and their supporting programs, the level of operation for associated capabilities, projects, and activities is determined by operational levels actually realized since 1996. Examples include the number of experiments performed at the Joint Actinide Shock Physics Experimental Research Facility (JASPER) or the U1a Complex; reasonable expectations for recently implemented projects, such as the number of shots for the Large-Bore Powder Gun; or the nature and number of activities, such as training undertaken for the Office of Secure Transportation.

Accordingly, under the No Action Alternative, Stockpile Stewardship and Management Program activities would continue at DOE/NNSA facilities in Nevada under the conditions of the ongoing nuclear testing moratorium. These activities would emphasize U.S. science-based stockpile stewardship tests, experiments, and projects to maintain the safety and reliability of the Nation's nuclear weapons stockpile without underground nuclear testing. By Presidential Decision Directive 15 (November 1993), DOE/NNSA must be able to resume underground nuclear weapons tests within 24 to 36 months if so directed by the President. This capability is maintained at the NNSS. However, conducting such a test is not included or analyzed under any of the alternatives in this SWEIS. A brief description of underground nuclear test phenomenology is included for informational purposes in Appendix H.

In support of the Nuclear Emergency Response, Nonproliferation, and Counterterrorism Programs, under the No Action Alternative, DOE/NNSA would continue its responsibilities regarding (1) support for the Nuclear Emergency Support Team, the Federal Radiological Monitoring and Assessment Center, the Accident Response Group, and the Radiological Assistance Program; (2) Aerial Measuring System activities; (3) weapons of mass destruction emergency responder training; (4) disposition of improvised nuclear devices and radiological dispersion devices; (5) support for DOE/NNSA's Emergency Communications Network; and (6) integration of existing activities and facilities to support U.S. efforts to control the spread of weapons of mass destruction.

Under the No Action Alternative, the Work for Others Program, which is hosted by DOE/NNSA, would entail the shared use of certain facilities, such as the Big Explosives Experimental Facility (BEEF), the Nonproliferation Test and Evaluation Complex, and the T-1 Training Area, with other agencies, such as DoD, as well as the shared use of resources at the NNSS, RSL, NLVF, and the TTR. DOE/NNSA would continue to host the projects of other Federal agencies, such as DoD and the U.S. Department of Homeland Security, as well as state and local government agencies and some nongovernmental organizations.

Under the No Action Alternative, in support of the Environmental Management Mission and Waste Management Program, the NNSS would continue accepting and disposing LLW and MLLW from approved generators as long as such wastes meet the NNSS waste acceptance criteria (WAC). The projected LLW volume analyzed is based on the average annual disposal of LLW from 1997 to 2010. The volume of MLLW analyzed is the permitted capacity of the Mixed Waste Disposal Unit (Cell 18) at the Area 5 Radioactive Waste Management Complex. The Environmental Restoration Program would continue to ensure compliance with the Federal Facility Agreement and Consent Order (FFACO) to characterize, monitor, and, if necessary, remediate locations that have sustained adverse environmental impacts from past DOE/NNSA activities. These impacts include hazardous material and radioactively contaminated areas, facilities, soils, and groundwater.

Under the No Action Alternative, the Nondefense Mission includes those activities that are necessary to support mission-related programs, such as construction and maintenance of facilities, provision of supplies and services, and warehousing. Activities related to supply and conservation of energy, including renewable energy and other research and development projects, are also conducted under the Nondefense Mission. DOE/NNSA would continue to identify and implement energy conservation measures and projects related to energy efficiency, renewable energy, water conservation, transportation/fleet management, and high-performance and sustainable buildings.

Federal Facility Agreement and Consent Order

The Nevada National Security Site Environmental Restoration Program includes activities to comply with the Federal Facility Agreement and Consent Order, which was entered into in 1996 by the U.S. Department of Energy, the U.S. Department of Defense, and the State of Nevada. The Federal Facility Agreement and Consent Order provides a process for identifying sites having potential historic contamination, implementing state-approved corrective actions, and instituting closure actions for remediated sites.

1.3.2 Expanded Operations Alternative

The Expanded Operations Alternative includes the level of operations under the No Action Alternative, plus the level of operations associated with additional capabilities at the NNSS and offsite locations in Nevada. The additional level of operations would include modification and/or expansion of existing facilities and construction of new facilities. An example of an additional level of operations would be the increased number of experiments that would be conducted at the NNSS with conventional high explosives (100 experiments within limited areas of the NNSS) compared with the number that would be conducted under the No Action Alternative (20 experiments in the same areas). An example of facility expansion would be adding a new firing table at BEEF. As with the No Action Alternative, the Expanded Operations Alternative reflects continued implementation of previous NEPA decisions (see Section 1.5) and retains the necessary capabilities from those decisions. The key differences from the No Action Alternative are shown in Chapter 3, Table 3–1, of this SWEIS, and a detailed description of the Expanded Operations Alternative is provided in Chapter 3, Section 3.2.

1.3.3 Reduced Operations Alternative

The Reduced Operations Alternative analyzed in this SWEIS reflects diminished activity levels, as well as decommissioned facilities and areas at the NNSS and other offsite locations in Nevada. The Reduced Operations Alternative includes continued implementation of previous NEPA decisions (see Section 1.5), but may not retain all capabilities from those decisions. Operational levels would be reduced relative to the No Action Alternative, and geographical and organizational constraints would be placed upon some activities under the Reduced Operations Alternative. Using the same example used for the Expanded Operations Alternative, the number of conventional high-explosives experiments under the Reduced Operations Alternative would be 10 experiments compared with the 20 experiments proposed under the No Action Alternative. A geographical constraint example would be the cessation of most activities in the northwest portion of the NNSS (although activities such as security, monitoring, environmental restoration, and military exercises would continue). The key differences from the No Action Alternative are shown in Chapter 3, Table 3–1, of this SWEIS, and a detailed description of the Reduced Operations Alternative is provided in Chapter 3, Section 3.3.

1.3.4 Preferred Alternative

CEQ regulations for implementing NEPA (40 CFR 1502.14(e)) require an agency to identify its preferred alternative or alternatives, if one or more exists, in the draft EIS. At the time the *Draft NNSS SWEIS* was published, DOE/NNSA had not selected a preferred alternative. Since publication of the *Draft NNSS SWEIS*, DOE/NNSA evaluated the agency's and other users' needs over the next 10 years, the information presented in this *NNSS SWEIS*, and the comments received on the draft SWEIS and has identified its Preferred Alternative.

DOE/NNSA's Preferred Alternative is based on the preferences expressed by commentors, the needs of DOE/NNSA and other users as reflected by contemporary priorities given anticipated funding, and a goal of minimizing potential environmental impacts to the extent practicable. DOE/NNSA's Preferred Alternative is a "hybrid" alternative comprising various programs, capabilities, projects, and activities selected from among the three alternatives. Section 3.4 and Table 3–3 describe the Preferred Alternative in greater detail and provide a comparison of mission-based program activities under the three alternatives and the Preferred Alternative.

1.3.5 Relationship to *1996 NTS EIS*

In 1996, DOE issued the final *NTS EIS* and its associated ROD. The *1996 NTS EIS* (DOE 1996c) evaluated four alternatives: (1) Continue Current Operations (No Action Alternative), (2) Discontinue Operations, (3) Expanded Use, and (4) Alternate Use of Withdrawn Lands. These alternatives are described below.

- Alternative 1, Continue Current Operations (No Action) – DOE and interagency programs, activities, and operations at the NNSS associated with five program areas would continue in the same manner and to the same degree (level of operations) as during the 3 to 5 years previous to 1996. For example, at the NNSS, DOE would continue nuclear weapons stockpile and stewardship experiments and operations; environmental restoration would continue in the form of characterization and remediation of contaminated areas and facilities; and waste would be disposed at then-current yearly rates or levels.

- Alternative 2, Discontinue Operations – DOE and interagency programs, activities, and operations at the NNSS would be terminated. Facilities would be placed in cold standby after operations cease. Only those environmental monitoring and security functions necessary for human health, safety, and security would be maintained at the NNSS.

- Alternative 3, Expanded Use – DOE and interagency programs, activities, and operations at the NNSS associated with the five program areas would be maintained, but in a manner and at a level above that of the 3 to 5 years previous to 1996. Defense Program activities associated with stockpile stewardship would increase, as would waste management and environmental restoration activities.

- Alternative 4, Alternate Use of Withdrawn Lands – All defense-related activities and most interagency programs would discontinue at the NNSS.

In its 1996 ROD, DOE selected the Expanded Use Alternative, which provided for increasing the level of operations of most programs, activities, and operations, but decided to manage LLW and MLLW at levels described under the No Action Alternative. However, in a 2000 amendment to the 1996 ROD, DOE selected the Expanded Use Alternative for waste management activities at the NNSS.

For the most part, the level of operations envisioned and analyzed in the *1996 NTS EIS* (DOE 1996c) has not been realized. **Table 1–1** provides a comparison of the *1996 NTS EIS* Expanded Use Alternative and the current *NNSS SWEIS* No Action Alternative. As shown in Table 1–1, under the Expanded Use Alternative, DOE proposed undertaking approximately 110 dynamic experiments (i.e., experiments designed to improve knowledge of plutonium properties and assess performance and safety of nuclear weapons) each year. Since then, however, fewer than 10 such experiments have occurred each year. Also, the Expanded Use Alternative analyzed the transport and disposal of about 37 million cubic feet of LLW and 11 million cubic feet of MLLW at the NNSS. At the end of 2010, however, almost 22 million cubic feet of LLW and 370,000 cubic feet of MLLW had been disposed.

This *NNSS SWEIS* includes three alternatives: (1) No Action, (2) Expanded Operations, and (3) Reduced Operations. The No Action Alternative reflects the DOE/NNSA and interagency programs, activities, and operations in the program areas addressed in the *1996 NTS EIS* Expanded Use Alternative, but at the historic or baseline level of operations experienced since 1996. For example, under the No Action Alternative in this *NNSS SWEIS*, DOE/NNSA analyzed 10 dynamic experiments per year and the transport and disposal of 15 million cubic feet of LLW and 900,000 cubic feet of MLLW.

The No Action Alternative also includes the level of operations associated with missions, programs, capabilities, and projects analyzed in other NEPA documents. For example, DOE/NNSA completed the *Final Environmental Impact Statement for the Proposed Relocation of Technical Area 18 Capabilities and Materials at the Los Alamos National Laboratory* (DOE 2002h; DOE/EIS-319) and its ROD (67 FR 79906) and then relocated materials and equipment associated with criticality experiments to the NNSS. Consistent with the baseline level of operations, under the No Action Alternative, the National Criticality Experiments Research Center is expected to conduct up to 500 criticality operations for training, experiments, and other purposes each year.

As described in Section 1.3.2, the Expanded Operations Alternative includes a higher level of operations than under the No Action Alternative, plus operations associated with proposed additional capabilities, which is a similar concept to the Expanded Use Alternative considered in the *1996 NTS EIS*. The Reduced Operations Alternative reflects diminished levels of operation, as well as geographic restrictions on some activities at the NNSS. There is no clear equivalent to the Reduced Operations Alternative in the *1996 NTS EIS.*

Table 1–1 Comparison of the *1996 NTS EIS* Expanded Use Alternative and the *NNSS SWEIS* No Action Alternative

Mission, Program, Project, or Activity Analyzed	*Analyzed in the* **1996 NTS EIS** [a]	*Analyzed in this* **NNSS SWEIS** [a]
General		
Mission/program	Five program areas: Defense, Waste Management, Environmental Restoration, Nondefense Research and Development, and Work for Others	Three mission areas: National Security/Defense Mission, Environmental Management Mission, and Nondefense Mission
NATIONAL SECURITY/DEFENSE MISSION		
Stockpile Stewardship and Management Program		
Maintain readiness to conduct an underground nuclear test	Addressed as overarching mission	Addressed as overarching mission
Conduct dynamic experiments	110 per year	10 per year
Conduct high-explosives tests and experiments	100 per year at BEEF, up to 70,000 pounds of high explosives per detonation, including limited use of certain hazardous materials; no SNM would be used in any experiment	To support Stockpile Stewardship and Management Program: 20 per year at BEEF (70,000 pounds TNT-equivalent maximum per event) and 10 per year at other locations within the Nuclear Test Zone and Nuclear and High Explosives Test Zone; explosives experiments at BEEF may include limited use of certain hazardous materials To support Work for Others Program: 40 experiments using up to 2,000 pounds TNT-equivalent of explosives at various locations on the NNSS No SNM would be used in any experiment
Disposition damaged U.S. nuclear weapon(s) on an as-needed basis	Disposition damaged U.S. nuclear weapon(s) on an as-needed basis	Disposition damaged U.S. nuclear weapon(s) on an as-needed basis
Reserve land and infrastructure for a large, heavy-industrial facility and/or next generation nuclear weapons simulators	Consistent with analyses in other NEPA documents that considered the NNSS as an alternative location, such as the *Pantex Plant Site-Wide EIS* and the National Ignition Facility in the *Stockpile Stewardship and Management PEIS*	Not analyzed
Conduct underground nuclear test, if so directed by the President of the United States	Yes	Not analyzed
Reserve land and infrastructure for nuclear weapons assembly/disassembly operations and/or long-term storage and disposition of weapons-usable fissile material	Yes	Not analyzed
Shock physics experiments	Not analyzed [b]	12 per year at JASPER and 10 per year at the U1a Complex
Criticality experiments at DAF	Not analyzed [b]	500 operations per year
Pulsed-power experiments at the Atlas Facility	Not analyzed [b]	Facility maintained on standby with capability to conduct up to 12 experiments per year
Plasma physics and fusion experiments	Not analyzed [b]	Conduct up to 600 per year at NLVF and 50 per year at Area 11 of the NNSS
Conduct drillback operations	Yes, as part of maintaining readiness to conduct or as part of actual conduct of an underground nuclear test	Up to five over the next 10 years as part of maintaining readiness to test

Mission, Program, Project, or Activity Analyzed	***Analyzed in the* 1996 NTS EIS** [a]	***Analyzed in this* NNSS SWEIS** [a]
Stage SNM, including nuclear weapons pits	Yes	Yes
Training for the Office of Secure Transportation	Yes, as part of conducting unspecified exercises and training	Yes, up to six times per year
Conduct stockpile stewardship activities at the TTR, including experiments using SNM, where containment is assured	Yes	Yes, but SNM use not expected
Nuclear Emergency Response, Nonproliferation, and Counterterrorism Programs		
Support various DOE/NNSA nuclear emergency response activities, including FRMAC, NEST, ARG, RAP, and AMS	Yes	Yes
Disposition improvised nuclear devices	Not analyzed [a]	Yes
Support U.S. efforts to control the spread of WMDs, including arms control, nonproliferation activities, nuclear forensics, and counterterrorism capabilities	Partial; counterproliferation and nonproliferation activities, treaty verification, and training and exercises were addressed	Yes; counterterrorism activities [b] are also included
Work for Others Program		
Support U.S. Department of Homeland Security testing and evaluation of detection devices for use in transportation-related applications at RNCTEC and other locations on the NNSS	Not analyzed [b]	Yes
Experiments using releases of chemicals and/or biological simulants	Partial; chemical releases at NPTEC (Liquefied Gaseous Fuels Spill Test Facility in the *1996 NTS EIS*) were addressed	Yes; an unspecified number of release experiments at NPTEC and up to 20 experiments using releases of low concentrations of chemicals and biological simulants per year NNSS-wide [a]
Support development of capabilities to detect and defeat assets in deeply buried/hardened targets	Yes	Yes
Host the use of various aerial platforms for tests, experiments, training, and exercise	Yes	Yes
ENVIRONMENTAL MANAGEMENT MISSION		
Waste Management Program		
LLW disposal MLLW disposal	Almost 36,800,000 cubic feet About 10,600,000 cubic feet	15,000,000 cubic feet 900,000 cubic feet [c]
Manage onsite-generated TRU and TRU mixed wastes pending shipment to offsite treatment and disposal facilities	Yes	About 9,600 cubic feet over the next 10 years
Generate and temporarily store hazardous waste pending shipment to a permitted treatment, storage, and disposal facility	Yes	About 190,400 cubic feet over the next 10 years
Operate the Area 11 Explosives Ordnance Disposal Unit	Yes	Yes
Operate the Area 6 hydrocarbon landfill	Yes	Yes
Operate the Area 23 and the U10c Solid Waste Disposal Sites	Yes	About 3,810,000 cubic feet of sanitary solid waste and construction/ decontamination and demolition debris
Environmental Restoration Program		
Underground Test Area Project to characterize, monitor, and remediate, as necessary, groundwater contaminated by underground nuclear testing	Yes	Yes, in accordance with the FFACO; analyze up to 50 additional characterization and/or monitoring wells over the next 10 years

Mission, Program, Project, or Activity Analyzed	***Analyzed in the* 1996 NTS EIS** [a]	***Analyzed in this* NNSS SWEIS** [a]
Soils Project to investigate and characterize soil contamination at non-industrial sites on the NNSS, TTR, and Nevada Test and Training Range and perform corrective actions, as necessary	Yes	Yes, in accordance with the FFACO
Industrial Sites Project to identify, characterize, and remediate, as necessary, industrial sites at the NNSS and TTR	Yes	Yes, in accordance with the FFACO
Conduct environmental restoration activities at Defense Threat Reduction Agency sites on the NNSS	Yes	Yes
Conduct environmental characterization and monitoring at two former offsite underground nuclear weapons test sites: Central Nevada Test Area and Project Shoal	Yes	No; stewardship of both sites has been assumed by the DOE Office of Legacy Management
NONDEFENSE MISSION		
General Site Support and Infrastructure Program		
Infrastructure	Upgrade, renovate, replace, and construct new common site support facilities to support ongoing and additional activities	Maintain, repair, and replace current infrastructure; the only new "infrastructure" would be LLW cells, as needed, and construction of the Underground Test Area Project wells, in consultation with the Nevada Division of Environmental Protection
Conservation and Renewable Energy Program		
Energy conservation	Not addressed	Reduce energy consumption and improve efficiency of energy use
Renewable energy	Up to 1,000 megawatts of solar power generation in one of two Solar Enterprise Zones on the NNSS: Area 22/23 and Area 25 Also considered solar power generation facilities at three non-DOE sites outside of the NNSS	"Solar Enterprise Zone" renamed "Renewable Energy Zone" Allow commercial entity to construct and operate up to 240 megawatts of solar power generation in the Renewable Energy Zone in Area 25
Other Research and Development Program		
Support nondefense research and development	Yes	Yes

AMS = Aerial Measuring System; ARG = Accident Response Group; BEEF = Big Explosives Experimental Facility; DAF = Device Assembly Facility; EIS = environmental impact statement; FFACO = Federal Facility Agreement and Consent Order; FRMAC = Federal Radiological Monitoring and Assessment Center; JASPER = Joint Actinide Shock Physics Experimental Research Facility; LLW = low-level radioactive waste; MLLW = mixed low-level radioactive waste; NEPA = National Environmental Policy Act; NEST = Nuclear Emergency Support Team; NLVF = North Las Vegas Facility; NNSS = Nevada National Security Site; NPTEC = Nonproliferation Test and Evaluation Complex; NTS = Nevada Test Site; PEIS = Programmatic Environmental Impact Statement; RAP = Radiological Assistance Program; RNCTEC = Radiological/Nuclear Countermeasures Test and Evaluation Complex: SNM = special nuclear material; SWEIS = site-wide environmental impact statement; TNT = 2,4,6 trinitrotoluene; TRU = transuranic; TTR = Tonopah Test Range; WMD = weapon of mass destruction.

[a] Quantitative bases for analyses used in this table were derived from the published *1996 NTS EIS* and assumptions used in this *NNSS SWEIS*. For some activities, such as training and exercises, the bases for impact assessment were not derived from the number of events but from the potential to disturb previously undisturbed land.

[b] Addressed in other NEPA documentation.

[c] Actual permitted capacity of the Mixed Waste Disposal Unit (Cell 18) is 899,996 cubic feet.

1.4 Potential Decisions Supported by this Site-Wide Environmental Impact Statement

This SWEIS analyzes and evaluates the potential impacts of existing and proposed capabilities and projects. The results documented in this SWEIS will provide the basis for DOE/NNSA to determine the nature of these capabilities, projects, and activities, as well as their associated level of operations, over about a 10-year period at the NNSS and offsite locations in Nevada. Where information is insufficient to support an implementing decision for more conceptual activities, implementation would require an appropriate level of new or additional NEPA analysis.

DOE/NNSA may choose to implement any alternative in its entirety or to select a hybrid that incorporates parts of the different proposed alternatives. DOE/NNSA may make the following decisions regarding its operations:

- *Implement the No Action Alternative, either wholly or in part.* Under the No Action Alternative, DOE/NNSA operations in Nevada would continue in accordance with previous decisions made pursuant to NEPA reviews.
- *Implement the Expanded Operations Alternative, either wholly or in part.* The Expanded Operations Alternative includes planned and proposed capabilities and projects and an overall increase in the level of operations, relative to the No Action Alternative, that could be implemented over about a 10-year period.
- *Implement the Reduced Operations Alternative, either wholly or in part.* The Reduced Operations Alternative involves reductions of operations. Choosing to implement this alternative in whole or in part would result in reductions of affected capabilities and projects.

DOE/NNSA capabilities and projects at the NNSS are located in seven land use zones that were developed and designated following decisions made in the *1996 NTS EIS* ROD. Implementation of any of the alternatives analyzed in this SWEIS, either in whole or in part, could result in changes to the name, size, or location of these land use zones, or in the location of proposed capabilities and projects within these zones.

Although an analysis of environmental restoration activities' impacts is included in this SWEIS, environmental restoration activities at the NNSS, the TTR, and sites on the Nevada Test and Training Range are driven by the FFACO. The State of Nevada, through the Nevada Division of Environmental Protection (NDEP), oversees FFACO compliance and enforces its provisions. Therefore, DOE/NNSA would not make any decisions regarding environmental restoration activities that are inconsistent with the FFACO without consultation with NDEP.

Although an analysis of LLW/MLLW shipping routes is included in this SWEIS, decisions on routing would not be made as part of this NEPA process. DOE/NNSA sought to understand the differences in potential environmental effects between different routing options, which incorporated changes to local transportation infrastructure since the *1996 NTS EIS*; communicate those differences to the public; and seek stakeholder comments on the range of transportation routes. The analysis of a Constrained (current routing protocol) and an Unconstrained Case (utilizing all routes within the Las Vegas Valley), as well as increased use of rail transport and rail-to-truck transfer stations, was undertaken to develop a greater understanding of the potential environmental consequences of shipping such waste through metropolitan Las Vegas. Any changes to existing routing would be made through revisions to the NNSS WAC. Revisions to the WAC are undertaken in coordination with NDEP, pursuant to the Agreement in Principle between the State of Nevada and DOE/NNSA NSO (State of Nevada 2011). While DOE/NNSA's environmental analyses showed no meaningful differences in potential environmental effects between the Constrained and Unconstrained Cases, the preponderance of stakeholder comments recommended that DOE/NNSA retain highway routing restrictions to avoid shipments of LLW/MLLW through greater

metropolitan Las Vegas (Constrained Case). In consideration of the environmental analyses and stakeholder comments, and after consultation with NDEP as part of the WAC revision process, DOE/NNSA determined that it would retain the highway routing restrictions for shipments of LLW/MLLW in the greater Las Vegas metropolitan area and, therefore, there would be no need to revise the WAC in this regard (DOE 2012). DOE/NNSA is not proposing to construct or cause to be constructed any new rail-to-truck transfer facilities to accommodate shipments of radioactive waste or materials under any of the alternatives considered in this SWEIS.

1.5 Relationship Between this Site-Wide Environmental Impact Statement and Other National Environmental Policy Act Analyses

Decisions made in the *1996 NTS EIS* ROD (61 FR 65551) and various subsequent NEPA documents have defined implementation of projects at the NNSS. This section summarizes past and ongoing NEPA compliance reviews and associated decisions (i.e., RODs and Findings of No Significant Impact [FONSIs]) that are germane to the estimation of direct, indirect, and cumulative environmental impacts resulting from the implementation of the projects and activities under each of the three alternatives.

***Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada (1996 NTS EIS)* (DOE/EIS-0243) (DOE 1996c) –** As discussed in Section 1.3.4, the *1996 NTS EIS* evaluated four alternatives for the continued operation of the Nevada Test Site (now called the NNSS): (1) Continue Current Operations (No Action Alternative), (2) Discontinue Operations, (3) Expanded Use, and (4) Alternate Use of Withdrawn Lands. Included in the *1996 NTS EIS* was an assessment of reasonable alternatives for flight testing for gravity weapons (bombs) at the TTR. DOE published a ROD on December 13, 1996 (61 FR 65551), selecting the Expanded Use Alternative plus the public education activities from the Alternate Use of Withdrawn Lands Alternative. Under that decision, DOE/NNSA continued the multipurpose, multiprogram use of the NNSS and a continuation and diversification of the DOE Nevada Operations Office (the predecessor of the DOE/NNSA NSO) and interagency programs and operations at the NNSS. The Expanded Use Alternative included support for ongoing DOE Nevada Operations Office program categories defined under the Continue Current Operations (No Action) Alternative and increased the use of the NNSS and its related resources and capabilities. The Expanded Use Alternative also made the NNSS more available to both public and private institutions for demonstration of new technologies.

A subsequent amendment to the *1996 NTS EIS* was included in a February 2000 ROD (65 FR 10061) for the *WM PEIS* (discussed below). This ROD announced DOE's decision to implement LLW and MLLW activities in accordance with the *1996 NTS EIS* Expanded Use Alternative.

***Final Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste (WM PEIS)* (DOE/EIS-0200) (DOE 1997) –** The *WM PEIS* examined the potential environmental impacts of strategic alternatives for managing five types of radioactive and hazardous wastes resulting from nuclear defense and research activities at DOE sites around the United States. When the *1996 NTS EIS* (DOE 1996c) was issued, the NNSS was under consideration in the *Draft WM PEIS* as a site for centralized or regional management of certain DOE wastes. In its 1996 ROD for the *1996 NTS EIS*, DOE selected the Expanded Use Alternative, but decided to manage LLW and MLLW at levels described under the No Action Alternative. However, in a 2000 amendment to the 1996 ROD (as a result of the third amended ROD for the *WM PEIS*), DOE selected the Expanded Use Alternative for waste management activities at the NNSS.

DOE published four RODs associated with the *WM PEIS*, three of which are relevant to the NNSS. In its ROD for the treatment and management of transuranic waste, published January 23, 1998 (63 FR 3629), and subsequent revisions to this ROD, published December 9, 2000, July 25, 2001, and September 6, 2002 (65 FR 82985, 66 FR 38646, and 67 FR 56989, respectively), DOE decided (with one

exception) that each DOE site that either had or might generate transuranic waste would prepare the waste for disposal and store it on site until it could be shipped to the Waste Isolation Pilot Plant near Carlsbad, New Mexico, for disposal. In the second ROD, published August 5, 1998 (63 FR 41810), DOE decided to continue using offsite facilities for the treatment of major portions of nonwastewater hazardous wastes generated at DOE sites.

In the third ROD, which addressed the management and disposal of LLW and MLLW and was published February 25, 2000 (65 FR 10061), DOE decided to perform minimal treatment of LLW at all sites and to continue, to the extent practicable, onsite disposal of LLW at Idaho National Laboratory, Los Alamos National Laboratory, Oak Ridge Reservation, and the Savannah River Site. DOE decided to establish regional disposal capacity at the Hanford Site and the NNSS. Specifically, in addition to disposing their own LLW, the Hanford Site and the NNSS would dispose LLW generated at other DOE sites, provided the waste met their respective WAC. DOE decided to treat MLLW at the Hanford Site, Idaho National Laboratory, Oak Ridge Reservation, and the Savannah River Site, with disposal at either the Hanford Site or the NNSS.[1]

Final Environmental Impact Statement for Construction and Operation of a Depleted Uranium Hexafluoride Conversion Facility at the Paducah, Kentucky, Site **(DOE/EIS-0359) (DOE 2004d) –** This EIS, tiered from the *Final Programmatic Environmental Impact Statement for Alternative Strategies for the Long-Term Management and Use of Depleted Uranium Hexafluoride* (DOE/EIS-0269) (DOE 1999c), considered the potential environmental impacts of construction, operation, maintenance, and decontamination and decommissioning of a proposed facility for converting depleted uranium hexafluoride to a more stable chemical form at alternative locations within the Paducah Site. DOE evaluated transportation of the depleted uranium conversion product to a commercial facility or the NNSS for disposal as LLW. The July 27, 2004, ROD (69 FR 44654) stated that DOE planned to decide the specific disposal location(s) after further NEPA review.

Final Environmental Impact Statement for Construction and Operation of a Depleted Uranium Hexafluoride Conversion Facility at the Portsmouth, Ohio, Site **(DOE/EIS-0360) (DOE 2004e) –** This EIS, tiered from the *Final Programmatic Environmental Impact Statement for Alternative Strategies for the Long-Term Management and Use of Depleted Uranium Hexafluoride* (DOE/EIS-0269) (DOE 1999c), considered the potential environmental impacts of construction, operation, maintenance, and decontamination and decommissioning of a proposed facility for converting depleted uranium hexafluoride to a more stable chemical form at alternative locations within the Portsmouth Site. DOE evaluated transportation of the depleted uranium conversion product to a commercial facility or the NNSS for disposal as LLW. The July 27, 2004, ROD (69 FR 44649) stated that DOE planned to decide the specific disposal location(s) after further NEPA review.

Draft Supplement Analysis for Location(s) to Dispose of Depleted Uranium Oxide Conversion Product Generated from DOE's Inventory of Depleted Uranium Hexafluoride **(DOE 2007d) (DOE/EIS-0359-SA1 and DOE/EIS-0360-SA1) –** DOE issued a Notice of Availability for this draft SA on April 3, 2007 (72 FR 15869). DOE is proposing to amend the two site-specific RODs (69 FR 44649 and 69 FR 44654) for depleted uranium hexafluoride conversion to decide whether the depleted uranium conversion product would be disposed at the NNSS or at the EnergySolutions (formerly Envirocare of Utah, Inc.) LLW disposal facilities.

[1] DOE has established a moratorium on the receipt of offsite waste at the Hanford Site until 2022 or until the Waste Treatment Plant at the Hanford Site is operational. This facility is currently under construction and is designed to treat radioactive waste from the Hanford Site's underground storage tanks.

Final Environmental Assessment for the Site Launch, Reentry and Recovery Operations at the Kistler Launch Facility, Nevada Test Site (NTS) **(FAA 2000) –** The Federal Aviation Administration (FAA) prepared an EA and issued a FONSI on May 3, 2002 (67 FR 22479), for the Kistler Launch Facility (KLF) which included proposed space launch and reentry activities. This EA analyzed preflight processing activities, launch/flight operations, and reentry and recovery operations. To conduct operations, Kistler Aerospace Corporation proposed to construct a base of operations consisting of a private launch site (including a vehicle processing facility); a vehicle reentry, landing, and recovery area; and a payload processing facility. KLF operations and activities were to occur in Area 18 and at an adjacent location in Area 19. The proposed launch site was on the southern slopes of Pahute Mesa, south of Rattlesnake Ridge and north of Stockade Wash, at an elevation of about 5,800 feet. FAA proposed to license Kistler's proposed space launch and reentry activities. FAA issued a FONSI, but the KLF project was subsequently cancelled.

The Nevada Test Site Development Corporation's Desert Rock Sky Park at the Nevada Test Site Environmental Assessment **(DOE/EA-1300) (DOE 2000) –** This EA analyzed the potential environmental effects of developing, operating, and maintaining a commercial/industrial park in Area 22 of the NNSS, between Mercury and U.S. Route 95, east of Desert Rock Airport. DOE issued a FONSI in March 2000, but the project was not implemented.

Aerial Operations Facility, Nevada Test Site Environmental Assessment **(DOE/EA-1334) (DOE 2001a) –** This EA analyzed the potential environmental effects of developing, operating, and maintaining an aerial operations facility for testing and operating aerial vehicles at an existing facility located at the southern end of Yucca Lake in Area 6 of the NNSS. DOE issued a FONSI based on this EA in 2001. The facility is in operation.

Final Environmental Assessment for Aerial Operations Facility Modifications, Nevada Test Site **(DOE/EA-1512) (DOE 2004g) –** This EA evaluated the potential impacts of constructing a new runway, hangars, and operations buildings and performing infrastructure upgrades to accommodate an increase in Aerial Operations Facility operations and personnel. DOE/NNSA issued a FONSI based on this EA in October 2004. The facility is in operation.

Atlas Relocation and Operation at the Nevada Test Site Final Environmental Assessment **(DOE/EA-1381) (DOE 2001b) –** This EA analyzed the relocation of the Atlas pulsed-power machine from Los Alamos National Laboratory to the NNSS. DOE/NNSA issued a FONSI based on this EA in May 2001. At the NNSS, the Atlas Facility was reassembled in a newly constructed building within a designated industrial, research, and support site in Area 6. The facility is currently in a standby status.

Supplement Analysis for the Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada (2002 NTS SA) **(DOE/EIS-0243-SA-01) (DOE 2002g) –** In 2002, DOE/NNSA completed the first of three SA reviews of the *1996 NTS EIS* (DOE 1996c). The *2002 NTS SA* provided a 5-year review of the *1996 NTS EIS* to determine whether there were sufficient changes to either the NNSS operations or environmental impacts to warrant a new SWEIS, a supplemental EIS, or whether no further NEPA action was warranted. DOE/NNSA found that there were no substantial changes to the actions proposed in the *1996 NTS EIS* and no significant new circumstances or information relevant to environmental concerns; thus, no further NEPA documentation was required (i.e., the existing *1996 NTS EIS* remained adequate based on the SA, in accordance with 10 CFR 1021.332(d)).

Final Environmental Impact Statement for the Proposed Relocation of Technical Area 18 Capabilities and Materials at the Los Alamos National Laboratory **(DOE/EIS-0319) (DOE 2002h) –** This EIS addressed the potential impacts of relocating criticality missions and materials from Technical Area 18 at Los Alamos National Laboratory to several sites, including the NNSS. In a December 31, 2002, ROD

(67 FR 79906), DOE/NNSA made the decision to relocate Security Category I/II missions and materials to the Device Assembly Facility at the NNSS. The relocation has been completed.

***Hazardous Materials Testing at the Hazardous Materials Spill Center, Nevada Test Site Environmental Assessment* (DOE/EA-0864) (DOE 2002i) –** This EA established potential environmental impacts from planned releases of hazardous and toxic materials at the Hazardous Materials Spill Center (formerly the Liquefied Gaseous Fuels Spill Test Facility and now the Nonproliferation Test and Evaluation Complex). DOE/NNSA issued a FONSI based on this EA in September 2002. The facility is in operation.

***Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada (Yucca Mountain EIS)* (DOE/EIS-0250-F) (DOE 2002e) –** Published in 2002, the *Yucca Mountain EIS* analyzed a proposed action to construct, operate, monitor, and eventually close a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain in Nye County, Nevada. Following issuance of the *Yucca Mountain EIS* in 2002, DOE modified its approach to repository design and operational plans. In 2008, DOE published the *Final Supplemental Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (DOE/EIS-0250F-S1) (DOE 2008g). This supplemental EIS evaluated the potential environmental impacts of DOE's modified repository design and operational plans. As reflected in the Administration's fiscal year 2010, 2011, and 2012 budget requests, however, the Administration has determined that a repository at Yucca Mountain is not a workable option and has called for all funding and activities related to development of a repository at Yucca Mountain to be eliminated.

***Supplement Analysis for the Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada to Address the Increase in Activities Associated with the National Center for Combating Terrorism and Counterterrorism Training and Related Activities* (DOE/EIS-0243-SA-02) (DOE 2003e) –** This second SA to the *1996 NTS EIS* was prepared to determine whether impacts of DOE/NNSA operations, which include activities and potential facility and infrastructure improvements proposed for the NNSS related to combating terrorism and performing counterterrorism training, would be within the limits of impacts identified in the *1996 NTS EIS.* DOE/NNSA determined that there were no significant new circumstances or information relevant to environmental concerns that would require preparation of a supplemental EIS or a new EIS (i.e., the existing *1996 NTS EIS* remained adequate based on the SA, in accordance with 10 CFR 1021.332(d)).

***Final Environmental Assessment for Activities Using Biological Simulants and Releases of Chemicals at the Nevada Test Site* (DOE/EA-1494) (DOE 2004c) –** This EA analyzed the potential environmental effects of conducting experiments, training, and other similar activities involving controlled releases of biological simulants (noninfectious bacteria, fungi, killed viruses, and similar materials) and low concentrations of various chemicals at the NNSS. DOE/NNSA issued a FONSI based on this EA in June 2004. These activities are ongoing at the NNSS.

***Radiological/Nuclear Countermeasures Test and Evaluation Complex, Nevada Test Site Final Environmental Assessment* (DOE/EA-1499) (DOE 2004f) –** This EA evaluated the potential effects of constructing and operating a Radiological/Nuclear Countermeasures Test and Evaluation Complex at the NNSS for post-bench-scale testing and evaluation of radiological and nuclear detection devices that may be used in transportation-related facilities. The new facility would be used by the U.S. Department of Homeland Security. DOE/NNSA issued a FONSI based on this EA in September 2004. The facility was constructed and is operational.

Final West Valley Demonstration Project Waste Management Environmental Impact Statement, West Valley Area Office, West Valley, NY (DOE/EIS-0337F) (DOE 2003) – This EIS evaluated the potential effects of the Department of Energy's proposed action to ship radioactive wastes that are either in storage, or that will be generated from operations over the specified 10-year period, to offsite disposal locations, and to continue its ongoing onsite waste management activities. The June 16, 2005, ROD (70 FR 35073) stated that DOE has decided to ship LLW and MLLW off site for disposal in accordance with all applicable regulatory requirements, including permit requirements, WAC, and applicable DOE Orders. DOE will dispose of LLW and MLLW at commercial sites (such as Envirocare, a commercial radioactive waste disposal site in Clive, Utah), one or both of two DOE sites (the Nevada Test Site [NTS] in Mercury, Nevada; or the Hanford Site in Richland, Washington), or a combination of commercial and DOE sites, consistent with DOE's February 2000 decision regarding LLW and MLLW disposal.

Draft Revised Environmental Assessment, Large-Scale, Open-Air Explosive Detonation, DIVINE STRAKE, at the Nevada Test Site **(DOE/EA-1550) (DOE 2006e) –** This draft revised EA was published in December 2006 to document an analysis of the potential impacts of a proposal by the Defense Threat Reduction Agency, a DOE/NNSA customer, to conduct a single large-scale, open-air explosive detonation of up to 700 tons of an ammonium nitrate and fuel oil mixture above an existing tunnel complex in Area 16 at the NNSS. This draft revised EA modified an earlier 2006 EA to include additional data and analyses. The proposed experiment was known as DIVINE STRAKE. The Defense Threat Reduction Agency cancelled the project.

Draft Environmental Impact Statement for the Disposal of Greater-Than-Class C (GTCC) Low-Level Radioactive Waste and GTCC-Like Waste (GTCC EIS) **(DOE/EIS-0375-D) –** On February 25, 2011, the U.S. Environmental Protection Agency issued a Notice of Availability (76 FR 10583) for this *Draft GTCC EIS* that addressed disposal of LLW generated by activities licensed by the U.S. Nuclear Regulatory Commission or an Agreement State that contains radionuclides in concentrations exceeding Class C limits, as defined in 10 CFR Part 61 (referred to as "greater-than-Class C [GTCC] LLW"), as well as disposal of DOE's GTCC-like waste. Currently, there is no location for disposal of GTCC LLW, although the Federal Government is responsible for such disposal under the Low-Level Radioactive Waste Policy Amendments Act (P.L. 99-240). The NNSS is being considered as one of seven candidate disposal sites in the *Draft GTCC EIS*. DOE is evaluating several disposal technologies in the *Draft GTCC EIS*, including above-grade vaults, intermediate-depth boreholes, and enhanced near-surface disposal facilities.

Draft Supplement Analysis for the Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada (2008 Draft NTS SA) **(DOE/EIS-0243-SA-03) (DOE 2008f) –** The *2008 Draft NTS SA* is the third SA and 5-year comprehensive review of the *1996 NTS EIS* (DOE 1996c). In preparation of the *2008 Draft NTS SA*, a systematic environmental impacts review was conducted to determine whether there were substantial changes in the actions considered in the *1996 NTS EIS* or significant new circumstances or information relevant to environmental concerns. Projects and activities introduced since the *1996 NTS EIS* ROD or proposed for the next 5 years were screened. The *2008 Draft NTS SA* was not finalized; instead, DOE/NNSA elected to proceed with a new SWEIS (this *NNSS SWEIS*) to provide an updated analysis of DOE/NNSA operations in Nevada. All comments from the *2008 Draft NTS SA* were considered in the scoping of this SWEIS.

Complex Transformation Supplemental Programmatic Environmental Impact Statement (Complex Transformation SPEIS) **(DOE/EIS-0236-S4) (DOE 2008l) –** In the *Complex Transformation SPEIS*, alternatives were analyzed for the potential environmental impacts of transforming the nuclear weapons complex into a smaller, more-efficient enterprise that can respond to changing national security challenges and ensure the long-term safety, security, and reliability of the nuclear weapons stockpile. The

NNSS was evaluated, but not selected, as a potential location for a consolidated plutonium center or a consolidated nuclear production center, both of which would entail consolidation of Category I/II special nuclear material. The NNSS was also evaluated, but not selected, as a potential site for consolidated hydrotesting, high-explosives research and development, and environmental testing.[2] In addition, existing DoD and DOE/NNSA test ranges (such as White Sands Missile Range in New Mexico and the NNSS) were considered as alternatives to continued use of the TTR for DOE/NNSA flight test operations. Two RODs were issued on December 19, 2008. In the ROD for Tritium Research and Development, Flight Test Operations, and Major Environmental Test Facilities (December 19, 2008, 73 FR 77656), DOE/NNSA decided to continue to conduct flight testing at the TTR in Nevada under a reduced footprint (i.e., 1 square mile) permit using a campaign mode of operations. The "campaign mode of operations" would continue operations at the TTR but reduce permanent staff and conduct tests and experiments by deploying DOE/NNSA and national laboratory personnel from other locations, as needed. In the ROD for Operations Involving Plutonium, Uranium, and the Assembly and Disassembly of Nuclear Weapons (December 19, 2008, 73 FR 77644), DOE/NNSA decided to transform the plutonium and uranium aspects of the complex into smaller and more-efficient operations while maintaining the capabilities DOE/NNSA needs to perform its national security missions.

***Environmental Assessment for a Solar Demonstration Project at the Nevada National Security Site* (DOE/EA-1842) –** DOE's Office of Energy Efficiency and Renewable Energy was preparing this EA in 2011 on its proposal to support the demonstration of concentrating solar power (CSP) technologies in Area 25 of the NNSS. The intent was to demonstrate technology advancements that are proven at a prototype level, but have not yet been demonstrated at a scale or for a sufficient period for deployment in a commercial setting. This proposed action has been indefinitely postponed and is no longer being addressed as a reasonably foreseeable action in this SWEIS.

1.6 Cooperating Agencies/Tribal Involvement

DOE/NNSA is the lead agency for this SWEIS. Under CEQ NEPA regulations, other Federal agencies, as well as state and local agencies and American Indian tribes, may request designation as cooperating agencies in the preparation of an EIS if they can offer special, relevant expertise or have legal jurisdiction over one of the affected areas being studied (40 CFR 1501.6 and 1508.5). Three government agencies requested cooperating agency status for this SWEIS: the U.S. Bureau of Land Management; the U.S. Air Force; and Nye County, Nevada. DOE/NNSA, as the lead agency, has designated these three organizations as cooperating agencies.

As mentioned in Section 1.1, American Indian groups were invited to participate in the preparation of this SWEIS, in accordance with DOE Order 144.1, *Department of Energy American Indian Tribal Government Interactions and Policy*. As a result of consultation with the CGTO, the AIWS prepared the summary assessments and recommendations that appear in text boxes placed throughout this SWEIS. The text boxes are shaded light brown and have a CGTO feather logo. The AIWS also prepared the text provided in Appendix C, "The American Indian Assessment of Resources and Alternatives Presented in the SWEIS." Appendix C summarizes the beliefs expressed by the CGTO regarding this SWEIS and contains (a) general concerns regarding long-term impacts of DOE/NNSA operations on the NNSS and (b) a synopsis of specific comments made by the AIWS for various chapters of this SWEIS. Although the consultation focused specifically on the three alternatives analyzed in this *NNSS SWEIS*, the CGTO responses in the text boxes and Appendix C also integrate relevant recommendations made by American Indian people regarding previous DOE/NNSA projects in which American Indians participated.

[2] *In this context, "environmental testing" refers to subjecting a test unit to specified, controlled environments such as vibration, shock, or static acceleration.*

1.7 Public Involvement Process in this *NNSS SWEIS*

During development of an EIS, the two main opportunities for public involvement occur during scoping and after issuance of the draft EIS (see **Figure 1–2**). This section describes the public involvement processes during scoping and after the *Draft NNSS SWEIS* was issued, as well as how the comments received from the public were incorporated into the development of this *Final NNSS SWEIS*.

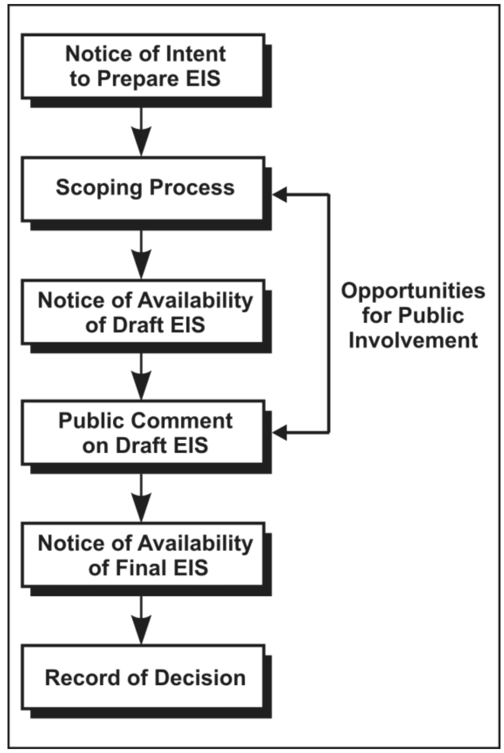

Figure 1–2 The National Environmental Policy Act Process

1.7.1 Scoping

As an early step in the development of an EIS, the regulations established by CEQ (40 CFR 1501.7) and DOE require "an early and open process for determining the scope of issues to be addressed and for identifying the significant issues related to a Proposed Action." The purpose of the scoping process is (1) to inform the public about a proposed action and the alternatives being considered and (2) to identify and clarify issues relevant to the EIS by soliciting public comments.

The *NNSS SWEIS* public scoping process began with issuance of a Notice of Intent (NOI) (74 FR 36691) on July 24, 2009, and concluded on October 16, 2009. In the NOI, DOE/NNSA invited public comment on the scope of this SWEIS and described four alternatives (No Action, Expanded Operations, Reduced Operations, and Renewable Energy Operations) and environmental issues to be considered. As discussed in Table 1–2, the components of the Renewable Energy Operations Alternative were incorporated as part of the three other alternatives in response to public comments, and Renewable Energy Operations was removed as a separate alternative. Public scoping meetings for this SWEIS were conducted in Las Vegas, Nevada (September 10, 2009); Pahrump, Nevada (September 14, 2009); Tonopah, Nevada (September 16, 2009); and St. George, Utah (September 18, 2009). DOE/NNSA received approximately 150 scoping comment documents regarding this *NNSS SWEIS*, submitted by email, fax, U.S. mail, telephone message, written comment forms at public meetings, or transcribed oral statements at public meetings. In addition, comments provided on the *2008 Draft NTS SA* were considered in developing the scope of this SWEIS.

While many of the comment documents were from private individuals, comment documents were also received from government and nongovernmental organizations, including the U.S. Environmental Protection Agency, the State of Nevada (Office of the Attorney General, State Historic Preservation Officer, Commission on Minerals, and Division of State Lands), Nye County, the Western Shoshone National Council, Tri-Valley Communities Against a Radioactive Environment (Tri-Valley CAREs), the Western States Legal Foundation, Citizens for Dixie's Future, and Nuclear Watch New Mexico. Comments on similar or related topics were grouped into common categories as a means of summarizing them. After the issues were identified, they were evaluated to determine whether they were appropriately relevant to the SWEIS. Relevent issues are addressed in the appropriate chapters or appendices of this SWEIS.

Scoping comments are summarized in **Table 1–2**, including DOE/NNSA's response and how the comments were incorporated into this SWEIS.

Table 1–2 Summary of Major Scoping Comments and DOE/NNSA Responses

General Topic	*Issue and Response*
Land Withdrawal	Commentors asked DOE/NNSA to identify concrete steps to reconcile the current uses of the NNSS with the uses identified in existing land withdrawals (i.e., to assure that ongoing or proposed activities at the NNSS will be lawful and permitted under existing Federal law). One commentor also recommended that DOE/NNSA consider each of its activities within the context of the land withdrawals and make a judgment as to whether it meets the purpose for which the withdrawal was issued. One commentor was concerned about the status of the land withdrawal. ***Response:*** *DOE/NNSA believes the land withdrawals are not restrictive with respect to NNSS activities in support of its three missions (National Security/Defense, Environmental Management, and Nondefense). As part of a Settlement Agreement (April 1997) between the State of Nevada and DOE, consultation with the U.S. Department of the Interior was initiated concerning the status of existing land withdrawals with regard to LLW storage and disposal. The consultation process concluded in November 2009, when DOE/NNSA accepted custody and control of the approximately 740 acres constituting the NNSS Area 5 Radioactive Waste Management Complex. Land withdrawal is discussed in Chapter 4, Section 4.1.1.3.*
Alternatives	DOE/NNSA received several comments related to the range of reasonable alternatives and the recommended scope of those alternatives. One commentor requested that this SWEIS be a programmatic document, given the range of decisions intended to be supported by the proposed EIS. Some commentors favored the cessation of all defense-related activities at the NNSS and the removal of associated infrastructure, with only environmental remediation and monitoring activities allowed to continue. One commentor specifically favored expansion of programs aimed at controlling the illicit use and transportation of nuclear materials. Another commentor provided a detailed recommendation for a "curatorship" approach in lieu of the current Stockpile Stewardship and Management Program. A commentor also requested that DOE/NNSA evaluate an alternative whereby the NNSS lands would be withdrawn permanently and DOE/NNSA would take responsibility for environmental impacts far into the future. In addition, commentors supported the inclusion of renewable energy development projects under the No Action, Expanded Operations, and Reduced Operations Alternatives, as opposed to under a separate alternative. One commentor stated that the Expanded Operations Alternative and the Renewable Energy Operations Alternative described in the "Alternatives for the SWEIS" section of the *Federal Register* NOI should be combined into a single Expanded Operations Alternative. ***Response:*** *This SWEIS tiers from DOE/NNSA and DOE programmatic EISs that have facilitated decisionmaking regarding the assignment of missions to the NNSS, such as supporting stockpile stewardship, maintaining nuclear testing capability, and disposing LLW and MLLW. These NEPA documents and related decisions are described in Section 1.5 of this chapter. This* NNSS SWEIS *would not provide the basis for a DOE complex-wide programmatic decision, but would provide the basis for site-specific implementation of those decisions that have already been made in existing programmatic EISs and other NEPA documents. DOE NEPA regulations (10 CFR 1021.330(c)) require that large, multiple-facility DOE sites, such as the NNSS, prepare SWEISs. This* NNSS SWEIS *addresses the full range of missions, programs, capabilities, projects, and activities under the purview of DOE/NNSA in Nevada.* *In response to public comments, conservation and renewable energy projects are addressed under each of the SWEIS alternatives (No Action, Expanded Operations, and Reduced Operations), and the Renewable Energy Operations Alternative was eliminated from consideration as a separate alternative. A curatorship approach, or cessation of NNSS' primary activities in support of DOE/NNSA's Defense Mission would be counter to national security policy as established by the Congress and the President. Therefore, ending these activities at NNSS (including switching to a curatorship approach) is not being considered in the SWEIS. Expansion of programs aimed at controlling the illicit use and transportation of nuclear materials is evaluated under the Expanded Operations Alternative (see Section 3.2.1.1). Chapter 3, Section 3.5, of this SWEIS provides further discussion of alternatives eliminated from detailed study.*

General Topic	*Issue and Response*
Alternatives (continued)	A commentor stated that the only actions that should be considered within the No Action Alternative are actions that are currently ongoing or in existence at the NNSS. ***Response:*** *In response to this comment, SWEIS alternatives were restructured. The No Action Alternative now reflects the current missions, programs, capabilities, projects, and activities. It includes reasonably foreseeable actions not yet implemented, but analyzed and approved under previous NEPA decisions.* Commentors showed preferences for particular alternatives. One commentor stated that the Nation's pressing needs in the areas of defense technology testing and counterterrorism preparedness, along with the suitability of the NNSS to support such programs, make the Expanded Operations Alternative the preferred choice. Another commentor favored the Reduced Operations Alternative, with a focus on phasing out unnecessary defense programs in light of changing national policies to focus more on remediation and alternative energy research. ***Response:*** *DOE/NNSA has selected a Preferred Alternative and included it in this* Final NNSS SWEIS. *The Preferred Alternative is a hybrid that incorporates programs and projects from all three of the analyzed alternatives. Additional information on the Preferred Alternative is included in Chapter 3, Section 3.6, of this SWEIS. Renewable energy projects have been consolidated into the Conservation and Renewable Energy Program under the Nondefense Mission and have been incorporated into each of the three alternatives considered in this NNSS SWEIS: No Action, Expanded Operations, and Reduced Operations.* A commentor stated that this SWEIS should evaluate a potential future scenario in which DOE/NNSA must maintain sole control of vast areas of the NNSS that must remain perpetually isolated from other uses. This alternative would require DOE/NNSA to seek congressional legislation to establish a perpetual withdrawal of land and would have significant implications in terms of long-term stewardship, costs, etc. Additionally, a commentor stated that this SWEIS should consider closing the NNSS in its entirety (Discontinued Operations Alternative). ***Response:*** *Closure of the NNSS with or without perpetual control and isolation would not meet the purpose and need for agency action as identified in Section 1.2 of this chapter. Should the missions of the NNSS change such that perpetual control and isolation is a valid scenario during the 10-year planning period, either through presidential decision directives or congressional direction, DOE/NNSA would determine through the supplement analysis process whether additional NEPA analysis is warranted.* A commentor stated that this SWEIS should describe how each alternative was developed, how it addresses each project objective, and how it would be implemented. ***Response:*** *Chapter 3 of this SWEIS describes how each alternative was developed and presents information on programs supporting the missions, as well as specific information on the implementation of the projects (such as the number of tests, experiments, or training activities; location/facility; and purpose of activity).*

<table>
<tr><th>General Topic</th><th>Issue and Response</th></tr>
<tr><td>Transportation</td><td>DOE/NNSA received comments regarding how analyses such as transportation of waste and other materials should be addressed. Commentors stated that this SWEIS should evaluate impacts associated with the transportation of wastes on communities along the shipping routes within Nevada and in corridor states. In addition, a commentor asked for assurances that shipments from offsite waste generators would continue to be prohibited from routes through the Las Vegas metropolitan area. One commentor asked that the waste disposal analysis identify waste volumes by specific generator or origin location, as well as specific transportation routes and times.

Response: This SWEIS presents the potential transportation impacts on communities along shipping routes in Nevada including routes through Las Vegas and representative routes in corridor states (see Chapter 5, Section 5.1.3.1, and Appendix E, "Evaluation of Human Health Effects from Transportation"). DOE/NNSA sought to understand the differences in potential environmental effects between different routing options, which incorporated changes to local transportation infrastructure since the 1996 NTS EIS; communicate those differences to the public; and seek stakeholder comments on the range of transportation routes. Specific LLW/MLLW waste generators tied to specific waste streams are not addressed in the transportation analysis; instead, reference routes were used. Existing waste generators are identified in Appendix A, "Detailed Description of Alternatives." Total estimated waste volumes by waste type were used to calculate transportation impacts.

A commentor stated that this SWEIS should contain an analysis of how intermodal transport (rail-to-truck transfer) would be done (if planned) and a comprehensive evaluation of risks and impacts, regardless of where the intermodal transfer(s) would take place.

Response: An analysis of rail-to-truck transport is included in the transportation analysis of this SWEIS (see Chapter 5, Section 5.1.3.1).</td></tr>
<tr><td>Contamination</td><td>DOE/NNSA received comments requesting that this SWEIS contain the following analyses:
A comprehensive analysis of contamination from all activities that have occurred and are ongoing at the NNSS and offsite locations
An assessment of what has been "cleaned up" since the inception of DOE's Environmental Management Mission and what remains to be assessed and remediated for industrial sites, contaminated soils, and groundwater under the Environmental Management Mission programs at the NNSS and all offsite locations for the foreseeable future
An extensive analysis of groundwater contamination within the NNSS to determine to what extent and where contamination is or could be migrating off site
Response: Impacts from contamination (including impacts to groundwater) are analyzed in Chapter 5, "Environmental Consequences," and Chapter 6, "Cumulative Impacts." A description of the Environmental Restoration Program, (including an update on Environmental Restoration Program projects and activities and remaining projects and activities to clean up the NNSS) is included in Chapter 3, Section 3.1.2.2, and in more detail in Appendix A, Section A.1.2.2.</td></tr>
<tr><td>Nye County Impacts</td><td>DOE/NNSA received the following comments from Nye County, in summary: (1) Nye County believes that significant adverse impacts and losses of natural resources have occurred that must be mitigated; (2) environmental monitoring will not suffice as a mitigation measure; and (3) this SWEIS must address the legacy of environmental insult that has occurred and define appropriate measures to mitigate the massive loss of natural resources.

Response: Groundwater resources at the NNSS, including groundwater groundwater monitoring and quality and known contamination, are described in Chapter 4, Section 4.1.6.2, of this SWEIS. Section 4.1.5.4 describes soil contamination at the NNSS. Impacts from previous activities at the NNSS and offsite locations are included in the analysis of cumulative impacts presented in Chapter 6, "Cumulative Impacts," of this SWEIS. Chapter 6 analyses of potential environmental impacts generally encompass the impacts of past, present, and reasonably foreseeable actions. Text provided by Nye County describing its perspective on cumulative impacts of primarily Federal actions has been included in its entirety in Chapter 6. Programs to identify contamination from previous activities are ongoing and the results made public when available.</td></tr>
</table>

General Topic	***Issue and Response***
Waste Disposal	Commentors requested that this SWEIS contain a comprehensive and thorough evaluation of all current and potential waste disposal activities at the NNSS, including LLW, MLLW, transuranic waste, GTCC waste, depleted uranium, and any other existing or foreseeable waste stream. ***Response:*** *The Waste Management Program is part of the Environmental Management Mission performed at the NNSS. Chapter 3 describes the Waste Management Program activities to be performed under each of the alternatives analyzed in this SWEIS. Under all of the alternatives, the NNSS would continue to receive LLW and MLLW, including depleted uranium waste streams, for disposal. Transuranic waste would not be disposed at the NNSS, but would be transferred off site for disposal at the Waste Isolation Pilot Plant. DOE has prepared the* Draft Environmental Impact Statement for the Disposal of Greater-Than-Class C (GTCC) Low-Level Radioactive Waste and GTCC-Like Waste *(DOE/EIS-0375) to evaluate the potential environmental impacts of siting and operating a GTCC disposal facility or facilities. The GTCC facility is included in the cumulative impacts analysis in Chapter 6. Chapter 5, Section 5.1.11, of this SWEIS contains a thorough analysis of the capacity of the waste management system to manage all current and potential NNSS waste streams.* Commentors requested that this SWEIS also identify waste volumes by generator/origin location, where such waste would be disposed, the facilities required (existing and new), the transportation requirements for moving various waste streams from generator locations to the NNSS for disposal, the interrelationships of waste disposal activities, and the cumulative impacts associated with all of the current and future NNSS onsite and offsite waste disposal activities. ***Response:*** *Consistent with the* 1996 NTS EIS *Record of Decision and the 2000 amended 1996 ROD, this SWEIS does not evaluate specific generators tied to specific waste streams because of the variability that can occur in both waste stream characteristics and future waste volumes. Instead, this SWEIS evaluates the potential impacts of transporting and disposing LLW and MLLW that meet the NNSS WAC based on transportation from various regions of the country. The list of waste generators used in the analysis of potential impacts is included in Appendices A and E.*
	Commentors requested that this SWEIS discuss the following topics and assess their programmatic, environmental, and legal ramifications: disposal of various waste streams; the interrelationships of waste disposal activities; and the cumulative impacts associated with all of the current and future on- and offsite NNSS waste disposal activities, and, in particular, plans to accept new LLW streams, including any that may be of commercial origin. ***Response:*** *Chapter 5, Section 5.1.11, of this SWEIS contains a thorough analysis of all current and potential NNSS waste disposal activities and waste streams. Additionally, cumulative impacts of waste management activities are evaluated in Chapter 6, "Cumulative Impacts." See the next response concerning waste of commercial origin.* A commentor requested that this SWEIS address DOE's proposal for taking LLW from commercial entities, subsequently declaring it to be DOE waste, and disposing it at the NNSS. ***Response:*** *In reference to activities performed by DOE's Office of Global Threat Reduction, the goal of the Offsite Source Recovery Project is to recover excess, unwanted, or abandoned sealed (radioactive material) sources that pose a potential risk to health, safety, and national security. DOE/NNSA takes ownership of some sealed sources under its Global Threat Reduction Initiative. If no reuse of these sealed sources is identified, they may be declared waste and be disposed as LLW. Within this SWEIS these sealed sources are included in the waste management and transportation analyses, representing less than 0.03 percent of the volume of LLW for the No Action and Reduced Operations Alternatives and less than 0.02 percent of the Expanded Operations Alternative LLW volume.*

General Topic	*Issue and Response*
Coordination and Consultation	A commentor stated that this SWEIS should acknowledge Nevada's important role in overseeing aspects of NNSS activities that are of special concern to the state and the importance of the Agreement in Principle framework for cooperative efforts. In addition, commentors stated that this SWEIS should evaluate the potential for more formal state regulatory oversight of LLW activities, such as the application of the state's authority (delegated by the U.S. Nuclear Regulatory Commission) to oversee LLW disposal operations at the NNSS. ***Response:*** *LLW is managed solely under DOE directives pursuant to DOE's Atomic Energy Act authority. The U.S. Nuclear Regulatory Commission does not have regulatory authority over DOE's LLW program. However, DOE and NDEP have an Agreement in Principle whereby NDEP participates in the Low-Level Waste Acceptance Program. The discussion of the Agreement in Principle, under which the State of Nevada provides enhanced oversight of DOE's management of MLLW is included in Section 9.1.1 of this SWEIS.* DOE/NNSA received several comments addressing outreach and consultations. Commentors urged continued dialogue and collaborative planning efforts with local American Indian groups in the NEPA process. A commentor stressed the need for consultations with the State Historic Preservation Office on this SWEIS and recommended that the alternatives describe the consultation process for key issues, including cultural resources surveys and impact assessments. Commentors stated that the NNSS should pursue more partnerships with local organizations, including the University of Nevada at Las Vegas and Nye County businesses, for future research and testing projects. One commentor stated that DOE/NNSA should consider additional opportunities for training local first responder personnel at the NNSS. ***Response:*** *Outreach and consultations are discussed in Section 1.6 and Chapter 10, "Consultation and Coordination." American Indian groups have been invited to participate in the preparation of this SWEIS. Text prepared by the Consolidated Group of Tribes and Organizations' American Indian Writers Subgroup appears in text boxes throughout this SWEIS and as Appendix C. DOE/NNSA is carrying out consultations with the State Historic Preservation Office and the U.S. Fish and Wildlife Service, as appropriate. Descriptions of these consultation processes appear in the cultural resources and biological resources impacts sections of this SWEIS. DOE/NNSA will consider proposals for research and development projects from academic institutions, other government agencies, and private companies and individuals. First responder training is included under the Nuclear Emergency Response, Nonproliferation and Conterterrorism Programs, and the Work for Others Program described in Chapter 3.* Nye County requested that DOE/NNSA consider the benefits of partnering with Nye County for delivery of infrastructure services. ***Response:*** *Although this comment is not within the scope of this SWEIS, DOE/NNSA will take this under consideration.*
	Nye County suggested that it conduct the groundwater characterization program for DOE/NNSA. Nye County offered to provide a fully developed programmatic alternative for review in this SWEIS. ***Response:*** *DOE/NNSA conducts a robust Underground Test Area (UGTA) Project. DOE/NNSA will continue to interact with Nye County on this UGTA Project. Nye County did not prepare an alternative for the SWEIS.*
	Nye County suggested that the draft and final SWEIS incorporate text it prepared for inclusion in the discussion of cumulative impacts presenting the Nye County perspective. ***Response:*** *Nye County text has been included in its entirety in the cumulative impacts discussion in Chapter 6.*

General Topic	*Issue and Response*
Land Use	A comment was made that this SWEIS should address the land transfer and all incidental activities contemplated for this area, including closure of Pit 3 and new state-imposed permitting requirements under RCRA. ***Response:*** *In November 2009, 740 acres in Area 5 of the NNSS were transferred for custody and control to DOE/NNSA. Chapter 5, Section 5.1.11, of this SWEIS contains a thorough analysis of all current and potential NNSS waste disposal activities, including establishment of a new mixed-waste cell under a new RCRA permit.*
Yucca Mountain	A commentor stated that this *NNSS SWEIS* must: • Fully evaluate the relationship between the potential repository and NNSS activities • Assess any potential cumulative impacts with respect to the former DOE Yucca Mountain Project • Identify, assess, and address the combined effects of these two facilities and related associated activities ***Response:*** *As indicated in the fiscal year 2010, 2011, and 2012 budget requests, the Administration decided to cease funding and activities related to development of a repository at Yucca Mountain while developing alternative storage and disposal approaches for spent nuclear fuel and high-level radioactive waste. Proposed actions associated with the former Yucca Mountain Project included construction, operation, monitoring, and eventual closure of a geologic repository at Yucca Mountain for disposal of spent nuclear fuel and high-level radioactive waste in storage or projected to be generated at 72 commercial and 5 DOE sites across the United States. In 1994, the DOE/Nevada Operations Office (the predecessor of the DOE/NNSA NSO) entered into a management agreement with the DOE Yucca Mountain Site Characterization Office for use of about 58,000 acres of NNSS land for site characterization activities related to the former Yucca Mountain Project. Under the agreement, the former Yucca Mountain Project was responsible for meeting the same environmental requirements that applied to the NNSS independent of, but in coordination with, the NNSS organizations. DOE/NNSA now maintains the infrastructure and buildings and provides security and support to DOE to remain compliant with Federal and state regulations pursuant to existing site permits.* *DOE recognizes that it has an obligation to remediate lands disturbed by past activities associated with the former Yucca Mountain Project. Accordingly, DOE has evaluated the potential cumulative impacts of remediating the lands and closing the infrastructure and buildings at Yucca Mountain (see Chapter 6 of this SWEIS). This analysis is based on the preliminary approach to remediating and closing the Yucca Mountain Site and facilities described under the No Action Alternative in the* Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada *(DOE 2002e). The preliminary approach analyzed in Chapter 6 of this SWEIS represents but one of many approaches. Upon receipt of appropriations, DOE plans to prepare a detailed proposal to remediate the lands and close the infrastructure and buildings, as required by law, regulations, and applicable agreements, and then undertake further NEPA review, as appropriate. After completion of site closure, DOE will initiate a long-term surveillance program.*
Cumulative Impacts	A commentor stated that the analysis of cumulative impacts in this SWEIS must include the following: • A comprehensive evaluation of the combined impacts of all activities, programs, and projects currently ongoing at the NNSS or reasonably foreseeable in the future • An assessment of impacts from past NNSS activities and an examination of how they interact with impacts from current and future activities • An assessment of the cumulative impacts on groundwater from past activities, in combination with potential additional contamination from current and future NNSS activities ***Response:*** *Chapter 6, "Cumulative Impacts," contains a comprehensive evaluation of cumulative impacts, including past, present, and reasonably foreseeable activities and cumulative groundwater impacts.*

General Topic	*Issue and Response*
Project Shoal, Central Nevada Test Area, and the Tonopah Test Range	A commentor stated that this SWEIS should contain an assessment of environmental conditions (surface and subsurface) for Project Shoal and the Central Nevada Test Area to establish environmental baselines against which any future impacts may be measured. ***Response:*** *Remediation of the surface contamination at the Project Shoal and Central Nevada Test Area sites was completed. Responsibility for the sites and ongoing characterization, monitoring, and/or remediation of subsurface impacts has been transferred to the DOE Office of Legacy Management for long-term stewardship. These sites are no longer under DOE/NNSA control and, by agreement with the DOE Office of Legacy Management, they are not addressed in this* NNSS SWEIS.
	A commentor stated that this SWEIS should address DOE/NNSA Environmental Management Mission and DOE/NNSA activities at the NNSS and NNSS-related sites and locations. Of particular concern is plutonium contamination on the Tonopah Test Range. ***Response:*** *DOE/NNSA Environmental Management Mission activities (under the Environmental Restoration Program) at the NNSS, Tonopah Test Range, and Nevada Test and Training Range are evaluated in this SWEIS.*
NEPA Implementation	A commentor requested that the period for comments on the draft SWEIS should be no less than 180 days. ***Response:*** *DOE/NNSA lengthened the comment period from 60 days (see NOI) to 126 days in response to commentors' requests.* A commentor requested that the public hearings be held in locations throughout Nevada and in other states affected by NNSS activities (including, but not limited to, the transportation of radioactive and hazardous materials to and from the NNSS). ***Response:*** *Public hearings were held in Las Vegas, Pahrump, Tonopah, and Carson City in Nevada and St. George in Utah.* A commentor requested that the hearings be structured so as to meaningfully facilitate public comments, i.e., in such a way that permits individuals to make comments for the record in a public forum. ***Response:*** *Comments were taken and recorded in a public hearing format. In addition, the open-house format was set up to allow the general public a better forum to ask questions and have one-on-one discussions with the DOE/NNSA subject matter experts.* A commentor requested that all related EISs, environmental assessments, categorical exclusions, and referenced documents be made publicly available online. ***Response:*** *Many DOE EISs and environmental assessments are available online at the DOE NEPA website (http://nepa.energy.gov). Occasionally, due to national security requirements, some NEPA documents are not available online. The references for this SWEIS are available at the public reading rooms listed on the cover page of this SWEIS, and copies also may be obtained by request.* A commentor stated that the purpose and need should be a clear, objective statement of the rationale for the proposed project. ***Response:*** *DOE/NNSA has provided a detailed description of the purpose and need in Section 1.2.*
Terrorism and Sabotage	A commentor requested that this SWEIS evaluate risks and impacts relating to acts of terrorism and sabotage against NNSS-related radioactive materials shipments. ***Response:*** *A classified appendix with this information was prepared in conjunction with this SWEIS. Pertinent unclassified data from the appendix are included in Chapter 5, Section 5.1.12.3.*

General Topic	Issue and Response
Renewable Energy	Commentors stated that renewable energy should be adopted as a secondary mission. ***Response:*** *Renewable energy research and development, as well as commercial development, are discussed in this SWEIS.* A commentor stated that the environmental consequences associated with reasonable buildout of renewable energy facilities should be evaluated in this SWEIS. ***Response:*** *DOE/NNSA concurs with the commentor and has included renewable energy projects in all alternatives evaluated in this SWEIS.* The U.S. Environmental Protection Agency commented that it supports increasing the development of renewable energy resources. ***Response:*** *DOE/NNSA acknowledges the U.S. Environmental Protection Agency's support for renewable energy.* Commentors asked for clarification of the renewable energy technologies considered in this SWEIS. ***Response:*** *Each of the three alternatives includes renewable energy projects. Each alternative includes a commercial solar power generation facility that varies among the alternatives in terms of electricity-generating capacity, as described in Chapter 3. All the commercial solar projects would be located in Area 25 of the NNSS. In addition, the Expanded Operations Alternative includes a project to install a photovoltaic system in Area 6 and a project to demonstrate the feasibility of enhanced geothermal electricity-generating systems in other locations on the NNSS. Because there are no proposals for the commercial-scale solar power generation facilities or geothermal electricity generation, additional NEPA review would be required if a specific proposal is considered by DOE/NNSA.*
Water Resources	Nye County stated that access limitations to water resources on withdrawn lands constitute a significant, adverse impact on the socioeconomic condition of Nye County. The impact is an indirect result of land access restrictions that have no demonstrated basis and must be recognized and identified as an impact on Nye County in this SWEIS. ***Response:*** *Access restrictions are an integral part of the security of the NNSS. Nye County text concerning lack of access to water resources on withdrawn lands is incorporated in its entirety in Chapter 6, "Cumulative Impacts."*
Potential Impacts	The U.S. Environmental Protection Agency requested that specific discussions and data regarding the following issues related to renewable energy projects be incorporated into this SWEIS: • Water supply and quality • Disposal of discharges • Clean Water Act, Sections 404 and 303(d) • Biological resources and habitat • Invasive species • Indirect and cumulative impacts • Implementation of adaptive management techniques for mitigation measures • Climate change • Air quality • Coordination with American Indian tribal governments • Environmental justice • Hazardous materials/hazardous waste/solid waste • Mitigation and pollution prevention • Coordination with land use planning activities ***Response:*** *The renewable energy projects in this SWEIS are not sufficiently defined to include this level of detail and would require additional NEPA review before being implemented.*

General Topic	*Issue and Response*
Potential Impacts (cont'd)	A commentor stated that this SWEIS should clearly describe the rationale used to determine whether impacts of an alternative are significant and suggested that thresholds of significance consider the context and intensity of an action and its effects. ***Response:*** *Wherever possible, impacts are quantified and compared with regulatory standards, system capacities, or other appropriate data. The criteria for determining whether the proposed alternatives impact each resource are identified in each of the Chapter 5 resource impacts sections.* A commentor requested that groundwater contamination from radionuclides or other materials, airborne pollutants, and the full range of other environmental impacts be evaluated in relation to their impacts on people and the environment in communities and areas surrounding the site and along transportation corridors leading to and from the NNSS. ***Response:*** *This SWEIS analyzes the potential direct and indirect impacts on people and the environment from groundwater contamination, transportation impacts, airborne pollutants, and all other emissions, as well as impacts on other resources (such as cultural resources and socioeconomic resources). These impacts are presented in Chapter 4, "Affected Environment," Chapter 5, "Environmental Consequences," and Chapter 6, "Cumulative Impacts."* A commentor stated that impacts must be considered in a global context. ***Response:*** *Global impacts such as the contribution of greenhouse gas emissions from activities at the NNSS and offsite locations and as a result of the transportation of radioactive materials and wastes are analyzed and included in Section 5.1.8, Air Quality and Climate. DOE/NNSA complex-wide impacts were analyzed in a separate programmatic EIS (*Final Complex Transformation Supplemental Programmatic Environmental Impact Statement *[DOE 2008l]).*
Treaty of Ruby Valley	A commentor was in favor of returning lands to the Western Shoshone. ***Response:*** *The U.S. Supreme Court ruled against claims by the Western Shoshone under the Ruby Valley Treaty. DOE/NNSA is aware of significant disagreement with the rulings of the U.S. Supreme Court by the Western Shoshone.*

CFR = *Code of Federal Regulations*; EIS = environmental impact statement; GTCC = greater-than-Class C; LLW = low-level radioactive waste; MLLW = mixed low-level radioactive waste; NDEP = Nevada Division of Environmental Protection; NEPA = National Environmental Policy Act; NNSA = National Nuclear Security Administration; NNSS = Nevada National Security Site; NOI = Notice of Intent; NSO = Nevada Site Office; NTS = Nevada Test Site; RCRA = Resource Conservation and Recovery Act; SWEIS = site-wide environmental impact statement; UGTA = Underground Test Area; WAC = waste acceptance criteria.

1.7.2 *Draft NNSS SWEIS* Public Involvement

On July 29, 2011, DOE/NNSA published a notice in the *Federal Register* (76 FR 45548) announcing the availability of the *Draft NNSS SWEIS*, the duration of the period for the public to submit comments, the location and timing of the public hearings, and the various methods for submitting comments on the draft to DOE/NNSA (such as online, email, fax, telephone, U.S. postal service, or oral/written comments at public meetings). DOE/NNSA announced a 90-day comment period, from July 29, 2011, to October 27, 2011, to provide time for interested parties to review the *Draft NNSS SWEIS*. In response to requests for additional review time, the comment period was extended by 36 days, through December 2, 2011, giving commentors a total review and comment period of 126 days (76 FR 65508).

During the public comment period, five public hearings were held to provide interested members of the public with opportunities to learn more about DOE/NNSA missions, programs and activities and the content of the draft SWEIS from exhibits, factsheets, and discussion with DOE/NNSA subject matter experts. From September 20 through 28, 2011, public hearings were held in Las Vegas, Pahrump, Tonopah, and Carson City, Nevada and St. George, Utah. An additional SWEIS hearing was conducted for the CGTO on October 6, 2012. Members of the public provided oral and written comments during the

hearings. Additional information on the public hearing and other stakeholder informational meetings is contained in the Comment Response Document (Volume 3 of this *NNSS SWEIS*).

Additionally, a website (www.nv.energy.gov/sweis) was established to further inform the public about the draft SWEIS, how to submit comments, and other pertinent information.

1.7.2.1 *Draft NNSS SWEIS* Comment Summary

In reviewing the comments on the *Draft NNSS SWEIS*, DOE/NNSA identified several topics that were of heightened interest or concern to stakeholders, or resulted in generally substantive changes to relevant information and analyses in this SWEIS. These topics include:

- ***Radioactive Waste Transportation***. Commentors were concerned that DOE/NNSA was considering changing routes for shipping radioactive waste to allow shipment of waste through Las Vegas, and indicated the analysis should address site-specific conditions along the routes in the vicinity of Las Vegas. Additionally, commentors stated that the analysis of rail transfer stations was incomplete because specific operations and accidents that could occur at the analyzed rail transfer stations were not addressed.
- ***Groundwater Quality and Use***. Commentors stated that groundwater contamination from historic nuclear weapons testing poses an unacceptable risk to human health, and that the *Draft NNSS SWEIS* did not characterize this risk adequately. Commentors allege that this groundwater contamination and restrictions on public access to other groundwater on the NNSS constituted a loss of a valuable resource, which contributed to a lack of economic development.
- ***Former Yucca Mountain Project Site***. Commentors believed that DOE/NNSA should analyze, as a reasonably foreseeable future action, either the construction and operation of a high-level radioactive waste repository at Yucca Mountain, or the remediation and reclamation of the Yucca Mountain Site.
- ***American Indian Rights***. Commentors expressed concern that the U.S. Government is not abiding by the terms of the Treaty of Ruby Valley, and the lands encompassing the NNSS rightfully belong to the Western Shoshone people.
- ***Use of the NNSS***. Commentors contended that ongoing and proposed activities at the NNSS were not consistent with the purposes for which the land was originally withdrawn from public use, and stated that DOE/NNSA should consider returning some or all of the lands to public use.
- ***Nuclear Weapons Testing***. Commentors were opposed to resumption of nuclear weapons testing, and were concerned that resumption of testing was possible, despite the current moratorium on such tests.
- ***Renewable Energy***. Commentors were generally supportive of using the NNSS for research- and commercial-scale renewable energy projects, but expressed concerns that such projects, particularly commercial-scale projects, have the potential to cause adverse environmental impacts on many resources.

DOE/NNSA has responded to each public comment in the Comment Response Document (Volume 3) of this *Final NNSS SWEIS*.

1.7.2.2 Changes from the Draft Site-Wide Environmental Impact Statement

DOE/NNSA revised the *Draft NNSS SWEIS* in response to public comments, and provided additional environmental baseline information and new and revised analyses, including, but not limited to, the following:

- DOE/NNSA added information (figures and supporting text) regarding current and projected levels of surface soil and groundwater contamination.
- DOE/NNSA enhanced its cumulative effects analysis by including the remediation of the former Yucca Mountain Project Site as a reasonably foreseeable future action.
- DOE/NNSA added a human health impacts analysis for an alternate maximally exposed individual based upon a "subsistence consumer" lifestyle pattern.
- DOE/NNSA added an analysis of potential impacts associated with wildland fire events.
- DOE/NNSA has included new information regarding existing environmental conditions based upon more-recent, routine sampling and field data collection (e.g., groundwater contaminant sampling).

DOE/NNSA also corrected inaccuracies, made editorial corrections, and clarified text.

1.7.3 Next Steps

DOE/NNSA will announce its decision regarding the selected alternative or alternatives in a ROD no sooner than 30 days after the U.S. Environmental Protection Agency Notice of Availability for this *Final NNSS SWEIS* is published. The ROD will be published in the *Federal Register* and explain all factors, including the potential environmental impacts, considered by DOE/NNSA in reaching its decision. The ROD will identify the environmentally preferred alternative or alternatives. If mitigation measures, monitoring, or other conditions are adopted as part of DOE/NNSA's decision, these will be summarized in the ROD, as applicable, and included in a mitigation action plan that would be prepared following issuance of the ROD. The mitigation action plan would explain how and when mitigation measures would be implemented and how DOE/NNSA would monitor the mitigation measures over time to judge their effectiveness.

After DOE/NNSA issues its ROD, both the ROD and the mitigation action plan will be posted on DOE's NEPA website (http://nepa.energy.gov), and copies will be placed in the DOE/NNSA Reading Room in Las Vegas, Nevada, and in public libraries in southern Nevada and southwestern Utah; they also would be made available to interested parties upon request.

CHAPTER 2
SITE OVERVIEW AND UPDATE

2.0 SITE OVERVIEW AND UPDATE

Among the responsibilities of the U.S. Department of Energy and National Nuclear Security Administration (DOE/NNSA) are continued stewardship of the Nation's nuclear weapons stockpile and maintenance of a nuclear weapons testing capability. Historically, the primary mission at the Nevada National Security Site (NNSS) (formerly known as the Nevada Test Site) was to conduct nuclear weapons tests. Since the moratorium on nuclear weapons testing in October 1992, the focus at the NNSS has been to support the Stockpile Stewardship and Management Program. However, under a November 1993 Presidential Decision Directive, DOE/NNSA must be able to resume underground nuclear tests within 24 to 36 months if so directed by the President. The DOE/NNSA Nevada Site Office (NSO) maintains this test readiness at the NNSS. Because of its favorable environment and infrastructure, the NNSS also supports DOE waste management and disposal; DOE/NNSA counterterrorism training, research, and development; nuclear emergency response; nonproliferation; and other research related to national security and nondefense-related research, development, and testing programs.

This chapter of the *Site-Wide Environmental Impact Statement for the Continued Operation of the Department of Energy/National Nuclear Security Administration Nevada National Security Site and Off-Site Locations in the State of Nevada (NNSS SWEIS)* provides background on the NNSS and its main facilities, as well as other locations used to support DOE/NNSA missions. These facilities include the Remote Sensing Laboratory (RSL), the North Las Vegas Facility (NLVF), and the Tonopah Test Range (TTR) (see Chapter 1, Figure 1–1). While many programs and activities take place on the NNSS, several administrative and technical operations occur at other locations. Research, testing, and operations at RSL focus on conducting emergency response procedures and support, remote sensing, counterterrorism, and radiological incident response. RSL houses fabrication laboratories, shops, and advanced scientific equipment. The DOE/NNSA NSO's primary administrative offices are located at NLVF and house Federal and contractor personnel. In addition, facilities for engineering, fabrication, assembly, and calibration and laboratories are located at NLVF. Activities at the TTR support the Stockpile Stewardship and Management Program, as well as research and design of new weapons and weapon components. An overview of the changes that have occurred since DOE issued the *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada (1996 NTS EIS)* (DOE 1996c) is also provided. Some of the site descriptions include American Indian perspectives prepared by the American Indian Writers Subgroup (AIWS); the AIWS input is in text boxes identified with a Consolidated Group of Tribes and Organizations (CGTO) feather icon.

2.1 Nevada National Security Site

The NNSS occupies approximately 1,360 square miles of desert and mountain terrain in southern Nevada at the southern end of the Great Basin. Elevations range from 2,700 feet on Jackass Flats in the southern part of the NNSS to 7,680 feet on Rainier Mesa in the mountainous northern region (DOE/NV 2009d) (see **Figure 2–1**). Sparsely vegetated basins or flats, separated by low mountains, dominate the eastern side and southern end of the NNSS—Jackass Flats in the southwestern quadrant, Frenchman Flat and Mercury Valley in the southeastern quadrant, and Yucca Flat in the northeastern quadrant. Frenchman and Yucca Flats each contain a large playa. The northwestern quadrant of the site comprises mountains with a pinyon-juniper forest and sagebrush shrublands separated by canyons; the dominant topographic features in this area are the Shoshone and Timber Mountains near the center and western border and Rainier Mesa and Pahute Mesa in the northwestern region of the site (DOE 2002f; Wills and Ostler 2001).

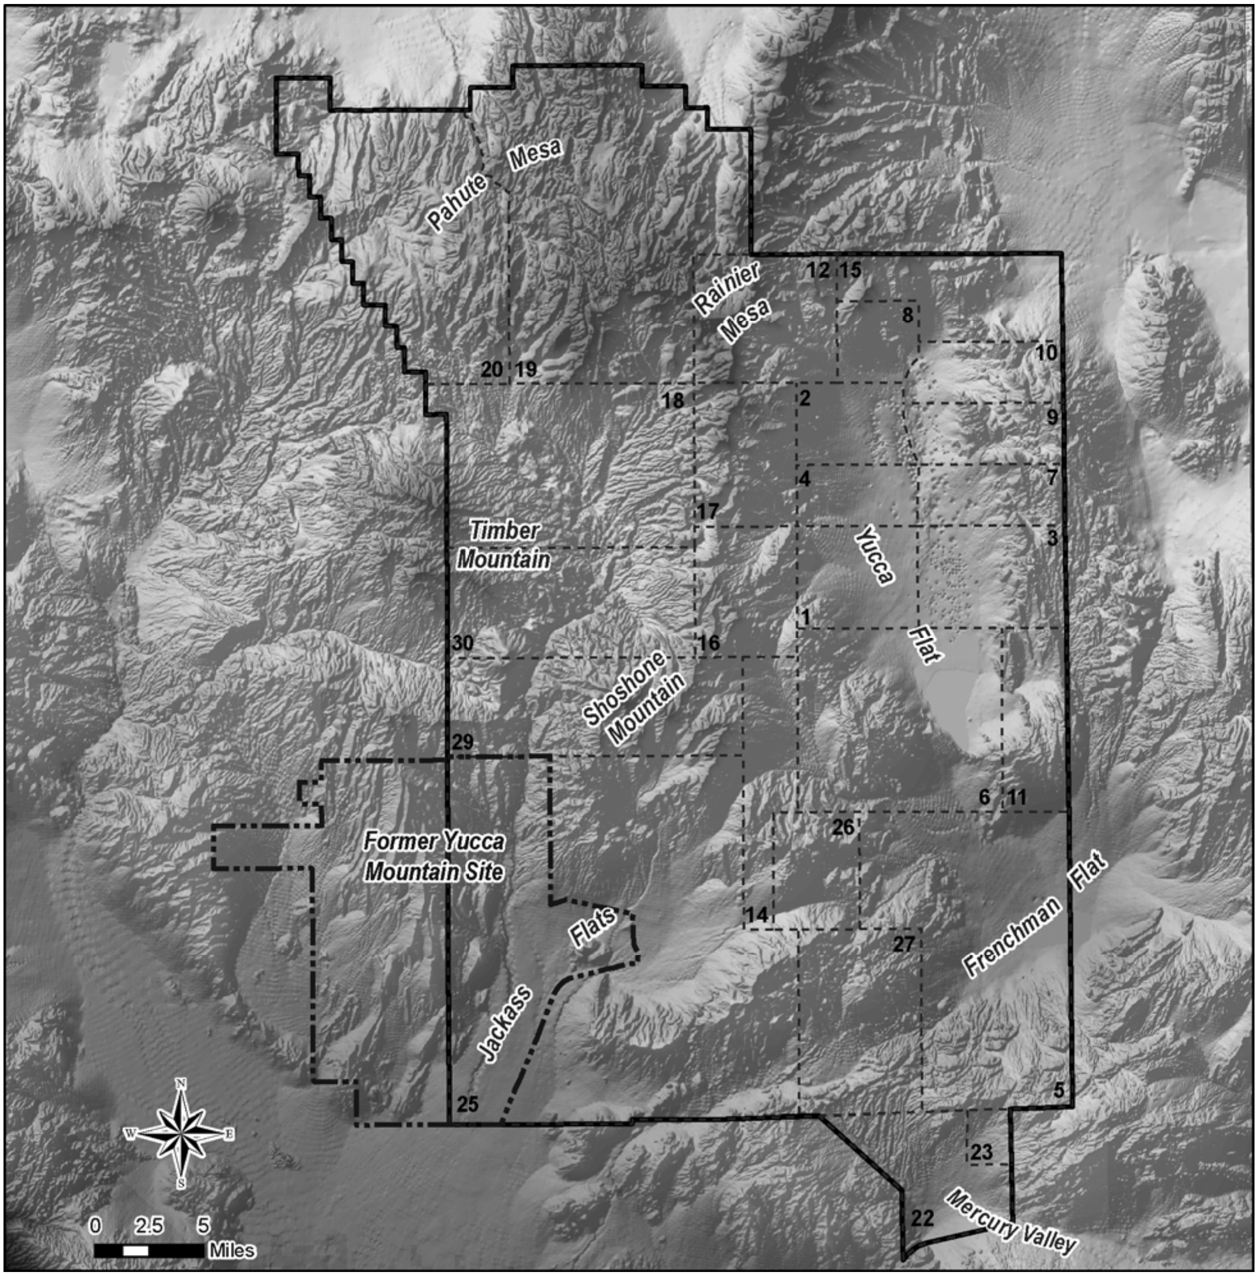

Figure 2–1 Geographic Areas of the Nevada National Security Site

About 6,500 square miles of the U.S. Air Force's (USAF's) Nevada Test and Training Range (formerly the Nellis Air Force Range) and the Desert National Wildlife Refuge surround the NNSS on the northern, western, and eastern sides. Most of the land adjacent to the NNSS is the Nevada Test and Training Range, which is used by the USAF for armament and high-hazard testing; aerial gunnery, rocketry, electronic warfare, and tactical maneuvering training; and equipment and tactics development and training. Public access to this land is restricted, so it serves as an additional buffer between NNSS activities and the general public. The overland distance from the southern edge of the NNSS (Gate 100 near Mercury) to downtown Las Vegas (the intersection of Interstate 15 and U.S. Route 95) is about 57 miles (NNSA 2007).

The NNSS is divided into numbered areas to facilitate management; communications; and the distribution, use, and control of resources (see **Figure 2–2**). The areas are numbered from 1 to 30, although four numbers are missing from the sequence (there are no Areas 13, 21, 24, or 28 on the NNSS). The numbering designations originated when the NNSS was part of the former Nellis Air Force Range (now called the Nevada Test and Training Range). The USAF has since changed the designations for the Nevada Test and Training Range, but the old numerical designations remain for the NNSS. The missing area numbers previously denoted areas on the range. The approximate size of each area (rounded to whole square miles) and a description of its function are provided in **Table 2–1**.

In addition to dividing the site into administrative areas, DOE/NNSA also categorizes the NNSS into land use zones. These zones are discussed in Chapter 4, Section 4.1.1.

American Indian Perspective of the NNSS Area and Offsite Locations

CGTO

The Nevada National Security Site (NNSS) area and offsite locations are part of the traditional holy lands of the Southern Paiute, Western Shoshone, and Owens Valley Paiute and Shoshone people. We share this land for medicinal purposes, food, and culturally significant places necessary for traditional narratives and religious ceremonies.

The Consolidated Group of Tribes and Organizations (CGTO) knows these lands contain archaeological remains left by our ancestors. They are home to countless natural resources, such as plants, animals, water, and minerals which are critical to American Indian daily life and religious beliefs. Our ancestral lands contain natural landforms that mark important locations for keeping our history alive and for teaching our children about our culture in detailed Winter Stories. We use traditional sites within these lands to make doctoring tools, stone objects, and ceremonial items. They contain many sites associated with traditional healing ceremonies and power places necessary for our cultural survival. Despite the current physical separation of tribes from our ancestral lands stemming from the actions by the Federal Government, American Indians continue to value and recognize their meaningful role in our culture and continued survival.

Numerous sites have been identified within the NNSS boundaries that are important to American Indian People. For example, Fortymile Canyon is a significant crossroad where trails from distant places such as Owens Valley, Death Valley, and the Avawatz Mountain come together. Black Cone in Crater Flat is an important religious site that is considered an entry to the underworld. Prow Pass is a unique ceremonial site and, because of this religious significance, tribal representatives have recommended DOE avoid affecting this area. Oasis Valley is a known area for trade and doctoring ceremonies. Other locations throughout this area are considered important based on the abundance of artifacts, traditional-use plants and animals, rock art, and potential burial sites.

See Appendix C for more details.

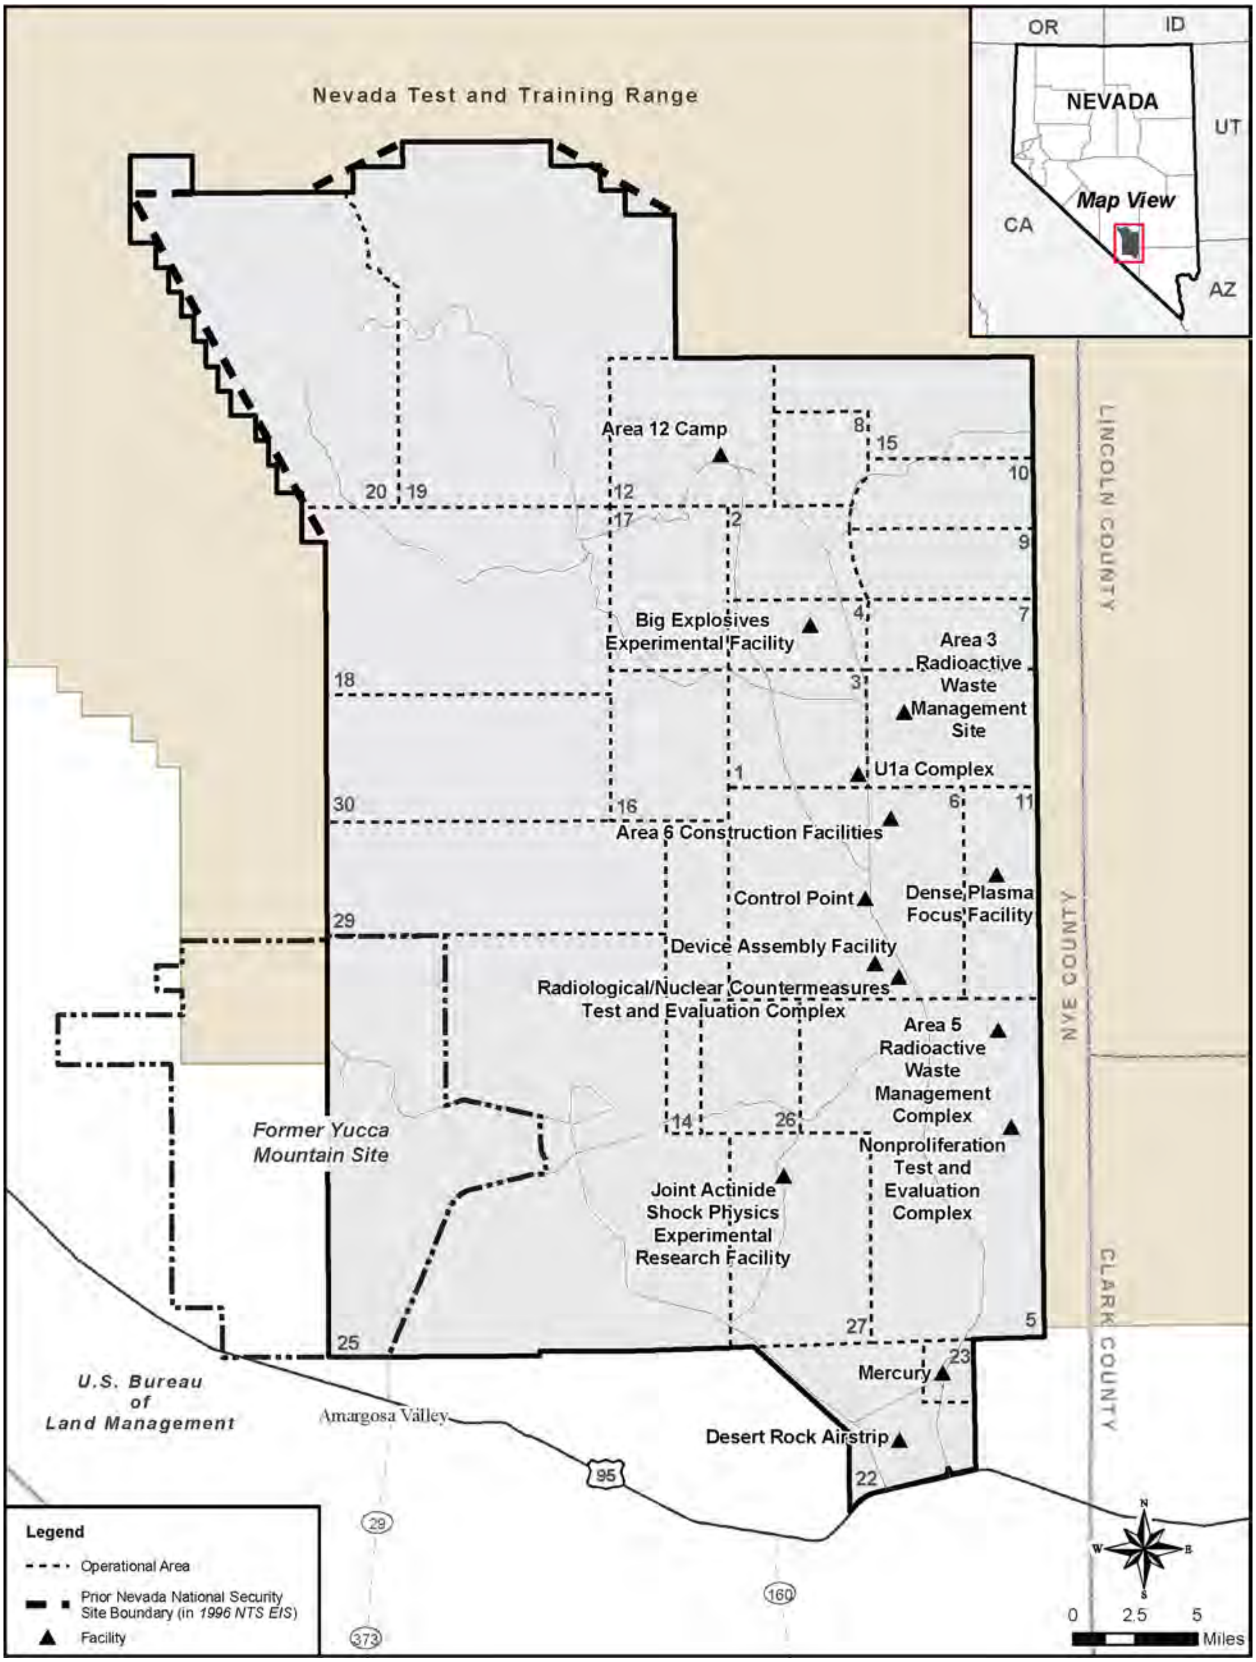

Figure 2–2 Nevada National Security Site Areas and Major Facilities

Table 2–1 Description and Historical Use of Nevada National Security Site Areas

Description of Nevada National Security Site (NNSS) Areas
Area 1—Area 1 occupies approximately 26 square miles of the Yucca Flat basin near the center of the site. The U1a Complex and the Area 1 Industrial Complex are located in Area 1. Area 1 was the site of four atmospheric nuclear tests between 1952 and 1955, and three underground tests (one in 1971 and two in 1990).
Area 2—Area 2 occupies approximately 19 square miles in the northern half of the Yucca Flat basin. The eastern portion of Area 2 was the site of 7 atmospheric nuclear tests conducted between 1952 and 1957. The first of 137 underground nuclear tests in Area 2 took place in late 1962, and tests continued through 1990.
Area 3—Area 3 occupies approximately 32 square miles near the center of the Yucca Flat basin. The Area 3 Radioactive Waste Management Site, which makes use of a group of subsidence craters for low-level radioactive waste disposal, is located in this area. Area 3 was the site of 17 atmospheric tests conducted between 1952 and 1958, and 251 underground nuclear tests from 1958 through 1992.
Area 4—Area 4 occupies approximately 16 square miles near the center of the Yucca Flat basin. The Big Explosives Experimental Facility is located in Area 4. Area 4 was the site of 5 atmospheric nuclear tests conducted between 1952 and 1957. From the mid-1970s through 1991, 35 underground nuclear tests were conducted in Area 4, mainly in the northeastern corner.
Area 5—Area 5 occupies approximately 111 square miles in the southeastern portion of the site and includes the Area 5 Radioactive Waste Management Complex, the Nonproliferation Test and Evaluation Complex, and the Nevada Desert Free Air Carbon Dioxide Enrichment and Mojave Global Change Facility environmental research sites. From 1951 through early 1962, 14 atmospheric tests were conducted at Frenchman Flat, in the northeastern portion of Area 5. Five underground nuclear weapons tests were conducted at Frenchman Flat between 1965 and 1968.
Area 6—Area 6 occupies approximately 81 square miles from the northern part of Frenchman Flat to the southern part of Yucca Flat, straddling Frenchman Mountain. Facilities in Area 6 include the Control Point Complex, Area 6 Construction Facilities, the Device Assembly Facility, the Radiological/Nuclear Countermeasures Test and Evaluation Complex, the Yucca Lake Aerial Operations Facility, and a Hydrocarbon Contaminated Soils Disposal Site. One atmospheric nuclear test was conducted in Area 6 (in 1957). Between 1968 and 1990, five underground nuclear tests were conducted in this area.
Area 7—Area 7 occupies approximately 19 square miles in the northeastern quadrant of the Yucca Flat basin. Twenty-six atmospheric tests were conducted in this area between 1951 and 1958. From 1964 through 1991, 62 underground nuclear tests were conducted in Area 7.
Area 8—Area 8 occupies approximately 14 square miles in the northern part of the Yucca Flat basin. Area 8 was the site of 3 atmospheric nuclear tests conducted in 1958. From 1966 through 1988, 10 underground nuclear tests were conducted in this area.
Area 9—Area 9 occupies approximately 20 square miles in the northeastern quadrant of the Yucca Flat basin. A construction and demolition debris landfill, using a subsidence crater, operates in Area 9. In Area 9, 17 atmospheric tests were conducted between 1951 and 1958, and 100 underground tests were conducted from 1961 to 1992.
Area 10—Area 10 occupies approximately 20 square miles in the northeastern quadrant of the Yucca Flat basin. Area 10 was the location of the Nation's first nuclear missile system test, an air-to-air rocket, detonated in mid-1957. There were 57 underground and shallow (called cratering) nuclear tests conducted in Area 10 between 1962 and 1991. The Sedan Crater, formed by a thermonuclear device in July 1962 as part of the Plowshare Program, is in Area 10. The Plowshare Program was designed as a research and development activity to explore the technical and economic feasibility of using nuclear explosives for industrial applications. The Sedan Crater is listed in the National Register of Historic Places.
Area 11—Area 11 occupies approximately 26 square miles along the central-eastern border of the NNSS. The Dense Plasma Focus Facility and an explosives ordnance disposal site are located in this area. Because of residual radioactive contamination from historic uses, this area is used intermittently for realistic drills in radiation monitoring and sampling. Four atmospheric safety tests were conducted in the northern portion of Area 11 in 1955 and 1956 in what is now known as Plutonium Valley. In addition to the aboveground safety tests, five underground nuclear weapons effects tests were conducted in Area 11 between 1966 and 1971.
Area 12—Area 12 occupies approximately 40 square miles along the northern boundary of the NNSS on Rainier Mesa. There are a number of tunnel complexes mined into Rainier Mesa that are used for experiments, including E-, G-, N-, P-, and T-Tunnel complexes. The Area 12 Camp was renovated and upgraded and will provide a secure base camp for military units and other government agencies for conducting counterterrorism and other exercises in the northern region of the NNSS. It provides an urban terrain setting, utilizing existing commercial, residential, and industrial buildings. The camp includes 200 dormitory rooms, a cafeteria, weapons and munitions storage, and numerous operations and support buildings. The DOE/NNSA Office of Secure Transportation currently uses it as a training facility. No atmospheric tests were conducted in Area 12; 61 underground nuclear tests were conducted in Area 12 between 1957 and 1992.

Table 2–1 Description and Historical Use of Nevada National Security Site Areas (continued)

Area 14—Area 14 occupies approximately 26 square miles in the central portion of the NNSS. Various outdoor experiments are conducted in this area. No atmospheric or underground nuclear tests were conducted in Area 14.
Area 15—Area 15 occupies approximately 35 square miles in the northeastern corner of the NNSS. No atmospheric tests were conducted in this area; between 1962 and 1966, three underground nuclear tests were carried out in Area 15. A facility that evaluated the effects of residual radiation on farm animals, called the EPA Farm, previously operated in this area.
Area 16—Area 16 consists of approximately 29 square miles in the central portion of the NNSS. Currently, DoD uses this area for high-explosives research and development in support of programs involving the detonation of conventional or prototype nonnuclear explosives and munitions and for developing tactics to defeat deeply buried and hardened targets. Area 16 was established in 1961 for DoD to conduct nuclear effects experiments. From mid-1962 through mid-1971, six underground nuclear weapons effects tests (all in the U16a Tunnel complex) were conducted in this area.
Area 17—Area 17 occupies approximately 31 square miles in the north-central portion of the NNSS. This area has been used primarily as a buffer between testing activities in other areas. No atmospheric or underground nuclear weapons tests were conducted in Area 17.
Area 18—Area 18 occupies approximately 88 square miles along the western border of the NNSS. The inactive Pahute Airstrip is located in the east-central portion of the area. The airstrip was used for the shipment of supplies and equipment for Pahute Mesa test operations. Area 18 was the site of five nuclear weapons tests from 1962 to 1964, two atmospheric tests, two cratering tests, and one underground test.
Area 19—Area 19 occupies approximately 146 square miles along the northern side of the NNSS. Area 19 was developed for high-yield underground nuclear tests. No atmospheric nuclear tests were conducted in Area 19. From the mid-1960s through 1992, 35 underground nuclear tests were conducted in this area.
Area 20—This area occupies approximately 97 square miles on Pahute Mesa in the northwestern corner of the NNSS. Area 20 was developed in the mid-1960s for high-yield underground nuclear tests. No atmospheric nuclear tests were conducted in Area 20. From the mid-1960s through 1992, 46 underground nuclear weapons tests were conducted in Area 20. In addition, 1 nuclear test detection experiment and 3 Plowshare Program tests were conducted in this area.
Area 22—Area 22 occupies approximately 31 square miles in the southernmost portion of the NNSS and serves as the main entrance (Gate 100) to the NNSS. Before 1958, this area included Camp Desert Rock, a U.S. Army installation used for housing troops taking part in military exercises at the NNSS. After 1958, the camp was removed, with the exception of the Desert Rock Airport. The airport is currently operational, but is only used by those authorized by DOE/NNSA.
Area 23—Area 23 occupies approximately 5 square miles near the southeastern corner of the NNSS. It is the location of Mercury, the largest operational support complex on the NNSS. Mercury was established in 1951 and serves as the main administrative and industrial support center at the NNSS. Mercury is located approximately 5 miles from U.S. Route 95. The Area 23 landfill, used to dispose nonhazardous solid waste, is located west of Mercury.
Area 25—Area 25, the largest area on the NNSS, occupies approximately 254 square miles in the southwestern corner of the site and includes an inactive entrance gate to the NNSS. Portions of Area 25 are used by the military for training exercises. The U.S. Army Ballistic Research Laboratory conducts open-air and X-tunnel tests using depleted uranium in Area 25. Research sites within Area 25 include the Treatability Test Facility (inactive) and Bare Reactor Experiment Nevada Tower, a 1,527-foot tower used by a number of organizations for a wide variety of research (e.g., sonic booms, meteorology, gravity drop tests, satellite infrared imaging). Located roughly in the center of Area 25, Jackass Flats was the site of ground experiments for reactors, engines, and rocket stages as part of a program to develop nuclear reactors for use in the Nation's space program.
Area 26—Area 26 occupies approximately 21 square miles in the south-central part of the NNSS. The southern portions of this area were used for nuclear-powered ramjet engine experiments, known as Project Pluto.
Area 27—Area 27 occupies approximately 49 square miles in the south-central portion of the NNSS. The Joint Actinide Shock Physics Experimental Research Facility is located in Area 27. Area 27 was used for weapons assembly and staging.
Area 29—Area 29 occupies approximately 62 square miles on the west-central border of the NNSS and includes portions of Fortymile Canyon. It is used primarily for military training and exercises. No nuclear weapons tests were conducted in Area 29.
Area 30—Area 30 occupies approximately 59 square miles at the center of the western edge of the NNSS. Area 30 has rugged terrain and includes the northern reaches of Fortymile Canyon. It is used primarily for military training and exercises. Area 30 had limited use in support of the Nation's nuclear weapons testing program, but was the site of Project Buggy, an experiment in the Plowshare Program.

DoD = U.S. Department of Defense; EPA = U.S. Environmental Protection Agency; NNSA = National Nuclear Security Administration; NNSS = Nevada National Security Site.
Source: DOE 1996c; DOE/NV 2000e.

2.1.1 Major Facilities

The NNSS provides a large area remote from the public at which a broad variety of research, experimentation, and training can be performed. Some of the activities conducted take advantage of the expanses of land at the NNSS. However, a comparatively small part of the NNSS is developed and has facilities that are routinely occupied or visited by NNSS personnel. The following is a list of the more prominent facilities at the NNSS. The locations of these facilities are shown in Figure 2–2.

U1a Complex. The U1a Complex (formerly called the Lyner Complex) in Area 1 is an underground laboratory used for performing subcritical experiments (see text box) in support of the Stockpile Stewardship and Management Program. **Figure 2–3** shows the aboveground facilities at the U1a Complex. It consists of a series of underground alcoves and test chambers about 960 feet below the ground surface. Three vertical shafts connect to the underground tunnels to provide ventilation, as well as personnel, equipment, instrumentation, and utility access. At the surface are 27 support buildings and a mechanical hoist for accessing the belowground areas. Experiments with high explosives and special nuclear material, including dynamic plutonium experiments (see text box), are conducted in small alcoves mined into the sidewalls or floors of the underground tunnels (DOE/NV 2004b). A Large-Bore Powder Gun used for shock physics experiments is scheduled to be installed in an alcove of the U1a Complex in 2015.

Subcritical Experiments

Subcritical experiments are performed using special nuclear material (for example, plutonium) in a manner that prevents it from achieving a nuclear explosion. Subcritical experiments are designed to improve knowledge of the dynamic properties of new or aged nuclear weapons parts and materials and to assess the effects of new manufacturing techniques on weapon performance. Subcritical experiments can vary any or all factors that influence criticality (mass, density, shape, volume, concentration, moderation, reflection, neutron absorption, enrichment, and interactions). Because there is no nuclear explosion, subcritical experiments are consistent with the U.S. nuclear testing moratorium.

Dynamic Plutonium Experiments

Dynamic plutonium experiments are designed to improve knowledge of plutonium material properties, including equation of state (an equation that expresses the relationship between temperature, pressure, and volume of a substance) and strength, over broad ranges of relevant pressures, temperatures, and time scales. They range from essentially static experiments to increasingly dynamic experiments. None of these experiments reaches nuclear criticality or involves a self-sustaining nuclear reaction.

Area 3 Radioactive Waste Management Site (RWMS). The Area 3 RWMS consists of five disposal cells that contain waste and two unused disposal cells located in subsidence craters created by previous nuclear weapons tests. The approximately 120-acre site has been used for disposal of bulk and containerized low-level radioactive waste (LLW). The Area 3 RWMS is maintained in a standby condition and could be activated if necessary to dispose nonhazardous solid waste or particular, usually large-volume, LLW streams.

Hydrodynamic Experiments

Hydrodynamic experiments are high-explosives-driven experiments to assess the performance and safety of nuclear weapons. During a nuclear weapon function test, the behavior of solid materials is similar to liquids, hence the term "hydrodynamic." These experiments do not use special nuclear material (plutonium or enriched uranium), but are conducted using test assemblies that are representative of nuclear weapons.

Hydrodynamic experimentation is a central component in maintaining nuclear weapons design and assessment capability. It is coupled with high-performance computer modeling and simulation to certify, without underground nuclear testing, the safety, reliability, and performance of the nuclear physics package of weapons.

Big Explosives Experimental Facility (BEEF). BEEF, located in Area 4, is an open-air hydrodynamic experimentation facility (see text box) where high-explosives-driven experiments are performed to provide data to support the Stockpile Stewardship and Management Program (DOE/NV 2005c). The facility consists of two earth-covered bunkers, a control bunker, a camera bunker, a gravel firing table, and other support facilities.

Figure 2–3 Aboveground Facilities of the U1a Complex

Diagnostics equipment used to monitor explosions includes high-speed optics and x-ray radiography. Scientists conduct weapons physics experiments using explosives, pulsed laser power, and shaped charges. BEEF is certified to handle high-explosives loads up to 70,000 pounds. Materials used in explosives experiments may include beryllium and depleted uranium, among others.

Nonproliferation Test and Evaluation Complex (NPTEC). NPTEC (previously called the Liquefied Gaseous Fuels Spill Test Facility and the Hazardous Materials Spill Center) supports experimentation using open-air releases of chemical and biological simulants to create realistic environments for experiments and training (see **Figure 2–4**). The main NPTEC facility has the means of releasing materials from stacks or a wind tunnel, or on spill pads. Experimental data are collected using video cameras, sensors, arrays, and meteorological instrumentation. NPTEC is in Area 5, but experiments using low-concentration chemical or biological simulant releases and portable release systems can be performed at various locations at the NNSS. Public and private users perform experiments at NPTEC to independently analyze and evaluate sensor systems to determine their operational characteristics before their transition from the developmental to the operational phase (DOE/NV 2005e).

Figure 2–4 Large-scale Release Experiment Under Way at the Nonproliferation Test and Evaluation Complex

Area 5 Radioactive Waste Management Complex (RWMC). The Area 5 RWMC comprises about 740 acres, including about 160 acres of existing and proposed disposal cells for burial of LLW and mixed low-level radioactive waste. The Waste Examination Facility and Transuranic (TRU) Pad and TRU Pad Cover Building are also included in the Area 5 RWMC. Approximately 580 acres of land are available for future radioactive waste management facilities and disposal cells.

Control Point Complex. The Control Point Complex is located in Area 6 on the ridge between Yucca Flat and Frenchman Flat. The Control Point Complex consists of facilities to support testing and experiments in the forward areas of the NNSS (i.e., the experimental areas away from Mercury and areas of daily occupancy). It houses the command center used for nuclear tests and experiments (Control Point 1).

Device Assembly Facility (DAF). DAF, in Area 6, is a collection of more than 30 heavy-steel-reinforced concrete buildings connected by a common corridor (see **Figure 2–5**). The entire 100,000-square-foot complex is covered by compacted earth. Operational buildings in DAF include five assembly cells, three assembly bays (one with a downdraft table and one with a glovebox), four high bays, and two radiography bays. Support buildings include five bunkers for staging nuclear components or high explosives, two shipping/receiving bays, three small vaults, two decontamination areas, two laboratories, and an administration building (DOE/NV 2004c). Operations at DAF include staging and preparing special nuclear material for transportation and preparation of dynamic plutonium experiments and other unique experiments. DAF is approved for nuclear explosives operations and special nuclear material assemblies. DAF is also the home of the National Criticality Experiments Research Center, which was transferred from Technical Area 18 at Los Alamos National Laboratory in New Mexico and includes critical assemblies and machines used to conduct criticality experiments and training. In addition, DAF provides nuclear weapons assembly and disassembly capabilities; a damaged nuclear weapon could be sent to DAF for disassembly.

Figure 2–5 Device Assembly Facility at the Nevada National Security Site

Radiological/Nuclear Countermeasures Test and Evaluation Complex (RNCTEC). RNCTEC, in Area 6, is a facility constructed on behalf of the U.S. Department of Homeland Security for analyzing and evaluating countermeasures against potential terrorist attacks using radiological and/or nuclear weapons. The facility consists of several venues that simulate various transportation-related facilities (see **Figure 2–6**) (DOE 2004f).

Area 6 Construction Facilities. The Area 6 Construction Facilities provide craft and logistical support to activities performed in the forward areas of the NNSS (i.e., the experimental areas away from Mercury and areas of daily occupancy). The Area 6 Construction Facilities are also home to the Atlas Facility, a pulsed-power machine used to investigate the properties of nonnuclear materials under extreme conditions. The Atlas Facility can be used to conduct dynamic experiments and produce hydrodynamic data to validate computer models of material response for weapons applications; it was last used for such purposes in 2006. Since 2007, it has been maintained in cold standby, meaning that it can be reactivated, but may require repair and maintenance actions to ready it for use.

Figure 2–6 Radiological/Nuclear Countermeasures Test and Evaluation Complex Provides Capabilities for Evaluating Transportation Monitoring Equipment

Dense Plasma Focus Facility. The Dense Plasma Focus Facility in Area 11 supports research that provides active interrogation (a process that uses an external radiation source to interrogate an unknown object and induce a response) of special nuclear material and calibration of nuclear detection equipment. The focus of this research is enhancement of national security, with the goal of improving capabilities of detecting a smuggled nuclear device or material. The dense plasma focus machines use mixtures of deuterium and tritium.

Area 12 Camp. The Area 12 Camp is generally maintained in a standby condition, but can be reactivated for special projects. Most recently, DOE/NNSA activated the Area 12 Camp for use as a training facility by the Office of Secure Transportation. The camp includes 200 dormitory rooms, a full-service cafeteria, weapons and ammunition storage, and support buildings. Office of Secure Transportation training and exercises occur on roadways in Area 12 and throughout the NNSS.

The Area 12 Camp also supports activities at the tunnel complexes in Area 12. DOE/NNSA and the Defense Threat Reduction Agency use the various tunnels at the NNSS to conduct experiments and training in support of hard/deeply buried target location and defeat, conventional munitions effects and demilitarization, and other experiments and testing. Additionally, tunnel complexes in the northern area of the NNSS support DOE/NNSA programmatic activities, including safe management of improvised nuclear devices, if needed.

Desert Rock Airstrip. Desert Rock Airstrip in Area 22 supports operations of aircraft up to the size of a C-130 (about the length of a Boeing 727-200, but with a much larger wingspan). The airstrip is closed to public carriers, but is used by DOE/NNSA and others approved by DOE/NNSA for transport of material and personnel to the NNSS.

Mercury. Mercury (formerly called Base Camp Mercury), in Area 23 north of the entrance to the NNSS, is equivalent to a small town. It provides office facilities, dormitories, a cafeteria, classrooms, and various other support facilities for the NNSS. The Homeland Security and Defense Applications Operations and Coordination Center is located in Mercury. This center provides critical information exchange during exercises or real-world events and incidents.

Joint Actinide Shock Physics Experimental Research Facility (JASPER). JASPER, located in Area 27, houses a two-stage light-gas gun that is designed to propel a projectile into a target at extremely high velocities of up to 8 kilometers per second (see **Figure 2–7**). The JASPER gas gun is specifically designed to conduct research on plutonium and surrogate target materials. JASPER plays an integral role in the certification of the Nation's nuclear weapons stockpile by providing a means of generating and measuring data pertaining to the properties of materials (radioactive chemical elements) at high shock pressures, temperatures, and strain rates. These extreme laboratory conditions approximate those experienced in nuclear weapons. Data from the experiments are used to determine material equations of state (equations that express the relationship among temperature, pressure, and volume of a substance) and to validate computer models of material response for weapons applications. Experiment results are used for code refinement to provide better predictive capability and to ensure confidence in the U.S. nuclear stockpile.

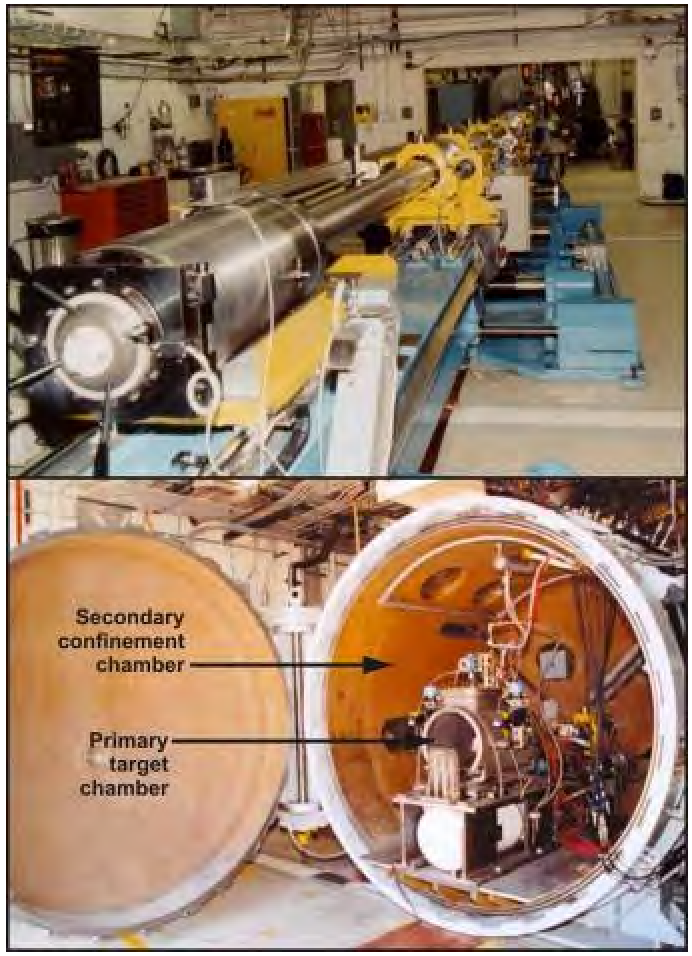

Figure 2–7 The Joint Actinide Shock Physics Experimental Research Facility Two-stage Gas Gun (top) and Target Chamber (bottom)

The nearby Baker Compound supports activities at JASPER, as well as other locations on the NNSS, by providing staging and storage necessary to support high-explosives experiments. The Baker Compound can receive shipments and safely store and transport explosives materials.

2.2 Remote Sensing Laboratory

RSL is located on 35 acres at Nellis Air Force Base in North Las Vegas, approximately 59 miles southeast of the nearest NNSS boundary (60 miles southeast of Gate 100, near Mercury, on the NNSS). RSL is adjacent to the Nellis Air Force Base runway and has seven permanent buildings. Radiological emergency response, the Aerial Measuring System, radiological sensor development and testing, Secure Systems Technologies, nuclear nonproliferation capabilities, and information and communication technologies are maintained at RSL.

2.3 North Las Vegas Facility

NLVF, located approximately 55 miles southeast of the nearest NNSS boundary (56 miles southeast of Gate 100, near Mercury, on the NNSS), comprises 29 buildings that support ongoing NNSS missions. The facility includes office buildings, a high bay, machine shop, laboratories, experimental facilities, and various other mission-support facilities. Among the NLVF buildings is the Nevada Support Facility, the location of most of the DOE/NNSA personnel offices.

2.4 Tonopah Test Range

The TTR, located approximately 12 miles north of the nearest NNSS boundary (73 miles north of Gate 100, near Mercury, on the NNSS), is a USAF facility. It consists of a 280-square-mile area north of the NNSS on the Nevada Test and Training Range. DOE/NNSA operations at the TTR are conducted pursuant to a land use permit from the USAF under the direction of Sandia National Laboratories and the DOE/NNSA Sandia Site Office. DOE/NNSA operations at the TTR include flight-testing of gravity weapons (bombs) and research, development, and evaluation of nuclear weapons components and delivery systems.

In its December 15, 2008, Record of Decision for the *Complex Transformation Supplemental Programmatic Environmental Impact Statement (Complex Transformation SPEIS)* (73 FR 77656), DOE/NNSA decided to implement a campaign mode of operations at the TTR, reducing its permitted operating area and upgrading its equipment. The "campaign mode of operations" would continue operations at the TTR but reduce permanent staff and conduct tests and experiments by deploying DOE and national laboratory personnel from other locations, as needed. The intent of reducing the footprint for the TTR and instituting a campaign mode of operations was to continue to meet mission and program requirements and reduce costs. After further review, DOE/NNSA, in consultation with the USAF, determined that maintaining the current footprint for the TTR would actually be the most cost-effective option. In addition, DOE/NNSA is reviewing implications of instituting a campaign mode of operations. The *Complex Transformation SPEIS* addresses operating with the existing TTR footprint in both campaign mode (Campaign Mode Operation of TTR, Option 2 – Campaign under existing Agreement) and in the existing (non-campaign) mode (No Action).

2.5 Overview of Changes Since the *1996 NTS EIS*

The *1996 NTS EIS* analysis of the potential environmental impacts was based on the physical site, facilities, and activities in existence or contemplated by DOE at the time the environmental impact statement was prepared. The primary missions at the NNSS and other sites in the state of Nevada remain unchanged; however, since the *1996 NTS EIS* was prepared, the administration of the sites and their physical boundaries and facilities have changed and there has been an evolution in the programs and activities conducted in support of the DOE/NNSA missions. This section provides an overview of these changes to bridge the gap between the sites, data, and analyses in the *1996 NTS EIS* and this *NNSS SWEIS*.

2.5.1 Administrative Changes

Creation of NNSA. Established by Congress in 2000 through the National Nuclear Security Administration Act (Title XXXII of the National Defense Authorization Act for Fiscal Year 2000, Public Law [P.L.] 106-65), NNSA is a separately organized, semiautonomous agency within DOE. DOE/NNSA is responsible for the management and security of the Nation's nuclear weapons, certain nuclear nonproliferation programs, and naval reactor programs. It also responds to nuclear and radiological emergencies in the United States and abroad. Additionally, DOE/NNSA Federal agents provide safe, secure transportation of nuclear weapons and components and special nuclear material, as well as support

for other missions related to national security. DOE/NNSA administers the NNSS, RSL, and NLVF and is a tenant on the USAF's TTR.

Transfer of Responsibility for Project Shoal and the Central Nevada Test Area. Responsibility for Project Shoal and Central Nevada Test Area environmental restoration sites was transferred to the DOE Office of Legacy Management in 2006. The DOE/NNSA NSO's Environmental Management Program completed surface remediation at these sites before the transfer; the remaining work is associated with long-term surveillance (groundwater monitoring) and maintenance. These sites are no longer under DOE/NNSA control and, by agreement with the DOE Office of Legacy Management, are not further addressed in this *NNSS SWEIS*.

Renaming the Nevada Test Site. In order to better reflect the diversity of nuclear, energy, and homeland security activities conducted at the site, the former Nevada Test Site was renamed the Nevada National Security Site in 2010.

2.5.2 Physical Changes

The NNSS boundary and land withdrawal changes. The *1996 NTS EIS* identified various public land orders and withdrawals, as well as a Memorandum of Understanding between the USAF and the DOE Nevada Operations Office (the predecessor of the DOE/NNSA NSO), as the basis for the lands composing the NNSS. The Military Lands Withdrawal Act of 1999 (P.L. 106-65) revoked Public Land Order 1662 in its entirety and legislatively withdrew the area that makes up the northwestern corner of the NNSS for exclusive DOE use. The Military Lands Withdrawal Act resulted in changes to the border around the northwestern corner of the NNSS, which was historically used for nuclear weapons testing under the Memorandum of Understanding. Figure 2–2 shows both the current NNSS boundary and the boundary as it existed in 1996.

Area 5 Land Transfer. As part of an April 1997 settlement agreement (which resulted in dismissal of *Nevada v. Pena* [CV-5-94-00576-PMP (RLH)] by the U.S. District Court in Nevada) between the State of Nevada and DOE, consultation with the U.S. Department of Interior was initiated concerning the status of existing land withdrawals with regard to LLW waste storage and disposal. This consultation process concluded with DOE/NNSA's formal acceptance of custody and control of the approximately 740 acres constituting the Area 5 RWMC in a land transfer action.

Yucca Mountain Management Agreement. As indicated in the fiscal year 2010, 2011, and 2012 budget requests, the Administration decided to cease funding and activities related to the development of a repository at Yucca Mountain, while developing alternative storage and disposal approaches for spent nuclear fuel and high-level radioactive waste. Proposed actions associated with the former Yucca Mountain Project included construction, operation, monitoring, and eventual closure of a geologic repository at Yucca Mountain for disposal of spent nuclear fuel and high-level radioactive waste already in storage or projected to be generated at 72 commercial and 5 DOE sites across the United States. In 1994, the DOE Nevada Operations Office entered into a management agreement with the DOE Yucca Mountain Site Characterization Office for use of about 58,000 acres of the NNSS land for site characterization activities related to the former Yucca Mountain Project. Under the agreement, the Yucca Mountain Project was responsible for meeting the same environmental requirements that applied to the NNSS independent of, but in coordination with, the NNSS organizations. DOE/NNSA maintains the infrastructure and buildings and provides security and support to DOE to remain compliant with Federal and state regulations pursuant to existing site permits. DOE recognizes that it has an obligation to remediate lands disturbed by past activities associated with the former Yucca Mountain Project. Accordingly, DOE has evaluated the potential cumulative impacts of remediating the lands and closing the infrastructure and buildings at Yucca Mountain (see Chapter 6 of this SWEIS). This analysis is based

on the preliminary approach to remediating and closing the Yucca Mountain site and facilities described under the No Action Alternative in the *Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (DOE 2002e). The preliminary approach analyzed in Chapter 6 of this SWEIS represents but one of many potential approaches. Upon receipt of appropriations, DOE plans to prepare a detailed proposal to remediate the lands and close the infrastructure and buildings, as required by law, regulations, and applicable agreements, and then undertake further National Environmental Policy Act reviews, as appropriate. After the completion of site closure, DOE would initiate a long-term surveillance program.

Notwithstanding the decision to terminate the Yucca Mountain Project, DOE remains committed to meeting its obligations to manage and ultimately dispose spent nuclear fuel and high-level radioactive waste. The Blue Ribbon Commission on America's Nuclear Future was established in March 2010 to conduct a comprehensive review of the back end of the fuel cycle and evaluate alternative approaches for meeting these obligations. The Blue Ribbon Commission provided a final report in January 2012 that highlights the Commission's findings and conclusions and presents recommendations for consideration by the Administration and Congress, as well as interested state, tribal, and local governments; other stakeholders; and the public (BRC 2012).

Higher-than-expected growth in Clark and Nye Counties. The *1996 NTS EIS* projected that, in 2005, the populations of Clark and Nye Counties would be 1,380,920 and 38,516 persons, respectively (DOE 1996c). The actual populations in mid-2005 were 1,796,380 and 41,302 persons for Clark and Nye Counties, respectively (NSBDC 2010). These numbers represent an approximate 30 percent increase over projected values for Clark County and a 7 percent increase for Nye County. In Clark County, much of the growth occurred in the northwestern portion of the Las Vegas Valley, projecting toward the NNSS. This growth is potentially relevant to the analysis in this *NNSS SWEIS* because it creates a greater demand for resources and a larger number of people closer to the NNSS. Most recently, however, there has been a small decrease in population for both Clark and Nye Counties. Clark County decreased 0.8 percent from a high of 1,967,716 in mid-2008 to 1,952,040 in mid-2009. Nye County decreased 2.1 percent from a high of 47,370 in mid-2008 to 46,360 in mid-2009. The population used as the baseline for analysis in this *NNSS SWEIS* is provided in Chapter 4, Section 4.1.4. Information on the analysis of socioeconomic impacts is located in Chapter 5, Section 5.1.4.

As the populations in Clark and Nye Counties have increased, concern over water rights and water use has also increased. The Southern Nevada Water Authority has sought to purchase water rights in Lincoln, White Pine, and Nye Counties to meet the growing demand in Clark County. Nye County established the Nye County Water District in 2009 to manage, evaluate, and mitigate groundwater and surface-water resources in Nye County and to develop a long-range sustainability plan (Nye 2010). Water consumption at the NNSS has decreased compared with the 2,975 million gallons per year projected in the *1996 NTS EIS* over the 10-year planning period. While NNSS water use has decreased, solar power generation facilities, described in Chapter 3 of this *NNSS SWEIS*, could increase the demand for water in the southern areas of the NNSS. Further information on NNSS water use and groundwater availability is presented in Chapter 4, Sections 4.1.2.1 and 4.1.6.2. Potential impacts from implementation of alternatives are presented in Chapter 5, Sections 5.1.2.1 and 5.1.6.2, and in Chapter 6, Section 6.3.6.2.

2.5.3 Program and Activity Changes

A number of changes related to NNSS programs and activities have occurred since the *1996 NTS EIS* after the appropriate level of National Environmental Policy Act review was conducted. The most important of these changes are described as follows:

- DOE/NNSA relocated its operational capabilities associated with Security Category I and II special nuclear material and the critical assembly machines from Technical Area 18 at Los Alamos National Laboratory in New Mexico to DAF at the NNSS. DOE/NNSA conducts nuclear criticality operations at DAF to enable personnel to gain knowledge and expertise in advanced nuclear technologies that support nuclear materials management and criticality safety, emergency response, nonproliferation, safeguards, arms control, and stockpile stewardship science.

- DOE/NNSA expanded BEEF (initial operation began in 1994), as planned and analyzed in the *1996 NTS EIS*. It was modified to perform explosives-driven, pulsed-power experiments.

- DOE/NNSA completed construction and modifications of JASPER to conduct experiments that provide data on the Nation’s nuclear weapons stockpile.

- DOE/NNSA relocated the Atlas Facility from Los Alamos National Laboratory to the NNSS. The Atlas Facility was used to conduct pulsed-power experiments until it was placed in standby mode in 2007.

- DOE/NNSA identified the U12g Tunnel for the activities of the Improvised Nuclear Device Program. If an improvised nuclear device were to be recovered, the tunnel would be used to stage, assess, and safeguard the weapon.

- A Counterterrorism Support Program was instituted that makes use of site facilities for training and adds activities at NPTEC in Area 5 to address emergency response and counterterrorism training.

- RNCTEC was constructed in Area 6 to provide analysis and evaluation capability for radiological and nuclear detection devices.

- DOE/NNSA completed upgrades to the Aerial Operations Facility in Area 6, including construction of a runway and a broad variety of infrastructure improvements.

- A Solar Enterprise Zone was identified at the NNSS, as described in the *1996 NTS EIS*, but a proposed commercial solar facility was cancelled by the project proponent.

- The Nevada Desert Free Air Carbon Dioxide Enrichment Facility and the Mojave Global Change Facility were built in Area 5. These facilities are used to perform controlled manipulative experiments (e.g., analyses of carbon dioxide enrichment, increased precipitation, and evolving soil conditions on natural systems) under controlled conditions.

- The U.S. Military Development and Training in Tactics and Procedures for Counterterrorism Threats and National Security Defense Program was instituted to develop methods for combating adversaries in a desert environment. This activity could occur at any location on the NNSS.

- The Area 5 RWMC resumed acceptance of mixed low-level radioactive waste from approved offsite generators in 2006 after a restriction on the receipt of these wastes was lifted by the Nevada Division of Environmental Protection during the renewal of the interim status permit in December 2005.

- Environmental Restoration Program activities have been ongoing since the *1996 NTS EIS* (DOE 1996c) was published. These activities have included the following:
  - Underground Test Area Project – Activities included conducting groundwater characterization and monitoring, drilling new monitoring wells, and developing groundwater flow and transport models.
  - Soils Project – Activities included characterization, monitoring, sampling, and corrective actions.
  - Industrial Sites Project – The majority of sites under the Federal Facility Agreement and Consent Order have been closed. Activities under this project included remediating, decontaminating, and decommissioning unneeded facilities.
  - Defense Threat Reduction Agency sites – The Defense Threat Reduction Agency is responsible for these sites. Surface-disturbing activities associated with these sites have been completed. Environmental monitoring, such as water sampling, was initiated and is ongoing.
  - Borehole Management Program – Most unneeded boreholes have been plugged at the NNSS. The program's expected completion date is the end of 2013.

Overview of Changes to the American Indian Writing Contributions Since the *1996 NTS EIS*

In 1995, the U.S. Department of Energy (DOE) invited the Consolidated Group of Tribes and Organizations (CGTO) to participate in the development of the *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada (1996 NTS EIS)*, to represent the American Indian perspective of the actions proposed and analyzed by DOE, and to consider and address the resources impacted. In response, the CGTO developed Appendix G for the *1996 NTS EIS* and provided italicized text for selected sections.

Appendix G and the italicized Final Environmental Impact Statement (EIS) text presented the American Indian perspective and recommended impact mitigation approaches for reducing potential impacts to Indian resources and other heritage values within the analyzed areas. American Indian involvement with the *1996 NTS EIS* and the development of Appendix G followed an American Indian Consultation Model[1] for government-to-government interactions among DOE and culturally affiliated American Indian Tribes. This was considered an innovative approach by Federal agencies at that time.

During the 2009 DOE Annual Tribal Meeting with the CGTO, DOE invited the CGTO to revisit the *1996 NTS EIS* and subsequent National Environmental Policy Act (NEPA) Supplement Analyses, to review the current and proposed activities presented in this site-wide environmental impact statement (SWEIS), and to develop text that reflects the CGTO's perspective and current concerns. DOE also expanded the CGTO's involvement by providing us with the opportunity to write culturally appropriate text summarizing our perspective and concerns for every section and appendix within the SWEIS, as appropriate, in addition to writing Appendix C, "The American Indian Assesment of Resources and Alternatives Presented in the SWEIS".

See Appendix C for more details.

[1] *The American Indian Consultation Model was based on the Consultation Model produced for the DoD Legacy Project, which was modified by the American Indian Writers Subgroup (AIWS) for the CGTO and implemented during the development of the 1996 NTS EIS. This model was again revisited and implemented by the AIWS for the CGTO in the development of the SWEIS, and is presented in Section 10.2.1.*

CHAPTER 3
DESCRIPTION OF ALTERNATIVES

3.0 DESCRIPTION OF ALTERNATIVES

This chapter contains descriptions of the alternatives that are being evaluated by the U.S. Department of Energy and National Nuclear Security Administration (DOE/NNSA) for continued operation of the Nevada National Security Site (NNSS) (formerly known as the Nevada Test Site), the Remote Sensing Laboratory (RSL) at Nellis Air Force Base, the North Las Vegas Facility (NLVF), the Tonopah Test Range (TTR), and environmental restoration sites located on the Nevada Test and Training Range (formerly the Nellis Air Force Range). Three alternatives are addressed in this *Site-Wide Environmental Impact Statement for the Continued Operation of the Department of Energy/National Nuclear Security Administration Nevada National Security Site and Off-Site Locations in the State of Nevada* (*NNSS SWEIS*)*:* (1) the No Action Alternative, described in Section 3.1; (2) the Expanded Operations Alternative, described in Section 3.2; and (3) the Reduced Operations Alternative, described in Section 3.3. Other sections of this chapter include Section 3.4, Comparison of Potential Consequences of the Alternatives; Section 3.5, Alternatives Eliminated from Detailed Study; and Section 3.6, Identification of the Preferred Alternative. Appendix A of this *NNSS SWEIS* provides a more detailed description of the alternatives. Some of the descriptions include American Indian perspectives prepared by the American Indian Writers Subgroup; the American Indian Writers Subgroup input is in text boxes identified with a Consolidated Group of Tribes and Organizations feather icon.

Descriptions of the alternatives are organized under three mission areas, each with two or more associated programs. These missions and their associated programs are: (1) the National Security/Defense Mission, which includes the Stockpile Stewardship and Management, Nuclear Emergency Response, Nonproliferation, Counterterrorism, and Work for Others Programs; (2) the Environmental Management Mission, which includes the Waste Management and Environmental Restoration Programs; and (3) the Nondefense Mission, which includes the General Site Support and Infrastructure, Conservation and Renewable Energy, and Other Research and Development Programs.

The three alternatives include similar types of projects and activities, but differ primarily in operational intensity and facilities requirements. Under all of the alternatives in this site-wide environmental impact statement (SWEIS), DOE/NNSA would maintain the capability to conduct an underground nuclear test. Only if directed by the President in the interest of national security would DOE/NNSA conduct such a test; however, conducting such a test is not included or analyzed under any of the alternatives in this SWEIS. A brief description of underground nuclear test phenomenology is included for informational purposes in Appendix H. The No Action Alternative generally reflects the use of existing facilities to maintain operations at levels consistent with those experienced since 1996, as well as those anticipated by project-specific National Environmental Policy Act (NEPA) analyses and agency decisions made since 1996 (see Chapter 2, Section 2.5). The Expanded Operations Alternative differs from the No Action Alternative in that, for many activities, the levels of operation would be higher and a number of new facilities would be constructed to support these higher levels of operation. In addition, under the Expanded Operations Alternative, DOE/NNSA would modify NNSS land use zones to better reflect the kinds of activities that would be undertaken. Under the Reduced Operations Alternative, DOE/NNSA would conduct some activities at levels similar to those under the No Action Alternative, but for other activities, the levels of operations would be lower or would cease. DOE/NNSA would also make NNSS land use zone changes under the Reduced Operations Alternative that would limit most activities in the northwestern portion of the NNSS. Mission-related capabilities, projects, and programmatic activities are identified for each of the proposed alternatives in the following sections and **Table 3–1** summarizes the similarities and differences among the three alternatives evaluated in this SWEIS. Detailed descriptions of the activities included under each alternative are provided in Appendix A.

DOE "National Environmental Policy Act Implementing Procedures" (10 *Code of Federal Regulations* [CFR] Part 1021) define site-wide NEPA documents as broad-scope environmental impact statements (EISs) or environmental assessments (EAs) that are programmatic in nature and identify and assess the individual and cumulative impacts of ongoing and reasonably foreseeable future actions at a DOE/NNSA site. This SWEIS considers ongoing and proposed programs, capabilities and projects (i.e., activities) at DOE/NNSA facilities in Nevada over the next 10 years.

The nature of ongoing activities and their associated environmental impacts are well understood. In contrast, however, the nature of some proposed activities is less well known. In the interest of disclosing potential environmental impacts that could occur at the NNSS and offsite locations over the next 10 years, this SWEIS includes ongoing activities, as well as activities that are more conceptual in nature.

To assess potential environmental impacts from all such activities, it was necessary for DOE/NNSA to estimate at a programmatic level certain aspects of the more conceptual proposed activities, such as the potential area of land disturbance or the amount of groundwater that may be required. DOE/NNSA incorporated these programmatic-level estimates, along with more-detailed information on ongoing and better-understood activities, into the analysis of impacts. For instance, estimated areas of land disturbance for both potential future activities and well-defined activities were used in estimating impacts on resources such as soils (area of disturbance and erosion), cultural resources (number of sites potentially affected), and biology (vegetation/habitat loss, number of desert tortoises affected).

DOE/NNSA understands that the level of NEPA analysis conducted for some proposed future activities may not be sufficient to permit implementation, and such activities could require additional NEPA analysis. These activities are identified in this chapter. DOE/NNSA will conduct NEPA reviews for these activities, as appropriate, in the future. DOE/NNSA's NEPA review procedures are described in Chapter 9, Section 9.1.1.

DOE/NNSA has at various times considered the possibility of supporting commercial solar projects at the NNSS. In this *NNSS SWEIS*, DOE/NNSA evaluates potential commercial solar power generation facilities under each of the three alternatives; however, there is no specific proposal for such a project at this time. For this reason, DOE/NNSA cannot be certain regarding the size of any solar power generation facility that might be constructed or whether DOE/NNSA support for such a facility might extend beyond providing access to land and certain infrastructure, such as providing partial funding. However, to ensure consideration of potential environmental impacts in a decision by DOE/NNSA to actively support development of one or more commercial solar power generation facilities at the NNSS, each alternative in this *NNSS SWEIS* addresses commercial-scale projects (the size of the potential facility varies with each alternative). DOE/NNSA selected the potential size of the generation facility under each alternative in terms of megawatts of generating capacity to provide a reasonable range of generating capacities, not to portray any actual project under consideration. Neither did DOE/NNSA intend to stipulate a certain generating capacity per unit of land area, realizing that as technology improves, smaller parcels of land may be sufficient to generate the same amount of electricity than are currently required. The assumptions used in the analyses of impacts from a potential solar power generation facility at the NNSS were selected to provide conservative analyses that would not underestimate impacts. If a commercial solar power project were proposed at the NNSS in the future, project-specific NEPA review would be required.

Detailed Description of Alternatives—American Indian Perspective

C G T O The Consolidated Group of Tribes and Organizations (CGTO) is concerned about culturally perceived harmful land disturbing U.S. Department of Energy (DOE) actions described in this chapter and Appendix A of this site-wide environmental impact statement (SWEIS). We are concerned because these actions adversely impact the Nevada National Security Site (NNSS) land and offsite locations, which in turn affect the American Indian cultural landscape.

Since 1987, DOE has provided opportunities for representatives of the CGTO to visit portions of the NNSS and identify important places, spiritual trails, and landscapes of traditional and contemporary cultural significance.[1] These actions by DOE are considered positive steps towards fulfilling its trust responsibility through facilitating co-stewardship and land management strategies between DOE and the CGTO; however, this is an ongoing process.

To avert or minimize further impacts, the CGTO recommends DOE and the CGTO develop co-management strategies to help protect the land by implementing the following actions before continuing with these current or proposed activities:

- Identify those areas that have been disrespected and culturally damaged, so that balance can once again be restored.
- Avoid further harmful ground-disturbing activities
- Make mitigation of restorable areas a top priority
- Avert or minimize damage to geological formations important to the cultural and ecological landscape, songscapes and storyscapes
- Implement collaborative environmental restoration techniques that require minimal ground disturbing activities (see CGTO response to Section 3.1.2.2)
- Continue to pursue systematic consultations with American Indians so potentially impacted resources can be readily identified, alternative solutions discussed, and adverse impacts averted
- Provide American Indian people increased access to culturally significant areas so that we can use our knowledge, prayers, and traditions to effectively restore balance to the natural and spiritual harmony of the NNSS area and offsite locations

In addition, the CGTO recommends DOE and the CGTO continue to hold annual meetings to discuss current and proposed actions in greater depth, deliberate potential impacts, and consider and develop mutually acceptable mitigation measures. This is particularly necessary for those actions requiring additional National Environmental Policy Act (NEPA) analysis, including but not limited to solar and geothermal energy development.

In the view of Indian people, the ideal alternative would be to avoid any action that further disturbs the land and resources associated with the NNSS and the offsite locations.

We believe we have been created and placed on these lands. Because of our birth-right and strong ties to our ancestral land, the CGTO believes we have undeniable rights to interact with its precious resources, and a continuous obligation to protect it. The CGTO takes this responsibility very seriously and has developed our input for the alternatives presented throughout Chapter 3 so we may fulfill this obligation.

See Appendix C for more details.

[1] *Because this is a public document, the exact locations of these areas will not be revealed unless determined necessary during government-to-government consultation.*

Table 3–1 Comparison of Mission-Based Program Activities Under the Proposed Alternatives

NO ACTION ALTERNATIVE	EXPANDED OPERATIONS ALTERNATIVE	REDUCED OPERATIONS ALTERNATIVE
National Security/Defense Mission		
Stockpile Stewardship and Management Program (see Sections 3.1.1.1, 3.2.1.1, and 3.3.1.1 of this chapter for additional information)		
Maintain readiness to conduct underground nuclear tests.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Conduct up to 10 dynamic experiments per year within NNSS Areas 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 16, 19, or 20.	Conduct up to 20 dynamic experiments per year within NNSS Areas 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 16, 19, or 20.	Conduct up to 6 dynamic experiments per year at the NNSS; no dynamic experiments would be conducted in Areas 19 or 20.
Conduct up to 20 conventional explosives experiments per year at BEEF and up to 10 per year within NNSS Areas 1, 2, 3, 4, 12, or 16 using up to 70,000 pounds TNT-equivalent of explosive charges; would also support Work for Others Program.	• Conduct up to 100 conventional explosives experiments per year within NNSS Areas 1, 2, 3, 4, 12, or 16 using up to 120,000 pounds TNT-equivalent of explosive charges (50 of these would be at BEEF with a TNT-equivalent limitation of 70,000 pounds); would also support Work for Others Program. • Add second firing table and high-energy x-ray capability at BEEF. • Establish up to three areas at the NNSS for conducting explosive experiments with depleted uranium and conduct up to 20 experiments per year.	Conduct up to 10 conventional explosives experiments per year at BEEF using up to 70,000 pounds TNT-equivalent of explosive charges per year to directly support the Stockpile Stewardship and Management Program; no other explosives experiments would be conducted.
Conduct up to 12 shock physics experiments per year at the NNSS using actinide targets at JASPER in Area 27 and up to 10 experiments per year using the Large-Bore Powder Gun in Area 1.	Conduct up to 36 shock physics experiments per year at the NNSS using actinide targets at JASPER in Area 27 and up to 24 experiments per year using the Large-Bore Powder Gun in Area 1.	Conduct up to 6 shock physics experiments per year at the NNSS using actinide targets at JASPER in Area 27 and up to 8 experiments per year using the Large-Bore Powder Gun in Area 1.
Conduct up to 500 criticality operations (experiments, training, and other operations) per year at the National Criticality Experiments Research Center at DAF in Area 6.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Maintain the Atlas Facility in standby with the capability to conduct up to 12 pulsed-power experiments per year.	Activate the Atlas Facility and conduct up to 24 pulsed-power experiments per year.	Decommission and disposition the Atlas Facility.
Conduct up to 600 plasma physics and fusion experiments each year at NLVF and 50 per year in NNSS Area 11.	Conduct up to 1,000 plasma physics and fusion experiments each year at NLVF and 650 per year in NNSS Area 11, increasing the size and complexity of such experiments.	Conduct up to 350 plasma physics and fusion experiments each year at NLVF and 25 per year in NNSS Area 11.
Conduct five drillback operations at the NNSS over about a 10-year period.	Same as under the No Action Alternative.	Same as under the No Action Alternative.

NO ACTION ALTERNATIVE	EXPANDED OPERATIONS ALTERNATIVE	REDUCED OPERATIONS ALTERNATIVE
Conduct Stockpile Stewardship and Management Program activities in NNSS Areas 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 16, 19, or 20, including the following:	Same as under the No Action Alternative, plus:	Same as under the No Action Alternative, except: Stockpile Stewardship and Management Program activities would not be conducted in Areas 19 and 20.
– Disposition damaged U.S. nuclear weapons on an as-needed basis.	– Stage nuclear devices pending dismantlement, modification/maintenance, and/or transportation to another location. – Dismantle up to 100 nuclear weapons per year. – Replace limited-life components of up to 360 nuclear devices and conduct associated maintenance activities. – Test weapons components for quality assurance under the Limited Life Component Exchange Program.	
– Stage special nuclear material, including nuclear weapon pits.	– Transfer special nuclear material, including nuclear weapon pits, to and from other parts of the DOE complex for staging and use in experiments at the NNSS.	
Conduct training for the Office of Secure Transportation up to six times per year at various locations on NNSS roads.	Same as under the No Action Alternative, plus: Develop facilities in Area 17 and upgrade or construct new facilities in Area 6, 12, or 23 to support training for the Office of Secure Transportation.	Conduct training for the Office of Secure Transportation up to four times per year at various locations on NNSS roads.
Conduct the following stockpile stewardship operations at the TTR: – Conduct tests and experiments, including flight test operations for gravity weapons (i.e., bombs). – Conduct ground/air-launched rocket and missile operations. – Conduct impact testing. – Conduct passive testing of joint test assemblies and conventional weapons. – Conduct fuel-air explosives testing.	Same as under the No Action Alternative, except: Certain safeguards and security functions and other administrative functions would be returned to the U.S. Air Force	Same as under the No Action Alternative, except: – Discontinue ground/air-launched rocket and missile operations. – Discontinue fuel-air explosives testing at the TTR.
Nuclear Emergency Response, Nonproliferation, and Counterterrorism Programs (see Sections 3.1.1.2, 3.2.1.2, and 3.3.1.3 of this chapter for more information)		
Provide support for the Nuclear Emergency Support Team, the Federal Radiological Monitoring and Assessment Center, the Accident Response Group, and the Radiological Assistance Program. Most of this support is out of RSL at Nellis Air Force Base.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Conduct Aerial Measuring System activities from RSL at Nellis Air Force Base.	Same as under the No Action Alternative.	Same as under the No Action Alternative.

NO ACTION ALTERNATIVE	EXPANDED OPERATIONS ALTERNATIVE	REDUCED OPERATIONS ALTERNATIVE
Conduct WMD emergency responder training at various DOE/NNSA NSO venues.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Support the DOE Emergency Communications Network.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Disposition improvised nuclear devices and deploy the DOE/NNSA Disposition Program and FBI Disposition Forensic Program to the NNSS for training and exercises or for an actual event, as needed.	Same as under the No Action Alternative, plus disposition of radiological dispersion devices, as needed.	Same as under the No Action Alternative.
Integrate existing activities and primarily NNSS facilities to support U.S. efforts to control the spread of WMDs, particularly nuclear WMDs, including arms control, nonproliferation activities, nuclear forensics, and counterterrorism capabilities.	Same as under the No Action Alternative, plus: At the NNSS: • Construct laboratory space and other facilities for design and certification of treaty verification technology, training of inspectors, and development of arms control confidence-building measures as part of the Arms Control Treaty Verification Test Bed.[a] • Develop and construct new facilities to support a Nonproliferation Test Bed to simulate chemical and radiological processes that an adversary would clandestinely conduct.[a] • Construct an Urban Warfare Complex to support counterterrorism training.[a]	Same as under the No Action Alternative.
Work for Others Program (see Sections 3.1.1.3, 3.2.1.3, and 3.3.1.3 of this chapter for more information)		
Continue to conduct Work for Others Program activities in all appropriate zones on the NNSS, and at RSL and NLVF.	Same as under the No Action Alternative, except: The NNSS land use zone designation for Area 15 would be changed from "Reserved Zone" to "Research, Test, and Experiment Zone."	Same as under the No Action Alternative, except: Work for Others Program activities, with the exception of military training and exercises, would not be conducted in Areas 18, 19, 20, 29, and 30 at the NNSS.
Host treaty verification activities.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Conduct nonproliferation projects and counterproliferation research and development at the NNSS, including:	Same as under the No Action Alternative.	Same as under the No Action Alternative, except:
– Conduct conventional weapons effects and other explosives experiments.		Discontinue Work for Others Program conventional weapons effects and other explosives experiments.
– Support development of capabilities to detect and defeat military assets in deeply buried hardened targets.		Discontinue development of capabilities to defeat military assets in deeply buried hardened targets.
– Conduct up to 20 controlled chemical and biological simulant release experiments per year (each experiment would include multiple releases by a variety of means, including explosive).		Discontinue projects requiring explosive releases of chemical or biological simulants.

NO ACTION ALTERNATIVE	EXPANDED OPERATIONS ALTERNATIVE	REDUCED OPERATIONS ALTERNATIVE
– Support training, research and development of equipment, specialized munitions, and tactics related to counterterrorism.		
Support the U.S. Department of Defense and other Federal agencies in developing counterterrorism capabilities.	Develop and construct new facilities to support counterterrorism training and research and development activities.	Same as under the No Action Alternative.
Conduct criticality experiments to support NASA's deep space power source development within the parameters for criticality experiments established under the Stockpile Stewardship and Management Program.	Same as under the No Action Alternative, plus: Support NASA's deep space power source development, including conducting experiments using existing boreholes at the NNSS to sequester emissions such as radionuclides.[a]	Same as under the No Action Alternative.
Host the use of various aerial platforms, such as airplanes, unmanned aerial systems and helicopters, at various locations at the NNSS for research and development, training, and exercises.	• Increase use of various aerial platforms, such as airplanes, unmanned aerial systems, and helicopters, for research and development, training, and exercises, including constructing additional hangars, shops, and buildings at existing airports at the NNSS. • Conduct up to 3 underground and 12 open-air radioactive tracer experiments per year. • Host treaty verification activities, including development of a facility for simulating nuclear fuel cycle-related radionuclide release detection and characterization.[a] • Develop a facility for specialized explosive experiments and simulated manufacture to support high-explosives experiments.[a] • Support increased research and development of active interrogation equipment, methods, and training. • Develop new facilities to support research and development in radio frequency generation and infrasonic observations.[a] • Develop new facilities, including simulated clandestine laboratories, to support chemical and biological simulant experiments.[a]	Same as under the No Action Alternative.
Conduct Work for Others Program activities at the TTR, including robotics testing, smart transportation-related testing, smoke obscuration operations, infrared tests, and rocket development.	Same as under the No Action Alternative, except: Certain safeguards and security functions and other administrative functions would be turned over to the U.S. Air Force.	Same as under the No Action Alternative.

NO ACTION ALTERNATIVE	EXPANDED OPERATIONS ALTERNATIVE	REDUCED OPERATIONS ALTERNATIVE
Environmental Management Mission		
Waste Management Program (see Sections 3.1.2.1, 3.2.2.1, and 3.3.2.1 of this chapter for more information)		
Dispose up to 15,000,000 cubic feet of LLW and 900,000 cubic feet of MLLW [b] in the Area 5 RWMC.	Dispose up to 48,000,000 cubic feet of LLW and 4,000,000 cubic feet of MLLW at the Area 5 RWMC and Area 3 RWMS.	Same as under the No Action Alternative.
Maintain the Area 3 RWMS on standby.	Open the Area 3 RWMS for disposal of authorized and/or permitted waste.	Same as under the No Action Alternative.
Repackage onsite-generated MLLW.	Same as under the No Action Alternative, plus: At the Area 5 RWMC, store MLLW received from on- and offsite generators pending treatment via macroencapsulation and microencapsulation (i.e., repackaging), sorting/segregating, and bench-scale mercury amalgamation, as appropriate, and/or dispose this waste.	Same as under the No Action Alternative.
Store onsite-generated TRU waste (up to 9,600 cubic feet over the next 10 years) pending offsite disposal.	Same as under the No Action Alternative, except a larger volume (up to 19,000 cubic feet over the next 10 years) of TRU waste would be generated by increased activities at NNSS facilities, such as JASPER.	Same as under the No Action Alternative, except smaller volumes (up to 7,100 cubic feet over the next 10 years) of TRU waste would be generated by reduced operational levels at NNSS facilities, such as JASPER.
Store onsite-generated hazardous waste as needed at the Area 5 Hazardous Waste Storage Unit pending offsite treatment or disposal. Up to 170,000 cubic feet would be generated over the next 10 years.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Operate the Area 11 Explosives Ordnance Disposal Unit. No more than 41,000 pounds of explosives would be treated over the next 10 years.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Operate the Area 6 Hydrocarbon Landfill.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Operate the Area 23 Solid Waste Disposal Site and the U10c Solid Waste Disposal Site. Up to 3,400,000 cubic feet would be disposed over the next 10 years.	Same as under the No Action Alternative, plus: Larger volumes of solid sanitary waste (up to 8,500,000 cubic feet) would be generated by increased activity levels at the NNSS over the next 10 years. Construct new sanitary solid waste disposal facilities as needed in Area 23 and develop a new solid waste disposal site in Area 25 to support environmental restoration activities.	Same as under the No Action Alternative, except lower volumes of solid sanitary waste (up to 3,300,000 cubic feet) would be generated by reduced activity levels at the NNSS over the next 10 years.

NO ACTION ALTERNATIVE	EXPANDED OPERATIONS ALTERNATIVE	REDUCED OPERATIONS ALTERNATIVE
Environmental Restoration Program (see Sections 3.1.2.2, 3.2.2.2, and 3.3.2.2 of this chapter for more information)		
Underground Test Area Project – Comply with the FFACO; monitor groundwater from existing wells; drill new characterization and monitoring wells; develop groundwater flow and transport models; and continue to evaluate closure strategies.	Same as under the No Action Alternative, except: Characterization and monitoring wells would be developed more quickly.	Same as under the No Action Alternative.
Soils Project – Identify and characterize areas with contaminated soils and perform corrective actions in compliance with the FFACO.	Same as under the No Action Alternative, except: If stricter cleanup standards are implemented, larger volumes of radioactive waste would be generated and disposed.	Same as under the No Action Alternative.
Industrial Sites Project – Identify, characterize, and remediate industrial sites under the FFACO and continue decontaminating and decommissioning facilities.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Defense Threat Reduction Agency sites – In accordance with the FFACO, perform remediation activities at sites that are the responsibility of the Defense Threat Reduction Agency.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Execute the Borehole Management Program.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Nondefense Mission		
General Site Support and Infrastructure Program (see Sections 3.1.3.1, 3.2.3.1, and 3.3.3.1 of this chapter for more information)		
Conduct small projects to maintain the present capabilities of DOE/NNSA NSO facilities in all areas of the NNSS and at NLVF, RSL, and the TTR. Maintain existing infrastructure, manage various permits and agreements, and provide security for the former Yucca Mountain site.	Same as under the No Action Alternative, plus: • Construct a new 85,000-square-foot multistory security building in Area 23. • Replace the NNSS 138-kilovolt electrical transmission system. • Expand cellular telecommunication system on the NNSS. • Reconfigure Mercury.[a]	Same as under the No Action Alternative, except: Only critical infrastructure would be maintained within Areas 18, 19, 20, 29, and 30 of the NNSS, including certain communications facilities; electrical transmission lines and substations; and Well 8. Roads within these areas would only be maintained to provide access to the infrastructure and environmental restoration sites.
Conservation and Renewable Energy Program (see Sections 3.1.3.2, 3.2.3.2, and 3.3.3.2 of this chapter for more information)		
Continue to identify and implement energy conservation measures and renewable energy projects in compliance with applicable Executive Orders and DOE Orders.	Same as under the No Action Alternative, plus:	Same as under the No Action Alternative, except:
– Reduce energy intensity by 3 percent annually through the end of fiscal year 2015, for a total 30 percent reduction.		
– Reduce greenhouse gas emissions by 28 percent by fiscal year 2020.		
– Install advanced electric metering systems.		

NO ACTION ALTERNATIVE	EXPANDED OPERATIONS ALTERNATIVE	REDUCED OPERATIONS ALTERNATIVE
– Obtain at least 7.5 percent of the NNSS annual electricity and thermal consumption from renewable energy sources.		
– Support development of a 240-megawatt commercial solar power generation facility in Area 25.[a c]	• Modify NNSS land use zones to establish a 39,600-acre Renewable Energy Zone in Area 25 and support development of commercial solar power generation facilities in Area 25 with a maximum combined generating capacity of 1,000 megawatts.[a, c] • Construct a 5-megawatt photovoltaic solar power generation facility near the Area 6 Construction Facilities. • Support a Geothermal Demonstration Project and Geothermal Research Center at the NNSS.[a]	Support development of a 100-megawatt commercial solar power generation facility in Area 25.[a c]
– Reduce water use by 16 percent by 2015.		
– Maximize use of alternative fuels (e.g., E85 and biodiesel).		
– Ensure all new construction and renovation projects implement high-performance building goals.		
Other Research and Development Programs (see Sections 3.1.3.3, 3.2.3.3, and 3.3.3.3 of this chapter for more information)		
Support the DOE National Environmental Research Park Program and other non-DOE/NNSA research and development activities in all areas of the NNSS.	Same as under the No Action Alternative.	National Environmental Research Park Program and other non–DOE/NNSA research and development activities would be conducted in all areas of the NNSS except Areas 18, 19, 20, 29, and 30.

BEEF = Big Explosives Experimental Facility; DAF = Device Assembly Facility; FBI = Federal Bureau of Investigation; FFACO = Federal Facilities Agreement and Consent Order; JASPER = Joint Actinide Shock Physics Experimental Research Facility; LLW = low-level radioactive waste; MLLW = mixed low-level radioactive waste; NASA = National Aeronautics and Space Administration; NLVF = North Las Vegas Facility; NNSA = National Nuclear Security Administration; NNSS = Nevada National Security Site; NSO = Nevada Site Office; NNSS = Nevada National Security Site; RSL = Remote Sensing Laboratory; RWMC = Radioactive Waste Management Complex; RWMS = Radioactive Waste Management Site; TNT = 2,4,6-trinitrotoluene; TRU = transuranic; TTR = Tonopah Test Range; WMD = weapon of mass destruction.

[a] These potential projects have not reached a point of development to allow full analysis in this *NNSS SWEIS* and would be subject to project-specific NEPA review before DOE/NNSA would make any decision regarding implementation.

[b] The actual permitted capacity of the Mixed Waste Disposal Unit (Cell 18) is 899,996 cubic feet.

[c] DOE/NNSA has not received or solicited proposals for any commercial solar power generation projects.

3.1 No Action Alternative

As defined in this *NNSS SWEIS*, the No Action Alternative reflects the use of existing facilities and ongoing projects to maintain operations consistent with those experienced in recent years at the NNSS and offsite locations in Nevada. For each mission and its supporting programs, levels of operations for associated capabilities and projects were determined by evaluating historic operational values since 1996, such as the number of experiments performed at the Joint Actinide Shock Physics Experimental Research Facility (JASPER) or the U1a Complex; reasonable expectations for newer projects, such as the number of projected shots for the Large-Bore Powder Gun; or the nature and number of proposed activities, such as training undertaken for the Office of Secure Transportation. For example, in 2004 and 2006, DOE/NNSA conducted 8 experiments with plutonium at JASPER; for the No Action Alternative, DOE/NNSA is analyzing up to 12 such experiments at JASPER. The operational level for disposal operations of low-level radioactive waste (LLW) in the No Action Alternative was based on the volumes of LLW actually disposed during fiscal years (FY) 1997 through 2010. The No Action Alternative level of operations represents the baseline against which the other alternatives are compared. In the *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (*1996 NTS EIS*) (DOE 1996c), DOE/NNSA identified land use zones in which certain categories of activities, such as nuclear, dynamic, and hydrodynamic experiments and other compatible defense and nondefense research and development and testing, would be conducted. The land use zones are used to manage activities at the NNSS to prevent interference among the various missions, programs, projects, and activities, but are not considered absolute descriptors of the range of activities that may occur in a particular zone. **Figure 3–1** depicts these land use zones and the major facilities at the NNSS that would continue under the No Action Alternative.

3.1.1 National Security/Defense Mission

Under the No Action Alternative, DOE/NNSA would continue to pursue the Stockpile Stewardship and Management, Nuclear Emergency Response, Nonproliferation, Counterterrorism, and Work for Others Programs.

3.1.1.1 Stockpile Stewardship and Management Program

The term "stockpile stewardship" refers to core competencies in activities associated with research, design, development, and testing of nuclear weapons components, as well as assessment and certification of their safety and reliability. DOE/NNSA's science-based Stockpile Stewardship and Management Program maintains and enhances the safety, reliability, and performance of the U.S. nuclear weapons stockpile, including the ability to design, produce, and test weapons, to meet national security requirements. Stockpile stewardship and management activities at DOE/NNSA facilities in Nevada are conducted via a variety of methods, including experiments involving special nuclear materials (SNM) and high explosives (either in combination or separately), shock physics, nuclear criticality, pulsed power, and plasma physics and nuclear fusion. Under the No Action Alternative, diagnostics and other instrumentation would be developed and used in related tests and experiments. In addition, DOE/NNSA would conduct drillback operations; support Office of Secure Transportation training; and, as necessary, disposition damaged nuclear weapons. Major facilities at the NNSS where stockpile stewardship and management activities would be performed include the Device Assembly Facility (DAF), the U1a Complex, the Big Explosives Experimental Facility (BEEF), and JASPER. DOE/NNSA also conducts stockpile stewardship and management activities at the TTR.

> **Special Nuclear Material (SNM)**
>
> SNM is (1) plutonium, uranium-233, uranium enriched in isotopes of uranium-233 or -235, or any other material that the U.S. Nuclear Regulatory Commission determines to be SNM, or (2) any material artificially enriched by any of these radioactive materials.

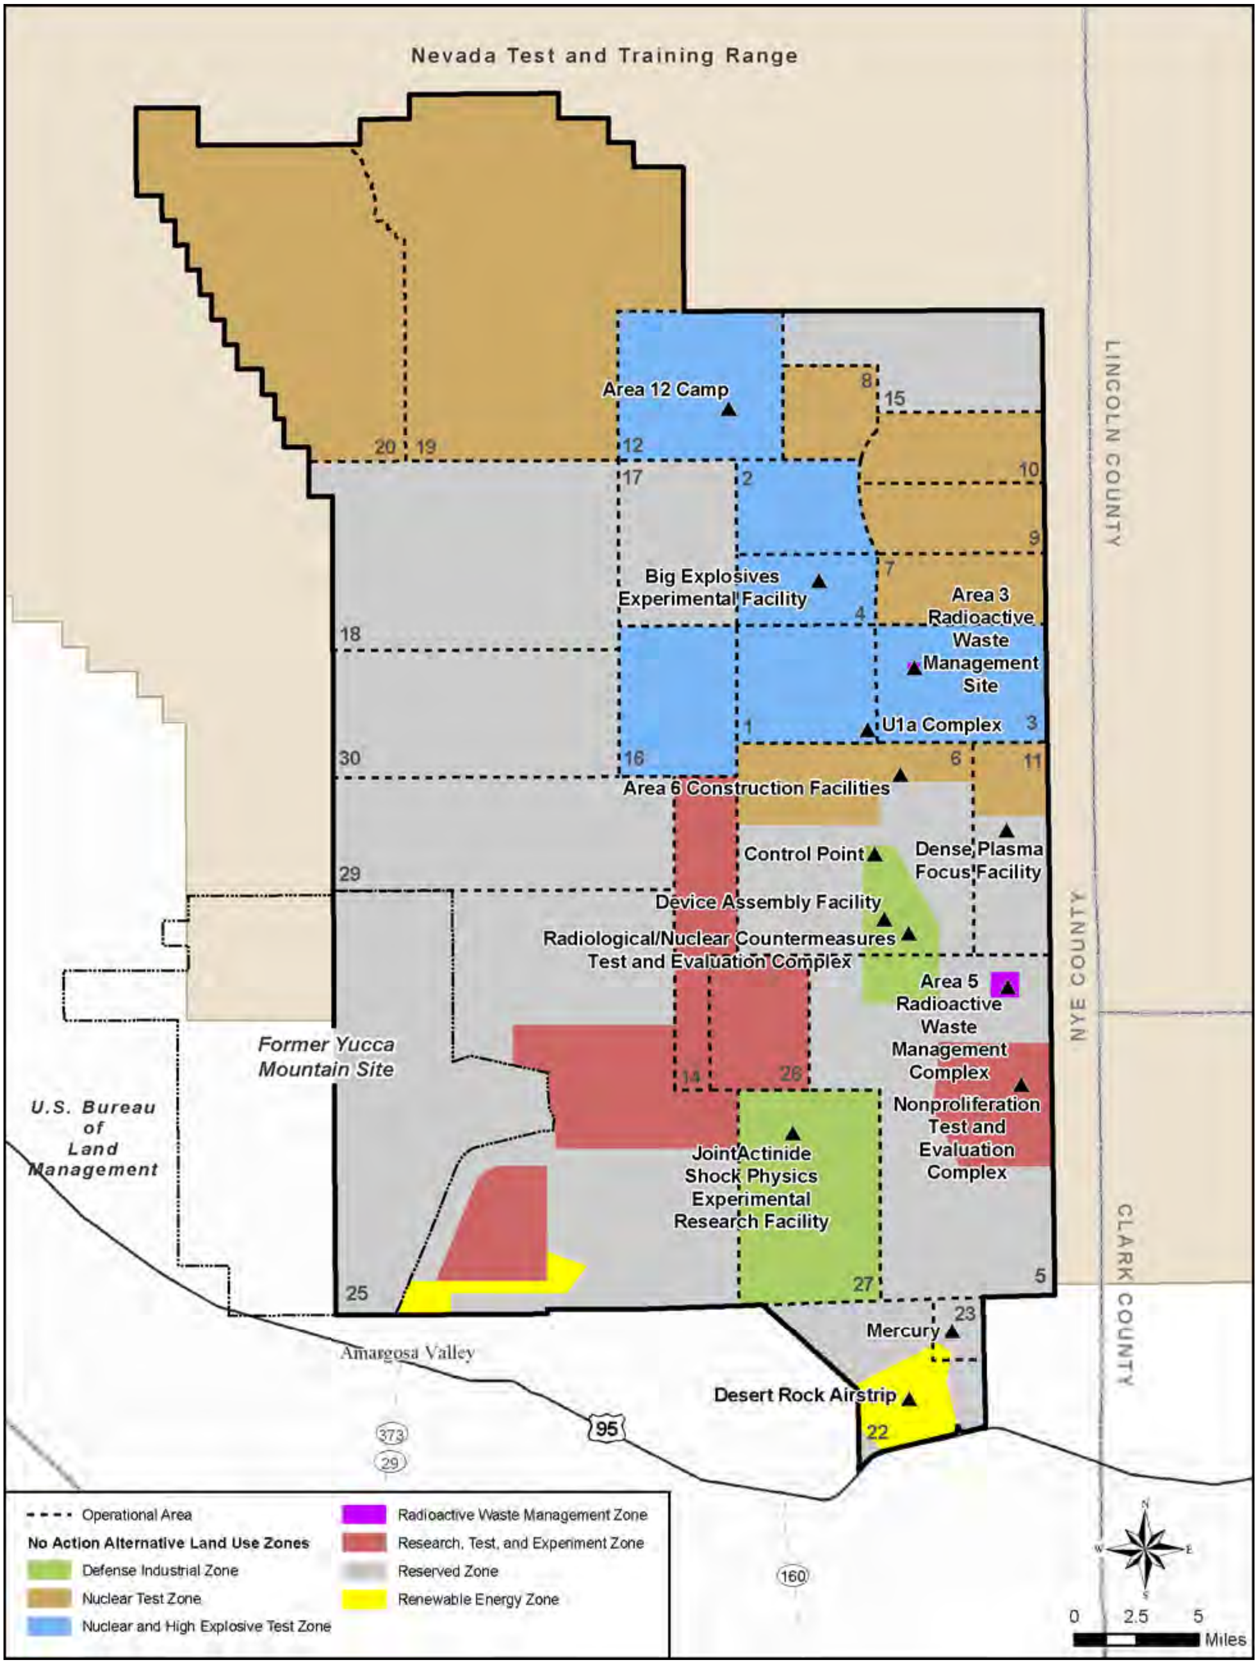

Figure 3–1 Nevada National Security Site Land Use Zones and Major Facilities Under the No Action Alternative

Stockpile stewardship and management activities would continue at DOE/NNSA facilities in Nevada under the conditions of the ongoing nuclear testing moratorium. These activities would emphasize science-based stockpile stewardship tests, experiments, and projects to maintain the safety and reliability of the nuclear weapons stockpile without underground nuclear testing. However, the No Action Alternative includes those activities necessary to maintain the capability to conduct underground nuclear tests. Such a test would be conducted only if so directed by the President in the interest of national security. Therefore, conducting an underground nuclear test is neither included nor analyzed under any of the alternatives in this *NNSS SWEIS*. Readiness-to-test capabilities include maintaining the necessary infrastructure and, more importantly, exercising the research and engineering disciplines of the U.S. nuclear weapons program through an active science-based Stockpile Stewardship and Management Program at the NNSS to ensure the continued competence of its technical staff. As part of its readiness-to-test activities, DOE/NNSA would conduct training and exercises using various kinds of nuclear weapon simulators. A generic description of underground nuclear testing is provided in Appendix H.

In addition to maintaining the capability to conduct nuclear weapon tests and in support of stockpile stewardship and management at the NNSS, DOE/NNSA would perform a variety of national security activities under the No Action Alternative, consistent with the program goals and direction provide in Annex D of DOE/NNSA's *2011 Biennial Plan and Budget Assessment on the Modernization and Refurbishment of the Nuclear Security Complex* (NNSA 2010) and as summarized in the following descriptions. Detailed descriptions of these activities are included in Appendix A of this *NNSS SWEIS.*

Dynamic experiments. Dynamic experiments, including subcritical and hydrodynamic experiments, would be conducted in alcoves at the U1a Complex, in unused nuclear test vertical emplacement holes, or at other sites within the Nuclear Test and Nuclear and High Explosives Test Zones of the NNSS, which include all or parts of Areas 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 16, 19, and 20. Under the No Action Alternative, DOE/NNSA would conduct up to 10 dynamic tests per year. Over the next 10 years, a total of 5 dynamic experiments would be conducted in emplacement holes and cause new land disturbances.

Dynamic Experiments

Dynamic Plutonium Experiments

Dynamic plutonium experiments are designed to improve knowledge of plutonium material properties, including equation of state (an equation that expresses the relationship between temperature, pressure, and volume of a substance) and strength, over broad ranges of relevant pressures, temperatures, and time scales. They range from essentially static experiments to increasingly dynamic experiments. None of these experiments reaches nuclear criticality nor involves a self-sustaining nuclear reaction.

Hydrodynamic Experiments

Hydrodynamic experiments are high-explosives-driven experiments to assess the performance and safety of nuclear weapons. During a nuclear weapon function test, the behavior of solid materials is similar to liquids, hence the term "hydrodynamic." These experiments do not use special nuclear material (plutonium or enriched uranium), but are conducted using test assemblies that are representative of nuclear weapons.

Hydrodynamic experimentation is a central component in maintaining nuclear weapons design and assessment capability. It is coupled with high-performance computer modeling and simulation to certify, without underground nuclear testing, the safety, reliability, and performance of the nuclear components of weapons.

Subcritical Experiment

Subcritical experiments are performed with special nuclear material (for example, plutonium) in a manner that prevents it from achieving a nuclear explosion. Subcritical experiments are designed to improve current knowledge of the dynamic properties of new or aged nuclear weapons parts and materials and to assess the effects of new manufacturing techniques on weapon performance. Subcritical experiments can vary any or all factors that influence criticality (mass, density, shape, volume, concentration, moderation, reflection, neutron absorption, enrichment, and interactions). Because there is no nuclear explosion, subcritical experiments are consistent with the U.S. nuclear testing moratorium.

Conventional explosives experiments. Experiments using explosives, including high explosives, would be conducted at BEEF and other locations at the NNSS. Experiments would use up to 70,000 pounds

TNT [2,4,6-trinitrotoluene]-equivalent of explosive charges. Experiments within the BEEF operational area could include potentially hazardous materials such as beryllium, depleted uranium, deuterium, and tritium. Up to 20 conventional explosives experiments would be conducted each year at BEEF and up to 10 per year would be conducted at other locations at the NNSS under the No Action Alternative. The experiments would consist of both open-air and contained (no release to the atmosphere) research and diagnostic experiments using a variety of explosive compounds. These totals do not include the dynamic experiments addressed in the preceding paragraph. Conventional explosives operations supporting other programs at the NNSS are described under those programs. All explosive operations would be conducted in compliance with DOE Manual 440.1-1A, *DOE Explosives Safety Manual*.

Shock physics experiments. Shock physics experiments are a subset of dynamic experiments, but are not included in the dynamic experiments described above. There are two shock physics facilities at the NNSS: JASPER in Area 27, and the Large-Bore Powder Gun at the U1a Complex in Area 1. Up to 12 SNM experiments per year would be conducted at JASPER under the No Action Alternative. The Large-Bore Powder Gun would be operated in an alcove in the U1a Complex and would be used to conduct up to 10 experiments per year using SNM. Additional operations would be conducted without SNM at each of these facilities.

Criticality experiments, training, and other activities. Under the No Action Alternative, DOE/NNSA would conduct up to 500 criticality operations at the National Criticality Experiments Research Center within DAF each year for experiments, training, and other purposes in support of Stockpile Stewardship and Management and other programs.

Categories of Special Nuclear Material (SNM)
(Security Categories I, II, III, and IV)

The U.S. Department of Energy (DOE) uses a graded approach to provide SNM safeguards and security. Quantities of SNM stored at each DOE site are categorized into Security Categories I, II, III, and IV, with the greatest quantities included under Security Category I, and lesser quantities included in descending order under Security Categories II through IV.

Pulsed-power experiments. Under the No Action Alternative, the Atlas Facility would be maintained in a standby status with the capability to conduct up to 12 pulsed-power experiments per year. A description of the Atlas Facility may be found in Appendix A, Section A.1.1.1.

Plasma physics and fusion experiments. Using the Dense Plasma Focus Machines located in Area 11 of the NNSS and at NLVF, DOE/NNSA would conduct plasma physics and fusion experiments to support the Stockpile Stewardship and Management and Work for Others Programs. In the future, fusion experiments at the NNSS and NLVF could support energy production research. Up to 650 plasma physics and fusion experiments would be conducted yearly under the No Action Alternative: 50 in Area 11 of the NNSS and 600 at NLVF.

Drillback operations. DOE/NNSA assumes that five drillback operations to obtain samples from former underground nuclear test cavities would take place under the No Action Alternative over the next 10 years. Each drillback operation would be conducted near a former underground nuclear test location and would disturb approximately 5 acres of land.

Stockpile management activities. Stockpile management activities are the hands-on, day-to-day functions and operations involved in maintaining an enduring nuclear weapons stockpile. The following stockpile management activities would be conducted by DOE/NNSA at the NNSS under the No Action Alternative:

Nuclear Weapon Pit

The pit is the central core of a nuclear weapon containing plutonium-239 and/or highly enriched uranium that undergoes fission when compressed by high explosives. The pit and the high explosive are known as the "primary" of a nuclear weapon.

- Disposition of damaged U.S. nuclear weapons, as needed
- Staging, assembly, and disassembly of nuclear devices –

"Staging" means to maintain programmatic material, such as nuclear devices, SNM, or other materials, in a safe and secure manner until needed for a test, experiment, or other activity. Staging does not include maintaining material with no reasonable expectation of use in the foreseeable future.

- SNM staging, including nuclear weapon pits

Training for the Office of Secure Transportation. The DOE/NNSA Office of Secure Transportation would use existing NNSS infrastructure to conduct training and exercises up to six times per year to maintain and improve the skills of its agents to safely and securely transport nuclear weapons, weapons components, and SNM. Training includes practicing convoy activities on existing NNSS roads and adjacent off-road areas.

TTR operations. The primary mission of DOE/NNSA at the TTR is to ensure that U.S. nuclear weapons systems meet the highest standards of safety and reliability. In addition, Work for Others Program activities are conducted at the TTR. DOE/NNSA activities at the TTR are conducted under the conditions set forth in a land use permit from the U.S. Air Force (USAF) and are the responsibility of the Sandia Site Office, located in Albuquerque, New Mexico. Under the No Action Alternative, in support of stockpile stewardship and management, DOE/NNSA would use the TTR for the following activities:

- Tests and experiments, including flight tests for gravity weapons (bombs), would be conducted to ensure the compatibility of the hardware necessary for the interface between weapons and delivery systems and to assess weapon system functions in realistic delivery conditions. DOE/NNSA does not expect to use Category I/II SNM in flight tests.
- Testing would be conducted to test various parameters of a weapon while in flight or when dropped, including penetration of the ground surface. Weapons tested would include joint test assemblies and conventional and inert projectiles. Joint test assemblies are nuclear weapons with a portion of the nuclear package omitted, making them incapable of achieving the criticality required to produce a nuclear detonation. Impact tests would include the following:
  - Air-drop operations
  - Ground/air-launched rocket operations
  - Ground/air-launched missile operations
  - Compressed-air gun operations
  - Davis Gun operations
  - Fuel-air explosives operations
  - Open-air and underground detonation of explosives
  - Post-test procedures and recovery operations
- Tests would be conducted to check the systems in joint test assemblies and conventional weapons. Tests would also be conducted on behalf of nonproliferation research to develop equipment and techniques for determining whether other countries are using or developing nuclear capabilities. Passive tests would include the following:
  - Telemetry, microwave, and photometrics operations
  - Radar operations
  - Laser tracker operations
  - Radiographic operations
  - Electromagnetic radiation testing

Although not listed under the Work for Others description in Section 3.1.1.3, all of these Stockpile Stewardship and Management Program activities listed for the TTR are similar to activities that may be conducted as Work for Others at the TTR.

3.1.1.2 Nuclear Emergency Response, Nonproliferation, and Counterterrorism Programs

DOE/NNSA facilities in Nevada provide a broad support base for Nuclear Emergency Response Program activities, including a variety of areas and facilities that may be used for training and exercise activities. Under the No Action Alternative, DOE/NNSA would support the Nuclear Emergency Response, Nonproliferation, and Counterterrorism Programs by conducting the activities summarized in the following discussion. Detailed descriptions of these activities are included in Appendix A of this *NNSS SWEIS.*

- Personnel and logistical support for the Nuclear Emergency Support Team would be provided at RSL. Nuclear Emergency Support Team activities would also occur at the NNSS and other locations.
- Support consequence management, including personnel and early-phase activities management, would be provided for the Federal Radiological Monitoring and Assessment Center (FRMAC).
- Fixed-wing and rotary-wing aircraft would be provided for emergency response and aerial mapping activities as part of the Aerial Measuring System. These assets are based at RSL and activities are conducted at various locations around the country.
- Personnel and logistical support would be provided to the Accident Response Group.
- Logistical support would be provided to the Radiological Assistance Program.
- Weapons of mass destruction emergency responder training would be provided.
- Equipment and technical support would be provided for the DOE-dedicated Emergency Communications Network.

Radiological Emergency Response Assets

Nuclear Emergency Support Team (NEST) – NEST provides specialized technical expertise in resolving nuclear or radiological terrorist incidents. The National Nuclear Security Administration (NNSA) assists the Federal Bureau of Investigation and the U.S. Department of State with conducting, directing, and coordinating search and recovery operations for nuclear materials, weapons, or devices, and assists in identifying and deactivating improvised nuclear devices or radiological dispersal devices.

Aerial Measuring System (AMS) – AMS provides rapid response to radiological emergencies with helicopters and fixed-wing aircraft equipped to detect and measure radioactive material. In addition, AMS surveys U.S. Department of Energy (DOE) sites, participates in interagency exercises, and performs work for other Federal agencies. AMS can also provide detailed aerial photographs and multi-spectral imagery and analyses.

Radiological Assistance Program (RAP) – RAP is a first-response resource in assessing a radiological emergency, conducting the initial radiological assessment of the area of the emergency and providing assistance to minimize immediate radiation risks. RAP also provides emergency response training to first responders, and is involved in the Weapons of Mass Destruction First Responder Training Program. RAP is implemented on a regional basis, with eight Regional Coordinating Offices in the United States. The NNSA Nevada Site Office (NSO) is part of Region 7, headquartered in Oakland, California.

Federal Radiological Monitoring and Assessment Center (FRMAC) – FRMAC coordinates the efforts of 17 agencies to integrate the Federal response to a radiological emergency within the United States. DOE's responsibility is to set up and initially manage a FRMAC and NNSA provides the Consequence Management Response Team, which draws from NNSA Emergency Response Assets, including the RAP and AMS. The Phase 1 Consequence Management Response Team is deployed from among NNSA/NSO assets.

Accident Response Group (ARG) – ARG develops and maintains readiness to efficiently manage the resolution of accidents or significant incidents involving nuclear weapons that are in DOE's custody and support the U.S. Department of Defense for similar incidents with weapons in its custody. ARG's role in an emergency situation involving a nuclear weapon includes initial onsite assessment; performing evaluations for the safety and health of emergency response personnel, the public, and the environment; weapon recovery; and support for onsite radiological monitoring, analysis, and assessment.

- Improvised nuclear devices would be dispositioned as needed, including conducting forensics activities on such a device and its components under the DOE/NNSA Disposition Program and the Federal Bureau of Investigation (FBI) Disposition Forensics Program. Training drills and exercises would be conducted at existing NNSS facilities to maintain a readiness capability for the NNSA Disposition Program and FBI Disposition Forensics Program.

  The NNSA Disposition Program and FBI Disposition Forensics Program would deploy to the NNSS for periodic exercises and training or for an actual incident. All activities would take place in existing facilities at the NNSS.

- Nonproliferation- and counterterrorism-related activities would continue in the areas of arms control (see below), nonproliferation, and counterterrorism. Nonproliferation- and counterterrorism-related activities would provide scientific research and development, technology realization, process and procedure development, equipment testing and certification, and training. The kinds of activities that would be involved in supporting nonproliferation and counterterrorism include use of underground detonations of conventional explosives for seismic studies, releases of biological and chemical simulants, geological studies, and experiments to simulate radio frequencies resulting from various nuclear fuel cycle technologies. These activities are addressed in more detail in Section 3.1.1.3. Some activities supporting U.S. nonproliferation and counterterrorism efforts would occur at RSL and NLVF, but activities would primarily be conducted at the NNSS.

  Under the No Action Alternative, nonproliferation- and counterterrorism-related activities would integrate existing capabilities (i.e., research and development, training, nonproliferation tests and experiments, counterterrorism training, etc.) under an overall program. There would be no new facilities constructed, although existing buildings and other facilities would be modified to accommodate these activities.

Nuclear Forensics

Nuclear forensics is the analysis of nuclear materials recovered from either the capture of unused materials or the radioactive debris following a nuclear explosion. Nuclear forensics can contribute significantly to the identification of the sources of the materials and the industrial processes used to obtain them. In the case of an explosion, nuclear forensics can also reconstruct key features of the nuclear device (AAAS 2008).

Arms control. A key component of nonproliferation activities would be the use of existing facilities as part of an Arms Control Treaty Verification Test Bed dedicated to supporting U.S. arms control initiatives and commitments. This component would support design and certification of treaty verification technology, training of inspectors, and development of arms control confidence-building measures.

Test Bed

A test bed is an area that includes physical structures or designated terrain where tests and experiments are conducted. Test beds may be permanent facilities or temporary sites.

Nonproliferation. Facilities would be provided for Federal agencies to develop remote sensing equipment, methodologies, and training to support national and international nonproliferation programs. Under the No Action Alternative, DOE/NNSA would use existing facilities in Nevada to support research and development in the following areas:

- Safeguarding fissile materials in nations with nuclear weapons or nuclear industries
- Tightening export controls on technology with potential application to weapons of mass destruction
- Improving border protection by installing detectors for radioactive materials

- Inspecting commercial shipments for smuggled nuclear materials

Counterterrorism. DOE/NNSA would support research, development, and training associated with detecting and countering various types of improvised explosive devices, including those that are vehicle-borne. These activities would occur at BEEF, the Nonproliferation Test and Evaluation Complex, and other locations at the NNSS. Detonations of high explosives associated with counterterrorism-related activities would be conducted at various existing facilities and other locations on the NNSS. All explosive operations would be conducted in compliance with DOE Manual 440.1-1A, *DOE Explosives Safety Manual*.

3.1.1.3 Work for Others Program

The Work for Others Program, hosted by DOE/NNSA, facilitates the use by other agencies and organizations of DOE/NNSA facilities and capabilities, such as BEEF, the Nonproliferation Test and Evaluation Complex, T-1 Training Area, and other areas of the NNSS as well as resources at RSL, NLVF, and the TTR. Under the No Action Alternative, DOE/NNSA would continue to host the projects of agencies such as the U.S. Department of Defense (DoD) and the U.S. Department of Homeland Security (DHS), as well as other Federal, state, and local government agencies and nongovernmental organizations, by conducting the activities summarized in the following discussion. Detailed descriptions of these activities are included in Appendix A of this *NNSS SWEIS.*

Treaty verification. DOE/NNSA would continue to host projects related to verification of compliance under a number of nuclear weapon-related treaties. The projects would range from hosting inspections by other nations to conducting research and development in the area of detecting violations of treaties by others.

Nonproliferation projects and counterproliferation research and development. DOE/NNSA would continue to provide support for the following types of activities by other agencies:

- Conventional weapons effects testing, including live-drop and static detonations

- Development and demonstration of capabilities and technologies using conventional high explosives and other methods to effectively threaten and defeat military missions protected in tunnels and other deeply buried and hardened facilities

- Explosives experiments and other explosives operations using up to 2,000 pounds of explosives at various locations on the NNSS. All explosive operations would be conducted in compliance with DOE Manual 440.1-1A, *DOE Explosives Safety Manual*.

- Controlled experiments involving releases (including explosive releases) of biological and chemical simulants. Up to 20 controlled chemical and biological simulant release experiments (each experiment would consist of multiple releases) would be conducted yearly. More-detailed information regarding releases of chemicals and biological simulants is included in Appendix A, Section A.1.1.3.

Counterterrorism. DOE/NNSA would continue to support DoD and other Federal agencies in developing methods for engaging or neutralizing an adversary in a variety of topographical environments. In addition to ground-based operations, military operations would be conducted in the restricted airspace above the NNSS and the TTR.

DHS and DoD would continue to use facilities at the NNSS to develop technology for homeland security applications. The NNSS would continue to provide land and infrastructure to support testing and

evaluation of radiological and nuclear detection devices for use in transportation-related applications. DHS would continue to use the Radiological/Nuclear Countermeasures Test and Evaluation Complex (RNCTEC), a facility constructed at the NNSS on behalf of DHS, as well as other NNSS land and infrastructure, to conduct its activities.

DOE/NNSA's Counterterrorism Operations Support Program would continue to support the Federal Emergency Management Agency's efforts to develop and implement national programs to enhance the capability of state and local agencies to respond to incidents involving weapons of mass destruction through coordinated training, equipment acquisition, technical assistance, and support for state and local exercise planning.

Military Training and Exercises. DOE/NNSA would continue to support DoD by providing land, airspace, and infrastructure for use by various branches of the military to conduct training and exercises. These activities range from small-scale exercises, i.e., focused at a specific building or site, to large-scale exercises involving multiple air and/or ground assets with live-fire operations. These activities would include live fire of military munitions, including small arms, hand grenades, rocket-propelled grenades, etc. Military training and exercises may be conducted throughout the NNSS, but would be primarily conducted in the western portions, including Areas 18, 19, 20, 25 (northern portion), 29, and 30 to preclude interference with and from other NNSS activities. Military training and exercises are subject to all applicable regulatory requirements and to DOE/NNSA NSO work authorization processes (NSO O 412.X1E, *Real Estate/Operations Permit*), which are designed to minimize hazards to workers, the environment, and NNSS physical assets.

Support for the U.S. National Aeronautics and Space Administration (NASA). DOE/NNSA would conduct criticality experiments at DAF in support of NASA's efforts to develop power sources for use in future missions to Mars and similar deep space exploration.

Miscellaneous Work for Others Program activities. DOE/NNSA would continue to provide facilities and airspace for use of aerial platforms for various purposes, including research and development to assess and mitigate operational safety and efficiency of unmanned aerial systems, training and exercises, and deployment of sensors for detection of various items. These types of operations would use a variety of manned and unmanned aerial systems, including fixed-wing aircraft (airplanes) and helicopters.

Work for Others Program activities at the TTR. These activities would be similar to those addressed under the Stockpile Stewardship and Management Program, with the following additions:

- Robotics testing and development (handling, application, and recovery of hazardous [chemical] material)
- Smart transportation-related testing – preprogrammed/remote-controlled air and ground vehicles
- Smoke obscuration operations
- Infrared tests
- Rocket development, testing, and deployment

National Security/Defense Mission—American Indian Perspective

The Consolidated Group of Tribes and Organizations' (CGTO) concerns and perspective regarding the National Security/Defense Mission are presented in the following text, which summarizes our views and applies to all aspects of this mission, including those pertaining to the Stockpile Stewardship and Management Program; the Nuclear Emergency Response, Nonproliferation, and Counterterrorism Program; and the Work for Others Program.

According to tribal elders, *"There is always going to be testing. Areas such as U1a that support underground testing are where the effects are evaluated. There are programs and facilities where stockpile stewardship and management activities are currently performed. The CGTO knows that the U.S. Department of Energy (DOE) maintains and conducts experiments and testing at various locations throughout the NNSS. We continue to be concerned about these activities and their impacts to the cultural landscape. Our involvement is essential to restoring and maintaining the balance to the land and its resources."*

The CGTO understands the National Security Defense Mission includes complying with the nuclear weapons test moratorium of 1992, which precludes new underground nuclear testing. We also understand DOE is required to maintain a state of readiness to resume nuclear tests if so directed by the President. The CGTO continues to be intensely opposed to all nuclear testing. In consideration of our ancestral ties and proximity to the land, the DOE, as a representative of the Federal government, must fulfill its trust responsibility by fully informing the CGTO and culturally affiliated tribal governments prior to any proposed testing activities. This step is vital to protecting the spiritual and physical health of our people by preparing for the desecration of our Holy Land and its resources.

The CGTO understands the fundamental intent of the Nonproliferation and Counterterrorism projects is to promote world peace and reduce the need to use the Nevada National Security Site (NNSS) and its offsite locations for nuclear weapons production, storage, assembly, and testing. However, the CGTO believes these activities may increase the number of weapons stored, disassembled, and disposed. These dangerous conditions may result in the land becoming angry and further contaminated, thereby impeding our ability to access important resources on our ancestral land.

The CGTO knows from past experience, but not formal study, that military training exercises and weaponry tests can adversely impact cultural resources. Military people move across the land on foot and in vehicles without either the time or the purpose to pay attention to delicate plants being disturbed, animals that are being dislocated, or the archaeological material and other important resources underfoot.

Often geographically distinctive power places or culturally sensitive areas are targeted without regard or knowledge of the significance to Indian people. Military exercises involving aircraft disrupt the harmony within the cultural landscape. Cultural resources may be damaged when conventional weapons are fired nearby. The environmental setting is disrupted from the noise and vibrations associated with these military operations and overflights. Noise and vibrations upset the spirituality and solitude of the area, negatively impacting songscapes and storyscapes. When the thoughts and focus are interrupted, the balance and well-being of the community as a whole become affected. Cultural resources are damaged when conventional weapons are fired nearby. Without a formal study, the exact impacts of military training exercises will not be fully understood. Thus, the CGTO again recommends adequate funds and time be provided for the CGTO to develop a guidance document. At a minimum, applicable CGTO representatives must obtain appropriate military clearances and access to pray for (talk to) and prepare the land and its resources prior to these military exercises.

See Appendix C for more details.

3.1.2 Environmental Management Mission

DOE/NNSA's Environmental Management Mission includes the Waste Management and Environmental Restoration Programs. Related activities under the No Action Alternative are described in the following sections. A more detailed description of these activities is provided in Appendix A, Section A.1.2.

Environmental Management Mission—American Indian Perspective

The Consolidated Group of Tribes and Organizations' (CGTO) concerns and perspective regarding the Environmental Management Mission are presented under the Waste Management Program (Section 3.1.2.1) and the Environmental Restoration Program (Section 3.1.2.2), as appropriate.

See Appendix C for more details.

3.1.2.1 Waste Management Program

The Waste Management Program would continue to store, treat, and/or dispose various wastes at the NNSS. These wastes include LLW, mixed low-level radioactive waste (MLLW), transuranic (TRU) waste, mixed TRU waste, hazardous waste, asbestos and polychlorinated biphenyl (PCB) wastes, hydrocarbon-contaminated soil and debris, and solid wastes such as construction debris or sanitary solid waste. Liquid nonhazardous wastes (such as sewage and other wastewater) are not included under the Waste Management Program, but are addressed in Section 3.1.3.1, General Site Support and Infrastructure Program. All DOE/NNSA waste management activities operate in compliance with applicable regulatory requirements and DOE Orders. Waste management activities at DOE/NNSA sites in Nevada under the No Action Alternative would include the following:

Waste Definitions

Radioactive Waste – Solid, liquid, or gaseous materials that contains radionuclides regulated under the Atomic Energy Act of 1954, as amended, and of negligible economic value, considering costs of recovery.

Transuranic (TRU) Waste – Radioactive waste containing alpha particle-emitting radionuclides having an atomic number greater than 92 (the atomic number of uranium) and half-lives greater than 20 years, in concentrations greater than 100 nanocuries per gram.

Low-Level Radioactive Waste (LLW) – Radioactive waste not classified as high-level radioactive waste, TRU waste, spent fuel, or byproduct material as defined by Section 11e(2) of the Atomic Energy Act of 1954, as amended. Test specimens of fissionable material irradiated for research and development only, and not for the production of power or plutonium, may be classified as LLW, provided the concentration of TRU elements is less than 100 nanocuries per gram.

Hazardous Waste – A category of waste regulated under the Resource Conservation and Recovery Act (RCRA). To be considered hazardous, waste must be a solid waste under RCRA and must exhibit at least one of four characteristics described in 40 *Code of Federal Regulations* (CFR) 261.20-24 (ignitability, corrosivity, reactivity, and toxicity) or be specifically listed by the U.S. Environmental Protection Agency in 40 CFR 261.31-33.

Mixed Waste – Waste containing both radioactive and hazardous components, as defined by the Atomic Energy Act and RCRA, respectively. Mixed waste intended for disposal must meet the Land Disposal Restrictions as listed in 40 CFR Part 268. Mixed waste is a generic term for specific types of mixed waste, such as mixed low-level radioactive waste (MLLW) and mixed TRU waste.

Waste Generator – An individual, facility, corporation, government agency, or other institution that produces waste material for certification, treatment, storage, or disposal.

Waste Acceptance Criteria – A document that establishes the National Nuclear Security Administration Nevada Site Office waste acceptance criteria. The document provides the requirements, terms, and conditions under which the Nevada National Security Site (NNSS) accepts LLW and MLLW for disposal. It includes requirements for the generator's waste certification program, characterization, traceability, waste form, packaging, and transfer. The criteria apply to radioactive waste received at the NNSS Area 3 Radioactive Waste Management Site and Area 5 Radioactive Waste Management Complex for storage or disposal.

LLW and MLLW management. LLW and MLLW from approved generators that meet the NNSS waste acceptance criteria would be accepted for disposal. The volume of LLW projected for disposal at the NNSS over the next 10 years and analyzed under the No Action Alternative is based on the actual volume of LLW disposed at the NNSS during FY 1997 through FY 2010, and is estimated to total about 15,000,000 cubic feet. Up to 1 percent of the total projected LLW volume could consist of nonradioactive, classified waste forms that require disposal in a manner similar to LLW. These classified waste forms would be disposed in the Area 5 Radioactive Waste Management Complex (RWMC) at the NNSS. In order to provide a conservative analysis of potential human health impacts, DOE/NNSA assumed that the entire volume of waste was composed of only radioactive wastes. The volume of MLLW projected for disposal at the NNSS over the next 10 years is based on the disposal capacity of the new Mixed Waste Disposal Unit, Cell 18,[1] and is estimated to total about 900,000 cubic feet.

DOE/NNSA would continue to manage onsite-generated MLLW by a combination of several options: (1) treatment at the TRU Pad in the Area 5 RWMC, when appropriate; (2) storage at the TRU Pad or at a new MLLW storage facility, pending

[1] *The actual permitted volume of MLLW that may be disposed in Cell 18 is 899,996 cubic feet.*

certification for disposal; and/or (3) shipment to a permitted facility, such as Energy Solutions in Clive, Utah, or the Materials and Energy Corporation in Oak Ridge, Tennessee, for appropriate treatment. Onsite-generated MLLW treated at another location would be returned to the NNSS for disposal or would be disposed at a permitted commercial facility. Under the No Action Alternative, offsite-generated MLLW would not be treated at the NNSS.

Under the No Action Alternative, the Area 5 RWMC would continue to operate within the approximately 740-acre area set aside for waste management purposes. LLW disposal units would be developed, filled, and closed as needed, in compliance with applicable regulatory requirements and DOE Orders. NNSS- and offsite-generated LLW would be disposed within these units. The Nevada Division of Environmental Protection (NDEP) issued a Resource Conservation and Recovery Act (RCRA) Part B permit effective December 1, 2010, for a new MLLW disposal unit, Cell 18, at the Area 5 RWMC. Construction of the new MLLW disposal unit is complete and it began accepting MLLW for disposal in January 2011. Temporary storage operations for MLLW would continue at RCRA-permitted facilities. Support facilities within the Area 5 RWMC would continue to operate.

The Area 3 Radioactive Waste Management Site (RWMS) would not be utilized under the No Action Alternative.

Small quantities (a few cubic feet over the next 10 years) of LLW may be generated at RSL and NLVF. Normal operations at the TTR are not expected to generate radioactive waste, but environmental restoration activities at the TTR would generate LLW and possibly unknown quantities of TRU waste. These environmental restoration wastes would be disposed at appropriate disposal sites, such as the Area 5 RWMC and/or the Waste Isolation Pilot Plant, as appropriate.

TRU and mixed TRU waste management. TRU waste generated by DOE/NNSA operations or by the Environmental Restoration Program (an estimated 9,600 cubic feet over the next 10 years) would be safely stored at the TRU Pad, pending characterization and shipment either to the Waste Isolation Pilot Plant for disposal or to another facility, such as Idaho National Laboratory, for processing before being sent to the Waste Isolation Pilot Plant.

TRU and mixed TRU wastes would not be generated at RSL, NLVF, or by DOE/NNSA Sandia Site Office activities at the TTR. However, an unknown quantity of TRU waste may be generated by environmental restoration projects at the TTR.

Hazardous waste management. DOE/NNSA activities would generate about 170,000 cubic feet of hazardous waste at the NNSS over the next 10 years under the No Action Alternative. The Hazardous Waste Storage Unit in Area 5 of the NNSS would continue to operate under a RCRA Part B permit issued by NDEP. Onsite-generated hazardous waste would be stored for up to 1 year prior to shipment to offsite treatment and/or disposal facilities.

RSL is a small-quantity generator of hazardous waste. As it is generated, hazardous waste would be accumulated at RSL for no more than 90 days and then transported off site to a permitted facility for treatment and/or disposal. Waste management field activities at RSL are provided by the USAF as landlord services under a Memorandum of Agreement. USAF personnel pick up and dispose miscellaneous laboratory and process equipment wastes under the terms of Nellis Air Force Base Plan 12 (Hazardous Waste Management Plan, October 2007).

NLVF is a conditionally exempt, small-quantity generator of hazardous waste. Hazardous waste would continue to be accumulated at NLVF and transferred off site to a commercially permitted facility for treatment and/or disposal.

Excess materials that may otherwise be considered hazardous waste would continue to be shipped off site for recycling. Excess materials are those that are no longer needed or are unusable but can be recycled.

The TTR is a small-quantity generator of hazardous waste. Hazardous wastes would continue to be accumulated at the TTR for no more than 180 days before being transferred off site to a permitted treatment, storage, and disposal facility.

Used oil from all DOE/NNSA NSO facilities and the TTR would continue to be collected and sent off site for recycling.

Asbestos and PCB waste management. Friable, nonradioactive asbestos waste would continue to be disposed at the Area 23 Solid Waste Disposal Site and possibly at the U10c Solid Waste Disposal Site, pending permit modification and review. Radioactive asbestos waste would continue to be disposed at the Area 5 RWMC. Nonfriable asbestos waste would continue to be disposed at the U10c Solid Waste Disposal Site. Nonradioactive PCB wastes would be accumulated at the Hazardous Waste Storage Unit in Area 5, pending transfer to a permitted treatment and/or disposal facility. Radioactive PCB-contaminated waste meeting 40 CFR Part 761 requirements would continue to be disposed in the MLLW Disposal Unit at the Area 5 RWMC.

DOE/NNSA would continue to dispose asbestos and PCB wastes generated at the TTR at a permitted treatment, storage, and disposal facility.

Explosives waste treatment. DOE/NNSA would continue to treat old and/or unusable explosives by open-air detonation at the permitted Explosive Ordnance Disposal Unit in Area 11.

Hydrocarbon-contaminated soil and debris management. The Area 6 Hydrocarbon Solid Waste Disposal Site would continue to operate under a permit issued by NDEP and would accept onsite-generated soil and debris contaminated with hydrocarbons. The U10c Solid Waste Disposal Site would also continue to operate under a permit issued by NDEP and would accept limited amounts of onsite-generated soil and debris contaminated with hydrocarbons. Onsite-generated hydrocarbon-contaminated LLW would continue to be disposed in the Area 5 RWMC. During routine activities at RSL and NLVF, no hydrocarbon-contaminated waste would be generated. If an accidental release of hydrocarbon-contaminated waste were generated, it would be disposed at a facility permitted to receive such waste. The TTR would continue to dispose hydrocarbon-contaminated soil and debris at an offsite permitted/approved landfill.

Solid waste management. DOE/NNSA activities would generate about 3,700,000 cubic feet of sanitary solid waste and construction and demolition waste over the next 10 years. Sanitary solid waste would be disposed at existing permitted facilities at the NNSS. DOE/NNSA would continue to operate the Area 23 Solid Waste Disposal Site. This permitted facility accepts less than 20 tons of sanitary waste per day. Industrial solid waste and construction and demolition debris would continue to be disposed at the U10c Solid Waste Disposal Site. An estimated 370,000 cubic feet of sanitary solid waste would be sent off site for recycling, rather than landfill disposal during the next 10 years.

At RSL and NLVF, sanitary solid waste would continue to be disposed off site by a municipal waste service.

At the TTR, sanitary solid waste would continue to be disposed at the USAF sanitary waste landfill. Industrial solid waste such as construction or demolition debris would be disposed at a USAF landfill or shipped off site for disposal at the NNSS or a permitted commercial landfill.

Excess materials that are suitable for recycling or reuse, such as scrap metal, would be shipped off site for recycling.

Waste Management Program—American Indian Perspective

The Consolidated Group of Tribes and Organizations (CGTO) understands current and proposed waste management activities identified under the Environmental Management Mission include high-hazard experiments involving nuclear material and high explosives, and storing nuclear materials. The CGTO is aware the Nevada National Security Site (NNSS) is used to store hazardous waste, to store and dispose of non-hazardous waste and debris, and to secure and dispose of low-level radioactive waste, low-level mixed radioactive waste (i.e., containing certain hazardous wastes). After many years, the CGTO continues to be greatly concerned with the ongoing storage and disposal of these various waste streams at the NNSS, and the transportation of radioactive waste to the NNSS from locations in Nevada and from other states.

We understand the radioactive and hazardous materials and waste described in this site-wide environmental impact statement (SWEIS) are defined in scientific terms and governed by state and federal regulations. For example, to scientists, radioactive rocks are well understood with specific quantifiable physical properties. Scientists believe if they manage radioactivity in a purely scientifically appropriate manner, they are largely safe for use and disposal at the NNSS, an area often perceived by non-Indian people as a barren wasteland.

Contrary to scientific belief, American Indian people hold complex traditional views of radioactivity, based upon the fundamental knowledge that all resources—including the rocks—are alive. Indian people believe radioactive rocks are very powerful.

We know that radioactive rocks can become "angry rocks" if they are removed without proper ceremony, used in a culturally inappropriate way, disposed of without ceremony, or placed where they do not want to be. The angry rock constitutes a threat that can neither be contained nor controlled by conventional means. It has the power to pollute food, medicine, and places, none of which can be used afterward by Indian people. Spiritual impacts are even more threatening, considering the angry rock would be transported along highways before ultimately being disposed of at the NNSS, affecting animal creation places, access to spiritual beings, and unsung human souls.

Indian knowledge and use of radioactive rocks, or minerals, in the western United States goes back for thousands of years. Areas with high concentrations of these minerals are called dead zones. Such areas contain places of power or energy and could only be visited or certain minerals used under the supervision of specially-trained Indian people, who are sometimes referred to in the English language as a shaman or medicine man Therefore, the U.S. Department of Energy would benefit from this knowledge if applied correctly.

Continuing to transport the waste is detrimental to the public and the tribes. We are specifically concerned about the downtown transportation route. According to a tribal elder, "The springs are located there and, if contaminated, can seep into many other water sources and contaminate the people and the environment."

According to tribal elders, *"We are not sure how long Nellis and the NNSS have been designated as these types of facilities, and how much waste has been created, stored, and transported. This information is necessary for the CGTO to fully understand how significant the people and our resources may have been affected, and to prepare ceremonies, prayers, and culturally appropriate mitigation measures to attempt to restore balance. For example, Sunrise Mountain is a very significant mountain. Behind this mountain is an important cave, Gypsum Cave, which some Indian people fear but is highly respected. There are traditional stories surrounding this area. The mountain and the cave are both culturally significant. Caves are supposed to hold much power. They are supposed to interact with your mind. When you leave a cave, you are much more powerful."* Gypsum Cave, which is protected and monitored by culturally affiliated tribes and the Bureau of Land Management (BLM), is awaiting designation as a Traditional Cultural Property that may be impacted by the transportation of the waste.

See Appendix C for more details.

3.1.2.2 Environmental Restoration Program

Under the No Action Alternative, the DOE/NNSA Environmental Restoration Program would continue, in compliance with the most recent version of the Federal Facility Agreement and Consent Order (FFACO), to characterize, monitor, and remediate identified contaminated areas, facilities, soils, and groundwater. The Environmental Restoration Program is organized into three projects and supports the Defense Threat Reduction Agency in addressing its environmental restoration sites at the NNSS. The three projects are the Underground Test Area (UGTA) Project, Soils Project (includes contaminated soil sites from the TTR and the Nevada Test and Training Range), and the Industrial Sites Project (includes the Decontamination and Decommissioning Project and facilities to be remediated at the TTR and the NNSS described in the *1996 NTS EIS*). In addition, DOE/NNSA's Borehole Management Program work is executed by the Environmental Restoration Program. Activities that would be undertaken over the next 10 years by the Environmental Restoration Program are described in the following discussion. More-detailed descriptions of these activities are provided in Appendix A of this *NNSS SWEIS*.

Underground Test Area Project. In compliance with the FFACO, the UGTA Project would continue to characterize and monitor groundwater from existing wells; drill new characterization wells; expand

groundwater monitoring to include new wells; develop groundwater flow and transport models; and evaluate closure strategies including adaptive monitoring and management. Up to 50 new groundwater characterization and monitoring wells would be developed over the next 10 years. UGTA Project activities would occur on the NNSS, Nevada Test and Training Range, U.S. Bureau of Land Management land, and privately owned land as necessary and as permission is obtained.

Soils Project. The Soils Project would continue to investigate and characterize soil sites (using in situ monitoring, air monitoring, surface-water contaminant transport studies, and soil sampling) and perform corrective actions, as necessary. The Soils Project would ensure that proper use restrictions are in place to implement site closure so that worker doses are below the applicable regulatory limits and are kept as low as reasonably achievable. Under the FFACO, one of two strategies is implemented in remediating contaminated soils sites: clean closure or closure-in-place. Clean closure would include removing contaminated media from a site, rendering the site "clean" (i.e., the remaining levels would be below levels considered safe for the designated use of the site). In cases where the benefit (including reducing hazards to workers, the public, and environment) derived from removal of contaminated material justifies the cost of removal, clean closure would be the preferred closure strategy. However, because the NNSS, TTR, and Nevada Test and Training Range are remote, secure sites with no unescorted public access allowed, most soils sites may be closed using the closure-in-place strategy. Under a closure-in-place scenario, potential source material (e.g., lead bricks, batteries, hazardous waste) would generally be removed, with the radioactively contaminated soil left in place. Under either closure strategy, the Soils Project would implement the controls necessary to prevent the spread of unsafe concentrations of remaining contamination, and, if necessary, would ensure that proper use restrictions are in place to implement the site closure. The current closure strategy for soil project sites at the NNSS is based on current industrial land use scenarios with a 25-millirem-per-year exposure action level. Soils sites on the Nevada Test and Training Range, including the TTR, would be remediated to action levels that are mutually agreed upon by DOE/NNSA, the USAF, and NDEP. The potential for stricter cleanup levels is addressed under the Expanded Operations Alternative. NNSA anticipates that all identified Soils Project sites will be closed under the FFACO by the end of 2022.

Federal Facility Agreement and Consent Order

The Nevada National Security Site Environmental Restoration Program includes activities to comply with the Federal Facility Agreement and Consent Order (FFACO), which was entered into in 1996 by the U.S. Department of Energy, the U.S. Department of Defense, and the State of Nevada. The FFACO provides a process for identifying sites having potential historic contamination, implementing state-approved corrective actions, and instituting closure actions for remediated sites.

Industrial Sites Project. The Industrial Sites Project would continue its field program to identify, characterize, and remediate industrial sites under the FFACO and to decontaminate and decommission unneeded facilities. The majority of FFACO industrial sites have been closed. Remediation, decontamination, and decommissioning activities are projected to be complete by the end of 2018. Industrial Sites Project activities would continue at present levels, although alternate uses of remediated facilities may require revised cleanup levels.

Defense Threat Reduction Agency sites. The Defense Threat Reduction Agency sites are identified as part of the DOE/NNSA Environmental Restoration Program because their site activities are considered environmental remediation on the NNSS. However, the Defense Threat Reduction Agency is responsible for implementing and funding these activities in compliance with applicable agreements with NDEP. Surface-disturbing activities associated with these sites have been completed and environmental monitoring, such as water sampling, would continue.

Borehole Management Program. Under the No Action Alternative, DOE/NNSA would continue to plug unneeded boreholes on the NNSS. Based on the current schedule and known inventory of unneeded boreholes on the NNSS that need to be plugged, the Borehole Management Program would be complete by the end of 2012.

Environmental Restoration Program—American Indian Perspective

According to tribal elders, *"The Creator placed everything—the land, rocks, plants and animals-where they are for a purpose. However, now that the NNSS land is disturbed and has become upset, we must come up with the appropriate prayers and ceremonies to rebalance the land and its resources."*

The Consolidated Group of Tribes and Organizations (CGTO) views environmental restoration activities attributed to the Environmental Management Mission as a positive effort to rebalance the world as everything is connected. Individual restoration projects are insufficient alone but are starting points and should be considered as stages or steps in a comprehensive and complex spiritual and ecological restoration program. The CGTO's view coincides with the principles of holistic ecosystem management subscribed to by the public and many Federal agencies.

A key component to environmental restoration is revegetating the disturbed areas to resemble its original condition. According to tribal elders, *"Prior to re-vegetation efforts, we talk to the land to apologize for what has been done and to let it know what we plan to do. Then we ask the Creator for its help. We choose our seeds from the sweetest and/or best plants, and store them for the winter to dry. When the winter is over, we place the seeds in a moist towel or sock and allow the new plant to sprout. We then plant the sprouts in small containers with soil until they are strong enough to be transplanted into the ground. This is a long and delicate process, requiring patience and traditional ecological knowledge passed down from our ancestors. If the plants are struggling to grow, we tag them and move them to face the same direction as the Sun."*

The U.S. Department of Energy (DOE) would benefit from this unique knowledge to further enhance their re-vegetation efforts of disturbed sites. The CGTO knows DOE struggles with the success rates of the density and diversity of native plants during their re-vegetation efforts. A co-stewardship approach between the CGTO and DOE to collectively manage this land would enable DOE to enhance their re-vegetation efforts, thereby saving time, money, and resources.

In the 1996 *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada (1996 NTS EIS)* and in the 2002 *Supplement Analysis for the Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada (2002 NTS SA)*, the CGTO continued to express concerns about the removal of contaminated soils and the need for religious leaders to conduct balancing ceremonies and healing prayers at these disturbed locations. The CGTO recommended that tribal representatives provide information about the re-vegetation of a portion of the Double Tracks Site located on the Tonopah Test Range (TTR). The CGTO maintains our involvement is still necessary for the Double Tracks site as well as for the Clean Slates site located at TTR; however, we are awaiting DOE's approval to proceed. Because of the long lapse of time since the last visits, the CGTO believes it is necessary to revisit and reevaluate site conditions.

As stated earlier, the CGTO is supportive of restoring the environment. However, we are concerned about the future plans to decontaminate and decommission (D&D) some buildings that may have asbestos and other contamination, which will be released during the process. Specifically, the CGTO is concerned about potential impacts to the air, water, plants and animals. In addition, nearby tribes may be performing ceremonies and prayers and need to be notified so the D&D process does not negatively impact these important religious and traditional events through elevated noise, vibration levels and the spreading of dead air.[1]

Over the past 14 years, various initiatives have been undertaken to restore animal habitats and reintroducing certain animals, such as the desert big horn sheep near the southern portion of the Nevada National Security Site (NNSS), without participation from the CGTO. Modification of habitat or the restocking of animals is considered a highly sensitive religious act and requires participation from the CGTO. For these activities to be successful and to properly restore environmental balance, it is essential to have tribal representatives involved throughout this process.

In the 2008 *Draft Supplement Analysis for the Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada (2008 Draft NTS SA)*, the AIWS presented information regarding the successful reintroduction of a gray wolf in Idaho during the late 1970's, which was a collaborative effort between American Indians and a Federal agency. On the day of release, a Federal liaison unlatched the door of the cage and the animal scrambled out. Waiting for the wolf was an American Indian holy man in traditional regalia, sitting on a horse and watching. The wolf and man gazed at each other and the man spoke words welcoming the wolf back to its natural habitat. The wolf stood for a few more seconds and accepted the holy man's encouragement and blessing. Then the wolf turned and ran into the forest. Everyone present was very moved by the welcoming back ceremony. They knew that was the right thing to do. The CGTO believes collaborative projects such as this underscores the need for American Indian involvement whenever plant or animal species transplanted from other locations are reintroduced to the NNSS area.

We recommend conducting ethnographic studies involving the CGTO to better understand sites such as, but not limited to, Water Bottle Canyon, Timber Mountain, Shoshone Mountain, and other sites identified by the CGTO. Spiritual and ecological restoration assessments and projects require traditional management practices, and the involvement of tribal cultural experts to be successful. These specialists are needed to conduct initial assessments and site inventories, and to make recommendations for the next steps of the restoration effort. This strategy will result in the identification of resources, features, and other site aspects both tangible and intangible, that are in need of healing and restoration using culturally appropriate steps necessary to achieve restoration and balance.

[1] *Refer to Appendix C.2.8, Air Quality and Climate, for additional information regarding dead air.*

Environmental Restoration Program—American Indian Perspective (cont'd)

Clearly, members of the CGTO have unique and extensive experience in collaborative spiritual and ecological restoration. We have many examples of successful collaboration among our tribal members and Federal agencies. For example, the Big Warm Spring near the Duckwater Shoshone Tribe has been used throughout history for spiritual cleansing and healing. Young men are taken there during the "coming of age" to wash and cleanse themselves. In 2005, in collaboration with the U.S. Fish and Wildlife Service, the Duckwater Shoshone Tribe restored the Big Warm Spring to its original size and removed the non-native fish species. In 2007, during the final phase of the project, tribal members reintroduced the Railroad Valley Spring Fish to the Big Warm Spring in a culturally appropriate manner, successfully completing the spiritual and ecological restoration for this collaborative effort.

There are many potential spiritual and ecological restoration projects on the NNSS in need of attention, all with the goal of balancing the spiritual, cultural, and ecological inner-workings of those places. Based on CGTO experience with environmental restoration projects, we encourage DOE to implement a more aggressive collaborative environmental restoration program. Potential projects focusing on the protection of wildlife, plant resources, and geological features, include the following:

Restoration of Water Bottle Canyon

Water Bottle Canyon is a natural water tank area and an exceptional cultural site. Cultural resources include *pohs*, tanks, rock rings, tonal rocks, and traditional-use plants. Any activities impacting the side canyon or Water Bottle Canyon affect the rest of the gully system, which is connected through physical and spiritual flows. Presently, the spiritual aspects of Water Bottle Canyon are out of balance and require cultural interactions to bring the canyon back into balance. The cleaning of the *pohs* and tanks in this canyon system is one of several cultural practices needed to begin spiritual and ecological restoration. This project can reduce drought conditions, and provide spiritual, cultural, and ecological benefits to the area while concurrently fulfilling the primary goal of spiritual and ecological rebalancing. Implementation of this project will require the appropriate cultural experts to identify project sites, inventory and evaluate the conditions, resources, and features of the sites, and develop a compatible restoration plan. The Project would require overnight camping, annual activities, and monitoring of site conditions.

Evaluation of Traditional Cultural Property

During the DOE Annual Tribal Meeting with the CGTO, held September 12, 2009, the CGTO recommended the DOE support the nomination of a Traditional Cultural Property, previously identified as *Wunjikuda*. The CGTO recommended expanding the studies to enhance previously collected ethnographic information, and determining an appropriate title using knowledgeable tribal elders identified by the CGTO. The CGTO also recommended the DOE sponsor overnight camping activities at this site to elicit additional information from knowledgeable tribal representatives for the development and submittal of the nomination to the National Register of Historic Places.

Cleaning Pohs and Tanks

The *pohs* and tanks found throughout the NNSS require traditional attention and cultural management to function effectively. The *pohs* and tanks at Water Bottle Canyon and Ammonia Tanks, for example, are interrelated and tie each location to one another. Both sites are used to store water from the rain needed and used for ceremonial purposes to restore balance. American Indian people have Rain Shaman who have the ability to talk to all of the elements responsible for bringing water or rain to the land, people and animals. According to tribal elders, *"When the water arrives, it is approached with great respect and awakened very carefully when prayed upon. In appreciation and in honor of the water's return, the animals come back, the plants flourish and people will continue to pray and give thanks all ultimately leading to balance and restoration of the area."* Customarily, Indian people cleaned the *pohs* and tanks through the use of songs, stories and prayers. Cleaning of the *pohs* and tanks were followed by the Rain Shaman who called the rain.

By supporting the CGTO's proposed project to clean the *pohs* and tanks, DOE will reduce drought conditions and restore balance to the area. It will provide spiritual, cultural, and ecological benefits to the land and environment, thereby facilitating our obligation of spiritual and ecological rebalancing. Implementation of this project will require the appropriate cultural experts to identify project sites, to inventory and evaluate the conditions, resources, and features of the site, and to develop a culturally compatible restoration plan.

See Appendix C for more details.

3.1.3 Nondefense Mission

The Nondefense Mission generally includes those activities that are necessary to support mission-related programs, such as constructing and maintaining facilities, providing supplies and services, warehousing, and similar activities. Activities related to supply and conservation of energy, including renewable energy and other research and development projects, are included under the Nondefense Mission. Sections 3.1.3.1 and 3.1.3.2 describe Nondefense Mission activities that DOE/NNSA would undertake at its facilities in Nevada under the No Action Alternative. A more detailed description of these activities is included in Appendix A of this *NNSS SWEIS*.

3.1.3.1 General Site Support and Infrastructure Program

Like any large facility, the NNSS has a substantial infrastructure that provides all site-support services. Under the No Action Alternative, infrastructure-associated activities would continue, including projects such as repairs and replacements to maintain present facility capabilities. For instance, maintenance and repair projects include: repair Area 23 sewer main, remediate underground storage tanks, replace five roll-up doors, renovate and reactivate several water tanks, replace electric hot water heaters, install water tank security ladders, replace roofs on several buildings, and repair/maintain NNSS roadways.

In addition to maintaining and repairing its infrastructure at the NNSS, RSL, NLVF, and the TTR, DOE/NNSA would maintain the existing infrastructure, provide site security, and manage all applicable existing permits and agreements for the former Yucca Mountain site. DOE/NNSA would perform these functions pending decisions on the disposition of the former Yucca Mountain site.

Nondefense Mission—American Indian Perspective

There are a variety of current and proposed actions considered under the Nondefense Mission. Many of these are related to the Nevada National Security Site (NNSS) Environmental Research Park, which allows universities and other Federal agencies to conduct research. Other projects involve solar and geothermal energy development, and constructing the Nevada Desert Free-Air Carbon Dioxide Enrichment and the Mojave Global Change facilities proposed in Area 5. The Consolidated Group of Tribes and Organizations' (CGTO) concerns and perspective regarding the Nondefense Mission, including activities associated with the Infrastructure, Conservation and Renewable Energy, and Other Research and Development Programs, are summarized here.

Indian people view each proposed project under the Nondefense Mission as potentially impacting cultural resources. Non-Indian people unfamiliar with the importance of leaving cultural resources untouched may find and collect artifacts or remove plants that are significant to American Indian people. Construction of the proposed solar generating facility in Area 25 involves draining the Sun of its power unnaturally and making it weak. Construction also involves scraping the land, generating dust emissions, facilitating erosion, and impeding visual resources.

All landforms within the NNSS are highly sensitive to American Indians. The ability to see the land without the distraction of buildings, towers, cables, roads, and other objects is central to the spiritual interaction between Indian people and their traditional lands. Visual resources may be negatively impacted if proposed solar and geothermal projects are pursued. The CGTO must be part of any future discussions of these projects due to potential impacts on visual resources that may impede traditional and cultural ceremonies.

Only Indian people know which places are appropriate for visits by non-Indian people and how to manage plants, animals, and soil samples so that these activities do not disrupt the land and its associated spirituality. Because of the potential effects on the environment and its resources from Nondefense Mission projects, the CGTO must become an integral part of site-specific studies and develop culturally appropriate text for future National Environmental Policy Act (NEPA) analyses, including environmental assessments and mitigation plans.

See Appendix C for more details.

Although they are part of DOE/NNSA's infrastructure, characterization and monitoring wells developed under the UGTA Project are addressed under the Environmental Management Program, and proposed and potential renewable energy projects are addressed under the Conservation and Renewable Energy Program, rather than the General Site Support and Infrastructure Program.

3.1.3.2 Conservation and Renewable Energy Program

Under the No Action Alternative, DOE/NNSA would continue to identify and implement conservation measures and renewable energy projects in the following areas:

- Energy efficiency
- Renewable energy

- Water conservation
- Transportation/fleet management
- High-performance and sustainable buildings

Table 3–2 summarizes the NNSS Conservation and Renewable Energy Program.

Commercial solar power facility. Under the No Action Alternative, DOE/NNSA is evaluating a hypothetical 240-megawatt parabolic trough commercial solar power generation facility at the NNSS. DOE/NNSA has determined that the southwestern portion of Area 25 would be the only reasonable location on the NNSS for a commercial solar power generation facility. Area 25 includes an extensive area of suitable terrain for solar power generation facilities, has existing vehicular access from Highway 95 via Lathrop Wells Road and an existing 138-kilovolt transmission line, and is removed from national security-related activities on the NNSS that require limited access to uncleared individuals. Although it possesses many of the same attributes as Area 25, Area 22 is not being considered as a potential location for solar power development in this *NNSS SWEIS* because all current solar power technologies require the use of substantial amounts of water for cooling and other purposes and there would be potential impacts on Devil's Hole (see Chapter 5, Section 5.1.6) resulting from construction of any facility built in Area 22 that would draw water from the underlying hydrographic basin. Low-water-use renewable energy projects may be considered for Area 22 in the future.

The solar technologies that are most likely to be deployed at utility scale over the next 20 years are photovoltaic and concentrating solar power, such as parabolic trough, power tower, and dish engine (DOE/BLM 2012). It is unknown what technology would be used in a solar power generation facility at the NNSS, but the analysis in this *NNSS SWEIS* assumes a concentrating solar power parabolic trough facility using a dry-cooling system, based on the prevalence of that technology in other operating, proposed, and potential solar energy projects in southern Nevada (see Chapter 6, Table 6–2), and because impacts on sensitive resources, such as groundwater, would be greater than those from a photovoltaic facility, resulting in a more conservative analysis (i.e., impacts would not likely be underestimated). It is estimated that a concentrating solar power facility using parabolic trough technology would require between 9 and 10 acres of land for each megawatt of generating capacity, based on the proposed Amargosa Farm Road Solar Project (BLM 2010c). This acres-per-megawatt rate of generating capacity is about double that used in the *Final Programmatic Environmental Impact Statement for Solar Energy Development in Six Southwestern States* (DOE/BLM 2012), but is consistent with proposed parabolic trough solar power facilities currently being considered in southern Nevada. The assumptions used in the *Final Programmatic Environmental Impact Statement for Solar Energy Development in Six Southwestern States* are shown in Appendix A, Section A.1.3.2. Using the ratio scaled from the Amargosa Farm Road Solar Energy Project, the projected amount of power generated from a 2,400-acre Renewable Energy Zone on the NNSS is about 240 megawatts (West 2010). As stated in Chapter 5, Section 5.1.6.2.1, operation of a 240-megawatt commercial solar power generation facility using concentrating solar power technology would require up to approximately 250 acre-feet of water per year. In addition, electrical transmission capacity would be required to integrate the electricity generated by a 240-megawatt facility into the regional grid system. Approximately 10 miles of new 230-kilovolt transmission line, disturbing about 250 acres of land (all of it off of the NNSS) is assumed to be required for purposes of this analysis. Valley Electric Association is in the process of upgrading parts of its 138-kilovolt transmission line system in Amargosa Valley to 230 kilovolts, and other entities are planning/proposing construction of 500-kilovolt transmission lines into Amargosa Valley (see Chapter 6, Section 6.2.4.4). Currently, there are no specific proposals for commercial-scale solar power generation projects at the NNSS. Therefore, additional project-specific NEPA review would be required to identify, analyze, and document project-specific impacts if such a commercial-scale solar power generation facility were proposed.

Table 3–2 The National Nuclear Security Administration Conservation and Renewable Energy Program Under the No Action Alternative [a]

Energy Efficiency – DOE/NNSA would improve energy efficiency and reduce greenhouse gas emissions at the NNSS by reducing energy intensity by 3 percent annually, or a total of 30 percent through the end of FY 2015, relative to the 2003 baseline. Energy efficiency can be defined for a component or service as the amount of energy required in the production of that component or service; for example, the amount of steel that can be produced with one billion British thermal units of energy. Energy efficiency is improved when a given level of service is provided with reduced amounts of energy inputs, or services or products are increased for a given amount of energy input. Energy intensity is defined as the amount of energy used in producing a given level of output or activity. It is measured by the quantity of energy required to perform a particular activity (service), expressed as energy per unit of output or activity measure of service. Energy intensity measures energy consumption per gross square foot of building space, including industrial and laboratory facilities. Additional activities to improve energy efficiency would include the following: • Installing advanced electric metering systems to the maximum extent practicable at all NNSS buildings and implementing a centralized data collection, reporting, and management system • Using standardized operations and maintenance and measurement and verification protocols coupled with real-time information collection and centralized reporting capabilities to the extent practicable • Expediting improvement in the quality, consistency, and centralization of data collected and reported through the use of commercially available software • Reducing greenhouse gas emissions by 28 percent by FY 2020
Renewable Energy – DOE/NNSA would maximize installation of onsite renewable energy projects at the NNSS where technically and economically feasible. The initial goal would be to acquire at least 7.5 percent of the NNSS' annual electricity and thermal consumption from onsite renewable sources. In the event commercial-scale renewable energy projects are implemented at the NNSS (following additional National Environmental Policy Act analysis), DOE/NNSA would enter into an agreement with a commercial entity to construct a solar power generation project at the NNSS with the provision that a portion of the electric power generated would be provided to meet NNSS electrical needs.
Water – In FY 2007, DOE/NNSA established a water production baseline (210.6 million gallons) in accordance with Executive Order 13423 (72 FR 3919). Specific water consumption figures are not available by facility because the NNSS does not meter individual buildings. Instead, water production data were used to provide metrics in this area. DOE/NNSA sites began saving water through several conservation measures, including installation of WaterSense™ products, xeric landscaping, use of nonpotable water for dust suppression, and 4-day workweeks. DOE/NNSA established a goal of reducing potable water production at the NNSS by 2 percent a year, to 177 million gallons per year, by FY 2015. Water production was reduced by 18 percent in FY 2008 compared with the FY 2007 baseline, thereby exceeding the FY 2015 goal of 16 percent water reduction. Water production was reduced by an additional 8 percent in FY 2009. Efforts to identify water-saving projects and obtain funding to complete them are ongoing to ensure that the water production goals that have been met are maintained.
Transportation/Fleet Management – The current DOE/NNSA fleet has 540 alternative-fuel vehicles, equal to 96 percent of the covered fleet. DOE/NNSA requires that its fleet operate any alternative-fuel vehicles on alternative fuels to the maximum extent practicable. In FY 2007, DOE/NNSA constructed an E85 fuel station in Mercury and implemented a plan to promote the use of E85 fuel (an alcohol–fuel mixture that typically contains a mixture of up to 85 percent denatured fuel ethanol and gasoline or other hydrocarbon by volume). In FY 2007, the total actual usage of E85 was 135,141 gallons; the consumption for FY 2008 was 182,997 gallons, a 35 percent increase in usage. For every gallon of E85 used, 85 percent of the petroleum base fuel is reduced; for every gallon of B-20 biodiesel used, 20 percent is reduced; and for every gallon of unleaded gasoline used, 10 percent is reduced. Biodiesel fuel is used in all equipment, with the exception of emergency generators and boilers, and is currently at the maximum possible usage level.
High-Performance Sustainable Buildings – DOE/NNSA would ensure that (1) all new construction and renovation projects implement design, construction, maintenance, and operation practices in support of the high-performance building goals of Executive Order 13423 (72 FR 3919) and statutory requirements and (2) existing facilities' maintenance and operations practices meet the goals of Executive Order 13423. The DOE/NNSA NSO's High-Performance Building Plan would also align with Executive Order 13327 (69 FR 5897) and DOE Order 430.1B, *Real Property Asset Management*. At a minimum, the High-Performance Building Plan would include employment of integrated design principles, optimization of energy efficiency, use of renewable energy, protection and conservation of water, enhancement of indoor environmental quality, and reduction of environmental impacts of materials in accordance with the annual Site Sustainability Plan for DOE/NNSA facilities in Nevada.

FR = *Federal Register*; FY = fiscal year; NNSA = National Nuclear Security Administration; NSO = Nevada Site Office; NNSS = Nevada National Security Site.
[a] Goals and information as of December 2009.

3.1.3.3 Other Research and Development Programs

In 1992, the NNSS became the seventh unit of the DOE National Environmental Research Park Program. The NNSS program operated under a cooperative agreement between the DOE Nevada Operations Office (now the DOE/NNSA NSO); the University of Nevada, Reno; and the University of Nevada, Las Vegas, whereby the DOE Nevada Operations Office's Environmental Management Office provided financial assistance for scientific research projects unique to the Nevada National Environmental Research Park. In addition, scientific research projects conducted by parties other than those in the above-mentioned agreement could be conducted, but would be funded by sources other than DOE/NNSA.

Nevada National Security Site (NNSS) Environmental Research Facilities

The Nevada Desert Free-Air Carbon Dioxide Enrichment (FACE) Facility and Mojave Global Change Facility (MGCF) are two environmental research facilities located in Area 5 of the NNSS that conduct long-term environmental research. FACE is a state-of-the-art facility designed to study responses of an undisturbed desert ecosystem to increasing levels of atmospheric carbon dioxide. This facility is in a standby condition due to lack of funding.

MGCF was established in Area 5 of the NNSS to examine the impact of global climate change factors other than increased carbon dioxide (i.e., increasing summer monsoon rains, increased nitrogen deposition, and disturbance or destruction of the desert soil crust) on the Mojave Desert ecosystem.

3.2 Expanded Operations Alternative

The scope of the Expanded Operations Alternative in this SWEIS is defined to include the capabilities and projects described under the No Action Alternative, plus additional newly proposed capabilities and projects. These additional activities would include modification and/or expansion of existing facilities and construction of new facilities. In addition, some ongoing activities would be conducted more frequently than under the No Action Alternative. For each activity addressed in this section, the differences from the No Action Alternative are noted. In addition to changes in activities, under the Expanded Operations Alternative, there would be two changes in NNSS land use zones: (1) the designated use for Area 15 would be changed from "Reserved" to "Research, Test, and Experiment"; and (2) approximately 39,600 acres within Area 25 would be designated as a Renewable Energy Zone. These land use zone changes would clarify the availability of Area 15 as a location for conducting various types of research, tests, and experiments, and the Renewable Energy Zone would designate an area where the DOE/NNSA NSO has determined it would be reasonable and feasible to locate commercial renewable energy projects, as explained in Section 3.1.3.2 of this chapter. **Figure 3–2** depicts the land use zones and major facilities at the NNSS under the Expanded Operations Alternative.

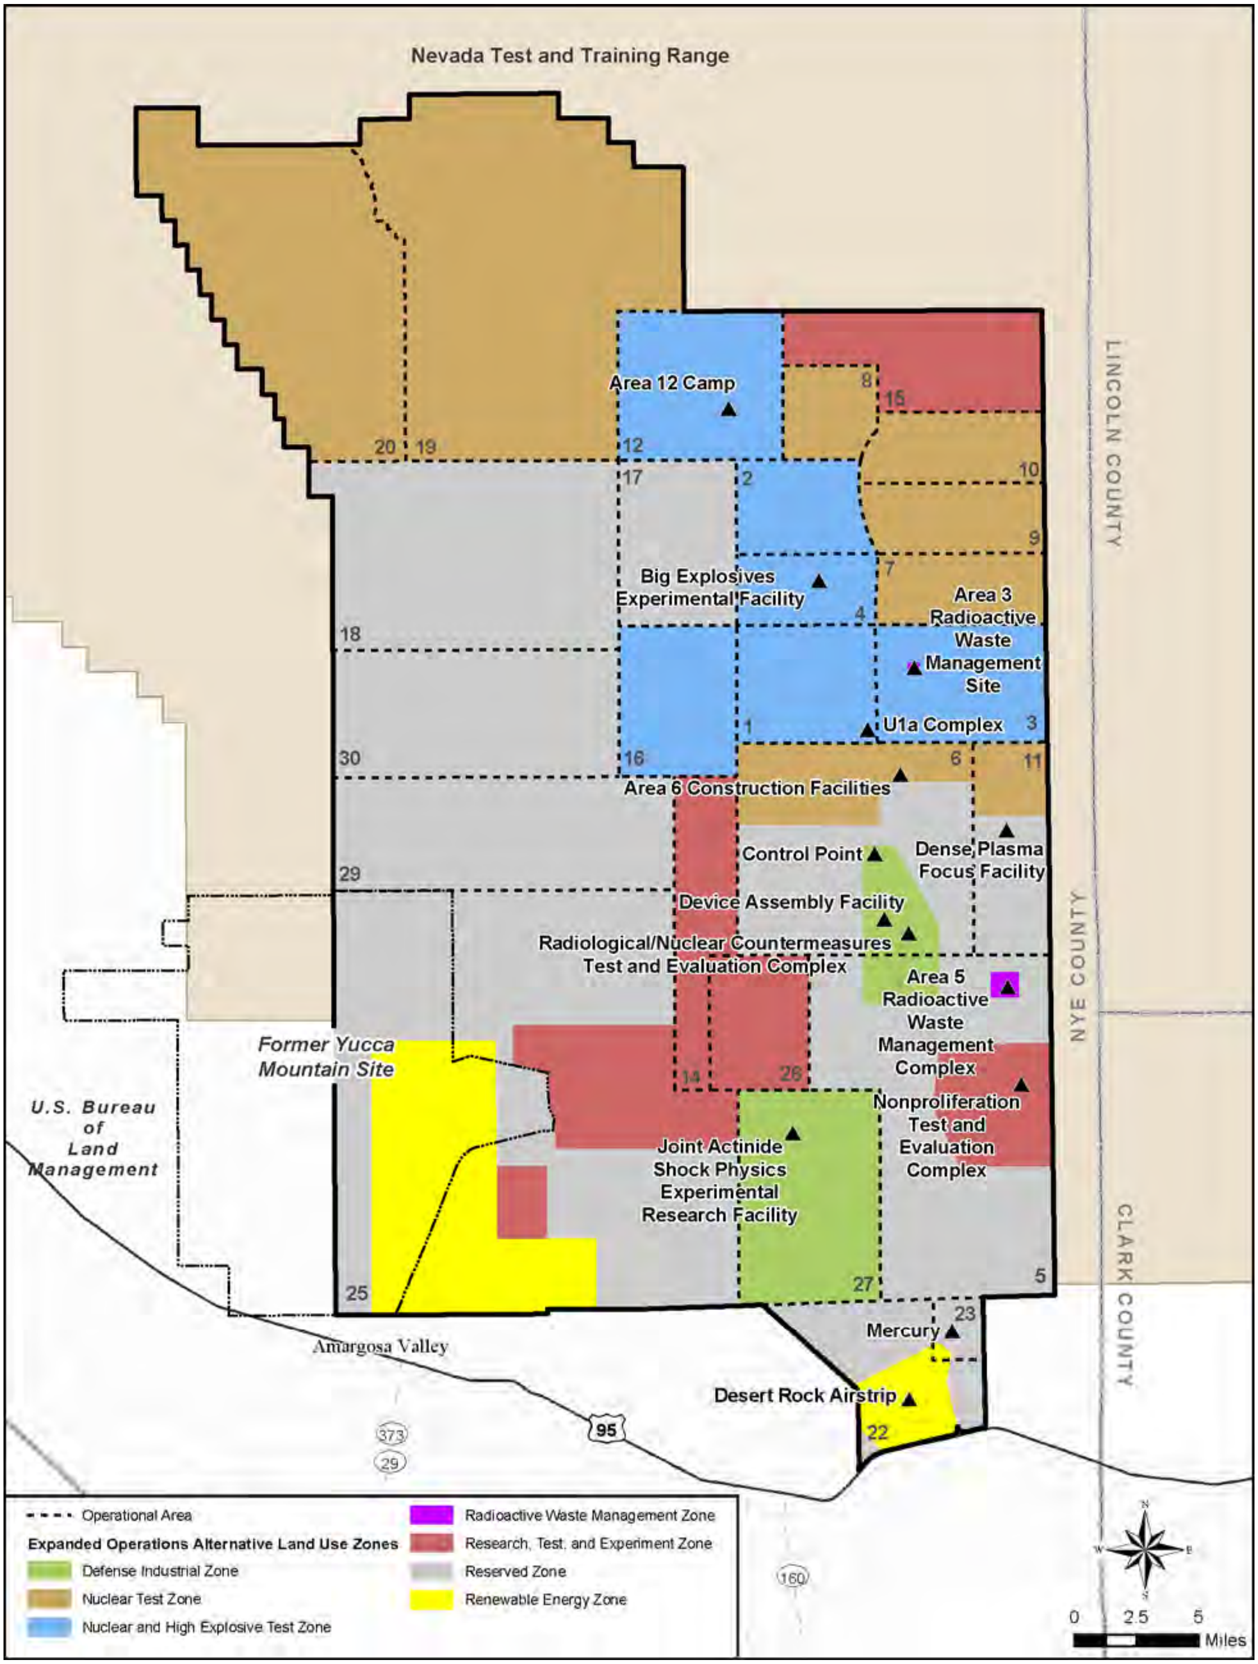

Figure 3–2 Nevada National Security Site Land Use Zones and Major Facilities Under the Expanded Operations Alternative

3.2.1 National Security/Defense Mission

Under the Expanded Operations Alternative, DOE/NNSA would pursue additional activities associated with the Stockpile Stewardship and Management, Nuclear Emergency Response, Nonproliferation, Counterterrorism, and Work for Others Programs.

3.2.1.1 Stockpile Stewardship and Management Program

Stockpile Stewardship and Management Program activities are described in more detail in Appendix A of this *NNSS SWEIS*. As under the No Action Alternative, the Expanded Operations Alternative includes those activities necessary to maintain the capability to conduct underground nuclear tests. Such a test would be conducted only if so directed by the President in the interest of national security. Therefore, conducting an underground nuclear test is neither included nor analyzed under any of the alternatives in this *NNSS SWEIS*. A generic description of underground nuclear testing is provided in Appendix H.

Under the Expanded Operations Alternative, there would be no changes from the No Action Alternative for the following Stockpile Stewardship and Management Program projects and activities:

- Criticality experiments in DAF
- Drillback operations
- Disposition of damaged U.S. nuclear weapons

Stockpile stewardship and management activities that would change relative to the No Action Alternative under the Expanded Operations Alternative include the following:

Dynamic experiments. DOE/NNSA would conduct up to 20 dynamic experiments per year. Over the next 10 years, a total of 5 dynamic experiments would be conducted in emplacement holes and cause new land disturbances.

Conventional explosive experiments at BEEF and other locations in the Nuclear and High Explosives Test Zone. DOE/NNSA would conduct up to 100 explosives experiments per year. DOE/NNSA would add a second firing table and ancillary features within the already developed area at BEEF, and would develop and test for proof-of-concept a high-energy x-ray capability at BEEF. Following successful testing, the new x-ray system would be moved to the U1a Complex for operational use.

In addition to explosives experiments at BEEF (limited to 70,000 pounds TNT-equivalent based on facility design), at the request of the Defense Threat Reduction Agency, DOE/NNSA would support experiments using up to 120,000 pounds of TNT-equivalent of explosives at various locations other than BEEF within the Nuclear and High Explosives Test Zone at the NNSS. These detonations would be conducted both underground and in the open air. Conventional explosives operations supporting other programs at the NNSS are described under those programs. All explosive operations would be conducted in compliance with DOE Manual 440.1-1A, *DOE Explosives Safety Manual*.

DOE/NNSA would establish one or more areas dedicated to conducting explosives experiments with depleted uranium. Up to three depleted uranium experiment areas, each about 40 acres in size, may be established in Areas 2, 4, 12, or 16. An annual maximum of 4,000 pounds of depleted uranium and 12,000 pounds of explosives (TNT-equivalent) would be used to conduct up to 20 of these experiments per year.

Shock physics experiments. DOE/NNSA would make the shock physics experimental facilities available for academic and other research on a no-conflict basis and would increase the number of experiments with actinide materials up to 36 per year at JASPER and 24 at the Large-Bore Powder Gun.

Pulsed-power experiments. The Atlas Facility would be activated, and up to 24 pulsed-power experiments per year would be conducted. A description of the Atlas Facility is included in Appendix A, Section A.1.1.1.

Fusion experiments at the NNSS and NLVF. New experimental uses would be pursued for the Dense Plasma Focus Machines that require deuterium-deuterium, deuterium-tritium, and tritium-tritium fusion and pulsed x-ray production. These experiments would require a much larger capacitive energy storage bank than the one currently in use at the Area 11 facility. To facilitate the new uses for the Dense Plasma Focus Machine currently located in Area 11 of the NNSS, it would be relocated to an existing building in Area 6 of the NNSS. Following the relocation, the Area 11 facility would be placed in standby. DOE/NNSA would conduct up to 1,650 plasma physics and fusion experiments per year: 1,000 would use the Dense Plasma Focus Machine at NLVF, and 650 would use the machine in Area 11 (or Area 6 if it were moved).

Stockpile management activities. As it would under each alternative, DOE/NNSA would conduct nuclear explosives operations at the NNSS in association with conducting an underground nuclear test, if such a test were directed by the President. In addition, under the Expanded Operations Alternative, DOE/NNSA would conduct the following activities:

- Stage (i.e., maintain programmatic material, such as SNM, or other materials, in a safe and secure manner until needed in a test, experiment, or other activity; staging does not include maintaining material with no reasonable expectation of use in the foreseeable future) nuclear devices pending disassembly, modification/maintenance, and/or transportation to or from another location
- Conduct dismantlement of weapons or weapon systems to aid the United States in meeting its commitment to reduce its nuclear weapons stockpile (weapons shipments to the NNSS under this activity would not exceed 100 per year)
- Modify and maintain nuclear devices at DAF, including replacing limited-life components in nuclear weapons systems (weapons shipments to the NNSS under this activity would not exceed 360 per year)
- Test weapons components for quality assurance purposes at DAF

SNM staging, including pits. DOE/NNSA would continue to stage SNM at appropriate facilities on the NNSS. SNM would be relocated from and/or to other DOE/NNSA sites, as necessary to meet program needs. For example, the following materials would be moved to the NNSS: up to 4 metric tons of SNM from the Zero Power Physics Reactor Program at Idaho National Laboratory (for use in criticality experiments); about 200 kilograms of global security SNM staged at Lawrence Livermore National Laboratory (for use in detector development and as radiation test objects); 2 kilograms of uranium-233 staged at Los Alamos National Laboratory (associated with test readiness); and 500 kilograms of highly enriched uranium, depleted uranium, and uranium staged at Lawrence Livermore National Laboratory (associated with criticality safety). In addition, DOE/NNSA would stage weapon pits at DAF, pending their transport to the Pantex Plant in Texas or another appropriate location.

Training for the Office of Secure Transportation. In addition to hosting training and exercises on NNSS roads, DOE/NNSA would construct new facilities in Area 17 to support Office of Secure Transportation training programs. The new facilities would occupy approximately 10,000 acres. A total of about 25 miles of roads and fire breaks would be developed surrounding active training areas and between individual training venues. Potable water would be obtained from an existing well approximately

4.5 miles away, requiring construction of a water pipeline. An electrical distribution line would also be constructed to extend electrical service from the vicinity of the well to the new facilities. Main access to the complex would be from the Tippipah Highway.

Facilities would be expanded in the 12 Camp (Area 12), Area 6 Control Point, or Mercury (Area 23), and maintenance and administrative buildings and a dormitory would be constructed to support training operations. These facilities would also be available to other NNSS customers when not in use by the Office of Secure Transportation.

These new and expanded facilities projects are conceptual at this time and would require an appropriate level of NEPA review before they could be implemented.

Stockpile stewardship and management activities at the TTR. There would be changes in some site support functions, such as site security, which would be transferred to the USAF and could affect the number of employees.

3.2.1.2 Nuclear Emergency Response, Nonproliferation, and Counterterrorism Programs

Nuclear Emergency Response, Nonproliferation, and Counterterrorism Program projects and activities are described in detail in Appendix A of this *NNSS SWEIS*. Under the Expanded Operations Alternative, there would be no changes from the No Action Alternative for the following Nuclear Emergency Response, Nonproliferation, and Counterterrorism Program projects and activities:

- Support for the Nuclear Emergency Support Team
- Consequence management support for FRMAC, the Aerial Measuring System, Accident Response Group, and Radiological Assistance Program
- Training for weapons of mass destruction emergency responders
- Equipment provision and technical support for the DOE-dedicated Emergency Communications Network

Nuclear emergency response, nonproliferation, and counterterrorism activities that would change relative to the No Action Alternative under the Expanded Operations Alternative include the following:

Disposition of improvised nuclear devices on an as-needed basis. In addition to improvised nuclear devices, radiological dispersion devices would be dispositioned on an as-needed basis at the NNSS under the Expanded Operations Alternative.

Nonproliferation- and counterterrorism-related activities. DOE/NNSA nonproliferation- and counterterrorism-related activities would include four related areas: arms control, nonproliferation, nuclear forensics, and counterterrorism. Although the purpose of nonproliferation- and counterterrorism-related activities would be the same as that under the No Action Alternative, new nonproliferation and counterterrorism facilities, described below, would be constructed at various locations on the NNSS to undertake enhanced activities. Because the new nonproliferation and counterterrorism facilities (Arms Control Treaty Verification Test Bed, Nonproliferation Test Bed, and Urban Warfare Complex) are still conceptual in nature and their locations are unknown, they are analyzed at a programmatic level in this SWEIS, and an appropriate level of NEPA review would be required before they could be implemented.

Arms control. The Arms Control Treaty Verification Test Bed would require construction of both indoor and outdoor laboratory space and test areas for design and certification of treaty verification technologies, training of inspectors, and development of arms control-related confidence-building measures. These facilities would be sited at various locations at the NNSS, and construction of new facilities would require a total of about 100 acres of land. A new facility for data fusion, analysis, and visualization would be

constructed. The new building would have approximately 10,000 square feet of floor space and would be integrated with a building constructed to house other Arms Control Treaty Verification functions.

Nonproliferation. A Nonproliferation Test Bed would require construction of a new facility for simulations of chemical and radiological processes that could be conducted clandestinely by an adversary.

Counterterrorism. In addition to counterterrorism training at existing facilities, an Urban Warfare Complex would be constructed at the NNSS. This complex would include full-scale, modular replicas of the types of urban areas where terrorists and insurgents typically seek refuge. The Urban Warfare Complex would be constructed on about 100 acres in a remote area on the NNSS.

3.2.1.3 Work for Others Program

Work for Others Program activities are described in more detail in Appendix A of this *NNSS SWEIS*. Under the Expanded Operations Alternative, there would be no changes from the No Action Alternative for the following Work for Others Program activities:

- Treaty verification
- Military training and exercises
- Work for Others Program activities at the TTR

Work for Others Program activities that would change relative to the No Action Alternative under the Expanded Operations Alternative include the following:

Nonproliferation projects and counterproliferation research and development. Support would be provided for development of radiation detection capabilities, additional sensor technologies, and active interrogation programs to detect nuclear material.

Counterterrorism. Counterterrorism activities would include research, development, testing, and evaluation of unmanned aerial systems, as well as integration of training and exercises. Other activities would include development and testing of sensors for detection and defeat of improvised explosive devices, which would require construction of test beds (roads, intersections, small towns, etc.) and support facilities. Construction of these facilities would include new buildings with about 10,000 square feet of new floor space and would disturb about 75 acres of land.

DHS counterterrorism operations support would include construction of new training facilities (about 10,000 square feet of floor space). In addition, RNCTEC would be operated up to the level of a Hazard Category 2 nonreactor nuclear facility, which would allow larger amounts of radioactive material in alternative configurations to be used in tests and experiments. A high-speed road, a short section of full-scale railroad line, a simulated seaport facility, and a mock urban area would also be added to RNCTEC (DOE 2004f), requiring about 125 acres of additional land in Area 6. These new facilities are still conceptual in nature and their potential locations have not been identified; however, their potential impacts are analyzed at a programmatic level in this *NNSS SWEIS*. An appropriate level of NEPA review (beyond this SWEIS) would be required before DOE/NNSA makes any decision regarding these facilities.

Support for NASA. DOE/NNSA would support NASA nuclear rocket motor development, including using existing boreholes to examine for proof of concept the use of deep alluvial basins for sequestering radionuclides released as part of emissions from tests of a yet-to-be-developed prototype nuclear rocket motor. Over about a 10-year period, NASA would not likely test a nuclear rocket motor, but may conduct proof-of-concept tests using a surrogate, such as spiked xenon, in a borehole to evaluate the

effectiveness of the alluvium for this purpose. DOE/NNSA would identify and comply with all applicable regulatory requirements for both proof-of-concept experiments and any actual test of a nuclear rocket motor. If NASA proposes to test an actual nuclear rocket motor, a NEPA review would be conducted.

Aviation Work for Others. Activities would include increased research, development, and use of aerial platforms at the NNSS. To support these activities, additional facilities would be required at Desert Rock Airport (hangars, shops, and other buildings occupying approximately 200,000 square feet) and the Area 6 Aerial Operations Facility (a hangar occupying approximately 20,000 square feet). Additional facilities occupying approximately 5,000 square feet may be required at other locations to support air operations, including testing of various types of manned and unmanned aerial systems such as small, remote-controlled, fixed-wing airplanes and helicopters. Research and development would be conducted with unmanned aerial systems to assess and mitigate operational safety and efficiency issues. In addition, unmanned aerial systems would be tested for a wide variety of potential uses, such as carrying sensors for collecting environmental data (e.g., multi- and hyperspectral imagery) to be used in digital environmental model development and for terrain analysis in arid and semiarid regions.

Active interrogation. Active interrogation involves the use of a radiation source to detect nuclear material. Under the Expanded Operations Alternative, Work for Others Program activities would include support for development of active interrogation systems to detect nuclear material and other materials of interest. DOE/NNSA would support research and development of active interrogation equipment, including accelerators and other radiation-generating devices and associated radiation detection systems/methods, and training. DHS would conduct active interrogation activities at RNCTEC, but other Federal agencies would require an additional facility, most likely located in Area 12 or 16. In addition to fixed facilities, temporary test beds would be used to provide various terrain, roadway patterns, and other factors to simulate conditions that may be encountered in actual deployment of the active interrogation system. The temporary test beds would be used primarily for testing mobile accelerators and other radiation-generating devices (from man-portable up to units housed in large transportation containers) and detectors. In general, temporary active interrogation test beds would use existing NNSS roads, but could also include some off-road areas. Construction of additional support facilities and temporary test beds would disturb about 100 acres of previously undisturbed land over the next 10 years.

Active interrogation research and development would involve operation of accelerators/radiation-generating devices at energy levels in the range of 10 to 100 million electron volts to irradiate various materials using, for example, electrons, protons, or other types of radiation such as x-rays or neutrons (proton-generating units may attain energy levels of up to 4 billion electron volts). The devices would be used for either radiography or for interrogation of objects to detect and identify such things as fissionable materials, chemicals, or contraband. Other devices may produce gamma rays to be used for the same purposes. Still other systems would include deuterium-deuterium or deuterium-tritium neutron generators (see description of fusion experiments in Sections 3.1.1.1 and 3.2.1.1) that produce from 2.5 to 14 million electron volt neutrons.

Test objects would be irradiated using interrogation beams produced by the accelerators/radiation-generating devices. Test objects would consist in part of fissionable materials such as uranium and plutonium. Fissionable material in a test object would be limited to quantities that can be demonstrated to be subcritical under all normal, abnormal, and accident conditions (quantity and nature of process activities must preclude the potential for a nuclear criticality). Test objects that incorporate fissionable material would be used in either shielded or unshielded configurations or surrounded by, for example, naturally occurring radioactive material. The interrogation beams would also be used to irradiate nonfissionable materials, such as chemicals or simulated contraband, to determine the signatures produced by the real materials. Test objects would be placed up to 1.25 miles from the beam source, and

radiation and other detection systems would be placed at various distances away to detect radiation from the test objects.

Radioactive tracer experiments. Radioactive tracer experiments would be conducted to validate sensor technology. These experiments would include both underground releases and open-air releases of radioactive noble gases and nonradioactive gases (i.e., helium and sulfur hexafluoride). The underground experiments would release up to 27 curies of radioactive noble gases with short half-lives (5 to 36 days); nonradioactive releases would include up to 300 gallons of helium and 2,000 gallons of sulfur hexafluoride. The underground experiments would include explosive gas releases, pressurized releases, explosive radioactive particulate releases, and a baseline survey of contamination from previous activities. The open-air experiments would release small quantities of radionuclides with short half-lives. Up to 12 experiments involving open-air releases would be conducted each year. DOE/NNSA would comply with all relevant regulatory and reporting requirements, including applicable requirements of 40 CFR Part 61, Subpart H, for all experiments that could result in a release of radioactive material to the air. DOE/NNSA would ensure that the cumulative annual radiological dose at the boundary of the NNSS resulting from all activities involving radioactive materials would comply with the U.S. Environmental Protection Agency's annual emission standard of 10 millirem (40 CFR 61.92).

New test beds. Additional test beds would be developed to support research and development for sensors, high-power microwaves, and high-power lasers. New test beds (including approximately 50,000 square feet of new building spaces) would be constructed at various locations on the NNSS and would disturb approximately 200 acres of previously undisturbed land. Because there are no specific plans for construction of these new test beds at this time, additional NEPA reviews would be necessary before they could be implemented.

The following new test beds would be developed at the NNSS under the Expanded Operations Alternative:

Nuclear-Fuel-Cycle-Related Radionuclide Release, Diagnostics and Solids Detection, and Characterization Test Bed. In support of the various nuclear nonproliferation treaties in which the United States participates or anticipates participation, DOE/NNSA would create test beds for use in developing sensors to support treaty verification and nonproliferation validation. Facilities to support deployment of fixed uranium oxides and controlled amounts of depleted uranium would include static concrete display pads, static target display pans, thermal targets, and ponds and pools of water.

Specialized Explosive Testing and Manufacture Test Bed. Support for DoD and the U.S intelligence community would expand to include development of sensors and techniques for detection and defeat of improvised explosive devices, homemade explosives, conventional military ordnance, and chemical explosives, as well as explosives-driven, shaped-charge development and evaluation.

Radio Frequency Generation Test Bed. Technologies would be developed to detect, sample, characterize, and identify radio frequency signatures and observables. The test bed would be used to develop the ability to generate specific signals, to characterize the radio frequency environment, and to monitor tests.

Infrasonic Observations Test Bed. Technologies would be developed to monitor earthquakes and underground disturbances. This test bed would be used to develop the ability to detect specific signals, characterize the seismic environment, and monitor tests.

Chemical Test Bed. Activities at this test bed would include simulated manufacture and release of illegal drugs by authorized Federal organizations to develop detection and prevention technologies. An

existing facility would be used to train personnel and test sensors and procedures for detection of toxic industrial chemicals.

Biological Simulants Test Bed. These operations would include production of biological simulants in an appropriate laboratory by authorized Federal organizations for use in detection technology development. Biological simulant releases to the soil, the air, or an NNSS sewer/septic system would emulate anticipated real-world scenarios. Construction to support these functions would disturb up to 50 acres of land.

3.2.2 Environmental Management Mission

The DOE/NNSA Environmental Management Mission includes the Waste Management and Environmental Restoration Programs. Under the Expanded Operations Alternative, the Waste Management Program would accept greater volumes of LLW and MLLW from both offsite and onsite sources. As under the No Action Alternative, the Environmental Restoration Program would continue to meet the requirements of the most recent FFACO.

3.2.2.1 Waste Management Program

Under the Expanded Operations Alternative, waste management activities associated with some waste types would increase. In particular, up to approximately 48,000,000 cubic feet of LLW and 4,000,000 cubic feet of MLLW would be disposed at the NNSS over the next 10 years. Up to 1 percent of the total projected LLW volume could consist of nonradioactive, classified waste forms that require disposal in a manner similar to LLW. These classified waste forms would be disposed in the Area 5 RWMC at the NNSS. In order to provide a conservative analysis of potential human health impacts, DOE/NNSA assumed that the entire volume of waste was composed of only radioactive wastes. Within the existing Area 5 RWMC, new disposal units would be constructed, filled, and closed to accommodate these additional waste volumes. New MLLW disposal cells would require a RCRA permit(s) from NDEP. Under the Expanded Operations Alternative, the Area 3 RWMS could be opened to receive LLW generated from environmental restoration and other activities at DOE/NNSA sites within the State of Nevada. Specifically, this action could be triggered by a need for additional disposal space beyond that available in the Area 5 RWMC for disposal of large on-site remediation debris, or soils from clean-up activities on the NTTR. While there is no near-term need to use the Area 3 RWMS, However, should DOE/NNSA need to activate the Area 3 Radioactive Waste Management Site, it would first undergo detailed consultation with the State of Nevada, and would limit disposal to in-state generated LLW.

The basis for the estimated waste volumes under this alternative is described in Appendix A. The increase in waste volumes between this and the No Action Alternative is largely due to an assumed extensive removal of contaminated soil from cleanup activities at Nevada locations outside the NNSS (e.g., the TTR and the Nevada Test and Training Range) with shipment to the NNSS for disposal, and to increased projections of wastes that may be shipped to the NNSS from out-of-state generators. These projections of waste are considered upper-bound estimates; actual volumes that may be generated depend on programmatic and regulatory decisions by the generators that would be addressed in separate NEPA reviews, as well as funding considerations. Although for purposes of analysis it was assumed that the projected wastes would be disposed at the NNSS, there may be other cost-effective options for disposing the wastes, such as the use of commercial disposal capacity.

Use of rail-to-truck transloading would increase, including the use of transloading facilities within Nevada, should commercial vendors establish such a facility. DOE/NNSA is not proposing to construct or cause to be constructed any new rail-to-truck transfer facilities to accommodate shipments of radioactive waste or materials under any of the alternatives considered in this SWEIS.

Under the Expanded Operations Alternative, DOE/NNSA would treat and store various types of MLLW received from on- and offsite generators. MLLW treatment capacity would be developed within the Area 5 RWMC, including repackaging by means of macroencapsulation and/or stabilization/microencapsulation, sorting/segregating, and bench-scale mercury amalgamation of both onsite- and offsite-generated MLLW. Initially, MLLW storage capacity would be developed on the TRU Pad to accommodate MLLW treatment (for either onsite- or offsite-generated wastes), pending development of MLLW storage capacity in existing or new facilities within the Area 5 RWMC. To handle the increased volumes and more-frequent shipment receipt rates of LLW and/or MLLW, a waste offloading and staging area would be established at the Area 5 RWMC. Appropriate permits would be obtained before expanding MLLW storage capacity or implementing any of these treatment technologies.

In addition, waste management activities at the NNSS under the Expanded Operations Alternative would include the following:

- Because of the projected increased annual number of experiments at JASPER and other national security activities, somewhat larger quantities of TRU waste would be generated annually (about 1,900 cubic feet per year from all activities). As with the No Action Alternative, TRU waste generated by DOE/NNSA activities in Nevada would be safely stored at the TRU Pad pending shipment off site for disposition along with other legacy waste (waste or contamination resulting from previous nuclear weapons-related activities) or newly generated environmental restoration waste.
- Continued treatment by evaporation of liquids containing small concentrations of tritium; and continued management of hazardous waste, asbestos and PCB wastes, and hydrocarbon-contaminated soil and debris in compliance with applicable regulations and permits. An estimated 170,000 cubic feet of hazardous waste would be generated by DOE/NNSA activities.
- Continued treatment of explosives at the Explosives Ordnance Disposal Unit in Area 11.
- Continued operation of the Area 23 Class II Solid Waste Disposal Site, the Area 6 Class III Solid Waste Disposal Site (Hydrocarbon Landfill), and the U10c Class III Solid Waste Disposal Site. To accommodate the potential increases in solid wastes (up to about 9,400,000 cubic feet generated over the next 10 years) that may be generated by various operations at the NNSS under the Expanded Operations Alternative, DOE/NNSA would seek permits to construct and operate new solid waste disposal facilities, as needed. A new sanitary waste landfill in Area 23 would require approximately 15 acres of land. To support environmental restoration work in Area 25, DOE/NNSA would obtain appropriate permits to construct and operate a construction/demolition debris landfill that would disturb up to 20 acres in Area 25 of the NNSS. Approximately 970,000 cubic feet of the generated sanitary solid waste would be sent off site for recycling during the next 10 years.
- Under the Expanded Operations Alternative, DOE/NNSA would establish staging and maintenance support capacity at the Area 5 RWMC for radioactive material transport packagings. DOE/NNSA would temporarily stage, inspect, and perform maintenance on DOE/NNSA-certified (and possibly commercial) and U.S. Department of Transportation (DOT)-authorized transport packagings for transport of radioactive material.

Packaging means the assembly of components necessary to ensure compliance with Federal packaging requirements. It may consist of use of one or more receptacles; absorbent materials; spacing structures; thermal insulation; radiation shielding; service equipment for filling, emptying, venting, and pressure relief; or devices for cooling or absorbing mechanical shocks.

Package means, for radioactive materials, the packaging together with its radioactive contents as presented for transport.

Source: 49 CFR 173.403

The transport packagings would be emptied of radioactive material before inspection, maintenance, or staging. This proposed capability would allow consolidation of specialty packagings at a centralized location that is convenient to DOE/NNSA sites in the western United States. The proposed capability would be located in a fenced area within the Area 5 RWMC on approximately 1 acre of previously disturbed land. The area would be graded and covered with a gravel or asphalt pad. No more than 15 transport packagings would be staged within the area at any time. Operation of the area would use a small amount of electrical power and require only two to three workers on an as-needed basis to perform radiation surveys, container maintenance, or pre-use inspections. Minimal waste generation is expected.

3.2.2.2 Environmental Restoration Program

Under the Expanded Operations Alternative, the DOE/NNSA Environmental Restoration Program would continue in compliance with the FFACO in the form of characterization, monitoring, and, if necessary, remediation of identified contaminated areas, facilities, and environmental media. The UGTA and Industrial Sites Projects, remediation of Defense Threat Reduction Agency sites, and Borehole Management Program would all continue as under the No Action Alternative, although the pace of cleanup activities could be accelerated. Cleanup standards for Soils Project sites on lands under the jurisdiction of the USAF are subject to agreement among the USAF, NDEP, and DOE/NNSA. The No Action Alternative addressed cleanup levels consistent with current land uses; however, if more-stringent cleanup standards are adopted than currently planned or additional sites are included under the FFACO, the volumes of waste requiring transport and disposal would increase. Although the FFACO is the primary driver for the Soils Project, for purposes of analysis under the Expanded Operations Alternative, this SWEIS assumes that a clean closure strategy would be implemented for a number of contaminated soil sites on the Nevada Test and Training Range and the TTR (i.e., Clean Slate 2 and 3, Project 57, and Small Boy), whereby a total of about 504 acres would be excavated to a depth of 0.5 feet and the removed soil would be disposed as LLW. The impact of this estimated additional volume of waste that would need to be disposed at the NNSS is analyzed in Chapter 5, Section 5.1.11.

3.2.3 Nondefense Mission

The Nondefense Mission generally includes those activities that are necessary to support mission-related programs, such as construction and maintenance of facilities, provision of supplies and services, warehousing, and similar activities. Activities related to energy supply and conservation, including renewable energy, are considered part of the Nondefense Mission, as are other research and development activities that may occur at DOE/NNSA facilities in Nevada, including activities at the Nevada National Environmental Research Park. As described in the following paragraphs, all Nondefense Mission programs would be modified to some extent under the Expanded Operations Alternative.

3.2.3.1 General Site Support and Infrastructure Program

Under the Expanded Operations Alternative, in addition to small projects to maintain the present capabilities of the NNSS, infrastructure-associated activities would include increasing capacities and capabilities or extending the ranges of facilities and/or services to accommodate new operational programs and projects. A detailed description of new activities associated with the General Site Support and Infrastructure Program and the reasons they are proposed under the Expanded Operations Alternative may be found in Appendix A, Section A.2.3.1.

In addition to accommodating operational requirements and constructing the new facilities described in Sections 3.2.1 and 3.2.2, the following infrastructure enhancements would be implemented:

- A security building in Area 23 would be constructed to replace outdated facilities and consolidate security facilities and functions into a new, approximately 85,000-square-foot, two-story facility. The buildings replaced would be evaluated and either demolished or used for another purpose.
- The existing 138-kilovolt electrical transmission system would be replaced between Mercury Switching Center in Area 23 and Valley Substation in Area 2 to increase the capacity of the system from about 40 megawatts to 100 megawatts. The efficiency of the system would be improved, but the system operating voltage would not increase.
- The telecommunication system on the NNSS would be upgraded to better integrate wired and wireless systems.
- Buildings in Mercury are typically 30 to 50 years old. To maintain an efficient and effective operation in support of national security activities, it is necessary to replace most of these facilities and supporting infrastructure due to their lack of energy efficiencies and deteriorating condition. Under the Expanded Operations Alternative, Mercury would be reconfigured to provide the modern facilities and infrastructure necessary to support advanced experimentation and production at the NNSS. Because the reconfiguration of Mercury is conceptual in nature, an appropriate level of NEPA review would be required before it could be implemented.

These projects would contribute to meeting DOE/NNSA Strategic Goal 2.1: Transform the Nation's nuclear weapons stockpile and supporting infrastructure to be more responsive to the threats of the twenty-first century.

As under the No Action Alternative, in addition to maintaining and repairing its infrastructure at the NNSS, RSL, NLVF, and the TTR, DOE/NNSA would maintain the existing infrastructure, provide site security, and manage all applicable existing permits and agreements for the former Yucca Mountain site. DOE/NNSA would perform these functions pending decisions on the disposition of the former Yucca Mountain site.

As noted under the No Action Alternative, although considered infrastructure, characterization and monitoring wells developed under the UGTA Project are addressed as part of the Environmental Management Program and proposed and potential renewable energy projects are addressed under the Conservation and Renewable Energy Program, rather than the General Site Support and Infrastructure Program.

3.2.3.2 Conservation and Renewable Energy Program

Under the Expanded Operations Alternative, DOE/NNSA would continue to identify and implement energy conservation measures and renewable energy projects as described under the No Action Alternative. In addition, NNSA would pursue renewable energy projects, including geothermal and solar.

NNSS Photovoltaic Power Project. Under the Expanded Operations Alternative, DOE/NNSA proposes to build a 5-megawatt photovoltaic solar power system near the Area 6 Construction Facilities. The 5-megawatt photovoltaic system would require about 50 acres of land, based on a similar project at Nellis Air Force Base (USAF 2006c).

Commercial solar power generation. Under the Expanded Operations Alternative, DOE/NNSA would allow development of one or more full-scale commercial solar power generation facilities in Area 25 of the NNSS with a combined generating capability of up to 1,000 megawatts. As shown in Figure 3–2, the

solar power generation facilities would be located within an area of about 39,600 acres in the southwestern part of the NNSS. The reasons for DOE/NNSA's consideration of commercial solar power development only in Area 25 and decision to assess the concentrating solar power parabolic trough technology in this *NNSS SWEIS* are addressed in Section 3.1.3.2. The facility(ies) could use a variety of solar power-generating technologies (i.e., parabolic trough, power tower, dish engine, photovoltaic) with a combined generating capability of up to 1,000 megawatts. Construction of 1,000 megawatts of commercial solar power generation facilities using concentrating solar power technology and a hybrid cooling system would disturb up to about 10,000 acres of land, as noted in Chapter 5, and operation would require up to approximately 700 acre-feet of water per year, as noted in Section 5.1.6.2.2. Approximately 10 miles of new 500-kilovolt electrical transmission line (outside of the NNSS) would be required to integrate the electricity generated into the regional system, which would disturb approximately 350 acres of land. The analysis in this SWEIS is based on assumptions for a representative commercial solar project (West 2010). Because there is no specific proposal for a commercial solar power generation project, a NEPA review would be required to evaluate any such proposals in the future.

Geothermal Demonstration Project. There are no proposals to develop a Geothermal Demonstration Project at the NNSS, at this time; however, there has been recent interest in such a project. Under such a project, the NNSS would be evaluated to determine the feasibility of demonstrating an enhanced geothermal electrical generating system. If the initial evaluation were favorable, the location for a Geothermal Demonstration Project on the NNSS would depend on a combination of factors, including the system's potential, land use zone restrictions, and environmental and economic considerations. Approximately 30 to 50 acres of land would be disturbed by construction of a Geothermal Demonstration Project. Several boreholes would be drilled up to 20,000 feet deep. Up to 20 acre-feet of water would be required to initially prime the system. A continuously operating 50-megawatt power plant would require an estimated 50 acre-feet of water per year. As a separate but related project, a Geothermal Research Center, would be established in Mercury using existing facilities. A Geothermal Demonstration Project would be interconnected to the NNSS electrical transmission system, but would not generate sufficient power to exceed the capacity of the rebuilt NNSS 138-kilovolt transmission system addressed in Section 3.2.3.1. Because there are no specific proposals for geothermal exploration or development on the NNSS at this time, additional NEPA review would be required before such work could be conducted.

3.2.3.3 Other Research and Development Programs

Under the Expanded Operations Alternative, DOE/NNSA would continue to host existing environmental research projects at the NNSS and would actively promote and expand the National Environmental Research Park Program. DOE/NNSA would consider new environmental or other proposed research and/or development projects not related to DOE/NNSA National Security/Defense or Environmental Management missions on a case-by-case basis.

Expanded Operations Alternative—American Indian Perspective

The Consolidated Group of Tribes and Organizations' (CGTO) concerns and perspective regarding the Expanded Operations Alternative include those discussed previously under Sections 3.0, 3.1.1, 3.1.2, 3.1.2.1, 3.1.2.2, and 3.1.3, as well as those summarized here. Under the Expanded Operations Alternative, the U.S. Department of Energy (DOE) would pursue geothermal electrical generation in a variety of locations depicted in Figure A.2.3-1, and solar energy systems and facilities in Areas 6 and 25, respectively.

The CGTO understands that DOE is proposing to construct modular geothermal power plants that have a relatively small surface footprint. However, the initial project support activities will reportedly impact 30 to 50 acres. The CGTO also understands that DOE may pursue solar power by constructing a 5 megawatt photovoltaic system, and commercial solar power generating facilities. These proposed solar power electrical generation projects would impact approximately 50 acres and 39,600 acres of land, respectively. The CGTO is particularly concerned with the land and resources potentially impacted by these projects.

Construction of the proposed solar power electrical generation system and facilities, and the geothermal electrical generation facility involves scraping the land, irreparably destroying the land and vegetation. Facility construction will facilitate erosion, impede visual resources, and will emit dust and other potentially hazardous pollutants into the air. This will, in turn, impact the land, water, air, plants, animals, and cultural resources, and will affect the solitude and cultural integrity of the land. Some examples of resources impacted have been highlighted throughout this section.

The CGTO is concerned that DOE's proposed activities unnaturally harnesses the earth's power without understanding the implications of these actions or all that is necessary to begin to prepare the earth and its resources. Numic people have a complex understanding of *power* and believe it is special force that was placed in all things at the time the world was created. It is that spark which keeps the world going and all of its elements thinking, talking, moving, and interacting. This special *power* moves and has the ability to move down hill, often concentrating or pooling in certain places like mineral outcrops, cliffs, and caves. It has characteristics similar to water, and can be understood as having the ability to return to the sky to become like rain and snow, which are called down from the sky by the highest mountains. This special *power* has a rotation of movement similar to the hydrological cycle and has the ability to impact all things.

The CGTO is concerned about unnaturally harnessing the power of the Sun. According to tribal elders, *"The Sun is like a big battery. Once you drain its power, will it die? For those of us spiritually connected to the Sun, what will happen to us if it is killed? We know the Sun has only so much energy. If the Sun is drained, how will it be replenished? If the Sun goes away, everything will die. Because of the complexity and potential implications to the environment, cultural landscape, and our own survival, we strongly encourage the DOE to pursue a study that evaluates the cultural implications of pursuing solar energy. The stories and activities of our ancestors are tied greatly to the Sun. Today, our prayers and ceremonies still travel or rely on its strength."*

According to information presented throughout the site-wide environmental impact statement, the proposed geothermal electrical generation facilities would use the power of rocks that are hot. Rocks, or minerals, are culturally important and have significant roles in many aspects of Indian life. For example, the Chalcedony would have made an attractive offering acquired and then left at the vision quest or medicine site located to the north on top of a volcano like Scrugham Peak. In particular, Indian people have observed the presence of the following minerals used as offerings on the Nevada National Security Site (NNSS): (1) Obsidian, (2) Chalcedony, (3) Yellow Chert (otherwise known as Jasper), (4) Black Chert, (5) Pumice, (6) Quartz Crystal, and (7) Rhyolite Tuff.

Obsidian is a glass-like stone produced by volcanoes when they talk. According to information obtained by Dr. Richard Stoffle with the University of Arizona and presented in the report *Black Mountain: Traditional Uses of Volcanic Landscapes*, Southern Paiutes use a green volcanic glass during curing ceremonies that involved bleeding the patient. Volcanic glass found below Scrugham Peak was used in the first arrow making lessons for young men. Such lessons were held in small rock shelters found along the base of the basalt flow that constitutes Buckboard Mesa. Obsidian flakes were placed before important rock art panels as offering to the spirits who lived on the other side of the passageway provided by the panel. Small obsidian stones, commonly called *Apache Tears*, cover a depth of 4 inches on the face of Shoshone Mountain in southern Nevada. This massive deposit of obsidian stones is interpreted by Indian people as being provided by the mountain as both a spiritual backdrop and a location for vision quests.

Volcanic rocks are used in a wide range of ceremonial activities. According to a tribal elder, *"Indian women enhance the quality of breast milk by squirting it on heated rocks."* Volcanic rocks are used for medicine society sweat lodge meetings. Indian people call some volcanic rocks "grandfather stones," a designation that reflects reverence as well as wisdom. Such rocks are sought in special places of power and carried over long distances to serve as the heated stones in sweat lodges.

Other traditional use minerals are known to exist throughout the NNSS and offsite locations. In order to document the cultural significance of these areas, additional ethnographic mineral studies are needed to fully understand the location and importance of these minerals at the proposed project site locations prior to any surface disturbing activities. The CGTO is particularly apprehensive about the potential impacts or use of these minerals resulting from proposed geothermal activities.

Expanded Operations Alternative—American Indian Perspective (cont'd)

Some of the locations proposed for geothermal electrical power plants are recognized as traditionally or spiritually important. In particular, the CGTO is concerned about activities that have the potential to impact Oasis Valley, Amargosa River, Timber Mountain Caldera Complex, Black Mountain, Gold Meadows, Cane Springs, Calico Hills area, Crater Flats, Scrugham Peak, Shoshone Mountain, Devil's Hole, Ash Meadows, and Death Valley. The CGTO is concerned about locating the proposed geothermal project along hydrological basins, whose power is derived from volcanic activity.

We know the forces of power in the world move along channels and combine into specific nodes or places of power. A common set of these channels follows the path of water. From this beginning, the water moves downhill in rivulets, washes, and streams. The water often goes underground where it forms similar networks of channels moving in various directions, corresponding to hydrological basins. Water is often attracted to volcanic activity, thus producing power places like hot mineral springs.

The CGTO is concerned the DOE may impact hot springs in their pursuit of geothermal power. According to information obtained by Dr. Richard Stoffle with the University of Arizona and presented in the report *Black Mountain: Traditional Uses of Volcanic Landscapes*, hot springs come from the earth where volcanic activity still occurs even if the magma cannot be seen on the surface. Such springs are a combination of water and volcanoes producing a special place where both ceremonial and medicine activities occur. Indian people from Owens Valley have a single origin story for all of the hot springs in the southern Great Basin and northern Mohave Desert. According to traditional stories, a great ball of fire came from the sky and landed at Coso Hot Springs and then splashed to form at once all of the other hot springs.

Hydrological Impacts

According to information presented in the Site-Wide Environmental Impact Statement, the proposed solar and geothermal projects will require a tremendous amount of water. A modular geothermal power plant alone will require up to 20 acre-feet to initially prime the system.

Indian people believe water is a living being that is fully sentient and willful. Water is already stressed throughout the region. The CGTO is concerned about the use of this very limited and important resource.

Because water is a powerful being it is associated with other powerful beings, such as water babies, a supernatural being that lives in and protects the water. These beings are like the people of the water. They are highly respected by American Indian culture. If water is contaminated and misused, the water babies may cause harm and move to other areas that are not contaminated.

Air Quality and Climate Impacts

Construction of these proposed facilities will impact large areas of land, potentially emitting dust and contaminants. The CGTO knows the air is alive. The Creator puts life into the air, which is shared by all living things. Air can be destroyed, causing pockets of dead air. There is only so much living air that surrounds the world. If it is destroyed, it is gone forever and cannot be restored. Dead air lacks the spirituality and life necessary to support other life forms. The CGTO is concerned about emitting things into the air that are unnatural, and raises the potential health and environmental issues associated with these emissions.

Visual Resource Impacts

All landforms within the NNSS have high sensitivity levels for American Indians. The ability to see the land without obstructions like buildings, towers, cables, roads, and other objects is essential for the spiritual interaction between Indian people and their traditional homelands. Visual resources may be negatively impacted if proposed solar and geothermal projects are pursued. The CGTO must be part of any future discussions as these may impact visual resources and may impede traditional and cultural ceremonies.

Final Thoughts

Only Indian people have traditional ecological knowledge that tells us how and where to interact with plants and animals, water sources, and collect soil samples to minimize impacts to the land while maintaining its spiritual integrity. Because of the potential effects to our ancestral land and its delicate resources, the CGTO must be an integral part of the solar power electrical generation and geothermal electrical generating power projects by conducting systematic ethnographic studies before the ground is disturbed.

The CGTO strongly encourages DOE to evaluate the cultural impacts of pursuing solar and geothermal energy in culturally sensitive areas because of the complexity and potential implications to the environment, cultural landscape, and our survival. The CGTO recommends developing culturally appropriate text for future National Environmental Policy Act (NEPA) analyses, including the environmental assessments and mitigation plans required for these proposed undertakings.

See Appendix C for more details.

3.3 Reduced Operations Alternative

The Reduced Operations Alternative addressed in this SWEIS includes the same types of activities as the No Action Alternative; however, for many programs, the levels of operations would be reduced. Perhaps the most important change from No Action under the Reduced Operations Alternative would be cessation of all activities other than environmental restoration, environmental monitoring, site security operations, military training and exercises, and maintenance of Well 8 and critical communications and electrical transmission systems in the northwestern portion of the NNSS (Areas 18, 19, 20, 29, and 30). Maintenance of Pahute Mesa, Stockade Wash, and Buckboard Mesa Roads would be minimized to provide only access for maintaining necessary infrastructure and conducting environmental restoration activities and operations at Pahute Mesa Airstrip would be limited to those necessary to provide access for the activities that would continue in these areas. The electrical transmission/distribution system beyond the Echo Peak Substation in Areas 19 and 20 would be de-energized. Ceasing all activities other than those mentioned in Areas 18, 19, 20, 29, and 30 would reduce DOE/NNSA's maintenance requirements at the NNSS and allow scarce resources to be focused on the more used areas of the NNSS. It may also reduce impacts on some resources, relative to the No Action and Expanded Operations Alternatives. **Figure 3–3** illustrates the configuration of the NNSS under the Reduced Operations Alternative.

Reduced Operations Alternative—American Indian Perspective

The Consolidated Group of Tribes and Organizations' (CGTO) concerns and perspective regarding the Reduced Operations Alternative include those discussed previously under Sections 3.0, 3.1.1, 3.1.2, 3.1.2.1, 3.1.2.2, and 3.1.3. The CGTO is supportive of a decrease in culturally perceived harmful land-disturbing activities within the Nevada National Security Site (NNSS) area and the offsite locations. To successfully reduce operations and restore environmental balance, it is essential to have tribal representatives involved throughout the process to help guide the U.S. Department of Energy (DOE) in conducting culturally appropriate activities. *See Appendix C for more details.*

The following description of the missions, programs, capabilities, projects, and activities that would be conducted under the Reduced Operations Alternative primarily addresses only this alternative's differences from the No Action Alternative; that is, those projects and activities that would be conducted at a lower level of intensity or not at all.

3.3.1 National Security/Defense Mission

Under the Reduced Operations Alternative, DOE/NNSA would continue to pursue activities in support of the Stockpile Stewardship and Management, Nuclear Emergency Response, Nonproliferation, Counterterrorism, and Work for Others Programs.

3.3.1.1 Stockpile Stewardship and Management Program

Stockpile stewardship and management operations would continue under the conditions of the ongoing nuclear testing moratorium. As under the No Action Alternative, the Reduced Operations Alternative includes those activities necessary to maintain the capability to conduct underground nuclear tests. Such a test would be conducted only if so directed by the President in the interest of national security. Conducting an underground nuclear test is neither included nor analyzed under any of the alternatives in this *NNSS SWEIS*. A generic description of underground nuclear testing is provided in Appendix H. Detailed descriptions of Stockpile Stewardship and Management Program activities under the Reduced Operations Alternative are provided in Appendix A, Section A.3.1.1.

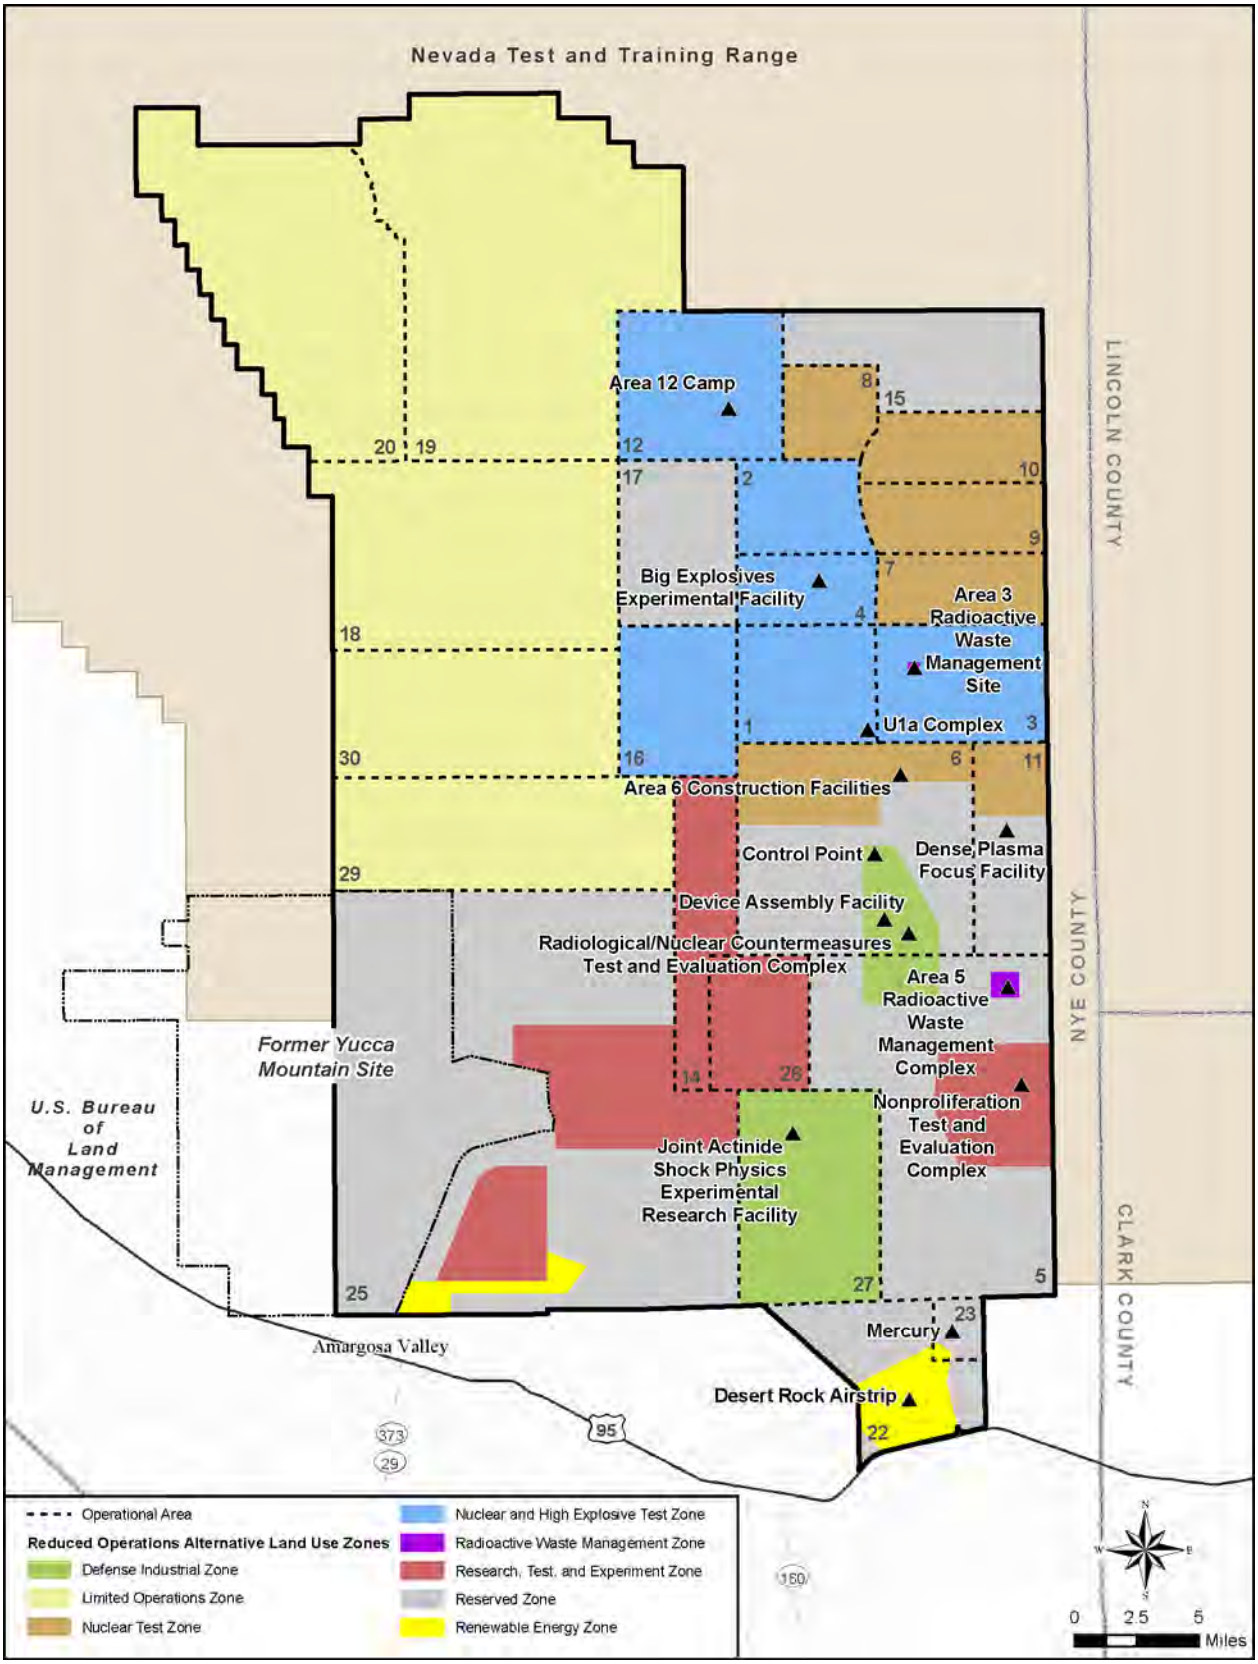

Figure 3–3 Nevada National Security Site Land Use Zones and Major Facilities Under the Reduced Operations Alternative

Under the Reduced Operations Alternative, there would be no change from the No Action Alternative for the following Stockpile Stewardship and Management Program projects and capabilities:

- Shock physics experiments at the Large-Bore Powder Gun
- Criticality experiments at DAF
- Disposition of damaged U.S. nuclear weapons
- Storage and staging of nuclear devices
- Staging of SNM, including pits
- Readiness-related training and exercises using various kinds of nuclear weapon simulators

In addition to maintaining these capabilities, under the Reduced Operations Alternative, the following changes in stockpile stewardship and management capabilities at DOE/NNSA facilities in Nevada would occur:

Dynamic experiments. DOE/NNSA would conduct no more than six of these experiments per year. Over the next 10 years, a total of five dynamic experiments would be conducted in emplacement holes and cause land disturbances. No dynamic experiments would occur in Areas 19 or 20 of the NNSS.

Conventional explosives experiments. DOE/NNSA would annually conduct up to 10 conventional explosives experiments in the Nuclear and High Explosives Test Zone to directly support the Stockpile Stewardship and Management Program. No other explosives experiments would be conducted.

Shock physics experiments. No more than six shock physics experiments with SNM would be annually conducted at JASPER.

Pulsed Power Experiments at the Atlas Facility. The Atlas Facility would be decommissioned and dispositioned.

Fusion experiments at the NNSS and NLVF. DOE/NNSA would conduct up to 375 plasma physics and fusion experiments per year: up to 350 would use the Dense Plasma Focus Machine at NLVF, while no more than 25 would use the machine in Area 11.

Support for Office of Secure Transportation Training. The number of times per year that Office of Secure Transportation training and exercises would be supported would be reduced to four.

Stockpile stewardship and management activities at the TTR. DOE/NNSA would not conduct fixed rocket launcher operations, cruise missile operations, or fuel-air explosives operations at the TTR.

3.3.1.2 Nuclear Emergency Response, Nonproliferation, and Counterterrorism Programs

There would be no change from the No Action Alternative for Nuclear Emergency Response, Nonproliferation, or Counterterrorism Program activities. See Appendix A, Section A.1.1.2, for a detailed description of these activities.

3.3.1.3 Work for Others Program

Under the Reduced Operations Alternative, DOE/NNSA would continue to host the projects of other Federal agencies, state and local governments, and nongovernmental organizations; however, certain activities, such as large-scale explosives tests and experiments, would not be conducted. DOE/NNSA

also would no longer support the following Work for Others Program activities, which are associated with nonproliferation projects and counterproliferation research and development:

- Conventional weapons effects tests, including live-drop and static high-explosives detonations
- Development and demonstration of capabilities and technologies to attack and defeat military targets protected in tunnels and other deeply buried hardened facilities
- Explosives experiments
- Experiments requiring explosive releases of chemical and biological simulants

No Work for Others Program activities, except military training and exercises, would be conducted in Areas 18, 19, 20, 29, and 30 of the NNSS under the Reduced Operations Alternative. The reason for this exception is that military training and exercises are currently conducted primarily in the western half of the NNSS to ensure adequate separation and avoid interference with other DOE/NNSA activities. This separation would need to be continued for safety and security considerations.

3.3.2 Environmental Management Mission

The DOE/NNSA Environmental Management Mission includes the Waste Management and Environmental Restoration Programs. Under the Reduced Operations Alternative, both of these programs would be the same as under the No Action Alternative, except that less TRU waste would be generated annually (about 710 cubic feet per year from all activities) because of the projected reduced annual number of experiments at JASPER and other national security activities. As with the No Action Alternative, this waste would be safely stored at the TRU Pad pending shipment off site for disposition along with other legacy or newly generated environmental restoration waste. DOE/NNSA activities would generate an estimated 170,000 cubic feet of hazardous waste. Smaller quantities of solid wastes (3,600,000 cubic feet) were also projected (compared to the No Action Alternative) because of reduced employment and construction activities. About 360,000 cubic feet of sanitary solid waste would be sent off site for recycling. Under the Reduced Operations Alternative, environmental restoration activities would continue in accordance with the most recent FFACO.

3.3.3 Nondefense Mission

The Nondefense Mission generally includes those projects and capabilities necessary to support DOE/NNSA-related programs such as construction and maintenance of facilities, provision of supplies and services, warehousing, and similar activities. Activities related to supply and conservation of energy, including renewable energy and other research and development, are considered part of the Nondefense Mission. Activities under the Reduced Operations Alternative would be the same as those under the No Action Alternative, including maintenance of the "cold standby" status of the former Yucca Mountain site, but at a lower level of effort, reflective of operational levels and establishment of the "Limited Use Zone."

3.3.3.1 General Site Support and Infrastructure Program

Under the Reduced Operations Alternative, infrastructure-associated activities would include repairs, replacements, and projects to maintain the reduced capabilities of the NNSS. DOE/NNSA would maintain only critical infrastructure within Areas 18, 19, 20, 29, and 30, including the Echo Peak, Motorola, and Shoshone communications facilities; the Echo Peak, Castle Rock, and Stockade Wash Substations; electrical transmission lines interconnecting these substations; and Well 8. Roads within Areas 18, 19, 20, 29, and 30 would be minimally maintained to provide the basic access necessary to maintain the noted infrastructure and to access environmental restoration sites in those areas. As noted

under the No Action Alternative, although considered infrastructure, characterization and monitoring wells developed under the UGTA Project are addressed under the Environmental Management Program and proposed and potential renewable energy projects are addressed under the Conservation and Renewable Energy Program, rather than the General Site Support and Infrastructure Program.

3.3.3.2 Conservation and Renewable Energy Program

Commercial Solar Power Generation. Under the Reduced Operations Alternative, DOE/NNSA assumes development of a 100-megawatt commercial solar power generation plant in Area 25 of the NNSS. The reasons for DOE/NNSA's consideration of commercial solar power development only in Area 25 and decision to assess the concentrating solar power parabolic trough technology in this *NNSS SWEIS* are addressed in Section 3.1.3.2. DOE/NNSA estimated 1,200 acres of land would be required for a 100-megawatt parabolic trough solar power generation facility. Operation of a commercial 100-megawatt concentrating solar power generation facility using hybrid cooling technology would require up to approximately 175 acre-feet of groundwater per year, as noted in Section 5.1.6.2.3. Unlike under the No Action and Expanded Operations Alternatives, the existing electrical transmission system on the NNSS has sufficient capacity to transmit the electrical energy produced by a 100-megawatt facility and new transmission line construction would not be required. Minor infrastructure construction and maintenance may be required to support the development of up to 100 megawatts of solar power generation within Area 25. The analysis in this SWEIS was based on assumptions for a representative commercial solar project. Because there are no current proposals for a commercial solar power generation facility on the NNSS, a separate NEPA review would be required for any specific proposal.

3.3.3.3 Other Research and Development Programs

Under the Reduced Operations Alternative, DOE/NNSA would continue to host existing environmental research projects at the NNSS, but would not actively promote the National Environmental Research Park Program. DOE/NNSA would consider any new environmental or other proposed research and/or development projects not related to DOE/NNSA National Security/Defense or Environmental Management Missions in all areas of the NNSS except Areas 18, 19, 20, 28, 29, and 30 on a case-by-case basis.

3.4 Identification of the Preferred Alternative

Council on Environmental Quality regulations for implementing NEPA (40 CFR 1502.14(e)) require an agency to identify its preferred alternative or alternatives, if one or more exists, in the draft EIS. At the time the *Draft NNSS SWEIS* was published, DOE/NNSA had not selected a preferred alternative. Since publication of the *Draft NNSS SWEIS*, DOE/NNSA has identified its Preferred Alternative (see Table 3–3).

In identifying its Preferred Alternative, DOE/NNSA considered the current and future needs of DOE/NNSA and other users of the NNSS and offsite locations. In doing so, DOE/NNSA balanced mission requirements established by the U.S. Congress with contemporary goals and objectives identified in planning documents such as the *10 Year Site Plan Fiscal Year 2012* for the NNSS (DOE 2011c), and anticipated funding levels for DOE/NNSA, as well as other users of the NNSS and offsite locations, such as DHS. DOE/NNSA also considered the preferences expressed by commentors on the *Draft NNSS SWEIS* and sought to balance those preferences with the needs of the agency and other users of the NNSS and offsite locations in Nevada.

DOE/NNSA's Preferred Alternative is a "hybrid" comprising various programs, capabilities, projects, and activities selected from among the three alternatives. Table 3–3 provides a comparison of mission-based program activities under the three alternatives and visually identifies by light blue shading which elements of the three alternatives were selected for the Preferred Alternative. In some cases, DOE/NNSA identified preferences from each alternative for different activities within a single program area. For example, under the Stockpile Stewardship and Management Program, DOE/NNSA identified its preference for conducting up to 10 dynamic experiments per year (consistent with the No Action Alternative), conducting up to 36 shock physics experiments per year at JASPER (consistent with the Expanded Operations Alternative), while also decommissioning the Atlas Facility (consistent with the Reduced Operations Alternative) as part of the Preferred Alternative.

As the Preferred Alternative is a "hybrid" composed of elements of each of the three alternatives that were examined in the Draft *NNSS SWEIS*, DOE/NNSA determined that the potential environmental consequences of the Preferred Alternative would fall within the range of magnitudes seen between the No Action and Expanded Operations Alternatives, varying by the affected environmental resource area, and there would be no synergistic effects resulting in previously unanalyzed impacts stemming from the hybrid alternative. For some environmental resources, the range of potential impacts is closer to that estimated for the No Action Alternative. For example, land disturbance under the Preferred Alternative is estimated at 8,107 acres, with the No Action and Expanded Operations Alternatives resulting in approximately 4,460 and 25,877 acres, respectively. Impacts on environmental resources closely tied to land disturbance (e.g., habitat loss, takes of threatened or endangered species, loss of cultural resources) would therefore also be closer in magnitude to those estimated for the No Action Alternative. For other environmental resources, the potential impacts would be much closer or identical to those estimated for the Expanded Operations Alternative. For example, radiological human health impacts result largely from LLW transportation and disposal activities. Under the Preferred Alternative, the volume of LLW requiring transportation and disposal would be identical to that identified under the Expanded Operations Alternative; thus, the potential impacts would be the same. **Tables 3–4, 3–5, 3–6** and **3–7** provide summaries of the potential impacts of the Preferred Alternative for each DOE/NNSA site, as well as the impacts of the three alternatives examined in the *Draft NNSS SWEIS*.

3.5 Comparison of Potential Consequences of the Alternatives

A summary of the potential impacts of the alternatives evaluated in this SWEIS is provided in this section. Tables 3–4 through 3–7 present side-by-side comparisons of the impacts under the alternatives at the NNSS, RSL, NLVF, and the TTR, respectively. The information presented in Tables 3–4 through 3–7 is a summary only; for detailed discussion, please refer to the appropriate resource section(s) of Chapter 5.

Table 3–3 Mission-Based Program Activities Under the Preferred Alternative (in blue)

NO ACTION ALTERNATIVE	EXPANDED OPERATIONS ALTERNATIVE	REDUCED OPERATIONS ALTERNATIVE
National Security/Defense Mission		
Stockpile Stewardship and Management Program (see Sections 3.1.1.1, 3.2.1.1, and 3.3.1.1 of this chapter for additional information)		
Maintain readiness to conduct underground nuclear tests.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Conduct up to 10 dynamic experiments per year within NNSS Areas 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 16, 19, or 20.	Conduct up to 20 dynamic experiments per year within NNSS Areas 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 16, 19, or 20.	Conduct up to 6 dynamic experiments per year at the NNSS; no dynamic experiments would be conducted in Areas 19 or 20.
Conduct up to 20 conventional explosives experiments per year at BEEF and up to 10 per year within NNSS Areas 1, 2, 3, 4, 12, or 16 using up to 70,000 pounds TNT-equivalent of explosive charges; would also support Work for Others Program.	• Conduct up to 100 conventional explosives experiments per year within NNSS Areas 1, 2, 3, 4, 12, or 16 using up to 120,000 pounds TNT-equivalent of explosive charges (50 of these would be at BEEF with a TNT-equivalent limitation of 70,000 pounds); would also support Work for Others Program. • Add second firing table and high-energy x-ray capability at BEEF. • Establish up to three areas at the NNSS for conducting explosive experiments with depleted uranium and conduct up to 20 experiments per year.	Conduct up to 10 conventional explosives experiments per year at BEEF using up to 70,000 pounds TNT-equivalent of explosive charges per year to directly support the Stockpile Stewardship and Management Program; no other explosives experiments would be conducted.
Conduct up to 12 shock physics experiments per year at the NNSS using actinide targets at JASPER in Area 27 and up to 10 experiments per year using the Large-Bore Powder Gun in Area 1.	Conduct up to 36 shock physics experiments per year at the NNSS using actinide targets at JASPER in Area 27 and up to 24 experiments per year using the Large-Bore Powder Gun in Area 1.	Conduct up to 6 shock physics experiments per year at the NNSS using actinide targets at JASPER in Area 27 and up to 8 experiments per year using the Large-Bore Powder Gun in Area 1.
Conduct up to 500 criticality operations (experiments, training, and other operations) per year at the National Criticality Experiments Research Center at DAF in Area 6.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Maintain the Atlas Facility in standby with the capability to conduct up to 12 pulsed-power experiments per year.	Activate the Atlas Facility and conduct up to 24 pulsed-power experiments per year.	Decommission and disposition the Atlas Facility.
Conduct up to 600 plasma physics and fusion experiments each year at NLVF and 50 per year in NNSS Area 11.	Conduct up to 1,000 plasma physics and fusion experiments each year at NLVF and 650 per year in NNSS Area 11, increasing the size and complexity of such experiments.	Conduct up to 350 plasma physics and fusion experiments each year at NLVF and 25 per year in NNSS Area 11.
Conduct five drillback operations at the NNSS over about a 10-year period.	Same as under the No Action Alternative.	Same as under the No Action Alternative.

NO ACTION ALTERNATIVE	EXPANDED OPERATIONS ALTERNATIVE	REDUCED OPERATIONS ALTERNATIVE
Conduct Stockpile Stewardship and Management Program activities in NNSS Areas 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 16, 19, or 20, including the following:	Same as under the No Action Alternative, plus:	Same as under the No Action Alternative, except: Stockpile Stewardship and Management Program activities would not be conducted in Areas 19 and 20.
– Disposition damaged U.S. nuclear weapons on an as-needed basis.	– Stage nuclear devices pending dismantlement, modification/maintenance, and/or transportation to another location. – Dismantle up to 100 nuclear weapons per year. – Replace limited-life components of up to 360 nuclear devices and conduct associated maintenance activities. – Test weapons components for quality assurance under the Limited Life Component Exchange Program.	
– Stage special nuclear material, including nuclear weapon pits.	– Transfer special nuclear material, including nuclear weapon pits, to and from other parts of the DOE complex for staging and use in experiments at the NNSS.	
Conduct training for the Office of Secure Transportation up to six times per year at various locations on NNSS roads.	Same as under the No Action Alternative, plus: Develop facilities in Area 17 and upgrade or construct new facilities in Area 6, 12, or 23 to support training for the Office of Secure Transportation.	Conduct training for the Office of Secure Transportation up to four times per year at various locations on NNSS roads.
Conduct the following stockpile stewardship operations at the TTR:	Same as under the No Action Alternative, except: Certain safeguards and security functions and other administrative functions would be returned to the U.S. Air Force	Same as under the No Action Alternative, except:
– Conduct tests and experiments, including flight test operations for gravity weapons (i.e., bombs). – Conduct ground/air-launched rocket and missile operations. – Conduct impact testing. – Conduct passive testing of joint test assemblies and conventional weapons. – Conduct fuel-air explosives testing.		– Discontinue ground/air-launched rocket and missile operations. – Discontinue fuel-air explosives testing at the TTR.
Nuclear Emergency Response, Nonproliferation, and Counterterrorism Programs (see Sections 3.1.1.2, 3.2.1.2, and 3.3.1.3 of this chapter for more information)		
Provide support for the Nuclear Emergency Support Team, the Federal Radiological Monitoring and Assessment Center, the Accident Response Group, and the Radiological Assistance Program. Most of this support is out of RSL at Nellis Air Force Base.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Conduct Aerial Measuring System activities from RSL at Nellis Air Force Base.	Same as under the No Action Alternative.	Same as under the No Action Alternative.

NO ACTION ALTERNATIVE	EXPANDED OPERATIONS ALTERNATIVE	REDUCED OPERATIONS ALTERNATIVE
Conduct WMD emergency responder training at various DOE/NNSA NSO venues.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Support the DOE Emergency Communications Network.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Disposition improvised nuclear devices and deploy the DOE/NNSA Disposition Program and FBI Disposition Forensic Program to the NNSS for training and exercises or for an actual event, as needed.	Same as under the No Action Alternative, plus disposition of radiological dispersion devices, as needed.	Same as under the No Action Alternative.
Integrate existing activities and primarily NNSS facilities to support U.S. efforts to control the spread of WMDs, particularly nuclear WMDs, including arms control, nonproliferation activities, nuclear forensics, and counterterrorism capabilities.	Same as under the No Action Alternative, plus: At the NNSS: • Construct laboratory space and other facilities for design and certification of treaty verification technology, training of inspectors, and development of arms control confidence-building measures as part of the Arms Control Treaty Verification Test Bed.[a] • Develop and construct new facilities to support a Nonproliferation Test Bed to simulate chemical and radiological processes that an adversary would clandestinely conduct.[a] • Construct an Urban Warfare Complex to support counterterrorism training.[a]	Same as under the No Action Alternative.
Work for Others Program (see Sections 3.1.1.3, 3.2.1.3, and 3.3.1.3 of this chapter for more information)		
Continue to conduct Work for Others Program activities in all appropriate zones on the NNSS, and at RSL and NLVF.	Same as under the No Action Alternative, except: The NNSS land use zone designation for Area 15 would be changed from "Reserved Zone" to "Research, Test, and Experiment Zone."	Same as under the No Action Alternative, except: Work for Others Program activities, with the exception of military training and exercises, would not be conducted in Areas 18, 19, 20, 29, and 30 at the NNSS.
Host treaty verification activities.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Conduct nonproliferation projects and counterproliferation research and development at the NNSS, including:	Same as under the No Action Alternative.	Same as under the No Action Alternative, except:
– Conduct conventional weapons effects and other explosives experiments.		Discontinue Work for Others Program conventional weapons effects and other explosives experiments.
– Support development of capabilities to detect and defeat military assets in deeply buried hardened targets.		Discontinue development of capabilities to defeat military assets in deeply buried hardened targets.
– Conduct up to 20 controlled chemical and biological simulant release experiments per year (each experiment would include multiple releases by a variety of means, including explosive).		Discontinue projects requiring explosive releases of chemical or biological simulants.

NO ACTION ALTERNATIVE	EXPANDED OPERATIONS ALTERNATIVE	REDUCED OPERATIONS ALTERNATIVE
– Support training, research and development of equipment, specialized munitions, and tactics related to counterterrorism.		
Support the U.S. Department of Defense and other Federal agencies in developing counterterrorism capabilities.	Develop and construct new facilities to support counterterrorism training and research and development activities.	Same as under the No Action Alternative.
Conduct criticality experiments to support NASA's deep space power source development within the parameters for criticality experiments established under the Stockpile Stewardship and Management Program.	Same as under the No Action Alternative, plus: Support NASA's deep space power source development, including conducting experiments using existing boreholes at the NNSS to sequester emissions such as radionuclides.[a]	Same as under the No Action Alternative.
Host the use of various aerial platforms, such as airplanes, unmanned aerial systems and helicopters, at various locations at the NNSS for research and development, training, and exercises.	• Increase use of various aerial platforms, such as airplanes, unmanned aerial systems, and helicopters, for research and development, training, and exercises, including constructing additional hangars, shops, and buildings at existing airports at the NNSS. • Conduct up to 3 underground and 12 open-air radioactive tracer experiments per year. • Host treaty verification activities, including development of a facility for simulating nuclear fuel cycle-related radionuclide release detection and characterization.[a] • Develop a facility for specialized explosive experiments and simulated manufacture to support high-explosives experiments.[a] • Support increased research and development of active interrogation equipment, methods, and training. • Develop new facilities to support research and development in radio frequency generation and infrasonic observations.[a] • Develop new facilities, including simulated clandestine laboratories, to support chemical and biological simulant experiments.[a]	Same as under the No Action Alternative.
Conduct Work for Others Program activities at the TTR, including robotics testing, smart transportation-related testing, smoke obscuration operations, infrared tests, and rocket development.	Same as under the No Action Alternative, except: Certain safeguards and security functions and other administrative functions would be turned over to the U.S. Air Force.	Same as under the No Action Alternative.

NO ACTION ALTERNATIVE	EXPANDED OPERATIONS ALTERNATIVE	REDUCED OPERATIONS ALTERNATIVE
Environmental Management Mission		
Waste Management Program (see Sections 3.1.2.1, 3.2.2.1, and 3.3.2.1 of this chapter for more information)		
Dispose up to 15,000,000 cubic feet of LLW and 900,000 cubic feet of MLLW [b] in the Area 5 RWMC.	Dispose up to 48,000,000 cubic feet of LLW and 4,000,000 cubic feet of MLLW at the Area 5 RWMC and Area 3 RWMS. [d]	Same as under the No Action Alternative.
Maintain the Area 3 RWMS on standby.	Open the Area 3 RWMS for disposal of authorized and/or permitted waste.	Same as under the No Action Alternative.
Repackage onsite-generated MLLW.	Same as under the No Action Alternative, plus: At the Area 5 RWMC, store MLLW received from on- and offsite generators pending treatment via macroencapsulation and microencapsulation (i.e., repackaging), sorting/segregating, and bench-scale mercury amalgamation, as appropriate, and/or dispose this waste.	Same as under the No Action Alternative.
Store onsite-generated TRU waste (up to 9,600 cubic feet over the next 10 years) pending offsite disposal.	Same as under the No Action Alternative, except a larger volume (up to 19,000 cubic feet over the next 10 years) of TRU waste would be generated by increased activities at NNSS facilities, such as JASPER.	Same as under the No Action Alternative, except smaller volumes (up to 7,100 cubic feet over the next 10 years) of TRU waste would be generated by reduced operational levels at NNSS facilities, such as JASPER.
Store onsite-generated hazardous waste as needed at the Area 5 Hazardous Waste Storage Unit pending offsite treatment or disposal. Up to 170,000 cubic feet would be generated over the next 10 years.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Operate the Area 11 Explosives Ordnance Disposal Unit. No more than 41,000 pounds of explosives would be treated over the next 10 years.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Operate the Area 6 Hydrocarbon Landfill.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Operate the Area 23 Solid Waste Disposal Site and the U10c Solid Waste Disposal Site. Up to 3,400,000 cubic feet would be disposed over the next 10 years.	Same as under the No Action Alternative, plus: Larger volumes of solid sanitary waste requiring disposal (up to 8,500,000 cubic feet) would be generated by increased activity levels at the NNSS over the next 10 years. Construct new sanitary solid waste disposal facilities as needed in Area 23 and develop a new solid waste disposal site in Area 25 to support environmental restoration activities.	Same as under the No Action Alternative, except lower volumes of solid sanitary waste requiring disposal (up to 3,300,000 cubic feet) would be generated by reduced activity levels at the NNSS over the next 10 years.

NO ACTION ALTERNATIVE	EXPANDED OPERATIONS ALTERNATIVE	REDUCED OPERATIONS ALTERNATIVE
Environmental Restoration Program (see Sections 3.1.2.2, 3.2.2.2, and 3.3.2.2 of this chapter for more information)		
Underground Test Area Project – Comply with the FFACO; monitor groundwater from existing wells; drill new characterization and monitoring wells; develop groundwater flow and transport models; and continue to evaluate closure strategies.	Same as under the No Action Alternative, except: Characterization and monitoring wells would be developed more quickly.	Same as under the No Action Alternative.
Soils Project – Identify and characterize areas with contaminated soils and perform corrective actions in compliance with the FFACO.	Same as under the No Action Alternative, except: If stricter cleanup standards are implemented, larger volumes of radioactive waste would be generated and disposed.	Same as under the No Action Alternative.
Industrial Sites Project – Identify, characterize, and remediate industrial sites under the FFACO and continue decontaminating and decommissioning facilities.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Defense Threat Reduction Agency sites – In accordance with the FFACO, perform remediation activities at sites that are the responsibility of the Defense Threat Reduction Agency.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Execute the Borehole Management Program.	Same as under the No Action Alternative.	Same as under the No Action Alternative.
Nondefense Mission		
General Site Support and Infrastructure Program (see Sections 3.1.3.1, 3.2.3.1, and 3.3.3.1 of this chapter for more information)		
Conduct small projects to maintain the present capabilities of DOE/NNSA NSO facilities in all areas of the NNSS and at NLVF, RSL, and the TTR. Maintain existing infrastructure, manage various permits and agreements, and provide security for the former Yucca Mountain site.	Same as under the No Action Alternative, plus: • Construct a new 85,000-square-foot multistory security building in Area 23. • Replace the NNSS 138-kilovolt electrical transmission system. • Expand cellular telecommunication system on the NNSS. • Reconfigure Mercury.[a]	Same as under the No Action Alternative, except: Only critical infrastructure would be maintained within Areas 18, 19, 20, 29, and 30 of the NNSS, including certain communications facilities; electrical transmission lines and substations; and Well 8. Roads within these areas would only be maintained to provide access to the infrastructure and environmental restoration sites.
Conservation and Renewable Energy Program (see Sections 3.1.3.2, 3.2.3.2, and 3.3.3.2 of this chapter for more information)		
Continue to identify and implement energy conservation measures and renewable energy projects in compliance with applicable Executive Orders and DOE Orders.	Same as under the No Action Alternative, plus:	Same as under the No Action Alternative, except:
– Reduce energy intensity by 3 percent annually through the end of fiscal year 2015, for a total 30 percent reduction.		
– Reduce greenhouse gas emissions by 28 percent by fiscal year 2020.		
– Install advanced electric metering systems.		
– Obtain at least 7.5 percent of the NNSS annual electricity and thermal consumption from renewable energy sources.		

NO ACTION ALTERNATIVE	EXPANDED OPERATIONS ALTERNATIVE	REDUCED OPERATIONS ALTERNATIVE
– Support development of a 240-megawatt commercial solar power generation facility in Area 25.[a c]	• Modify NNSS land use zones to establish a 39,600-acre Renewable Energy Zone in Area 25 and support development of commercial solar power generation facilities in Area 25 with a maximum combined generating capacity of 1,000 megawatts.[a, c] • Construct a 5-megawatt photovoltaic solar power generation facility near the Area 6 Construction Facilities. • Support a Geothermal Demonstration Project and Geothermal Research Center at the NNSS.[a]	Support development of a 100-megawatt commercial solar power generation facility in Area 25.[a c]
– Reduce water use by 16 percent by 2015.		
– Maximize use of alternative fuels (e.g., E85 and biodiesel).		
– Ensure all new construction and renovation projects implement high-performance building goals.		
Other Research and Development Programs (see Sections 3.1.3.3, 3.2.3.3, and 3.3.3.3 of this chapter for more information)		
Support the DOE National Environmental Research Park Program and other non-DOE/NNSA research and development activities in all areas of the NNSS.	Same as under the No Action Alternative.	National Environmental Research Park Program and other non–DOE/NNSA research and development activities would be conducted in all areas of the NNSS except Areas 18, 19, 20, 29, and 30.

= Activities included as part of the Preferred Alternative.

BEEF = Big Explosives Experimental Facility; DAF = Device Assembly Facility; FBI = Federal Bureau of Investigation; FFACO = Federal Facilities Agreement and Consent Order; JASPER = Joint Actinide Shock Physics Experimental Research Facility; LLW = low-level radioactive waste; MLLW = mixed low-level radioactive waste; NASA = National Aeronautics and Space Administration; NLVF = North Las Vegas Facility; NNSA = National Nuclear Security Administration; NNSS = Nevada National Security Site; NSO = Nevada Site Office; RSL = Remote Sensing Laboratory; RWMC = Radioactive Waste Management Complex; RWMS = Radioactive Waste Management Site; TNT = 2,4,6-trinitrotoluene; TRU = transuranic; TTR = Tonopah Test Range; WMD = weapon of mass destruction.

[a] These potential projects have not reached a point of development to allow full analysis in this *NNSS SWEIS* and would be subject to project-specific NEPA review before DOE/NNSA would make any decision regarding implementation.

[b] The actual permitted capacity of the Mixed Waste Disposal Unit (Cell 18) is 899,996 cubic feet.

[c] DOE/NNSA has not received or solicited proposals for any commercial solar power generation projects.

[d] Reactivation of the Area 3 RWMS would only occur based upon mission need and as stated in Section 4.1.11.1.1.1, including detailed consultation with the State of Nevada.

Table 3–4 Summary of Potential Impacts at the Nevada National Security Site

	No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*	*Preferred Alternative*
Land Use (for details go to Chapter 5, Sections 5.1.1.1, 5.1.1.2, and 5.1.1.3)				
National Security/ Defense Mission	No impacts were identified from the continuation of activities at the current levels of operations or foreseeable actions because activities under this alternative would continue to be compatible with existing land use designations on the NNSS and primary land uses adjacent to the site.	No impacts were identified from the increased activities and change in land use designations under this alternative because activities would be compatible with the proposed land use designations and primary land uses adjacent to the NNSS. The Reserved Zone would decrease in area by 5.5 percent; the Research, Test, and Experiment Zone would increase by 21 percent.	No impacts were identified from the decreased activities and change in land use designations under this alternative because activities would be compatible with the proposed land use designations and primary land uses adjacent to the NNSS. The Reserved Zone would decrease in area by 71 percent, and Areas 18, 19, 20, and 30 would change from Reserved to Limited Use, which is a new land use zone designation.	No impacts were identified from the increased activities and change in land use designations under this alternative because activities would be compatible with the proposed land use designations and primary land uses adjacent to the NNSS. Area 15 would change from the Reserved to the Research, Test, and Experiment zone designation. Areas 18, 19, 20, and 30 would change from Reserved to Limited Use, which is a new land use zone designation.
	<u>*Airspace*</u> No new impacts were identified from airspace activities because these activities would be maintained at the current level of air traffic, navigational aid services, and airspace structure, and would be coordinated and scheduled by the controlling entity responsible for NNSS airspace, the Nellis Air Traffic Control Facility.	<u>*Airspace*</u> Minimal impacts would result from increased usage of aerial platforms and airspace usage, as these activities would continue to be coordinated with the Nellis Air Traffic Control Facility.	<u>*Airspace*</u> Same as under the No Action Alternative.	<u>*Airspace*</u> Minimal impacts would result from increased usage of aerial platforms and airspace usage, as these activities would continue to be coordinated with the Nellis Air Traffic Control Facility.
Environmental Management Mission	No impacts were identified from the continuation of activities at the current levels of operations because activities under this alternative would not change.	No impacts were identified from the increased activities under this alternative, as these activities would be compatible with land use designations and primary land uses adjacent to the site.	Same as under the No Action Alternative.	No impacts were identified from the increased activities under this alternative, as these activities would be compatible with land use designations and primary land uses adjacent to the site.
Nondefense Mission	No impacts were identified from the continuation of activities at the current levels of operations or foreseeable actions because activities under this alternative would continue to be compatible with existing land use designations on the NNSS and primary land uses adjacent to the site. The Solar Enterprise Zone would be renamed the Renewable Energy Zone.	Same as the No Action Alternative, plus: Area 15 would be changed from a Reserved Zone to a Research, Test, and Experiment Zone, and the Solar Enterprise Zone would be renamed the Renewable Energy Zone and increase in area by 276 percent.	Same as under the No Action Alternative.	Same as the No Action Alternative, plus: Area 15 would be changed from a Reserved Zone to a Research, Test, and Experiment Zone.

	No Action Alternative	***Expanded Operations Alternative***	***Reduced Operations Alternative***	***Preferred Alternative***
Infrastructure and Energy (for details go to Chapter 5, Sections 5.1.2.1 and 5.1.2.2)				
Infrastructure	Buildings, transportation, water supply, and services are adequate to handle temporary increases in demands during construction and long-term demands during operations. Infrastructure would be maintained as needed to accommodate ongoing activities. In addition, new LLW cells would be developed to accommodate disposal of those waste types. Up to 50 new wells would be developed by the UGTA Project.	Same as under the No Action Alternative, plus: New buildings (about 479,000 square feet), ranges and training facilities (13,455 acres), water distribution lines, wastewater treatment systems (septic tanks), power lines, and communication systems would be added and improvements would be made to existing infrastructure. In addition, new LLW/MLLW cells would be developed to accommodate disposal of increased volumes of those waste types and new sanitary and construction/D&D waste landfills in Areas 23 and 25. An upgrade to the NNSS electrical transmission system would increase capacity from 40 to 100 megawatts. A 5-megawatt photovoltaic solar power generation facility would be developed in Area 6.	Same as under the No Action Alternative, except: Buildings, transportation, water supply, and services would experience reduced demands. Because most operations in the northwestern portion of the NNSS (within Areas 18, 19, 20, 29, and 30) would be discontinued, non-essential infrastructure in those areas would be shut down or removed.	Same as under the No Action Alternative, plus: New buildings (about 350,000 square feet), ranges and training facilities (approximately 3,455 acres), water distribution lines, wastewater treatment systems (septic tanks), power lines, and communication systems would be added and improvements would be made to existing infrastructure. In addition, new LLW/MLLW cells would be developed to accommodate disposal of increased volumes of those waste types and new sanitary and construction/D&D waste landfills in Areas 23 and 25. An upgrade to the NNSS electrical transmission system would increase capacity from 40 to 100 megawatts. A 5-megawatt photovoltaic solar power generation facility would be developed in Area 6. Because most operations in the northwestern portion of the NNSS (within Areas 18, 19, 20, 29, and 30) would be discontinued, non-essential infrastructure in those areas would be shut down or removed.
	A commercial 240-megawatt solar power generation plant would be developed in Area 25 of the NNSS. Up to 10 miles of new 230-kilovolt transmission lines would be required to interconnect the new generation facility with the main power grid. The commercial facility would provide a portion of the electrical power at the NNSS. Sanitary needs of construction and operational employees would be provided by the commercial entity and are not	Up to 1,000 megawatts of commercial solar power generating capacity would be developed in Area 25 of the NNSS. Up to 10 miles of new 500-kilovolt transmission lines would be required to interconnect the new generating facilities with the main power grid. The commercial facilities would provide a portion of the electrical power at the NNSS. Sanitary needs of construction and operational employees would be provided by the commercial entity and are not expected to affect the NNSS solid waste or	A commercial 100-megawatt solar power generation plant would be developed in Area 25 of the NNSS. No new transmission lines would be required to interconnect the new generating facility with the main power grid. The commercial facility would provide a portion of the electrical power at the NNSS. Sanitary needs of construction and operational employees would be provided by the commercial entity and are not expected to affect the NNSS solid waste or	A commercial 240-megawatt solar power generation facility would be developed in Area 25 of the NNSS. Up to 10 miles of new 230-kilovolt transmission lines would be required to interconnect the new generation facility with the main power grid. The commercial facility would provide a portion of the electrical power at the NNSS. Sanitary needs of construction and operational employees would be provided by the commercial entity and are not

	No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*	*Preferred Alternative*
Traffic (for details go to Chapter 5, Sections 5.1.3.2.1, 5.1.3.2.2, and 5.1.3.2.3)				
Onsite traffic impacts	There would be about 20 additional vehicle trips per day on Mercury Highway, which would operate at a level of service A during peak traffic hours. Construction of a 240-megawatt commercial solar power generation facility would result in 500 (average over the period of construction) and 1,000 (during the peak of the construction period) additional vehicle trips on a daily basis during the peak commute hours on Lathrop Wells Road; increased roadway maintenance or improvements may be required.	There would be about 800 additional vehicle trips per day on Mercury Highway, which would operate at a level of service B or better during peak traffic hours. Construction of 1,000 megawatts of commercial solar power generation facilities would result in 750 (average over the period of construction) and 1,500 (during the peak of the construction period) additional vehicle trips on a daily basis during the peak commute hours on Lathrop Wells Road; increased roadway maintenance or improvements may be required.	There would be about 150 fewer vehicle trips per day on Mercury Highway, which would operate at a level of service A during peak traffic hours. Construction of a 100-megawatt commercial solar power generation facility would result in 400 (average over the period of construction) and 800 (during the peak of the construction period) additional vehicle trips on a daily basis during the peak commute hours on Lathrop Wells Road; increased roadway maintenance or improvements may be required.	There would be about 800 additional vehicle trips per day on Mercury Highway, which would operate at a level of service B or better during peak traffic hours. Construction of a 240-megawatt commercial solar power generation facility would result in 500 (average over the period of construction) and 1,000 (during the peak of the construction period) additional vehicle trips on a daily basis during the peak commute hours on Lathrop Wells Road; increased roadway maintenance or improvements may be required.
Regional traffic impacts	U.S. Route 95, State Route 160, and State Route 372 would experience the greatest increases in daily traffic volumes in the area around the NNSS; however, these would be relatively minor and would not affect the levels of service on regional roadways. Overall traffic volumes would increase during peak hours because of additional traffic attributable to the construction of a solar power generation facility.	Segments of State Route 372, State Route 160, U.S. Route 95, and State Route 164 would experience moderately high percent increases in daily traffic compared to the No Action Alternative. Most of the increase in daily traffic volumes during the peak hours would be attributable to workers commuting to the NNSS. Any detectable changes in traffic volumes would primarily occur during the main commuting hours and at the entry gates of the NNSS (the main entrance gate for regular NNSS employees and Gate 510 for those associated with the construction and operation of the commercial solar power generation facilities in Area 25). However, the levels of service on public roadways in the region would not change.	Although the number of commuter trips for the reduced NNSS workforce would decrease, overall traffic volumes would increase slightly during peak hours because of additional traffic volumes attributable to construction and operation of the solar power generation facility. Impacts on regional traffic under this alternative would, therefore, be slightly less than or similar to those described under the No Action Alternative; volume-to-capacity ratios and levels of service would not change.	Segments of State Route 372, State Route 160, U.S. Route 95, and State Route 164 would experience moderately high percent increases in daily traffic compared to the No Action Alternative. Most of the increase in daily traffic volumes during the peak hours would be attributable to workers commuting to the NNSS. Any detectable changes in traffic volumes would primarily occur during the main commuting hours and at the entry gates of the NNSS (the main entrance gate for regular NNSS employees and Gate 510 for those associated with the construction and operation of a commercial solar power generation facility in Area 25). However, the levels of service on public roadways in the region would not change.

Socioeconomics (for details go to Chapter 5, Sections 5.1.4.1, 5.1.4.2, and 5.1.4.3)				
	Operation of a 240-megawatt commercial solar power facility would increase employment by 150 FTEs, of which about 15 solar power facility employees would relocate from outside of the region. Sufficient housing exists to support the increased population. A total of 22 new students relocating to Clark County would create a need for 1 additional teacher to maintain the student-to-teacher ratio. An increase of 6 new students in Nye County would not result in a need for additional teachers. Direct jobs would reduce unemployment by 0.07 and 0.99 percent, respectively, in Clark and Nye Counties.	Site employment would increase by 625 FTEs; about 63 employees would relocate from outside of the region. Sufficient housing exists in the area to support the increased population. A total of 92 new students relocating to Clark County would create a need for 4 new teachers to maintain the student-to-teacher ratio. An increase of 27 new students in Nye County would create a need for 1 new teacher to maintain the student-to-teacher ratio. Direct jobs would reduce unemployment by 0.31 and 4.2 percent, respectively, in Clark and Nye Counties.	Site employment would decrease by 45 FTEs, increasing unemployment in Clark County by about 0.03 percent and in Nye County by about 0.39 percent. Additional employees would not relocate to Clark or Nye County and there would be no need for new housing or teachers.	Site employment would increase by approximately 575 FTEs; about 60 employees would relocate from outside of the region. Sufficient housing exists in the area to support the increased population. A total of approximately 90 new students relocating to Clark County would create a need for 4 new teachers to maintain the student-to-teacher ratio. An increase of approximately 25 new students in Nye County would create the need for 1 new teacher to maintain the student-to-teacher ratio. Direct jobs would reduce unemployment by 0.3 and 4.0 percent, respectively, in Clark and Nye Counties.
	Approximately 500 FTEs over 35 months, with a peak of 1,000 FTEs, would need to be hired for construction of the solar power generation facility.	Approximately 750 FTEs over 42 months, with a peak of 1,500 FTEs, would need to be hired for construction of the solar power generation facility. Other construction projects at the NNSS would require approximately 250 FTEs over the 10-year period.	Approximately 400 FTEs over 32 months, with a peak of 800 FTEs, would need to be hired for construction of the solar power generation facility.	Approximately 500 FTEs over 35 months, with a peak of 1,000 FTEs, would need to be hired for construction of the solar power generation facility. Other construction projects at the NNSS would require approximately 250 FTEs over the 10-year period.
	Direct jobs, indirect jobs, and construction materials purchases would reduce unemployment and have a beneficial effect on local government revenues.	Direct jobs, indirect jobs, and construction materials purchases would reduce unemployment and have a beneficial effect on the local economy and government revenues.	Job loss would have a small negative impact on the local economy; construction material purchases for the solar power generation facility would have a small positive economic impact, including generating additional revenues for local governments. Direct construction jobs and indirect jobs would reduce unemployment and would have a beneficial impact on the economy in the region.	Direct jobs, indirect jobs, and construction materials purchases would reduce unemployment and have a beneficial effect on local government revenues.
	Buildings associated with construction and operation of a solar power generation facility and increased site personnel would create an increased demand for onsite security and fire and rescue services.	Buildings associated with construction and operation of a larger solar power generation facility and other facilities on site and the increase in personnel would create a greater demand for onsite security and fire and rescue services.	Buildings associated with construction and operation of a solar power generation facility would create an increased demand for onsite security and fire and rescue services.	Buildings associated with construction and operation of a solar power generation facility and increased site personnel would create an increased demand for onsite security and fire and rescue services.

Geology and Soils (for details go to Chapter 5, Sections 5.1.5.1, 5.2.5.2, and 5.1.5.3)				
National Security/ Defense Mission	About 700 acres of soil would be disturbed by dynamic experiments in boreholes, explosives experiments, drillback operations, OST training and exercises, experiments involving biological simulants, and counterterrorism training.	About 13,455 acres of soil would be disturbed by the same kinds of activities as under the No Action Alternative, including: Up to 10,000 acres of soil would be disturbed for an OST training facility, 120 acres for depleted uranium experiment sites, and 3,335 acres for additional explosives experiments, new test beds and training facilities, drillback operations, and additions to existing aviation facilities at the NNSS.	About 430 acres of soil would be disturbed by many of the same kinds of activities as under the No Action Alternative, except: There would be 50 percent fewer explosive experiments and 33 percent less OST training and exercises.	About 3,455 acres of soil would be disturbed by the activities including: dynamic experiments, explosives experiments, drillback operations, OST training and exercises, experiments involving biological simulants, counterterrorism training, depleted uranium experiments, new test beds and training facilities, and additions to existing aviation facilities at the NNSS.
Environmental Management Mission	About 190 acres of soil would be disturbed for construction of new waste cells at the Area 5 RWMC. Up to 420 acres of soil would be disturbed as part of the Environmental Restoration Program, Soils Project cleanup. Up to 500 acres of soil would be disturbed for development of UGTA Project monitoring wells.	About 600 acres of soil would be disturbed for construction of new waste cells at the Area 5 RWMC. About 35 acres of soil would be disturbed for new sanitary and D&D/construction waste landfills in Areas 23 and 25. Environmental Restoration Program impacts would be the same as under the No Action Alternative.	Same as under the No Action Alternative.	About 600 acres of soil would be disturbed for construction of new waste cells at the Area 5 RWMC. About 35 acres of soil would be disturbed for new sanitary and D&D/construction waste landfills in Areas 23 and 25. Up to 420 acres of soil would be disturbed as part of the Environmental Restoration Program, Soils Project cleanup. Up to 500 acres of soil would be disturbed for development of UGTA Project monitoring wells.
Nondefense Mission	Construction of a 240-megawatt commercial solar power generation facility and associated transmission lines would disturb approximately 2,650 acres.	Construction of 1,000 megawatts of commercial solar power generation facilities and associated transmission lines would disturb up to 10,300 acres. Replacing the existing 138-kilovolt NNSS electrical transmission line would temporarily disturb about 467 acres of soil. Construction of a DOE/NNSA photovoltaic solar power generation facility would disturb about 50 acres of land. Minor soil disturbance is expected from several additional research projects. Development of a Geothermal Demonstration Project would disturb up to 50 acres of soil.	Construction of a 100-megawatt commercial solar power generation facility could disturb up to 1,200 acres.	Construction of a 240-megawatt commercial solar power generation facility and associated transmission lines would disturb approximately 2,650 acres. Replacing the existing 138-kilovolt NNSS electrical transmission line would temporarily disturb about 467 acres of soil. Construction of a DOE/NNSA photovoltaic solar power generation facility would disturb about 50 acres of land. Minor soil disturbance is expected from several additional research projects. Development of a Geothermal Demonstration Project would disturb up to 50 acres of soil.

	No Action Alternative	Expanded Operations Alternative	Reduced Operations Alternative	Preferred Alternative
Hydrology (for details go to Chapter 5, Section 5.1.6)				
Surface Water Resources (for details go to Chapter 5, Sections 5.1.6.1, 5.1.6.1.1, 5.1.6.1.2, and 5.1.6.1.3)				
National Security/ Defense Mission	Disturbance of about 700 acres of land by dynamic experiments in boreholes, explosives experiments, drillback operations, OST training and exercises, experiments involving releases of chemicals and biological simulants, and counterterrorism training would cause alterations of natural drainage pathways, contamination of ephemeral surface waters via chemical agents, and sedimentation to ephemeral surface waters.	About 13,455 acres of soil and near-surface geologic media would be disturbed by activities similar to those under the No Action Alternative, including: Up to 10,000 acres of disturbance for OST training facilities, 120 acres for depleted uranium experiment sites, and 3,335 acres for additional explosives experiments, new test beds and training facilities, drillback operations and additions to existing aviation facilities at the NNSS. This would result in proportionately larger impacts on ephemeral waters compared to the No Action Alternative.	About 430 acres of soil and near-surface geologic media would be disturbed by many of the same kinds of activities as under the No Action Alternative, except: There would be 50 percent fewer explosives experiments, and 33 percent less OST training and exercises. This would result in proportionately smaller impacts on ephemeral waters compared to the No Action Alternative.	Disturbance of about 3,455 acres of land would cause alterations of natural drainage pathways, contamination of ephemeral surface waters via chemical agents, and sedimentation to ephemeral surface waters.
Environmental Management Mission	Disturbance of up to 190 acres of soil to construct, use, cover, and close disposal units within the existing Area 5 RWMC would result in impacts on ephemeral waters due to alteration of natural drainage pathways, increased erosion, and subsequent sedimentation.	Disturbance of up to 600 acres of soil to construct, use, cover, and close disposal units within the existing Area 5 RWMC, plus up to 35 acres of disturbance for new sanitary/D&D/construction waste landfills would result in impacts on ephemeral waters due to alteration of natural drainage pathways, increased erosion, and subsequent sedimentation.	Same as under the No Action Alternative for both Waste Management and Environmental Restoration.	Disturbance of up to 600 acres of soil to construct, use, cover, and close disposal units within the existing Area 5 RWMC, plus up to 35 acres of disturbance for new sanitary/D&D/ construction waste landfills would result in impacts on ephemeral waters due to alteration of natural drainage pathways, increased erosion, and subsequent sedimentation.
	The Soils Project would reduce or stabilize legacy contamination in soil and could result in disturbance of up to 420 acres. Soil disturbance on about 500 acres of land from drilling additional wells for the UGTA Project could cause localized erosion, as could D&D of industrial sites, remediation of Defense Threat Reduction Agency sites, and the Borehole Management Program. These activities would affect ephemeral waters by altering natural drainage pathways and increasing sedimentation. Stabilization and/or removal of contaminated facilities	Environmental Restoration impacts would be the same as under the No Action Alternative.		The Soils Project would reduce or stabilize legacy contamination in soil and could result in disturbance of up to 420 acres. Soil disturbance on about 500 acres of land from drilling additional wells for the UGTA Project could cause localized erosion, as could D&D of industrial sites, remediation of Defense Threat Reduction Agency sites, and the Borehole Management Program. These activities would affect ephemeral waters by altering natural drainage pathways and increasing sedimentation. Stabilization and/or removal of contaminated facilities

	No Action Alternative	***Expanded Operations Alternative***	***Reduced Operations Alternative***	***Preferred Alternative***
	and soils would reduce the potential for contamination of ephemeral waters.			and soils would reduce the potential for contamination of ephemeral waters.
Nondefense Mission	No new land disturbances would occur during infrastructure-related activities under the No Action Alternative.	Up to 517 acres of land would be disturbed by rebuilding the existing 138-kilovolt transmission line on the NNSS and constructing a 5-megawatt photovoltaic solar power generation facility. These disturbances would result in alterations of natural drainage pathways and increased sedimentation of ephemeral waterways.	Same as under the No Action Alternative, except: The land area associated with the development of a 100-megawatt solar power generation facility would be 1,200 acres.	Development of a 240-megawatt commercial solar power generation facility and associated transmission lines would alter natural drainage pathways over 2,650 acres in Area 25, though it is expected that larger ephemeral waters (e.g., Fortymile Wash) would be avoided; however, there would be a potential for chemical contamination of and sedimentation to ephemeral waters during construction-related land preparation. Up to 517 acres of land would be disturbed by rebuilding the existing 138-kilovolt transmission line on the NNSS and constructing a 5-megawatt photovoltaic solar generating facility. Development of a Geothermal Demonstration Project would disturb up to 50 acres. These disturbances would result in alterations of natural drainage pathways and increased sedimentation of ephemeral waterways.
	Development of a 240-megawatt commercial solar power generation facility and associated transmission lines would alter natural drainage pathways over 2,650 acres in Area 25, though it is expected that larger ephemeral waters (e.g., Fortymile Wash) would be avoided; however, there would be a potential for chemical contamination of and sedimentation to ephemeral waters during construction-related land preparation.	Development of up to 1,000 megawatts of commercial solar power generation facilities and associated transmission lines would disturb drainage pathways over 10,300 acres and increased erosion and construction/operational activities would potentially increase sedimentation to and chemical contamination of ephemeral waterways. Development of a Geothermal Demonstration Project would disturb up to 50 acres and cause sedimentation to ephemeral waters, as well as long-term alteration of natural drainage pathways.		

	No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*	*Preferred Alternative*
Groundwater Resources (for details go to Chapter 5, Sections 5.1.6.2, 5.2.6.2.1, 5.1.6.2.2, and 5.1.6.2.3)				
Total water use (excluding solar power facility)				
	Total water use for DOE/NNSA activities would not exceed 691 acre-feet per year. This water demand would exceed published estimates of the sustainable yield for Basin 160 (Frenchman Flat), although other yield estimates suggest that adverse impacts on water supply may not occur.	Total water use for DOE/NNSA activities would increase by 25 percent from the No Action Alternative, to 862 acre-feet per year. This water demand would exceed published estimates of the sustainable yield for Basin 160 (Frenchman Flat), although other yield estimates suggest that adverse impacts on water supply may not occur.	Total water use for DOE/NNSA activities would decrease by 10 percent from the No Action Alternative, to 622 acre-feet per year. This water demand would exceed published estimates of the sustainable yield for Basin 160 (Frenchman Flat), although other yield estimates suggest that adverse impacts on water supply may not occur.	Total water use for DOE/NNSA activities would total as much as 862 acre-feet per year. This water demand would exceed published estimates of the sustainable yield for Basin 160 (Frenchman Flat), although other yield estimates suggest that adverse impacts on water supply may not occur.
National Security/ Defense Mission	No new or additional impacts on groundwater resources.	The following would be additional impacts on the groundwater resource, compared to the No Action Alternative: • 5.5 acre-feet per year of potable water for construction workers. • Water use for new construction of facilities included in the overall 25 percent increase in all water uses.	Same as under the No Action Alternative.	The following would be additional impacts on the groundwater resource, compared to the No Action Alternative: • 5.5 acre-feet per year of potable water for construction workers. • Water use for new construction of facilities included in the 862 acre-feet per year.
Environmental Management Mission	Through 2020, 30 acre-feet per year of nonpotable water for the drilling of new wells under the UGTA Project. Less than 7 acre-feet of total water use for dust suppression during D&D of facilities.	Same as under the No Action Alternative.	Same as under the No Action Alternative.	Through 2020, 30 acre-feet per year of nonpotable water for the drilling of new wells under the UGTA Project. Less than 7 acre-feet of total water use for dust suppression during D&D of facilities.
Nondefense Mission	Positive impact of reducing potable water production 16 percent by 2015 utilizing water conservation measures.	Same as under the No Action Alternative, plus: • A 5-megawatt photovoltaic solar power system near Area 6 would use 0.5 acre-feet per year of nonpotable water. • A one-time nonpotable water demand of 20 acre-feet to prime a geothermal power plant. Once operational, the geothermal power plant would use 50 acre-feet of water per year.	Same as under the No Action Alternative.	Positive impact of reducing potable water production 16 percent by 2015 utilizing water conservation measures and partially offset by: • A 5-megawatt photovoltaic solar power system near Area 6 would use 0.5 acre-feet per year of nonpotable water. • A one-time nonpotable water demand of 20 acre-feet to prime a geothermal power plant. Once operational, the geothermal power plant would use 50 acre-feet of water per year.

Cultural Resources (for details go to Chapter 5, Section 5.1.10, 5.5.1.10.1, 5.1.10.2, and 5.1.10.3)				
National Security/ Defense Mission	Approximately 700 acres of undisturbed land would be affected by activities in Frenchman Flat, Yucca Flat, Jackass Flats, Mercury Valley, and Fortymile Canyon. An estimated 24 cultural resources sites would be involved, of which an estimated 10 may be NRHP-eligible.	Approximately 13,455 acres of undisturbed land would be affected in the same areas as under the No Action Alternative. An estimated 624 cultural resources sites would be involved, of which an estimated 265 may be NRHP-eligible.	Approximately 430 acres of undisturbed land would be affected in the same areas as under the No Action Alternative. An estimated 16 cultural resources sites would be involved, of which an estimated 6 may be NRHP-eligible.	Approximately 3,335 acres of undisturbed land would be affected in the same areas as under the No Action Alternative. An estimated 180 cultural resources sites would be involved, of which an estimated 63 may be NRHP-eligible.
Environmental Management Mission	Approximately 1,110 acres of undisturbed land would be affected, primarily by environmental restoration activities in Frenchman Flat, Yucca Flat, Jackass Flats, Emigrant Valley, Mercury Valley, and Fortymile Canyon. An estimated 29 cultural resources sites would be involved, of which an estimated 7 may be NRHP-eligible.	Approximately 1,555 acres of undisturbed land would be affected because of additional waste management activities. An estimated 43 cultural resources sites would be involved, of which an estimated 12 may be NRHP-eligible.	Same as under the No Action Alternative.	Approximately 1,555 acres of undisturbed land would be affected because of additional waste management activities. An estimated 43 cultural resources sites would be involved, of which an estimated 12 may be NRHP-eligible.

	No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*	*Preferred Alternative*
Nondefense Mission	No impacts on cultural resources for DOE/NNSA infrastructure and energy conservation activities.	Approximately 517 acres of undisturbed land would be affected by DOE/NNSA infrastructure and renewable energy projects. An estimated 15 cultural resources sites may be involved, of which an estimated 6 would be NRHP-eligible.	Same as under the No Action Alternative.	Approximately 517 acres of undisturbed land would be affected by DOE/NNSA infrastructure and renewable energy projects. An estimated 15 cultural resources sites may be involved, of which an estimated 6 would be NRHP-eligible.
	Approximately 2,650 acres of undisturbed land in the Jackass Flats area would be affected by development of a 240-megawatt commercial solar power generation facility and associated transmission lines. An estimated 1,802 cultural resources sites would be involved, of which an estimated 557 would be NRHP-eligible.	Approximately 10,300 acres of undisturbed land in the Jackass Flats area would be affected by development of up to 1,000 megawatts of commercial solar generation facilities and associated transmission lines. An estimated 7,004 cultural resources sites would be involved, of which an estimated 2,163 would be NRHP-eligible. Approximately 50 acres of undisturbed land would be affected by development of a Geothermal Demonstration Project in the Yucca Flat area. An estimated 2 cultural resources sites may be involved, of which 1 would be NRHP-eligible.	Approximately 1,200 acres of undisturbed land in the Jackass Flats area would be affected by development of a 100-megawatt commercial solar power generation facility. An estimated 816 cultural resources sites would be involved, of which an estimated 252 may be NRHP-eligible.	Approximately 2,650 acres of undisturbed land in the Jackass Flats area would be affected by development of a commercial solar power generation facility and associated transmission lines. An estimated 1,802 cultural resources sites would be involved, of which an estimated 557 would be NRHP-eligible.
Waste Management (10-year volumes) (for details go to Chapter 5, Sections 5.1.11.1, 5.1.11.2, and 5.1.11.3)				
LLW	15,000,000 cubic feet of LLW is within the disposal capacity of the Area 5 RWMC.	48,000,000 cubic feet of LLW is within the disposal capacity of the Area 3 RWMS and the Area 5 RWMC. [i]	Same as under the No Action Alternative.	48,000,000 cubic feet of LLW is within the disposal capacity of the Area 3 RWMS and the Area 5 RWMC. [i]
MLLW	900,000 cubic feet of MLLW is within the permitted disposal capacity of Cell 18 in the Area 5 RWMC.	Disposal of 4,000,000 cubic feet of MLLW would require additional permitted MLLW disposal capacity at the Area 5 RWMC.	Same as under the No Action Alternative.	Disposal of 4,000,000 cubic feet of MLLW would require additional permitted MLLW disposal capacity at the Area 5 RWMC.
TRU waste	9,600 cubic feet generated by DOE/NNSA activities in Nevada. All TRU waste disposed within available capacity at WIPP.	19,000 cubic feet generated by DOE/NNSA activities in Nevada. All TRU waste disposed within available capacity at WIPP.	7,100 cubic feet generated by DOE/NNSA activities in Nevada. All TRU waste disposed within available capacity at WIPP.	19,000 cubic feet generated by DOE/NNSA activities in Nevada. All TRU waste disposed within available capacity at WIPP.

	No Action Alternative	Expanded Operations Alternative	Reduced Operations Alternative	Preferred Alternative
Hazardous waste	Total of 210,000 cubic feet, including 42,000 cubic feet generated by a commercial solar power generation facility. All would be recycled, treated, and/or disposed within available offsite capacity. Disposal of hazardous solid waste generated by a commercial solar power generation facility would be the responsibility of that project. NNSS hazardous waste management capabilities would not be impacted under current permit conditions.	Total of 340,000 cubic feet, including 170,000 cubic feet generated by commercial solar power generation facilities. All would be recycled, treated, and/or disposed within available offsite capacity. Disposal of hazardous solid waste generated by a commercial solar power generation facility would be the responsibility of that project. NNSS hazardous waste management capabilities would not be impacted under current permit conditions.	Total of 190,000 cubic feet, including 17,000 cubic feet generated by a commercial solar power generation facility. All would be recycled, treated, and/or disposed within available offsite capacity. Disposal of hazardous solid waste generated by a commercial solar power generation facility would be the responsibility of that project. NNSS hazardous waste management capabilities would not be impacted under current permit conditions.	Total of 212,000 cubic feet, including 42,000 cubic feet generated by a commercial solar power generation facility. All would be recycled, treated, and/or disposed within available offsite capacity. Disposal of hazardous solid waste generated by a commercial solar power generation facility would be the responsibility of that project. NNSS hazardous waste management capabilities would not be impacted under current permit conditions.
Solid waste	Total of 3,800,000 cubic feet, including 3,700,000 cubic feet generated by DOE/NNSA activities in Nevada and 160,000 cubic feet generated by operation of a 240-megawatt commercial solar power generation facility. DOE/NNSA solid waste disposed at the NNSS would not exceed the disposal capacity at NNSS landfills. Included in the DOE/NNSA volume are 370,000 cubic feet that would be transported off site to be recycled within available offsite capacity. Disposal of nonhazardous solid waste generated by a commercial solar power generation facility would be the responsibility of that project. NNSS disposal capacity would not be impacted under current permit conditions.	Total of 10,000,000 cubic feet, including 9,400,000 cubic feet generated by DOE/NNSA activities in Nevada and 630,000 cubic feet generated by operation of 1,000 megawatts of commercial solar power generation facilities. DOE/NNSA solid waste disposed at the NNSS would not exceed the disposal capacity at NNSS landfills. Included in the DOE/NNSA volume are 970,000 cubic feet that would be transported off site to be recycled within available offsite capacity. Disposal of nonhazardous solid waste generated by a commercial solar power generation facility would be the responsibility of that project. NNSS disposal capacity would not be impacted under current permit conditions.	Total of 3,700,000 cubic feet, including 3,600,000 cubic feet generated by DOE/NNSA activities in Nevada and 77,000 cubic feet generated by operation of a 100-megawatt commercial solar power generation facility. DOE/NNSA solid waste disposed at the NNSS would not exceed the available capacity at NNSS landfills. Included in the DOE/NNSA volume are 360,000 cubic feet that would be transported off site to be recycled within available offsite capacity. Disposal of nonhazardous solid waste generated by a commercial solar power generation facility would be the responsibility of that project. NNSS disposal capacity would not be impacted under current permit conditions.	Total of 9,560,000 cubic feet, including 9,400,000 cubic feet generated by DOE/NNSA activities in Nevada and 160,000 cubic feet generated by operation of a 240-megawatt commercial solar power generation facility. DOE/NNSA solid waste disposed at the NNSS would not exceed the disposal capacity at NNSS landfills. Included in the DOE/NNSA volume are 970,000 cubic feet that would be transported off site to be recycled within available offsite capacity. Environmental Justice (for details go to Chapter 5, Sections 5.1.13.1, 5.1.13.2, and 5.1.13.3)				
	Impacts on low-income and minority populations would be identical to those of the general population. Therefore, no disproportionately high and adverse impacts on minority or low-income populations are expected. An increase in construction jobs for the solar power generation facility could provide jobs for unemployed individuals, which would have a beneficial impact on low-income individuals.	Same as under the No Action Alternative, except there would be a larger number of construction jobs created.	Same as under the No Action Alternative, except there would be fewer construction jobs created.	Impacts on low-income and minority populations would be identical to those of the general population. Therefore, no disproportionately high and adverse impacts on minority or low-income populations are expected. An increase in construction jobs for the solar power generation facility could provide jobs for unemployed individuals, which would have a beneficial impact on low-income individuals.

CO = carbon monoxide; CO_2-equivalent = carbon dioxide-equivalent; D&D = decontamination and decommissioning; DAF = Device Assembly Facility; DART = days away, restrictive, or transferred; FTE = full-time equivalent; LCF = latent cancer fatality; LLW = low-level radioactive waste; MEI = maximally exposed individual; MLLW = mixed low-level radioactive waste; NNSA = National Nuclear Security Administration; NNSS = Nevada National Security Site; NO_x = nitrogen oxides; NRHP = National Register of Historic Places; OST = Office of Secure Transportation; PM_{n} = particulate matter with an aerodynamic diameter of *n* micrometers or less; rem = roentgen equivalent man; RWMC = Radioactive Waste Management Complex; RWMS = Radioactive Waste Management Site; SO_2 = sulfur dioxide; TRC = total recordable cases; TRU = transuranic waste; UGTA = Underground Test Area; VOC = volatile organic compound; WIPP = Waste Isolation Pilot Plant.

[a] The reported radiological risks are the projected number of LCFs in the population and are therefore presented as whole numbers. The calculated value is shown in parentheses.

[b] Potential dose to a subsistence consumer includes the MEI dose plus a 10-millirem per year dose from consuming crops raised in soil contaminated by past testing and contaminated game animals. The latter dose component would be independent of current site operations.

[c] Based on 500 full-time equivalent workers for a 35-month construction period for the No Action Alternative; 750 full-time equivalent workers for a 42-month construction period for the Expanded Operations Alternative; and 400 full-time equivalent workers for a 32-month construction period for the Reduced Operations Alternative.

[d] Annual value includes value from DOE/NNSA construction activities and an annualized rate from solar power generation facility construction (see footnotes e, f, and g).

[e] Annualized value based on 500 full-time equivalent workers for a 35-month solar power generation facility construction period.

[f] Annualized value based on 750 full-time equivalent workers for a 42-month solar power generation facility construction period.

[g] Annualized value based on 400 full-time equivalent workers for a 32-month solar power generation facility construction period.

[h] The risk is the annual increased likelihood of an LCF in the MEI or the noninvolved worker or the increased likelihood of a single LCF occurring in the offsite population, accounting for the estimated probability (frequency) of the accident occurring.

[i] Reactivation of the Area 3 RWMS would only occur based upon mission need and as stated in 4.1.11.1.1.1, including detailed consultation with the State of Nevada.

Table 3–5 Summary of Potential Impacts at the Remote Sensing Laboratory

	No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*	*Preferred Alternative*
Land Use (for details go to Chapter 5, Section 5.2.1)				
	No impacts were identified from the continuation of activities at the current levels of operations or foreseeable actions because activities under this alternative would continue to be compatible with existing land use designations on Nellis Air Force Base.	Same as under the No Action Alternative.	Same as under the No Action Alternative.	No impacts were identified from the continuation of activities at the current levels of operations or actions because activities under this alternative would continue to be compatible with existing land use designations on Nellis Air Force Base.
Infrastructure and Energy (for details go to Chapter 5, Sections 5.2.2.1, and 5.2.2.2, and 5.2.2.3)				
	Infrastructure would be maintained as needed to accommodate ongoing activities. No new buildings or facilities are planned. Energy demand is expected to continue at about 4,850 megawatt-hours per year and the existing electrical distribution is adequate to support this demand. Natural gas use is expected to continue to be about 33,673 therms per year. There is adequate capacity to serve this demand and the condition of the gas lines is satisfactory. Approximately 11,000 gallons of JP-8 jet fuel are used each year for aircraft operations. An adequate supply of JP-8 fuel is available directly through Nellis Air Force Base.	Same as under the No Action Alternative.	Same as under the No Action Alternative.	Infrastructure would be maintained as needed to accommodate ongoing activities. Impacts on low-income and minority populations would be identical to those of the general population. Therefore, no disproportionately high and adverse impacts on minority or low-income populations are expected.	

CO = carbon monoxide; CO_2-equivalent = carbon dioxide-equivalent; DART = days away, restrictive, or transferred; NO_x = nitrogen oxides; PM_n = particulate matter with an aerodynamic diameter of *n* micrometers or less; RSL = Remote Sensing Laboratory; SO_2 = sulfur dioxide; TRC = total recordable cases; VOC = volatile organic compound.

Table 3–6 Summary of Potential Impacts at the North Las Vegas Facility

	No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*	*Preferred Alternative*
Land Use (for details go to Chapter 5, Section 5.3.1)				
	No impacts were identified from the continuation of activities at the current levels of operations or foreseeable actions because activities under this alternative would continue to be compatible with existing land use designations.	Same as under the No Action Alternative.	Same as under the No Action Alternative.	No impacts were identified from the continuation of activities at the current levels of operations or foreseeable actions because activities under this alternative would continue to be compatible with existing land use designations.
Infrastructure and Energy (for details go to Chapter 5, Sections 5.3.2.1 and 5.3.2.2)				
	Infrastructure would be maintained as needed to accommodate ongoing activities. No new buildings or facilities are planned. Electric energy demand is expected to continue at about 15,000 megawatt-hours per year and the existing electrical distribution is adequate to support this demand. Natural gas use is expected to continue to be about 48,000 therms per year. There is adequate capacity to serve this demand.	Same as under the No Action Alternative for infrastructure. Electric energy demand would increase by no more than 10 percent. The capacity of the electrical distribution system and the capability of commercial providers are adequate to supply the needed electrical energy.	Same as under the No Action Alternative for infrastructure. Electrical energy demand is expected to be the same as under the No Action Alternative or slightly lower.	Infrastructure would be maintained as needed to accommodate ongoing activities. No new buildings or facilities are planned. Electric energy demand would increase by no more than 10 percent, for a total of 16,500 megawatt-hours per year, and the existing electrical distribution is adequate to support this demand. Natural gas use is expected to continue to be about 48,000 therms per year. There is adequate capacity to serve this demand.

	No Action Alternative	*Expanded Operations Alternative*	*Reduced Operations Alternative*	*Preferred Alternative*
Transportation [a] (for details go to Chapter 5, Sections 5.3.3.1 and 5.3.3.2)				
Transportation	No radioactive materials analyzed. Nonradioactive material transports are included in NNSS impacts.	Same as under the No Action Alternative.	Same as under the No Action Alternative.	No radioactive materials analyzed. Nonradioactive material transports are included in NNSS impacts.
Traffic	No increase in traffic volume due to NLVF-related traffic compared to the projected baseline; levels of service would remain the same.	Approximately a 2 percent increase in daily traffic volumes during peak hours on local roads, when compared to the projected baseline; levels of service would remain the same.	Less than 1 percent decrease in daily traffic volumes during peak hours on local roads; levels of service would remain the same.	Approximately a 2 percent increase in daily traffic volumes during peak hours on local roads, when compared to the projected baseline; levels of service would remain the same.
Socioeconomics (for details go to Chapter 5, Sections 5.3.4.1, 5.3.4.2, and 5.3.4.3)				
	There would be no change in employment; therefore, there would be no change in socioeconomic impacts.	Employment would increase by 361 FTEs; about 36 employees would relocate from outside the region. Up to 3 new teaching jobs would need to be filled to maintain the current student-to-teacher ratio. Sufficient housing exists in the region to support the increased population. Direct jobs would reduce unemployment by 0.27 and 0.12 percent in Clark and Nye Counties, respectively. Direct jobs and indirect jobs would have a beneficial effect on the local economy and government revenues. The addition of 361 employees would result in an increase in the number of service calls, but would have a negligible impact on area hospitals and hospital personnel.	Employment would decrease by 45 FTEs, increasing unemployment in Clark County by about 0.12 percent and in Nye County by about 0.04 percent. Additional employees would not relocate to Clark or Nye County and there would be no impact on student-to-teacher ratios. Job loss would have a small negative impact on the local economy and government revenues. There would be no impact on public services.	Employment would increase by 361 FTEs; about 36 employees would relocate from outside the region. Up to 3 new teaching jobs would need to be filled to maintain the current student-to-teacher ratio. Sufficient housing exists in the region to support the increased population. Direct jobs would reduce unemployment by 0.27 and 0.12 percent in Clark and Nye Counties, respectively. Direct jobs and indirect jobs would have a beneficial effect on the local economy and government revenues. Environmental Justice				
	Impacts on low-income and minority populations would be identical to those of the general population. Therefore, no disproportionately high and adverse impacts on minority or low-income populations are expected.			Impacts on low-income and minority populations would be identical to those of the general population. Therefore, no disproportionately high and adverse impacts on minority or low-income populations are expected.

CO = carbon monoxide; CO_2-equivalent = carbon dioxide-equivalent; DART = days away, restrictive, or transferred; FTE = full-time equivalent; LCF = latent cancer fatality; LLW = low-level radioactive waste; MEI = maximally exposed individual; MLLW = mixed low-level radioactive waste; NNSA = National Nuclear Security Administration; NNSS = Nevada National Security Site; NO_x = nitrogen oxides; PM_n = particulate matter with an aerodynamic diameter of *n* micrometers or less; rem = roentgen equivalent man; RWMC = Radioactive Waste Management Complex; RWMS = Radioactive Waste Management Site; SO_2 = sulfur dioxide; TRC = total recordable cases; TTR = Tonopah Test Range; VOC = volatile organic compound.

[a] The reported radiological risks are the projected number of LCFs in the population and are therefore presented as whole numbers. The calculated value is shown in parentheses.

[b] The emissions under the Expanded Operations would be less than the levels projected under the No Action Alternative because certain site support functions would be transferred from DOE/NNSA to the U.S. Air Force, resulting in fewer DOE/NNSA and DOE/NNSA contractor employees at the TTR.

[c] The risk is the annual increased likelihood of an LCF in the MEI or noninvolved worker or the increased likelihood of a single LCF occurring in the offsite population, accounting for the estimated probability (frequency) of the accident occurring.

3.6 Alternatives Eliminated from Detailed Study

This section identifies the alternatives that were considered but eliminated from detailed study and provides a brief explanation of the reason for elimination.

3.6.1 Discontinue Operations at the Nevada National Security Site

In its *1996 NTS EIS*, DOE considered cessation of all operations at the NNSS and placing all facilities into a cold standby status (Discontinue Operations Alternative) and considered discontinuing all Defense mission-related and most Work for Others Program activities at the NNSS (Alternate Use of Withdrawn Lands Alternative). In its December 9, 1996, Record of Decision (ROD) (61 *Federal Register* [FR] 65551), DOE decided that it would implement the Expanded Use Alternative for all activities other than LLW and MLLW management, which was to continue under the Continue Current Operations Alternative. DOE later decided to implement the Expanded Use Alternative for LLW and MLLW management at the NNSS (65 FR 10061).

Because discontinuing operations at the NNSS was previously considered but rejected by DOE in 1996 and because there is a continuing need for the NNSS for National Security/Defense Mission programs, closing the NNSS or discontinuing National Security/Defense Mission programs, projects, and activities are considered unreasonable alternatives.

Ceasing operations at the NNSS would result in a loss of support for a number of missions and other activities that are critical to national security, including Stockpile Stewardship and Management, Nonproliferation and Counterterrorism, and Homeland Security. In addition, as the only U.S. nuclear weapons testing facility, the NNSS must be available to conduct an underground nuclear test if so directed by the President. Because these activities are vital to national security and are among the major components of the missions assigned to the NNSS by DOE/NNSA, discontinuing operations at the NNSS would not achieve the purpose and need stated in Chapter 1.

3.6.2 Transfer the Nevada National Security Site to Another Agency

One organization provided a scoping comment that suggested that the NNSS should be transferred "out of NNSA control and, indeed, out of the 'active' nuclear weapons complex altogether" (a curatorship alternative). The comment cited statements by the President, United Nations resolutions, the Comprehensive Test Ban Treaty, and U.S. initiatives to strengthen the Nonproliferation Treaty as support for considering such an alternative. Although the United States has not ratified the Comprehensive Test Ban Treaty, since 1992, it has observed a moratorium on underground nuclear testing. However, there have been no new policies or legislative direction to abandon the capability to conduct an underground nuclear test if extraordinary events jeopardize the supreme national interests, which, if the United States were a signatory, would be allowed by Article IX of the Comprehensive Test Ban Treaty. The *Final Complex Transformation Supplemental Programmatic Environmental Impact Statement* (DOE/EIS-0236S4) (DOE 2008l) addressed alternatives for consolidating Nuclear Weapons Complex facilities and activities. Thus, closure of the NNSS and/or transfer of responsibility to another organization as part of a larger plan to consolidate the Nuclear Weapons Complex are not being considered in this SWEIS.

3.6.3 Prepare a Programmatic Environmental Impact Statement

In scoping comments for this *NNSS SWEIS*, the Nevada Attorney General opined that a programmatic EIS should be prepared for the NNSS. DOE defines a site-wide NEPA document as "a broad scope EIS or EA that is programmatic in nature and identifies and assesses the individual and cumulative impacts of ongoing and reasonably foreseeable future actions at a DOE site." Although this *NNSS SWEIS* is

"programmatic in nature" with regard to DOE/NNSA facilities and activities in the State of Nevada, it would not provide the basis for a DOE programmatic decision, but would provide the basis for site-specific implementation of programmatic decisions that have already been made in existing programmatic EISs and other NEPA documents. Those EISs and other NEPA documents include the *Final Programmatic Environmental Impact Statement for Stockpile Stewardship and Management* (DOE 1996d); *Final Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste* (DOE 1997); *Complex Transformation SPEIS* (DOE 2008l); and the *Final Environmental Impact Statement for the Proposed Relocation of Technical Area 18 Capabilities and Materials at the Los Alamos National Laboratory* (DOE 2002h), as well as a number of project-specific environmental assessments. With regard to this *NNSS SWEIS*, DOE NEPA regulations (10 CFR 1021.330(c)) require large, multiple-facility DOE sites, such as the NNSS, to prepare SWEISs. This *NNSS SWEIS* addresses the full range of missions, programs, capabilities, projects, and activities under the purview of DOE/NNSA in Nevada. Where project information is sufficiently specific, the analyses are similarly specific and will support implementing decisions by DOE/NNSA. Where project information is insufficient to support an implementing decision, or if there are statutory or regulatory uncertainties, a more programmatic description is provided and implementation would require an appropriate level of additional NEPA review.

3.6.4 Renewable Energy Alternative

DOE/NNSA announced in its Notice of Intent for this SWEIS (74 FR 36691) that it would address a Renewable Energy Alternative. During the scoping meetings, several suggestions were made to include renewable energy in each of the alternatives addressed in this SWEIS. DOE/NNSA recognizes the need to incorporate, as appropriate, conservation and renewable energy planning as part of the activities it undertakes at the NNSS. Therefore, the Renewable Energy Alternative was not addressed as a separate alternative, but was made part of each of the alternatives addressed in detail in this SWEIS.

3.6.5 1996 Record of Decision-Based No Action Alternative

As indicated in its Notice of Intent to prepare this SWEIS, dated July 24, 2009 (74 FR 36691), DOE/NNSA initially defined the No Action Alternative as "the continued implementation of the *1996 NTS EIS* ROD, and the amendment to the ROD for the *1996 NTS EIS* (65 FR 10061 at 10065) at DOE/NNSA sites in Nevada over the next 10 years." The Notice of Intent also stated that No Action would "include the implementation of other decisions supported by separate NEPA analyses completed since the issuance of the *1996 NTS EIS*" as well as "actions analyzed in eight environmental assessments and their associated Findings of No Significant Impacts, as well as actions categorically excluded from the preparation of either an EA or EIS." The original No Action Alternative considered for analysis in this SWEIS would have addressed significantly higher numbers of many DOE/NNSA activities, based on levels of activities analyzed in the *1996 NTS EIS*. As development of this SWEIS progressed, it became apparent that those potential levels of activities were unrealistically high in some cases. For this reason, DOE/NNSA decided to base the analysis for the No Action Alternative in this SWEIS on actual levels of operations known to have occurred since 1996. For instance, the *1996 NTS EIS* analyzed 1,100 potential dynamic plutonium experiments over a 10-year period. Under the No Action Alternative, this SWEIS considers up to 10 such experiments per year, or 100 over the next 10 years. Chapter 1, Table 1–1 provides a comparison of the Expanded Use Alternative from the *1996 NTS EIS* and the No Action Alternative in this *NNSS SWEIS*.

CHAPTER 4
AFFECTED ENVIRONMENT

4.0 AFFECTED ENVIRONMENT

This chapter describes the existing environmental conditions of the Nevada National Security Site (NNSS) (formerly known as the Nevada Test Site), the Remote Sensing Laboratory (RSL) at Nellis Air Force Base, the North Las Vegas Facility (NLVF), and the Tonopah Test Range (TTR). During the preparation of this *Site-Wide Environmental Impact Statement for the Continued Operation of the Department of Energy/National Nuclear Security Administration Nevada National Security Site and Off-Site Locations in the State of Nevada (NNSS SWEIS)*, the most up-to-date and accurate information available was used to describe existing environments, facilities, activities, and projects. This information serves as a baseline from which to identify and evaluate environmental changes resulting from the proposed alternatives. The baseline conditions, for the purpose of analysis, are the conditions that currently exist.

The environmental resources discussed in this chapter include land use, infrastructure and energy, transportation and traffic, socioeconomics, geology and soils, hydrology, biological resources, air quality and climate, visual resources, cultural resources, waste management, human health and safety, and environmental justice. For some environmental resource areas, the regions of influence (ROIs) are limited to the areas contained within each U.S. Department of Energy/National Nuclear Security Administration (DOE/NNSA) jurisdictional boundary. For other environmental resource areas, such as transportation and air quality, the ROIs are larger and include all of southern Nevada, as well as portions of Utah, Arizona, and California.

4.1 Nevada National Security Site

This section describes the existing environmental conditions found at the NNSS, a unique national resource managed by the DOE/NNSA Nevada Site Office (NSO) that is located approximately 57 miles from the intersection of Interstate 15 and U.S. Route 95 in Las Vegas, Nevada. The NNSS covers approximately 1,360 square miles (larger than the state of Rhode Island) and is one of the largest restricted access areas in the United States. The NNSS is surrounded by thousands of additional acres of land withdrawn from the public domain for use as a protected wildlife range and a military gunnery range, creating an unpopulated land area of nearly 6,500 square miles.

DOE/NNSA consulted with American Indian tribes and groups that have cultural affiliation with the NNSS to obtain input for this site-wide environmental impact statement (SWEIS). American Indian input regarding natural and cultural resources at the NNSS was provided by the American Indian Writers Subgroup of the Consolidated Group of Tribes and Organizations (CGTO) and may be found in shaded text boxes throughout this chapter identified with a CGTO feather icon.

4.1.1 Land Use

The NNSS is located about 57 miles northwest of downtown Las Vegas in the remote desert and mountainous terrain of southern Nye County, Nevada, at the southern end of the Great Basin. The Federal Government (primarily the U.S. Bureau of Land Management [BLM], the U.S. Department of Defense [DoD], DOE/NNSA, and the U.S. Forest Service [USFS]) manages more than 85 percent of the land in Nevada, and 93 percent in Nye County (DOE 2008g). Approximately 22 percent of the total land area in Nye County, including the NNSS, is designated for federally restricted access for U.S. Government activities.

The NNSS consists of sparsely vegetated basins or flats—Jackass Flats in the southwestern quadrant, Frenchman Flat in the southeastern quadrant, and Yucca Flat in the northwestern quadrant—separated by low mountains that dominate the western and southern sides of the site. Frenchman Flat and Yucca Flat each contain a large playa (the flat-floored bottom of a desert basin that may contain water after a seasonally high runoff). The northeastern quadrant of the site comprises mountains with a pinyon-juniper and sagebrush forest separated by canyons. The dominant mountains in this quadrant are Rainier Mesa

near the center of the northern border and Pahute Mesa in the northwestern region of the site (DOE 2002f; Wills and Ostler 2001).

The NNSS is controlled by DOE/NNSA and is the largest and most extensive of DOE/NNSA's sites in terms of the complexity of its facilities, buildings, and infrastructure, and its land area. Although the NNSS is under DOE/NNSA management, DoD and other customers use the site for National Security/Defense and Nondefense Mission-related experiments, training, and research. Chapters 2 and 3 of this SWEIS describe in more detail the missions, levels of operation, and clients that use the NNSS. Numerous offices, laboratories, and support buildings are located throughout the NNSS to assist in these missions.

In 1998, the DOE Nevada Operations Office (now the DOE/NNSA NSO) prepared a Resource Management Plan for the NNSS, as specified in the Record of Decision (ROD) (65 *Federal Register* [FR] 10061) for the 1996 *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (*1996 NTS EIS*). The goals for managing the NNSS resources (both natural and manmade) were developed in consideration of the balance between the primary mission of the NNSS, economic development, and the limits of ecological sustainability. While the principles of the Resource Management Plan have been retained, the primary planning document for new facilities and programs throughout the DOE complex is the Ten-Year Site Plan. Ten-year site plans are required by DOE Order 430.1B, *Real Property Asset Management* (DOE 2008e), and the NNSS Ten-Year Site Plan is used as an integrated planning tool to help develop an efficient and responsive infrastructure that effectively supports the DOE/NNSA NSO's missions.

4.1.1.1 Adjacent Land Use

The lands adjacent to the NNSS include the Nevada Test and Training Range (formerly Nellis Air Force Range), Desert National Wildlife Refuge, and Nye County. The NNSS is located within Nye County, which comprises communities widely separated by distance and which, in 2008, had a population of 43,600 people (USCB 2008b). The nearest community to the NNSS is Amargosa Valley, located about 2 miles south of the NNSS, with a population of 1,400. Additional nearby communities include Indian Springs (about 16 miles southeast of the NNSS, population 1,400); Beatty (about 17 miles west of the NNSS, population 800); Pahrump (about 26 miles south of the NNSS, population 38,200); and Alamo (about 42 miles northeast of the NNSS, population 460). There are other urban and residential land uses outside of and adjacent to the NNSS in the Pahrump Valley (about 22 miles southwest of the NNSS), which is the largest populated area near the NNSS (NV State Demographer's Office 2008). Las Vegas is the closest major metropolitan area (about 57 overland miles southeast of the NNSS, population 564,484) (USCB 2008b).

Nevada Test and Training Range. The Nevada Test and Training Range surrounds the NNSS to the north, east, and west, and is managed by the U.S. Air Force (USAF). It provides a safe and secure remote desert location to test equipment and train military personnel. Testing and training activities occurring on the Nevada Test and Training Range include armament and high-hazard testing (aerial gunnery, rocketry, electronic warfare), tactical maneuvering training, and equipment and tactics development and training. The Nevada Test and Training Range also provides a 3-million-acre security and safety buffer area for activities occurring on the NNSS because it is withdrawn from public use and has limited public access.

Desert Wildlife National Refuge. The Desert National Wildlife Refuge, administered by the U.S. Fish and Wildlife Service (USFWS), is located mostly within the southeastern section of the Nevada Test and Training Range, along the eastern border of the NNSS. The refuge was established in 1936 with the primary objective being the sustainability of the desert bighorn sheep and its habitat. The portion of the refuge that is within the Nevada Test and Training Range is closed to public access. This results in approximately 5,470 acres of additional remote, unpopulated land area surrounding the NNSS, withdrawn from public domain and use (USFWS 2009b).

Bureau of Land Management Land. BLM manages lands adjacent to the NNSS to the south and southwest. BLM is responsible for carrying out numerous programs for the management and conservation of public lands and resources throughout Nevada. Land uses occurring on BLM-managed lands include agriculture, energy and mineral extraction, livestock grazing, and recreation. These lands also provide resources for fish and wildlife habitat (including wild horses and burros); wilderness areas; and archaeological, paleontological, and historic sites. A small portion of the Nevada Wild Horse Range, one of the many herd management areas within Nevada, overlaps the northwestern corner of the NNSS. BLM is responsible for managing the wild horse population under the Wild Free-Roaming Horses and Burros Act of 1971; however, access to the range is coordinated through DOE/NNSA.

Nye County. Primary land uses in Nye County occurring in close proximity to the NNSS include mining, grazing, agriculture, and recreation. Section 4.1.5.3 describes soils, including the status of prime farmland soils at the NNSS. **Figure 4–1** depicts land ownership and uses surrounding the NNSS.

BLM has identified seven solar energy study areas in Nevada. The closest study area to the NNSS is in Amargosa Valley, located south and west of the NNSS's southwestern corner, along the U.S. Route 95 corridor between Beatty and Pahrump. Lands identified as solar energy study areas have excellent solar resources and suitable slope, as well as proximity to roads and transmission lines or designated corridors, and include at least 2,000 acres of BLM-administered public lands. Sensitive lands, wilderness, and other high-conservation-value lands, as well as lands with conflicting uses, were excluded from consideration as solar study areas. BLM published a Notice of Intent in the *Federal Register* on July 13, 2009, announcing the development of an environmental impact statement for the Amargosa Farm Road Solar Energy Project. An application for a 4,350-acre right-of-way on public lands was submitted to BLM for two 224-megawatt, dry-cooled solar power generation facilities, as well as thermal storage tanks. This document is expected to be finalized after publication of this SWEIS.

DOE and BLM have issued the final programmatic environmental impact statement that evaluates utility-scale solar energy development, to develop and implement agency-specific programs that would establish policies and mitigation strategies for solar energy projects, and to amend relevant BLM land use plans with the intent of establishing a new BLM solar energy development program.

4.1.1.2 Historical Nevada National Security Site Development and Current Land Use

Historical Nevada National Security Site Development. Until the mid-1900s, the land on which the NNSS would be established provided traditional, ceremonial, and recreational areas for American Indians. The first European Americans known to traverse what is now the NNSS were emigrants on their way to California in 1849. Short-lived periods of mining and ranching occurred in this region. Military use of the area began in 1940 and, since that time, the NNSS has remained associated with national security and defense activities (DOE 2002f). Section 4.1.10 includes a more detailed description of the history of the NNSS.

There are 19 historic mining districts on the NNSS, as described in the *1996 NTS EIS*. These mining districts would be of interest for economic mining if the NNSS were opened for public access; however, the NNSS has been closed for commercial mineral development since the 1940s (DOE 1996c).

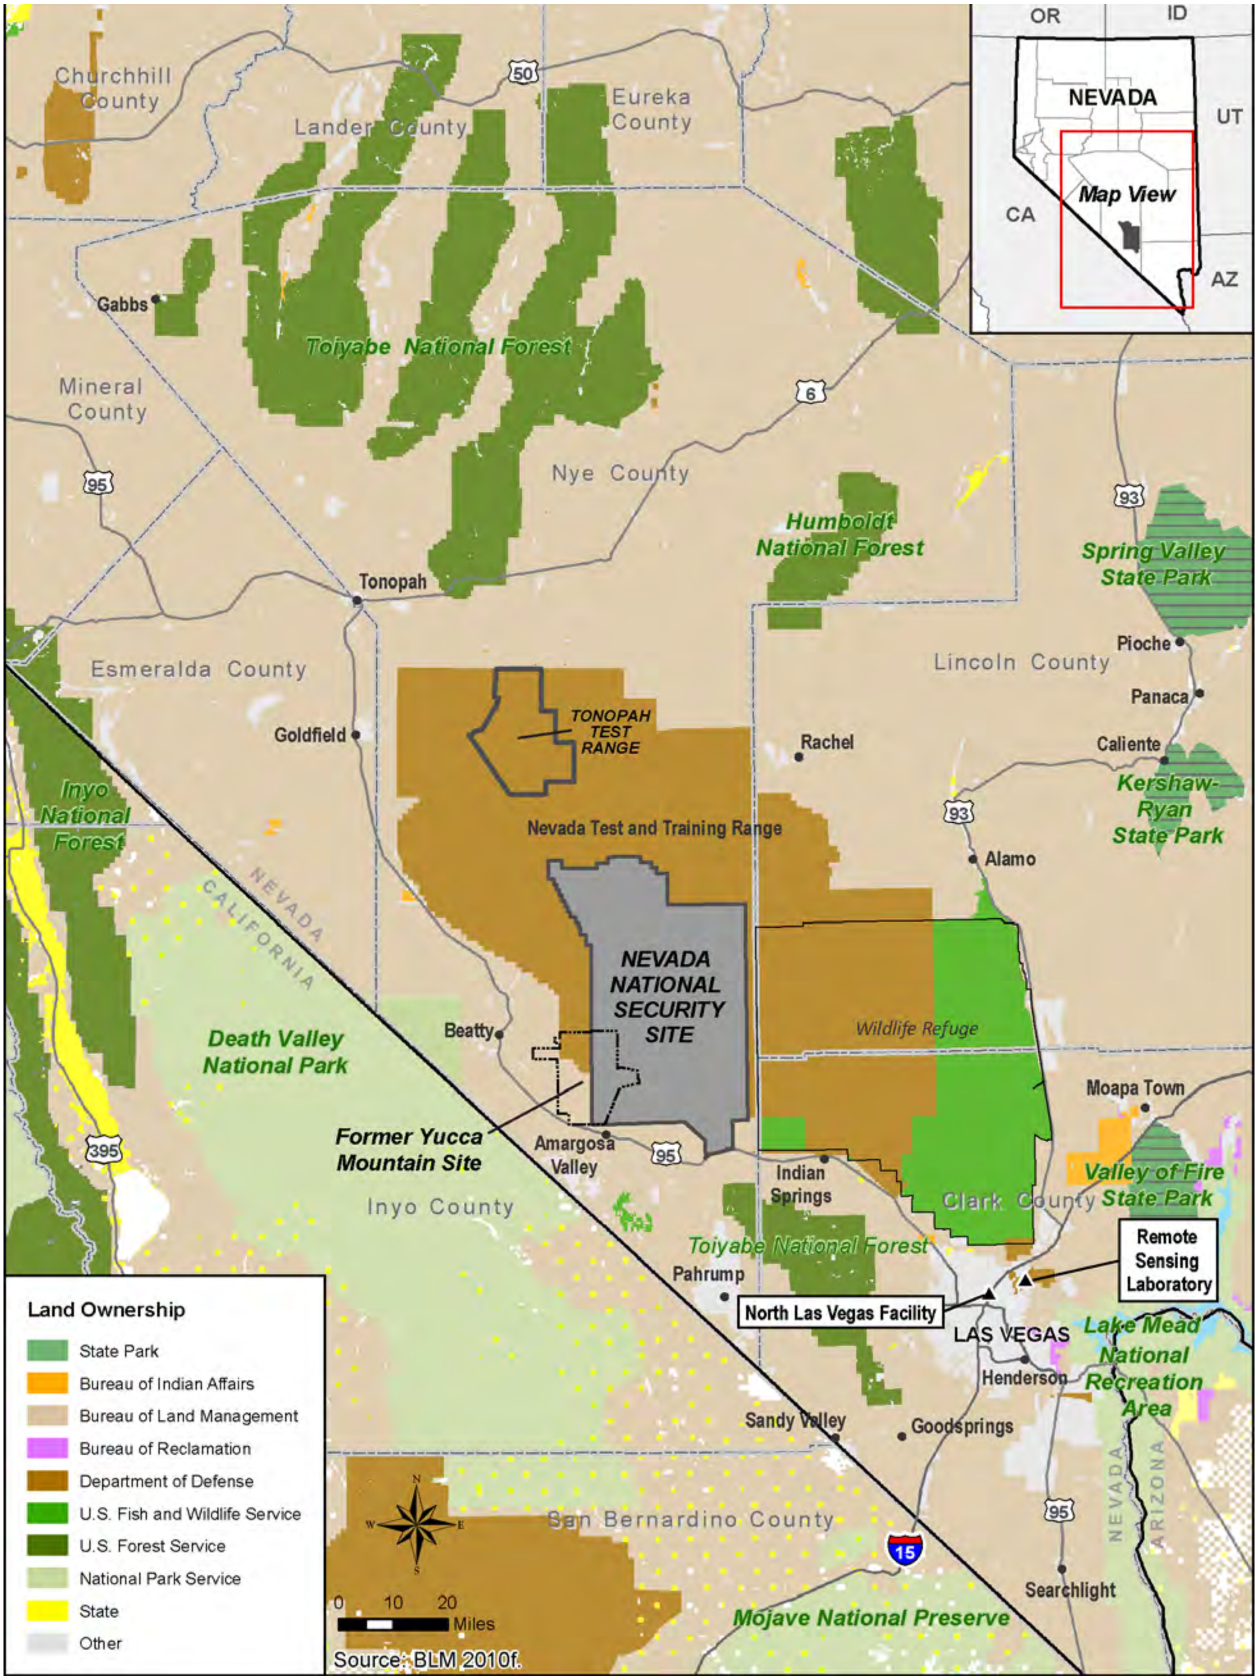

Figure 4–1 Location of Nevada National Security Site and Offsite Locations in the State of Nevada

The first atmospheric nuclear test detonation at the NNSS took place in 1951 on Area 5 of Frenchman Flat. Atmospheric detonations associated with nuclear testing continued through the 1950s until international test ban negotiations culminated in the Limited Test Ban Treaty of 1963, which banned atmospheric testing, but continued to allow underground testing. Nuclear testing occurred at the NNSS for over 40 years until the President declared a moratorium on nuclear weapons testing in October 1992. During the same time that the NNSS was being used for testing nuclear weapons, tests and experiments under the Plowshare Program were conducted there to support and promote peaceful uses of nuclear detonations. Testing and activities associated with these other projects continued until the mid-1970s. These weapons effects experiments have left behind damaged or demolished military hardware, as well as everyday structures and artifacts of domestic life, such as a bank vault, a train trestle, an underground parking garage, and houses built of various materials. Hundreds of saucer-like craters, formed by the subsidence of the ground above an underground test, are located throughout the areas where these detonations occurred.

Plowshare Program

Beginning in 1961, the Plowshare Program was a research development activity, consisting of 35 individual nuclear detonations, established to explore a wide variety of peaceful uses for the inexpensive energy available from nuclear explosions. The majority of detonations that took place at the Nevada National Security Site occurred in the Yucca Flat region.

Peaceful applications utilizing the explosive energy from aboveground detonations that were explored include rock-moving exercises to facilitate the construction of canals, harbors, and dams and aid in the construction of highway and railroad corridors through mountainous areas. Underground engineering applications that were explored include stimulation of natural gas production and formation of underground natural gas and petroleum storage reserves.

Despite great expectations, many projects within the Plowshare Program did not progress past the planning phase. A lack of confidence that projects could be completed at less cost than by conventional means and insufficient public and congressional support led to the program's termination.

Inaccessible to the public, Mercury (formerly called Base Camp Mercury), the "town" located at the entrance to the NNSS, is about 5 miles north of U.S. Route 95. Development of this built-up area increased after 1951, when it served as a base camp area providing basic facilities for personnel involved with NNSS operations, reaching its peak usage by the end of the 1960s. Mercury served, and continues to serve, as the center of administrative services and activities for the NNSS. It provides a variety of structures and services, including office space, laboratory facilities, fire and medical facilities, and overnight living quarters for personnel (DOE 2007a). Mercury is described in more detail in Chapter 2 of this SWEIS.

The NNSS is divided into numbered operational areas to facilitate management; communications; and distribution, use, and control of resources. Chapter 2, Table 2–1, of this SWEIS describes these operational areas and identifies where atmospheric and underground nuclear testing previously occurred.

Current DOE/NNSA Use. The NNSS currently supports work under three missions: (1) National Security/Defense, (2) Environmental Management, and (3) Nondefense. Further details are included in Chapter 2 of this SWEIS. Since the cessation of nuclear testing in 1992 and the subsequent creation of the Stockpile Stewardship and Management Program, DOE/NNSA has consolidated working environments and disposed many excess facilities. As of 2008, the NNSS has 486 buildings, 113 trailers, a 340-mile onsite network of paved roads, and over 300 miles of unpaved roads within its 880,000 acres (DOE 2008i). Most of the experimental facilities and infrastructure are concentrated along the main roadway thoroughfare (Mercury Highway); the majority of maintenance, support, and development activities also are located along this corridor.

Current Military Use. Military organizations use portions of the NNSS for land area exercises and training involving navigation, maneuvering through obstacles, mission rehearsal, and related tactics. The remote areas of the NNSS also provide these organizations with the ability to perform classified exercises.

Existing facilities at the NNSS that resemble real-world chemical, water, and nuclear plant facilities are used by DoD for training scenarios and test beds for sensors for both counterproliferation exercises and

defensive security force training. The geology, geography, and tunnel complexes of the NNSS provide unique training venues for DoD and other Federal agencies because these features replicate real-world interests.

Public Use. Access to the NNSS is restricted and limited to public bus tours. Tours must be scheduled in advance. Timber Mountain Caldera, a unique volcanic feature listed as a National Natural Landmark by the National Park System, is located on both the NNSS and USAF-managed Nevada Test and Training Range lands. The U.S. National Park Service manages the Timber Mountain Caldera site, except for portions within the NNSS that are managed by DOE/NNSA. Access to this site through portions located within the NNSS is coordinated by DOE/NNSA.

Under Executive Order 13007, *Indian Sacred Sites*, Federal land agencies are directed, to the extent practical, to allow access to and ceremonial use of American Indian sacred sites by American Indian religious practitioners (DOE 2008f).

Land Use—American Indian Perspective

CGTO

The Nevada National Security Site (NNSS) area is part of the traditional Holy Lands of the Western Shoshone, Southern Paiute, and Owens Valley Paiute and Shoshone peoples. We rely on these lands for medicinal purposes, religious activities and ceremonies, food, recreational use, and integral places described in traditional narratives and religious ceremonies.

Indian people know these lands contain not only archaeological remains left by our ancestors but also natural resources and geologic formations in the region, such as plants, animals, water sources and minerals; natural landforms that mark important locations for keeping our history alive and for teaching our children about our culture. We use traditional sites in the NNSS region to make tools, stone artifacts, and ceremonial objects; many sites are also associated with traditional healing ceremonies and power places.

For many centuries, the NNSS area has been a central place in the lives of American Indian tribes, continuously used by these tribes from antiquity to contemporary times. Until the mid-1900s, traditional festivals involving religious and secular activities attracted American Indian people to the area from as far as San Bernardino, California. Similarly, groups came to the area from a broad region during the hunting season and used animal and plant resources that were crucial for their survival and cultural practices.

Several areas in the NNSS region are recognized as traditionally or spiritually important. For example, Fortymile Canyon is an important crossroad where trails from such distant places as Owens Valley, Death Valley, and the Avawatz Mountain come together. Black Cone, in Crater Flats is an important religious site that is considered to be an entry to the underworld. Prow Pass continues to be an important ceremonial site and, because of this religious significance, tribal representatives recommend that the U.S. Department of Energy (DOE) avoid affecting this area. Oasis Valley was historically an important area for trade, and continues to be a place recognized for ceremonial use. Other areas are considered important based on the abundance of artifacts, traditional-use plants and animals, rock art, and possible burial sites. Despite the current physical separation of tribes from the NNSS and neighboring lands, we continue to recognize the meaningful role of these lands in our culture and continued survival.

The Consolidated Group of Tribes and Organizations (CGTO) maintains we have Creation-based rights to protect, use, and have access to lands of the NNSS and the immediate area. These rights were established at Creation and persist forever. Despite the loss of many traditional lands on the NNSS to pollution and reduced access, Indian people have neither lost our ancestral ties nor have we forgotten our responsibilities in caring for it. As one elder noted, *"Land is to be respected. It sustains us economically, spiritually, and socially."*

During the past decade, representatives of the CGTO have visited portions of the NNSS and have identified places, spiritual trails, and cultural landscapes of traditional and contemporary cultural significance. Because this is a public document, the exact locations of these areas will not be revealed; however, they do include a burial cave, a Native American Graves Protection and Repatriation Act (NAGPRA) reburial area, and a local trail and ceremonial landscape near a large water tank. These actions by DOE are considered positive steps towards facilitating co-stewardship arrangements between DOE and the CGTO to help co-manage important Indian resources of the NNSS and to regain balance.

See Appendix C for more details.

4.1.1.3 Public Land Orders and Withdrawals

The NNSS comprises several separate land transfers from other Federal agencies to DOE/NNSA, as well as land from a legislative withdrawal. The NNSS is federally owned, access-controlled, and withdrawn from public settlement, location, or entry. Withdrawal of land from public use also excludes public mining and mineral leasing.

Public lands may be withdrawn and reserved for military training and testing in support of the Nation's national defense requirements. Lands designated as withdrawn are typically withdrawn from all forms of appropriation under public land laws. The term "withdrawal," as defined by the Federal Land Policy and Management Act of 1976, as amended in 2001 (Public Law [P.L.] 92-579), means withholding an area of Federal land from settlement, sale, location, or entry, under some or all of the general land laws, for the purpose of (1) limiting activities under those laws to maintain other public values in the area; (2) reserving the area for a particular public purpose or program; or (3) transferring jurisdiction of an area of Federal land, other than "property" governed by the Federal Property and Administrative Services Act, as amended (40 *United States Code* [U.S.C.] 472), from one department, bureau, or agency to another department, bureau, or agency.

The following three administrative land withdrawals (public land orders) by the Secretary of the Interior and one legislative withdrawal by Congress, provide the jurisdictional basis for DOE/NNSA's stewardship and management of the lands constituting the NNSS:

Public Land Order 805. Public Land Order 805, issued on February 12, 1952, reserved approximately 435,000 acres of land for use by the Atomic Energy Commission as a weapons testing site.

Public Land Order 2568. Public Land Order 2568, issued on December 19, 1961, transferred 318,000 acres of land previously reserved for the USAF to the jurisdiction of the Atomic Energy Commission for use in connection with the NNSS for test facilities, roads, and safety distances.

Public Land Order 3759. Public Land Order 3759, issued on August 3, 1965, reserved 21,108 acres of land for placement under the jurisdiction of the Atomic Energy Commission for use in connection with the NNSS.

Military Lands Withdrawal Act of 1999, Public Law 106-65. Enacted on October 5, 1999, this act renewed the withdrawal of lands known as "Pahute Mesa" that are an integral part of the NNSS and provided the site of nuclear weapons testing activities. Pursuant to the act, these lands were transferred from DoD to DOE/NNSA, thus aligning jurisdictional responsibilities consistent with DOE/NNSA's retention of environmental, safety, and health responsibilities at the NNSS. Use of this area by DOE/NNSA was previously covered under a Memorandum of Understanding with the USAF.

Figure 4–2 depicts the current NNSS boundary and the boundary prior to 1999.

Area 5 Land Transfer. As part of an April 1997 settlement agreement between the State of Nevada and DOE/NNSA, consultation with the U.S. Department of Interior, which oversees BLM, was initiated concerning the status of existing land withdrawals with regard to low-level radioactive waste (LLW) storage and disposal. This consultation process concluded in November 2009, when DOE/NNSA formally accepted permanent custody of and accountability for the 740-acre Area 5 Radioactive Waste Management Complex (RWMC).

Yucca Mountain Project. In 1994, the DOE Nevada Operations Office (now the DOE/NNSA NSO) entered into a management agreement with the Yucca Mountain Site Characterization Office for use of about 58,000 acres of NNSS land for site characterization activities related to the Yucca Mountain Project. Under this agreement, the Yucca Mountain Project was responsible for meeting the same environmental requirements that apply to the NNSS independent of, but in coordination with, DOE/NNSA.

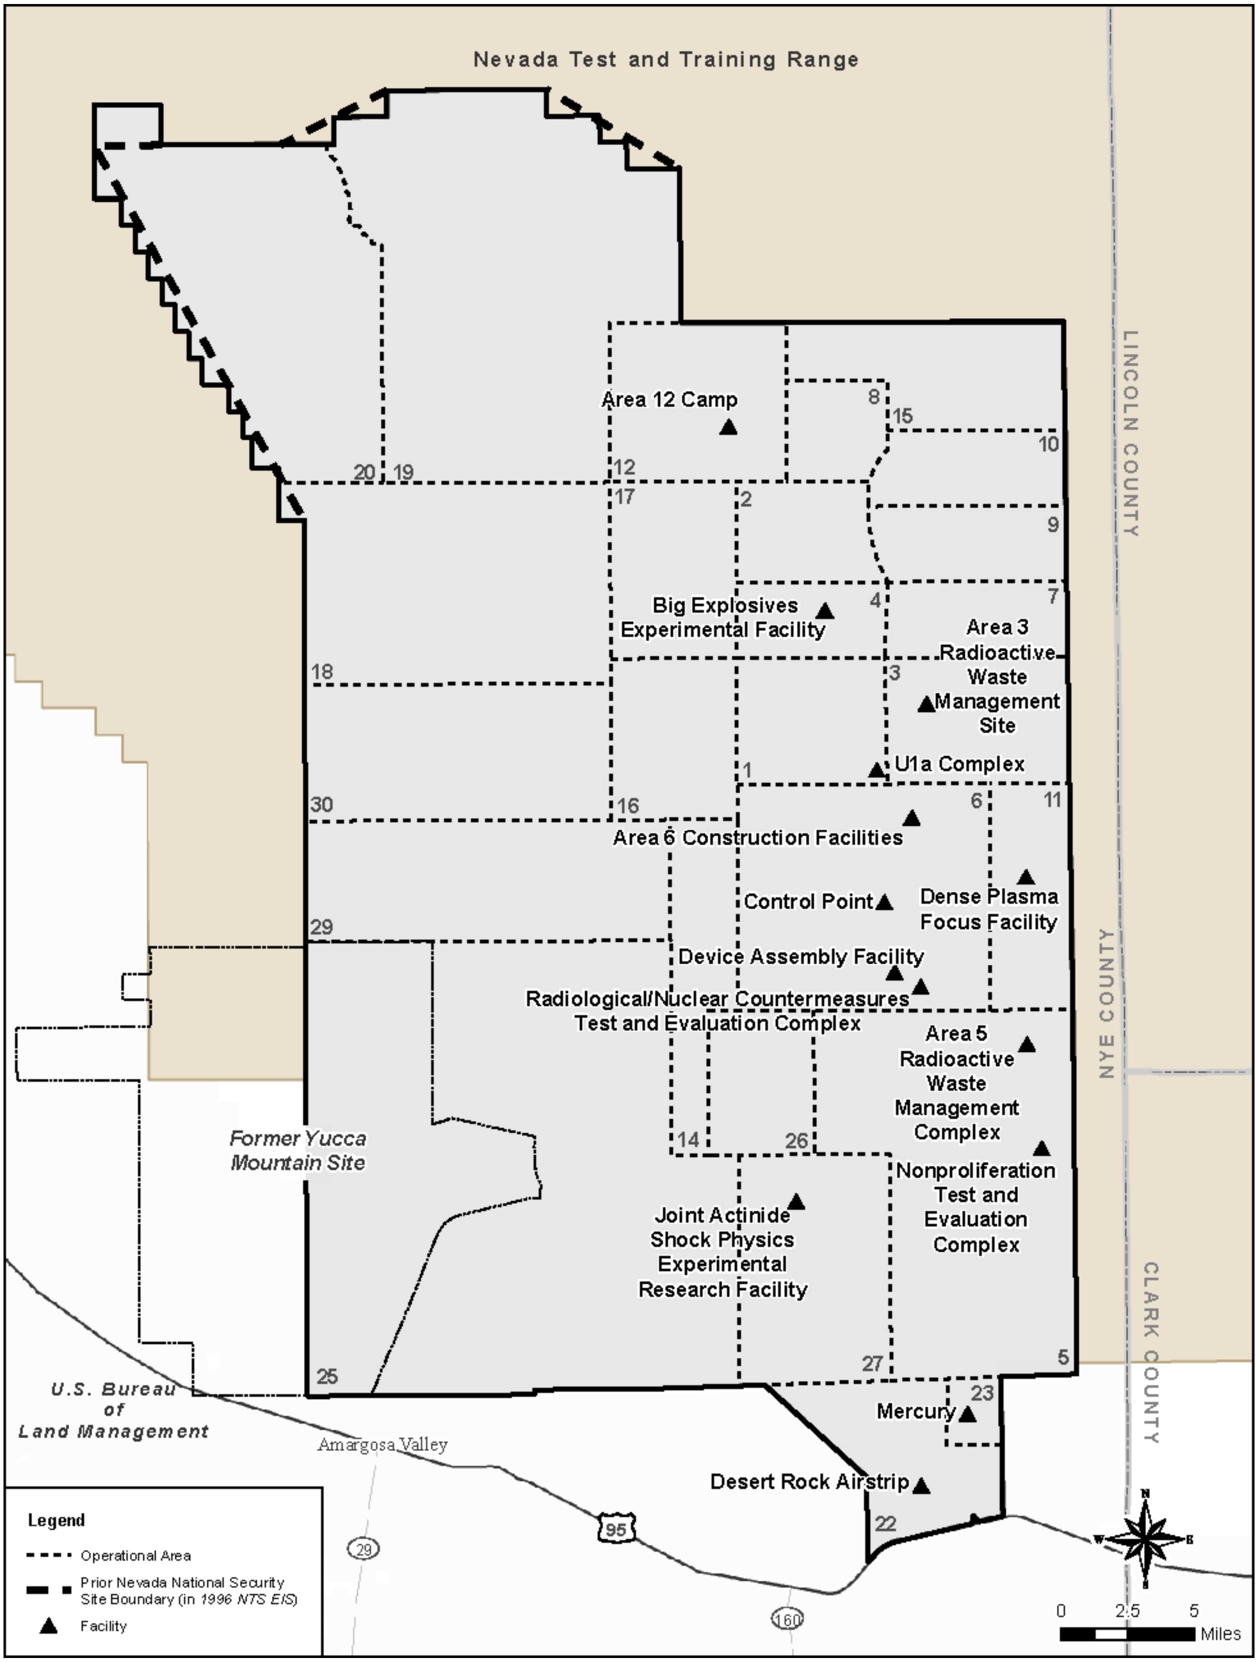

Figure 4–2 Nevada National Security Site Boundary Resulting from the Military Lands Withdrawal Act of 1999 (Public Law 106-65)

DOE's portion of *The Budget of the United States Government Fiscal Year 2011* states, "The Administration has determined that Yucca Mountain, Nevada, is not a workable option for a nuclear waste repository and will discontinue its program to construct a repository at the mountain in 2010. The Department will carry out its responsibilities under the Nuclear Waste Policy Act within the Office of Nuclear Energy as it develops a new nuclear waste management strategy."

4.1.1.4 Land Use Designations

Existing land use on the NNSS is divided into seven zone designations that support the three NNSS missions: National Security/Defense, Environmental Management, and Nondefense.

These land use zone designations, which are described in **Table 4–1**, include previously disturbed areas, areas with desirable slope and soil conditions for construction, and areas that have mission requirements such as remoteness and space for safety and security reasons. The areas within the land use zones may be sensitive to development for mission, environmental, or cultural reasons, and certain areas are protected from certain uses; however, these zones may host activities not normally associated with the particular zone designation, pending compatibility with existing activities or other factors that would affect collocation of activities, including the health and safety of personnel or avoidance of environmentally sensitive areas. Additionally, DOE/NNSA considers all zone designations compatible with environmental restoration activities.

Most of the experimental facilities are consolidated along a central corridor leading to Mercury Highway (the main thoroughfare on the NNSS). To help simplify the distribution, use, and control of resources, the NNSS is also divided into 26 numbered operational areas. The zone designations generally encompass portions of one or more NNSS areas and are depicted in **Figure 4–3**. Chapter 2, Table 2–1, describes the historical use of the NNSS operational areas, and Section 2.1.1 describes the major facilities. Section 4.1.2 describes the facilities located within each of the numbered areas, and Section 4.1.11 describes waste management activities and support facilities in detail.

4.1.1.5 Airspace

Approximately 40 percent of the airspace within Nevada is military "special use" airspace. Airspace in Nevada is managed in a manner that best serves the competing needs of commercial, general, military, and DOE/NNSA's aviation interests. The Federal Aviation Administration (FAA) is responsible for the overall management of airspace and has established different airspace designations that are designed to protect aircraft flying to or from an airport, transiting between airports, or operating within special use areas identified for defense-related purposes. Flight rules and air traffic control procedures have been established to govern how aircraft must operate within each type of designated airspace.

FAA regulates military operations in the National Airspace System through the implementation of FAA Order JO 7400.2G, *Procedures for Handling Airspace Matters*, and FAA Handbook 7610.4J, *Special Military Operations*. The latter was jointly developed by DoD and FAA to establish policy, criteria, and specific procedures for air traffic control planning, coordination, and services during defense activities and special military operations.

Special Use Airspace

Airspace where activities must be confined because of their nature or where limitations are imposed upon aircraft operations that are not part of those activities, or both. This airspace includes restricted airspace, military operations areas, and controlled firing areas.

Restricted Airspace

An area of airspace in which the controlling authority has determined that air traffic must be restricted, if not continually prohibited. It denotes the existence of unusual, often invisible, hazards to aircraft such as artillery firing, aerial gunnery, or guided missiles.

Table 4–1 Description of the Nevada National Security Site Land Use Zone Designations

Zone Designation	*Description of Zone Designation*	*Acres of Zone Designation on the NNSS*	*Operational Area within Zone Designation*
Defense Industrial Zone	Land area designated for stockpile stewardship experiments and operations to maintain confidence in the safety and reliability of the stockpile without underground nuclear testing. Activities include exercises, operations, and experiments (including subcritical experiments involving special nuclear materials). The land area is located around critical assembly areas and is dedicated to defense-related activities.	41,700 acres	Area 27; portions of Areas 6 and 5
Nuclear Test Zone	Land area reserved for underground hydrodynamic tests, dynamic experiments, and underground nuclear weapons and weapons effects tests. This zone includes compatible defense and nondefense research, development, and testing activities. The emplacement hole inventory, underground alcove areas where radioactive materials are tested (designed such that radioactive materials will not reach aboveground environments), is located within this zone.	224,000 acres	Areas 7, 8, 9, 10, 19, and 20; portions of Areas 6 and 11
Nuclear and High Explosives Test Zone	Land area designated for additional underground and aboveground high-explosive tests or experiments. This zone includes compatible defense and nondefense research, development, and testing activities.	103,800 acres	Areas 1, 2, 3, 4, 12, and 16
Radioactive Waste Management Zone	Land area designated for the shallow land burial of low-level and mixed low-level radioactive wastes.	820 acres	Portions of Areas 3 and 5
Research, Test, and Experiment Zone	Land area designated for small-scale research, development projects, pilot projects, and outdoor tests and experiments related to development, quality assurance, or reliability of materials and equipment under controlled conditions. This zone contains compatible defense and nondefense research, development, and testing projects and activities.	76,200 acres	Areas 14 and 26; portions of Areas 5 and 25
Reserved Zone	Controlled-access land area that provides a buffer between nondefense research, development, and testing activities. The Reserved Zone includes areas and facilities that provide widespread flexible support for diverse short-term nondefense research, testing, and experimentation. This land area is also used for short-duration exercises and training, such as Nuclear Emergency Search Team and Federal Radiological Monitoring and Assessment Center training and land navigation exercises and training.	410,100 acres (includes acreage from the former Yucca Mountain Project Zone)	Areas 15, 17, 18, 29, and 30; portions of Areas 5, 6, 11, 22, 23, and 25
Renewable Energy Zone	Land area and infrastructure reserved for future solar power development, light industrial equipment, and commercial manufacturing capability.	11,900 acres	Portions of Areas 22, 23, and 25

NNSS = Nevada National Security Site.

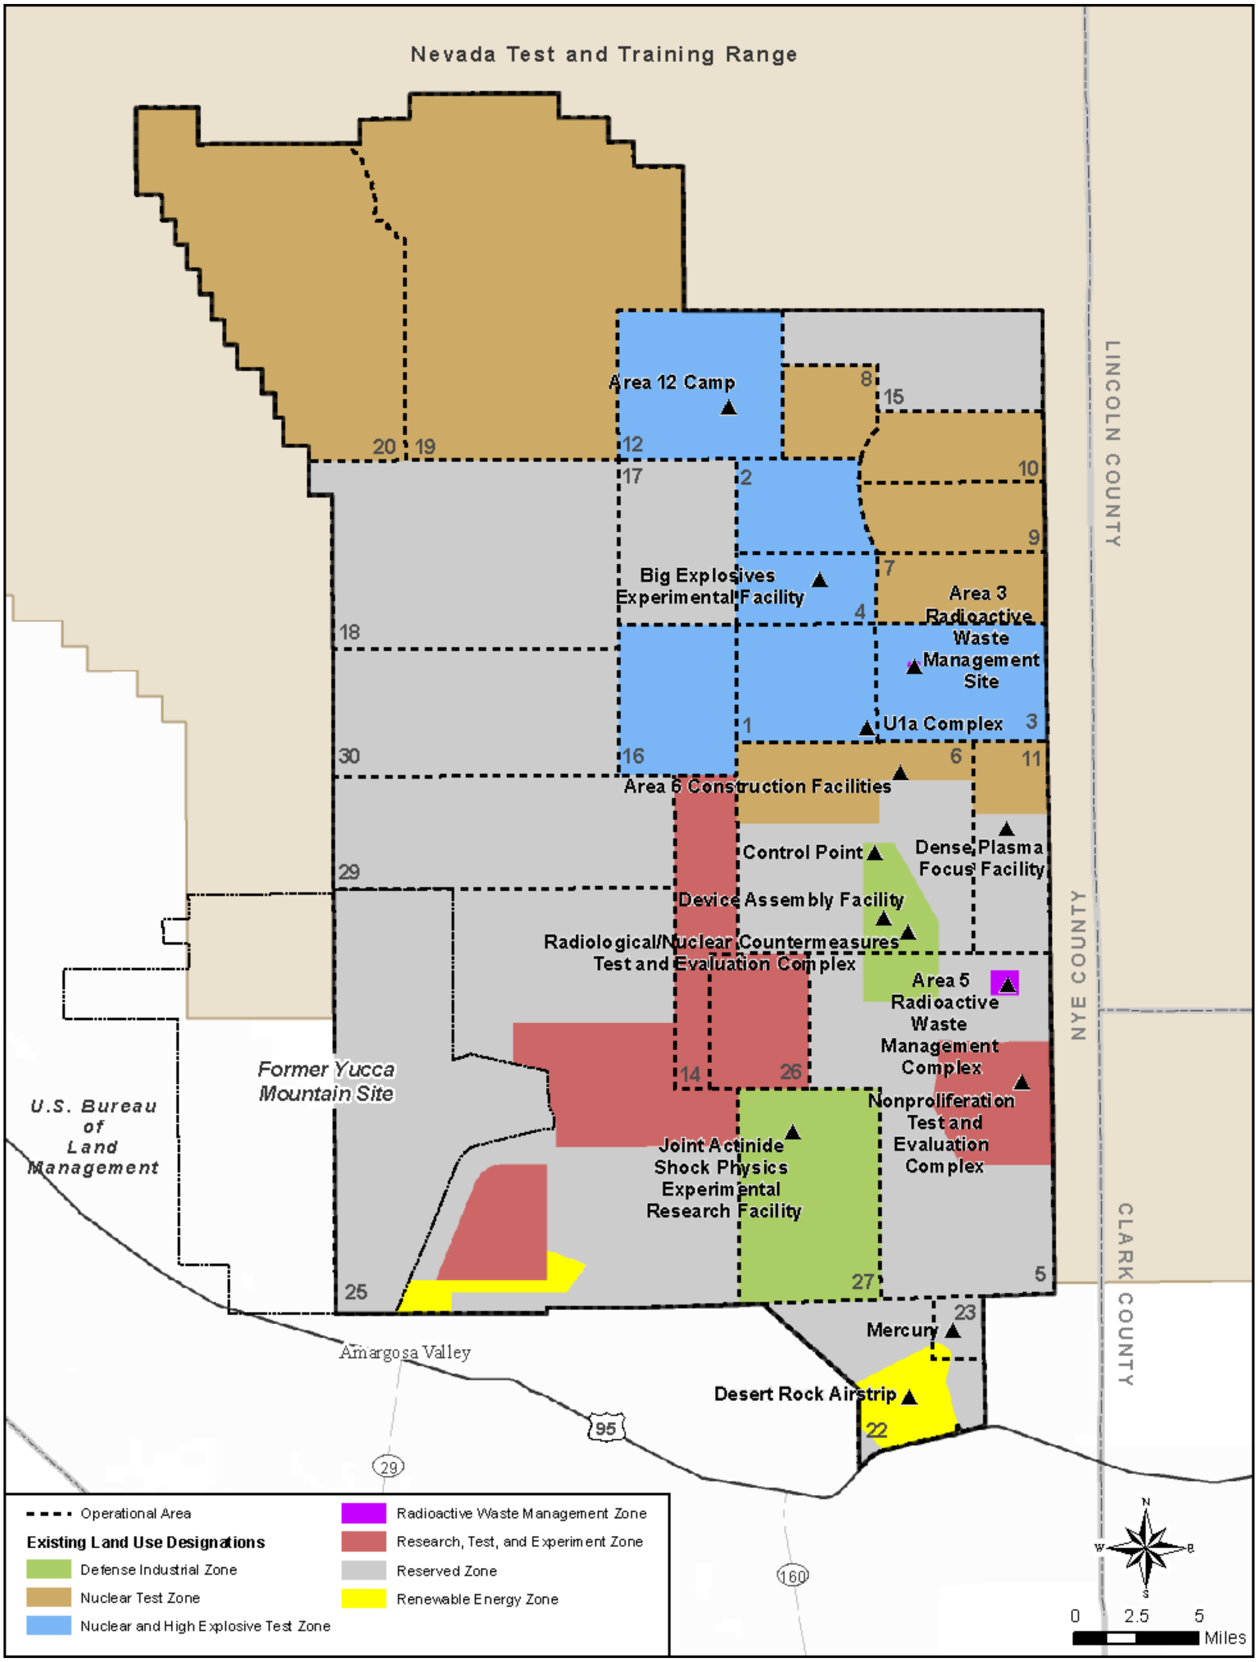

Figure 4–3 Existing Land Use Zones and Major Facilities on the Nevada National Security Site

The airspace above the NNSS was withdrawn and designated as Restricted Area 4808 (R-4808), special use airspace, by FAA and DOE/NNSA. The restricted area within this airspace is used by DOE/NNSA, which has established that this parcel of airspace is used by DOE/NNSA 24 hours a day, 365 days per year, and is not accessible by the public, except under certain conditions. R-4808 (the airspace above the NNSS and the northeastern portions of the Nevada Test and Training Range) and R-4809 (the airspace above the TTR) are managed by DOE/NNSA and are never authorized for use by civilian aircraft, except under conditions such as flights in direct support of a project at or proposed for the NNSS, meeting minimum security requirements, being scheduled in the airspace by DOE/NNSA, and other project-dependent conditions. The restricted airspace surrounding the NNSS to the north, east, and west is controlled by the Nevada Test and Training Range (DOE/NV 1998b).

Airspace associated with the NNSS and its vicinity is shown in **Figure 4–4**. The NNSS airspace is part of the Nevada Test and Training Range, which includes four restricted areas, the desert military operating areas/air traffic control assigned airspace, two low-altitude tactical navigation areas, 29 military training routes (established to provide low-altitude and high-speed training, allowing the military to conduct training for combat tactics), and three refueling routes (DOE 1996c). The NNSS contains four airstrips and seven helipads, located in Areas 6, 12, 22, 23, and 25.

4.1.2 Infrastructure and Energy

4.1.2.1 Infrastructure and Utilities

This section discusses the buildings and transportation infrastructure and potable water, wastewater, and communications utilities. Further transportation-related information is discussed in Section 4.1.3. Solid waste collection and landfills are discussed in Section 4.1.11. Energy systems distribution, use, and demand (electricity, natural gas, and liquid fuels) are discussed in Section 4.1.2.2. Discussions of NNSS and outside community support services, including law enforcement and security, fire protection, and health care, are presented in Section 4.1.4.

4.1.2.1.1 Infrastructure

Facilities. As of November 2009, there were 486 buildings and 113 trailers that support activities at the NNSS. **Table 4–2** presents the building floor space maintained at the NNSS, as well as the building floor space for leased properties off site, delineated by their respective functions, including administration, storage, industrial and production processes; research and development; services; and other uses (e.g., hangars, guard stations, and dormitories). As of November 2009, NNSS floor space totaled 2,231,602 square feet and offsite floor space totaled 214,071 square feet (NNSA/NSO 2009b). Most of these facilities and the supporting infrastructure at the NNSS are 30 to 50 years old and are rapidly deteriorating (DOE 2008f; NSTec 2009e).

DOE/NNSA ensures that existing facilities' maintenance and operation practices, as well as all new construction and renovation projects, conform to the requirements of Executive Order 13423, *Strengthening Federal Environmental, Energy, and Transportation Management* (72 FR 3919), and Executive Order 13514, *Federal Leadership in Environmental, Energy, and Economic Performance* (74 FR 52117), signed by President Obama on October 5, 2009, which expands on Executive Order 13423. In accordance with DOE Order 436.1, *Departmental Sustainability*, DOE/NNSA prepares an annual Site Sustainability Plan, which identifies performance goals and accomplishments in meeting High Performance and Sustainable Building Guidance of the Interagency Sustainability Working Group (ISWG 2008).

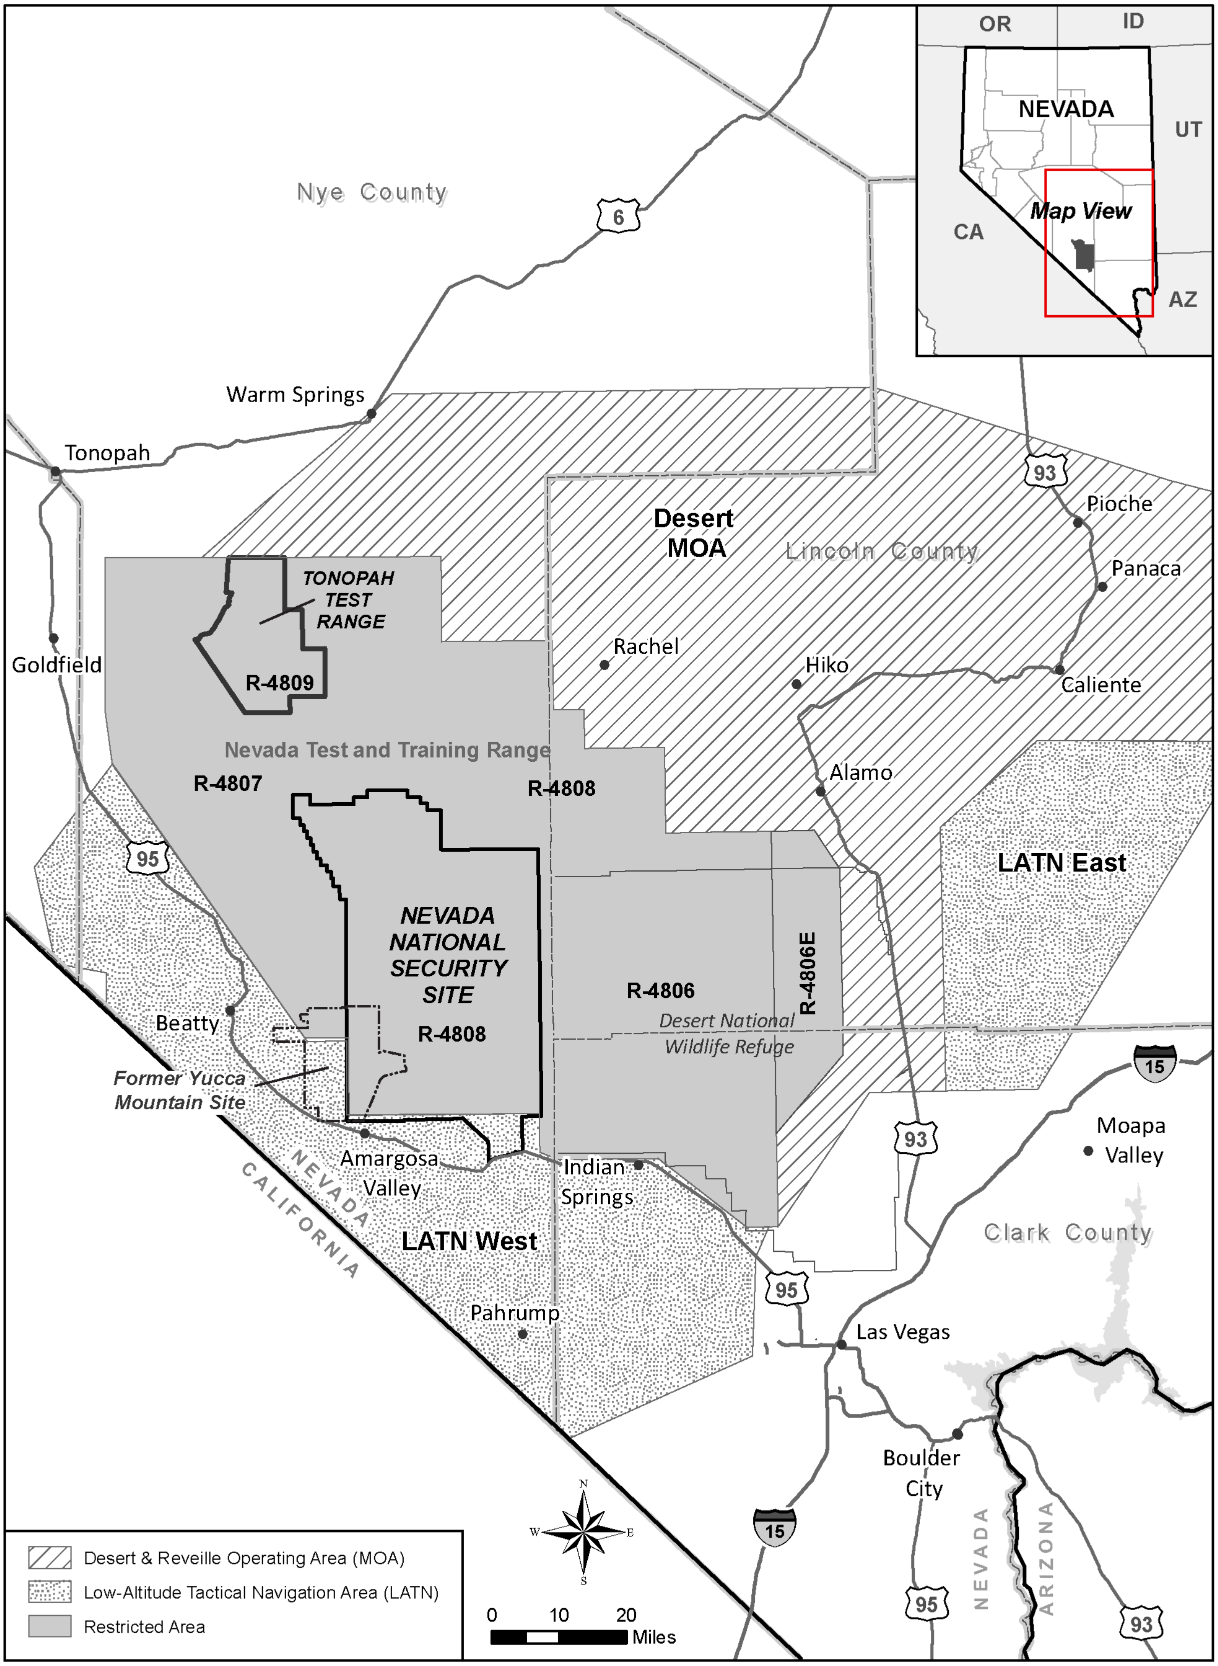

Figure 4–4 Airspace Within the Vicinity of the Nevada National Security Site

Table 4–2 Nevada National Security Site Building Floor Space by Function

Function	*Floor Space (square feet)*	*Offsite Leased Floor Space (square feet)*
Administrative	383,336	117,263
Storage	332,877	1,104
Industrial and Production Processes	359,980	8,253
Research and Development	486,405	87,451
Service Buildings	413,948	0
Other	255,056	0
TOTAL	2,231,602	214,071

Source: NNSA/NSO 2009b.

Transportation Systems. The NNSS is accessible and navigable by vehicles via a network of paved and unpaved roads, accompanied by parking areas. The onsite road network consists of approximately 340 miles of paved roads, including 195 miles considered mission essential, and over 300 miles of unpaved roads.

The primary paved roads in the southern part of the NNSS include Mercury Highway, Jackass Flats Road, Cane Spring Road, and Lathrop Wells Road. Mercury Highway is the primary access route to the NNSS from U.S. Route 95. Mercury Bypass is well constructed and runs from just north of gate 100 to north of Mercury. This 26-foot-wide road was built to enable the rerouting of all traffic with a forward area destination.

The primary paved roads on the northern part of the NNSS are Pahute Mesa Road, Buckboard Mesa Road, and Tippipah Highway. The areas served by these roads are Pahute Mesa, Buckboard Mesa, and Rainier Mesa, respectively. Pahute Mesa Road from Yucca Flat to the Area 20 camp is typical of hot-mix paved roads on the NNSS. At the higher elevations, the road is winding and crosses rugged terrain that may be hazardous under winter conditions.

Three basic types of roads have evolved over the years at the NNSS to support direct mission and mission support requirements: major transport routes, e.g., Mercury Highway, constructed of asphalt concrete suitable for sustained highway loads and speeds; spur roads of shorter length to specific activity locations, e.g., Road 5-01 Radioactive Waste Management Site, generally consisting of multiple applications of oil and chip suitable for use at reduced speeds and loads; and unpaved routes, e.g., Fortymile Canyon Road, graded and passable at low speed suitable for construction or maintenance vehicles.

Determining the level of road serviceability required to meet operational demands on the NNSS is a solid basis for establishing design, construction, maintenance, and safety criteria. The following hierarchy has been established to evaluate existing and proposed roadways:

- Level I – Roads that provide safe access to heavily used areas at highway speeds (currently 55 miles per hour); basic emergency response; and critical personnel and material movement routes. Level I roads handle the entire spectrum of vehicular traffic encountered at the NNSS.
- Level II – Roads that provide access to more-remote areas and/or complete loop access to most used areas. Highway speed and load capabilities are important. Roads facilitate periodic operations, construction, and maintenance, and provide a bypass during selected operations. Level II roads are primarily program-specific and receive all types of vehicular traffic except for tour buses and heavy construction machinery.
- Level III – Roads that maintain established access to specific active programmatic, campaign, or Directed Stockpile Work sites. Level III roads are limited in capacity and serviceability.
- Level IV – Unpaved roads that provide more direct and efficient access to selected locations or direct access to established isolated activities. Level IV roads are not routinely used.

Using this hierarchy of roads, **Table 4–3** presents roads assigned to each level.

Table 4–3 Roads Assigned to Each Level of Hierarchy Established on the Nevada National Security Site

Level 1	**Road Segment/Classification [a]**
Mercury Highway	U.S. 95 to BJY Intersection (RA)1
Mercury Bypass	South Turnout to North Turnout (RF)
Rainier Mesa Road	BJY Intersection to Area 12 Camp (RA)
Tippipah Highway	Mercury Highway to Area 12 Camp (RA)
Cane Spring Road	Mercury Highway to 27-01 Road (RC)
5-01 Road	Mercury Highway to Area 5 RWMC site (RC)
3-03 Road	Mercury Highway to Area 3 RWMS site (RC)
Level II	**Road Segment/Classification [a]**
Stockade Wash Road	A-12 Camp to Pahute Mesa Road (RC)
Buckboard Mesa Road	18-03 Road to Pahute Mesa Road North (RF)
Cane Spring Road 27-01	Road to Jackass Flats Road (RC)
Jackass Flats Road (South)	Mercury Bypass to 27-01 Road (RC)
27-01 Road	Cane Spring Road to Jackass Flats Road (RC)
Pahute Mesa Road	Mercury Highway to Stockade Wash Road (RA)
Tweezer Road	Mercury Highway to Construction Area (RF)
18-03 Road/Airport Road	Pahute Mesa Road to Buckboard Mesa Road (RC)
Level III	**Road Segment/Classification [a]**
Jackass Flats Road (North)	27-01 Road to Cane Spring Road (RC)
Pahute Mesa Road	Stockade Wash Road to Buckboard Mesa Road N (RF)
4-04 Road	Rainier Mesa Road to BEEF site (RF)
Level IV	**Road Segment/Classification [a]**
Mercury Highway	Old BJY Intersection to Gate 700 (RA)
Lathrop Wells Road	Cane Spring Road to NNSS boundary (RA) (Gate 510)
Desert Rock Road	Mercury Highway to Desert Rock Airport (RF)
Airport Road (Area 18)	18-03 Road to Pahute Mesa Airport (RF)
5-07 Road	Mercury Highway to 5-01 Road (RF)
5-06 Road	5-01 Road to Spill Test Facility (RF)
Tunnel Access Roads	Multiple spurs (RF)
Other existing paved, gravel, or graded roads	

BEEF = Big Explosives Experimental Facility; RWMC = Area 5 Radioactive Waste Management Complex; RWMS = Area 3 Radioactive Waste Management Site.
[a] Comparison with Nevada state road classifications is shown:
Rural Arterial (RA); Rural Connector (RC); Rural Feeder (RF).
Source: FY 2007 Utility Management Plan, Table 2-1.

With the exception of Mercury Highway, the 340 miles of paved and 300 miles of unpaved roads were not designed or intended for use at the loads and speeds of today's traffic, e.g., 55 miles per hour. While numerous repairs and safety improvements to various segments have allowed continuous operations along most NNSS roadways, portions of the paved road system are currently substandard (DOE 2008i). Approximately 15 miles of roadway (amount usually determined by funding) are oiled and chipped each year to prevent deterioration and provide safe road surfaces. Based on this level of effort, each of the 340 miles of paved road can only be treated every 22 years. However, in 2010, a major Mercury Highway road improvement project was completed on the entire length of the road.

Traffic conditions on NNSS roads are discussed in Section 4.1.3.

Parking for government and private vehicles is available at most buildings on the NNSS; and paved parking areas are available for commuter buses at support facilities in Areas 6, 12, 23, and 25. Collectively, the NNSS has approximately 1 square mile of paved land comprising parking areas. A bus fleet operation is used to transport personnel to and from the NNSS and Las Vegas/Pahrump, Nevada. These buses are operated by a private firm under subcontract to DOE/NNSA (NNSA/NSO 2009c). There are no operational railroads that access the NNSS.

The NNSS transportation-related infrastructure also includes the following air facilities:

Pahute Airstrip. This airstrip is located in Area 18 and has a paved runway and a secondary support facility. It is currently limited to helicopter use due to runway deterioration.

Desert Rock Airport. Located in Area 22, this airport has a paved runway with radio-activated lights, an administrative/control building, aircraft parking areas, and other ancillary features. It is unmanned, but operational, and its use is controlled by DOE/NNSA.

Yucca Lake Airstrip. This airstrip is located in Area 6 and has a secondary support facility and an unpaved runway that is subject to flooding following local storms.

Area 6 Aerial Operations Facility. Located in Area 6, this is an unmanned aerial system research and development facility. It has a paved runway, taxiways, and aircraft parking areas, as well as hangars, shops, and administrative buildings.

Helipads. Helipads with windsocks, fire extinguishers, and painted markings are located in seven locations across the NNSS.

All roads, parking areas, and air facilities at the NNSS are maintained for mission-related uses.

4.1.2.1.2 Utilities

The utility systems discussed in this section include the potable water supply, wastewater collection and treatment, and communication systems.

Water Supply. The NNSS water systems provide potable, fire-protection, construction, and wildlife preservation water throughout the expanse of the installation. Water production and distribution systems have been in place at the NNSS for over 50 years, serving work populations of up to 10,000 workers.

Drinking water needs are met by deep-well groundwater draws from two major aquifers (the volcanic and the alluvial aquifers) that are not influenced by surface waters. In addition, groundwater is withdrawn from the carbonate, volcanic, and alluvial aquifers for nonpotable, construction, and fire protection purposes.

The NNSS comprehensive water production and distribution system consists of three permitted public water systems (PWSs), two wildlife preservation reservoirs, and two isolated environmental sampling wells (DOE 2008l).

The three discrete PWSs permitted by the Nevada Division of Environmental Protection (NDEP) to provide potable water to the NNSS are served by six wells (Well 4/4a, Well 5b/5c, Well 8, Well 16D, Well C-1, and Well J-12). The transmission and distribution systems include mains, valves, hydrants, booster pump stations, pump suction tanks, and reservoir storage tanks. Each PWS extends to the point of the service connection. Two tanker trucks used to haul potable water from the permitted wells to remote work sites are also permitted, but are not considered PWSs (NSTec 2010d).

The NNSS water system is spread over four distinct water service areas and consists of eight water systems; two wildlife preservation reservoirs; numerous water storage tanks, fillstands, and construction water open pit reservoirs, as well as approximately 140 miles of pipeline located throughout the site

(DOE 2008l). These water service areas are discussed in detail below in relation to their location and the areas they support.

Water Service Area A. Encompasses Areas 19 and 20. System capabilities within this service area have been abandoned for more than a decade. There are two wells in this area (Wells 19c and 20), both of which are out of service and have monitoring casing to prevent vandalism or contamination (DOE/NV 2008c).

Water Service Area B. Encompasses Areas 2, 4, 7, 8, 9, 10, 12, 15, 17, and 18. PWS NV0004099 serves Area 12. Well 2, which is within this service area, is out of service and is locked to prevent vandalism or contamination. Well 8 provides water to Area 12 and supplies water to the construction water open pit reservoir system. Water Service Area B also includes one pumping station and two water storage tanks (DOE 2009f; DOE/NV 2008c).

Water Service Area C. Encompasses Areas 1, 3, 5, 6, 11, 22, 23, 26, and 27. PWS NV0000360 serves Areas 5, 6, 22, and 23. Five active wells provide water in this service area (Wells C-1, 4, 4a, 5b, and 5c). Fillstand A-6 is used to supply potable water via water trucks to the Joint Actinide Shock Physics Experimental Research Facility (JASPER), Area 12, and the Big Explosives Experimental Facility (BEEF). Water Service Area C also includes five pumping stations and nine water storage tanks (DOE 2009f; DOE/NV 2008c).

Water Service Area D. Encompasses Areas 14, 16, 25, 29, and 30. PWS NV0004098 serves Area 25. It consists of two active wells (Wells J12 and 16d). Water Service Area D also includes three pumping stations and 12 water storage tanks (DOE 2009f; DOE/NV 2008c).

Water is currently hauled into Areas 26 and 27 by truck. There are four elevated tanks in Area 26 that store construction water and one tank in Area 27 that stores fire protection and potable water (DOE/NV 2008c).

The annual maximum production capacity of the site's potable supply wells (based on equipment capacity) is approximately 2.1 billion gallons per year, although the combined sustainable yield of the groundwater basins is substantially lower, and the sustainable yield of each basin is considered in groundwater withdrawals. Section 4.1.6.2 and Chapter 5, Section 5.1.6.2, provide additional information on groundwater wells, basins, and sustainable yields.

Water Conservation. DOE/NNSA is currently implementing programs to maximize compliance with Executive Order 13423, *Strengthening Federal Environmental, Energy, and Transportation Management*, as detailed in the Annual Site Sustainability Plan required by DOE Order 436.1, *Departmental Sustainability,* and in the annual Executable Energy Plans. One of the goals of these plans is to reduce the use of energy and water in DOE/NNSA facilities by advancing water conservation (NSTec 2011c).

According to DOE/NNSA's Energy Executable Plan of December 2008, the goal is to reduce potable water consumption by no less than 16 percent from the 2007 level by 2015. This reflects an average reduction in water consumption of approximately 2 percent per year. To accomplish this goal, the NNSS began saving water through several water conservation measures and best management practices for water efficiency. Examples include the installation of WaterSense™ products (including toilets and urinals, faucets and showerheads, boiler systems, and other water uses), xeric landscaping, water-efficient irrigation, system audits and leak repairs, use of nonpotable water for dust suppression when possible, and institution of 4-day workweeks (NSTec 2011c). Potable water consumption for the NNSS is presented in **Table 4–4** (see Section 4.1.6.2 for further information on water usage at the NNSS).

Gray water recycling was deemed cost-prohibitive at the NNSS due to the quantity of flow and lack of redistribution means. Gray water is sometimes used for dust control; however, depending on the extent of treatment, there are restrictions on how the water may be used (NSTec 2008b).

Table 4–4 Potable Water Consumption for the Nevada National Security Site by Year

Year	*Potable Water Consumption (gallons, approximate)*
2005	182,650,000
2006	221,250,000
2007	225,150,000
2008	172,550,000
2009	190,000,000
2010	185,765,000
2011	184,073,000

Source: NSTec 2010c; Rudolph 2012.

Wastewater Collection and Treatment Systems. The NNSS sanitary sewer system consists of approximately 100 linear miles of cast iron or polyvinylchloride mains and service laterals. Domestic and industrial wastewater is treated using either sewage treatment lagoon systems or septic tanks with leach field systems.

In fiscal year (FY) 2003, due to insufficient flow in the lagoons, to remain compliant with Nevada regulations, DOE/NNSA placed 8 of the 10 sewage lagoon systems in inactive status and installed new septic systems that allowed the lagoons to be bypassed. Only the Area 23 (Mercury) and Area 6 (Yucca Lake Complex) lagoon systems remain operative (NSTec 2010g). These two active lagoons operate under NDEP Water Pollution Control General Permit GNEV93001, with design flow capacities of 73,407 gallons per day (Area 23, Mercury) and 10,850 gallons per day (Area 6, Yucca Lake Complex) (NDEP 2005). The current rate of wastewater production for the two operating lagoons is presented in **Table 4–5**.

Table 4–5 Wastewater Production for the Mercury and Yucca Lake Lagoons at the Nevada National Security Site by Year

Year	*Wastewater Production (average gallons per day)*		*Total Treated in Lagoon Systems (average gallons per day)*
	Mercury Sewage Lagoon System	*Yucca Lake Sewage Lagoon System*	
2005	44,510	8,229	52,739
2006	42,124	9,219	51,343
2007	42,367	7,427	49,794
2008	32,588	1,084	33,672
2009	26,550	1,049	27,599
Permit capacity	73,407	10,850	84,257
Percentage of lagoon capacity used in 2009	36%	10%	33%

Source: NSTec 2010g.

Sludge removed from the wastewater treatment systems is disposed in the Area 23 sanitary landfill or the Hydrocarbon Disposal Site in Area 6, depending on the hydrocarbon content (DOE 2008f).

Installation of new septic tank systems to supplement the NNSS's wastewater treatment capacity enabled the NNSS to meet current site needs and comply with state regulations (DOE 2008f). There are currently 23 permitted septic tank systems at the NNSS (NSTec 2010h). Each septic tank has a capacity for handling 5,000 gallons of wastewater per day. Seven of the septic tanks are maintained by the National Security Technologies, LLC, Department of Water and Waste, and the remaining units are maintained by the individual facilities with which they are connected. Collectively, the 23 septic systems provide a capacity for treating 115,000 gallons of wastewater per day. The currently permitted septic systems at the NNSS and the approximate number of people they serve per workday are presented in **Table 4–6**.

Total capacity		**115,000**	**367**
Demand	**Assuming 20 gpd per person,[b] total treatment demand**	**7,340**	**6% of collective capacity**

DAF = Device Assembly Facility; gpd = gallons per day; LANL = Los Alamos National Laboratory; NNSS = Nevada National Security Site; NPTEC = Nonproliferation Test and Evaluation Complex; RWMC = Area 5 Radioactive Waste Management Complex.

[a] Source: NSTec 2010h.

[b] Liu and Liptak 1997; CMU 2004.

DOE/NNSA assumes that a typical wastewater generation rate for the NNSS would be approximately 20 gallons per day, based on the upper limits of an average flow rate for an office setting (7 to 16 gallons per day) and a school with cafeteria setting (10 to 20 gallons per day) (Liu and Liptak 1997). This estimate is further confirmed by a study done at Carnegie Mellon University that calculated per capita water use in 2004 for the NNSS at 20.81 gallons per day (CMU 2004).

As shown in Table 4–6, the septic tank systems at the NNSS are currently being used at approximately 6 percent of their collective capacity. As shown in **Table 4–7**, the population at the NNSS is currently using approximately 17 percent of the collective total capacity of wastewater treatment at the NNSS (the capacity of the two lagoons and 23 septic tanks).

Areas not serviced by a permanent wastewater system are provided with portable sanitary units. The portable sanitary units are serviced regularly, and the wastewater is discharged to a permitted onsite treatment system (DOE 2008f).

Table 4–7 Estimated Total Wastewater Treatment Capacity at the Nevada National Security Site

Wastewater Treatment System	*Capacity (gallons per day)*
Lagoons: Mercury and Yucca Lake Systems [a]	84,257
Septic Systems [b]	115,000
Total NNSS Capacity	199,257
Total Wastewater Generation [c]	34,000
Percentage of Capacity Used	17%

NNSS = Nevada National Security Site.
[a] Based on NDEP permit design flow capacity.
[b] Based on 23 septic systems at 5,000 gallons per day each.
[c] Based on 20 gallons per day of wastewater per person for the current population of 1,700 persons.

Communication Systems. Communication systems cover not only the entire area of the NNSS, but also reach far beyond its boundaries. The NNSS telecommunications/information technology infrastructure is composed of fiber optic and copper cabling and microwave systems. The distribution architecture is composed of approximately 205 miles of fiber optic cabling, thousands of circuit miles of legacy copper telecommunications cabling, and seven major microwave links. The systems include telephone network, data transmission, and storage systems, as well as video, radio, and mail systems. Parts of the NNSS telecommunications/information infrastructure are technologically dated and have been degraded in many locations (DOE 2008f).

4.1.2.2 Energy

Electrical power and liquid fuels are necessary for the continued operations of the NNSS, RSL, NLVF, and the TTR. These sources provide energy to support the buildings, vehicles, and operations at the facilities.

4.1.2.2.1 Electrical Energy

Electrical service at the NNSS is supplied by two power sources: (1) NV Energy (previously Nevada Power) and (2) the Valley Electric Association (DOE 2008f). It is distributed to the site by an onsite 138-kilovolt transmission loop that supplies eight substations, one switching center, and one 138-kilovolt radial. The power distribution involves an extensive 34.5-kilovolt system, and short 69-kilovolt and 12-kilovolt systems. These voltages are transformed to a 4.16-kilovolt distribution voltage, and then subsequently to 480–208/120-volt working levels. The NNSS is served by approximately 600 miles of transmission and distribution lines (NSTec 2008b).

The electrical capacity at the NNSS is approximately 45 megawatts, and the current load is approximately 20 megawatts. From 2003 through 2006, electrical usage at the NNSS ranged from 57,000 to 95,000 megawatt-hours, averaging 81,000 megawatt-hours with a peak load usage of 27 megawatts (DOE 2008f). Electrical usage at the NNSS during FY 2009 was 84,577 megawatt-hours. Utility use in areas surrounding the NNSS is holding steady; the NNSS capacity should remain at 45 megawatts in the foreseeable future (NNSA/NSO 2010a).

4.1.2.2.2 Natural Gas

There is no infrastructure for natural gas supply at the NNSS.

4.1.2.2.3 Liquid Fuels

The NNSS uses various types of liquid fuel for its energy needs. Red dye fuel oil is used to heat many buildings and facilities (though numerous oil-fired boilers have been replaced with electric boilers). Unleaded gasoline, diesel fuel, and biofuels (such as ethanol/E85 and biodiesel) are used to power its vehicle fleet and equipment. **Table 4–8** presents liquid fuel usage at the NNSS in 2009 by type.

Table 4–8 Fuel Usage in Fiscal Year 2009 at the Nevada National Security Site

Fuel Type	*Quantity (gallons)*
#2 Red Dye Fuel Oil for Heating	66,433
Unleaded Gasoline	426,964
Ethanol/E85	216,616
#2 Diesel	64,844
Biodiesel	343,191

Source: NNSA/NSO 2010b.

The NNSS has two service stations, each with the capacity to store 10,000 gallons of unleaded gasoline and 9,500 gallons of biodiesel. E85 fueling stations are located near these NNSS gasoline/biodiesel service stations. The NNSS currently has a secure source for daily delivery of E85 fuel and currently has no need for a large onsite stored reserve.

The bulk storage tanks in Area 6 are capable of storing approximately 100,000 gallons of biodiesel and 40,000 gallons of unleaded gasoline (DOE 2008l). Both tanks are filled and maintained to support four weeks of biodiesel consumption and two weeks of unleaded fuel consumption in case of a fuel shortage (NSTec 2009e).

The trend over the last several years has been a decline in petroleum-based fuel usage. The majority of the NNSS fleet currently operates on alternative fuels. The NNSS uses E85 fuel for alternative-fuel vehicles and B-20 biodiesel for all diesel vehicles and off-road equipment. As of December 2008, the NNSS had 548 alternative-fuel vehicles that are E85-capable, equal to 94 percent of the NNSS vehicle fleet. The NNSS requires its fleet to operate all alternative-fuel vehicles on alternative fuels to the maximum extent practicable.

4.1.2.2.4 Conservation and Renewable Energy

The Federal Energy Policy Act of 2005 (EPACT 2005, Section 203(a) [42 U.S.C. 15,853 (a)]) requires DOE to reduce the use and cost of energy at its facilities by advancing energy efficiency, water conservation, and renewable energy sources. As a result, DOE/NNSA has implemented various energy and water conservation practices and is working toward maximizing installation of onsite renewable energy projects at the NNSS where technically and economically feasible.

NNSA has met the requirements for installing electrical meters (as set forth in Section 103 of the Energy Policy Act of 2005) for 90 percent of the electricity used by NNSS and NLVF (NSTec 2011c). The metering allows DOE/NNSA to better track its use of electricity to help improve its ability to identify conservation opportunities.

As part of energy conservation efforts under Energy Saving Performance Contract funding, some NNSS buildings have been retrofitted with low-energy light fixtures and programmable thermostats. Several onsite renewable energy projects have been implemented at the NNSS, including: (1) solar lighting installed for pedestrian footpaths, (2) solar light post in front of the cafeteria, (3) solar-powered monitoring stations, (4) solar-powered low-volume continuous air sampling systems, and (5) solar-powered pedestrian crosswalk lighting (NSTec 2008b).

4.1.3 Transportation and Traffic

This section addresses baseline transportation conditions with respect to onsite and regional traffic, including transportation of materials and wastes. "Onsite traffic" relates to the roadway network within site boundaries; "regional traffic" relates to the roadway network surrounding the site.

4.1.3.1 Onsite Transportation

Access to the NNSS is restricted; guard stations are located at entrances, as well as at other locations throughout the site. The main entrance to the NNSS, Gate 100, is located on Mercury Highway, which

originates at U.S. Route 95. Although there are access points at other locations, their use is restricted and they are usually barricaded. Vehicles accessing the NNSS are generally limited to the main entrance. Other existing roadways, some of which are unpaved, provide access or exit routes in cases of emergency or for special purposes.

The NNSS has 640 miles of roadways: 340 miles of paved roads and 300 miles of unpaved roads (DOE 2007c). The paved roads are considered primary roads; most are two-way, two-lane roads with speed limits of 55 miles per hour, unless posted otherwise. The speed limit in developed areas is 20 miles per hour. The maximum speed limit on dirt roads is 35 miles per hour. The majority of the paved roadway network was constructed prior to 1965 and is considered to be in substandard condition, requiring extensive and effective remedial reconstruction, rehabilitation, and resurfacing actions (DOE 2009f). The unpaved portion of the roadway system is composed of graded gravel roads and jeep trails. The NNSS also has numerous unpaved test- or experiment-related roads that are no longer used after a test or experiment is completed.

Figure 4–5 depicts the NNSS's onsite roadway network, which can be considered in terms of a southern network and a northern network. The primary paved roads in the southern part of the NNSS include Mercury Highway, Jackass Flats Road, Cane Spring Road, and Lathrop Wells Road. Mercury Highway is the primary access route to the NNSS from U.S. Route 95. South of Gate 100, Mercury Highway is a two-lane highway. At the gate, it widens to multiple lanes to facilitate entry through the guard station. North of the gate, the highway narrows to a two-lane highway and remains a two-lane highway northward to the transition to Rainier Mesa Road. Most of Mercury Highway is 26 feet wide (13 feet wide per travel lane), but the shoulders vary from 4 to 6 feet wide. Mercury Bypass runs from just north of Gate 100 to north of Mercury. This 26-foot-wide road was built to divert traffic around Mercury to outlying areas of the NNSS.

The primary roads in the northern part of the NNSS include Mercury Highway, Pahute Mesa Road, Buckboard Mesa Road, Stockade Wash Road, Rainier Mesa Road, and Tippipah Highway. The areas served by these roads are Buckboard Mesa, Pahute Mesa, and Rainier Mesa.

Mercury Highway is the main thoroughfare within the NNSS and handles most of the traffic volume at the site. The highway runs approximately 37 miles from the southern border of the NNSS to its intersection with Rainier Mesa Road. A 1999 traffic study estimated that approximately 1,500 vehicle trips were made through the main access gate at the NNSS per day. Peak hours were from 6:00 to 7:00 a.m. and from 5:00 to 6:00 p.m., Monday through Thursday (because most personnel work 4 days per week) (PBS&J 1999). The study also revealed that the mix of vehicles accessing the main gate was approximately 90 percent automobiles, 7 percent trucks, and 3 percent buses. In the northern roadway network, approximately 700 vehicle trips on Mercury Highway occurred per day, of which about 81 percent were automobiles, 15 percent were trucks, and 4 percent were buses. The study determined that the highway was operating at adequate capacity, but that overall surface conditions were suboptimal and could pose traffic safety concerns (PBS&J 1999). In 2010, a major Mercury Highway road improvement project was completed along the entire length of the road. Recent vehicle counts just north of the Mercury interchange at U.S. Route 95 indicate that the total volume of vehicles accessing the NNSS increased 29 percent between 1999 and 2008 (NDOT 2008a, Nye County). NNSS employment data indicate that the number of onsite employees was approximately 1,300 in 1999 and 1,700 in 2008, representing a 31 percent increase over this timeframe (NNSA 2000, 2008; DOE 2002g). Therefore, because of the similar increases in traffic levels and NNSS personnel, DOE/NNSA assumed that the number of onsite employees is a reasonable indicator of traffic levels at the NNSS and that current number of onsite vehicle trips per day has also increased by approximately 30 percent since the 1999 traffic study. Major roadway improvements and maintenance work on Mercury Highway and Rainier Mesa Road have occurred over the last decade and are ongoing.

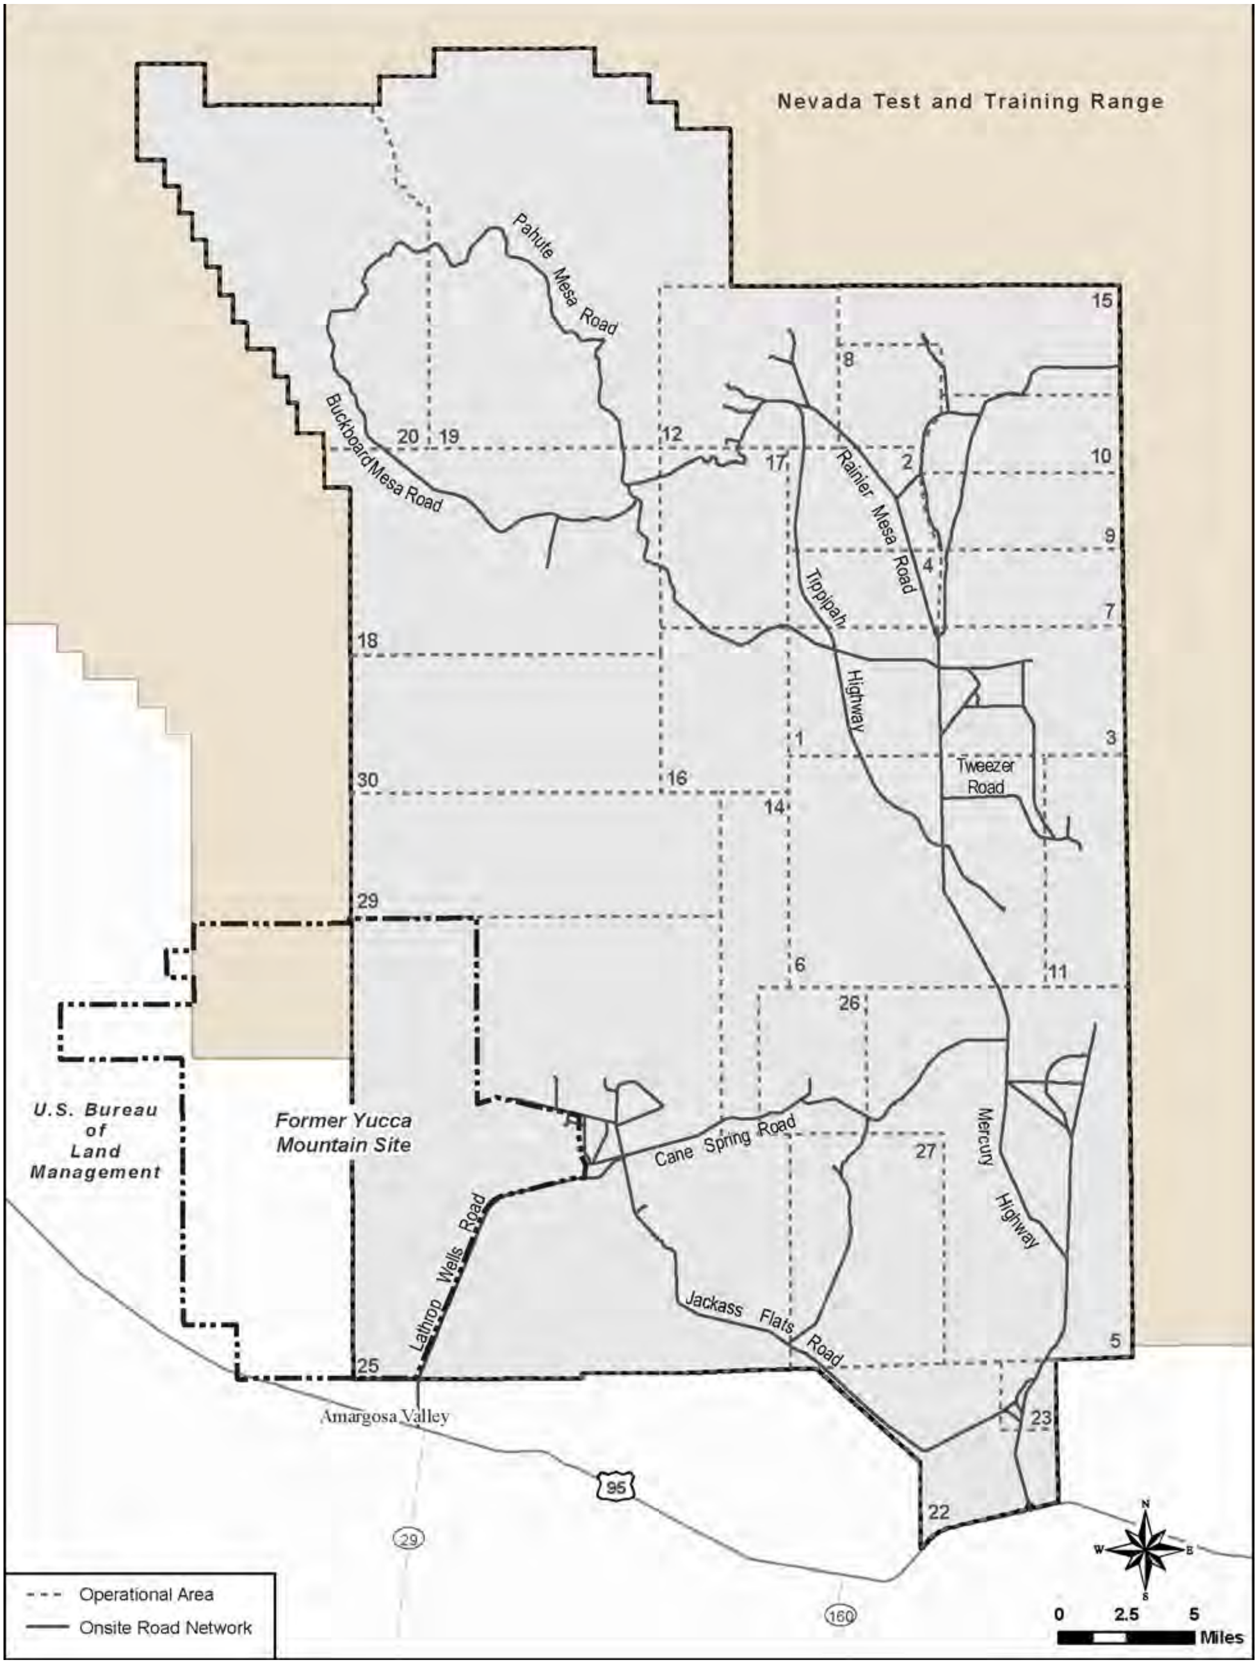

Figure 4–5 Nevada National Security Site Transportation System

Transportation facilities related to the onsite roadway network include bus parking and commuter-vehicle parking areas. At least 50 percent of NNSS employees commute to the site by bus, but the privately owned vehicles of commuting personnel still contribute to the majority of traffic accessing the NNSS (NSTec 2010a). Commuter buses provide daily passenger service to the NNSS from Las Vegas via U.S. Route 95 and from Pahrump via Nevada State Route 160 and U.S. Route 95. The number of buses entering and exiting the NNSS on a daily basis varies, depending on the onsite activities in progress. Currently, there are 15 buses serving the Las Vegas area and 2 buses serving the town of Pahrump. These buses have dedicated routes to the following locations: Mercury, the Area 6 Device Assembly Facility (DAF), the Control Point in Area 6, the Area 6 Construction Facilities, and Area 5 (when projects are being conducted in the area). Parking for government and private commuter vehicles is available at most buildings on the NNSS.

4.1.3.2 Regional Transportation

4.1.3.2.1 Regional Transportation System

The NNSS is located in a region served by a network of U.S., interstate, and state highways. A significant portion of the commuter and truck traffic associated with the NNSS (approximately 95 percent) arrives via U.S. Route 95 from the Las Vegas area (DOE 2008l). Although the transport of materials and waste includes a nationwide system, the ROI for the regional, nonradiological traffic analysis presented in this SWEIS primarily covers the major roadways within Nye and Clark Counties that are most frequently used by personnel and visitors of the NNSS and by vehicles transporting nonradioactive and radioactive materials and waste to or from the NNSS. **Figure 4–6** presents the major roadways in the southern Nevada region, including those serving RSL, NLVF, and the TTR (discussed in subsequent sections of this chapter), and highlights the major transportation routes for shipments of radioactive materials and waste to and from the NNSS. **Figure 4–7** shows the road network in the vicinity of Las Vegas and highlights the major transportation route used for shipments of radioactive materials and waste.

Interstate 15 is the major transportation artery in the Las Vegas area. It is a north–south highway that passes to the south of the NNSS, connecting San Diego, California, to Salt Lake City, Utah, and continuing northward. In southern Nevada, this interstate highway is generally a four-lane divided highway, except in the Las Vegas metropolitan area, where it expands to six lanes. The 53-mile Las Vegas Beltway (also known as Interstate 215 and Clark County Route 215) encircles all but the east side of Las Vegas. Interstate 40 is a major east–west highway approximately 100 miles south of Las Vegas. Interstate 80 and U.S. Route 50 are major east–west highways to the north of the NNSS. Interstate 80 passes about 250 miles north of the NNSS, and U.S. Route 50 passes about 150 miles north.

U.S. Route 95 is a major north–south roadway extending from the Mexican border north to the Canadian border. U.S. Route 95 is a four-lane road between Las Vegas and the interchange with Mercury Highway (the highway leading onto the NNSS) and a two-lane road as it continues north. The interchange of U.S. Route 95 and Interstate 15, also referred to as the "Spaghetti Bowl," has undergone some recent construction to improve traffic flow. U.S. Route 93 is a major north–south, two-lane roadway that enters Nevada south of Lake Mead, and then extends through Las Vegas to the Canadian border, intersecting U.S. Route 50 east of Ely, Nevada, and Interstate 80 near the town of Wells, Nevada. U.S. Route 6 is an east–west, two-lane roadway to the north of the NNSS that links U.S. Routes 93 and 95.

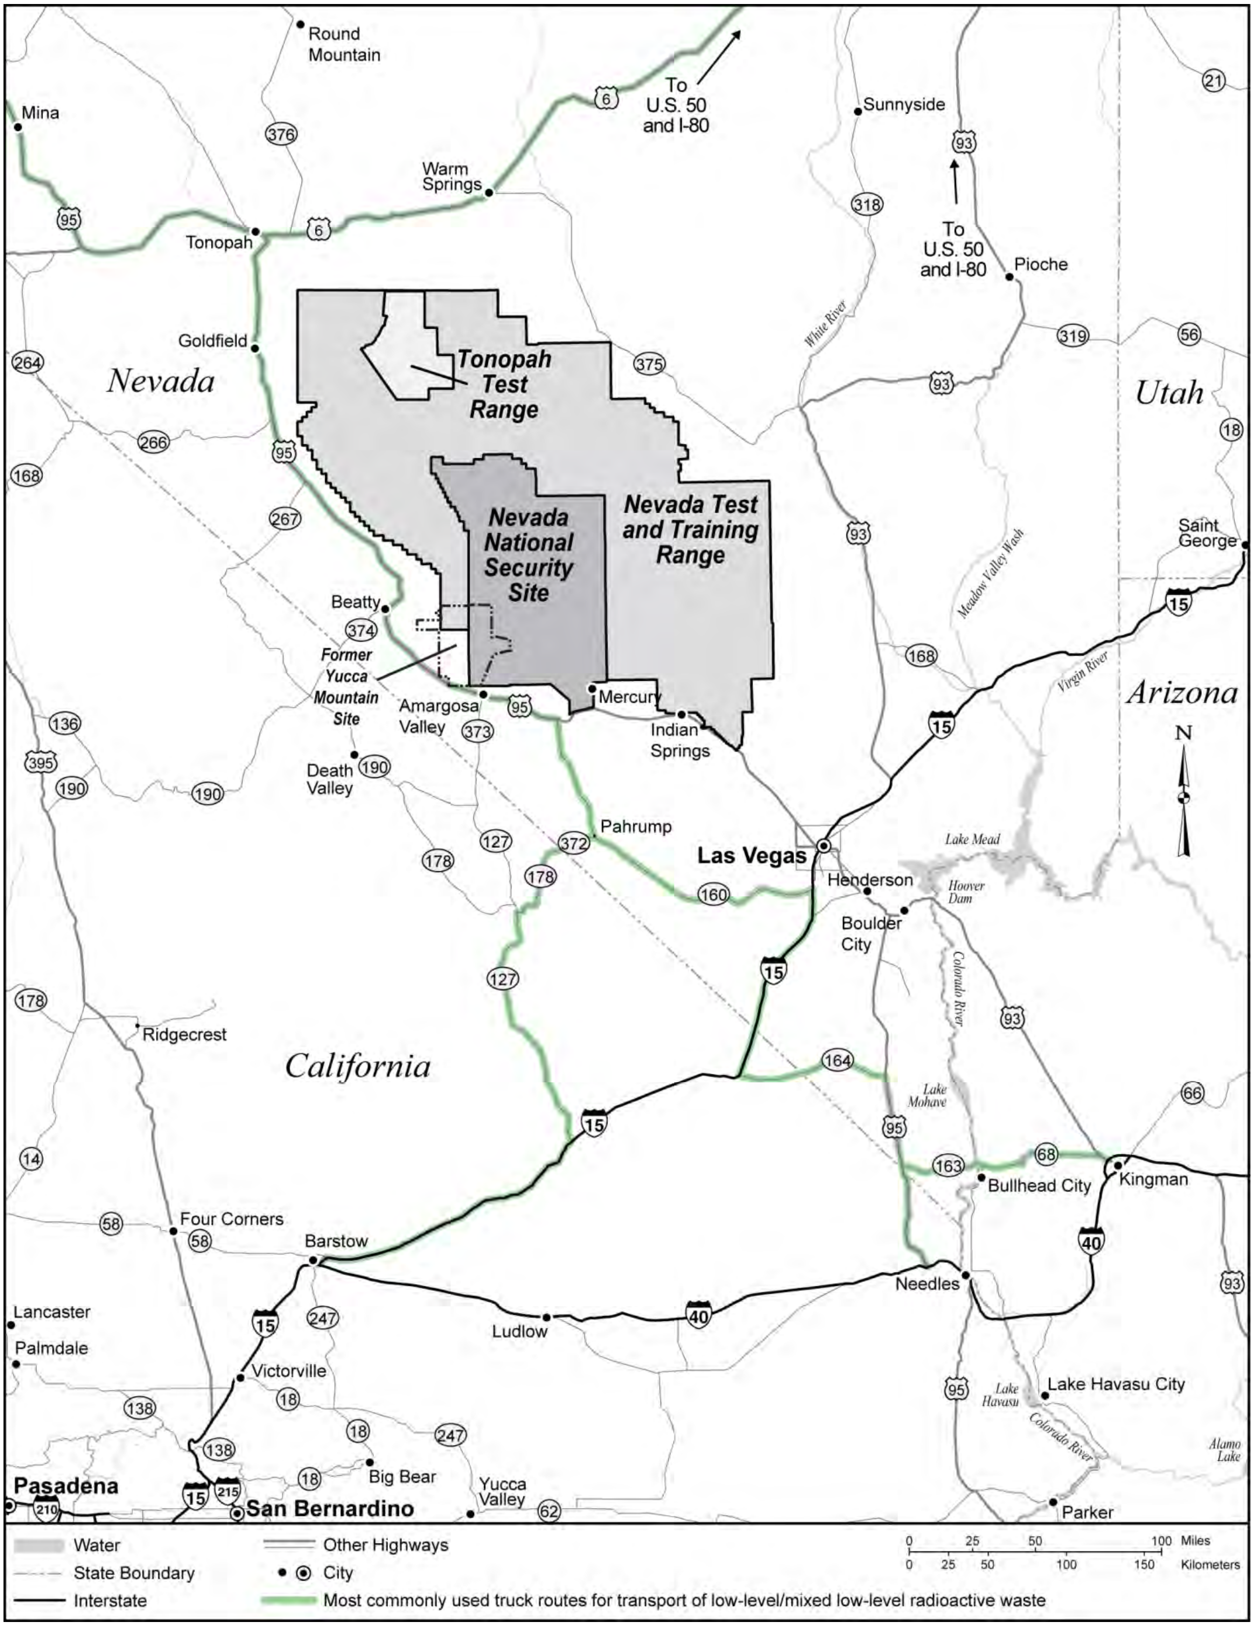

Figure 4–6 Regional Transportation Routes Surrounding the Nevada National Security Site

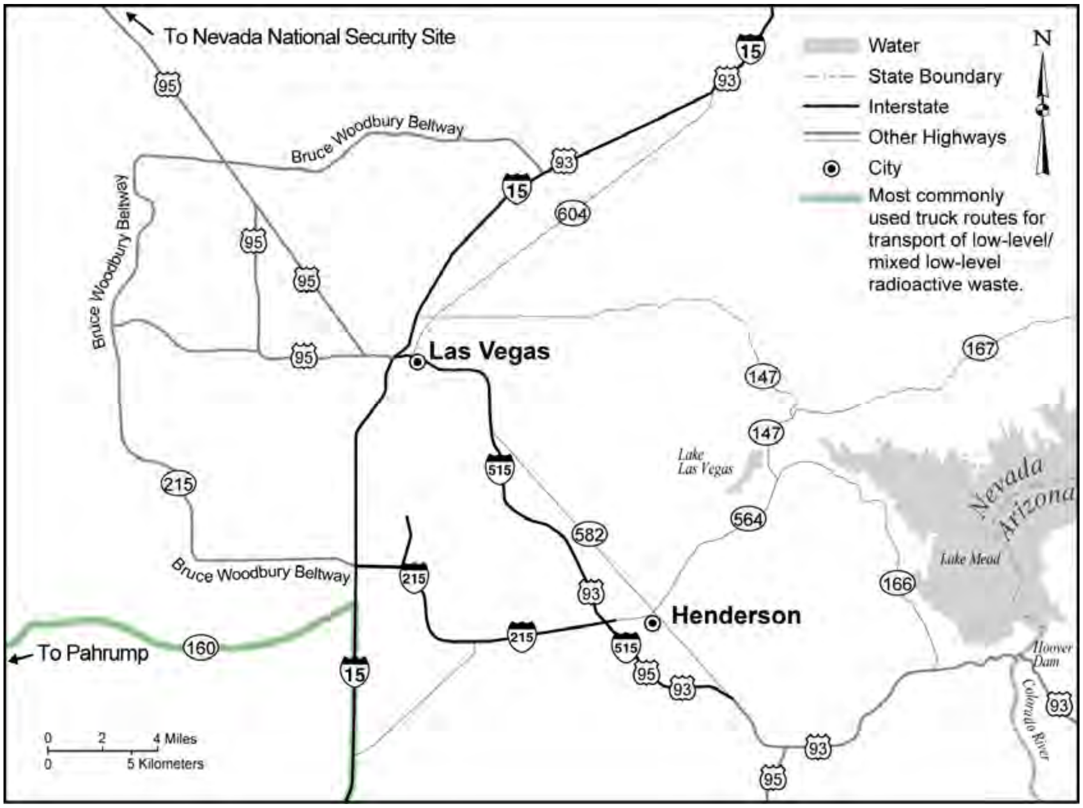

Figure 4–7 Transportation Routes Within the Las Vegas Metropolitan Area

The DOE/NNSA NSO has historically avoided shipping LLW and mixed low-level radioactive waste (MLLW) using the Interstate 15/U.S. Route 95 interchange, based on a verbal commitment from DOE/NNSA. This informal commitment was made at a time when the major highway infrastructure, specifically Interstate 15 and U.S. Route 95, was unable to safely handle the rapidly growing volume of traffic. Since the mid-2000s, U.S. Route 95 has been widened and expanded overpasses have been built to accommodate traffic much more safely. In addition, the Las Vegas Beltway, which extends around approximately three-quarters of the valley, was built at the far edges of Las Vegas to further reduce traffic loads on Interstate 15 and U.S. Route 95. In addition, a bypass bridge has been constructed adjacent to Hoover Dam. This bridge opened to all traffic in October 2010. Trucks transporting waste on Interstate 15 from the south avoid traveling through Las Vegas by taking Nevada State Route 160 to its intersection with U.S. Route 95. Radioactive waste being transported from points north of Las Vegas avoids Interstate 15 in Nevada by using U.S. Route 50, traveling west to U.S. Route 6 and then south on U.S. Route 95. As a result of DOE/NNSA's informal commitment, more-circuitous routes are used for the transport of radioactive materials and wastes. The following combinations of routes are most commonly used to ship radioactive materials and wastes to and from the NNSS (NNSA/NSO 2009a):

- From southern California: Interstate 15 to California State Route 127, to California State Route 127, to California State Route 178, to Nevada State Route 372, to Nevada State Route 160, to U.S. Route 95
- From the east via Interstate 40: Interstate 40 to U.S. Route 95, to Nevada State Route 164, to Interstate 15, to Nevada State Route 160, to U.S. Route 95 or Interstate 40, to U.S. Route 93, to Arizona State Route 68, to Nevada State Route 163, to U.S. Route 95, to Nevada State Route 164, to Interstate 15, to Nevada State Route 160, to U.S. Route 95

- From the east via Interstate 80: Interstate 80 to U.S. Route 93 (Alternate), to U.S. Route 93, to U.S. Route 6, to U.S. Route 95
- From the west via Interstate 80: Interstate 80 to U.S. Route 50 (Alternate), to U.S. Route 50, to U.S. Route 95
- From the east via U.S. Route 50: U.S. Route 50 to U.S. Route 6/50, to U.S. Route 6, to U.S. Route 95

There is no direct railroad access at the NNSS. An east–west rail line passes through northern Nevada, roughly paralleling Interstate 80. Another rail line extends northward through Barstow, California, and through Las Vegas and Caliente, Nevada, into Utah. Further south is a rail line through Arizona and California. Any materials or wastes that are destined for the NNSS and are initially transported by rail are offloaded at an intermodal site in Parker, Arizona, and placed onto trucks to complete the trip (NNSA/NSO 2009a).

Nonradioactive materials transported to and from the NNSS include construction materials and equipment that support site operations. Radioactive materials include source, special nuclear material, or other equipment that support research and development activities. Radioactive wastes transported to or from the NNSS include LLW, MLLW, and transuranic (TRU) waste (NNSA/NSO 2009a). DOE/NNSA received approximately 20,000 truck shipments of LLW and MLLW from 1997 through 2010. TRU waste is no longer transported to the NNSS; however, it is transported from the NNSS to the Waste Isolation Pilot Plant (WIPP) near Carlsbad, New Mexico, for disposal or to Idaho National Laboratory for processing prior to disposal at WIPP (NNSA/NSO 2007).

4.1.3.2.2 Traffic Volumes and Level of Service Analysis

Population and economic growth in Nevada over the past couple of decades have significantly increased demands on the state's major roads and highways, especially in the Las Vegas metropolitan area. In 2007, Nevada was ranked fourth in the Nation in terms of its share of congested urban interstates and other highways or freeways, with 59 percent of the state's urban highways carrying a level of traffic that is likely to result in significant delays during peak travel hours (TRIP 2009). Between 1991 and 2001, daily vehicle miles traveled increased by 53 percent in Clark County, which experienced the greatest amount of population growth of any metropolitan area in the country over this timeframe (NDOT 2003).

Traffic volumes on Mercury Highway at a location 0.2 miles north of the Mercury interchange are available from the Nevada Department of Transportation and are considered representative of the average daily traffic volumes generated by the NNSS because this highway serves as the main roadway onto the site. **Table 4–9** presents the annual average daily traffic volumes for this location from 1999 through 2008. According to these data, traffic volumes moderately increased (by approximately 30 percent) over this 10-year period.

Table 4–9 Annual Average Daily Traffic Volumes, 1999–2008

Location	*1999*	*2000*	*2001*	*2002*	*2003*	*2004*	*2005*	*2006*	*2007*	*2008*
Main Access Road to the Nevada National Security Site	855	1,000	960	960	960	1,250	1,350	1,250	1,100	1,100

Source: NDOT 2008a, Nye County.

The level of service is a measurement typically used by traffic professionals to gauge the adequacy of transportation facilities. All references to levels of service in this section are defined by the *2000 Highway Capacity Manual* published by the Transportation Research Board (TRB 2000). For analysis purposes, the manual defines six categories of level of service that reflect the level of traffic congestion and qualify the operating conditions of an intersection (CMPO 2006). The six levels are given letter designations ranging from "A" to "F," with "A" representing the best operating conditions (free flow, little delay) and "F" the worst (congestion, long delays). For this analysis, the quantitative value

that is computed and used to categorize the roadway (based on average daily traffic volumes and roadway characteristics) is the volume-to-capacity ratio. The level-of-service designations for associated ratio values are presented in **Table 4–10**.

Table 4–10 Level-of-Service and Volume-to-Capacity Criteria

Level of Service	*Operating Conditions*	*Criteria (Volume-to-Capacity)*		
		Freeway [a]	*Multilane Highway* [b]	*Two-Lane Highway* [c]
A	Very short delays; progression is extremely favorable.	0 – 0.35	0 – 0.33	0 – 0.12
B	Progression, short delay times.	0.36 – 0.54	0.34 – 0.50	0.13 – 0.24
C	Number of vehicles stopping is significant, although many still pass through the intersection without being required to stop.	0.55 – 0.77	0.51 – 0.65	0.25 – 0.39
D	Many vehicles must stop, and the proportion of vehicles not stopping declines.	0.78 – 0.93	0.66 – 0.80	0.40 – 0.62
E	Poor progression, and/or high volume-to-capacity ratios; considered by many agencies to be the limit of acceptable delay.	0.94 – 1.00	0.81 – 1.00	0.63 – 1.00
F	Intersection oversaturation; high volume-to-capacity ratios; poor progression and long delays; considered to be unacceptable to most drivers.	> 1.00	> 1.00	> 1.00

[a] A divided highway with full control of access and two or more lanes for the exclusive use of traffic in each direction.
[b] An undivided highway with four or more lanes (includes both directions); may be divided with medians with two-way left-turn lanes.
[c] A two-lane, undivided highway.

Major roadways in the Las Vegas metropolitan area, including segments of Interstate 15, Nevada State Route 160, and U.S. Route 95, typically experience high levels of traffic congestion (TRIP 2007). Many portions of these roadways within the city are operating at a level of service of E or F because of the heavy traffic volumes, especially during peak commuting hours.

Outside the Las Vegas metropolitan area, traffic within the ROI is generally considered light and free flowing. **Table 4–11** shows the daily traffic volumes and volume-to-capacity ratios during peak hour conditions, with corresponding levels of service, on the key regional and local roadways in the ROI. The NNSS contribution to the existing traffic congestion in the Las Vegas metropolitan area is considered minor compared to the city's existing traffic volumes, as presented in Table 4–11. Daily traffic volumes were projected to the year 2020 to provide a baseline comparison for future traffic conditions in terms of the potential impacts discussed in Chapter 5. These projected volumes take into account population growth (assuming approximately an annual traffic volume of 5 percent) (NV State Demographer's Office 2008) and are provided in Table 4–11.

Daily traffic volumes were projected to the year 2020 to provide a baseline comparison for future traffic conditions in terms of the potential impacts discussed in Chapter 5. These projected volumes take into account population growth (assuming an approximate annual traffic volume of 5 percent) (NV State Demographer's Office 2008) and are provided in Table 4–11.

4.1.4 Socioeconomics

4.1.4.1 Region of Influence

The ROI is defined as both the area in which the principal direct and secondary socioeconomic effects of site action are likely to occur and the area expected to be of the most consequence for local jurisdictions. The socioeconomic information presented in this SWEIS discusses current conditions in an ROI comprising Nye and Clark Counties, Nevada. This ROI includes most of the residential distribution of the employees of DOE/NNSA, its contractor personnel, and supporting government agencies.

Within this ROI, there are also several American Indian reservations, tribal enterprises, tribally controlled schools, tribal police departments, and tribal emergency response units (DOE 1996c). The following reservations are located within the designated ROI: Duckwater Shoshone Tribe, Las Vegas Paiute Tribe, Moapa Paiute Tribe, and Yomba Shoshone Tribe. In addition, there are tribes that are located geographically outside the ROI, but are potentially affected by NNSS activities. One of these tribes, the Timbisha Shoshone Tribe, based in Death Valley, California, is located closer to the NNSS than many towns in northern Nye County. As a consequence of this proximity, the people of the Timbisha Shoshone Tribe are a part of the social and economic ROI of the NNSS. For example, students from the Timbisha Shoshone Tribe attend public school in Beatty, Nevada, whereas many Shoshone students from Tacopa, California, attend school in Pahrump, Nevada. Timbisha tribal members both work and shop in Clark and Nye Counties. The Pahrump Paiute Tribe, located in Pahrump Valley, is composed of American Indian people who have been historically recognized by Federal and state agencies to be both qualified to receive services as American Indian people and a group that is seeking Federal acknowledgment.

4.1.4.2 Economic Activity

Economic activity impacts in the ROI of Clark and Nye Counties were analyzed separately for each county. The differences in size, economies, and contributions would produce a misleading analysis if both were analyzed as one aggregate area. For example, in 2008, Nye County accounted for 1.4 percent of total Nevada employment, contrasted with Clark County, which accounted for 71.6 percent of total Nevada employment (USCB 2008b).

Clark County. Between 2000 and 2008, total employment in Clark County increased an average of 13.3 percent annually (USCB 2008b).

Clark County, which covers an area of 7,927 square miles, is located in southern Nevada and is composed of large expanses of unincorporated land and five incorporated cities (DOE 1996c). These are Las Vegas, North Las Vegas, Henderson, Boulder City, and Mesquite. By 2008, total employment in Clark County had increased to 890,221, representing an average annual increase of 5.0 percent from the 2000 figure of 637,339 (USCB 2000, 2008b). Between 2000 and 2008, average annual employment growth in Nevada was 4.1 percent, higher than the United States' average of 1.3 percent.

In 2008, per capita income was $28,138 (USCB 2008b). The unemployment rate in Clark County in 2008 was 6.0 percent, the same as that of the state (6.0 percent) and slightly lower than the national unemployment rate of 6.4 percent. However, as of August 2010, the unemployment rate was 14.7 percent, up 8.7 percent from November 2008.

The largest employment sector in Clark County in 2010 comprised arts, entertainment, recreation, accommodation, and food services (28 percent) (USCB 2010a). Educational services, health care, and social assistance accounted for 12.5 percent of employment. Retail trade; professional, scientific, and management; construction; and finance, insurance, and real estate accounted for 11.2 percent, 10.8 percent, 9.4 percent, and 6.8 percent of employment, respectively. The remaining 20.5 percent was divided among the following sectors: transportation, warehousing, and utilities (4.8 percent); other services (4.2 percent); public administration (3.9 percent); manufacturing (3.4 percent); wholesale trade (2.2 percent); information (1.7 percent); and agricultural, forestry, fishing and hunting, and mining (0.3 percent). Employers of the largest workforces in the region are listed in **Table 4–12**.

Nye County. Nye County, located northwest of Clark County, covers an area of approximately 18,064 square miles (46,786 square kilometers) (DOE 1996c, 4-54). The Federal Government controls 93 percent of the land area. Mining, Federal installations, tourist and recreation attractions, and grazing allotments all occur largely on public land in Nye County.

Nye County comprises communities that are widely separated by distance, each with a distinct and independent economic base (DOE 1996c, 4-54). The NNSS and the TTR have been operating in Nye County for many decades. Federal facilities have provided employment for Nye County residents and a minor amount of procurement for local business. The economy in each community depends on different private companies and, in some cases, different industries. Because the communities are widely separated by distance, economic links between communities are limited. Metropolitan economies generally absorb a significant portion of business and residential purchases. Rural economies, such as Nye County, however, often leak large portions of both business and residential purchases to larger communities, resulting in economic loss and a different set of economic development needs from those of more-urban areas.

Nye County's strategy to increase economic development opportunities from Federal facilities is to engage the appropriate divisions of DOE/NNSA in a formal set of interactions (DOE 1996c, 4-54). Nye County has identified the need for a qualified workforce and business base to fulfill Federal requirements. To this end, Nye County has developed programs to inform local businesses of Federal procurement opportunities and continuing formal and informal interaction with appropriate Federal agencies. One example of this proactive approach is Nye County's status as a cooperating agency in the development of this *NNSS SWEIS*.

Between 2000 and 2008, total employment in Nye County increased an average of 4.3 percent annually (USCB 2000, 2008b). In 2008, per capita income in Nye County was $21,071 (USCB 2008b). The unemployment rate for Nye County in 2008 was 5 percent, lower than the state's (6 percent) and the Nation's (6.4 percent). However, as of August 2010, the unemployment rate was 17.2 percent, up 12.2 percent from 2008.

The largest employment sector in Nye County in 2010 comprised arts, entertainment, recreation, accommodation, and food services (19.0 percent) (USCB 2010b). Educational services, health care, and social assistance accounted for 15.1 percent. Construction accounted for 13.9 percent. Retail trade; agriculture, forestry, fishing and hunting, and mining; and professional, scientific, and management accounted for 10.4 percent, 8 percent, and 7.4 percent, respectively. The remaining 22.1 percent was divided among the following sectors: transportation, warehousing, and utilities (6.3 percent); public administration (6.3 percent); finance, insurance, and real estate (4.3 percent); other services (4.2 percent); manufacturing (2.2 percent); information (1.8 percent); and wholesale trade (1.3 percent). Employers of the largest workforces in the region are listed in **Table 4–13**.

4.1.4.3 Population

Clark County. In 2008, Clark County's total population was 1,821,359, an increase of 445,594 individuals, or approximately 32.4 percent, from 1,375,765 in 2000 (USCB 2000, 2008b). This increase was equivalent to an annual average growth of approximately 4.0 percent for the county over the 2000 to 2008 period. By comparison, the average annual growth was approximately 3.4 percent for Nevada and nearly 1 percent for the United States between 2000 and 2008. Most recently, however, there has been a small decrease in population. Clark County decreased 0.8 percent from a high of 1,967,716 in mid-2008 to 1,952,040 in mid-2009 (NSBDC 2010).

The population of the city of Las Vegas totaled 564,484 in 2008, an increase of 18 percent from the 2000 level of 478,434 (USCB 2000, 2008b). The average annual growth of 2.2 percent for the 2000 to 2008 period was below the county level. In 2000, the city of Las Vegas accounted for 34.8 percent of Clark County's population; in 2008, the city accounted for 31.0 percent of the total population in Clark County.

The population of the city of North Las Vegas was 115,488 in 2008, an increase of 78.9 percent from the 2000 level (USCB 2000, 2008b). The average annual growth of 9.9 percent for the 2000 to 2008 period was well above the county level. In 2008, the city of North Las Vegas accounted for 11.3 percent of Clark County's population, an increase from 2000, when the city accounted for 8.4 percent of the total population in Clark County. These data indicate a trend toward outward expansion of the Las Vegas metropolitan area.

Nye County. In 2008, the population for Nye County was 43,555, an increase of 11,070, or 34.1 percent, from the 2000 level (USCB 2000, 2008b). This overall increase is equivalent to an annual average growth for Nye County of about 4.3 percent over the 2000 to 2008 period; the average annual population growth in Nevada was about 3.4 percent, and in the United States, 1 percent. Most recently, however, there has been a small decrease in population. Nye County decreased 2.1 percent from a high of 47,370 in mid-2008 to 46,360 in mid-2009 (NSBDC 2010).

Pahrump is the largest and most rapidly growing community in Nye County. The 2008 population for the town of Pahrump was 36,390, up 47.7 percent from 24,631 in 2000 (USCB 2000, 2008b). The average annual growth was 6.0 percent for the 2000 to 2008 period. In 2008, Pahrump accounted for 83.5 percent of the population in Nye County.

The 2000 (2008 population data were not available) population in the town of Tonopah was 2,627, down from 3,810 in 1990 (USCB 2000, 2008b). In 2000, Tonopah accounted for 23.7 percent of the population in Nye County.

The 2000 (2008 population data were not available) population in Beatty was 1,154, down from 1,652 in 1990 (USCB 2000, 2008b). In 2008, Beatty accounted for only 2.6 percent of the population in Nye County.

4.1.4.4 Housing

Clark County. In 2008, the housing stock in Clark County consisted of 784,892 units, an increase of 234,113 units, or 42.5 percent, over the 2000 total of 550,799 (USCB 2000, 2008b). Between 2000 and 2008, Clark County housing unit vacancies increased from 47,546 units, or 8.5 percent of the housing stock, in 2000 to 208,275 vacant units, or 13.8 percent of the housing stock, in 2008. According to the Case-Shiller Home Price Index, single-family home prices in Las Vegas were down 28 percent in 2009, and off 46 percent from the peak in August 2006. Prices continue to fall because of an excess supply of housing. According to an April 2009 analysis, the number of excess single-family homes is over 7,000. Multifamily housing, condominiums, and townhouses are also overbuilt, with excess supply topping 7,800 units. Others estimate an excess supply of nearly 35,000 units (UNLV 2009).

An excess supply of residential real estate has caused permitting activity to come to a standstill (UNLV 2009). The number of building permits issued annually in Clark County rose sharply in the mid-2000s, with a peak of 39,015 permits issued in 2005. In 2008, the number of permits dropped, with only 24,596 issued. Monthly permitting from January to October 2009 averaged 508 units per month. Building permits issued in a given year may not represent the actual number of units built; however, they indicate the level of new residential development in the county.

In 2008, the housing stock in the city of Las Vegas consisted of 236,730 units, an increase of 46,006, or 24.1 percent, over the 2000 total of 190,724 (USCB 2000, 2008b). Between 2000 and 2008, housing unit vacancies in the city of Las Vegas increased from 13,974 units, or 7.3 percent of the housing stock, to 29,005 units, or 12.3 percent of the housing stock.

Nye County. In 2008, the housing stock in Nye County consisted of 16,592 units, an increase of 658 units, or 4.1 percent, over the 2000 total of 15,934 (USCB 2000, 2008b). Between 2000 and 2008, Nye County housing unit vacancies increased from 2,625 units, or 16.5 percent of the housing stock, to 3,202 units, or 19.3 percent of the housing stock. The vacancy rate does not reflect substandard units or houses held for occasional and recreational use.

4.1.4.5 Public Finance

The financial characteristics of Clark and Nye Counties are presented in this section. For many jurisdictions discussed, ad valorem taxes are a major source of revenue. These are taxes levied on the assessed valuation of real property. "Assessed valuation" is a valuation set upon real estate as a basis for levying taxes. Thirty-five percent of the taxable value placed on real property is used as the basis for levying property taxes in most Nevada jurisdictions.

Nevada has one of the most liberal tax structures in the Nation from a tax planning perspective. Nevada has no personal state income tax, unitary tax, corporate income tax, inventory tax, estate and/or gift tax, franchise tax, or inheritance tax.

Clark County. Clark County, incorporated in 1909, is governed by a Board of County Commissioners and a county manager (DOE 1996c). The seven members of the board are elected by each district to serve staggered four-year terms. Within the county are 5 incorporated cities, including Las Vegas, which is the county seat, and 13 unincorporated towns. County services include the county recorder, assessor, treasurer, social services, airport, hospital, and criminal justice. In addition, the county provides a full range of local services, such as fire, police, road maintenance and construction, animal control, building inspection, and water and sewage systems to county residents living in unincorporated areas.

In Clark County, the sales tax rate is 8.100 percent (NV Energy 2010a). The 2009 to 2010 average countywide property tax rate was 3.1849 percent. The formula for calculating real property tax is as follows:

$$\text{Taxable Value} \times 0.35 = \text{Assessed Value}$$
$$\text{Assessed Value} \times \text{Tax Rate} = \text{Total Real Property Tax}$$

In 2008, the county's primary revenue sources for government activities were ad valorem taxes ($799,257,814), consolidated taxes ($489,752,501), and sales and use taxes ($265,477,538) (Clark County 2008). These three revenue sources accounted for 25 percent, 15 percent, and 8 percent, respectively, or a total of 48 percent, of government activities revenues. The remaining 52 percent of revenue in Clark County came from interest income, franchise fees, fuel taxes, motor vehicle privilege taxes, room taxes, and other taxes. The county's total expenses were $4,205,515,941. Government activities constituted $2,506,782,626 of total expenses; the largest functional expenses were public safety ($1,082,216,327) and public works ($467,845,743). Business-type activities contributed $1,698,733,315 to total expenses; the largest components were hospital ($589,797,799), water ($431,929,066), and airport ($495,754,402).

Nye County. Nye County is governed by a Board of County Commissioners and a county manager. In Nye County, the sales tax rate is 7.100 percent (NV Energy 2010b). The 2009 to 2010 average countywide property tax rate was 3.1621 percent. The formula for calculating real property tax is the same as that for Clark County.

In 2008, the county's primary revenue sources for government activities were intergovernmental resources ($37,626,930), property taxes ($20,186,445), and miscellaneous ($8,268,727) (Nye County School District 2009). The county's total expenses were $70,843,657. Government activities constituted $20,347,092 of total expenses; the largest functional expenses were public safety ($18,861,475), capital projects ($9,123,301), and public works ($8,287,225).

4.1.4.6 Public Services

The key public services examined in this analysis are public education, police protection, fire protection, and health care. Providers of these services in the ROI are public school districts, police and fire departments, and hospitals and clinics. Existing conditions for each major public service are determined by student-to-teacher ratios at primary and secondary public schools and by the ratio of employees (sworn officers, professional firefighters, and health care personnel) to the serviced population.

4.1.4.6.1 Public Education

Higher Education. The University of Nevada, Las Vegas, was officially established in 1957 (UNLV 2010). More than 220 undergraduate, masters, and doctoral degree programs are offered to a student body of 28,605. The university has on-campus research facilities, including the Desert Biology Research Center, Center for Business and Economic Research, Nuclear Waste Transportation Research Center, and Parent/Family Wellness Center. The Desert Research Institute, a separate division of the University and Community College System of Nevada, was founded in 1959 as an international center for environmental research. The University of Nevada Medical School trains medical students and resident physicians at the University Medical Center, where the school is located. The Harry Reid Center is an environmental studies organization located on campus and operated by the university.

Clark County School District. The Clark County School District includes all of Clark County, which covers 7,910 square miles and includes the metropolitan Las Vegas area, all outlying communities, and rural areas (Clark County School District 2009). During the 2009–2010 school year, the district operated 350 schools: 212 elementary schools, 58 middle schools, 46 high schools, 25 alternative schools, and 9 special needs schools. The district operates one of the Nation's largest school construction and modernization programs. In fall 2009, the district opened 3 new elementary schools and 3 high schools. The student-to-teacher ratio is 21:1.

Nye County School District. During the 2009–2010 school year, the district operated 18 schools: 7 elementary schools, 3 elementary/middle schools, 1 middle school, 1 middle school/high school, 3 high schools; 1 combined K–12 (kindergarten through 12th grade) school; 1 combined 6th–12th grade school; and one tribally controlled school that is kindergarten through 8th grade (Nye County School District 2009). Some 426 certified personnel were employed by the district in the 2009–2010 school year, and the district had a 2008 enrollment of 6,348 students. The approximate average student-to-teacher ratio for the Nye County School District was 18.6:1.

American Indian Education. Under Federal and tribal law, American Indian children can be educated in tribally controlled, federally certified schools located on American Indian reservations (DOE 1996c). Federal funds are available for the education of American Indian children through the Indian Education Act. Compensation from the Federal Government is provided to any school district that enters into a cooperative agreement with federally recognized tribes regarding a public, private, or tribally controlled school.

In Nye County, there is one tribally controlled elementary school, which is operated by the Duckwater Shoshone Tribe. In 2009, the school had 16 students enrolled from preschool to 8th grade (Nye County School District 2009).

A tribally operated Head Start Program is located on the Moapa Paiute Indian Reservation (DOE 1996c). The program is open to all eligible preschool students, including both American Indian and non–American Indian students from nearby communities. This program is funded through the Inter-Tribal Council of Nevada, which operates Head Start Programs elsewhere in Nevada. American Indian students also attend public schools that are not tribally controlled.

4.1.4.6.2 Police Protection

Police protection in the ROI is provided by the Las Vegas Metropolitan Police Department, the North Las Vegas Police Department, and the Nye County Sheriff's Office, with stations at Tonopah, Pahrump, Beatty, Mercury, and Amargosa Valley. Each station provides law enforcement services in conjunction with other law enforcement agencies, including the Nevada Highway Patrol.

Las Vegas Metropolitan Police Department. The department is headed by the elected sheriff of Clark County. In addition to patrolling the city of Las Vegas, the department provides service for rural areas of the county. The department maintains 3,542 sworn personnel for a level of service of 6.27 personnel per 1,000 people (Castle 2010). There are 15 training personnel and 8 civilian crime prevention specialists, which include community relations, crime prevention, and Drug Abuse Resistance Education (DARE) officers. Some 2,200 vehicles (650 patrol cars), including four-wheel vehicles, motorcycles, and search and rescue vehicles, are used by the department. The holding facility capacity for the Clark County Detention Center is 2,984; the capacity of the Las Vegas Detention Center, operated by the City of Las Vegas, is 1,200.

North Las Vegas Police Department. The North Las Vegas Police Department was founded in 1946 with an original jurisdiction covering almost 4 square miles and approximately 3,000 people (NLVPD 2010). It now services 100.44 square miles and a population of approximately 221,003. The North Las Vegas Police Department, which consists of the police department and the detention center, currently employs a total of 739 employees, including 458 commissioned personnel and 281 civilian personnel. The commissioned staff consists of 310 police personnel and 148 detention personnel. The civilian staff consists of 265 full-time employees and 16 part-time employees, as well as 123 crossing guards employed on a part-time basis (whose numbers are not included in total of civilian personnel). Statistics show that there are 1.33 officers per 1,000 residents.

Nye County Sheriff's Office. The Nye County Sheriff's Office, whose main office is located in Tonopah, serves the entire county and supports substations located in Pahrump, Mercury, Amargosa Valley, Beatty, Smoky Valley, and Gabbs (Becht 2010).

There are 87 total patrol personnel, including administrative staff, 4 DARE/school resource officers, 3 assistant sheriffs, and 1 person specifically assigned to training (Becht 2010). In addition, there are approximately 106 vehicles, including detention transport vehicles and other specialty vehicles (SWAT [special weapons and tactics], Mobile Command Post, etc.)

Based on population estimates, current staffing levels are roughly 1.15 officers per 1,000 members of the population (Becht 2010).

There are 7 sworn detention personnel and 151 bed spaces for prisoners (Becht 2010).

Onsite Law Enforcement. Civilian law enforcement at the NNSS is provided under a contract with the Nye County Sheriff's Department. Officers work out of a substation located in Mercury. Nellis Air Force Base Security Forces respond to RSL when called. The Police Services portion of the current Inter-Service Support Agreement between DOE/NNSA and Nellis Air Force Base, dated January 2006, reads, "In the event of an emergency, Nellis Security Forces response will be limited to securing the

exterior of the facility only." Law enforcement for the TTR is also provided by the Nye County Sheriff's Department, and law enforcement at NLVF is provided by the North Las Vegas Police Department.

Onsite Security. Security enforcement is the responsibility of WSI, a private contractor. The NNSS is a controlled-access area and WSI provides site-wide protective services according to the guidelines established by the DOE/NNSA NSO.

4.1.4.6.3 Fire Protection

Fire protection for the ROI is provided by the Clark County Fire Department, Las Vegas Fire Department, and several volunteer fire departments in Nye County (including Tonopah, Pahrump, Beatty, and Amargosa Valley).

Clark County Fire Department. The Clark County Fire Department is divided into two sections: urban and rural (DOE 1996c). The urban fire stations are located in areas that are not cities and do not have their own fire departments. The rural fire stations are manned by volunteer firefighters and are discussed in the subsection on volunteer fire departments below.

In 2008, the Clark County Fire Department provided service to a population of 861,546 in an area covering 7,420 square miles (CCFD 2008). The Clark County Fire Department operates out of 27 paid fire stations and 13 volunteer fire stations. With 650 paid firefighters, 350 volunteer firefighters, 58 inspectors/investigators, and 50 support employees, the department provides a level of service equal to 1.28 firefighters per 1,000 people.

Las Vegas Fire and Rescue. Las Vegas Fire and Rescue has 18 fire stations that protect an area of 133.2 square miles and a population of 607,876 residents (Szymanski 2010). The department uses 19 engines, 6 ladder trucks, 20 emergency medical service rescue units, 3 battalion chief units, 1 heavy rescue unit, 1 hazardous material unit, 1 Chemical-Biological-Radiological-Explosives-Nuclear unit, 1 air/light resource unit, 1 3,000-gallon water tender, and 1 mobile command post. The department has 681 employees, including 12 battalion chiefs, 87 captains, 91 engineers, 126 firefighter/paramedics, and 179 firefighters. Last year, the department responded to nearly 85,000 incidents. Las Vegas Fire and Rescue is both an accredited and an ISO [International Organization for Standardization] Class One department.

City of North Las Vegas Fire Department. The North Las Vegas Fire Department is staffed by 234 uniformed and civilian employees who serve in divisions such as Administration, Fire Operations, Homeland Security and Special Operations, Business and Support Services, Community Life Safety, and Code Enforcement (NLVFD 2010). Personnel provide emergency services response, advanced life support, emergency management, department training and record-keeping, fire prevention, inspection, fire protection enforcement, fire investigations, code compliance, public information, and public education, as well as administrative services. The North Las Vegas Fire Department provides all-hazard 24-hour emergency response service from eight fire stations using seven engines, two trucks, six advanced life-support rescue units, and two battalion chief units. The department provides fire engineering and inspection services, along with a complete public education program. All "first-out" emergency vehicles provide medical services at the advanced-care (paramedic) level.

In 2007, the North Las Vegas Fire Department responded to 23,679 emergency incidents, resulting in 29,009 unit responses, and conducted 3,816 plan reviews, 10,930 fire and business inspections, and 122 fire investigations (NLVFD 2010). Public education activities reached over 62,000 citizens at 226 public events. The Tactical Medic Program started operations on April 18, 2007, and made 68 deployments in 2007 and 54 deployments in the first 4 months of 2008, all in support of the North Las Vegas Police Department. Additionally, 30 members of the North Las Vegas Fire Department are active participants in the Federal Emergency Management Agency's Nevada Urban Search and Rescue Task Force 1. Technical rescue and hazardous material response programs are currently under development.

Volunteer Fire Departments. Nye County's main hub for coordinating volunteer fire protection is Station 51, located in Pahrump, Nevada. Station 51 is the home of a quick response fire/HAZMAT [hazardous materials]/EMS [emergency medical services] station, and it also functions as the Southern Emergency Operations Center for the southern part of the county. Station 51 consists of 3 paid staff and approximately 20 volunteers. Equipment for Station 51 consists of Engine 51, Engine 52, Brush 51, Rescue 51, HAZMAT 51, Tender 51, Medic 51, Command 51, Command 52, two quads, a trailer containing decontamination supplies, a mass casualty trailer, a mobile command post, and a disaster supplies bus.

Station 11 is located in Tonopah, Nevada, and is the base for the Tonopah Volunteer Fire Department, Tonopah Volunteer Ambulance Service, and Emergency Services Northern Office and serves as the Emergency Operations Center for the northern part of the county. Station 11's volunteer fire department consists of approximately 20 volunteers and no paid staff. Equipment for Station 11 consists of Engine 11, Engine 12, Rescue 11, Ladder 11, Command 11, and a four-by-four utility terrain vehicle with a patient rescue trailer. The Tonopah Volunteer Ambulance Service, an intermediate-level service, has approximately 15 volunteers, and its equipment consists of Medic 11, Medic 12, a mass casualty trailer, and a disaster response trailer. The Emergency Services Department has 2 paid staff members at this location.

Station 21 is located in Round Mountain/Smoky Valley, Nevada, and is the base for the Round Mountain Volunteer Fire Department. A staff of approximately 14 volunteers and 1 paid member respond to fire and rescue calls from this station. Station 21 is also the home of the Northern HAZMAT Team. Equipment includes Engine 21, Engine 22, HAZMAT 21, Rescue 21, Command 21, and a trailer containing decontamination supplies. The Smoky Valley Volunteer Ambulance Service is an intermediate-level service with approximately 16 volunteers. Equipment includes Medic 21 and Medic 22.

Station 31 is located in Beatty, Nevada, and is the base for the Beatty Volunteer Fire Department and Beatty Volunteer Ambulance Service. Approximately 12 volunteers serve on the fire department and there is 1 paid station superintendent/responder. Equipment includes Engine 31, Engine 32, Rescue 31, Tender 31, Ladder 31, a quad, and Command 31. The Beatty Volunteer Ambulance Service consists of approximately 10 volunteers, who respond at an intermediate level. Equipment includes Medic 31, Medic 32, a mass casualty trailer, and a Point of Distribution trailer.

Station 61 is located in Manhattan, Nevada, and is the base for the Manhattan Volunteer Fire Department. Approximately eight volunteers serve on the department. Equipment includes Engine 61 and Rescue 61.

Station 71 is located in Gabbs, Nevada, and is the base for the Gabbs Volunteer Fire Department and the Gabbs Volunteer Ambulance Service. Approximately six volunteers serve on the fire department. Equipment includes Engine 71 and Rescue 71. The Ambulance Service has approximately eight volunteers and the equipment includes Medic 71 and Medic 72.

Station 81 is located in Belmont, Nevada, and is the base for the Belmont Community Emergency Response Team (CERT). Approximately 10 volunteers serve on the CERT team. Equipment includes CERT 81, CERT 82, and a mobile fire attack trailer.

Station 91 is located in Duckwater/Currant Creek, Nevada, and is the base for the volunteer fire department. Approximately eight volunteers serve on the fire department. Equipment includes Engine 91, Command 91, and a mobile fire attack trailer.

Each station has dedicated mutual aid areas and Station 51 provides mutual aid to Southern Inyo County in California, Clark County, BLM, USFWS, the NNSS, throughout Nye County, and anywhere dispatched, as determined by the director of emergency services. The NNSS Fire/HAZMAT/EMS Team provides mutual aid to Nye County in Crystal, Nevada, and along the transportation corridor leading to Amargosa.

The Pahrump Valley Fire Department is a combination career and volunteer department with 22 career positions (RCI 2005). According to a 2004 study, 22 volunteers were reported at the time of the assessment (RCI 2005). Seven career firefighters are on duty each day. Four fire stations are associated with the Pahrump Valley Volunteer Fire Department. Two fire stations are staffed on a 24-hour basis with career personnel; one is manned by a combination of career and volunteer personnel; and one is manned by volunteers and houses reserve equipment.

Equipment consists of one command car, four engines (plus one reserve engine), six medics, three tenders, two brushes, one tower ladder, one rescue unit, two attack units, and one hazardous material response unit.

Onsite Fire Protection. The fire protection capacity of the NNSS is structured to accommodate current mission requirements, and a self-contained firefighting department is responsible for suppression and prevention. Other services include rescue, hazardous material response, training of fire personnel, fire prevention inspection, installation of all fire extinguishers at the NNSS, and fire-prevention awareness programs. NNSS Fire and Rescue operates out of two fire stations; one is in Mercury, and a newly constructed station in Area 6 provides rapid response to emergencies in the forward areas of the NNSS (DOE 2009f).

4.1.4.6.4 Health Care

Health care services within the ROI include 15 full-service hospitals located in Clark and Nye Counties. These facilities provide a wide array of medical services, including physical examinations; treatment of illness; emergency, intensive, and coronary care; internal medicine; x-ray and laboratory; infertility, obstetrics, and gynecology; neonatal intensive care; inpatient and outpatient surgery; pharmaceuticals; optometry; dental; respiratory therapy; and skilled nursing and long-term care. Services provided by three special service hospitals include psychiatric, chemical dependency, and mental health treatment. In addition, the Clark County Health District provides public health services and coordinates the EMS system. The following information pertains to hospitals and medical facilities within the ROI.

Boulder City Hospital is a nonprofit, 20-bed acute-care critical access hospital and a 47-bed skilled nursing facility located in Boulder City, Nevada (Boulder City Hospital 2010). It has a medical staff of nearly 200 physicians, representing nearly 26 specialties.

Centennial Hills Hospital and Medical Center opened in January 2008 and is located in northwest Las Vegas. It provides 171 beds, including a 41-bed Emergency Department, 25-bed Women's Center, 6-bed Level II Nursery, 32-bed Intensive Care Unit, and 108 medical/surgical beds. It also provides a wide range of medical services and procedures (Centennial Hills Hospital 2011).

Mountainview Hospital is a short-term hospital located in Las Vegas, Nevada (NV Energy 2010c). It has 235 beds and two specialty units: adult and pediatric (191 beds) and intensive care (36 beds).

Desert Springs Hospital is a 351-bed, acute-care facility located in southeast Las Vegas that has been providing for the health care needs of Las Vegas residents since 1971 (NV Energy 2010c). The hospital provides 24-hour emergency services, including a fast-track area in the emergency room to treat less-acute patients and comprehensive cardiology services. New facilities include a maternity center featuring labor, delivery, recovery, and postpartum suites; a third catheterization laboratory; and a 107,000-square-foot medical office building and outpatient surgery facility.

Lake Mead Hospital Medical Center has served the North Las Vegas Community since 1960 (NV Energy 2010c). The facility now has 198 licensed beds. The medical staff consists of over 800 specialists and primary care physicians.

Mike O'Callaghan Federal Hospital is a joint venture between the U.S. Department of Veterans Affairs and DoD (99th Medical Group Hospital, Nellis Air Force Base) (NV Energy 2010c). It is situated on a 49-acre site adjacent to Nellis Air Force Base, approximately 11 miles northeast of downtown Las Vegas.

The facility has 114 beds, 52 of which are designated for Department of Veterans Affairs use: 36 for medical/surgical, 14 for psychiatric, and 2 for intensive care/coronary care.

St. Rose Dominican Hospital is a system of three acute-care facilities in southern Nevada: the Rose de Lima Campus in Henderson (opened in 1947), the Siena Campus in Henderson (opened in 2000), and the San Martín Campus in southwest Las Vegas (opened in 2006). Combined, the three campuses offer more than 500 patient beds and have a collective staff of nearly 3,000 employees.

Southern Hills Hospital, located in southwest Las Vegas and opened in 2004, is a full-service hospital. There are a total of 139 beds. Services include an accredited Chest Pain Center, certified Primary Stroke Center, the Nevada Neurosciences Institute, children's services, Emergency Department, and maternity services (Southern Hills Hospital 2011).

Spring Valley Hospital Medical Center opened in October 2003 and is a full-service acute care facility. It has 231 beds, including 105 medical/surgical beds, 22 rehabilitation beds, 18 intensive care beds, 21 intermediate care beds, 12 chest pain observations beds, 28 women's center beds, 9 Level II nursery beds, and 18 Level III Neonatal Intensive Care Unit beds (Spring Valley Hospital 2011).

Summerlin Hospital Medical Center features 169 licensed beds, all of which are private patient rooms (NV Energy 2010c). The acute-care facility has adjoining facilities for outpatient services such as surgery, a laboratory, and radiology, as well as two medical office buildings.

Sunrise Hospital and Medical Center is located in Las Vegas (Healthgrades 2010). This short-term hospital has 610 beds and three specialty units, including adult and pediatric (436 beds), intensive care (92 beds), and surgical intensive care (10 beds).

University Medical Center, which is affiliated with the University of Nevada School of Medicine, is the premier teaching hospital in the state. The medical center serves the medical needs of southern Nevada and parts of California, Utah, and Arizona, as well as those of millions of visitors to Las Vegas.

Valley Hospital Medical Center, founded in 1972, is a licensed, 409-bed, full-service acute-care hospital located in the heart of Las Vegas that serves the greater Las Vegas area and the surrounding rural communities of southern Nevada (NV Energy 2010c).

The Desert View Regional Medical Center, located in Pahrump, Nevada, opened April 27, 2006. It is a short-term acute-care hospital with 24 private rooms, expandable to 50 beds, a 24-hour emergency room, two surgical suites; diagnostic imaging; physical therapy; delivery suites and a nursery; a diagnostic sleep center; and a decontamination room.

Nye Region Medical Center is located in Tonopah (NV Energy 2010c). It has 44 beds, one physician, and three nurses.

Onsite Health Care. An eight-bed dispensary in Mercury serves as a clinic for the NNSS. Facilities include rooms for emergency care; examination and treatment; and x-ray and associated darkroom equipment, offices, and storage. First-aid stations are located near field activities for quick treatment of personnel.

4.1.5 Geology and Soils

This section presents an analysis of the regional geology and soil environment, including descriptions of the physiography, stratigraphy, structural geology, seismicity, volcanism, and mineralogy of the NNSS and the surrounding region. Although construction, facility operations, and surface and subsurface tests have reworked localized areas of soils and bedrock, the condition of the regional geology and soils remains largely unchanged. This section provides an updated review of the geology and soils in the affected environment as presented in Chapter 4, Section 4.1.4, of the *1996 NTS EIS*.

Beginning in 1951, shortly after the establishment of the NNSS, geologic studies were commissioned for the site. Initially used to support nuclear testing in the 1950s and 1960s, the surface and subsurface

geologic surveys were gradually expanded and then compiled into a series of databases now used to create a comprehensive knowledge of the region. Geologic mapping, site-wide geophysical surveys, exploratory drilling and testing, fault mapping, and detailed geotechnical studies have all contributed to the wide-ranging knowledge of the area's geology. The results of the military and academic investigations have been described in a Geological Society of America Memoir in 1968 (Eckel 1968), and updated with new groundwater studies (Laczniak et al. 1996; Sweetkind et al. 2010), and geology reports on the Yucca Mountain area (Stuckless and Levich 2007). The Annual NNSS Environmental Report summarizes the general geologic knowledge at the site, which has remained consistent from 2008 through 2011 (DOE/NV 2009d, 2011). Because of continuous investigations, the NNSS is considered geologically one of the most well-researched regions in the United States (DOE 1996a).

4.1.5.1 Physiography

The NNSS is located in the southern part of the Great Basin, the northernmost subprovince of the Basin and Range Physiographic Province. This region is characterized by north–south-trending, linear mountain ranges that are separated by broad sediment-filled basins. The mountain ranges, formed by tilted, fault-bounded blocks of bedrock, can extend as much as 50 miles in length and 15 miles in width. Extensive fault zones, including the Walker Lane shear zone, its subsidiary, the Las Vegas shear zone, and the southwestern Nevada volcanic field, also affect the area topography. The Walker Lane shear zone transverses the TTR from the north to the southeast and gradually merges with the Las Vegas shear zone, which borders the southern edge of the NNSS (Faulds and Henry 2008). The flat uplands of the northwest NNSS, including the Pahute and Rainier Mesas, are composed of volcanic units of the southwestern Nevada volcanic field. Vertical relief at the NNSS varies from 3,280 feet above sea level at Frenchman Flat and Jackass Flats to 7,216 and 7,675 feet above sea level on Pahute and Rainier Mesas, respectively.

The Great Basin Subprovince is an internally draining basin with no outlet to the Pacific Ocean. Two deserts, the Mojave Desert and the Great Basin Desert, are located within the Great Basin Subprovince and are characterized by their arid conditions and landforms formed by wind and water. The northern section of the NNSS is located in the Great Basin Desert; the southern third is located in the Mojave Desert, with transitional valleys in between. The topography of the region includes rugged mountain and mesas with steep sides. Eroded material from the ranges collects on alluvial fans that extend into the valley floors. The sediments in the alluvial fans and valleys are typically composed of coarse to fine alluvial debris (boulders, cobbles, sand, silt, and clay).

Yucca Flat and Frenchman Flat are topographically closed valleys. In the lowest portions of these valleys, water from snowmelt and other runoff from higher elevations collects during wet seasons. The collected water contains fine sediments and dissolved solids, including salts. As the water evaporates, these fine sediments and evaporite salts are left behind to form a playa. Jackass Flats is topographically open and drains via Fortymile Wash to the south off the NNSS.

Past actions by DOE, particularly underground nuclear testing, have significantly altered the topography at the NNSS. Yucca Flat and, to a much lesser extent, Pahute and Rainier Mesas are pockmarked with craters from surface explosions and collapsed test cavities. Buckboard Mesa, Shoshone Mountain, Dome Mountain, and Frenchman Flat also exhibit evidence of past tests. Other excavations on the NNSS include blasting for road construction, excavation of aggregate material (e.g., sand and gravel), flood and drainage control, and historical mining tunnels and shafts.

4.1.5.2 Regional Geology

The NNSS is located in a region of complex stratigraphic and structural elements that combines volcanic uplands and calderas, Basin-and-Range faulted bedrock, Mesozoic thrust faults, and modern alluvial basins. All of these features overlay a basement complex of highly deformed Proterozoic- and Paleozoic-age sedimentary and metasedimentary rocks. Approximately 40 percent of the NNSS surface is alluvium-filled basins; 40 percent is Tertiary-age volcanic rocks; and 20 percent is Paleozoic- and

Precambrian-age sedimentary rocks (DOE/NV 2011). **Figure 4–8** presents a simplified map of the geologic units expressed at the surface. **Table 4–15** presents a description and age of the geologic units found at the NNSS. A detailed compilation of the rock units at the NNSS can be found in Slate et al. (1999).

The regional tectonic history is complex, and the geologic record reflects a history of deposition of marine sediments, compressional deformation, erosion, and volcanic activity that spans an interval of hundreds of millions of years. During the late Paleozoic era, the region was a stable continental shelf, periodically covered by shallow seas that gradually deepened westward. Thick layers of limestone, dolomite, shale, and sandstone deposited in the Cambrian through the early Devonian periods are present on the NNSS. In the late Devonian era, uplift west and north of the NNSS resulted in the seas retreating, erosion, and deposition of Mississippian sandstones and shales in a foreland basin (Poole and Sandberg 1991).

Major east–west compression and deformation occurred during an event called the Sevier orogeny, which produced regional thrusts, folds, and strike-slip faults. As a result of the thrust faulting, sheets of older Paleozoic sedimentary rocks were thrust over younger rocks. Erosion continued through the early Tertiary period. This erosion was interrupted in the Miocene by episodes of silicic volcanism, emplacement of granitic rocks, and extensional deformation as widespread normal faults and local strike-slip faulting. Crustal extension in this region has continued for the last 20 million years but at diminished rates in the Pliocene and Quaternary (DOE 1996c). Extensional deformation accompanied by local strike-slip faulting formed large basins in the east (Yucca Flat, Frenchman Flat) and the south (Jackass Flats) of the NNSS; this deformation exposed Paleozoic and Mesozoic rocks in the ranges flanking the basins of Yucca and Frenchman Flat. The valleys subsequently filled with coarse gravels and sands eroded from the mountain ranges, which are layered with finer grains that were reworked by wind and water. Crustal extension is continuing today, and is recorded by instrumentally located earthquakes and the presence of local fault scarps in Quaternary alluvial deposits.

Most of the uplands along the western edge of the NNSS and the TTR are covered by middle Tertiary-age volcanic rocks that are part of the southwestern Nevada volcanic field (Sawyer et al. 1994). This volcanic field includes a broad volcanic plateau underlain by tuffs and lavas that erupted from multiple caldera complexes in the area. At least 17 ash-flow tuff sequences have been associated with eruptions from seven major, overlapping caldera complexes (Byers et al. 1989; DOE 1996c; DOE/NV 2011). Most of the calderas were formed from large-volume eruptions approximately 16 to 7.5 million years ago, while the youngest caldera-forming events most likely occurred about 7.5 million years ago, forming the Stonewall Caldera (DOE 1996c). These eruptions deposited high silica deposits of ash, tuff, and lava. The multiple layers of ash-flow tuff and lava are seen exposed today in the complex Tertiary volcanic sequences and mountain ranges. Approximately 8 million years ago, volcanic activity in the area transitioned to low-volume, nonexplosive eruptions of basalt scoria and lava. The volcanic activity is marked by basaltic scoria cones and associated lava flows at Crater Flat and Frenchman Flat. Since the last major eruptions about 7.5 million years ago, only scattered, short-duration volcanic activity has occurred in Nevada (DOE 1996c). The waning tectonism and transition to small-volume basaltic volcanism indicate that future large-scale volcanic activity is not expected at the NNSS (DOE 1996c).

There are over 300 described Tertiary volcanic units at the NNSS (DOE/NV 2011; Warren et al. 2000, 2003), although limited units are often grouped into larger, more-extensive units. Due to the large number of volcanic units and multiple caldera sources, the volcanic stratigraphy has been subsequently revised and updated with additional research. Byers et al. (1989) presents a detailed review of the past studies and the evolution of concepts on calderas of the southwestern Nevada volcanic field from 1960 to 1988; this work was updated by Sawyer et al. (1994). The revised stratigraphy was used to generate complex hydrogeologic models for use in analyzing the movement of groundwater near testing locations in support of the Underground Test Area (UGTA) Project.

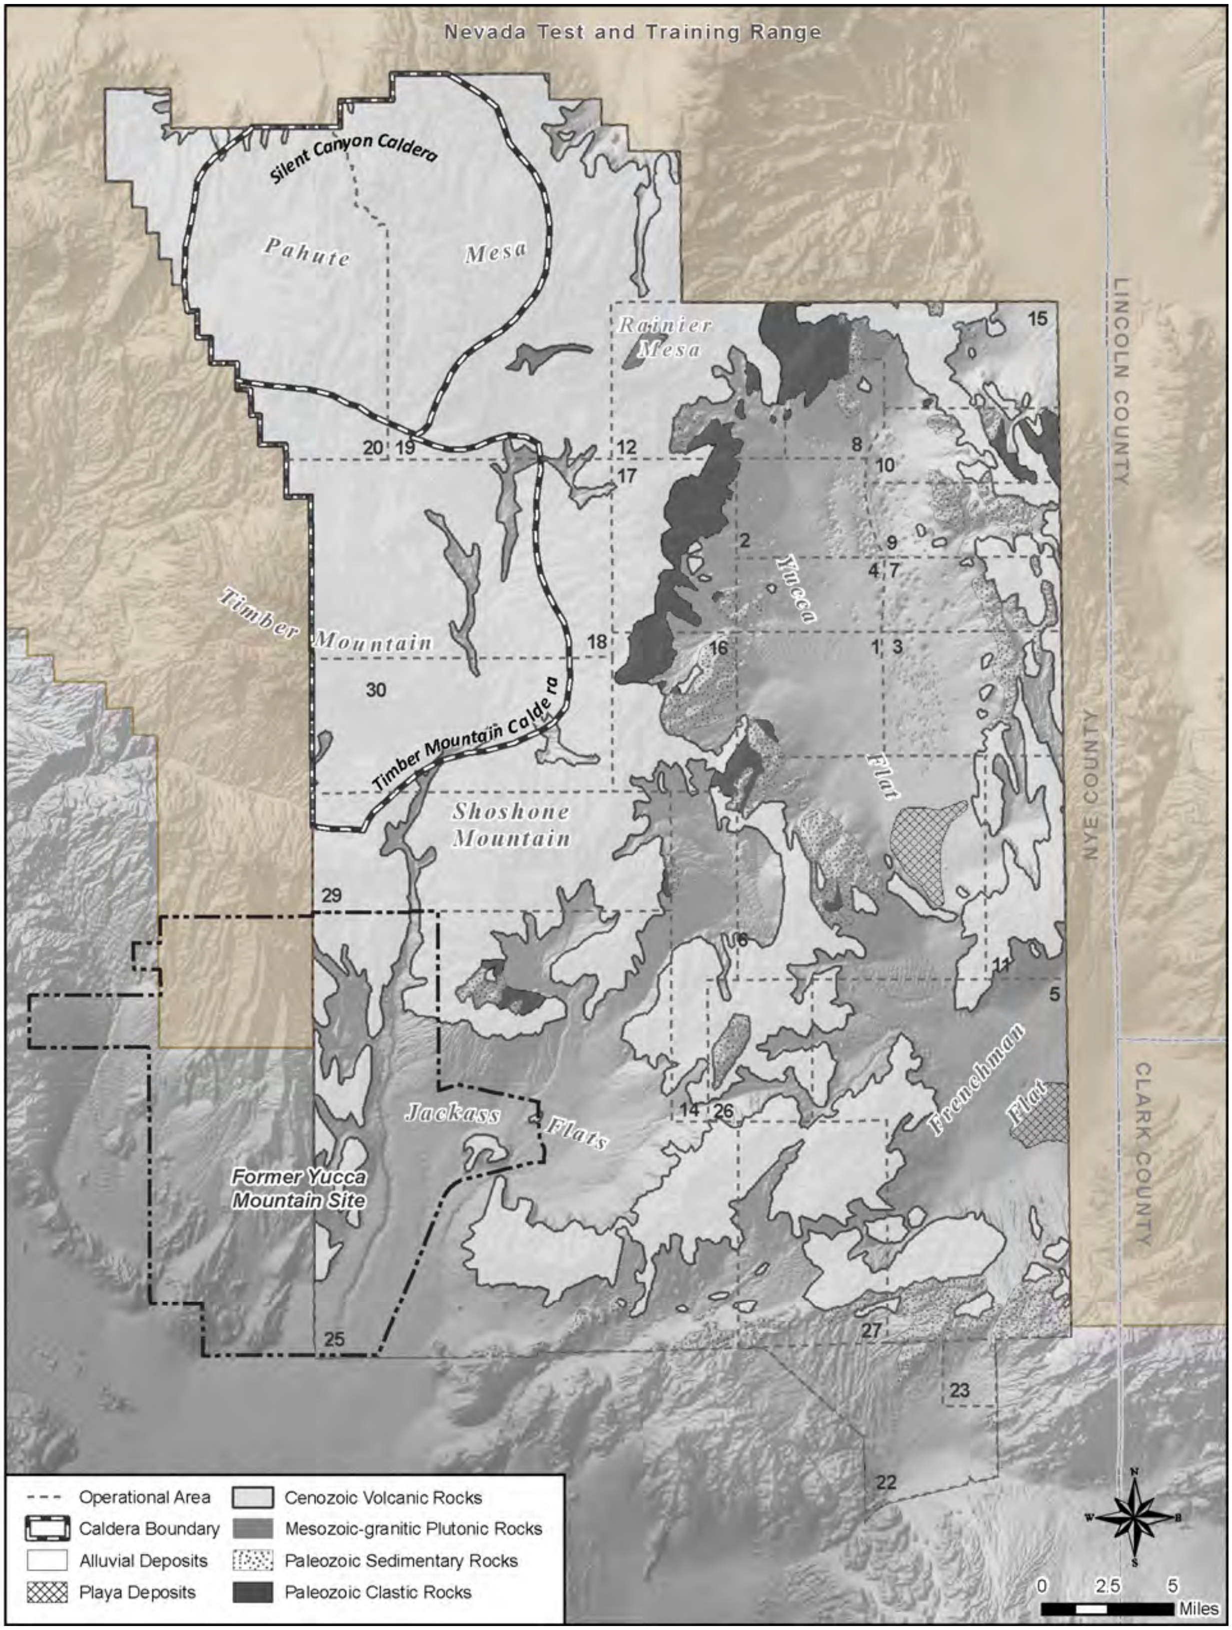

Figure 4–8 Simplified Map of the Geologic Units

Table 4–15 Summary Stratigraphy of the Nevada National Security Site

Era	*Period*	*Series*	*Group*	*Map Units*	*Description*	*Thickness*	*Example Location*
Cenozoic	Quaternary	Holocene – Present Day	Surficial & Volcanic Deposits	Young Alluvial Deposits	Intermixed gravel, sand, and silt, unconsolidated to poorly consolidated, poorly to moderately well-sorted, locally cross-bedded.	32.8 feet	Fortymile Wash
				Playa	Silt, fine sand and clay, poorly to moderately well-consolidated, calcareous, moderately well-sorted. Ocasionally saline.	65.6 feet	Yucca Flat, Frenchman Flat
		Early Holocene/ Pleistocene		Intermediate Alluvial Deposits	Intermixed and interbedded gravel, sand, and silt. Clasts are light and pinkish gray, with variable sorting and cross-beds. Moderately to densely packed pavement.	Up to 98.4 feet	Yucca Flat, Frenchman Flat
		Pleistocene		Youngest Basalt	Isolated black and reddish-brown cinder cones, lava flows, feeder.	Variable	Crater Flat
		Middle to early Pleistocene/ Pliocene		Old Alluvial Deposits	Intermixed and interbedded gravel, sand and silt, light brownish gray to light gray. Generally poorly sorted and moderately cemented with carbonate.	Greater than 131 feet	Yucca Flat, Frenchman Flat, Jackass Flat
	Tertiary (Miocene)	Miocene	Thirsty Canyon Group	Gold Flat Tuff, Pahute Mesa and Rocket Wash Tuffs, Basalt of Thirsty Mountain, Stonewall Flat Tuff	Ash-flow tuff, basalt lava flows and nonwelded tuff from the Black Mountain caldera. Multiple sequences of tuff formations from sequential volcanic eruptions. High-alkali feldspar and low-plagioclase minerals present in tuff.	Greater than 1,640 feet	Pahute Mesa, Buckboard Mesa
			Timber Mountain Group	Ammonia Tanks Tuff, Rainier Mesa Tuff	Rhyolite ash-flow tuff, subordinate rhyolite lava flows and volcanic domes, with related intracaldera breccias. Volcanic rocks erupted from the Timber Mountain caldera complex. Contains an abundance of quartz phenocrysts in rhyolite and iron-magnetic minerals in upper layers. Also contains some thin basaltic lava flows.	Greater than 1,640 feet	Timber Mountain Caldera Complex, Pahute Mesa
			Paintbrush Group	Paintbrush Tuff, Wahmonie Formation	Alkali rhyolite nonwelded tuff and lava flows erupted form Claim Canyon caldera. Biotite, hornblende, and some clinopyroxene present in sequence through the group. Rhyolite lava flows and related nonwelded tuff.	3,608 feet	West of Frenchman Flat, Shoshone Mountain, Yucca Mountain
			Crater Flat Group	Prow Pass Tuff, Bullfrog Tuff	Assemblage of ash-flow tuff and related lava flows and airfall tuffs.	Variable	South of Timber Mountain

Era	***Period***	***Series***	***Group***	***Map Units***	***Description***	***Thickness***	***Example Location***
			Belted Range Group	Grouse Canyon Tuff, Tunnel Formation, Comedites of Quartet Dome and Split Range	Voluminous assemblage of peralkine ash-flow tuff and related lava flows and air fall tuff. The source calderas were buried under later eruptions.	Greater than 1,640 feet	Pahute Mesa, Belted Range
		Oligocene/ Cretaceous		Gabbro dikes	Dark-green hornblende gabbro and diorite dikes that cut pre-Tertiary rocks. Medium-grained texture, with plagioclase, hornblende, clinopyroxene, and biotite as the component minerals.	Variable	Northern margin of Yucca Flats
		Upper		Granitic intrusion	Medium-grained intrusive rocks, hornblende-biotite granodiorite, quartz monzonite. Includes Climax stock.	Variable	Northern edge of Yucca Flat
Mesozoic	Cretaceous	Lower		Tippipah Limestone	Light to medium gray and light brown well-bedded marine limestone, calcareous mudstone, and minor chert pebble conglomerate. Forms ledges easily.	4,101 feet	West of Yucca Flat
Paleozoic	Permian	–		Eleana Formation	Chert-rich sandstone and pebble conglomerate, siliceous siltstone.		
	Penn.	–					
	Miss.	Upper and Middle		Guilmette Formation	Thick-bedded finely to coarsely crystalline marine limestone. Contains sandy limestone and thick beds of quartz sandstone; quartzite beds are brecciated.	1,148 feet	Shoshone Mountain
	Devonian	Upper, Middle, Lower		Slope-facies carbonate	Dark gray limestone, dolomite, silty carbonate rocks, well-bedded, locally laminated, debris-flow deposits. Locally fossiliferous.	Variable	Eastern Rainier Mesa
		Middle		Simonson Dolomite	Bedded dolomite and local sandy dolomite. Includes silty and cherty dolomite at base. Fossils present.	984 feet	
		Lower		Sevy Dolomite and Laketown Dolomite	Thick-bedded dolomite, beds of quartz, commonly brecciated. Base is well-bedded, locally cherty, with fossils present.	3,166 feet	West of Yucca Flat
		Lower Devonian/ Upper Silurian		Lone Mountain Dolomite	Varying color dolomite with increased bedding at base. Sparse fossils.	1,607 feet	Yucca Mountain
	Silurian	Upper		Lone Mountain Dolomite Ely Springs Dolomite	Varying color dolomite with increased bedding at base. Sparse fossils. Two major units: Upper is gray dolostone with silty and clay-rich dolostone, and a thin sandy zone. Lower is fine-grained, cherty dolomite.	Upper: 1,607 feet Lower: 164 to 492 feet	Yucca Mountain
	Ordovician	Middle		Eureka Quartzite	Two major parts. Upper is white, very fine medium-grained sandstone and quartzite. Lower is varicolored, medium-grained quartzite interval with thin limestone and dolomite.	246 to 475 feet	

Era	*Period*	*Series*	*Group*	*Map Units*	*Description*	*Thickness*	*Example Location*
		Middle to Lower	Pogonip Group	Antelope Valley Limestone, Ninemile Formation	Medium, well-bedded silty limestone, dolomite, with chert and siltstone.Various invertebrate fossils present.	3,444 feet	
	Cambrian	Upper		Nopah Formation	Poorly to well-bedded carbonates with shale and siltstones. Includes Dunderberg Shale Member. Invertebrate fossils present.	2,362 feet	
		Upper to Middle		Bonanza King Formation	Well-bedded dolomite and limestone with a banded appearance.	4,199 feet	East of Yucca Flat
		Middle to Lower		Carrara Formation	Heterogeneous sequence of shales, siltstone, sandstone, limestone and silty limestone. Clastic rocks at base, silty limestone beds at top. Stromatolith, trilobite fossils present.	1,148 to 1,541 feet	
		Lower		Zabriskie Quartzite	Resistant, massive, white quartz, pink quartz, and red quartz sandstone.	98.4 to 1,148 feet	
		Late		Wood Canyon Formation	Quartz sandstone, mica and quartz sandstone, clay-rich sandstones, and magnesium carbonates; may be slightly metamorphosed. Includes Stirling Quartzite.	2,296 to 3,772 feet	North of Rainier Mesa
				Stirling Quartzite	Medium to thick-bedded, commonly laminated, fine-grained quartz sandstone, mica quartz sandstone, interbedded with pebbly sandstone. Also limestone and dolostone. Locally metamorphosed.	4,921 feet	
Proterozoic	Precambrian	–		Johnnie Formation	Thick-bedded, few cross-beds, locally pebbly quartz sandstone, with laminated mica siltstone, limestone, and calcareous siltstone.	2,952 to 6,561 feet	
				Metamorphic and intrusive rocks	Light-gray and brown biotite schist, biotite-hornblende schist, and biotite-epidote schist intruded by gneissic monzogranite. Some aplite and pegmatite dikes, quartzofeldspathic gneiss and buiotite schist, minor metaconglomerate, and marble also present.	Bedrock	Gold Flat, Funeral Mountains

Source: Slate et al. 1999.

Soils form in the youngest geologic material at the NNSS, the late Tertiary and Quaternary alluvial, colluvial, spring, lake, playa, and eolian (windblown) deposits. The unconsolidated sediments are formed by erosion of Paleozoic and Tertiary volcanic materials from the surrounding ranges that are deposited in the alluvial fans formed at the basin margins. The alluvial fans consist of interbedded gravel, sand, and silt that vary in their cementation. Valleys that only have internal drainage often collect shallow water after seasonal storms and snowmelt in the spring. As the water evaporates, it leaves stratified lake bed

sediments and precipitated salts. The resulting playa sediments are typically bedded sand, silt, or clay. The playa typically looks like a dry lake bed that may contain water after a seasonally high runoff. Sand and silt from the playas can be eroded, transported by wind, and subsequently reworked by moving water. However, most sediments remain stable as long as they are not disturbed.

4.1.5.2.1 Site-Specific Geology

The oldest bedrock at the NNSS is the Paleozoic and Proterozoic sedimentary rock, which includes dolomite, limestone, quartzite, and mudstones (see Table 4–15). The carbonate section of the sedimentary rocks often forms the primary regional aquifer and a "basement" for the Great Basin's hydrology (DOE/NV 2011). The Paleozoic and Precambrian rocks have been subjected to thrust and extensional faulting, as described in Section 4.1.5.2.2. The rocks were formed from marine sediments and have a thickness of up to 32,800 feet (DOE/NV 2011).

The oldest formations of the Proterozoic basement consist of approximately 9,800 feet of lower Cambrian and Proterozoic quartzite and siltstones (DOE 1996c). Above these formations is approximately 15,100 feet of Cambrian through Devonian dolomite, interbedded limestone, and thin but persistent shale and quartzite layers. The youngest of the basement rocks is the Mississippian Eleana formation, which outcrops along the western edge of the Yucca Flat basins, and the Pennsylvanian limestone, which overlies the Eleana formation. In western Yucca Flat, east of the Eleana Range, the Paleozoic-age carbonate rocks have been thrust over the Eleana formation. More information on the basement formations at the NNSS is presented in several publications (Cole 1997; Cole and Cashman 1999; Trexler et al. 2003; Slate et al. 1999).

There are two outcroppings of Mesozoic intrusive rocks at the NNSS; both are granitic masses. The Gold Meadows Stock crops out north of Rainier Mesa, and the Climax Stock is located at the extreme north end of Yucca Flat (DOE/NV 2011). Three underground tests were performed within the Climax Stock. The stock is a granitic rock (quartz monzonite and granodiorite) of Late Cretaceous age that intruded into the Paleozoic sediments.

Pahute and Rainier Mesas are high volcanic plateaus dissected by modern drainages. The mesas are located in the northern portion of the southwestern Nevada volcanic field. Their Tertiary ash-flow tuffs were derived from the Timber Mountain–Oasis Valley caldera complex and the Silent Canyon and Black Mountain calderas. Pahute Mesa was formed from an overlapping complex of fault-controlled calderas, while the laterally extensive tabular outflow sheets of welded tuff covered the surrounding area. During faulting and uplift, the softer pre-Tertiary material was exposed, while the welded tuffs and lava flows resisted erosion. The result was flat-topped mesas with steep sides adjacent to down-dropped valleys. The Timber Mountain caldera, located to the southwest of Pahute and Rainier Mesas, is listed as a national natural landmark by the National Park Service (DOE 1996c).

There are two buried calderas at Pahute Mesa; drill hole and geophysical data indicate that their morphology may be largely controlled by the Basin and Range faults (Warren et al. 2000). All of the tests at Pahute and Rainier Mesas were underground tests that occurred within the Tertiary volcanic rocks and did not penetrate the pre-Tertiary bedrock.

Other historical testing locations are located at Buckboard Mesa, Dome Mountain, and Shoshone Mountain. Buckboard Mesa is located along the northeastern edge of Timber Mountain, while Dome Mountain is a foothill to the southeast. These two sites within the Timber Mountain caldera complex have similar geologic characteristics, including a thick sequence of volcanic rocks that also includes rhyolitic lavas and ash-flow tuffs; volcanic-derived sediments, including sandstone and conglomerate; and basalts. Radial fracturing and faulting typical of a caldera are present at both of these sites. Shoshone Mountain is located southeast of Timber Mountain. The mountain is capped by a unit called rhyolite of Shoshone Mountain, and lithic ridge tuff. North of Shoshone Mountain, the Paleozoic sandstone and conglomerate of Eleana formation and carbonates of the Tippipah limestone are exposed. Quartzite of the Guilmette formation is also present in the area.

Yucca Flat and Frenchman Flat are alluvium- and tuff-filled valleys bounded by mountain ranges with Paleozoic sedimentary and Tertiary volcanic rocks. Thick layers of sand and gravel have collected at the base of these valleys. At Yucca Flat, subsurface gravity surveys using isostatic gravity data from surface stations have estimated the thickness of the alluvial deposits to be up to 8,200 feet (Phelps et al. 1999). From the edge of the mountain ranges, coarse-grained deposits in alluvial fans grade laterally to clay deposits at playas in the lowest part of the valleys. Some windblown sand and silt may also collect at the basin troughs.

4.1.5.2.2 Structural History

As a result of the depositional periods interrupted by tectonic upheaval, the structural record in the region is complex. Geologic structures, such as faults and folds, strongly affect the regional hydrology. Groundwater predominantly travels through cooling joints and fractures, often enhanced proximal to faults. Other structures such as caldera faults or normal faults modify surface drainage and erosion patterns.

Five types of structural features occur in the region around the NNSS: (1) thrust faults (e.g., Belted Range thrusts); (2) normal faults (e.g., the Yucca and West Greeley faults); (3) transverse faults and structural zones (e.g., the Rock Valley fault, Walker Lane shear zone); (4) calderas (e.g., the Timber Mountain and Silent Canyon caldera complexes); and (5) detachment faults (e.g., the Fluorspar Canyon–Bullfrog Hills detachment fault).

The Belted Range thrust fault is the principal pre-Tertiary structure in the NNSS region and, therefore, only affects the pre-Tertiary rocks in the area. The fault can be traced or inferred from Bare Mountain, just south of the southwest corner of the NNSS, to the northern Belted Range north of the NNSS, a distance of more than 81 miles (DOE/NV 2011). The Belted Range thrust fault is an eastward thrust, which generally places late Proterozoic–early Cambrian rocks over rocks as young as the Mississippian Period. Several overlapping thrust faults occur east of the main thrust fault. Deformation related to the Belted Range thrust fault occurred sometime between 100 and 250 million years ago.

Normal faults associated with the formation of the Basin and Range mountain sequence are the most recent structural elements. The high-angle faults cut across Paleozoic volcanic, Precambrian sedimentary rocks, and early Cenozoic volcanic formations. Most of the faults in the region are northwest–northeast-striking and high angle (DOE/NV 2011). Good examples of normal faults at the NNSS are found at Yucca and Frenchman Flats. In Yucca Flat, the faults generally trend north–south; in Frenchman Flat, the faults generally strike west–southwest in the south, curving northward in the northern portion of the valley. Evidence of normal faulting is also visible in the Tertiary tuffs of Pahute and Rainier Mesas (e.g., the West Greeley fault) (DOE/NV 2011). Shoshone Mountain has normal faults that also have a strike-slip component.

The Walker Lane shear zone trends northwest to southeast of the TTR along the western edge of the NNSS (DOE 1996c). The Walker Lane shear zone is a major strike-slip fault zone that extends several hundred miles to merge with the Las Vegas shear zone. To the west of the Walker Lane shear zone and northwest of the NNSS is a series of volcanic centers, including Goldfield, Cactus Range, Stonewall Mountain, and Mount Helen (DOE 1996c).

4.1.5.2.3 Faulting and Seismic Activity

As seismic activity still occurs in the Basin and Range Physiographic Province, there have been earthquakes in the recent past around the NNSS. In addition, historical nuclear testing has generated ground motion and triggered seismic activity that could be felt miles away from the testing sites. Seismic activity in the Great Basin tends to be concentrated towards the west and, to a lesser extent, the east margins of the basin (USGS 2010a). Seismic activity in the NNSS region was described by Vortman (1991). The analysis determined that, from 1868 to 1991, 11,988 seismic events were recorded within 120 miles of the NNSS. Of these events, 8,161 were naturally occurring and 3,827 were induced

by humans (DOE 1996c). This is a minimum count of events because placement of seismic instruments capable of detecting low-magnitude events in the region began after testing in 1951. Other studies of Great Basin earthquakes have compared the regional stress field to earthquake occurrence and surface fault expression (Rodgers et al. 1987; Gomberg 1991; Smith et al. 2001). These studies correlated some earthquakes with faults with surface expression, although they also identified many other moderate-size earthquakes that could not be associated with mapped faults (e.g., Smith et al. 1991).

The southern Great Basin contains many Quaternary fault traces, but few indications of movement in the last 10,000 years. Quaternary faults are identified by the presence of discontinuous scarps in volcanic material or in the alluvial sediment in valleys. The Spotted Range–Mine Mountain structural zone appears to be the only currently active fault system within the site. The Spotted Range–Mine Mountain structural zone is the revised name for the Cane Spring and Rock Valley fault zones that were described in the *1996 NTS EIS*. These faults are located in southwestern Frenchman Flat and have a generally northeast strike and a left-lateral slip (Anderson 1998a). The Mine Mountain fault is also associated with the Spotted Range–Mine Mountain structural zone and trends northeast–southwest, but is located along the southwestern edge of Yucca Flat, east of Shoshone Mountain (Anderson 1998b).

Small earthquakes have occurred at or near the Spotted Range–Mine Mountain structural zone; although no surface displacements were associated with them (Carr 1974; DOE 1996c). The last earthquake with a magnitude over 5.0 was near Little Skull Mountain in 1992. The shallow 5.6-magnitude earthquake was associated with the Spotted Range–Mine Mountain structural zone and was potentially caused by a 7.5-magnitude earthquake near Landers, California (DOE 1996c). This earthquake was notable because it damaged several of the NNSS facilities that were built prior to revised building codes. Since 1992, several smaller earthquakes ranging between magnitudes of 3.0 to 4.0 have occurred near Little Skull Mountain, Frenchman Flat, and Calico Hills, all in the southern portions of the NNSS. The largest of these earthquakes had a magnitude of 4.0 in 1997, south of Calico Hills; earthquakes with magnitudes of 4.5 and 4.8 occurred in January 1999 in Frenchman Flat; and a 4.6-magnitude earthquake occurred southwest of Skull Mountain in 2002 (USGS 2010b).

Yucca Flat is bisected by a fault scarp called Yucca Fault, which stretches approximately north–south. Several investigations of the scarp height and sediment ages indicate that most of the recent movement occurred between 10,000 and 130,000 years ago. There is also evidence that southern sections of the fault were displaced by testing activities (Anderson 1998c). Testing in Yucca Flat during the 1970s and 1980s generated manmade earthquakes with magnitudes between 4.0 and 6.0 (Rodgers et al. 2005).

The Bare Mountain fault forms the border on the eastern side of Bare Mountain and the western edge of Crater Flat, and is the southernmost portion of the Walker Lane shear zone. The fault strikes generally north, and dips to the east-southeast. Trenches along the fault found that surface movement along the fault has likely not occurred within 130,000 years, although when movement did occur in the southern portion, it occurred in multiple locations at once (Anderson 1998d).

There are two fault systems in the Yucca Mountain property: the eastern area, which contains the Soltario Canyon, Iron Ridge, Stagecoach Road, Paintbrush Canyon, and Bow Ridge faults; and the western area, which contains the Black Cone, northern and southern Crater Flat, Windy Wash and Fatigue Wash faults (Anderson 1998e, 1998f). The faults within the fault sequences have a braided appearance, with clockwise movement along northerly striking fault lines, and extensional displacement. The Yucca Mountain eastern group shows movement within the late Quaternary (less than 130,000 years), while the western group cuts across Holocene and latest Pleistocene deposits, which would indicate movement within the last 15,000 years (Anderson 1998e, 1998f).

Sandia National Laboratories developed a program for recording surface and subsurface motions resulting from underground nuclear explosions (DOE 1996c). Test-induced ground motion is affected by several factors: (1) the yield of the device; (2) ground-coupling at the source of the explosion, which is a function of the test design, depth of the device, local geology, and stratigraphy; (3) geological complexity along

the ground wave path; and (4) the topography and geology at the location receiving ground motion (DOE 1996c). There is always some variation or unknown associated with estimating these factors; however, because of the long history of conducting nuclear weapon tests, ground motion predictions for tests at the NNSS have become increasingly accurate.

DOE policy is to design, construct, and operate its facilities so that workers, the general public, and the environment are protected from the impacts of natural phenomena hazards (including seismic events) on DOE facilities. Executive Order 12699, *Safety of Federal and Federally Assisted or Regulated New Building Construction* requires new buildings owned by the Federal government to be designed and constructed in accordance with appropriate seismic design and construction standards. DOE Order 420.1B, *Facility Safety*, and DOE G-420.1-2, *Guide for the Mitigation of Natural Phenomena Hazards for DOE Nuclear Facilities and Nonnuclear Facilities*, require that structures, systems, and components at DOE facilities be designed to withstand the effects of natural phenomena hazards using a graded approach. The graded approach is implemented by five performance categories requiring natural phenomena hazard protection, with Performance Category 0 for those structures, systems, and components requiring no natural phenomena hazard protection and Performance Category 4 for those structures, systems, and components requiring protection from the release of hazardous material similar to that provided by commercial nuclear power plants. For each performance category, DOE Standard 1020-2002, *Natural Phenomena Hazards Design and Evaluation Criteria for Department of Energy Facilities*, provides natural phenomena hazard design, evaluation, and construction requirements. DOE Standard 1023-95, *Natural Phenomena Hazards Assessment Criteria*, provides general and detailed criteria for establishing adequate design-basis load levels for DOE structures, systems, and components. DOE seismic design criteria also meet the requirements of the International Building Code (ICC 2009).

Seismic waves from nuclear explosions are believed to relieve tectonic stress, as seen by the aftershocks and movement along some Quaternary faults around the testing zones (DOE 1996c; Rodgers et al. 1991). The Yucca Fault and Carpetbag Fault, in Yucca Flat, showed indications of reactivation (Frizzell and Shulters 1990) by vertical and lateral displacement as a result of past nuclear detonations in Yucca Flat, though most of this movement is believed to be due to differential compaction of the porous alluvium over the existing buried fault scarp.

As a result of the ongoing moratorium on nuclear testing, the last underground nuclear tests at the NNSS occurred in 1992. The only architectural damage in surrounding communities resulting from underground nuclear testing occurred with test yields over 100 kilotons (DOE 1996c). For the period of time between the enactment of the Threshold Test Ban Treaty and the last underground nuclear test, only a few reports of very minor test-related damage were received (DOE 1996c). For communities farther than 30 miles from the test location, only multiple-story buildings would be affected by the larger tests, should testing resume (DOE 1996c).

4.1.5.2.4 Geotechnical Hazards

There are several geotechnical hazards at the NNSS and the TTR that may present a small risk to structures and roads. The main hazards include slope, soil, and ground instability. Areas near rugged topography and cliffs, combined with ground motion from earthquakes or nuclear tests (should testing resume), present an increased risk for slope stability hazards. However, most existing structures at the NNSS were built in locations with a lower potential for geotechnical hazards.

Many soils in Nevada contain clay minerals (e.g., montmorillonite) that swell when wet (DOE 1996c). Soils with a volume change of 3 percent or less when wet have low limitations when used for construction. Soils that swell from 3 to 6 percent of their volume have moderate limitations, while soils that swell greater than 6 percent of their dry volume have high limitations. Soils with moderate-to-high limitations due to shrink-swell properties could affect the stability of structures.

In general, ground stability is adversely affected by the presence of weathered or fractured bedrock, a high percentage of void space in the soil, lack of vegetation, freeze-thaw sequences, soil erosion from wind or flowing water, or ground motion. Knowledge of the subsurface activities is also important, as underground nuclear tests may have rubble chimneys that did not reach the surface, but would pose a hazard for any construction or other activity; these areas on the NNSS are known and are fenced and controlled.

Some soil processes enhance ground stability. Development of a pebble pavement as soil is stripped away by erosion, as well as accumulation of calcium carbonate minerals in subsurface horizons, can provide additional stability to certain structures. These areas are also less likely to be reworked by surface flow, so the soil column would be more comprehensive (Friesen 1992).

4.1.5.2.5 Geologic Resources

Potential geologic resources around the NNSS include mineral mining, aggregate, oil and natural gas, and geothermal resources. The availability of the resources has not changed significantly since the publication of the *1996 NTS EIS*.

For more than 100 years, sections of the southern Great Basin have produced amounts of base and precious metals, particularly gold, silver, copper, lead, zinc, tungsten, and uranium (Kral 1951). At the NNSS, there are four historic mining districts (SAIC/DRI 1991). These mining districts would be of interest for economic mining if the NNSS were open for public access. However, the NNSS has been closed to commercial mineral development since the 1940s (SAIC/DRI 1991).

Gold, silver, copper, lead, zinc, and mercury are present in the region around the NNSS. Gold and silver deposits are mined in the Goldfield mining district to the northwest of the Nevada Test and Training Range. Silver may still be present in the Oak Spring District, located at the north end of Yucca Flat; a significant amount of silver has been taken from the Groom mine (BLM 1979) located on the Nevada Test and Training Range, northeast of the NNSS. Economic quantities of copper, lead, and zinc have also been extracted from the Groom mine (SAIC/DRI 1991). On NNSS property, gold or silver deposits may be present in the Wahmonie District, located on the south-central NNSS, although prospecting in the 1930s found few ore deposits (SAIC/DRI 1991; NPS 2000).

In the 1950s and 1960s, commercial tungsten mining occurred at the Oak Spring District, which indicates that the NNSS has a moderate potential for economic tungsten deposits (SAIC/DRI 1991). Iron, in the form of magnetite, is also present in the region; however, there is a low potential for its commercial ores at the NNSS (Sherlock et al. 1996). Aggregate materials are typically mined from alluvial fans that border the region's mountain ranges. There are sufficient aggregate resources in the region to support foreseeable future demand from construction (DOE 1996c).

Uranium resources may be present in the northwestern part of the Nevada Test and Training Range (BLM 1979). Zeolitized rocks are common in the NNSS region. The widespread occurrence of zeolite deposits in the region suggests a low-to-moderate potential for development (SAIC/DRI 1991). Barite is known to occur in the Mine Mountain District, specifically in veins associated with quartz and mercury, antimony, and lead mineralization. However, barite veins at the NNSS are small and impure and do not represent a potential barite resource (SAIC/DRI 1991). Fluorite was reported to be present in the Calico Hills area, although little is known about the occurrence of fluorite, and its resource potential is assumed to be low to moderate (SAIC/DRI 1991).

The northeastern and southwestern portions of the NNSS and the Nevada Test and Training Range have a theoretical potential for hydrocarbon resources, as the rock type, age, and thermal maturity all contribute to a potential for pockets of oil or gas reserves (Grow et al. 1994). The northeastern and southern sections of the NNSS and Nevada Test and Training Range have potential for oil and gas, while the southern portion of the NNSS and southeastern portion of the Nevada Test and Training Range have a potential for gas. The presence of oil deposits at Railroad Valley, about 50 miles north of the NNSS, has led some

researchers to hypothesize that large petroleum deposits could also be present under similar conditions at the site (Chamberlain 1991). However, Trexler et al. (1996) states that the likeliest formation (Chainman shale) is less extensive than previously thought, and may have lost as much as 80 percent of the original hydrocarbon content from migration. Other investigations (SAIC/DRI 1991; Garside et al. 1988) have also determined that large-scale hydrocarbon resources would be very unlikely because there are few laterally extensive carbon-bearing formations, the thermal maturity of the region is just within acceptability, and the large fault complexes throughout the NNSS are likely to have fractured the confining bedrock. No surface occurrences of oil, gas, coal, tar, sand, or oil shale at the NNSS have been reported, and numerous boreholes drilled at the site have not revealed any hydrocarbon shows within the likeliest formations (DOE 1996c). There are also no oil or gas wells at the NNSS (Hess and Johnson 1996).

4.1.5.2.6 Geothermal Resources

The extensional forces that create seismicity in the Basin and Range Province have also thinned the crust so that the upward flow of heat from the mantle warms the shallow bedrock. Increased heat flow through aquifer-bearing bedrock creates hot springs that could be amenable for use with a geothermal plant facility. Hot springs are not present at the NNSS; however, several are located west of the NNSS (Coolbaugh et al. 2005). If downhole temperatures near Yucca Mountain are representative (120 degrees Fahrenheit [°F] to 140 °F), groundwater temperatures in the region may be insufficient for some types of commercial power development (DOE 1988). However, a 1994 preliminary assessment of the geothermal potential of the NNSS found good potential for development of a moderate-temperature geothermal resource. This resource potential was judged suitable for development of a binary geothermal power plant (HRCES 1994).

An Enhanced Geothermal System, a type of binary geothermal power-generating technology, would use steam created in bedrock to turn electricity-generating turbines. The bedrock would need to be at least 356 ºF to heat the steam. An open system could use steam from hot-water-bearing bedrock (wet), while a closed system could use heat from bedrock that does not contain an aquifer (dry). In a review of geothermal resources, DOE/NNSA determined that several locations at the NNSS appear to have the heat potential to support an Enhanced Geothermal System (Brown 2009). Hot-water-bearing bedrock is located outside the NNSS at East Yucca Flat, Wahmonie Volcanic Center, Crater Flat, and Oasis Valley. The hot dry rock areas include Halfpint Range, Climax Mine, Gold Meadows, the Timber Mountain Caldera Complex, and Calico Hills.

4.1.5.3 Soils

There are few soil surveys for the NNSS and surrounding areas because the site was established as a nuclear weapons testing site prior to the nationwide soil survey program. Radioactivity and nuclear testing have also resulted in restricted ready access to some parts of the NNSS. Soil surveys internal to the NNSS have been conducted at locations of interest, particularly those associated with the Yucca Mountain site, new facility construction sites, and onsite waste disposal sites. However, most of the soil characterization is limited to a series of geotechnical descriptions for a particular construction project, rather than a regional soil analysis. These documents are used for internal uses and permit applications. A great deal of research at the NNSS has been focused on defining areas of contamination at testing locations and the movement of contaminants through the soil column.

Soils at the NNSS are similar to those throughout southern Nevada. Most of the soils form on the alluvial fans and valley floors, with thin soils forming on mesa and mountain surfaces. The most common soils at the NNSS are aridisols and entisols. The amount of development these soils have undergone depends on their age, their parent materials, and particularly their geomorphic position. Entisols generally form on steep mountain slopes where erosion is active. Aridisols tend to be older and form on more-stable fans and terraces (DOE 1996c). Evaporate deposits found in playas tend to develop in aridisols. The parent materials for most of these soils are mixed alluvial sediments that were eroded from the surrounding

ranges. The soil texture generally grades from coarse-grained soil close to the mountain fronts to fine-grained sediments in playas at the bottom of valleys. This gradation can be seen in cross sections at Yucca Flat and Frenchman Flat. Overall, most of the soils are reasonably young, with low leaching, and retain their structures from when the parent materials were deposited.

Underlying the surface of more well-developed soils is a layer of caliche (calcium carbonate minerals precipitated from evaporating carbonate-saturated groundwater). The saltiness of the soils increases toward the center of internal drainage basins because snowmelt, rainfall, and groundwater tend to collect, concentrate, and then evaporate. The highest level of soluble salts at the NNSS can be found in the soil horizons at Frenchman Flat (DOE 1996c).

The soils at the NNSS are highly susceptible to erosion by wind and water. Although finer-grained soils on steep slopes are more easily erodible, mineral composition and topography can also affect the movement of topsoil. Because the NNSS has not undergone a comprehensive soil survey review, locations of soils that are easily erodible have not been identified.

Approximately 7,800 acres of surface and near-surface soils at the NNSS, the TTR, and the Nevada Test and Training Range contaminated from nuclear testing activities at a level requiring use restrictions are addressed by the DOE/NNSA NSO Environmental Restoration Program. These include about 6,006 acres on the NNSS, 571 acres on the TTR, and 1,222 acres on the Nevada Test and Training Range. The soils were contaminated by radioactive isotopes expelled from open air testing at Yucca Flat, Frenchman Flat, Plutonium Valley (Area 11), and other areas around the NNSS, the TTR, and the Nevada Test and Training Range. Section 4.1.5.4.1 provides a more detailed description of the soil contamination and isotopes at the NNSS and the surrounding areas.

Prime Farmland soils have not been identified at the NNSS and surrounding areas. However, agriculture production in Nevada often requires irrigation, so soil suitability for irrigation could be used as a proxy for soils with a potential to be classified as Prime Farmland. Previous maps by the Division of Water Resources show that the lowest elevations of Yucca Flat, Frenchman Flat, and Jackass Flats would be the most suitable at the NNSS for water retention (Rush 1974). Other soils at the NNSS tend to be too thin or too permeable to be effectively irrigated. In Yucca Flat, the cobbly, stony soils have moderately low water-holding capability, while Frenchman Flat and Jackass Flats have severe limitations with low water-holding capabilities. These areas tend to flood and drain, rather than retain groundwater directly below the surface (DOE 1996c).

4.1.5.4 Radiological Sources as a Result of Testing

4.1.5.4.1 Soils

There are approximately 143 releases of radioactivity onto surface and near-surface soils as a direct result of past nuclear weapons testing on the NNSS, the TTR, and the Nevada Test and Training Range (DOE/NV 2011). The impacts from radioactive contamination have been considerable and, in some cases, significant. The areas of greatest soil contamination were the locations of atmospheric testing of nuclear weapons, safety tests, and shallow borehole tests. Additional surface contamination occurred from crater tests and deep underground testing. This section describes the results of past tests and the remaining contamination in the soils.

DOE/NNSA is managing contaminated sites in accordance with the Federal Facility Agreement and Consent Order (FFACO), in conjunction with the State of Nevada. A variety of corrective actions are used to remediate soil contamination, including soil removal and "closure in place," in which the site is fenced, warnings are posted, and access is restricted (DOE/NV 2011). As of December 31, 2010, 18 sites have been approved for closure in accordance with the FFACO by the State of Nevada (DOE/NV 2011).

Under the FFACO, the goal of the Environmental Restoration Program is to characterize, monitor, and remediate identified contaminated areas, facilities, soils, and groundwater at the NNSS and its associated facilities. Within the Environmental Restoration Program, the Soils Project is responsible for the corrective action units (CAUs) that consist of surface and shallow subsurface contamination from nuclear experiments or testing on the NNSS, the TTR, and the Nevada Test and Training Range. **Figures 4–9** and **4–10** depict all Environmental Restoration Program corrective action sites (CASs) (i.e., sub-units of CAUs) for the Soils, Industrial Sites, and UGTA Projects on the NNSS, TTR, and Nevada Test and Training Range. Figure 4–9 depicts CASs that have been closed under the FFACO and Figure 4–10, CASs that that are not yet closed.

The Soils Project implements air monitoring and radiological surveying of affected soils and implements comprehensive remediation and/or monitoring plans. The Soils Project includes surface and near-surface releases from atmospheric testing, safety experiments, hydronuclear experiments, nuclear rocket engine tests, Plowshare excavation tests, and subsurface nuclear tests with corresponding surface releases (Bechtel Nevada 1998a). The tests that generated radiological soil contamination are described below.

A total of 105 atmospheric tests were conducted on the NNSS and Nevada Test and Training Range from 1951 to 1963, when the Limited Test Ban Treaty was signed (DOE 1996c). The majority of atmospheric tests were conducted at Yucca Flat and Frenchman Flat on the NNSS. Atmospheric weapons testing included weapons dropped by planes, detonated from towers, suspended from balloons, or detonated on the ground surface (DOE 1996c). Depending on the proximity of the explosion to the ground surface and the size of the yield, surface disturbances from atmospheric testing varied widely.

Radioactivity from atmospheric tests was dispersed by three primary mechanisms: (1) throwout, (2) base surge, and (3) fallout (DOE 1996c). Throwout occurs immediately after the initial detonation, when large volumes of rock and soils are thrown outward. Base surge follows as the throwout laterally expands and begins to settle. Fallout consists of the finest particles that remain suspended and mixed with the radioactive weapon residues before gradually being deposited on the ground surface. Fallout can be transported away from the test location because it can remain suspended for several hours after a test. Soil contaminated with radioactive fallout can also be transported limited distances through resuspension by wind. The extent and distribution of contamination from an atmospheric test are quite variable depending on the height of detonation, the yield and type of device, the nature of the ground surface, the mass of the inert material surrounding the device, and the weather conditions during and after the test (DOE 1988).

Various isotopes, including strontium, cesium, barium, hydrogen-3 (tritium), and iodine, form during a nuclear detonation. Most of these isotopes have short half-lives; however, strontium-90 and cesium-137 have half-lives of 28 and 30 years, respectively, so they are retained longer in the soil (Glasstone and Dolan 1977). Because most of the isotopes released during the atmospheric tests rapidly decayed, most of the radioactivity was reduced within the first 12 hours after detonation (OTA 1989). Americium, plutonium, cobalt, cesium, strontium, and europium are the primary radioactive isotopes still present in the soils from historical atmospheric testing. The surface radiation concentration in soils is concentrated near ground zero in the areas where atmospheric testing occurred (Frenchman Flats, Yucca Flat, and Buckboard Mesa) (DOE 1996c). McArthur estimated that, in Frenchman Flat, 20 curies of radioactivity remain at or near the soil surface (McArthur 1991). In Areas 2 and 4, approximately 11.0 and 10.4 curies of cesium-137 were measured at the Kepler and Shasta ground zero locations, respectively (McArthur and Kordas 1985). In Yucca Flat and Buckboard Mesa, some of the radioactivity in soils may also be attributed to underground testing in the area; however, it is likely that the majority is connected to atmospheric testing (DOE 1996c).

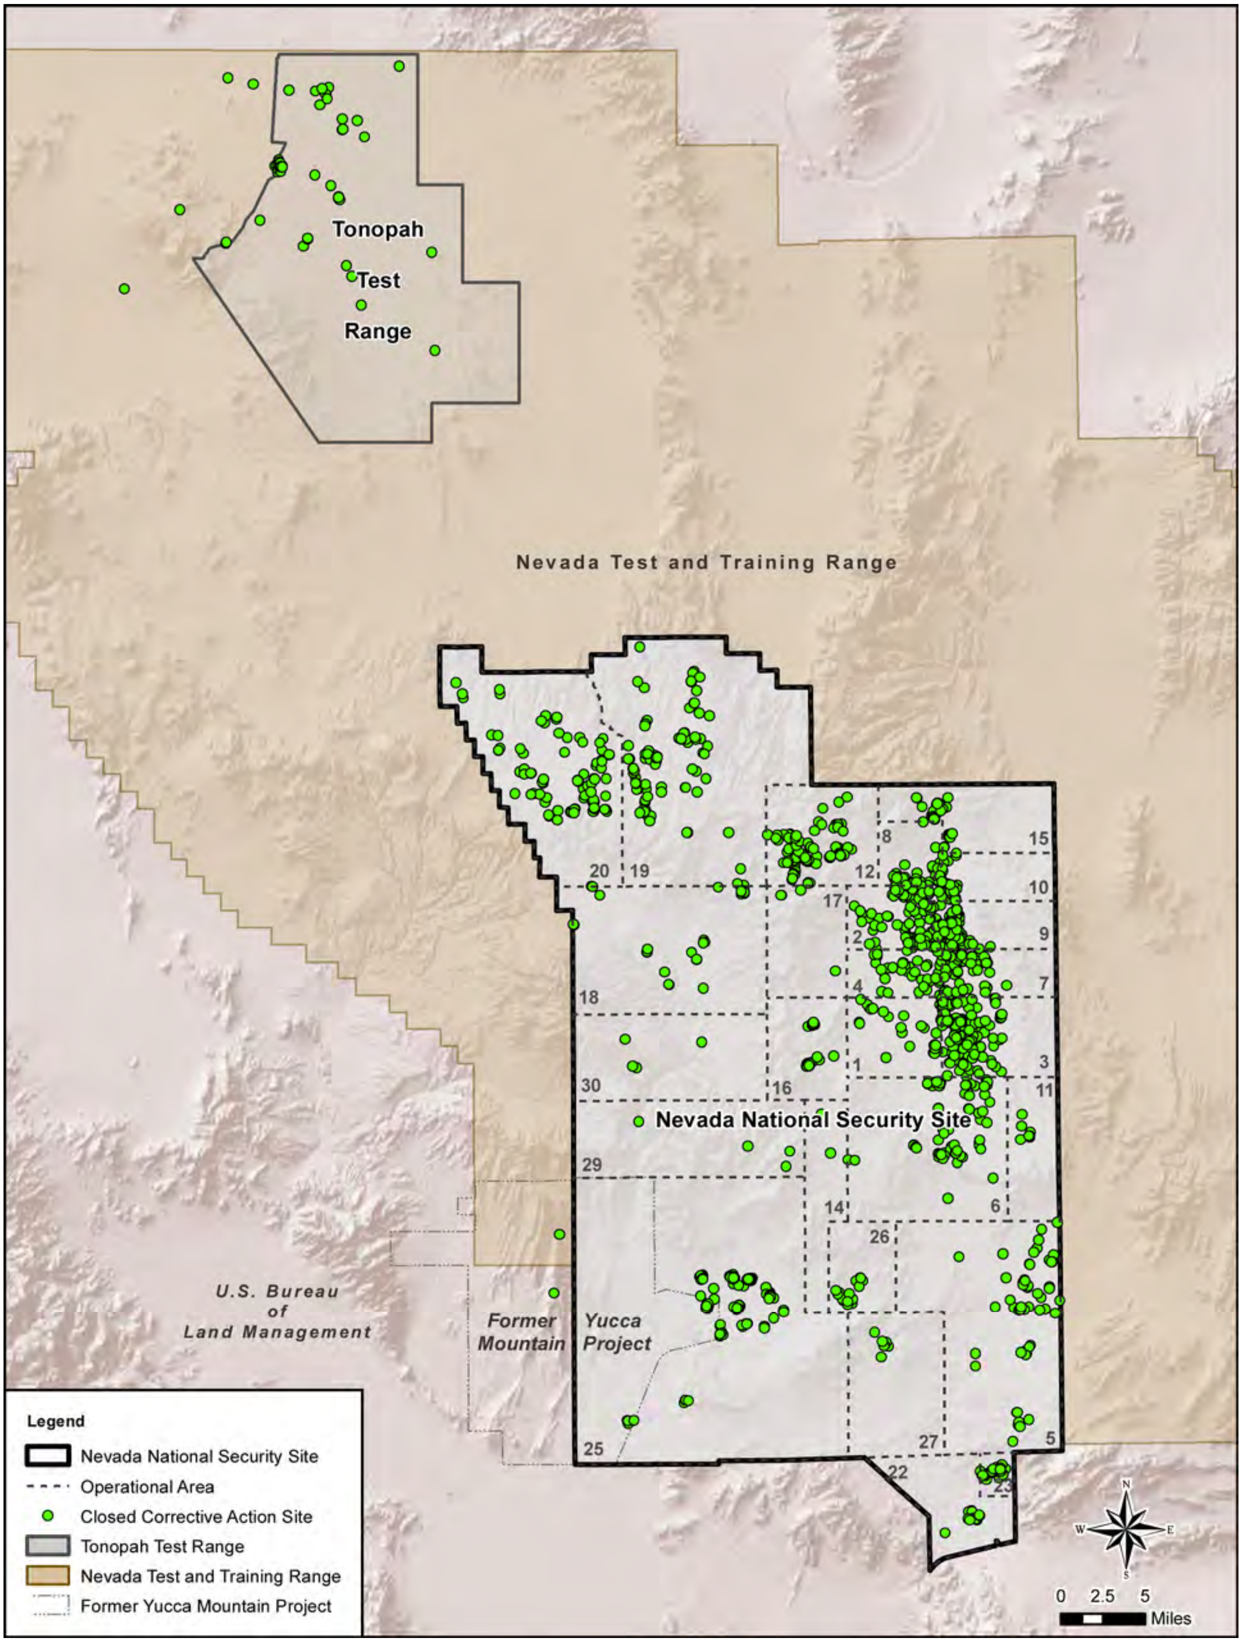

Figure 4–9 Location of Corrective Action Sites on the Nevada National Security Site, Tonopah Test Range, and Nevada Test and Training Range that are Closed under the Federal Facility Agreement and Consent Order

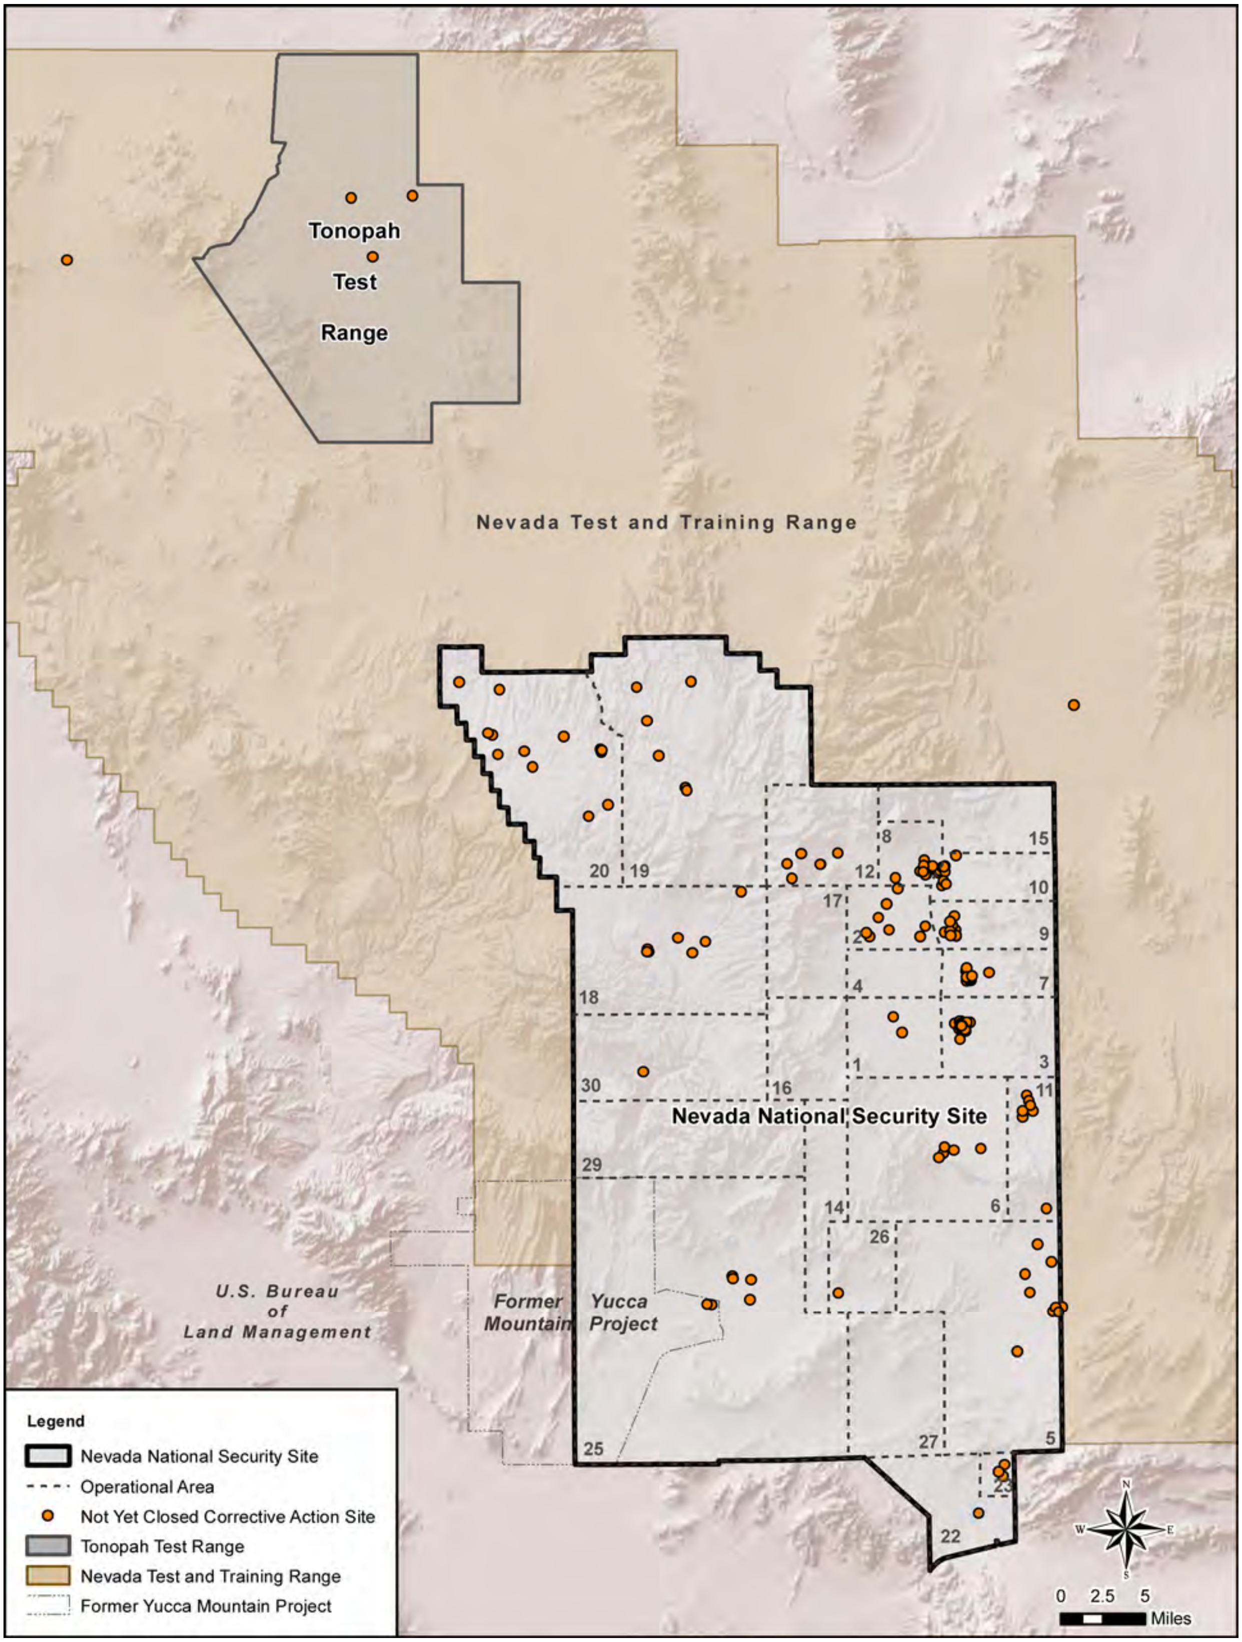

Figure 4–10 Location of Corrective Action Sites on the Nevada National Security Site, Tonopah Test Range, and Nevada Test and Training Range that are not yet Closed under the Federal Facility Agreement and Consent Order

As shown in **Figure 4–11**, areas of surface soil contamination on the NNSS have been identified, fenced, and/or posted as Radiation Areas and Contamination Areas, in accordance with the *Nevada Test Site Radiation Control Manual* (DOE/NV 2012c). The aggregated area of these contaminated areas is about 6,006 acres, or less than 1 percent of the overall area of the NNSS. A decay-corrected estimate of the total surface source term at the NNSS is about 1,614 curies as of January 2012 (Kidman 2012); however, there is a substantial level of uncertainty in this source term with a range as low as 820 and as high as 3,300 curies. Access to these contaminated areas is controlled.

Fifteen subsurface nuclear tests with corresponding surface releases were conducted on the NNSS between 1958 and 1972. In each of these tests, radioactivity from the subsurface detonation was released to surface soils around their ground zeros. While these releases consisted mostly of short-lived noble gases, cesium is the major long-lived source of radioactive dose at these sites.

Between 1955 and 1963, 27 safety experiments with surface or near-surface releases were conducted on the NNSS and the Nevada Test and Training Range, including the TTR. These safety experiments used mixtures of plutonium and uranium that were subjected to detonations of conventional explosives. Safety experiments at the NNSS were performed in Yucca Flat (Areas 3, 7, 8, and 9); Plutonium Valley (Area 11); Rainier Mesa (Area 12); and in the Nevada Test and Training Range (including the TTR) to the northeast and northwest of the NNSS. Although most tests had no nuclear yield, the explosions spread mostly plutonium, uranium, and americium.

Figures 4–12, **4–13**, and **4–14**, respectively, show the Double Tracks site; the Clean Slate 1, 2, and 3 sites; and the Project 57 site. DOE/NNSA has conducted interim remediation on the Double Tracks and Clean Slate 1 sites to remove all radioactive contamination that exceeds 400 picocuries per gram. The Clean Slate 2 and 3 and Project 57 sites have not yet been remediated. In addition to these sites, the Small Boy test resulted in an area of radioactive contamination extending from the northeastern portions of Area 5 east onto the Nevada Test and Training Range, as shown in Figure 4–11. Soils sites on the Nevada Test and Training Range, including the TTR, are expected to be remediated to an action level that is mutually agreed upon by DOE/NNSA, the USAF, and NDEP.

In addition to explosive tests, a series of activities was conducted at the Nuclear Rocket Development Station in Areas 25 and 26. From 1959 through 1973, the area was used for a series of experiments involving an open-air nuclear reactor, nuclear engine, and nuclear furnace tests, as well as for the High Energy Neutron Reactions Experiment (DOE 1996c). Equipment and facilities remain from some of these locations. Some limited areas of contaminated soils are also present. The total inventory of isotopes remaining in the soils in this area of the NNSS has been estimated to be about 1 curie (McArthur 1991). The primary soil contaminants in this area are isotopes of strontium, cesium, cobalt, and europium (DOE 1996c). Cleanup of contaminated soils resulting from nuclear rocket and related testing is addressed as part of the Environmental Management Mission under the Environmental Restoration Program (FFACO 2008).

At the end of 2010, two Soil Site corrective action sites were closed, leaving 110 CAS that remain to be closed (DOE/NV 2011).

4.1.5.4.2 Subsurface

Underground nuclear tests at Yucca Flat and Frenchman Flat were detonated primarily in alluvium or in the volcanic rocks. A few tests were detonated in the underlying carbonate rocks beneath the northern Yucca Flat during the early years of the testing program (DOE 1996c; OTA 1989). Testing near or below the water table was common in both the Yucca Flat weapons test basin and Frenchman Flat test area.

A total of 828 underground nuclear tests were conducted at the NNSS. This resulted in pockets of radiological contamination in the bedrock in underground nuclear testing areas at the subsurface and in the near vicinity of the testing locations. Underground testing is broken down into three main categories: (1) shallow borehole tests, (2) deep vertical tests, and (3) tunnel tests. This section presents the condition of the bedrock as a result of the tests.

From 1960 through 1968, shallow borehole tests were used to test a variety of explosives. "Shallow borehole tests" refer to the tests performed within 200 feet of the surface. Some of these were related to the safety experiments; others were conducted as part of Project Plowshare. Project Plowshare used nuclear detonations to determine whether the explosions could be used for large-scale excavations, such as creating harbors and canals. As a result, some large ejection craters were created at the NNSS, such as the Sedan Crater in Area 10 at the northern end of Yucca Flat and Buggy in Area 18. The Sedan Crater, a 1,280-foot-diameter crater, was generated from a 104-kiloton nuclear device detonated 635 feet underground. McArthur estimated that the remaining inventory of surficial radioactivity at the Sedan Crater is 344 curies (McArthur 1991). The craters contain radioactivity injected from the initial detonation that is being slowly covered as surrounding material is eroded into the craters. The total estimate for all releases from shallow borehole tests to the surficial soil horizon at the NNSS is 2,000 curies (DOE 1996c).

Deep vertical tests occurred at Frenchman Flat, Yucca Flat, Pahute Mesa, and Rainier Mesa. The tunnel complexes at Rainier Mesa and Shoshone Mountain were also used for horizontal tests. Radiological contamination, disruption of the geologic media, and seismic waves (i.e., ground motion) are other major impacts of underground nuclear testing. Some of the tests generated shock waves equivalent to 5.0-magnitude and 7.0-magnitude earthquakes, which were felt for miles outside of the NNSS with no permanent effects.

Following a deep underground nuclear detonation, a pocket of vaporized bedrock is almost instantaneously formed, which quickly fractures and propels a shock wave out from the test site. As the gases cool, molten rock begins to collect and solidify on the cavity sidewalls and settles in a puddle at the bottom of the cavity. When gas pressure decreases to the point that it can no longer support the overlying rock and soil, the cavity may collapse, forming a chimney upward above the cavity. The collapse of the overburden in the chimney occurs until the vertical stress is equalized or the chimney reaches the surface (DOE 1996c). The result is a saucer-like collapse crater. The collapse crater differs from the shallow borehole tests because the crater collapses inward, with no ejecta striations. The complete process usually occurs within a few hours after detonation. A more complete description of underground nuclear test phenomena is contained in Appendix H.

Yucca Flat is pockmarked with subsidence craters formed by deep vertical underground tests. The crater sizes range in diameter from 200 to 1,500 feet, and in depth from a few feet to 200 feet. The size of the crater depends on the depth of the test, the properties of the geologic units, and the explosive energy yield. The creation of craters is the principal visible consequence from underground nuclear testing. The seismic waves created by underground nuclear detonations also created pressure ridges, small displacement faults that occurred as the detonation created upward pressure initially and then released it. Young faults, such as the Yucca Fault in Yucca Flat, showed some signs of reactivation as a result of the bedrock equalizing to the new stress field around the testing area.

Some cratering occurred on Pahute Mesa due to underground tests; however, the greater competency of the volcanic tuffs and lavas prevented large-scale cratering. Some surface fracturing occurred on Pahute and Rainier Mesas. The amount of fracturing in a given test location is predictable, based on test parameters and the host bedrock. Site selection factors that were essential to both containment and the integrity of the test data ensured that failures within the test areas did not occur.

The fracturing of the rock in the near-test environment may have resulted in some alteration of the natural permeability of the rocks underlying portions of the NNSS. The shock wave and compressive forces from the tests can increase the permeability of the rock by creating more fractures near the test, but can also decrease the permeability by opening and closing fractures at greater distances from the test (DOE 1996c). The bedrock is generally unchanged beyond three cavity radii of the detonation site. At further distances, some fractures may open and then close because of the stress differential as the shock wave passes through. The process of opening and subsequent closing of existing rock fractures could reduce the permeability of the rock by reducing the fracture aperture.

Just as surface and atmospheric tests increased the radioactivity of the soils at the surface, underground nuclear tests created pockets of radioactive contamination around the detonation site. The amount of radiation in these pockets has to be estimated because, unlike surface tests, the detonation site is surrounded by fractured and unfractured bedrock. Immediately after the detonation, the amount of radiation spikes, then reduces as the isotopes with short half-lives decay. Most investigators have concluded that much of the radioactivity released during an underground detonation, exclusive of tritium, remains in the melt glass in the original cavity, especially the refractory isotope species; the more-volatile nuclides tend to condense on the chimney rubble (Borg et al. 1976). Refractory species include plutonium, rare earth elements, zirconium, and alkaline earth elements; volatile species include alkali metals, ruthenium, uranium, antimony, tellurium, and iodine. The most mobile isotopes are the gaseous species, including argon, krypton, tritium, and xenon, which tend to rise through the chimney and may ultimately seep out to the surface (DOE 1996c). The total amount of radioactivity released into the underground environment during a test is called the radiological source term. The source term includes both short- and long-half-life isotopes. The estimated radiological source term from all deep underground tests reported in the *1996 NTS EIS* was 300 million curies (DOE 1996c). In 2001, scientists at Los Alamos and Lawrence Livermore National Laboratories estimated the underground source term beneath the NNSS, decay-corrected to September 23, 1992, to be about 132 million curies (Bowen et al. 2001). Of the 132 million curies, approximately 95 percent (125 million curies) was estimated to be tritium, which has a half-life of about 12.3 years. As of September 2012, radioactive decay will have reduced the tritium component of the underground source term to about 23 million curies.

Geology and Soil—American Indian Perspective

CGTO When visiting Area 5 of the Nevada National Security Site (NNSS) in 2009, Indian people observed several traditional use minerals. In particular, Indian people have observed the presence of: (1) Chalcedony, (2) Obsidian, (3) Yellow Chert (otherwise known as Jasper), (4) Black Chert, (5) Pumice, (6) Quartz Crystal, and (7) Rhyolite Tuff. Other traditional use minerals are known to exist in other areas throughout the NNSS.

Minerals are culturally important and have significant roles in many aspects of Indian life. For example, the Chalcedony would have made an attractive offering, which could be acquired here and then left at the vision quest or medicine site located to the north on top of a volcano like Scrugham Peak. Upon return, traditional Indian people would bring offerings back to where we acquired offerings.

Obsidian is a glass-like stone produced by volcanoes. Indian people used a green volcanic glass during curing ceremonies that involved bleeding the patient. Volcanic glass found below Scrugham Peak was used in the first arrow making lessons for young men. Such lessons were held in small rock shelters found along the base of the basalt flow that constitutes Buckboard Mesa. Obsidian flakes were placed before important rock art panels as offering to the spirits that lived on the other side of the passageway provided by the panel. Small obsidian stones, commonly called Apache Tears, have been found on the face of Shoshone Mountain in southern Nevada. This massive deposit of obsidian stones is interpreted by Indian people as being provided by the mountain as both a spiritual backdrop and a location rationale for vision quests.

Volcanic rocks are used in a wide range of ceremonial activities. Indian women enhance the quality of breast milk by squirting it on heated rocks. They are used for medicine society sweat lodge meetings. Indian people call some volcanic rocks "grandfather stones," a designation that reflects reverence as well as wisdom. Such rocks are sought in special places of power and carried over long distances to serve as the heated stones in sweat lodges.

See Appendix C for more details.

4.1.6 Hydrology

4.1.6.1 Surface Water

The NNSS lies within the Basin and Range Physiographic Province and the Great Basin, which is a closed hydrographic basin from which no surface water leaves, except by evaporation. Much of Nevada is contained within the Great Basin, including the NNSS, the TTR, and all but the southern corner of the Nevada Test and Training Range. Consistent with the Great Basin, the internal drainage of regional hydrographic basins is controlled by topography (USAF 1999). The Great Basin comprises numerous smaller hydrographic basins; parts of nine different smaller basins occur within the boundaries of the NNSS. The basins that cover the greatest amount of land area on the NNSS include (1) Fortymile Canyon (the Buckboard Mesa and Jackass Flats Subdivisions), (2) Yucca Flat, (3) Rock Valley, and (4) Frenchman Flat. Hydrographic basins on the NNSS that are less extensive in land area include portions of Gold Flat, Kawich Valley, Emigrant Valley, Mercury Valley, and Oasis Valley (see **Figure 4–15**).

The similarity of physical environmental attributes throughout the region allows for a general discussion of surface-water features and characteristics of the NNSS, the TTR, and the Nevada Test and Training Range, as well as offsite features of importance in close proximity. Thus, the surface-water section begins with a brief discussion of regional conditions before focusing on the NNSS.

Surface-Water Features. None of the streams in the region perennially contains water. Thus, streams are ephemeral and are fed by runoff from snowmelt and precipitation during storm events. Storms are most common in winter and occur occasionally in fall and spring; localized thunderstorms often occur in the summer. Much of the runoff quickly infiltrates into rock fractures or into the dry soils. Some runoff is carried down alluvial fans in arroyos, and some drains onto playas where it may stand for weeks as a lake (DOE 1988). These usually dry playas illustrate a perennial water deficit that has been characteristic of southern Nevada since about 1850 (Forester et al. 1999).

The Amargosa River, in the Amargosa Desert, is the main ephemeral stream feature in the region, though it is normally dry, and lies approximately 20 miles southwest of the NNSS at its closest point. The Amargosa River continues to Death Valley, California (DOE 1988).

Springs are the only perennial surface-water sources throughout the region. Most perennial surface discharges from springs occur as pools at some large springs. In most instances, discharged spring water travels only a short distance from the source before evaporating or infiltrating the ground. Springs, seeps, and marsh areas of the region discharge from less than one to several thousand gallons of water per minute. In larger springs, discharges are typically several tens to several hundreds of gallons per minute. The largest discharge is at Crystal Pool in Ash Meadows, approximately 15 miles south of the NNSS southern boundary (DOE 1988). A small lake, locally known as Crystal Reservoir, with a storage capacity of 1,489 acre-feet, is present in Ash Meadows. Water for the reservoir is supplied by a flume from Crystal Pool (Giampaoli 1986).

NNSS-Specific Conditions. There are no important perennial or intermittent streams on the NNSS. During infrequent runoff events, ephemeral channel systems in the western half and southernmost parts of the NNSS carry runoff beyond the NNSS boundaries. Fortymile Canyon is the largest drainage system, draining to the Amargosa River approximately 20 miles southwest of the NNSS boundary. The main tributary in the Fortymile Canyon system is Fortymile Wash. On the NNSS, Fortymile Canyon and its ephemeral tributaries consist of well-defined canyons; however, the canyon splits into several tributaries beyond the NNSS boundary (DOE 1996a).

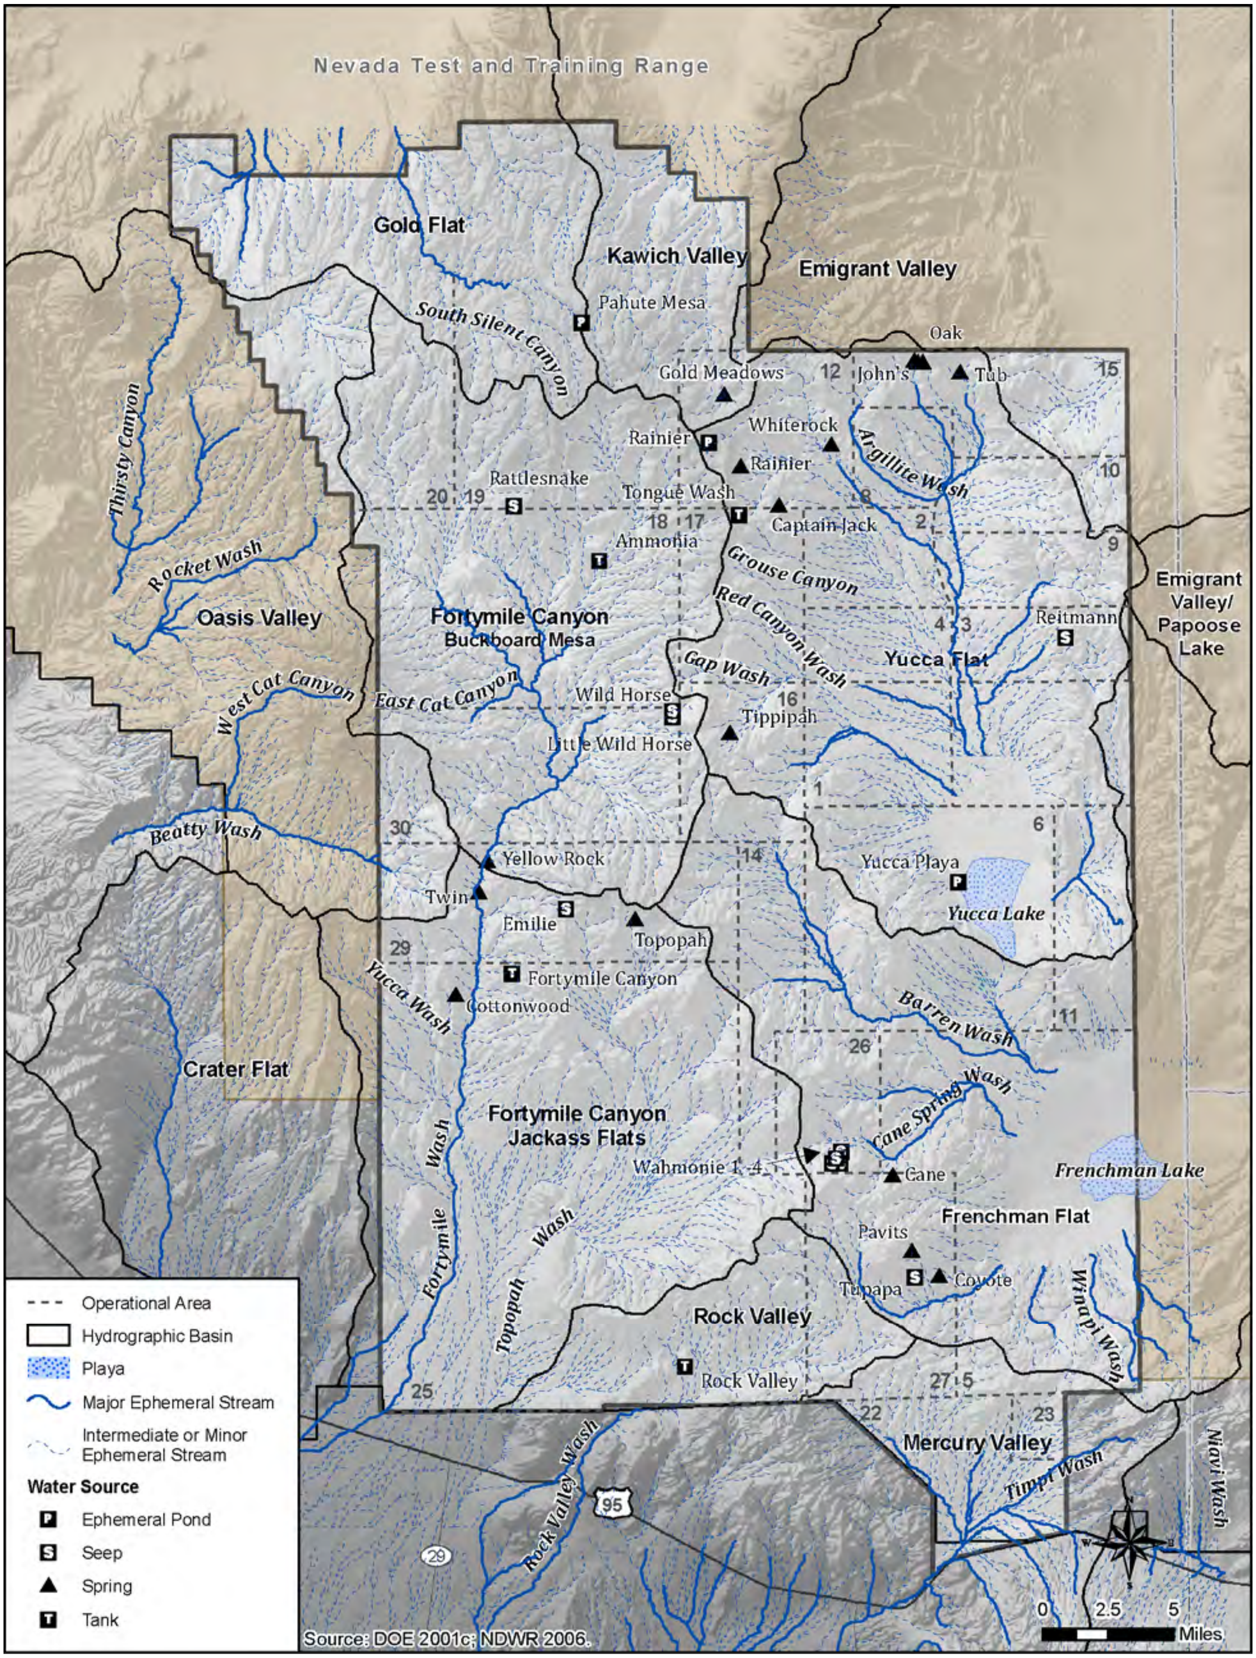

Figure 4–15 Hydrographic Basins and Surface-Water Features on the Nevada National Security Site

There are two other major NNSS drainages that discharge to the Amargosa River: (1) Topopah Wash and (2) Rock Valley. Topopah Wash originates in the Jackass Flats Subdivision of Fortymile Canyon in the south-central portion of the NNSS and trends southwesterly. Rock Valley drains from the southernmost portion of the NNSS westward (see Figure 4–15). Both of these drainage systems are dry throughout most years (DOE 1996a).

In general, ephemeral surface flows on the NNSS are infrequent, with no flow in some years, while in other years, flows may occur for only a few days (DOE 1996a). For example, stream flows measured in Fortymile Wash near the NNSS boundary (approximately 3 miles northwest of the intersection of Lathrop Wells Road and U.S. Route 95) for the water years of 2002 through 2004 (a water year runs from October 1 through September 30) showed no flow at all in 2002 and 2004 (USGS 2002, 2004). In 2003, a discharge of less than 0.1 cubic feet per second was recorded as the yearly maximum and the flow was not sufficient to measure a water height (USGS 2003). Recordable flow events do occur in Fortymile Wash periodically. The most notable of these occurred during March 11–13, 1995, when U.S. Route 95 was closed due to water flowing over the road. The peak discharge at the aforementioned stream flow gauging station during this event was 1,200 cubic feet per second. Historically, stream flow has occurred throughout the Fortymile Wash channel system in January and February 1969, March 1983, July and August 1984, and March 1995, with several other periods where flow occurred in portions of the overall system (Savard 1998). Although these washes contain water infrequently, when they do contain water, they provide many of the beneficial functions that surface-water resources typically provide, such as providing habitat for desert species and serving as flood control features.

There are several "tanks" on the NNSS, which are natural rock depressions that capture surface runoff. There are little data available on the hydrologic characteristics of the tanks. During a study conducted in 1997, the maximum surface areas of individual tanks on site measured approximately 160 square feet with maximum water depths of approximately 3 feet. In addition, there are three ephemeral ponds on the NNSS: (1) Yucca Playa Pond, (2) Pahute Mesa Pond, and (3) Rainier Pond. Yucca Playa Pond occurs in a low spot on the west side of Yucca Lake Playa, where water collects naturally from playa drainage (Hansen et al. 1997). Pahute Mesa Pond occurs in the northern portion of the NNSS near the boundary between Gold Flat and Kawich Valley. Pahute Mesa Pond typically contains water for short periods following summer rain events (DOE/NV 2011). Rainier Pond was discovered in 2009 (see Figure 4–15).

In areas where underground nuclear tests have occurred, ground surface disturbances and craters have altered natural drainage paths. Some craters have captured nearby drainage and headward erosion of drainage channels has occurred. In some areas of the NNSS, the natural drainage system has been completely altered by the craters (DOE 1996a). The majority of past underground nuclear tests and associated craters are concentrated in the following NNSS locations: Areas 2, 3, 4, 6, 7, 8, 9, 10, and 15. Areas 5, 11, 12, 16, 19, and 20 have been affected as well.

There are 26 known springs and seeps on the NNSS (DOE/NV 1999; Hansen et al. 1997), although some are dry for most of the year (see Figure 4–15). Additionally, 143 manmade impoundments (plastic-lined and earthen sumps) currently exist at the NNSS, but similar to natural water sources, not all of the manmade impoundments contain water year-round.

Records of Wells, Test Holes, and Springs in the Nevada Test Site and Surrounding Area (Moore 1961) provides data on discharges from eight springs on the NNSS and one spring approximately 10 miles north of the NNSS on the Nevada Test and Training Range (i.e., Indian Springs) sampled from 1957 to 1960. The largest two of the nine springs in the study located on the NNSS discharged more than 1 gallon per minute (Cane Spring, 2 to 3 gallons per minute; Whiterock Spring, 1 to 2 gallons per minute); all others discharged less than 1 gallon per minute. *Nevada Test Site Wetlands Assessment* (Hansen et al. 1997, Table 5-1) provides more-recent data (1996 to 1997) on 20 NNSS springs and seeps that indicate a general lowering of discharge rates since the early 1960s. Discharge rates ranged from 0.0 to 0.8 gallons per minute, with the greatest values measured at Cane Spring (0.8 gallons per minute), Tippipah Spring

(0.7 gallons per minute), and Whiterock Spring (0.5 gallons per minute). All others discharged less than 0.5 gallons per minute, with several exhibiting no discharge (i.e., Coyote, Gold Meadows, Pavits, and Rainier Springs, as well as Tupapa Seep and Wahmonie Seeps 2 and 3).

The Clean Water Act prohibits the discharge of pollutants (including dredged or fill material) into "waters of the United States," except as authorized by a permit. Joint guidance by the U.S. Environmental Protection Agency (EPA) and the U.S. Army Corps of Engineers, issued in response to a June 2006 Supreme Court decision, provides new guidelines for determining whether tributaries and wetlands are waters of the United States and are regulated under the Clean Water Act (EPA and Army 2007). Based on the new guidance, no wetlands at the NNSS are expected to qualify as waters of the United States (DOE/NV 2009d) due to a lack of surface hydrologic connections to navigable waterways or their tributaries, though certain tributaries on the NNSS may qualify (e.g., Fortymile Wash). If an activity is proposed that may affect a tributary or wetland that is potentially a water of the United States, a site-specific evaluation by the U.S. Army Corps of Engineers would be determinative in terms of jurisdictional status. **Table 4–16** provides a summary of the general characteristics of potential wetland areas known to exist on the NNSS. Some of the wetland areas have not yet been studied thoroughly due to their remote nature and, in some instances, their relatively recent discovery.

Table 4–16 General Characteristics of Potential Wetland Areas on the Nevada National Security Site

Potential Wetland Area	***Area of Surface Water (square feet)*** [a]	***Dominant Vegetation*** [b]	***Wildlife Types Observed***
Ammonia Tanks	323	Louisiana sagewort (*Artemisia ludoviciana*)	Mammals and upland game birds
Cane Spring	43	Goodding's willow (*Salix gooddingii*) Baltic rush (*Juncus balticus*) Basin wildrye (*Leymus cinereus*) Willow dock (*Rumex salicifolia*)	Mammals, upland game birds, migratory waterfowl, raptors, and passerine birds

Surface-Water Characteristics. There is no known human consumption of surface water on the NNSS. In fact, no public water supplies are drawn from springs in the Amargosa Valley, which is located downgradient from the NNSS along the primary pathway for surface-water flow. The closest surface-water supply used for public consumption is Lake Mead (NDEP 2010c), which is located approximately 100 miles southeast of the NNSS and supplies a large portion of the water demand of metropolitan Las Vegas.

Little data on the characteristics of water in the region are available because all streams in the region are ephemeral. *Records of Wells, Test Holes, and Springs in the Nevada Test Site and Surrounding Area* (Moore 1961) presented results on chemical analyses for eight springs on the NNSS (see **Table 4–17**). More-recent (1996 to 1997), but less extensive data are provided in **Table 4–18**.

Source: Hansen et al. 1997, Table 5-2.

Prior to 1998, natural springs on the NNSS were tested annually for radiological constituents. In 1998, in accordance with the Routine Radiological Environmental Monitoring (RREM) Plan, this sampling was discontinued because the onsite springs are fed by locally derived or "perched" groundwater (i.e., groundwater in a saturated zone of material separated from other groundwater bodies by a relatively impervious zone) (Hansen et al. 1997; Moore 1961) that is not hydrologically connected to any of the aquifers that may be affected by underground nuclear tests (Bechtel Nevada 1998a; DOE/NV 1999). In 1996 and 1997, seven natural springs on site were sampled because only seven had enough water to provide a sample. The sampled springs were (1) Rainier Mesa Spring, (2) Oak Spring, (3) Whiterock Spring, (4) Captain Jack Spring, (5) Tippipah Spring, (6) Topopah Spring, and (7) Cane Spring. In 1996, the average gross beta concentration of the sampled springs was 9.2×10^{-9} microcuries per milliliter, and in 1997 it was 9.8×10^{-9} microcuries per milliliter. These average values represent approximately 23 to 25 percent of the EPA Derived Concentration Guide for exposure to the public (based on a strontium-90 value for drinking water of 4 millirem effective dose equivalent). Although these values are much lower than the Derived Concentration Guide, it is important to note that spring water is not used for human consumption on the NNSS (DOE/NV 1997b, Table 5.11; 1998c, Table 5.6). It is also important to note that this radiation is due to elements that naturally exist in the volcanic geologic medium (e.g., uranium and potassium-40).

Flood Hazards. Flash flooding occurs on the NNSS in response to heavy precipitation events, especially during summer thunderstorms. The runoff from these storms is typically of short duration; however, the storms do result in large peak discharge rates. Flood hazards for DOE/NNSA facilities and activities are most likely associated with flooding in alluvial fans and playas. Throughout the NNSS, there is the potential for sheetflow or channelized flow through arroyos to cause localized flooding. In addition, a rise in any standing water on a playa creates a potential flood hazard. However, because of the size of the NNSS, no comprehensive floodplain analysis has been conducted to delineate the 100- and 500-year floodplains (Cohn 2010).

Playas in the Yucca Flat weapons test basin and Frenchman Flat in the eastern and southeastern parts of the NNSS, respectively, collect and dissipate runoff from their respective hydrographic basins. Control Point and News Knob arroyos (informal names), and Gap Wash, Red Canyon Wash, Tongue Wash, and the Aqueduct arroyos in the Yucca Flat weapons test basin pose a potential flood hazard to existing facilities (DOE 1996a). The Control Point and News Knob arroyos have been assessed for flood hazards (Miller et al. 1994).

Arroyos in Frenchman Flat that pose a potential flood hazard to existing facilities include Barren Wash, Scarp Canyon, Nye Canyon, and Cane Spring (DOE 1996a). There is a 100-year flood hazard area along the southwest corner of the Area 5 RWMC associated with Barren Wash (Schmeltzer et al. 1993). Areas prone to flooding surround Fortymile Wash, a major tributary of Fortymile Canyon. Topopah Wash runs southwesterly across the Jackass Flats Subdivision of Fortymile Canyon from Jackass Divide in the south-central part of the NNSS (DOE 1996a). The 100-year flood-prone areas of Topopah Wash and its tributaries would closely parallel most stream channels with few occurrences of out-of-bank flooding, though 500-year flood events would overtop the banks of all tributaries (not including Topopah Wash itself) and maximum flood events would inundate the entire area (Christensen and Spahr 1980). The Fortymile Canyon Hydrographic Basin poses a flood hazard to offsite areas (SAIC/DRI 1991). Arroyos trending southward from Red Mountain pose a potential flood hazard to sewage lagoons that service Mercury (DOE 1996a).

Water Discharges and Regulatory Compliance. Industrial discharges on the NNSS are limited to two operating sewage lagoon systems: (1) Area 6 Yucca Lake and (2) Area 23 Mercury (these lagoon systems also receive domestic wastewater). The Area 6 Yucca Lake system consists of two primary lagoons and two secondary lagoons. All lagoons in the Area 6 Yucca Lake system are lined with compacted native soils that meet State of Nevada requirements for hydraulic conductivity (3.937×10^{-8} inches per second). The Area 23 Mercury system consists of one primary lagoon, a secondary lagoon,

and an infiltration basin. The primary and secondary lagoons in the Area 23 Mercury system have a geosynthetic clay liner and a high-density polyethylene liner. The lining of the ponds allows the Area 23 lagoons to operate as a fully contained, evaporative, nondischarging system (DOE/NV 2011).

These Area 6 Yucca Lake and Area 23 Mercury lagoon systems are operated under a State of Nevada Water Pollution Control General Permit (Permit number: GNEV93001). Through 2008, this permit required annual monitoring of gross alpha, gross beta, and tritium radioactivity. The permit was revised on November 20, 2008, and annual monitoring requirements changed; the lagoons are now sampled for gross alpha, gross beta, and tritium radioactivity, as well as 29 organic and inorganic contaminants only in the event of specific or accidental discharges of potential contaminants (DOE/NV 2009d). There were no such discharges in 2010 (DOE/NV 2011). For the influent water, quarterly monitoring of 5-day biochemical oxygen demand, total suspended solids, and pH (a measure of acidity or basicity) continue to be permit requirements (DOE/NV 2009d). **Table 4–19** provides results of 2008 gross alpha, gross beta, and tritium sampling of the active lagoon systems. No concentrations exceeded permit limitations; tritium concentrations did not reach the sample-specific minimum detectable concentration levels.

Table 4–19 Annual Radiological Results for Sewage Lagoon Effluent (2008)

Monitoring Location	*Gross Alpha ± Uncertainty* [a]	*Gross Beta ± Uncertainty* [a]	*Tritium ± Uncertainty* [a]
	(minimum detectable concentration) (picocuries per liter)		
Area 6 Yucca Lake	4.7 ± 1.3 (1.3) [b]	23.8 ± 4.1 (2.0) [b]	136 ± 225 (370)
Area 23 Mercury	3.8 ± 1.3 (1.5) [b]	27.7 ± 5.0 (3.3) [b]	35 ± 222 (370)
Permit Limit	15	50	20,000

[a] ± 2 standard deviations.

pH	S.U.	6.0 – 9.0	8.20 – 8.70	8.00 – 8.50

BOD_5 = 5-day biochemical oxygen demand; lbs/d = pounds per day; pH = a measure of acidity or basicity; ppm = parts per million; S.U. = standard units of pH.
Source: DOE/NV 2011, Table 5-10.

E-Tunnel is a complex of tunnels and drifts in Area 12 that were constructed for underground testing of nuclear devices. Perched groundwater percolating through the pores and fractures of the volcanic tuffs constituting Rainier Mesa encounters radiological artifacts of nuclear experiments, as well as naturally occurring radiological constituents; some of that water exits through the E-Tunnel portal. Attempts were made to eliminate the discharge by plugging the tunnel, which were unsuccessful; therefore, disposal of this water has been performed via infiltration/evaporation in five unlined primary holding ponds, directing most of the effluent toward the groundwater regime. The NNSS manages and operates the E-Tunnel Waste Water Disposal System (ETDS) in Area 12 under a water pollution control permit issued by the NDEP Bureau of Federal Facilities (Permit number: NEV 96021). The permit governs the management of radionuclide-contaminated wastewater that drains from the E-Tunnel portal into the five holding ponds. The permit requires ETDS discharge waters to be monitored every 12 months for certain radiological and nonradiological parameters. In addition, monthly monitoring is required for flow rate, pH, temperature, specific conductance, total volume, and the structural integrity of the holding ponds. **Table 4–22** provides results of 2010 gross alpha, gross beta, and tritium sampling of the ETDS discharge water. Tritium concentrations were about 50 percent of the limit allowed under the permit. The discharge water was also within gross alpha/beta permit limits (DOE/NV 2011). Gross beta values represent radiation from both human-influenced (e.g., tritium) and naturally occurring sources (e.g., radium-228).

Table 4–22 Radiological Results for E-Tunnel Waste Water Disposal System Discharge Water Samples (2010)

Radiological Parameter	*Permit Limit (picocuries per liter)*	*Measured Value (picocuries per liter)*
Tritium	1,000,000	505,000 ± 77,100
Gross Alpha	35.1	8.0 ± 1.6
Gross Beta	101	37.7 ± 6.1

Note: Samples taken in October 2010.
Source: DOE/NV 2011, Table 5-6.

Table 4–23 shows the results of the 2010 water quality sampling of the ETDS holding ponds for nonradiological parameters that are required to be monitored under the water pollution control permit. All measurements were within permit limits and specifications for the annual sample. Most monthly measurements were also within permit limits except for specific conductance at the ETDS discharge point. Specific conductance is a measure of how well water can conduct an electrical current. Monthly specific conductance measurements were 379.0, 369.7, 385.7, 395.7, 371.5, 391.7, 380.2, 389.0, 388.2, and 393.3 microsiemens per centimeter in February, March, April, May, June, August, September, October, November, and December, respectively. These are all below the lower permit limit of 400 microsiemens per centimeter. NDEP determined that specific conductance measurements should continue to be collected after evaluating NNSS's study of this parameter. NDEP suspended the permit requirement for follow-on monitoring and will re-evaluate the permit limits for specific conductance when the permit is renewed in 2013 (DOE/NV 2011).

Table 4–23 Nonradiological Results for E-Tunnel Waste Water Disposal System Discharge Water Samples (2010)

4.1.6.2 Groundwater

This section is an overview of the general hydrogeologic setting and characteristics of groundwater underlying the NNSS. Water-resource features, including supply wells and monitoring wells used for access to groundwater, are described in relation to the hydrographic areas in which they lie.

Important characteristics of groundwater systems include recharge zones (areas where water infiltrates from the surface and reaches the saturated zone), discharge points (locations where groundwater reaches the surface), unsaturated zones (the portion of the groundwater system above the water table), saturated zones (the portion of the groundwater system below the water table), aquitards (confining units), and aquifers (water-bearing layers of rock that provide water in usable quantities). In combination, these characteristics define the quantity and quality of the available groundwater.

Hydrogeologic Setting. The NNSS is located within the southern portion of the Great Basin, occupying approximately 0.7 percent of the Great Basin. The Great Basin is a closed hydrographic province (a basin with no external drainage, from which water is lost only by evapotranspiration) with no outlet to the Pacific Ocean. It comprises many hydrographic basins (areas in which surface runoff collects and from which it is carried by a drainage system, such as a river and its tributaries). Hydrographic basins are mapped on the basis of topographic divides and are used by the State of Nevada for the purposes of water appropriation and management. The NNSS lies within a portion of 10 hydrographic basins (Mercury Valley, Rock Valley, Yucca Flat, Frenchman Flat, Buckboard Mesa, Jackass Flats, Oasis Valley, Gold Flat, Kawich Valley, and Emigrant Valley; see **Figure 4–16**).

> **Acre-foot**: The volume of water that will cover an area of 1 acre to a depth of 1 foot; 1 acre-foot is equivalent to 325,851 gallons.

The perennial yield for the 10 hydrographic basins partly or wholly located within the NNSS, as shown in **Table 4–24**, is estimated at 33,050 acre-feet per year. The perennial yield is an estimate of the quantity of groundwater that can be withdrawn from a basin on an annual basis without depleting the reservoir (Scott et al. 1971). The perennial yield values used by the Nevada State Engineer were applied for purposes of analysis to all basins. The values used by the Nevada State Engineer for most basins are conservative estimates (considering only recharge through precipitation in a basin), and are based upon a series of reports dating to 1970 and earlier. The term sustainable yield, as used in this *NNSS SWEIS*, means the quantity of groundwater that can be withdrawn in the future from a basin without depleting the reservoir, considering any resources (water rights) already committed to other users. Sustainable yield is effectively the value of a basin's perennial yield minus any existing annual withdrawals.

For Frenchman Flat, the Nevada State Engineer has previously estimated a perennial yield of only 100 acre-feet per year (NDWR 2010a). However, this yield is based upon previous assumptions that little or no groundwater recharge from precipitation occurred in Basin 160. More-recent studies suggest that in-basin recharge does occur in Basin 160, and that perennial yield values are much higher than 100 acre-feet per year. DOE/NNSA has extensively studied the groundwater recharge in Frenchman Flat, using a model from the UGTA program, two U.S. Geological Survey (USGS) models (Hevesi et al. 2003), and two Desert Research Institute models (Russell and Minor 2002). All of these models provide revised estimates of precipitation-driven recharge (and thus perennial yield) of Frenchman Flat using more-rigorous analytical methods and more-recent data. As an example, the UGTA model (yields an estimate of 1,070 acre-feet per year) for Frenchman Flat and the USGS and Desert Research Institute models provide perennial yield estimates of 1,830 and 1,320 acre-feet per year, respectively.

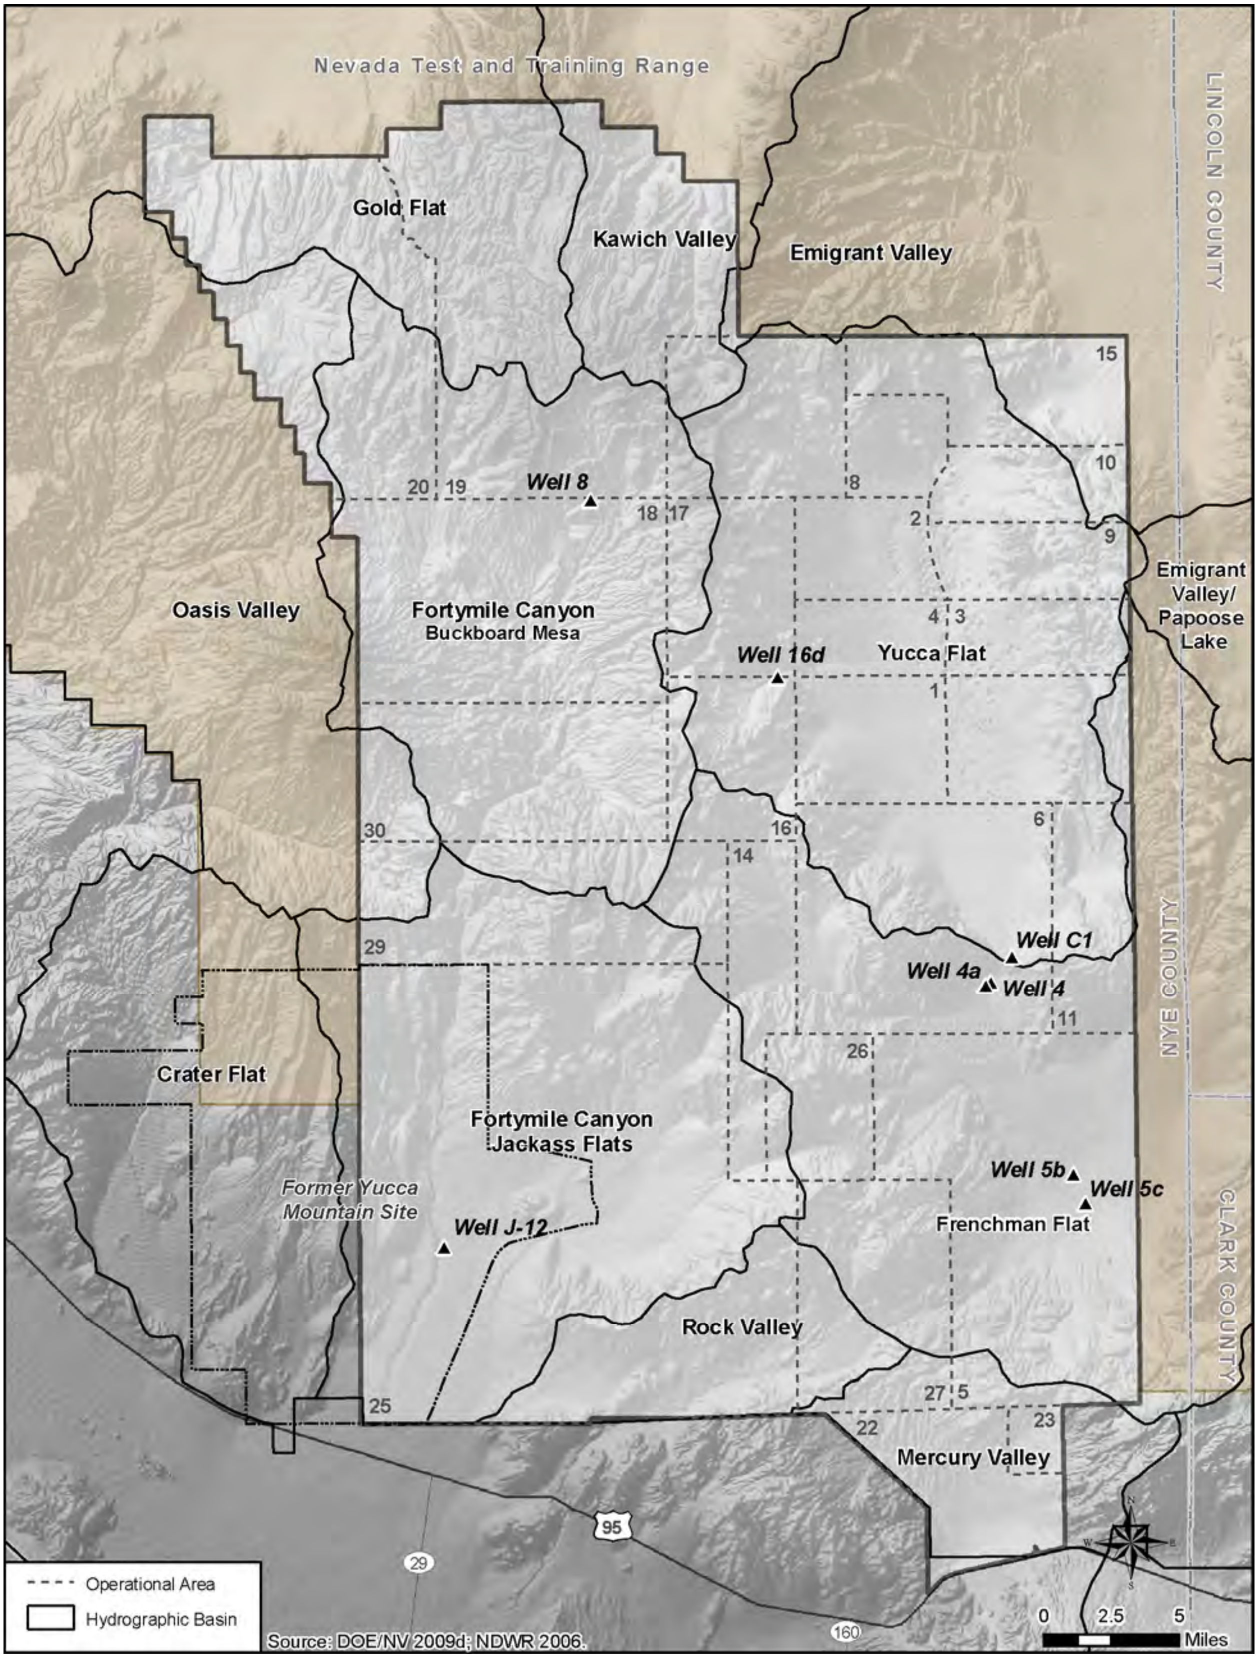

Figure 4–16 Hydrographic Basins at the Nevada National Security Site

Table 4–24 Perennial Yield of Hydrographic Basins at the Nevada National Security Site

Hydrographic Basin	*Hydrographic Basin Number*	*Perennial Yield (acre-feet per year)* [a]	*Total Committed Groundwater Resources (acre-feet per year)* [a, b]	*Sustainable Yield (acre-feet per year)*
Mercury Valley	225	8,000	0	8,000
Rock Valley	226	8,000	0	8,000

[b] Represents water rights appropriated to non-DOE/NNSA users off the NNSS.

The eight water supply wells currently used at the NNSS are located within the Fortymile Canyon Buckboard Mesa and Jackass Flats Subdivisions, Yucca Flat, and Frenchman Flat. These four hydrographic basins have a combined perennial yield of 8,050 acre-feet per year. Total water withdrawals at the NNSS between 2005 and 2009 ranged from 530 to 691 acre-feet per year, as shown later in this section in Table 4–27.

Groundwater beneath the NNSS exists within three groundwater subbasins (a subbasin is defined as the area that contributes water to a major surface discharge area), as shown in **Figure 4–17**. The eastern half of the NNSS is located within the Ash Meadows subbasin, where groundwater flows toward the Ash Meadows discharge area downgradient of the NNSS. The Ash Meadows discharge area contains the sensitive Ash Meadows National Wildlife Refuge. Within the northeast corner of this refuge lies Devils Hole, which is home to the Devils Hole pupfish, an endangered species (see Section 4.1.7 for more information regarding Devils Hole). In 1976, the Supreme Court ruled that the Devils Hole pupfish had prior water rights and that a minimum level of water must be preserved to ensure its protection (United States v Cappaert, 426 U.S. 128 [1976]). This decision resulted in the prohibition of any development that could lower the water level in Devils Hole. The western half of the site lies largely within the Alkali Flat Furnace Creek Ranch subbasin, which flows toward the Alkali Flat Furnace Creek Ranch discharge area, and a small section of the northwest corner of the site is located within the Pahute Mesa Oasis Valley subbasin, which flows toward the Pahute Mesa Oasis Valley discharge area. As displayed above, these three subbasins are named for their downgradient discharge areas. As all three discharge areas are located off site, any activity that may affect groundwater on the NNSS has the potential to affect groundwater off the NNSS.

The NNSS is located within the Death Valley regional groundwater flow system extending from central Nevada north of the NNSS to Death Valley. The Death Valley system encompasses approximately 16,000 square miles of the Great Basin (Belcher et al. 2010). It is very complex, involving many aquifers and aquitards, which vary in their characteristics and presence over distance.

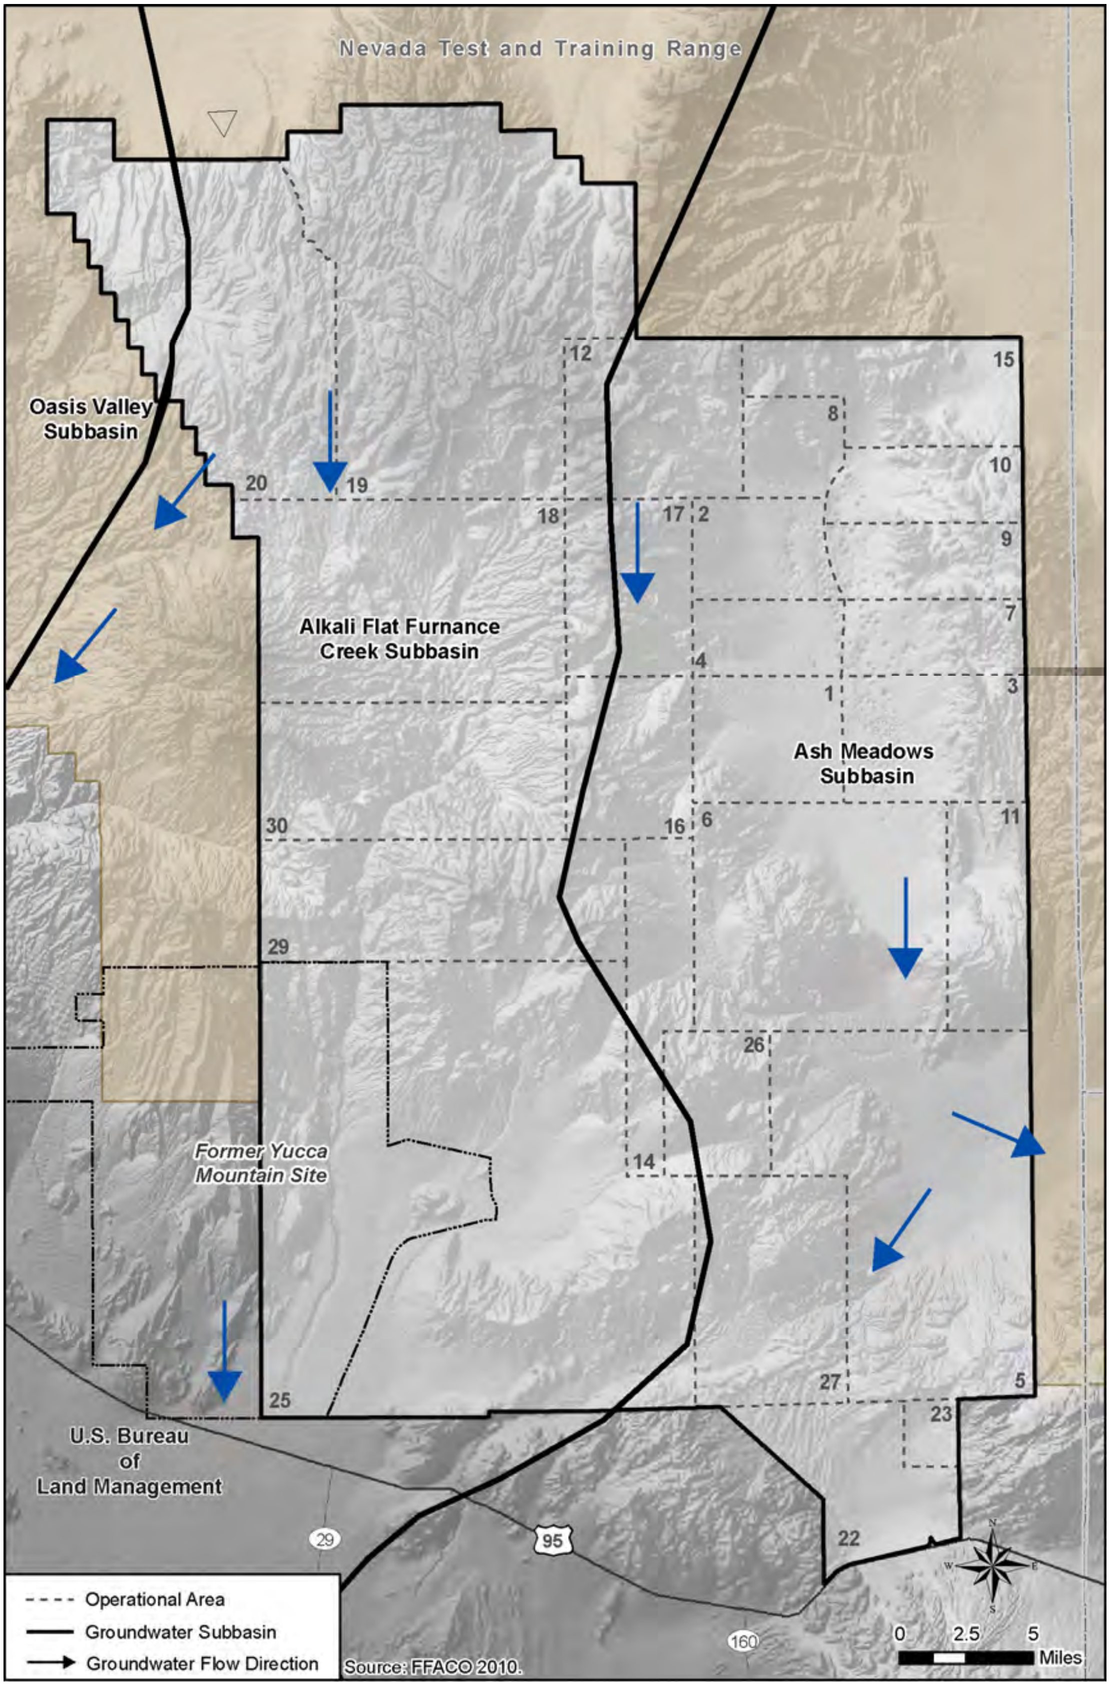

Figure 4–17 Groundwater Subbasins and Flow at the Nevada National Security Site

The principal hydrogeologic water-bearing units of the Death Valley regional groundwater flow system are grouped into three types of aquifers: (1) basin-fill alluvium (or alluvial aquifers), (2) volcanic aquifers, and (3) carbonate aquifers. An alluvial aquifer is in a permeable body of sand, silt, gravel, or other detrital material deposited primarily by running water. Volcanic and carbonate aquifers are permeable units of volcanic rocks and marine carbonate (limestone or dolomite) rock, respectively. The mountainous area that makes up the north-central portion of the NNSS is upheld by volcanic rocks associated with the Timber Mountain caldera complex and includes multiple volcanic aquifers associated with areas of fractured rock. The valley or basin areas in the region contain alluvial aquifers. Together, these volcanic and alluvial aquifers are referred to as "Cenozoic aquifers" because the rocks and sediments in which they occur are of Cenozoic geologic age. The rocks containing the carbonate aquifers are older (Paleozoic age) and regionally extensive, generally occurring at large depths below the Cenozoic aquifers. The major aquifers beneath the NNSS are the Lower Carbonate aquifer system and the Cenozoic aquifer system.

Hydrogeologic Terms

Aquifer: A permeable water-bearing unit of rock or sediment that yields water in a usable quantity to a well or spring.

Artesian: Where water in a lower aquifer is under pressure in relation to an overlying confining unit; when intersected by a well, the water will rise in the borehole to a level above the top of the aquifer.

Saturated zone: The area below the water table where all spaces (fractures and rock pores) are completely filled with water.

Aquitard (or confining unit): A rock or sediment unit of relatively low permeability that retards the movement of water in or out of adjacent aquifers.

Caldera: A near-circular volcanic feature formed by the collapse of rocks overlying a magma chamber from rapid emptying of the chamber during large-volume eruptions.

The Lower Carbonate aquifer system is found primarily in the eastern and southern part of the NNSS and is not present in all areas. The Cenozoic aquifer system is found beneath the main valleys, such as Yucca and Frenchman Flats, and caldera areas, including Pahute Mesa and Timber Mountain.

There is limited hydraulic connection between groundwater in the Lower Carbonate aquifer system and the Cenozoic aquifers (alluvial and volcanic) in many areas, controlled by the location and properties of low-permeability aquitards (see Section 4.1.5 for a discussion of geology and soils). Aquifer types are subdivided into regional and local aquifers dependent on their hydrologic connection to the regional groundwater flow system (Fenelon et al. 2010); in many locations, the alluvial and volcanic form local aquifers where they are separated from the Lower Carbonate aquifer system by volcanic confining units.

Table 4–25 shows the hydraulic parameters of the major aquifers found beneath the NNSS. Hydraulic conductivity is a measure of the ability of the hydrogeologic unit to transmit water, and effective porosity is that portion of the void space within a geologic unit through which groundwater moves (DOE/NV 1997a). The product of hydraulic conductivity and aquifer thickness is transmissivity. Transmissivity is the rate at which groundwater flows through a unit width of an aquifer under a unit hydraulic gradient. As displayed below, the Lower Carbonate aquifer is the most transmissive aquifer below the NNSS; therefore, it controls regional groundwater flow and the possible transport of contaminants. The mean hydraulic conductivity of the alluvial aquifer is lower than the Lower Carbonate aquifer and overlaps with the hydraulic conductivity of the volcanic aquifers. Local conductivity estimates for fractured volcanic rock can be high and approach the conductivity of the Lower Carbonate aquifer, but there is significant lateral variability in rock properties of the volcanic rocks. Mean conductivity of volcanic rocks averaged on a basin-wide scale can be lower than the conductivity of the alluvial aquifer. Their ability to transmit water is lower than that of the Lower Carbonate aquifer. Alluvial and volcanic aquifers are highly variable throughout the region and are assumed to be discontinuous. In most instances, the alluvial aquifer is confined to the basin in which it resides by surrounding mountain ranges. In general, these two aquifers only influence regional flow in localized areas.

Table 4–25 Hydraulic Parameters of the Major Aquifers Below the Nevada National Security Site

Aquifer	*Hydraulic Conductivity*		*Effective Porosity Range (percent)*
	Mean (meters per day)	*Range (meters per day)*	
Alluvial Aquifer	8.44	0.00005–83	31–35
Volcanic Aquifer	1.18	0.0003–12	0.00001–0.006
Carbonate Aquifer	31.71	0.0008–1,570	0.0006–10

Source: DOE/NV 1997a.

Groundwater flow at the NNSS is complex due to the discontinuous nature of the volcanic aquifers (discussed above) and due to major high-angle Basin and Range faults and other features such as caldera structural margins that can juxtapose rocks of contrasting hydraulic conductivity. Groundwater flow through these units is largely controlled by faults and fractures. Groundwater flows generally south and southwest on the NNSS. The flow system extends from the water table to a depth below ground surface that may exceed 4,900 feet where the transmissivity of the rocks becomes much smaller (DOE 1996a). The rates of groundwater flow through the hydrogeologic units are highly variable. The current understanding of groundwater flow at the NNSS is derived from work by Winogard and Thordarson (1975), which was summarized and updated by Laczniak et al. (1996) and Fenelon et al. (2010), and continues to be further developed by the UGTA Project hydrogeologic modeling team. In general, average flow rates over broad areas were estimated by Winogard and Thordarson (1975) to range from 7 to 660 feet per year, but rates can be much higher or lower over short distances in certain geologic settings.

Depth to Groundwater. The depth to groundwater at the NNSS varies from approximately 30 feet at Fortymile Wash to more than 700 feet in Frenchman Flat, to greater than 1,500 feet in portions of Yucca Flat, to finally more than 2,000 feet under the upland portions of Pahute Mesa. Perched groundwater (isolated lenses of water lying above the regional groundwater level) is known to occur in some parts of the NNSS, mainly in the volcanic rocks of Rainier Mesa. The greatest depth to water at the NNSS was measured near Tippipah Point in the central part of the NNSS at 4,093 feet (DOE 2008l; DOE/NV 1997a).

Groundwater Recharge and Discharge. The Death Valley groundwater flow system is recharged by underflow from upgradient areas, as well as precipitation in the higher elevations of the northern and eastern mountain ranges, while discharge areas such as Death Valley and the Amargosa Valley occur primarily in the south and southwest low-lying valleys.

Groundwater recharge includes the water contribution from precipitation and from interbasin underflow from upgradient areas. There are various processes that inhibit recharge of the groundwater from precipitation in arid areas. Therefore, depending on the type of soil, amount of vegetation, evaporation, and subsurface geology, only a fraction of precipitation contributes to recharge. The majority of precipitation recharge on the NNSS is limited to higher elevations, where precipitation is greatest and originates over upland areas of Pahute Mesa, Timber Mountain, and the Belted Range (see Section 4.1.8 for more information regarding precipitation and evaporation at the NNSS). However, total recharge (i.e., all of the water that moves into an aquifer) at the NNSS is dominated by subsurface, lateral regional flow, or interbasin flow. The estimated underflow onto the NNSS from adjacent areas ranges from 38,000 to 44,000 acre-feet per year. Total recharge for the NNSS regional groundwater flow system from both precipitation and lateral interbasin flow has been estimated at 69,097 acre-feet per year (DOE/NNSA/NSO 2008).

Groundwater discharge within the NNSS is minor, consisting of natural discharge at small springs found in mountainous regions that drain perched water within near-surface volcanic rocks and withdrawals at water supply wells. No direct discharge from the regional groundwater flow system occurs on the NNSS. Springs at the NNSS are located well above the regional water table level and have very low discharge

rates, ranging from 0.22 to 35 gallons per minute (see Section 4.1.6.1 for more information regarding the location of springs) (DOE/NNSA/NSO 2008). Discharge to these onsite springs is small when compared to the discharge of groundwater from the NNSS to Rock Valley and the Amargosa Desert, which totals an estimated 42,000 acre-feet per year (DOE 1996a).

Groundwater Supply. Groundwater is the only local source of potable water on the NNSS. Drinking water needs, as well as water required for nonpotable, construction, and fire protection purposes, are met by groundwater drawn from deep wells installed in the carbonate, volcanic, and alluvial aquifers.

Water production and distribution systems have been in place at the NNSS for over 50 years. Currently, the NNSS has three permitted PWSs served by six wells (Wells 4/4a, 5b/5c, 8, 16D, C-1, and J-12) (NSTec 2010d). Two of the PWSs are non-transient, non-community PWSs (NV0004099 and NV0000360) that operate under permit numbers NY-0360-12NTNC and NY-4099-12NTNC, respectively. The third PWS is a transient system (NV0004098) and operates under permit number NY-4098-12NTNC. See **Table 4–26** for a list of these wells and their associated characteristics (e.g., depth and pumping rate). All three systems are regulated under the Safe Drinking Water Act (DOE/NV 2008c). The transmission and distribution systems include mains, valves, hydrants, booster pump stations, pump suction tanks, and reservoir storage tanks. Potable water is hauled to support facilities not connected to the potable water system in two permitted water-hauling trucks; however, these are not considered part of the PWS (NSTec 2010d). The NNSS drinking water systems currently meet all applicable regulatory standards.

Water System Terms

Public Water System: A system that provides water for human consumption that has at least 15 service connections or serves at least 25 individuals daily at least 60 days out of the year. Public water systems are further categorized into three different types: community, non-transient non-community, and transient non-community.

Community Water System: A public water system that serves at least 15 service connections used by year-round residents or regularly serves at least 25 year-round residents.

Non-Transient Non-Community Water System: A public water system that regularly serves at least 25 of the same nonresident persons per day for more than 6 months per year. Examples of such systems are those serving the same individuals (industrial workers, school children) on a daily basis even though those individuals do not reside at that location.

Transient Non-Community Water System: A non-community public water system that does not serve 25 of the same nonresident persons per day for more than 6 months per year. Examples of such systems include a restaurant or convenience store with fewer than 25 permanent nonresident staff, but the number of people served exceeds 25.

The NNSS water system is spread over four distinct water service areas and consists of eight water systems, two wildlife preservation reservoirs, numerous water storage tanks, fillstands, and construction water open pit reservoirs, as well as approximately 140 miles of pipeline located throughout the site (DOE 2008l). These water service areas are discussed in detail below in relation to their location and the areas they support. The water service areas are also displayed in **Figure 4–18**.

Water Service Area A. Encompasses Areas 19 and 20. System capabilities within this service area have been abandoned for more than a decade. There are two wells in this area (Wells 19c and 20), both of which are out of service and have monitoring casings to prevent vandalism or contamination (DOE/NV 2008c).

Water Service Area B. Encompasses Areas 2, 4, 7, 8, 9, 10, 12, 15, 17, and 18. PWS NV0004099 serves Area 12. Well 2, which is within this service area, is out of service and has a monitoring casing to prevent vandalism or contamination. Well 8 provides water to Area 12 and supplies water to the construction water open pit reservoir system. Water Service Area B also includes one pumping station and two water storage tanks (DOE 2009f; DOE/NV 2008c).

Water Service Area C. Encompasses Areas 1, 3, 5, 6, 11, 22, 23, 26, and 27. PWS NV0000360 serves Areas 5, 6, 22, and 23. Five active wells provide water in this service area (Wells C-1, 4, 4a, 5b, and 5c). Fillstand A-6 is used to supply potable water via water trucks to JASPER, Area 12, and BEEF. Water Service Area C also includes five pumping stations and nine water storage tanks (DOE 2009f; DOE/NV 2008c).

Water Service Area D. Encompasses Areas 14, 16, 25, 29, and 30. PWS NV0004098 serves Area 25. It consists of two active wells (Wells J12 and 16d). Well 16d is a nonpotable well that serves the batch plant. Water Service Area D also includes three pumping stations and 12 water storage tanks (DOE 2009f; DOE/NV 2008c).

In 2010, a new water well (Well J-14) was designed and drilled in Area 25. Well J-14 and its associated water pipeline were permitted in 2011 as a part of the Area 25 PWS, which is located in Water Service Area D (Radack 2012). Well J-14 was designed to relieve water pressure on the PWS's existing long water transmission line (DOE/NV 2011).

Water is currently hauled into Areas 26 and 27 (Water Service Area C) by truck from Area 25 (Water Service Area D). There are four elevated tanks in Area 26 that store construction water and one tank in Area 27 that stores fire protection and potable water (DOE/NV 2008c).

Since the 1992 moratorium on underground nuclear testing, there has been a significant reduction in personnel and operational activities at the NNSS, and the amount of water consumed at the NNSS has dropped significantly. In 2005, the NNSS installed water volume meters on the active water wells that contribute to the water distribution system; in 2009, the NNSS installed meters on the fillstand locations.

Between 2005 and 2009, total annual water usage from active wells ranged from approximately 173 million to 225 million gallons (from 531 to 690 acre-feet, see **Table 4–27**) (NSTec 2010c), which is significantly less than the peak usage of 3,375 acre-feet per year in 1989 (DOE 1996a). When comparing historic pumping levels in Frenchman Flat to the State Engineer's perennial yield estimate of Frenchman Flat (100 acre-feet per year), the NNSS appears to be overdrawing water by a large percentage (see **Table 4–28**). However, based upon more-recent data derived from USGS studies, the water levels in Frenchman Flat have remained static and have not shown a downward trend of water drawdown, even during peak water usage at the NNSS in 1989. This suggests that the perennial yield of Frenchman Flat is significantly higher than 100 acre-feet per year, and more likely in the range of yields calculated by other DOE/NNSA and USGS models.

In general, water usage at the NNSS has declined since 1989 and the volume of water produced from characterization wells is minor, totaling typically less than 2 acre-feet per well (DOE/NNSA/NSO 2008).

Total Water Withdrawn From Fillstands in 2009			30,136,387	92.5

Source: NSTec 2010c.

The measured annual water usage from the active wells includes fillstand water withdrawals, which are used for nonpotable purposes such as dust suppression (NSTec 2010d). As meters were not installed on the fillstand locations until 2009, detailed information on the division of potable and nonpotable water use is only available for one calendar year. See Table 4–28 for a list of fillstands and corresponding water withdrawals for 2009 and **Table 4–29** for a breakdown of potable and nonpotable water use at the NNSS for 2009.

Table 4–30 provides a summary of historic water withdrawals from affected hydrographic basins at the NNSS from 2005 through 2009. Over 68 percent of the NNSS water withdrawals in this timeframe occurred in Frenchman Flat (Basin 160), with lesser contributions coming from Yucca Flat (Basin 159) and the Jackass Flats and Buckboard Mesa Subdivisions of Fortymile Canyon (Basins 227b and 227a). In terms of use of sustainable yield (perennial yield minus any rights already committed by the State Engineer to other users), Frenchman Flat was the most heavily used during this timeframe (375 to 501 percent of perennial yield used in any year), followed by Yucca Flat (25 to 42 percent in any year). The Jackass Flats and Buckboard Mesa Subdivisions of Fortymile Canyon showed very light use during this timeframe, never exceeding 2 percent of sustainable yield in any year.

Table 4–30 Summary of Water Withdrawals from Hydrographic Basins

Hydrographic Basin	*Sustainable Yield of the Basin (acre-feet per year)*	*NNSS Operational Water Wells by Basin*	*Percentage of Basin's Average Contribution to NNSS Water Supply 2005–2009*	*Range of Total Withdrawals, 2005–2009 (acre-feet per year)*	*Percentage of Perennial Yield Used, 2005–2009*
Frenchman Flat (160)	100	4, 4a, 5b, 5c	68.6%	375–501	375–501%
Fortymile Canyon, Buckboard Mesa Subdivision (227b)	3,600	8	6.1%	26–46	0.7–1.3%
Fortymile Canyon, Jackass Flats Subdivision (227a)	3,944	J-12	6.8%	17–72	0.4–1.8%
Yucca Flat (159)	350	C-1, 16d	18.5%	87–146	25–42%

NNSS = Nevada National Security Site.

Groundwater Monitoring and Quality. Water resources in and around the NNSS are monitored through the measurement of groundwater levels in wells and the quantity of water produced. USGS conducts the monitoring, maintains the databases, and reports the results annually in a statewide water resource summary. Over the long term, existing and new regional groundwater modeling will improve the understanding of water availability and planning. The groundwater at the NNSS is classified as Class II groundwater according to the EPA groundwater classification system, which means that it is currently or potentially could be a source of drinking water.

Water chemistry (see **Table 4–31**) varies from a sodium-potassium-bicarbonate type associated with volcanic aquifers, to a calcium-magnesium-bicarbonate type associated with carbonate aquifers, to a calcium-magnesium-sodium-bicarbonate type, which is a mixed type and may represent alluvial aquifers or the mixing of groundwater entering the Lower Carbonate aquifer from overlying volcanic units (DOE/NNSA/NSO 2008). Drinking water quality on the NNSS is monitored to assess compliance with primary and secondary drinking water standards according to the schedule set in applicable Federal and state laws, monitoring waivers, and permits issued by NDEP. The three PWSs and permitted water hauling trucks at the NNSS meet all of the primary and secondary drinking water standards (DOE/NV 2011). The trucks that are permitted to haul water to the PWSs are permitted by NDEP's Bureau of Safe Drinking Water, and the water they carry is subject to water quality standards for coliform bacteria (DOE/NV 2011).

The Safe Drinking Water Act Arsenic Rule amendment, approved in 2001, lowered the allowable maximum level of arsenic in drinking water to 10 parts per billion for PWSs (Congressional Research Service 2007) (note that the water chemistry data displayed in Table 4–31 were collected in 1993, before the Arsenic Rule amendment). Groundwater drawn from two wells serving the PWSs in Area 25 currently exceeds this limit. To maintain compliance with the Safe Drinking Water Act, the pumped groundwater is treated in a reverse osmosis system or a point-of-use treatment to remove the excess arsenic before being distributed for consumption (DOE 2007c).

There have been 828 underground nuclear tests conducted at the NNSS. Approximately one-third of these tests were detonated near or below the water table. Most of the NNSS underground nuclear detonations were conducted at Frenchman Flat, Yucca Flat, Pahute Mesa, and Rainier Mesa. This legacy of nuclear testing has resulted in groundwater contamination in areas now identified as CAUs in environmental studies. Between 30 and 38 percent of underground nuclear tests conducted at or below the water table have contaminated groundwater near underground nuclear test cavities. This groundwater is contaminated with 43 identified radionuclides, the most prevalent of which is tritium (Bowen et al. 2001). In a 2001 report, scientists from Los Alamos National Laboratory and Lawrence Livermore National Laboratory calculated the underground inventory of radionuclides resulting from underground nuclear testing at the NNSS between 1951 and 1992 (Bowen et al. 2001). That report estimated the remaining underground source term of radionuclides as of September 23, 1992, to be about 132 million curies; however, only a portion of this source term would be available as part of the hydrologic source term. The hydrologic source term is that portion of the overall underground source term that is available for transport in the groundwater. As mentioned above, nuclear tests were conducted close enough to the groundwater to potentially contribute to the hydrologic source term. Of the radionuclides produced by an underground nuclear detonation, only those that are readily soluble in water and/or are available to be transported (i.e., not encapsulated within the melt glass within the detonation cavity or otherwise immobile), may become part of the hydrologic source term.

Figure 4–19 shows the locations of underground nuclear tests and established CAU areas of potential groundwater contamination. This figure also illustrates the directions of predicted groundwater flow from the CAUs.

Several groups regularly test water at and surrounding the NNSS. There are approximately 120 active groundwater monitoring wells (see **Table 4–32** for a complete list of these wells used under the NNSS Environmental Restoration Program by the RREM Program and UGTA). The DOE/NNSA NSO’s RREM Program samples more than 80 locations, which include wells, springs, and surface-water sites, to make sure radionuclide levels do not exceed Safe Drinking Water Act standards. The UGTA Project samples a network of deep wells to help determine where contaminants are present in groundwater, what direction these contaminants are moving, and how quickly. UGTA wells that are not designated as source term characterization wells are made available for monitoring under the RREM Program (DOE/NV 2011).

RREM = Routine Radiological Environmental Monitoring; UGTA = Underground Test Area.

[a] Tunnel Water Conduit Hole.

Source: BLM 2010l.

In addition to the RREM Program and the UGTA Project sampling efforts, the Community Environmental Monitoring Program (CEMP) performs independent, annual monitoring of 29 springs and water supplies in communities surrounding the NNSS (DOE/NNSA/NSO 2010). In 2008, CEMP offsite water sampling locations included 21 wells, 3 surface-water supply systems, and 4 springs. All water samples had levels of tritium either below laboratory detection limits or less than background levels of tritium in surface waters (25 to 35 picocuries per liter) (DOE/NV 2009d). Laboratory detection limits for tritium vary from less than 10 picocuries per liter to about 1,000 picocuries per liter dependent on methods of sample preparation and analytical techniques.

In a study published in 2006, Healing Ourselves and Mother Earth (HOME) conducted groundwater sampling and analysis in an attempt to develop an environmental/health baseline for helping to ascertain if contamination from the NNSS and the then-proposed Yucca Mountain site was approaching surrounding communities. HOME sampled eight wells and two springs located downgradient of the NNSS, the former proposed Yucca Mountain site, and U.S. Ecology’s facility near Beatty, Nevada. The results of HOME’s study showed analyte levels well within expected concentrations, and below EPA maximum contaminant levels, i.e., action levels. Some uranium and a low but positive reading for some trace metals were also expected, due to all the mineral deposits in the region. HOME also compared its data with that collected from the Nye County Early Warning Drilling Program and found that its data corroborated the results of Nye County, illustrating a wide variation in groundwater chemistry and radiation activity. HOME expressed concern that a possible consequence of the wide variation in gross alpha and beta readings in the data is that the profile of radioactive elements in the groundwater could vary, without triggering action for a more detailed analysis and the possibility of contamination from either the NNSS or Yucca Mountain site moving off site and into the water supply, without activating a warning system. HOME speculates that the variation in groundwater chemistry and radiation could be due to an as-yet-unidentified natural non-uniform binding mechanism in play with the naturally occurring radioisotopes that could affect the appearance and movement of contaminants coming from the NNSS or Yucca Mountain site.

Analytes Monitored by the RREM Program and UGTA Project. Tritium was the radioactive species created in the greatest quantities and is widely believed to be the most mobile in groundwater. Therefore, tritium is the primary target analyte for both the RREM Program and UGTA Project; every groundwater sample is analyzed for this radionuclide (DOE/NV 2011). For this reason, tritium is the primary radionuclide discussed in this SWEIS.

Both the RREM Program and UGTA Project analyze water samples for more than just tritium. The UGTA Project typically performs the following radioisotope analyses on groundwater samples:

- Tritium
- Carbon-14
- Chlorine-36
- Iodine-129
- Strontium-90
- Technetium-99
- Plutonium (-238 and -239/240)
- Gamma emitters* (typically report: actinium-228, aluminum-26, americium-241, antimony-125, beryllium-7, bismuth-212, bismuth-214, cesium-134, cesium-137, cobalt-58, cobalt-60, curium-243/244, europium-152, europium-154, europium-155, lead-212, lead-214, niobium-94, potassium-40, thallium-208, thorium-227, thorium-234, uranium-235)

The RREM Program typically performs the following radioisotope analyses on groundwater samples (quarterly to every 3 years, depending on the radioisotope):

- Tritium
- Carbon-14
- Strontium-90
- Technetium-99
- Plutonium (-238 and -239/240)
- Gamma emitters* (typically report: actinium-228, americium-241, antimony-125, cerium-144, cesium-134, cesium-137, cobalt-60, europium-152, europium-154, europium-155, lead-212, potassium-40, promethium-144, promethium-146, ruthenium-106, thorium-234, uranium-235, yttrium-88)

**Only the following gamma emitters reported by the RREM Program and UGTA Project are included in the radionuclide summary in Bowen et al. 2001 as products of underground nuclear weapons testing: aluminum-26, potassium-40, niobium-94, cesium-137, europium-152, europium-154, uranium-235, and americium-241; all others may be considered as naturally occurring.*

In 1992, Ernest A. Bryant from Los Alamos National Laboratory published *The Cambridge Migration Experiment: A Summary Report* (LA-12335-MS). The Cambric Experiment was a long-term (October 1974 through August 1991) experiment that consisted of first measuring the distribution of radioactive materials in water and rock in the vicinity of the 1965 Cambric underground nuclear test explosion and then inducing an artificial hydraulic gradient by pumping water from a nearby well (91 meters from the well used to characterize the initial source term). The water samples pumped from the test well were regularly analyzed for the presence of radioactive species that might have migrated from the explosion cavity. Among other things, the Cambric Experiment demonstrated that tritium migrates at about the same rate as groundwater relative to most other contaminants. Other radionuclides that exhibited migration with the groundwater during the Cambric Experiment included krypton-85 (a noble gas), chlorine-36, iodine-129, technetium-99, and ruthenium-106. As noted above, each of these, with the exception of krypton-85, is included in the list of radioisotopes analyzed by either the UGTA Project or RREM Program.

As reported by Kersting et al. (1998), groundwater samples taken at Well ER-20-5 in 1997 contained plutonium, apparently associated with colloids. Well ER-20-5 is located on the southwestern part of Pahute Mesa, about 4,265 feet south of the Benham underground nuclear test and 984 feet west of the Tybo underground nuclear test. Analysis of the plutonium in the groundwater samples demonstrated that it was from the Benham test, rather than the Tybo test. Kersting et al. noted, “this is the first time Pu has been shown to be transported by groundwater and for a significant distance.” A low concentration of plutonium (0.42 picocuries per liter, which is well below the Safe Drinking Water Act EPA limit of 15 picocuries per liter) was found in samples taken from Well ER-20-5 #1 in 2004 (Eaton et al. 2007). In a study subsequent to the discovery of plutonium at Well EC-20-5, Smith et al. (2003) noted that general experience from the U.S. nuclear testing program based on radiochemical diagnostic data collected from a variety of test matrices suggests that only a small fraction (5 to 10 percent) of the total plutonium from an underground nuclear detonation would be available for transport in groundwater.

As evidenced by the above list of radiological analytes, DOE/NNSA has and will continue to track and report results of groundwater characterization and monitoring that demonstrates transport of any of the noted elements. Further, the data obtained from the ongoing groundwater characterization and monitoring are used in developing and refining the models used by DOE/NNSA and NDEP to site new characterization and monitoring wells and improve groundwater models.

Underground Test Area Project. The CAUs are investigated and monitored under the UGTA Project, which is the largest component of the NNSS Environmental Restoration Program, with the oversight of NDEP as part of the FFACO (DOE/NV 2010). The UGTA Project started in 1989 and is scheduled to be completed in 2027. This project evaluates the extent of radionuclide groundwater contamination due to past underground nuclear testing through hydrogeologic investigation and characterization, groundwater flow and transport modeling, and groundwater sampling and monitoring. The FFACO was amended in May 2011. Groundwater flow and transport models will be developed for each of the CAUs being evaluated under the UGTA Project to identify ensembles of contaminant boundaries where waters inside the boundaries exceed the radiological protection requirements of the Safe Drinking Water Act. The validity of the contaminant boundary forecasts will be tested through model evaluations that will lead to design and implementation of a long-term closure monitoring well network. The contaminant boundary evaluations provide the basis for establishing use-restriction areas and identifying a regulatory boundary by NDEP for protection of the health and safety of the public. Protection of the public is ensured through an in-depth approach that combines, for each CAU, model forecasts of contaminant transport over 1,000 years and long-term monitoring and institutional controls to restrict public access to contaminated groundwater (DOE/NV 2011).

Groundwater modeling for the UGTA Project is conducted in two steps. First, a regional three-dimensional groundwater flow model was developed for the Death Valley regional flow system to identify risks to the public, workers, and the environment (DOE/NV 1997a). Second, groundwater flow (boundary conditions) from this regional model is used in the development of CAU-scale groundwater flow and transport models. Individualized models are needed due to the complexity of geologic/hydrologic conditions within each CAU. These smaller-scale, site-specific groundwater models will be used to identify contaminant boundaries based on the maximum extent of contaminant migration over a 1,000-year time period. Results of the CAU-specific groundwater models will be used to develop a monitoring network, which augments current monitoring both on and off the NNSS. To ensure public health and safety, groundwater monitoring would continue until there is assurance that there is no remaining risk to public health and safety from groundwater contamination resulting from underground nuclear weapons testing.

CAU-specific groundwater flow and transport models have been completed for the Frenchman Flat CAU (Navarro Nevada Environmental Services 2010). The transport model included evaluations of ensembles of contaminant boundaries. The results of these models were reviewed and accepted by an external peer review panel (Navarro-Intera 2010a). The model results and peer review recommendations were accepted by NDEP, and the Frenchman Flat studies have moved into the model evaluation stage, the final stage before development of a long-term closure monitoring network. **Figure 4–20** shows the model-based estimation of the extent of groundwater contamination in the Frenchman Flat area over the next 1,000 years. As described above, depiction of groundwater contamination is based on the results of models that are being developed and refined. To date, the only UGTA CAU that has completed the Phase II investigation and the Phase II Transport Model is Frenchman Flat. Figure 4–20 depicts the area where there is a 95 percent certainty that groundwater contamination will exceed the Safe Drinking Water Act standards for radionuclides in the Frenchman Flat area over the next 1,000 years, as predicted by the Phase II Transport Model. The Central and Western Pahute Mesa CAUs have not completed Phase II milestones; therefore, a figure predicting groundwater contamination transport in Central and Western Pahute Mesa has not been included.

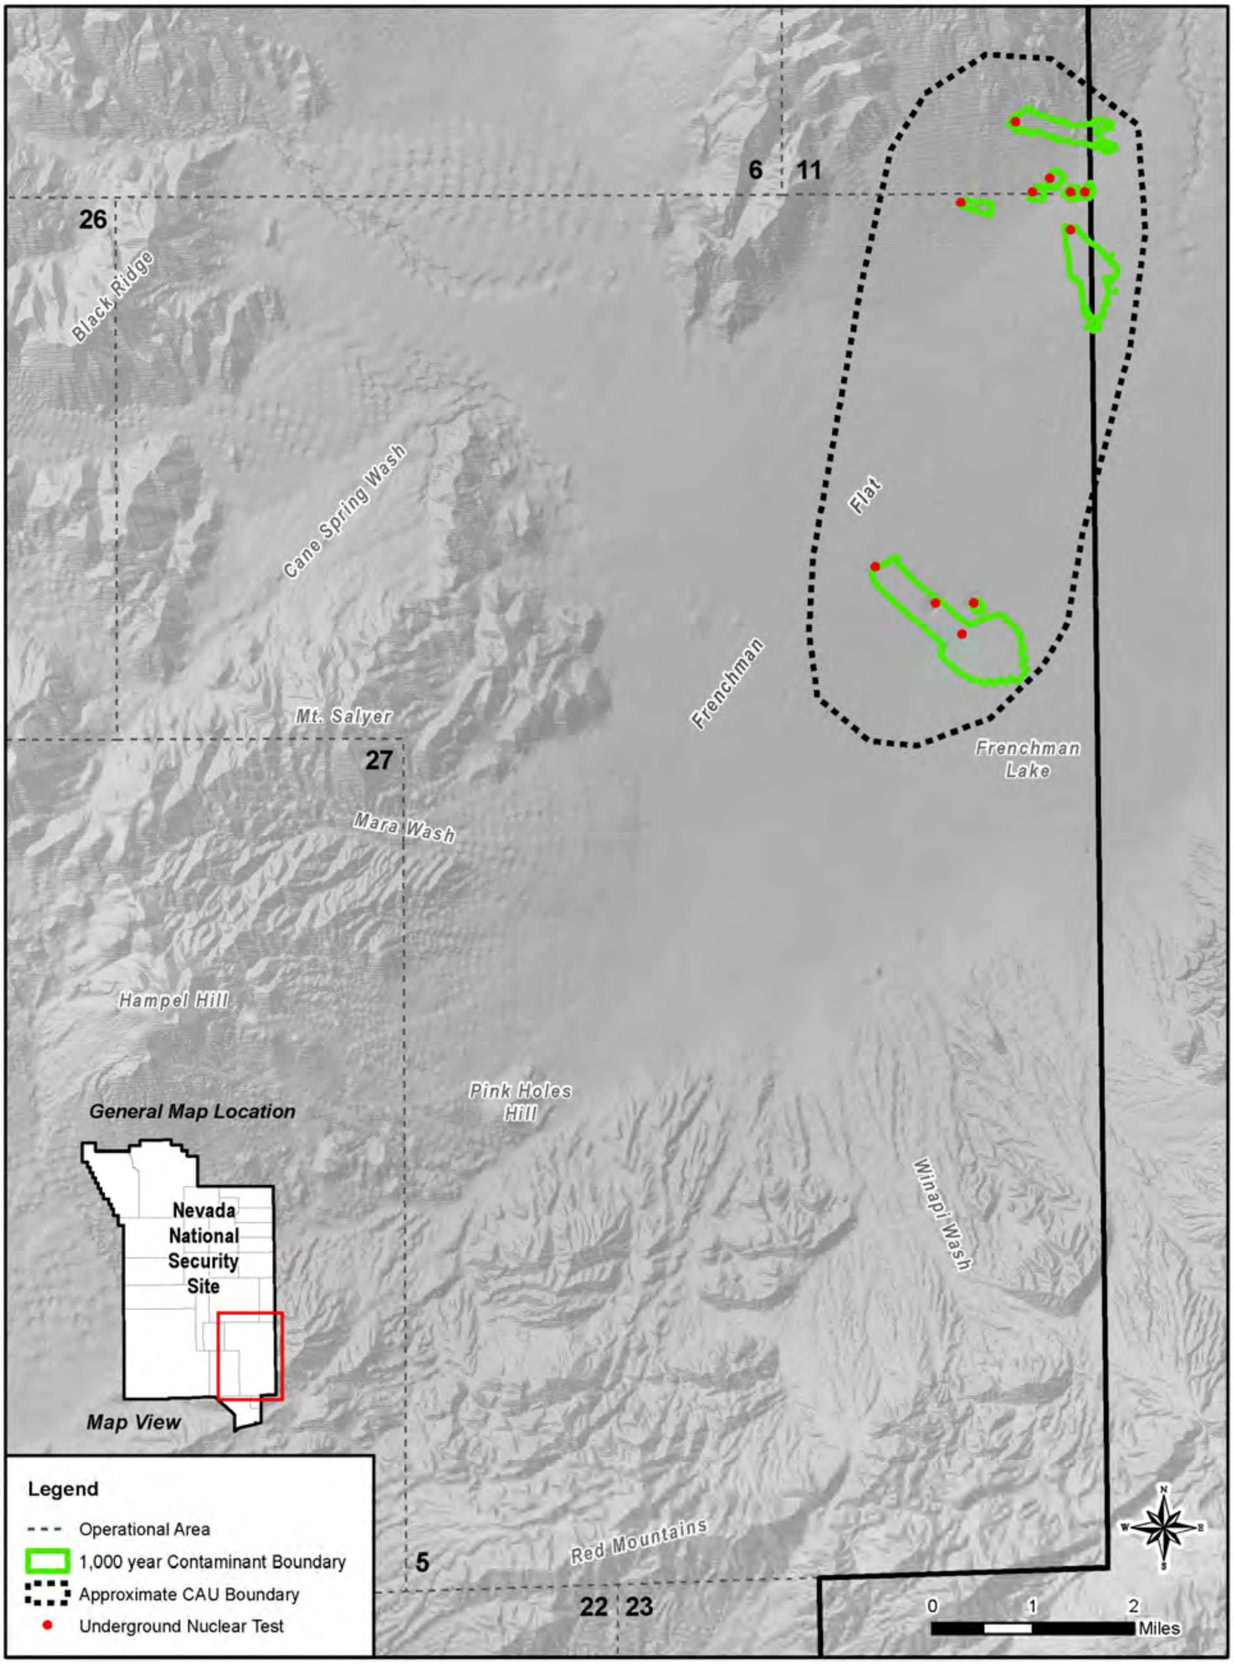

Figure 4–20 Modeled Extent of the Contaminant Boundary in the Frenchman Flat Corrective Action Unit in 1,000 Years

The UGTA Project has been routinely collecting groundwater samples from an average of six wells a year since 2000. The wells include new construction wells, existing on- and offsite monitoring wells (which may also be used under the RREM Program, along with post-shot/cavity wells). The post-shot/cavity wells are sampled as a part of the "hot well" sampling effort under the UGTA Project. Groundwater samples collected during the construction of new wells, as well as samples collected from existing on- and offsite monitoring wells generally did not display concentrations of tritium above the Safe Drinking Water Act standard of 20,000 picocuries per liter between 2000 and 2008. However, the samples taken under the hot well program consistently display tritium concentrations above the Safe Drinking Water Act standard. The hot well sampling effort supports DOE/NNSA's continuing effort to develop flow and transport models and design a long-term monitoring program for wells in or near underground nuclear test cavities. The program's objectives are to characterize the hydrologic source term and evaluate the effects of decay and potential migration of radionuclides through monitoring at or near the source (DOE/NV 2000c, 2001c, 2002b, 2003a, 2004a, 2005f, 2006a, 2007d, 2008a, 2009d, 2010). **Table 4–33** shows a summary of the hot well sampling effort and the associated tritium findings from 2003 to 2008. No post-shot/cavity well samples were taken between 2000 and 2003, nor were well samples taken between 2006 and 2008.

Table 4–33 "Hot Well" Tritium Analysis Summary Table (2003 to 2008)

Year Samples Taken	*Total Number of Samples Analyzed*	*Associated Underground Nuclear Test Cavity*	*Range of Results (picocuries per liter)*
2003	4	Gascon, Camembert, Almendro, and Cheshire	200,000 to 160,000,000
2004	4	Bilby, Chancellor, and Tybo	113,000 to 38,000,000
2005	1	Cheshire	37,000,000
2006–2008	0	–	–

Source: DOE/NV 2000c, 2001c, 2002b, 2003a, 2004a, 2005f, 2006a, 2007d, 2008a, 2009d.

A new well-drilling campaign, initiated in the summer of 2009 (as a part of Phase II characterization), identified the construction of nine additional wells over the next 3 years to gather additional data for developing groundwater models and contaminant boundary forecasts that would eventually aid in the implementation of a long-term monitoring network for the Pahute Mesa CAU (DOE/NV 2010). Three of the nine wells were drilled in 2009 (ER-EC-11, ER-20-8, and ER-20-7) in Pahute Mesa along the northwestern boundary of the NNSS, and the remaining six will also be located on or near Pahute Mesa. Well ER-EC-11 is located off site on USAF land, and Wells ER-20-8 and ER-20-7 are within the NNSS boundary. For the first time in October 2009, tritium was detected off site in Well ER-EC-11, located less than half a mile off the northwestern boundary of the NNSS and approximately 14 miles from the nearest public water source. The tritium level was found to be 13,180 picocuries per liter, which is below the EPA Safe Drinking Water Act standard of 20,000 picocuries per liter. The sample results were verified by a certified independent laboratory and reported to NDEP (DOE/NV 2011). Current groundwater models in the February 2009 Phase 1 Central and Western Pahute Mesa Transport Model and Western Pahute Mesa Corrective Action Plan display transport in this direction near Pahute Mesa. In 2010, a deeper portion of Well ER-EC-11 was sampled and no tritium was detected. This was not unexpected, as the aquifer sampled is isolated from the overlying contaminated aquifer by a confining unit, which does not readily conduct water (DOE/NV 2011).

In May 2010, Well PM-3, which is approximately 11,000 feet west of the NNSS border on the Nevada Test and Training Range, was found to have detectable levels of tritium at 48.3 picocuries per liter during monitoring under the RREM Program. Well PM-3 is 24,500 feet northwest of Well ER-EC-11 and 188 feet upgradient from Well ER-EC-11. The UGTA Project will collect and test additional water samples from Well PM-3 to confirm the presence of tritium in the well. The UGTA Project sampling results, as well as the RREM Program, will be considered in future data collection decisions and groundwater model evaluations (DOE/NV 2011).

Additionally, many wells have been drilled downgradient of the test cavities showing a migration trend of tritium transport at distance, and other radionuclides transporting very short distances over the same period of time. **Figure 4–21**, located at the end of this section, displays the locations of various wells used for monitoring groundwater at the NNSS and nearby offsite areas, as well as the concentration of tritium that has been detected. The sampling wells are located both at and near historic underground detonation sites and farther downgradient, where they have been strategically placed to intercept any contamination plumes originating from the historic underground tests.

In the past, a non-government group evaluated DOE/NNSA's groundwater monitoring network (Citizen's Alert 2004), pointing to a lack of monitoring wells in the area southwest of Pahute Mesa on the Nevada Test and Training Range. Citizen's Alert contended, among other things, that the monitoring well network was not properly designed and that the likelihood of detecting a plume of contamination off site was diminished because there had been no wells developed in the area southwest of Pahute Mesa on the Nevada Test and Training Range. Since that report was published, and based on DOE/NNSA's and NDEP's ongoing work to characterize groundwater flows and contaminant transport, as shown in Figure 4–21, nine groundwater characterization and monitoring wells have been developed so far within the area of concern by Citizen's Alert and, as previously noted, tritium has been detected at one of the offsite wells, ER-EC-11.

Routine Radiological Environmental Monitoring Plan. The RREM Plan was developed in 1998. The Long-Term Hydrological Monitoring Program was the RREM Plan's predecessor and had been in existence since 1972. Before 1972, groundwater was monitored by the U.S. Public Health Service, USGS, and the U.S. Atomic Energy Commission's contractor organizations. In 1999, there was a final transition from the Long-Term Hydrological Monitoring Program to the RREM Plan to have a single, integrated, and comprehensive monitoring program (DOE/NV 2000c). In 2002, the RREM Plan environmental surveillance system was revised in an effort to make the program more efficient. The purpose of the RREM Plan is to determine whether concentrations of radionuclides in groundwater and surface water at the NNSS pose a threat to public health or the environment. The RREM Plan includes a groundwater monitoring well network of 78 wells located on and off the NNSS, which are sampled at frequencies ranging from once every 3 months to once every 3 years. Ten additional wells have been added to the network and are sampled opportunistically. Of these 88 wells, 72 have been sampled since 1999. These 72 wells include 33 offsite monitoring wells, 29 onsite monitoring wells, and 10 onsite water supply wells. The remaining 16 wells identified by the RREM Plan, but not sampled since 1999, comprise 15 onsite monitoring wells and 1 offsite well. These 16 wells have not been sampled for one or more of the following reasons: they are not accessible, are used for other purposes, are blocked, provide water samples that are of poor quality or are contaminated (disqualifying them from monitoring), or contain waters with known high levels of radiological contamination that are not expected to change (DOE/NV 2009d).

Sampling of the NNSS potable supply wells continues to indicate that nuclear testing has not affected the NNSS water supply network. Gross alpha and gross beta radioactivity have been detected in supply wells at concentrations commensurate with background levels of naturally occurring radionuclides and not above the EPA maximum contaminant level (MCL) of 15 picocuries per liter. Tritium has not been detected above the Safe Drinking Water Act standard of 20,000 picocuries per liter in any of the potable supply wells (DOE/NV 2000c, 2001c, 2002b, 2003a, 2004a, 2005f, 2006a, 2007d, 2008a, 2009d). **Table 4–34** is a summary of the samples taken on site and off site, including potable and monitoring wells and the results from 2000 through 2008. The summary table dates back to 2000, as the Long-Term Hydrological Monitoring Program was transitioned over to the RREM Plan the previous year. The tritium analysis was conducted after the samples were enriched. The enrichment process concentrates tritium in a sample to provide very low minimum detectable concentrations (DOE/NV 2000c, 2001c, 2002b, 2003a, 2004a, 2005f, 2006a, 2007d, 2008a, 2009d). None of the samples taken within this timeframe under the RREM Plan has displayed concentrations of tritium greater than 11 percent of the Safe Drinking Water Act standard of 20,000 picocuries per liter.

Table 4–34 Routine Radiological Environmental Monitoring Plan Tritium Analysis Summary Table (2000 to 2008)

Year Samples Taken	*Total Number of Samples Analyzed* [a]	*Range of Results Minimum Detectable Concentration (picocuries per liter)*	*Percent of Safe Drinking Water Act Maximum Contaminant Level (20,000 picocuries per liter)*
2000	61	8 to 2,130	0.04 to 10.7
2001	60	10 to 32	0.05 to 0.16
2002	54	12 to 260	0.06 to 1.3
2003	45	18 to 28	0.09 to 0.14
2004	36	17 to 26	0.09 to 0.13
2005	55	13 to 35	0.07 to 0.18
2006	41	11 to 37	0.06 to 0.19
2007	39	17 to 28	0.09 to 0.14
2008	33	18 to 34	0.09 to 0.17

[a] Includes on- and offsite monitoring wells.
Source: DOE/NV 2000c, 2001c, 2002b, 2003a, 2004a, 2005f, 2006a, 2007d, 2008a, 2009d.

Only four onsite monitoring wells (PM-1, U-19BH, UE-7NS, and WW A) located within 0.6 miles of a historical underground nuclear test are known to have detectable concentrations of tritium above their respective minimum detectable concentrations; however, the concentrations are well below the Safe Drinking Water Act drinking water limit of 20,000 picocuries per liter (see **Table 4–35** for the 2008 sampling results). All have consistently had detectable levels of tritium in past years, and no trend of rising tritium concentrations has been observed in these wells since 2000.

Table 4–35 Tritium Analysis Results for the Nevada National Security Site Monitoring Wells (2008)

Underground Test Area Well	*Date Sampled*	*^{3}H±Uncertainty* [a] *(minimum detectable concentration) (picocuries per liter)*
PM-1	4-23-08	127 ± 25 (23)
U-19BH	3-17-08	31 ± 13 (19)
UE-7NS	2-27-08	90 ± 24 (30)
WW A	2-12-08	356 ± 59 (28)

^{3}H = tritium (hydrogen-3).
[a] ±2 standard deviations.
Source: DOE/NV 2009d.

Wells PM-1 and U-19BH are located in the Central Pahute Mesa CAU 101 (see Figure 4–19 for CAU and sampling well locations within the NNSS). PM-1 is located in Area 20 of the NNSS and has a history of tritium concentrations near 200 picocuries per liter over the last 10 years. Well U-19BH has a history of tritium concentrations and in 2002 measured with concentrations at approximately 48 picocuries per liter. The tritium concentrations measured at Well U-19BH since 1999 show a downward trend. Wells UE-7NS and WW A are located within the Yucca Flat CAU 97 (see Figure 4–19 for CAU locations within the NNSS). Well UE-7NS was routinely sampled from 1978 to 1987, with the resumption of sampling in 1991. In 2003, tritium concentrations ranged from 133 to 156 picocuries per liter, consistent with the trend of decreasing concentrations observed in recent years. Well WW A has had measureable tritium since the late 1980s. There was an increase in tritium concentrations between 1985 and 1999, which has been followed by a slight downward trend in concentrations since 2000 (DOE/NV 2000c, 2001c, 2002b, 2003a, 2004a, 2005f, 2006a, 2007d, 2008a, 2009d).

No adverse impacts on potable groundwater quality have resulted from operations since 1996 (DOE/NV 2002b). Due to the distance between existing water supply wells at the NNSS and the underground tests, DOE/NNSA believes that groundwater use at the NNSS has little or no effect on the migration or spread of contamination from underground nuclear testing. Groundwater at the NNSS is deep and slow moving, which affords protection to adjacent areas (DOE/NV 2010). Groundwater modeling is used to evaluate the effect of water use on potential radionuclide migration and assist in the selection of optimum water-production wells and monitoring wells. As studies are completed, monitoring plans are negotiated and approved for each of the underground test areas. Maintenance of the quality of waters that are currently clean is managed through the implementation of the Groundwater Protection Management Plan.

Offsite water use is far removed from the NNSS testing areas. The closest significant offsite withdrawals are in Oasis Valley, approximately 18.6 miles (30 kilometers) from the nearest underground test, and these withdrawals are not thought to affect contaminant migration.

The NNSS has implemented a Borehole Management Plan to protect groundwater from contamination via infiltration of contaminants at the wellhead. Over 4,000 boreholes were drilled on and off the NNSS in support of nuclear testing. Many of the boreholes are no longer used and are not candidates for future use. These boreholes could serve as a pathway for surface contamination to reach subsurface strata (DOE/NV 2002b). The NNSS has implemented the Borehole Management Plan, which identifies boreholes that should be plugged to avoid any potential contamination of groundwater. As of January 2009, the Borehole Management Program has plugged 617 of the 871 boreholes identified as needing closure. Of the boreholes requiring closure, 151 are believed to penetrate groundwater and underground nuclear test cavities and 93 of these boreholes have been plugged as of January 2009 (DOE/NV 2009d).

Water Resources—American Indian Perspective

Indian people believe water is a living organism that is fully sentient and willful. The forces of power in the world move along channels and combine into specific nodes or places of power. A common set of these channels follows the path of water. These paths begin at the tops of mountains, especially the highest peaks. Snow and rain falls on these highlands and peaks after being called down by the mountain itself. From this beginning, the water moves downhill in rivulets, washes, and streams. The water often goes underground where it forms similar networks of channels moving in various directions, only somewhat corresponding to what non-native people call hydrologic basins. Water is often attracted to volcanic activity, thus producing significant power places like hot mineral springs.

According to tribal elders, *"Water is life. Water is needed by the plants and animals. Indian people bless themselves with it. It purifies the body. Water is medicine and must be respected. American Indians need it to conduct religious ceremonies. It cleans the earth. It has a vast connection to the underground. Water shouldn't be contaminated or it will die and lose its spirit."*

Each of the discreet underground water basins, or hydrological basins, has its own origin story. One tribal story tells of a discreet underground water network created by Ocean Woman and where she placed her feet. According to this traditional story, there are points where the water emerges at the surface in springs and seeps. It was here that Ocean Woman placed her medicine staff into the ground and water emerged.

At other points, the surface water in low playa lakes meets the underground water channels. These points are like doorways between the surface world and the underworld.

Rain calling is a basic aspect of American Indian life and culture. Rain ceremonies from the spiritual world help facilitate rain production, and were led by rain callers, often called rain shamans or rain doctors in the English language. The rain caller calls upon the rain by singing songs, and is aided by his spirit helper, which is usually in the form of a mountain sheep. The mountains also had important roles in this activity, and were called up to interact with the clouds and the sky to call down the rain.

Even today, individual traditional Indian people can bring rain. One way this is done is by turning a stinkbug on his back. The rain will come, provided the stinkbug allows a person to tickle his belly with a small stick. As this person prays for rain, he tells the stinkbug why he is asking for rain.

Water Resources—American Indian Perspective (cont'd)

CGTO If too much rain fell, certain precautions are taken. For example, the children are not allowed to shake willows that will be used for weaving or to kill frogs as this brings more rain. Hummingbirds were not killed for many reasons, but if they are killed, there will be flooding and lightning storms, with lightning killing the person who killed the hummingbird.

The Snow Ceremony was performed to ensure a good winter with heavy snow fall. The spiritual leader, often called a weather doctor in the English language, would call the people together and meet at a special place in the mountains, sometimes near a pine nut gathering area. The spiritual leader would sing songs and offer prayers. According to Indian tradition, the Snow Ceremony is performed during the late fall when the weather becomes cold. A part of this ceremony involves calling on the Snow Fleas. They represent a special category of American Indian environmental knowledge because they are almost invisible and live at the highest elevations on the mountains. The Snow Fleas are the ones that make the snow wet and absorb into the mountain. Without them, the snow is dry and evaporates quickly, and there is less water for the mountains and the valleys below. The Snow Ceremony is conducted in relationship with ceremony of the seeds where young girls dance with seeds in winnowing trays and a spiritual person sings songs to bring whirlwinds, which surround the dancers and scatter the seeds as a gesture of fertilizing the earth. Water is called upon to nourish the soil and the seeds to make them fertile.

Because water is a powerful being it is associated with other powerful beings, such as water babies. Water babies are like the people of the water. They are highly respected by American Indian culture. If water is contaminated, the water babies will move to other areas that are not contaminated. Proof of their existence has been depicted in historic rock drawings throughout Nevada, including one pecked at the volcanic butte at Black Canyon, Pahranagat Valley.

According to a tribal elder, *"Water babies are important to our culture. They are supernatural. They connect everything and you don't want to disrespect them. The springs are all connected and they follow the water flow. Water babies are supernatural beings and are the guardians of the water. They can make sounds like a baby, and you don't want to startle them because they can disturb life. We are taking their native environment away when we drill and contaminate the water. It angers them. When they get mad, there are adverse impacts to wildlife as they can drain you spiritually and physically."*

Playas

The CGTO knows playas occupy a special place in American Indian culture. Playas are often viewed as empty and meaningless places by western scientists, but to Indian people, playas have a role and often contain special resources that do not occur anywhere else.

The CGTO knows that playas were used in traveling or moving to places where work, hunting, pine cutting, or gathering of other important foods and medicine could be done. One elder remembers crossing over dry lake beds and traveling around but near the edges, and how provisions were left there and at nearby springs by previous travelers at camping spots.

According to tribal elders, who were interviewed during previous NNSS evaluations, *"Indian people left caches in playa areas for people who crossed valleys when water and food was scarce. Frenchman playa is such a place. Indian people took advantage of traveling through this playa as mountains completely surround this area. The CGTO knows that most dry lakes are not known to be completely dry. An example is Soda Lake near Barstow, California. The Mohave River flows into this dry lake and most of the year it looks dry but it actually flows underground. Although some people continue to view Frenchman playa [and other playas] as a wasteland, the CGTO knows it is not."*

See Appendix C for more details.

4.1.7 Biological Resources

The NNSS is located within the Basin and Range physiographic province and along the transition zone between the Mojave Desert and Great Basin ecoregions in south-central Nevada (Beatley 1975, 1976; DOE/NV 2000d) (see Figure 4–15). As a result, this site has a diverse and complex mosaic of plant and animal communities that are representative of both ecosystems, as well as some communities common only in the transition zone. This transition zone extends to the east and west far beyond the NNSS. Thus, the range of almost all species found on the NNSS also extends beyond the site, and there are few rare or endemic species found within the NNSS (DOE 1996c).

Elevation is an important factor affecting the distribution of plant and animal communities on the NNSS. Elevations generally increase from south to north, from a low of 2,688 feet in Jackass Flats to a high of 7,679 feet on Rainier Mesa. Climate and elevation result in a progression from Mojave Desert communities in the south to Great Basin communities in the north.

The biological diversity within the NNSS is also a result of topography. The valleys in the southern and western parts of the NNSS (e.g., Jackass Flats, Rock Valley, and Mercury Valley) have hydrologic connections to drainages outside the NNSS. In contrast, the two large valleys on the eastern side of the NNSS (Frenchman Flat and Yucca Flat) are closed basins. The lack of surface-water drainage out of these closed basins contributes to soil conditions, temperatures, and biotic communities that differ from those found at similar elevations in the open basins (Beatley 1975, 1976; DOE/NV 2000d).

To ensure compliance with laws, regulations, orders, and policies designed to protect plants and animals, the DOE/NNSA NSO has developed an Ecological Monitoring and Compliance (EMAC) Program. Over time, as requirements have progressed, the EMAC Program has become an integral part of the DOE/NNSA NSO Environmental Management System specified in DOE Order 436.1, *Departmental Sustainability*. The EMAC Program consists of several sub-programs and procedures tailored to monitor and protect the flora and fauna of the NNSS and incorporate protection of biological resources into project planning and the day-to-day activities of the NNSS, including the Desert Tortoise Compliance Program, the Sensitive Plant Monitoring Program, the Sensitive and Protected/Regulated Animal Monitoring Program, the Habitat Restoration Program, pre-activity biological surveys, surveys to assess the potential for wildland fires, and surveillance and monitoring of other relevant aspects of the NNSS flora and fauna, including invasive species. The following is a brief description of the various aspects of the EMAC Program.

Desert Tortoise Compliance Program. In August 1989, the desert tortoise was emergency listed under the Endangered Species Act, and the Mojave population of the desert tortoise was listed as threatened in April 1990. In October 1989, the manager of the DOE Nevada Operations Office (now the DOE/NNSA NSO) issued direction to all employees and contractors to protect tortoises on the NNSS, in part by suspending all off-road driving in tortoise habitat; forbade injuring or handling of tortoises; and strengthened existing environmental review requirements. The DOE/NNSA NSO Desert Tortoise Compliance Program was developed in 1992, when, in compliance with Section 7 of the Endangered Species Act (16 U.S.C. 1531 et seq.), the USFWS issued the first Biological Opinion for the NNSS. Since that time, new NNSS Biological Opinions were issued by USFWS in 1996 and 2009. The Desert Tortoise Compliance Program serves to implement the terms and conditions of the Biological Opinion for the NNSS, to document compliance actions taken, and to assist the DOE/NNSA NSO with USFWS consultations. Some of the activities of the Desert Tortoise Compliance Program include (1) reviewing proposed activities at the NNSS to determine if they may be located in tortoise habitat and if clearance surveys and/or monitoring are required, (2) conducting clearance surveys at project sites within 1 day of the start of project construction, (3) ensuring that environmental monitors are on site during heavy equipment operations, (4) developing training modules and ensuring that all personnel working on the NNSS are trained in the requirements of the *Final Programmatic Biological Opinion for Implementation of Actions Proposed on the Nevada Test Site, Nye County, Nevada* (*2009 Biological Opinion*), and (5) preparing annual compliance reports for submittal to USFWS. By implementing the Desert Tortoise

Compliance Program, the DOE/NNSA NSO would ensure that most, if not all, impacts on desert tortoises addressed in this analysis would involve harassment, rather than injury or mortality.

Sensitive Plant Monitoring Program. Under the NNSS Sensitive Plant Monitoring Program, the status or ranking of sensitive plant species known to occur on the NNSS is evaluated annually to ensure such plants are afforded the appropriate protection under Federal and state laws. Sensitive plant species populations on the NNSS are routinely monitored to assess plant density and plant vigor to identify any threats or impacts on the species.

Sensitive and Protected/Regulated Animal Monitoring Program. As part of the Sensitive and Protected/Regulated Animal Monitoring Program, to ensure such animal species are afforded the appropriate protection under Federal and state laws, the DOE/NNSA NSO currently monitors 18 animal species on the NNSS. The DOE/NNSA NSO also monitors raptorial bird species, including the western burrowing owl (*Athene cunicularia hypugaea*). In addition, the DOE/NNSA NSO conducts monitoring and other studies to evaluate species that may be added to the list of sensitive species to determine their abundance and distribution on the NNSS and shares the findings with USFWS and state wildlife agencies to help inform their decisions regarding those species.

Habitat Restoration Program. The Habitat Restoration Program involves the revegetation of disturbed land and evaluation of previous revegetation efforts. These activities are conducted at both the NNSS and the TTR.

Biological Surveys. Biological surveys are performed at project sites where land-disturbing activities are proposed. The goal is to minimize adverse effects of land disturbance on sensitive and protected/regulated plant and animal species, their associated habitat, and other important biological resources. Survey reports document species and resources found and provide mitigation recommendations.

Wildland Fire Surveys. In 2004, the DOE/NNSA NSO began annual surveys each spring to assess wildland fire hazards on the NNSS. NNSS ecologists conduct these wildland fire surveys in coordination with NNSS Fire and Rescue.

Additional Monitoring. Additional monitoring is conducted for such things as natural wetlands to characterize seasonal baselines and trends in physical and biological parameters; West Nile virus to help the Southern Nevada Health District ascertain the presence and/or prevalence of the virus in the NNSS mosquito population; and constructed water sources to assess their use by wildlife and to develop and implement mitigation measures to prevent them from causing significant harm to wildlife.

4.1.7.1 Flora

Based on an analysis of field data collected from ecological landform units, 10 vegetation alliances and 20 associations have been recognized on the NNSS (DOE/NV 2000d) (see **Table 4–36**). **Figure 4–22** shows the 10 vegetation alliances. Each vegetation alliance and association was named for the dominant tree or shrub species, based on relative abundance and the conventions of the Federal Data Committee and Ecological Society of America (DOE/NV 2000d). In terms of total area, the Great Basin Desert occupies approximately 40 percent of the NNSS, followed by the transition zone, which occupies 37 percent. The Mojave Desert occupies the southern 22 percent of the NNSS (DOE/NV 2000d). Within each of these three zones on the NNSS, there are populations of noxious/invasive plant species that have become established over the years. Measures employed by DOE/NNSA to control these unwanted plant species are described in Chapter 5, Section 5.1.7, and Chapter 7, Section 7.7.

Table 4–36 Vegetation Alliances and Associations on the Nevada National Security Site

Ecoregion	*Alliance*	*Association*
Mojave Desert	*Lycium* sp. (Shrubland Alliance)	*Lycium shockleyi–Lycium pallidum* (Shrubland)

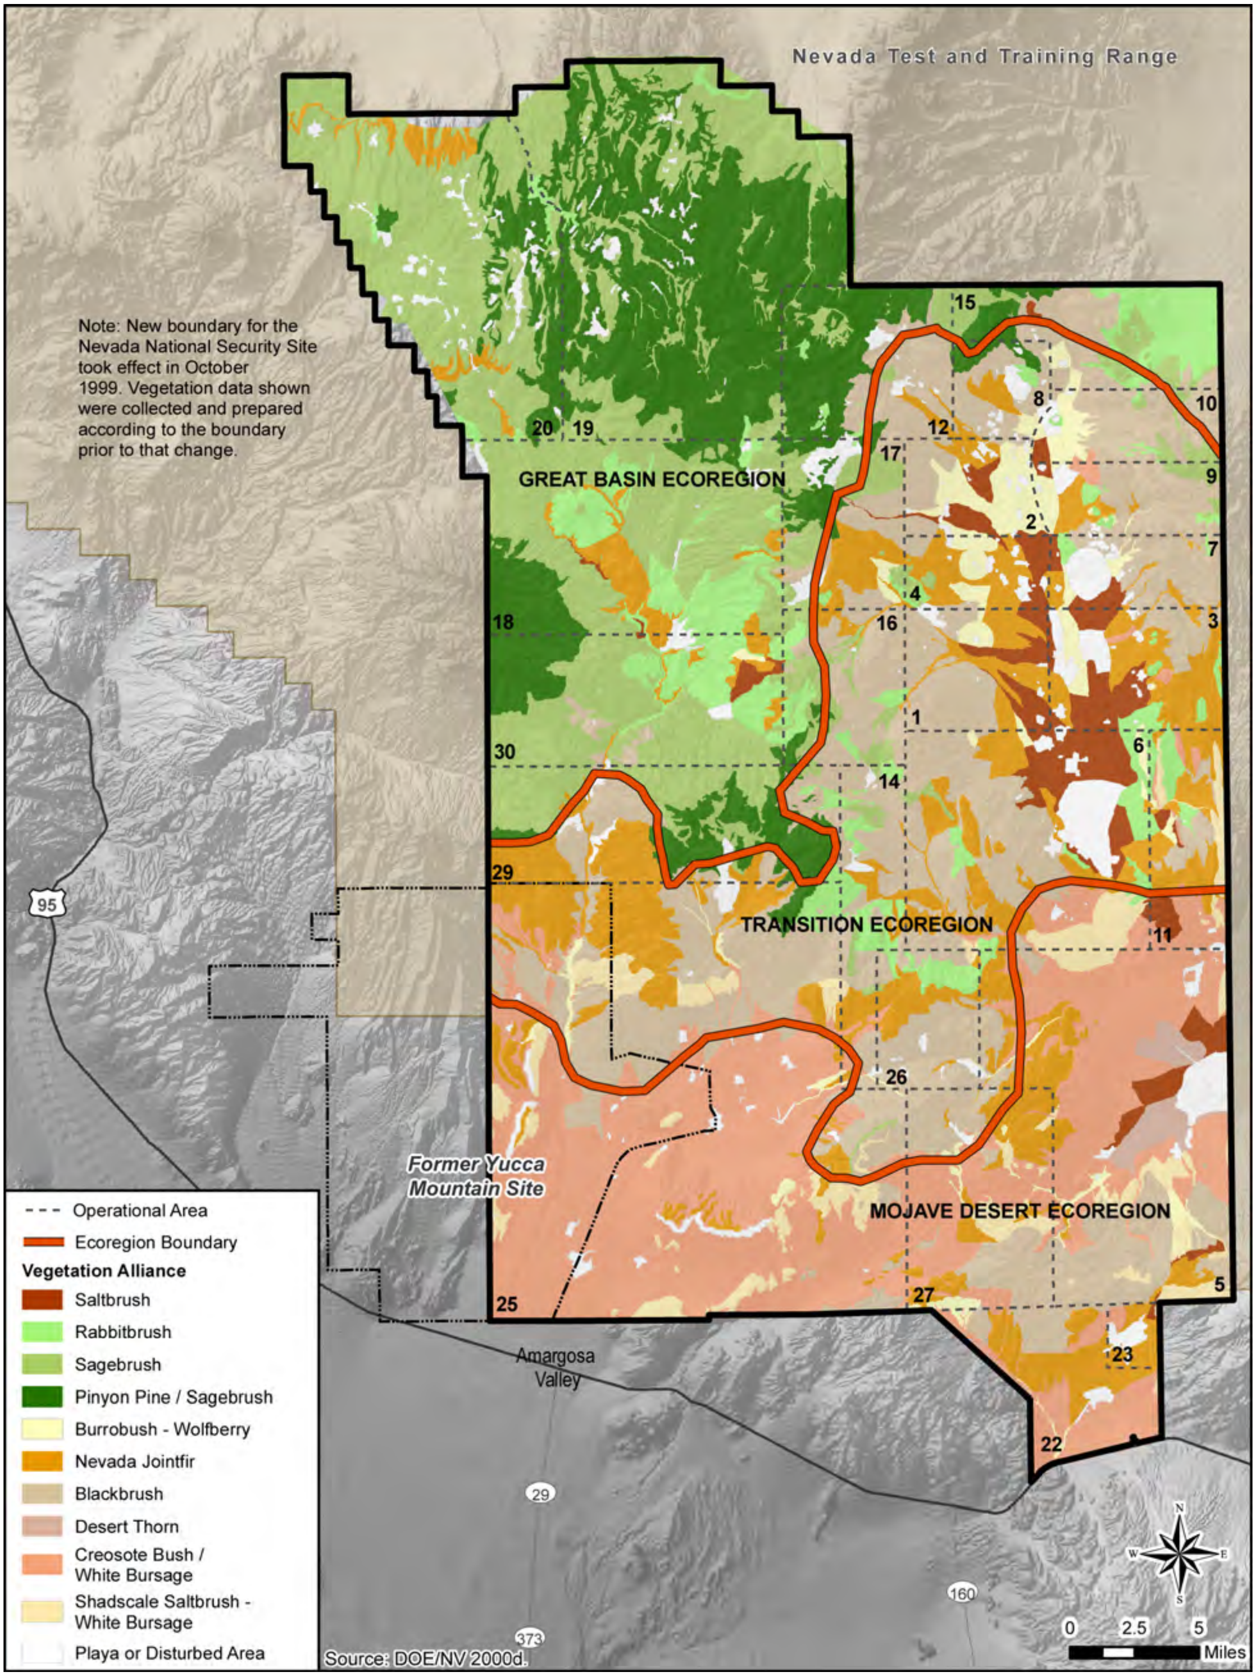

Figure 4–22 Nevada National Security Site Soil Alliances

The flora of the NNSS has been studied extensively and over 750 plant taxa have been collected (DOE/NV 2010). A list of plants found on the NNSS is presented in Appendix F, Tables F–2 and F–3. Table F–1 contains a list of sensitive plant species known to occur on or adjacent to the NNSS.

Early research on vegetation on the NNSS was conducted by Janice C. Beatley. Dr. Beatley established permanent plots on the NNSS in 1963, characterized the common plant associations of the northern Mojave and transition Great Basin Desert, and began documenting long-term changes in these ecosystems (Webb et al. 2003). Dr. Beatley collected data from these permanent plots between 1963 and 1975. In a 2003 USGS report, Webb et al. (2003) presented data on perennial vegetation on the Beatley plots from 1963 through 2003. Webb et al. relocated the Beatley plots and remeasured the vegetation, noting changes in vegetation since the original measurements made by Dr. Beatley. Webb et al. found a striking increase in plant biomass between 1963 and 2000. However, there were some changes in species composition since 1963. Plant associations dominated by creosote bush had large increases in the heights of individual plants, as well as increases in total cover, whereas those dominated by saltbush species had large decreases in cover. Some plots dominated by blackbrush had small decreases in perennial plant cover. The causes of the changes in vegetation are not certain, although Webb et al. indicated the most likely causes could be precipitation increases or increases in atmospheric carbon dioxide.

4.1.7.1.1 Mojave Desert

Mojave Desert plant communities are found at elevations below approximately 4,000 feet. These communities occur on the alluvial fans and valley bottoms of Jackass Flats, Rock Valley, and Mercury Valley and on the alluvial fans of Frenchman Flat. Creosote bush (*Larrea tridentata*) is the dominant shrub within these areas. The soil type and elevation are also contributing factors to the community composition. Shadscale saltbush (*Atriplex confertifolia*) is co-dominant with creosote bush on most alluvial fans where desert pavement is common. On deep, loose soil, such as exists on southern Jackass Flats and northeastern Frenchman Flat, creosote bush is co-dominant with white bursage (*Ambrosia dumosa*) and includes species such as winterfat (*Krascheninnikovia lanata*) and Indian ricegrass (*Achnatherum hymenoides*). Range ratany (*Krameria parvifolia*), Nevada jointfir (*Ephedra nevadensis*), and Fremont indigo bush (*Psorothamnus fremontii*) are common in both communities. At roughly an elevation of 3,500 to 4,000 feet along the northern and eastern slopes of Jackass Flats and the western half of Frenchman Flat, creosote bush, hopsage (*Grayia spinosa*), and wolfberry (*Lycium andersonii*, *L. pallidum*, and *L. shockleyi*) are the dominant shrub species.

4.1.7.1.2 Transition Zone

Two plant communities are unique to the transition zone between the Mojave Desert and Great Basin Desert ecoregions. The first is best developed at elevations from 4,000 to 5,000 feet on alluvial fans and valley floors. The dominant shrub in this community is blackbrush (*Coleogyne ramosissima*), which occurs in mixed stands with creosote bush on the northern alluvial fans of Jackass and Frenchman Flats below about 4,500 feet. At higher elevations (e.g., on the valley floor of Tonopah and Mid Valleys and on the western slopes of Yucca Flat), blackbrush occurs in large, nearly monotypic stands. The second unique transition community occurs in the bottom of the enclosed Frenchman Flat and Yucca Flat basins, where the trapped winter air lowers temperatures below those typical of the Mojave Desert (Beatley 1976). The most abundant shrubs in these areas are hopsage and three species of wolfberry. Winterfat is also common in silty soils. Shadscale saltbush, four-winged saltbush (*Atriplex canescens*), and horsebrush (*Tetradymia glabrata*) can also be found in enclosed basins. Little or no vegetation grows on the playas in these basins.

4.1.7.1.3 Great Basin Desert

Plant communities typical of the desert occur in the Great Basin at elevations generally above 5,000 feet in the northern third of the NNSS. Most of the basin floor is covered with shadscale, and winterfat is also common. On deep, loose soils at middle elevations (4,500 to 5,500 feet), the plant community is dominated by four-winged saltbush. Sagebrush (*Artemisia* sp.) begins to appear at 5,000 feet and is the

dominant plant on large parts of Pahute Mesa and Rainier Mesa, as well as elsewhere in the northwestern part of the NNSS. Big sagebrush (*Artemisia tridentata*) is the most abundant shrub on sites with deep soils in this area, and black sagebrush (*Artemisia nova*) is most abundant on the shallow soils of slopes and uplands. Pinyon pine (*Pinus monophylla*) and Utah juniper (*Juniperus osteosperma*) are co-dominant with sagebrush above 6,000 feet and form open shrub woodland. Sites on the NNSS with vegetation or soil modified by nuclear test activities, construction, or other disturbances usually have plant communities that are different from adjacent undisturbed areas. Some of the species that colonize disturbed areas (e.g., cheesebush *[Hymenoclea salsola]* and punctate rabbitbrush *[Chrysothamnus paniculatus]*) are native plants that usually occur in washes. However, most species found on disturbed sites are introduced plants such as red brome (*Bromus rubens*), cheatgrass (*Bromus tectorum*), Russian thistle (*Salsola tragus*), and red-stemmed filaree (*Erodium cicutarium*).

Natural succession of disturbed areas on the NNSS is generally a slow process. Studies of natural succession in the Mojave Desert have shown that several decades, or even centuries, may be required to establish similar plant cover and productivity (Angerer et al. 1994). Because of the increased and more-consistent precipitation, succession rates in the Great Basin Desert are generally quicker than those in the Mojave Desert. Active revegetation of sites can greatly enhance secondary succession. Variables that have been determined to be important in revegetation success are (1) adequate moisture during seed germination and establishment; (2) favorable soil conditions, including depth, texture, fertility, and reduced compaction; and (3) use of species adapted or native to the site.

The only biological communities on and around the NNSS that are not widespread are those associated with springs or other permanent sources of water. There are 16 springs, 10 seeps, 4 tank sites (natural rock depressions that catch and hold surface runoff), and 2 ephemeral ponds on the NNSS (Bechtel Nevada 1998b, 1999; Hansen et al. 1997). Most natural springs are on the mesas and mountains in the northern part of the NNSS (see Figure 4–22); most reservoirs are scattered through the valley bottom to the east and south. There are no springs in the valley bottom areas. Groundwater under the NNSS flows primarily to the south and west and discharges from springs in Ash Meadows, Oasis Valley, and Death Valley (see Section 4.1.5). Most of the springs at the NNSS support wetland (hydrophytic) vegetation, such as cattail, sedges, and rushes, which likely constitute wetlands, as defined by the U.S. Army Corps of Engineers and EPA (33 *Code of Federal Regulations* [CFR] 328.3(b) and 40 CFR 230.3(t), respectively).

4.1.7.1.4 Important Habitats

In 1998, DOE/NNSA evaluated selected biotic and abiotic data collected from ecological landform units to identify areas of the NNSS that may warrant active protection from land-disturbing activities (Bechtel Nevada 1999). Four habitat types on the NNSS were identified as "important habitats": (1) pristine habitat includes areas that have few manmade disturbances; (2) unique habitat contains uncommon biological resources, such as a natural wetland; (3) sensitive habitat includes areas in which vegetation recovers very slowly from direct disturbance (e.g., areas with high susceptibility to wind erosion); and (4) diverse habitat has high plant species diversity (DOE/NV 1998d). Important habitats are shown in **Figure 4–23**. DOE/NNSA believes that the long-term protection of these important habitats is one method by which overall cumulative impacts on biological resources may be minimized. During siting for new projects, these important habitats are avoided whenever possible. Important habitats on the NNSS are not based on regulatory requirements, but were developed as management tools.

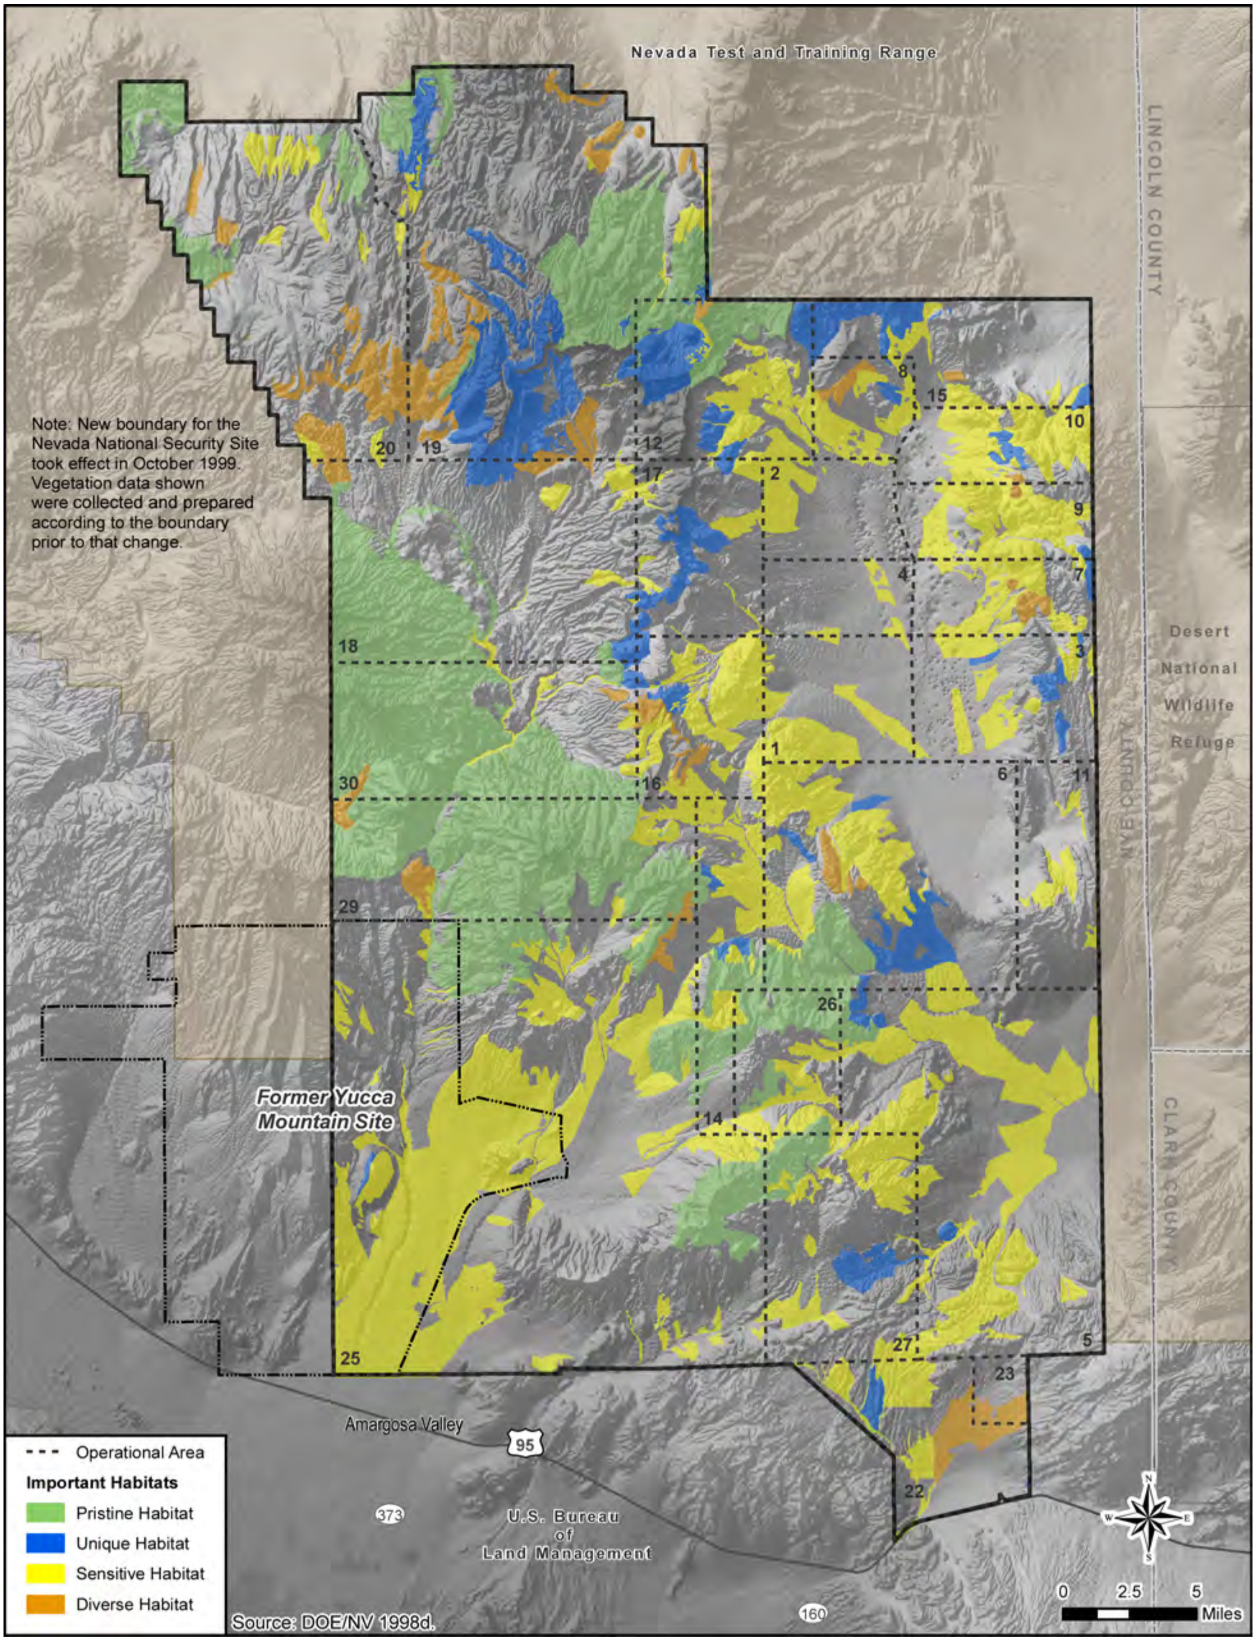

Figure 4–23 Important Habitats on the Nevada National Security Site

4.1.7.2 Fauna

At least 1,163 taxa of invertebrates within the phylum Arthropoda (animals that have an exoskeleton, a segmented body, and jointed appendages) have been identified on the NNSS. Of the known arthropods, 78 percent are insects (DOE/NV 2010). Ants, termites, and ground-dwelling beetles are probably the most important groups of insects on the NNSS in regard to distribution, abundance, and functional roles.

Approximately 300 vertebrate species have been observed on the NNSS, including 60 species of mammals, 239 species of birds, 34 species of reptiles, and 3 species of introduced fish (Wills and Ostler 2001). Approximately 80 percent of the bird species on the NNSS are migrants or seasonal residents (Wills and Ostler 2001). As of 2010, 26 bird species, including 9 raptor species (birds of prey), are known to breed on the NNSS. Raptors that breed on the NNSS include the golden eagle (*Aquila chrysaetos*), long-eared owl (*Asio otus*), red-tailed hawk (*Buteo jamaicensis*), Swainson's hawk (*Buteo swainsoni*), prairie falcon (*Falco mexicanus*), American kestrel (*Falco sparverius*), western burrowing owl (*Athene cunicularia hypugaea*), barn owl (*Tyto alba*), and great-horned owl (*Bubo virginianus*) (DOE 2002c). There have been about 300 sightings of golden eagles on the NNSS dating back to 1968. Golden eagle nesting at the NNSS is uncommon. There have been only two documented nests of golden eagles (both in 1999) and only one of those had confirmed young. One of these nests was located on Rainier Mesa near P Tunnel in Area 2 and the other was on the cliffs south of Tippipah Spring in Area 16 (Ostler 2012).

A list of animals that have been sighted on the NNSS is presented in Appendix F, Tables F–4 and F–5. See Table F–1 for a list of sensitive animal species known to occur on or adjacent to the NNSS. Many of the predators and scavengers in this region are widespread and utilize a variety of habitat types. These include coyote (*Canis latrans*), bobcat (*Lynx rufus*), common raven *(Corvus corax)*, red-tailed hawk, loggerhead shrike *(Lanius ludovicianus)*, speckled rattlesnake (*Crotalus mitchellii*), and gopher snake *(Pituophis catenifer)*. Other common species are the long-tailed pocket mouse (*Chaetodipus formosus*), desert woodrat (*Neotoma lepida*), white-tailed antelope squirrel (*Ammospermophilus leucurus*), black-tailed jackrabbit (*Lepus californicus*), black-throated sparrow (*Amphispiza bilineata*), horned lark (*Eremophila alpestris*), Say's phoebe (*Sayornis saya*), and western kingbird (*Tyrannus verticalis*). The side-blotched lizard (*Uta stansburiana*), western whiptail (*Cnemidophorus tigris*), and desert horned lizard (*Phrynosoma platyrhinos*) are the most abundant lizards on the NNSS (Wills and Ostler 2001). The nonnative bullfrog (*Rana catesbeiana*) is the only amphibian that is known to occur on the NNSS (DOE/NV 2010).

Many animal species on the NNSS are common only in the Mojave Desert habitats to the south or the Great Basin Desert habitats to the north. Typical Mojave Desert species found on the NNSS include kit fox (*Vulpes macrotis*), Merriam's kangaroo rat (*Dipodomys merriami*), desert tortoise (*Gopherus agassizii*), chuckwalla (*Sauromalus obesus*), western shovelnose snake (*Chionactis occipitalis)*, and sidewinder snake (*Crotalus cerastes*). Typical Great Basin species in this region include cliff chipmunk (*Eutamias dorsalis*), Great Basin pocket mouse (*Perognathus parvus)*, mule deer (*Odocoileus hemionus*), northern flicker (*Colaptes auratus*), western scrub-jay (*Aphelocoma californica*), Brewer's sparrow (*Spizella breweri*), western fence lizard (*Sceloporus occidentalis*), and striped whipsnake (*Masticophis taeniatus*). About 36 adult wild horses (*Equus caballus*) (not including foals) live on the northern part of the NNSS, usually on or near Rainier Mesa (NSTec 2010).

Some animal species on the NNSS have more-specific habitat requirements and are less widespread. Desert kangaroo rats (*Dipodomys deserti*) are associated with loose, sandy soils at lower elevations. Dark kangaroo mice (*Microdipodops megacephalus*) are restricted to fine, gravelly soils at higher elevations. Chuckwallas occur primarily in rocky outcrops. Desert night lizards (*Xantusia vigilis*) are usually found in stands of yuccas. Many of the birds on the NNSS, including almost all of the waterfowl and shorebirds, use the playas in Frenchman Flat and Yucca Flat, artificial ponds at springs, and sewage lagoons during their migration and/or during winter (Hayward et al. 1963). Bats often seek food over these water sources.

A total of 138 species of animals have been documented at NNSS wetland sites (Wills and Ostler 2001). The largest group of vertebrates using NNSS wetlands is birds (100 species). Passerine birds constitute the majority of birds recorded (80 species). Cane Spring and Yucca Playa Pond are the only natural NNSS locations that are known to attract migratory waterfowl. Many freshwater invertebrates occur in NNSS wetland sites, including an undescribed fairy shrimp. Scat of the desert tortoise has been found at the Rock Valley Tank site.

Wild horses occur in the northern half of the NNSS; their distribution may be related to the location of manmade ponds. Camp 17 Pond in the northwestern corner of Area 18 and Gold Meadows Spring in Area 12 (a natural water source) are heavily used by horses. Camp 17 Pond was used less frequently in 2008 compared with 2007 because 2008 had a wetter spring than 2007, which reduced the water needs of the wild horses (NSTec 2009a). Mule deer use these ponds as well.

An annual horse census is conducted by driving selected NNSS roads and using cameras to record individual markings of animals. Total numbers have dropped from 42 in 2007 to 35 in 2008 (see **Table 4–37**). A similar number of horses was observed in 2009 as in 2008 (i.e., 36 adults, 1 yearling, and 6 foals) (NSTec 2010j). Their estimated range of 222 square kilometers in 2009 is very similar in size to the horse range in 2007 and 2008 (NSTec 2010j). Camp 17 Pond and Gold Meadows Spring continue to be important summer water sources for horses.

Table 4–37 Number of Individual Horses Observed on the Nevada National Security Site by Age Class, Sex, and Year

	Year							
Age Class	***2001***	***2002***	***2003***	***2004***	***2005***	***2006***	***2007***	***2008***

[a] One of the nine was found dead.
[b] Excludes foals and dead horses.
Source: NSTec 2009a.

As described in Section 4.1.5.2, surface runoff periodically ponds on the playas in Yucca and Frenchman Flats. The length of time that water remains on playas and the extent to which playas are used by migratory shorebirds are not routinely monitored. However, water has been observed on the playas for periods of days to months following rainstorms. Occasionally, migratory shorebirds have been observed when the playas are inundated during the spring or fall migratory season.

Several species of state-designated game animals occur in the NNSS, including 412 mule deer (NSTec 2009a) and an unknown number of mountain lions (*Puma concolor*), desert and Nuttall's cottontails (*Sylvilagus nuttallii*), chukar (*Alectoris chukar*), Gambel's quail (*Callipepla gambelii*), mourning dove (*Zenaida macroura*), and several species of waterfowl. Pronghorn (*Antilocapra americana*) can be seen year-round on the NNSS, particularly in Yucca Flat and in Frenchman Flat in small numbers. Another game animal, the desert bighorn sheep (*Ovis canadensis* ssp. *nelsoni*), is a rare visitor on the NNSS, with only eight recorded observations of its presence on or near the NNSS since 1963. In the past, the species was observed in Mercury and on Rainier Mesa (Wills and Ostler 2001). During 2009, desert bighorn sheep were photographed by motion-activated cameras at Topopah Spring in Area 29 and on Skull Mountain in Area 25, and a ram was documented in Area 18. There is an established population of desert bighorns in the Specter Range south of the NNSS and other populations

north and west of the NNSS. Until recently, it was thought the NNSS might only provide a suitable corridor for movement between these populations; however, as part of a recent study of mountain lions on the NNSS, a total of five kills of young (1- to 4-month-old) lambs have been documented in the Fortymile Canyon/Calico Hills area. Although lambing areas have not been documented on the NNSS, this evidence suggests they do exist (Ostler 2012). Further field studies will be needed to determine if the observed desert bighorn sheep are transients or if they are, or will become, residents on the NNSS (NSTec 2010j). Bobcats (*Lynx rufus*), gray foxes (*Urocyn cinereoargenteus*), and kit foxes (*Vulpes macrotis*) are the only state-designated fur-bearing animals on the NNSS. No hunting or trapping is allowed on the NNSS.

4.1.7.3 Threatened and Endangered Species

The only species that has been listed by USFWS as threatened or endangered that occurs on the NNSS is the Mojave Desert population of the desert tortoise. The desert tortoise was listed as threatened by USFWS in 1990. The State of Nevada classifies the desert tortoise as a threatened species, and it is protected under *Nevada Revised Statutes,* Chapter 501.

In 1996, USFWS issued the *Final Programmatic Biological Opinion for Nevada Test Site Activities* (*1996 Biological Opinion*) (USFWS 1996) to the DOE/NNSA NSO, covering activities occurring within desert tortoise habitat on the NNSS. The *1996 Biological Opinion* authorized the incidental "take" (accidental killing, injury, harassment, etc.) of desert tortoises that may occur during NNSS activities. In July 2008, the DOE/NNSA NSO provided USFWS with a biological assessment of activities anticipated to occur on the NNSS over the following 10 years and entered into formal consultation with USFWS to obtain a new Biological Opinion. In February 2009, USFWS issued the *2009 Biological Opinion* (USFWS 2009a) to the DOE/NNSA NSO. Both the *1996 Biological Opinion* and the *2009 Biological Opinion* concluded that activities anticipated to occur on the NNSS would not jeopardize the continued existence of the Mojave population of desert tortoises and no critical habitat would be destroyed or adversely modified. Under the *2009 Biological Opinion,* before implementing any new activity in desert tortoise habitat, DOE/NNSA provides specified information and consults with USFWS to determine if the anticipated incidental take for each action, at the project level, complies with the programmatic *2009 Biological Opinion*. If a proposed activity or group of activities would result in an exceedance of the *2009 Biological Opinion*, DOE/NNSA would consult with USFWS, in accordance with Section 7 of the Endangered Species Act.

Desert tortoises generally occur throughout the southern third of the NNSS (Rautenstrauch et al. 1994). They are found more commonly in bajadas and lower slopes of southern mountains and are rare or absent from the lower basins, particularly in Frenchman Flat. The northern boundary of the desert tortoise range on the NNSS is shown in **Figure 4–24**. Because the Former Yucca Mountain site was not under the jurisdiction of the NNSA/NSO at the time tortoise surveys were conducted for developing the data in Figure 4–24 and compatible data is not available, that area does not have any population densities displayed in the figure; however, for purposes of analysis in this SWEIS, it was assumed that tortoise population densities would be similar to adjacent areas of the NNSS (i.e., ranging from "None to Very Low" to "Low"). The total area of the NNSS (including the portion that is shown as the "Former Yucca Mountain Site in Figure 4–24) that is within the range of the desert tortoise is about 328,400 acres. Overall, approximately 7,350 acres, or 2 percent, of NNSS land within desert tortoise range has been disturbed in the past by construction of facilities and infrastructure and other activities. The net area of desert tortoise habitat at the NNSS is about 321,050 acres. The population density of desert tortoises on the NNSS is considered to be "very low" (USFWS 2009a). Within the NNSS, the northern extent of the desert tortoise occurs between elevations of approximately 3,900 and 4,880 feet. The vegetation in the boundary region is dominated by blackbrush, creosote bush, white bursage, spiny hopsage, and Anderson wolfberry (Beatley 1976; DOE/NV 2000d).

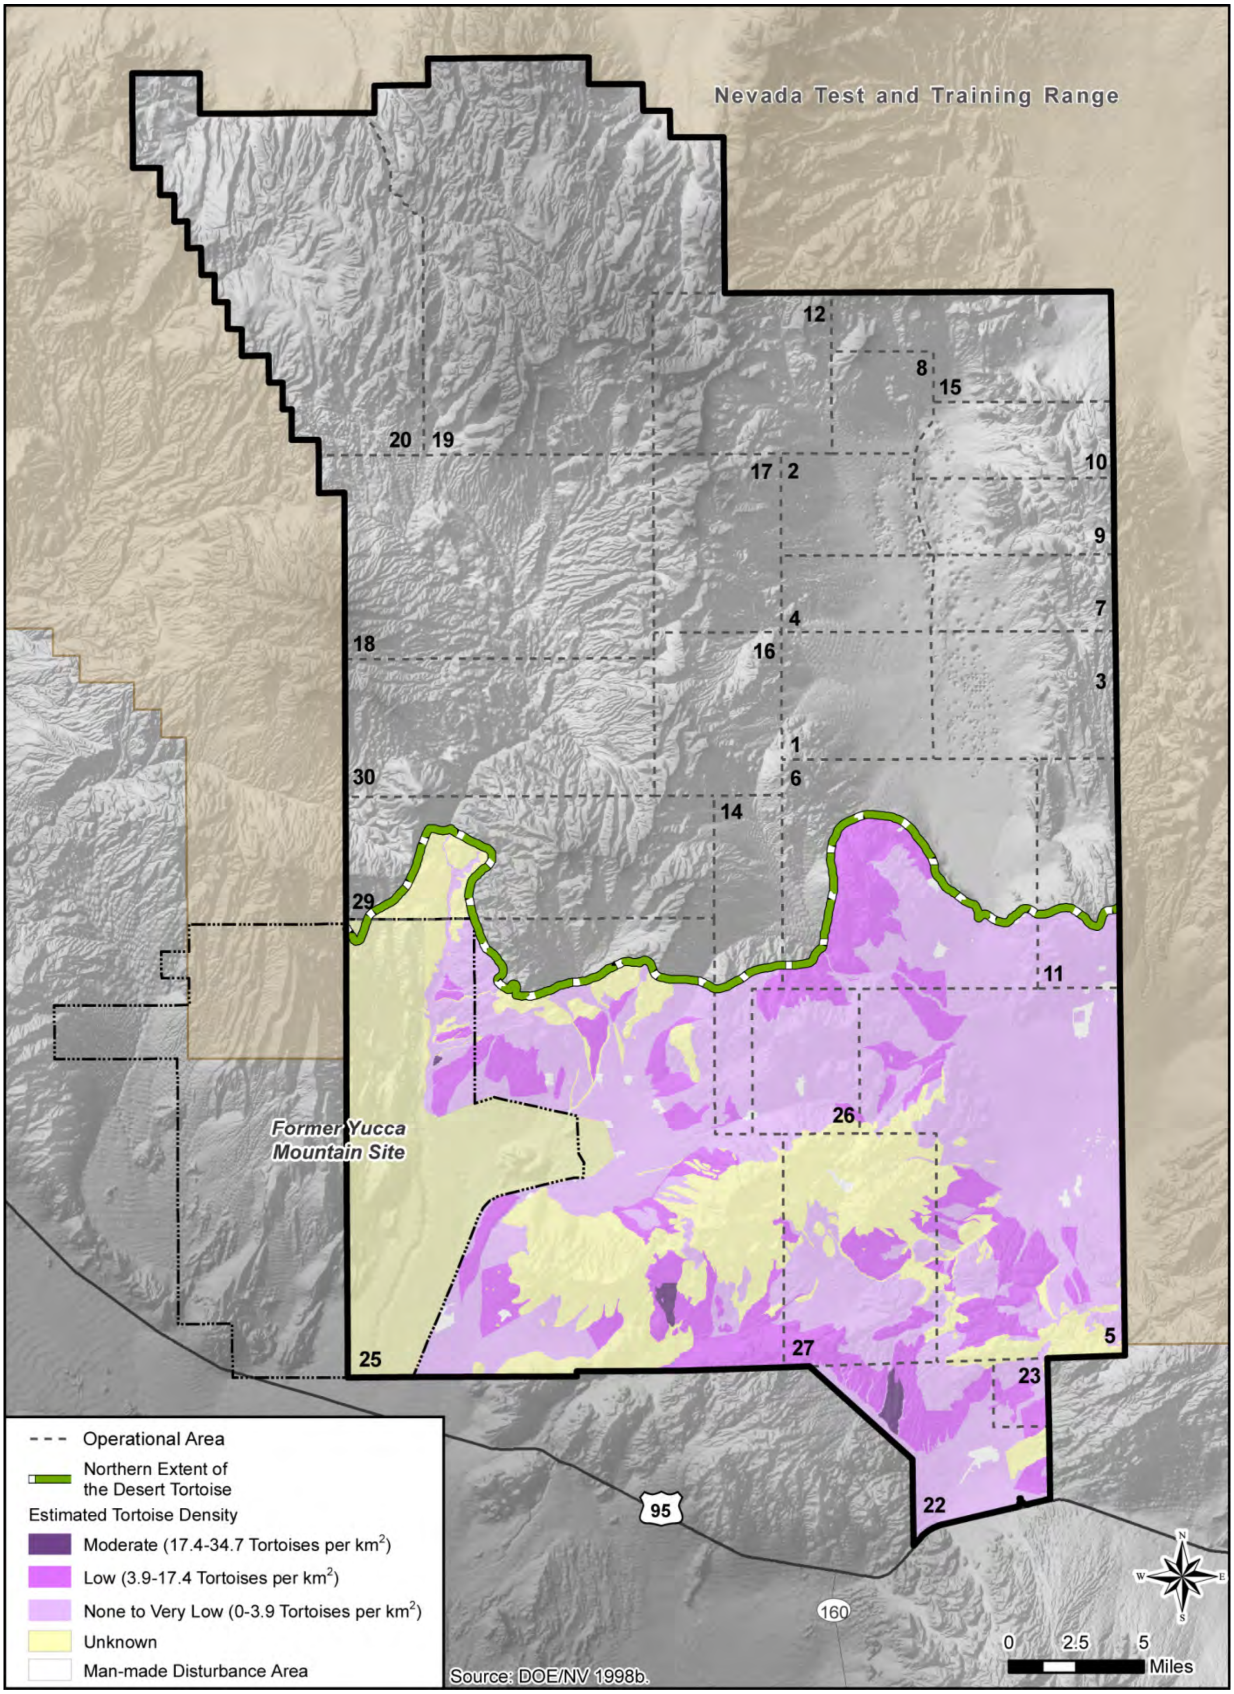

Figure 4–24 Northern Boundary of the Desert Tortoise Range on the Nevada National Security Site

Based on 1996 studies, the relative abundance of the desert tortoise on the NNSS ranges from very low or none (0–3.9 tortoises per square kilometer) to moderate (17.4–34.7 tortoises per square kilometer) (DOE/NV 1998b). Overall, the relative abundance of the desert tortoise on the NNSS is low to very low relative to other areas within the tortoise's range (EG&G 1991). The NNSS contains less than 1 percent of the total habitat of the overall desert tortoise population. A cumulative total of approximately 311 acres of desert tortoise habitat on the NNSS has been disturbed since the desert tortoise was listed in 1992 (NSTec 2009a). Critical habitat for the desert tortoise has not been designated on the NNSS, nor is the NNSS within any Desert Wildlife Management Area delineated in the *Desert Tortoise (Mojave Population) Recovery Plan* (USFWS 1994).

No federally listed threatened or endangered plants are known to occur on the NNSS (NSTec 2010j). However, 18 species of vascular plants and 1 non-vascular plant on the NNSS are considered to be sensitive by the Nevada Natural Heritage Program. Appendix F, Table F–1, includes a list of sensitive plant species known to occur on or near the NNSS. Also in Appendix F is a map showing the known locations of sensitive plant species on the NNSS.

The delisted peregrine falcon (*Falco peregrinus*) and delisted bald eagle (*Haliaeetus leucocephalus*) have also been reported on the NNSS. These species are rare migrants in this region and each has only been sighted once on the NNSS (Greger and Romney 1994). The peregrine falcon was removed from the threatened and endangered species list in 1999 (64 FR 46542), while the bald eagle was removed in 2007 (72 FR 37346). USFWS will monitor the bald eagle population status for a minimum of 5 years after delisting, as required by the Endangered Species Act. The bald eagle will continue to be protected under the Migratory Bird Treaty Act and the Bald and Golden Eagle Protection Act. The State of Nevada lists this species as endangered.

4.1.7.4 Other Species of Concern

There are 88 sensitive and protected/regulated species known to occur on or adjacent to the NNSS (NSTec 2010j): 1 moss, 22 flowering plants (including 3 species of yucca, 1 of agave, and 18 cacti), 1 mollusk, 2 reptiles (including the desert tortoise), 15 birds, and 27 mammals. Two of the bird species, chukar (*Alectois chukar*) and Gambel's quail (*Callipepla gambelii*), are regulated as game species and 7 mammals are regulated as game species, as follows: pronghorn antelope (*Antilocarpra americana*), Rocky Mountain elk (*Cervus elaphus*), desert bighorn sheep (*Ovis canadensis nelsoni*), mule deer (*Odocoileus hemionus*), mountain lion (*Puma concolor*), Audubon's cottontail (*Sylvilagus audubonii*), and Nuttall's cottontail (*Sylvilagus nuttallii*). Three species are regulated as furbearers: bobcat, gray fox, and kit fox. Protected and sensitive species of plants and animals are listed in Appendix F, Table F–1. DOE/NNSA reviews the list of sensitive and protected/regulated species each year and conducts ongoing biological surveys to ascertain the presence of sensitive plant and animal species at the NNSS as part of its Ecological Monitoring and Compliance Program.

As discussed above, the Ecological Monitoring and Compliance Program monitors the ecosystem of the NNSS and ensures compliance with laws and regulations pertaining to NNSS biota. An annual report is prepared that summarizes program activities.

As noted above, there are a large number of sensitive wildlife species on the NNSS. One species of potentially sensitive reptiles is present, the western red-tailed skink (*Eumeces gilberti rubricaudatus*). NNSS-wide population numbers are unknown; however, eight red-tailed skinks were captured at 4 of 31 survey sites in 2008 (NSTec 2009a). Western red-tailed skinks have been found primarily in the western and northern portions of the NNSS (NSTec 2010j).

The western burrowing owl (*Athene cunicularia hypugaea*) is the main bird species that may be affected by activities on the NNSS. This species is ground-dwelling and uses burrows found in dry, open areas with flat to gradually sloping terrain. It can be found in most of the major valleys in the eastern and southern portions of the NNSS. Western burrowing owl monitoring, including trapping, has been ongoing on the NNSS for a number of years. A total of 26 breeding pairs and 122 young were detected

over a 3-year period from 1999 to 2001 (Hall et al. 2003). There were 7, 8, and 11 breeding pairs and 24, 43, and 55 young detected during 1999, 2000, and 2001, respectively (Hall et al. 2003).

Eight bat species of concern that are known to occur on the NNSS include the spotted bat (*Euderma maculatum*), Townsend's big-eared bat (*Corynorhinus townsendii*), big free-tailed bat (*Nyctinomops macrotis*), long-eared myotis (*Myotis evotis*), small-footed myotis (*M. ciliolabrum*), fringed myotis (*M. thysanodes*), long-legged myotis (*M. volans*), and Yuma myotis (*M. yumaensis*) (Wills and Ostler 2001). Bat monitoring in 2008 included passive acoustic monitoring, preclosure monitoring at tunnels, and removing bats from buildings (NSTec 2009a).

Although not listed as sensitive, all bird species that occur on the NNSS, except chukar (*Alectois chukar*), Gambel's quail (*Callipepla gambelii*), English house sparrow (*Passer domesticus*), rock dove (*Columba livia*), and European starling (*Sturnus vulgaris*), are protected under the Migratory Bird Treaty Act (the noted bird species are not migratory and, therefore, are not covered by the Migratory Bird Treaty Act). As part of pre-activity planning on the NNSS, biological surveys are conducted to ensure protection of sensitive and otherwise protected species. Active nests of migratory birds are protected until the young fledge by avoiding activities that would cause direct harm, such as damaging or destroying a nest, or indirect harm, such as causing disturbance that would cause parent birds to abandon their eggs or young. For example, in 2009, three nests with chicks were protected from harm, including one Say's phoebe nest with four chicks and two nests of unknown species, each with chicks. NNSS activities that may have caused harm to these nests were postponed until the chicks fledged and the nests were empty (DOE/NV 2010).

4.1.7.5 Effects of Past Radiological Tests and Project Activities

A number of studies were conducted to document the types and extent of disturbances of the biological resources that may have resulted from past projects. Much of the focus was on determining the fate and effects of radionuclides, especially TRU radionuclides (Dunaway and White 1974; Gilbert et al. 1988; Howard and Fuller 1987; Howard et al. 1985; White and Dunaway 1975, 1976, 1978; White et al. 1977a, 1977b). Long-term impacts resulting from nuclear tests and nonradiological causes were also investigated (Hunter 1992, 1994a, 1994b, 1994c, 1995).

In areas where atmospheric tests, safety tests, or cratering experiments were conducted, there were measurable changes in the species composition and abundance of plants and animals. Immediately following some tests that deposited fallout containing beta-emitters, shrubs that were more radiosensitive, such as sagebrush, were killed, and a grass disclimax was established. The projects also involved nonradiological physical and mechanical disturbances that altered the characteristics of the soils and usually resulted in the removal of the shrubs, which are a key component of the structure and functioning of these desert ecosystems. The ecological changes observed were similar to effects associated with other human activities that disturb desert habitats, and few could be attributed solely to radiological impacts.

A herd of cattle was allowed to graze the northwestern part of the NNSS for 25 years (Smith and Black 1984). Periodically, tissues of cattle, deer, and bighorn sheep were analyzed for concentrations of radionuclides. Results of this program suggested that, since 1956, no significant amounts of biologically available radionuclides were contributed by activities on the NNSS. Except for periods immediately following the deposition of close-in fallout, tissue concentrations of cesium-137 and strontium-90 reflected the deposition of worldwide fallout. Concentrations of tritium were within the ranges present in the general environment, except in tissues of animals that had access to point sources of tritium, such as the Sedan Crater or the containment ponds in Area 12.

Hypothetical dose commitments for daily ingestion of NNSS beef over varying lengths of time were less than 2 percent of the Federal Radiation Council or the International Commission on Radiological Protection guidelines. Both the calving rate of the herd, which exceeded 85 percent annually, and the 180-day weaning weight, usually greater than 400 pounds, were above average. Routine necropsy and

histopathological examinations revealed no harmful health effects that could be attributed to ionizing radiation in herbivores maintained for a lifetime on the NNSS.

Concentrations of radionuclides in soils, plants, and animals in the vicinity of some past tests were above general background levels. Concentrations usually decreased by a factor of 10 between soils and plants and between plants and animals. This is likely due to the fact that plants do not take up all of the contaminants available in the soil and animals, being mobile, may obtain their food from both contaminated and uncontaminated areas. In addition, some contaminants may not be absorbed by the animals, moving through the digestive tract of the animal and being excreted. Chromosomal aberrations were observed in cells of spiny sagebrush collected from Area 11, but the yields may not have been greater than what would be observed in the population naturally, and whether they were valuable or detrimental to the population was undetermined. Depressed levels of circulating lymphocytes and total leukocyte counts were found in kangaroo rats collected in areas contaminated with plutonium, but they were considered to be physiologically inconsequential. Gross pathological changes in native mammals appeared to be minimal and nonspecific. Reproduction in and recruitment to mammalian populations inhabiting contaminated areas were determined to occur largely in response to changes in the food supply of winter annual plants rather than in response to levels of radiation.

In a 2001 paper, Theodorakis et al. reported on a study that examined the effects of radionuclide exposure on Merriam's kangaroo rats at two radiologically contaminated atomic detonation locations on the NNSS. This research found that while genotoxic effects were not observed when all individuals were analyzed, individuals with gene sequences unique to the contaminated sites had greater chromosomal damage than contaminated-site individuals with gene sequences shared with reference (i.e., noncontaminated) sites. The researchers hypothesized that shared-gene-sequence individuals are potential migrants and that unique-gene-sequence individuals are potential long-term residents. They concluded that the radiologically contaminated detonation sites are ecological sinks and that immigration masks the potential mutagenic/carcinogenic effects of radiation on the resident population (Theodorakis et al. 2001). This suggests that individuals of a species that spend a majority of their lives living in a radiologically contaminated area would be more likely to exhibit genetic damage from the radioactivity than members of the same species that may only spend a small portion of their lives in the contaminated area. This would tend to reduce the likelihood of animals from the NNSS passing on damaged genes to animal populations in offsite areas.

The long-term consequences of past DOE activities were studied at past ground zero locations above which atmospheric tests were conducted, within subsidence craters formed following underground tests, in burned areas, on compacted drill pads and scrapes, and along roadsides. One of the major findings was that ecological impacts resulting from DOE/NNSA programs on the NNSS did not differ in type or magnitude from those resulting from other human activities that disturb desert ecosystems. Changes in the vegetation resulted from changes in patterns and amounts of precipitation. Changes in the species composition of vertebrates appeared to be linked to the structure of the vegetation associations, and changes in abundance were in response to altered food supplies, which were linked to vegetation.

Changes to the structure and function of ecosystems were restricted to the immediate vicinity of project sites, and few long-term effects could be attributed to radiological impacts. Concentrations of radionuclides did not produce genetic or cytological abnormalities that appeared to be detrimental to species or populations either in the short or long term. Restoration of disturbed sites will likely follow the routes and rates of succession observed in comparable, manipulated desert ecosystems.

Public access to the NNSS is restricted and precludes the harvest of plants for direct consumption by humans. However, animals may consume contaminated vegetation or water on the NNSS and become contaminated. Because animals may travel off the NNSS, the ingestion of game animals is the primary potential biotic pathway of radiological exposure to the public. The annual radiological monitoring program for the NNSS includes sampling plants and animals at sites with the highest known

concentrations of radionuclides. Sampling includes both plants and small game animals and, when available, larger animals that have been found dead on the NNSS (DOE/NV 2003a).

4.1.7.6 Plant and Animal Monitoring for Radioactivity

Historical atmospheric nuclear weapons testing, outfalls from underground nuclear tests, and radioactive waste disposal sites provide sources of potential radiation contamination and exposure to NNSS plants and animals. DOE Order 458.1, *Radiation Protection of the Public and the Environment*, Change 2 (dated June 6, 2011), requires, in part, that radiological activities that have the potential to impact the environment must be conducted in a manner that protects populations of aquatic animals, terrestrial plants, and terrestrial animals in local ecosystems from adverse effects due to radiation and radioactive material released from DOE operations and that when actions taken to protect humans from radiation and radioactive materials are not adequate to protect biota then evaluations must be done to demonstrate compliance. To demonstrate compliance with this requirement, DOE/NNSA monitors plants, animals, and their habitat at the NNSS to determine if the radiological dose exceeds DOE-established limits expressed in "rad" (radiation absorbed dose). Radiological dose limits for plants and animals are found in DOE Standard 1153-2002. Under that standard, dose rates equal to or less than the following are expected to have no direct, observable effect on plant or animal reproduction:

- 1 rad per day (0.01 grays per day [Gy/d]) for aquatic animals
- 1 rad per day (0.01 Gy/d) for terrestrial plants
- 0.1 rad per day (1 milligray per day) for terrestrial animals

DOE/NNSA annually samples plants and game animals to measure the potential for radionuclide transfer through the food chain and determine if NNSS biota are exposed to radiation levels harmful to their own populations. This monitoring includes sampling plants, burrowing animals, and soils at the Area 3 Radioactive Waste Management Site (RWMS) and the Area 5 RWMC as a measure of the integrity of waste disposal cells.

The goal for vegetation monitoring is to sample the most contaminated plants within the NNSS environment. These plants are generally found inside demarcated radiological areas near the "ground zero" locations of historical aboveground nuclear tests. The species selected for sampling represent the most dominant plants, such as trees, shrubs, herbs, or grasses at these sites.

The goal of sampling animals for the purpose of determining potential dose to biota is to select species that are most exposed and most sensitive to effects from radiation. In general, mammals and birds are more sensitive to radiation than fish, amphibians, or invertebrates (DOE 2002a). In addition, animals are sampled to determine potential dose to the public from ingesting their meat. For these reasons, and because no native fish or amphibians are found on the NNSS, the game animals listed in **Table 4–38** are monitored. The sampling strategy used to assess the integrity of radioactive waste containment includes sampling plants, animals, and soil excavated by ants or small mammals on top of waste covers. The animals monitored for assessing the integrity of radioactive waste containment are listed in Table 4–38.

Table 4–38 Nevada National Security Site Animals Monitored for Radionuclides

Game Animals Monitored for Dose Assessments		
Small Mammals	***Large Mammals***	***Birds***
Cottontail rabbit (*Sylvilagus audubonii*) Jackrabbit (*Lepus californicus*)	Mule deer (*Odocoileus hemionus*) Pronghorn antelope (*Antelocarpa americana*)	Mourning dove (*Zenaida macroura*) Chukar (*Alectoris chukar*) Gambel's quail (*Callipepla gambelii*)
Animals Monitored for Integrity of Radioactive Waste Containment or as Game Animal Analogs		
Kangaroo rat (*Dipodomys* sp.) Mice (*Peromyscus* sp.) Antelope ground squirrel (*Ammospermophilius leucurus*) Desert woodrat (*Neotoma lepida*)		

Source: DOE/NV 2010.

As shown in **Table 4–39**, the results of this ongoing monitoring program have consistently demonstrated that, while plants and animals that inhabit radiological sites or radioactive waste containment covers may have elevated concentrations of radionuclides in their bodies, the concentrations are well below levels considered harmful to the health of the plants or animals.

Biological Resources—American Indian Perspective

The Consolidated Group of Tribes and Organizations (CGTO) knows the Nevada National Security Site (NNSS) contains an ancient playa, surrounded by mountain ranges. The runoff from these ranges serves to maintain a healthy desert floor and environment. Animals frequent the area, and there are numerous animal trails. Animals and the places where they live play a significant part in Indian history and lifestyle. The CGTO knows Indian people have lived on these lands since Creation value all plants and animals, yet some of these occupy more cultural significance in our lives. It is widely known that many Indian people still collect and use plants and animals that are found within the NNSS region. We describe these plants, animals, and insects in this section in an effort to demonstrate their importance to our well-being and survival, and their role in maintaining ecological balance to our Holy Land.

The CGTO knows, based on previous U.S. Department of Energy (DOE)-sponsored ethnobotany studies, that there are at least 364 American Indian traditional use plants on the NNSS (see Table C-1). Plants are still used for medicine, food, basketry, tools, homes, clothing, fire, and ceremony – both social and healing. Sage is used for spiritual ceremonies, smudging[1] and medicine. Indian rice grass and wheat grass are used for breads and puddings. Joshua tree is important for hair dye, basketry, foot ware, and rope. Globe mallow had traditional medicine uses, but in recent times is also used for curing European contagious diseases.

In order to convey the American Indian meaning of these plants, a series of ethnobotany studies were conducted and the findings used to establish a set of criteria for assessing the cultural importance of each plant and of places where plant communities exist. The CGTO provided these cultural guidelines so that National Environmental Poicy Act analyses and other agency decisions could be assessed from an American Indian perspective.

The CGTO knows, based on previous DOE-sponsored ethnofauna studies, there are at least 170 Indian use animals on the NNSS (see Table C-2). All are culturally important to Indian people.

The CGTO knows if they care for the earth and its resources, the Creator will always provide for them. The NNSS area was among the tribes' places to hunt and trap a variety of animals. It is known that special leaders within each tribe would organize large hunts where many Indian people participated. The Indian people would use these animals for many purposes, including food, bones for tool making, fur for warm blankets, ceremonial purposes, and described in traditional winter stories.

Indian people refrain from eating coyote, wolves, and some birds because these animals are fundamental to stories and songs that teach us life lessons to heal, to build character, and to become better people.

The relationships between the animals, the Earth, and Indian people are represented by the respectful roles they play in the stories of our lives then and now. For example, the NNSS contains a valley where an important spiritual journey occurred. It involved Wolf (*Tavats* in Southern Paiute, *Bia esha* in Western Shoshone, *Wi gi no ki* in Owens Valley Paiute) and is considered a Creation story. Out of respect to our traditional teachings, only parts of this story are presented here. When Wolf and Coyote had a battle over who was more powerful, Coyote killed Wolf and felt glorious. Everyone asked Coyote what happened to his brother Wolf. Coyote felt extremely guilty and tried to run and hide but to no avail. Meanwhile, the Creator took Wolf and made him into a beautiful Rainbow (*Paro wa tsu wu nutuvi* in Southern Paiute, *Oh ah podo* in Western Shoshone, *Paduguna* in Owens Valley Paiute). When Coyote saw this special privilege he cried to the Creator in remorse and he too wanted to be a Rainbow. Because Coyote was bad, the Creator put Coyote as a fine, white mist at the bottom of the Rainbow's arch. This story and the spiritual trails discussed in the full version are connected to the Spring Mountains and the large sacred cave in the Pintwater Range as well as to lands now called the NNSS. These areas comprise the home of Wolf, whose spirit is still present and watches over Indian people and our Holy Land.

Stink bugs, willows, frogs, hummingbirds, and snow fleas are all important to Indian people and our respect to rain and snow. (For additional information on these plants and animals, please see text box for Hydrological Resources, Section 4.5.)

The desert bighorn sheep and the desert tortoise are both culturally sensitive animals to Indian people. Among their many special qualities, when used ceremonially, they have the ability to bring rain and reduce drought impacts.

The desert tortoise has further significance to Indian people because of its healing powers, longevity, and wisdom. It is integral to our traditional stories, well-being and perpetuation of our native culture.

See Appendix C for more details.

---

[1] *Smudging is a spiritual cleansing involving the use of smoke from certain plants during prayers and ceremonies.*

4.1.8 Air Quality and Climate

4.1.8.1 Meteorology

Overview of NNSS Climate. The NNSS is located mostly in the southwestern corner of the Great Basin Desert, with the southern third of the NNSS located in the Mojave Desert (Warner 2004). The NNSS is located in the rain shadow (lee) of the southern Sierra Nevada mountain range and has the general climatic characteristics of a mid-latitude desert area, with relatively little precipitation throughout the year and low humidity, large diurnal and seasonal temperature ranges, and intense solar radiation in the summer. The normally dry desert climate specific to the NNSS can occasionally be interrupted by the southwestern monsoon and convective thunderstorms during the summer months, as well as Eastern Pacific tropical storm remnants in the late summer and fall. The climate conditions can be further modified from time to time during strong *El Niño* cycles, which generally bring more rainfall to the area.

Significant climate differences within the NNSS stem largely from differences in elevation. The NNSS generally slopes downward from north to south (from about 7,700 to 2,700 feet). There is considerable variability in terrain due to the number of mountain ranges (which are generally oriented north–south), mesas, basins, and flats. Local topographical features play an important role in defining local wind flow effects on both diurnal and seasonal time scales. Higher elevations within the NNSS generally experience cooler temperatures and more precipitation, while generally warmer temperatures and less precipitation occur in the basins.

Figure 4–25 shows the Meteorological Data Acquisition stations that monitor meteorological conditions across the NNSS. The NNSS areas are also labeled, and some geographic areas (e.g., Pahute Mesa, Frenchman Flat) are labeled and individually shaded. The following three major NNSS complexes that have historically released radiological and nonradiological hazardous air pollutants are labeled: BEEF, the Nonproliferation Test and Evaluation Complex (NPTEC), and Test Cell C. The Amargosa Valley CEMP station is shown, as is the Desert Rock hourly upper-air and Automated Surface Observing System. Terrain gradients are also shown.

Temperature. Average maximum temperatures range from 90 to 100 °F in the summer and from 50 to 60 °F in the winter. Average minimum temperatures range from 55 to 70 °F in the summer and 20 to 35 °F in the winter. At higher elevations, which are mostly in the northern NNSS, temperatures tend to be 10 to 15 °F cooler (NOAA 2006). For more information regarding temperature trends at the NNSS, please see Appendix D, Section D.1.1.1, of this SWEIS.

Precipitation. Higher elevations, mostly in the northern NNSS, receive an average of about 13 inches of precipitation per year, while locations in the southeastern NNSS near Frenchman Flat receive an average of about 5 inches per year, the lowest average amount (SORD 2008). Precipitation falls most often during winter and early spring (during Pacific storm passage) and during mid- to late-summer (during convective thunderstorms, monsoons, and occasional tropical storm remnants) (NOAA 2006). Nevada has had statewide drought conditions for most of the last decade, with precipitation amounts far below normal. For more information regarding precipitation patterns at the NNSS, including tornado statistics and snowfall and thunderstorm trends, please see Appendix D, Section D.1.1.1.

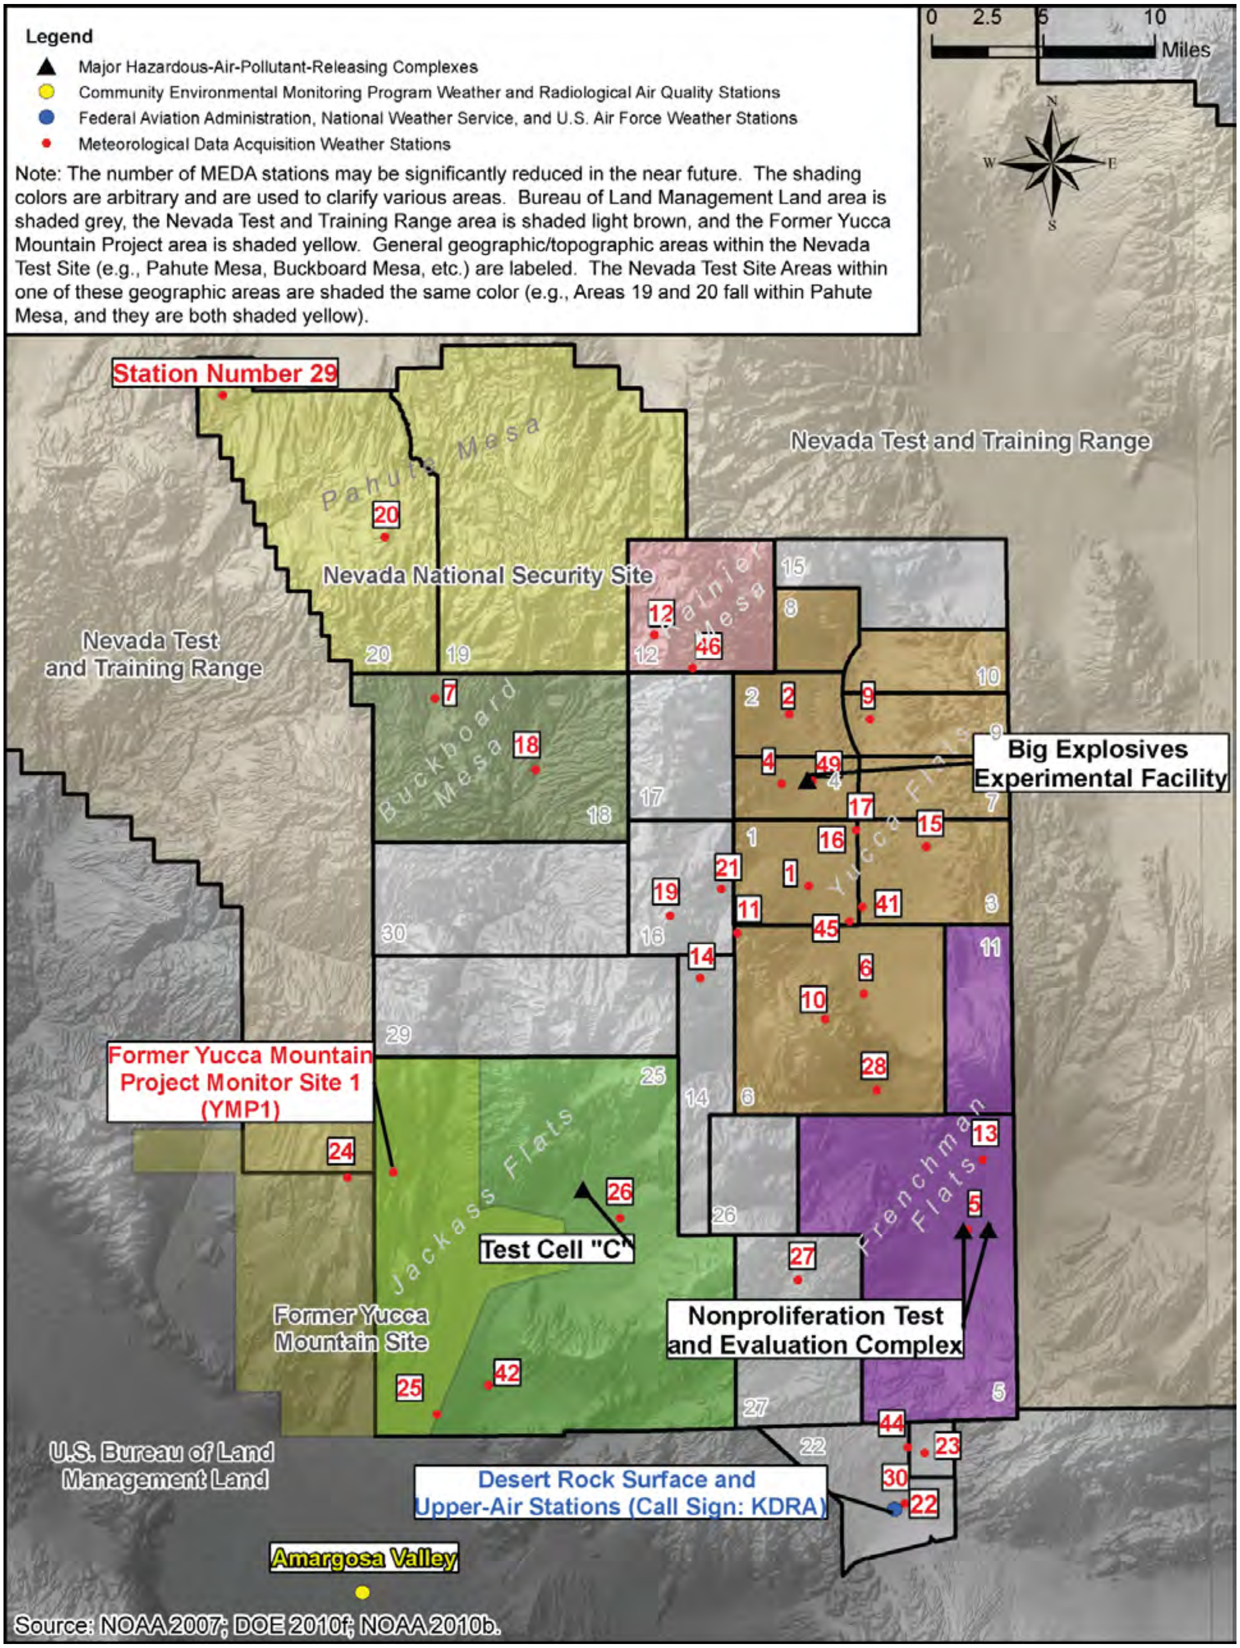

Figure 4–25 Meteorological Data Acquisition System Stations Across the Nevada National Security Site, as of 2010

Wind Flow

Wind conditions affecting the NNSS are perhaps the most complex of the site's meteorological conditions.

The surface winds show strong diurnal variations with distinct nighttime drainage winds in the basins and mountain slopes. Because the terrain tends to slope down in elevation from north to south, these nighttime drainage winds tend to be from the north. Localized terrain gradients that are not north-to-south modify this nighttime wind flow, as do rare low overcast conditions or conditions with extensive nighttime vertical mixing. **Figure 4–26** illustrates the localized wind patterns for the Meteorological Data Acquisition stations nearest the three NNSS sites that have historically, as well as recently, been permitted to release radiological and nonradiological hazardous air pollutants (i.e., BEEF, NPTEC, and Test Cell C). For more information regarding wind flow patterns at the NNSS, please see Appendix D, Section D.1.1.1.

Stability Overview

Cloud cover measurements used to estimate atmospheric stability are available from the Desert Rock site located in the southeastern corner of the NNSS. Based on data recorded from 1978 through 2004 at Desert Rock, stable conditions dominate at night, though stronger windspeeds will tend to mix in the atmosphere, leading to neutral conditions. Nighttimes tend to be more stable during the summer and fall months because of lighter winds at night, relative to the winter and spring periods. Because greater solar radiation leads to greater instability, unstable conditions dominate the daytime hours and the months with highest solar radiation (summer). These stability patterns would be slightly modified within the NNSS based primarily on windspeed differences and potentially on differences in local cloud cover and topology relative to what occurs at Desert Rock (NOAA 2006).

4.1.8.2 Ambient Air Quality

4.1.8.2.1 Region of Influence

The ROI for air quality and climate for the NNSS operations comprises southern Nye County, western Lincoln County, and northern Clark County, with prevailing downwind impacts extending into western Lincoln County. Historic data on pollutant emissions inventories and the compliance status for the State of Nevada are calculated at the county level, and these data provide a basis for determining both existing air quality in the ROI and a metric for emission comparison assessments.

4.1.8.2.2 Existing Air Quality

Current Ambient Air Quality Standards

Air quality is determined by measuring concentrations of certain pollutants in the atmosphere. EPA designates an area as "in attainment" for a particular pollutant if ambient air concentrations of that pollutant are below the National Ambient Air Quality Standards (NAAQS). Pollutants regulated under both the State of Nevada Ambient Air Quality Standards and NAAQS include the following:

- Ozone
- Carbon monoxide
- Nitrogen dioxide
- Sulfur dioxide
- Lead
- Particulate matter with an aerodynamic diameter less than or equal to 10 micrometers (PM_{10})
- Particulate matter with an aerodynamic diameter less than or equal to 2.5 micrometers ($PM_{2.5}$)

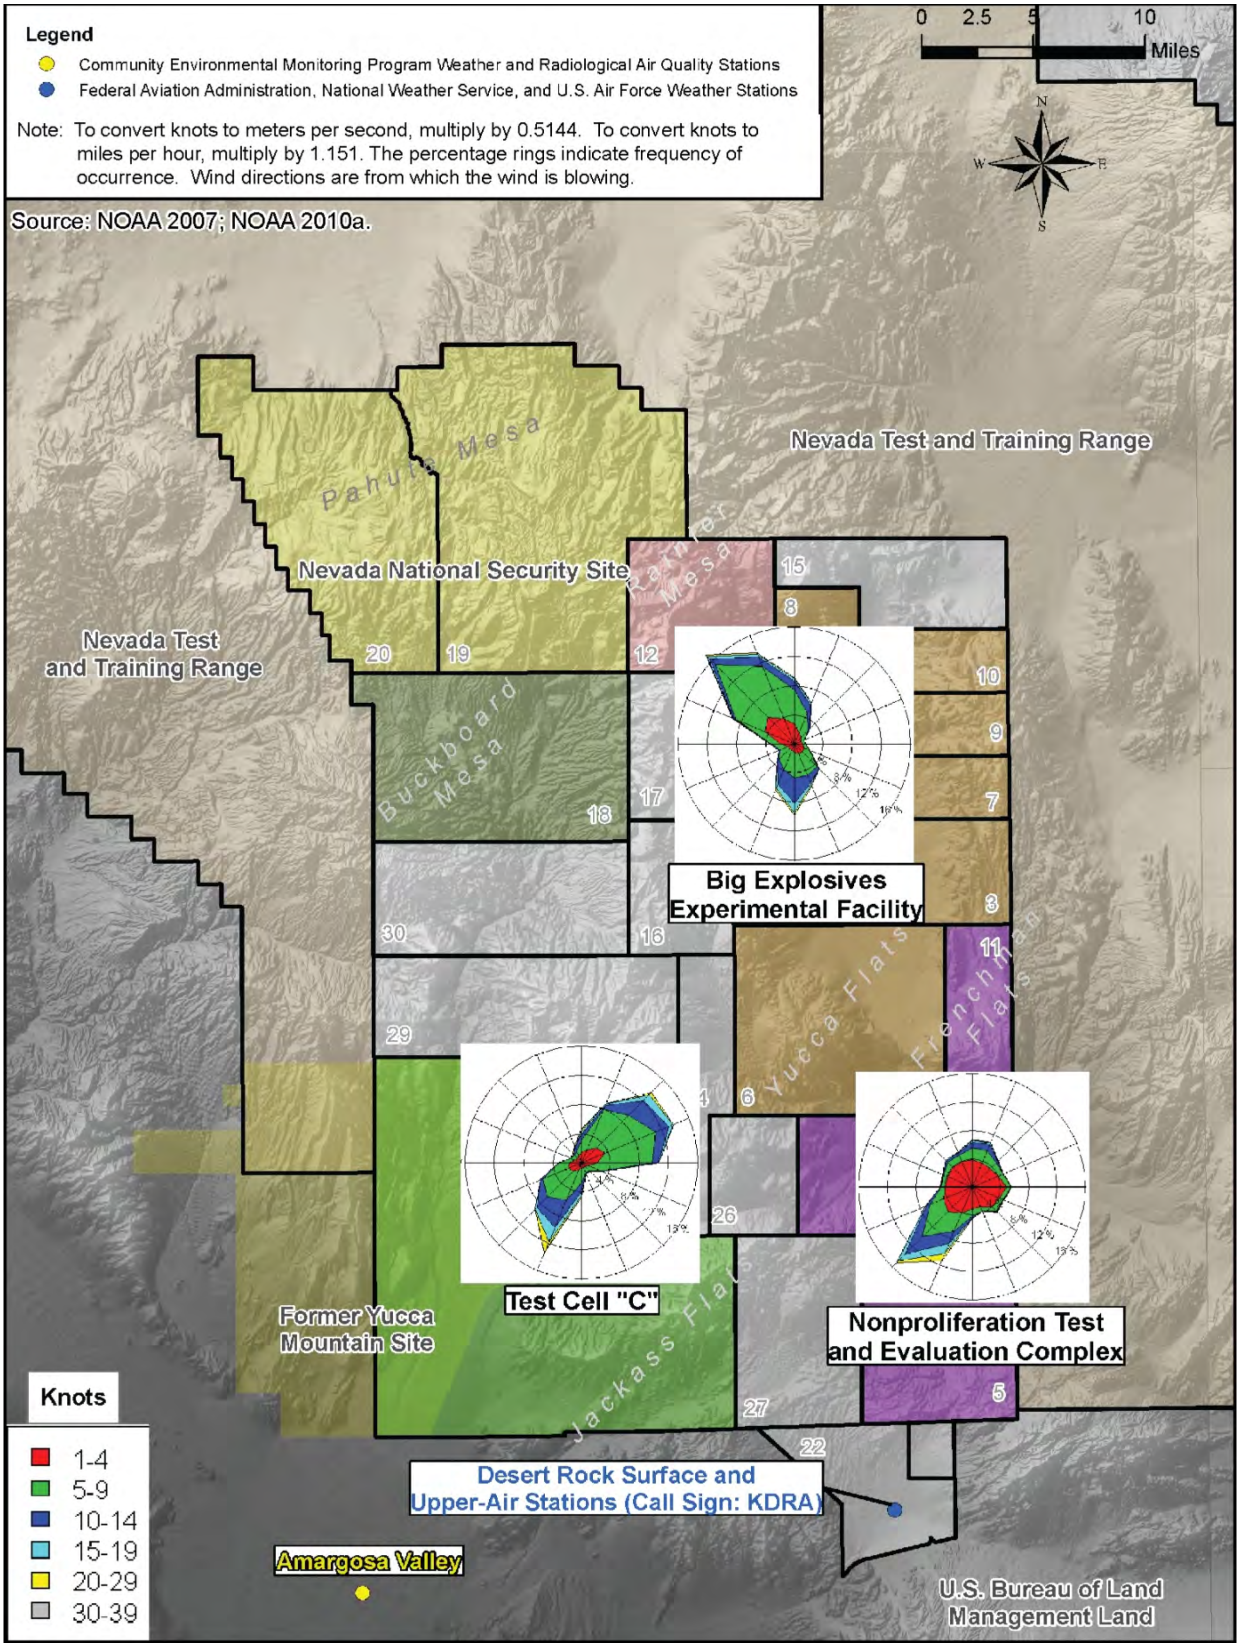

Figure 4–26 Annual Average Wind Roses for Meteorological Data Acquisition Stations near NPTEC, Test Cell C, and BEEF, 2004–2008

Collectively, these NAAQS pollutants are referred to as "criteria pollutants." **Table 4–40** lists NAAQS for both the primary public health standard and the secondary public welfare standard, which includes protection against decreased visibility and damage to animals, crops, vegetation, and buildings. Table 4–40 also lists the State of Nevada Ambient Air Quality Standards.

Table 4–40 State of Nevada and National Ambient Air Quality Standards

Air Quality Status. The NNSS is within Nevada Intrastate Air Quality Region 147. Nye County contains all of the NNSS, but has insufficient available data to determine the attainment status. Thus, it is designated as unclassified/attainment because EPA treats an unclassified area as if it is in attainment for regulatory purposes.

As of early 2010, the closest nonattainment areas to the NNSS are Inyo County, California (about 65 miles from the western border of the NNSS), and the Las Vegas Valley Area nonattainment area, located in Clark County (the closest distance is about 25 miles from the southeastern corner of the NNSS). Inyo County is in serious[1] nonattainment for PM_{10}, and the Las Vegas Valley Area of Clark County is in nonattainment for 8-hour ozone,[2] and serious nonattainment for both 8-hour carbon monoxide standards[3] and 24-hour PM_{10}[4] (EPA 2010c).

Prevention of Significant Deterioration (PSD) is a regulation incorporated into the Clean Air Act (CAA) that limits increases of certain pollutants in clean air areas (attainment areas) to certain increments even though ambient air quality standards are being met. CAA has three classes of areas with different increments. The smallest increments allowed are Class I areas, which are areas of special value (natural, scenic, recreational, or historic). Any degradation of existing air quality in these areas should be

[1] *EPA designates areas that do not obtain the NAAQS with respect to a particular air pollutant as nonattainment. Within that designation, classification categories have been established in the Clean Air Act based on the severity of the air pollution problem. Ozone has the broadest number of classification categories, including extreme, severe, serious, moderate, and marginal.*

[2] *Classification for 8-hour ozone under Subpart 2 as marginal with a nonattainment area that includes those portions of Clark County that lie in Hydrographic Areas 164A, 164B, 165, 166, 167, 212, 213, 214, 216, 217, and 218, but excludes the Moapa River Indian Reservation and the Fort Mojave Indian Reservation.*

[3] *Still designated as serious nonattainment for carbon monoxide, but has not had any violations of the carbon monoxide NAAQS since 1999. Clark County Department of Air Quality and Environmental Management submitted a request to EPA in September 2008 for a redesignation to attainment for carbon monoxide. The nonattainment area covers Hydrographic Area 212.*

[4] *Still designated as serious nonattainment for PM_{10}, but has not had any violations of the 24-hour or annual PM_{10} NAAQS since 2004. The nonattainment area covers Hydrographic Area 212.*

minimized. The closest PSD Class I areas to the NNSS are Grand Canyon National Park (about 130 miles to the southeast) and Sequoia National Park (about 105 miles to the west). The NNSS has no sources of pollution large enough to be subject to PSD requirements.

Calculations of Emissions on and near the NNSS

Table 4–41 shows the 2008 estimated air emissions for the criteria pollutants and hazardous air pollutants associated with various NNSS activities. PM_{10} and $PM_{2.5}$ emissions from diesel-fueled vehicles are included in the total PM_{10} and $PM_{2.5}$ emissions. Actions on efforts to mitigate diesel emissions are discussed in Chapter 7, Section 7.8. See Appendix D, Section D.1.1.2.1, for more information on how these emissions were determined and further partitioning by source type and vehicle type for the mobile sources.

Measurements of Ambient Air Concentrations on and near the NNSS

There are no regularly operating ambient air quality monitors for criteria pollutants and hazardous air pollutants within the NNSS. The most comprehensive source of representative data on ambient concentrations of criteria pollutants and hazardous air pollutants for the area surrounding the NNSS is a special study conducted in the southwest portion of the NNSS from October 1991 through September 1995 (see **Figure 4–27** for the locations of the monitors used in the study). During this period, the YMP1 station monitored carbon monoxide, nitrogen dioxide, PM_{10}, ozone, and sulfur dioxide. The YMP1 station was about 1 mile inside the western NNSS border in northwestern Area 25, and it is the only location on the NNSS where criteria pollutants other than PM_{10} have been measured for an extended period of time. Three additional sites monitored PM_{10} (DOE 1999a): YMP5 (about 6 miles southeast of YMP1 in Area 25, from April 1989 until 2002), YMP6 (about 4 miles northeast of YMP1 in extreme northwestern Area 25, from October 1992 until September 1999), and YMP9 (about 12 miles south-southeast of YMP1 in southwestern Area 25, from October 1992 until 2008). An earlier limited 1-month (August 15 – September 15, 1990) air quality monitoring study was done on the NNSS in Areas 6, 12, and 23 for carbon monoxide, sulfur dioxide, and PM_{10}; however, these results are not considered representative of today's ambient air quality concentrations, as overall activity levels at the NNSS have been substantially reduced since the 1992 nuclear testing moratorium. However, the monitored values were all well below the NAAQS and state ambient air quality standards.

The 1991 through 1995 ambient concentrations measured at the YMP1 station are conservative estimates of current concentrations at the NNSS for two reasons. First, the measured PM_{10} ambient concentrations among the four YMP monitors from 1989 through 2005 show a slight downward trend (see **Table 4–42**), and the NNSS onsite stationary emissions of criteria pollutants (see Appendix D, Section D.1.1.2) also trended downward from 1998 through 2008 (see Table 4–41). Second, the principal source of air pollutants is from population activity (vehicle trips and construction) and can be used as a surrogate for increases in PM emissions in the absence of new industrial activity. While Nye County's population increased by about 80 percent between 1990 and 2000, most of that growth occurred at the extreme southern tip of the county in the city of Pahrump, which is about 25 miles south-southeast of the extreme southern tip of the NNSS. Furthermore, the population directly bordering the Yucca Mountain site to its southwest (Amargosa Valley) grew by only about 16 percent, and the two counties in the prevailing upwind direction of the NNSS (Esmeralda County, Nevada, and Inyo County, California) had population decreases of up to almost 30 percent (USCB 2008b). Industrial activity has not changed over this period; thus, it is estimated that the criteria pollutant emissions near the NNSS have in general only decreased since the early 1990s.

Ozone [c]	1 hour [a]	0.12	**0.096**	0.093	0.081	0.083
	8 hours [d]	0.075	–	–	–	–
Sulfur dioxide	3 hours [a]	0.5	**0.002**	**0.002**	**0.002**	**0.002**
	24 hours [a]	0.14	**0.002**	**0.002**	**0.002**	**0.002**
	Annual [b]	0.03	**0.002**	**0.002**	**0.002**	**0.002**

NAAQS = National Ambient Air Quality Standards.
[a] Not to be exceeded more than once per year.
[b] Annual NAAQS are defined as a calendar year.
[c] The 1-hour Federal ozone standard of 0.12 parts per million, in place during the listed years, was phased out in 2005 and replaced with an 8-hour Federal ozone standard of 0.075 parts per million. The State of Nevada still retains the 1-hour ozone standard of 0.12 parts per million.
[d] The 3-year average of the fourth-highest daily maximum 8-hour average ozone concentrations measured at each monitoring station within an area over each year must not exceed this standard.
Note: The highest measured concentration in each row is shown in bold font.

As shown in Tables 4–42 and **4–43**, and further discussed in Appendix D, Section D.1.1.2, the Yucca Mountain site has been well within the attainment status of the applicable ambient air quality standards since at least the early 1990s. Given that the 1991 through 1995 ambient concentration measurements from the YMP1 station are still likely representative of the current concentrations on the NNSS as described above, it remains very likely that the ambient air quality on the NNSS is well within all applicable ambient air quality standards.

4.1.8.3 Radiological Air Quality

National Emission Standards for Hazardous Air Pollutants (NESHAPs) are established under Title I of CAA to limit ambient levels of some hazardous air pollutants. The radionuclide inhalation NESHAP for Federal facilities is set at the emissions total (cumulative across all radionuclides) that would cause a member of the public to receive an effective dose equivalent of 10 millirem in a year (DOE/NV 2009d). To put the dose of 10 millirem per year in perspective: a person would receive a dose of about 3 millirem from a single 5-hour jet flight, a dose of about 8 millirem from a single chest x-ray, and a dose of about 200 millirem per year from natural radon (DOE/NV 2009d). The average natural background radiation exposure, excluding that from radon, for persons residing in select U.S. cities is provided in **Table 4–44**.

Table 4–43 Summary of PM_{10} Concentrations, 1989 through 2005, for Four Monitoring Stations in Area 25

Monitoring Station	Measuring Time Increment	Ambient Air Concentration (micrograms per cubic meter)																	
		Current (2009) NAAQS	1989	1990	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003	2004	2005

Table 4–45 indicates the NESHAPs concentration levels for environmental compliance for isotopes of americium, cesium, hydrogen, and plutonium. Because analytical methods cannot readily distinguish between plutonium-239 and plutonium-240, the NESHAPs concentration level for plutonium-239 is used for both isotopes. Uranium is not shown because any uranium detected on the NNSS in recent years has been determined to be naturally occurring rather than enriched or depleted (DOE/NV 2009d). Note, however, that 0.06 curies of depleted uranium were estimated to have been released in 2008 from activities at BEEF, in Area 4 (DOE/NV 2009d). A curie is a common measurement of radioactivity and is defined as 3.7×10^{10} disintegrations per second, which is the approximate decay rate of 1 gram of radium (radium-226).

Table 4–45 The Concentration Levels for Five Radionuclides Corresponding to the NESHAPs Effective Dose Equivalent of 10 Millirem per Year in One Year

Radionuclide	*NESHAPs Annual Average Concentration Levels for Environmental Compliance ($\times 10^{-15}$ micrograms per milliliter)*
Americium-241	1.9
Cesium-137	19
Hydrogen-3 (Tritium)	1,500,000
Plutonium-238	2.1
Plutonium-239	2

NESHAPs = National Emission Standards for Hazardous Air Pollutants.
Source: DOE/NV 2009d.

To demonstrate that total radioactivity is in compliance with NESHAPs, the following steps are performed: (1) divide the concentration level of each detected manmade radionuclide by its NESHAP concentration level (concentration ÷ NESHAP concentration level); (2) sum those fractions for all radionuclides; and (3) confirm that the sum is less than 1.0 at each monitoring station used for monitoring NESHAPs compliance. The NNSS has been in compliance with NESHAPs since the *1996 NTS EIS* (DOE 1996c).

The locations of the ambient radiological monitors on and surrounding the NNSS are discussed in Section 4.1.8.3.1. The locations of potential radiation emissions on the NNSS and the types of activities that might produce them are discussed in Section 4.1.8.3.2. The recent radiation concentrations and exposure levels are discussed in Section 4.1.8.3.3.

4.1.8.3.1 Ambient Radiological Monitoring on and near the Nevada National Security Site

On the NNSS, 6 of the 16 sites established by DOE/NNSA that monitor ambient tritium levels are considered "critical receptors." These "critical receptors" are approved to monitor levels of various radionuclides for NESHAPs compliance. Most of these 16 ambient monitors are placed at or near locations of historical nuclear testing or current radiological operations (DOE/NV 2011). The locations of the 16 tritium monitors, with notations for the 6 that are critical receptors, are shown in **Figure 4–28**. The monitoring data from the 6 "critical receptors" demonstrate that the NNSS has been in compliance with the NESHAPs since the *1996 NTS EIS*. Further details on the NNSS ambient radiological monitoring can be found in Appendix D, Sections D.1.1.3.1 and D.1.1.3.

The Desert Research Institute of the Nevada System of Higher Education runs CEMP, which constitutes an offsite non-regulatory network of environmental monitors across southern Nevada, southeastern California, and southwestern Utah. CEMP is a public information and outreach program that monitors for radionuclides that might be released from the NNSS. As of 2008, there were 29 CEMP monitors; the 22 monitors near the Nevada Test and Training Range and Las Vegas area are shown in **Figure 4–29**. Since CEMP was upgraded in 1999 (DOE/DRI 2009), the CEMP monitors have not detected radiation that can be definitively attributed to NNSS activities, and the monitored radiation levels have been well within the background levels observed in other parts of the country (DOE/NV 2011). More details about the radiation detected at CEMP locations are provided in Appendix D, Sections D.1.1.3.1 and D.1.1.3.3.

4.1.8.3.2 Sources of Radiation on the Nevada National Security Site

Between 1951 and 1992, 100 atmospheric and 828 underground nuclear tests were conducted on the NNSS (DOE/NV 2011). Nuclear testing ended in 1992, and since then the NNSS radiation monitoring has focused on detecting airborne radionuclides from historically contaminated soils. Due to occasional high winds, some contaminated soil becomes airborne. Results from the air samplers in these areas indicate that americium-241 and plutonium-230+240 are routinely detected, but only in concentrations slightly above the minimum detectable concentrations. The total emissions (in curies) produced each year from all known legacy sites on the NNSS are estimated with a mathematical resuspension model. For 2008, total annual emissions from legacy sites were estimated as follows: americium-241 – 0.047 curies, plutonium-238 – 0.050 curies, and plutonium-239+240 – 0.29 curies (DOE 2009d). The methods used to estimate all NNSS radiological emissions (both point sources and fugitive dust from the legacy sites) include the use of annual field and water monitoring data, historical soil inventory data, and accepted soil resuspension and air transport models (DOE 2009d). Additional detail on radiological emissions and how they are determined is in Appendix D, Section D.1.1.2.2, Radiological Air Quality. In 1990, most areas within the NNSS had measureable amounts of americium-241 and plutonium-238, -239, and -240 in the first 2 inches of soil (McArthur 1991). Over time, the measurable airborne quantities of radionuclides have decreased as a result of radioactive decay, radionuclide immobilization in soil, and decreases in NNSS activities that would resuspend radionuclides from the soil to the air. According to a 1994 aerial survey, the largest areas of soil contamination correspond to the places where the bulk of nuclear testing occurred—especially the northeastern quarter of the NNSS (on Yucca Flat; locations north and east of Areas 1 and 17), but with notable locations in eastern Frenchman Flat (in Area 5), in northwestern Pahute Mesa (in Area 20), in central Buckboard Mesa (in Area 18), and near Dome Mountain (in Area 30). Evaporation and evapotranspiration can also resuspend tritium from contaminated soil, plants, and ponds such as the ones in Area 12 that receive tritium-contaminated water from East Tunnel. For more information regarding the sources of radiation at the NNSS, please see Section D.1.1.3.2.

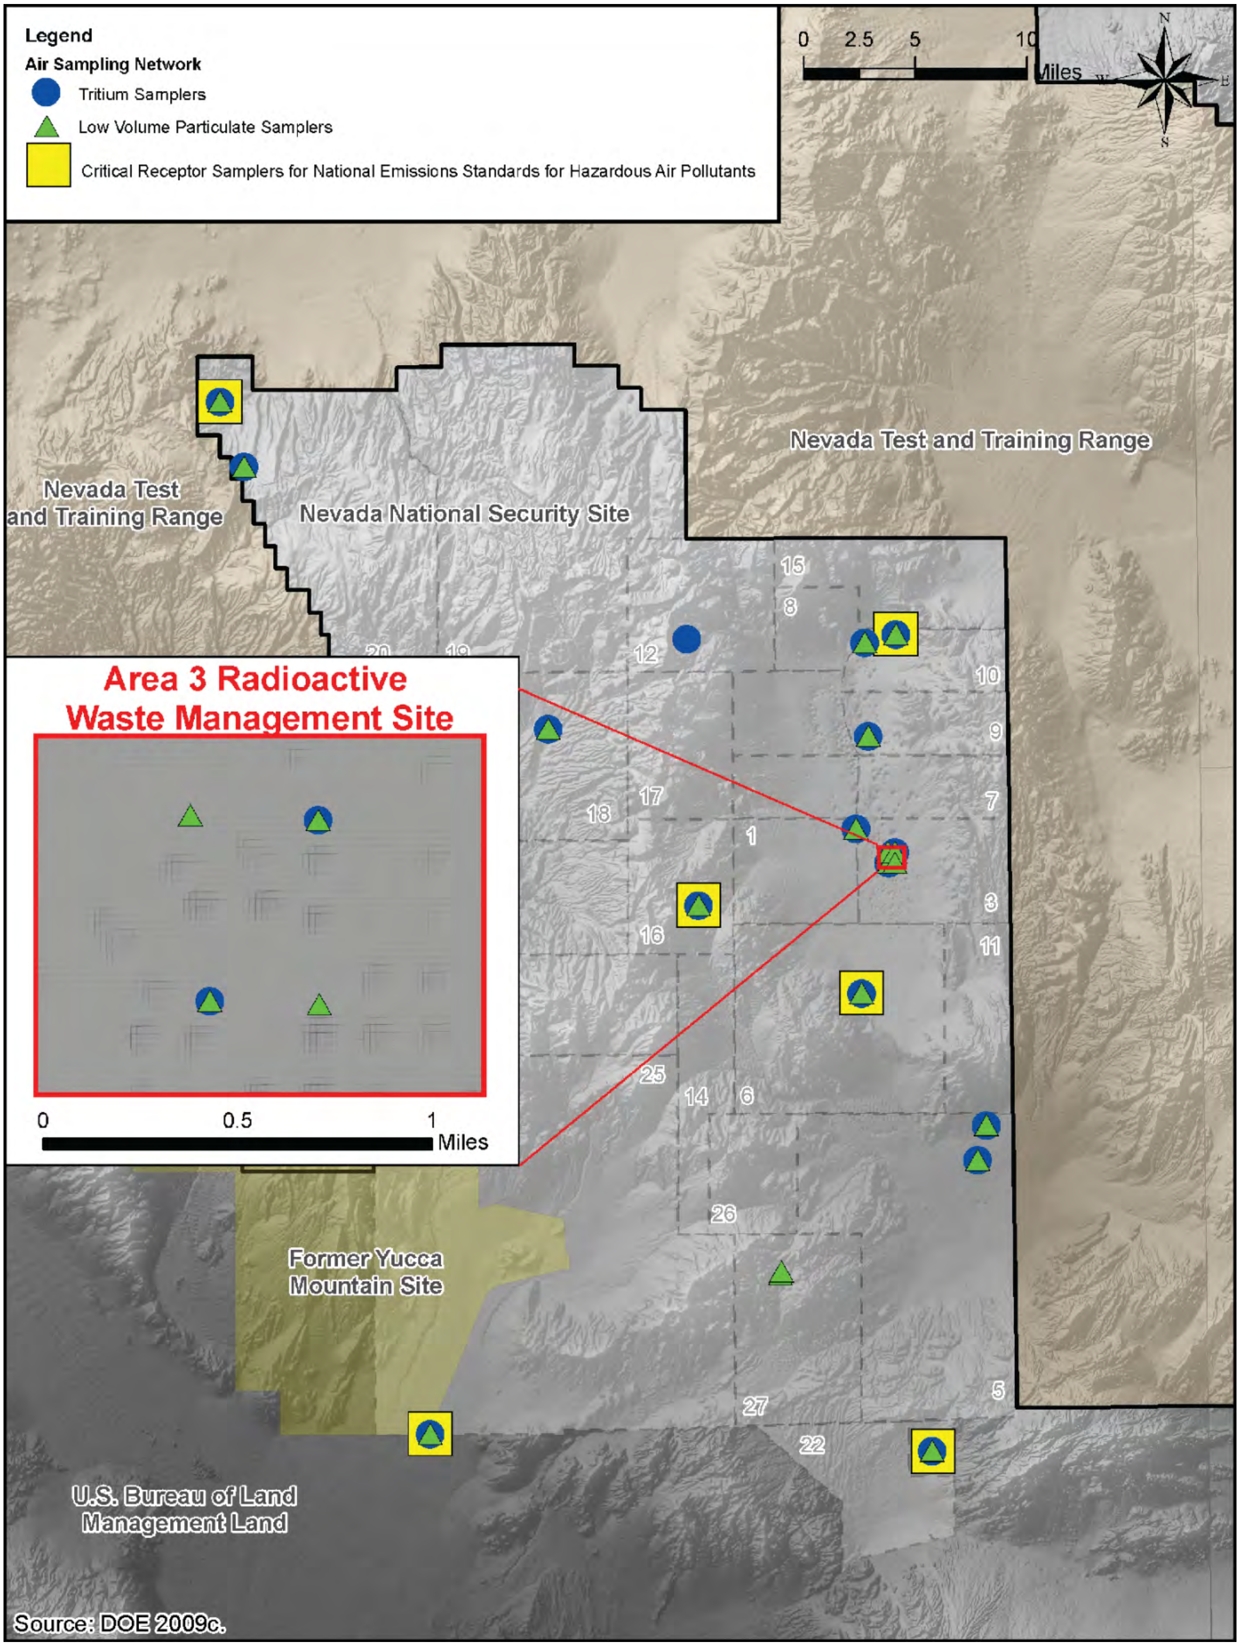

Figure 4–28 Ambient Radiological Monitoring and Critical Receptor Sampling Locations for Air Particulates and Tritium

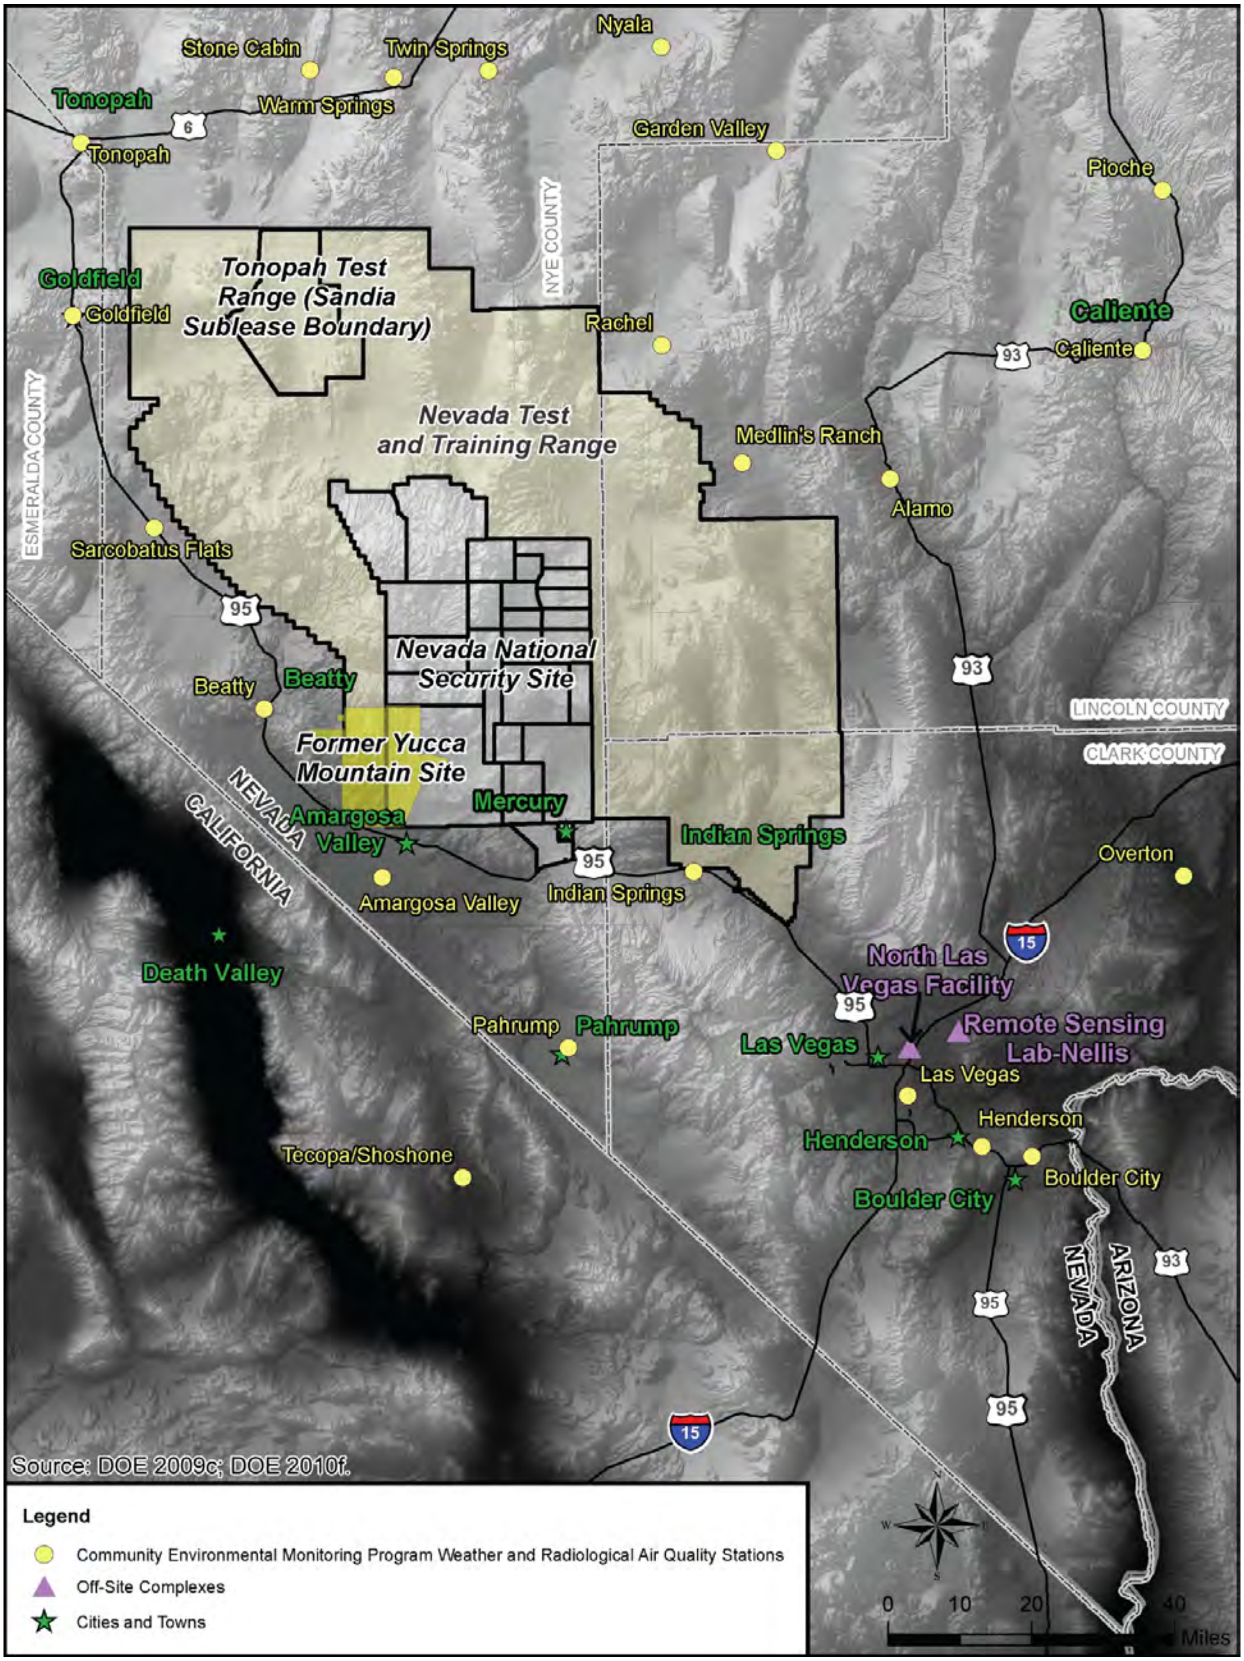

Figure 4–29 Community Environmental Monitoring Program Air Surveillance Network Locations near the Nevada Test and Training Range and Las Vegas, 2008

4.1.8.3.3 Radiation Levels on and near the Nevada National Security Site

The NNSS has been in compliance with the NESHAPs since the *1996 NTS EIS* (DOE 1996c). The maximum annual average radiation at critical receptor locations was from tritium over the most recent years, 2002 through 2008, with a measured concentration of 434×10^{-12} microcuries per milliliter, which is 29 percent of the NESHAPs concentration level. The radiological monitoring network overall indicates that levels of americium-241; plutonium-238, -239, and -240; cesium-137; and tritium on the NNSS have been well below the NESHAPs concentration levels since the *1996 NTS EIS*. In addition, offsite CEMP stations continue to show radiation levels that are well within natural background radiation levels (DOE/NV 2011). For more information regarding the radiation levels on and near the NNSS, please see Appendix D, Section D.1.1.2.2.3.

4.1.8.4 Climate Change

This section describes the affected environment in terms of current and anticipated trends in greenhouse gas emissions and climate. The effects of emissions on the climate involve very complex processes and interact with natural cycles, complicating the measurement and detection of changes. Recent advances in the state of the science, however, are contributing to an increasing body of evidence that it is very likely (greater than 90 percent probability) that anthropogenic greenhouse gas emissions affect climate in detectable and quantifiable ways (IPCC 2007b).

This section begins with a discussion of emissions and then turns to climate. Both discussions start with a description of conditions in the United States, followed by a description of conditions on the NNSS.

4.1.8.4.1 Greenhouse Gas Emissions

Greenhouse gas emissions in the United States in 2007[5] were estimated at 7,150.1 million carbon-dioxide-equivalent[6] metric tons (EPA 2009a), which is about 18 percent of total global emissions[7] (WRI 2009). Annual national emissions, which have increased 17 percent since 1990 and typically increase each year, are heavily influenced by "general economic conditions, energy prices, weather, and the availability of non-fossil alternatives" (EPA 2009a). Carbon dioxide is by far the primary greenhouse gas emitted in the United States, representing almost 85.4 percent of all U.S. greenhouse gas emissions in 2007 (EPA 2009a). The other gases include methane, nitrous oxide, and a variety of fluorinated gases, including hydrofluorocarbons, perfluorinated carbons, and sulfur hexafluoride. The fluorinated gases are collectively referred to as "high global warming potential" (GWP) gases. Methane accounts for 8.2 percent of the remaining greenhouse gases on a GWP-weighted basis, followed by nitrous oxide (4.4 percent) and high-GWP gases (2.1 percent) (EPA 2009a).

Greenhouse gases are emitted from a wide variety of sectors, including energy, industrial processes, waste, agriculture, and forestry. Most U.S. greenhouse gas emissions are from the energy sector, largely due to carbon dioxide emissions from the combustion of fossil fuels, which alone account for 80 percent of total U.S. greenhouse gas emissions (EPA 2009a). Fossil fuel combustion contributes 97 percent of national total carbon dioxide emissions. As stated, carbon dioxide emissions from fossil fuel combustion are dominated by electricity generation, which contributes 42 percent of the total carbon dioxide emissions; the transportation sector contributes 33 percent; the industrial sector, 15 percent; the residential sector, 6 percent; and the commercial sector, 4 percent (EPA 2009a).

---

[5] *Most recent year for which an official EPA estimate is available.*
[6] *Each greenhouse gas has a different level of radiative forcing—that is, the ability to trap heat. To compare their relative contributions, gases are converted to a carbon-dioxide equivalent using their unique global warming potential.*
[7] *Based on 2005 data and excludes carbon sinks from forestry and agriculture.*

4.1.8.4.2 Greenhouse Gas Emissions Due to Nevada National Security Site-Related Activities

Table 4–46 provides greenhouse gas emissions due to NNSS-related activities for 2008. The greenhouse gas emissions are presented in carbon-dioxide-equivalent form and are partitioned by various mobile and stationary source types. These emissions were derived from fuel use, vehicle activity, and power consumption data. The greenhouse gas emissions were calculated using the EPA Climate Leaders Simplified Greenhouse Gas Emissions Calculator (EPA 2010b). These emissions were compared with a reference amount of 25,000 metric tons (27,558 tons), which is an indicator for when a quantitative assessment may be warranted (CEQ 2010).

Power generation (electrical energy generation) is by far the largest single source of greenhouse gas emissions related to NNSS activities. Overall, NNSS-related activities created about 50,478 carbon-dioxide-equivalent tons of greenhouse gas emissions in 2008, about 83 percent over the reference level.

Table 4–46 Carbon-Dioxide-Equivalent Emissions of Greenhouse Gases by Activities Related to the Nevada National Security Site in 2008

Source Type	*Carbon-Dioxide-Equivalent Emissions (tons per year)*	*Fraction of Reference Point of 27,558 Tons Per Year* [a]
STATIONARY SOURCES		
Power generation	28,517	1.03
Natural gas heating	0	0
Other stationary sources, except air conditioning/refrigeration and natural gas heating	747	0.03
Sulfur hexafluoride from refrigeration/air conditioning	690	0.03
Hydrofluorocarbons from refrigeration/air conditioning	326	0.01
All Stationary Sources	*30,280*	*1.10*
MOBILE SOURCES		
Onsite government vehicles	4,920	0.18
Commuting	13,201	0.48
Hazardous waste transport (nongovernment)	837	0.03
Commercial vendors	1,240	0.05
All Mobile Sources	*20,198*	*0.73*
Total	***50,478***	***1.83***

Note: Fractional amount may not match the shown emission rate due to rounding.

4.1.8.4.3 Current Changes in Climate

This section describes observed historical and current climate change impacts on the United States and, in particular, on the desert southwest. Much of the material that follows is drawn from the following sources, including the citations therein: *Technical Support Document for Endangerment and Cause or Contribute Findings for Greenhouse Gases under Section 202(a) of the Clean Air Act* (EPA 2009b) and the *Scientific Assessment of the Effects of Global Change on the United States* (NSTC 2008).

The past decade has been the warmest in more than a century of direct observations; average temperatures for the contiguous United States have risen at a rate near 0.58 °F per decade in the past few decades. In the southwest, the average annual temperature has increased by 1.4 °F over the 1960 to 1978 baseline (Karl et al. 2009). The annual average temperature across the region is projected to rise approximately 4 to 10 °F over the 1960 to 1978 baseline by the end of the century, depending upon how much greenhouse gas emissions increase (Karl et al. 2009).

Higher temperatures cause higher rates of evaporation and plant transpiration, meaning that more water vapor is available in the atmosphere for precipitation events. Depending on atmospheric conditions, increased evaporation means that some areas experience increases in precipitation events, while other areas are left more susceptible to droughts. For the southwest, a severe drought prevailed from 1999 to 2008 (NSTC 2008). Most climate models project a decrease in precipitation for many areas in the southwestern United States throughout the twenty-first century (EPA 2009b; NSTC 2008).

Melting snow and ice, increased evaporation, and changes in precipitation patterns all affect surface water. Stream flow decreased about 2 percent per decade over the past century in the central Rocky Mountain region (NSTC 2008). Annual peak stream flow (dominated by snowmelt) in western mountains occurs at least a week earlier than in the middle of the twentieth century. Changes in temperature and precipitation also affect frozen surface water. Spring and summer snow cover has decreased in the west. In mountainous regions of the western United States, the April snow water equivalent has declined 15 to 30 percent since 1950, particularly at lower elevations and primarily due to warming (NSTC 2008). This decrease in stream flow will likely reduce the groundwater recharge throughout the southwestern United States (NSTC 2008).

Air Quality and Climate—American Indian Perspective

CGTO The Consolidated Group of Tribes and Organizations (CGTO) knows that the air is alive. The Creator puts life into the air, which is shared by all living things. When a child is born, he pulls in the air to begin its life. The mother watches carefully to make sure that the first breath is natural and that there is no obstruction in the throat. It is believed if the day of birth is a windy day, it is a good day and the child will have a good life.

According to tribal elders' perspectives from Area 5 Nevada National Security Site activities, "*…You can listen to the wind. The wind talks to you. Things happen in nature. Our people had weather watchers, who are kinds of people who will know when crops and things should be done. They watch the different elements in nature and pray to ask the winds to come and talk about these things. Sometimes you ask the north wind to come down and cool the weather. The north wind is asked to blow away the footsteps of the people who have passed on to the afterlife. That kind of wind helps people, it is positive. The wind also brings you songs and messages. Sometimes the messages are about healing people, a sign that the sickness is gone now from the person, or that it is coming to get that sickness to take it away, or it is coming to bring you the strength that you will need to deal with the illness.*"

See Appendix C for more details.

4.1.9 Visual Resources

Identifying an area's visual resources and conditions involves three steps: (1) objective identification of the visual features (visual resources) of the landscape; (2) assessment of the character and quality of those resources relative to overall regional visual character; and (3) determination of the importance to people, or *sensitivity*, of views of visual resources in the landscape.

The aesthetic value of an area is a measure of its visual character and quality, combined with the viewer response to the area (FHA 1988). Scenic quality can best be described as the overall impression that an individual viewer retains after driving through, walking through, or flying over an area (BLM 1980). Viewer response is a combination of viewer exposure and viewer sensitivity. Viewer exposure is a function of the number of viewers, number of views seen, distance of the viewers from key observation points to what is being viewed, and viewing duration. Viewer sensitivity relates to the extent of the public's concern for a particular viewshed. These terms and criteria are described in greater detail in the following sections.

Visual Character. Natural and artificial landscape features contribute to the visual character of an area or view. Visual character is influenced by geologic, hydrologic, botanical, wildlife, recreational, and urban features. Urban features include those associated with landscape settlements and development, including roads, utilities, structures, earthworks, and the results of other human activities. The perception of visual character can vary significantly seasonally, even hourly, as weather, light, shadow, and elements that compose the viewshed change. The basic components used to describe visual character for most visual assessments are the elements of form, line, color, and texture of the landscape features (BLM 1980; USFS 1995; FHA 1988). The appearance of the landscape is described in terms of the dominance of each of these components.

Scenic Quality. Scenic quality was evaluated using the scenic quality classes established in the *1996 NTS EIS* and includes the following:

- Class A – The visual environment is made up of outstanding natural and manmade physical features.
- Class B – The visual environment is made up of a combination of outstanding natural and manmade physical features and those that are common to the region.
- Class C – The visual environment is made up of natural and manmade physical features that are common to the region.

Visual Exposure and Sensitivity. The measure of the quality of a view must be tempered by the overall sensitivity of the viewer. Viewer sensitivity or concern is based on the visibility of resources in the landscape, proximity of viewers to the visual resource, elevation of viewers relative to the visual resource, frequency and duration of views, number of viewers, and type and expectations of individuals and viewer groups.

Public roadways, mostly highways, provide the only public vantage points of the NNSS. Commuters and nonrecreational travelers have generally fleeting views and tend to focus on commute traffic, not on surrounding scenery; therefore, they are generally considered to have low visual sensitivity. Highways pass by the NNSS in areas that are largely undeveloped, and views of the sites are fleeting at standard highway speeds. Because roadways provide the majority of views and the viewer sensitivity of roadway users is generally low, the number of viewers that pass by and have views of the NNSS and other DOE/NNSA-managed offsite locations was used to determine the level of sensitivity and to analyze effects on visual resources (see Chapter 5, Section 5.1.9). The 2008 *Annual Traffic Report* (NDOT 2008c) was used to determine traffic volumes on public roadways with views of the NNSS and other DOE/NNSA-managed offsite locations. **Figure 4–30** shows the sensitivity levels assigned to roadways near the NNSS and other DOE/NNSA-managed offsite locations based on traffic volumes; these are as follows:

- High Visual Sensitivity – 3,000 or more average annual daily viewers
- Moderate Visual Sensitivity – 1,000 to 2,999 average annual daily viewers
- Low Visual Sensitivity – 0 to 999 average annual daily viewers

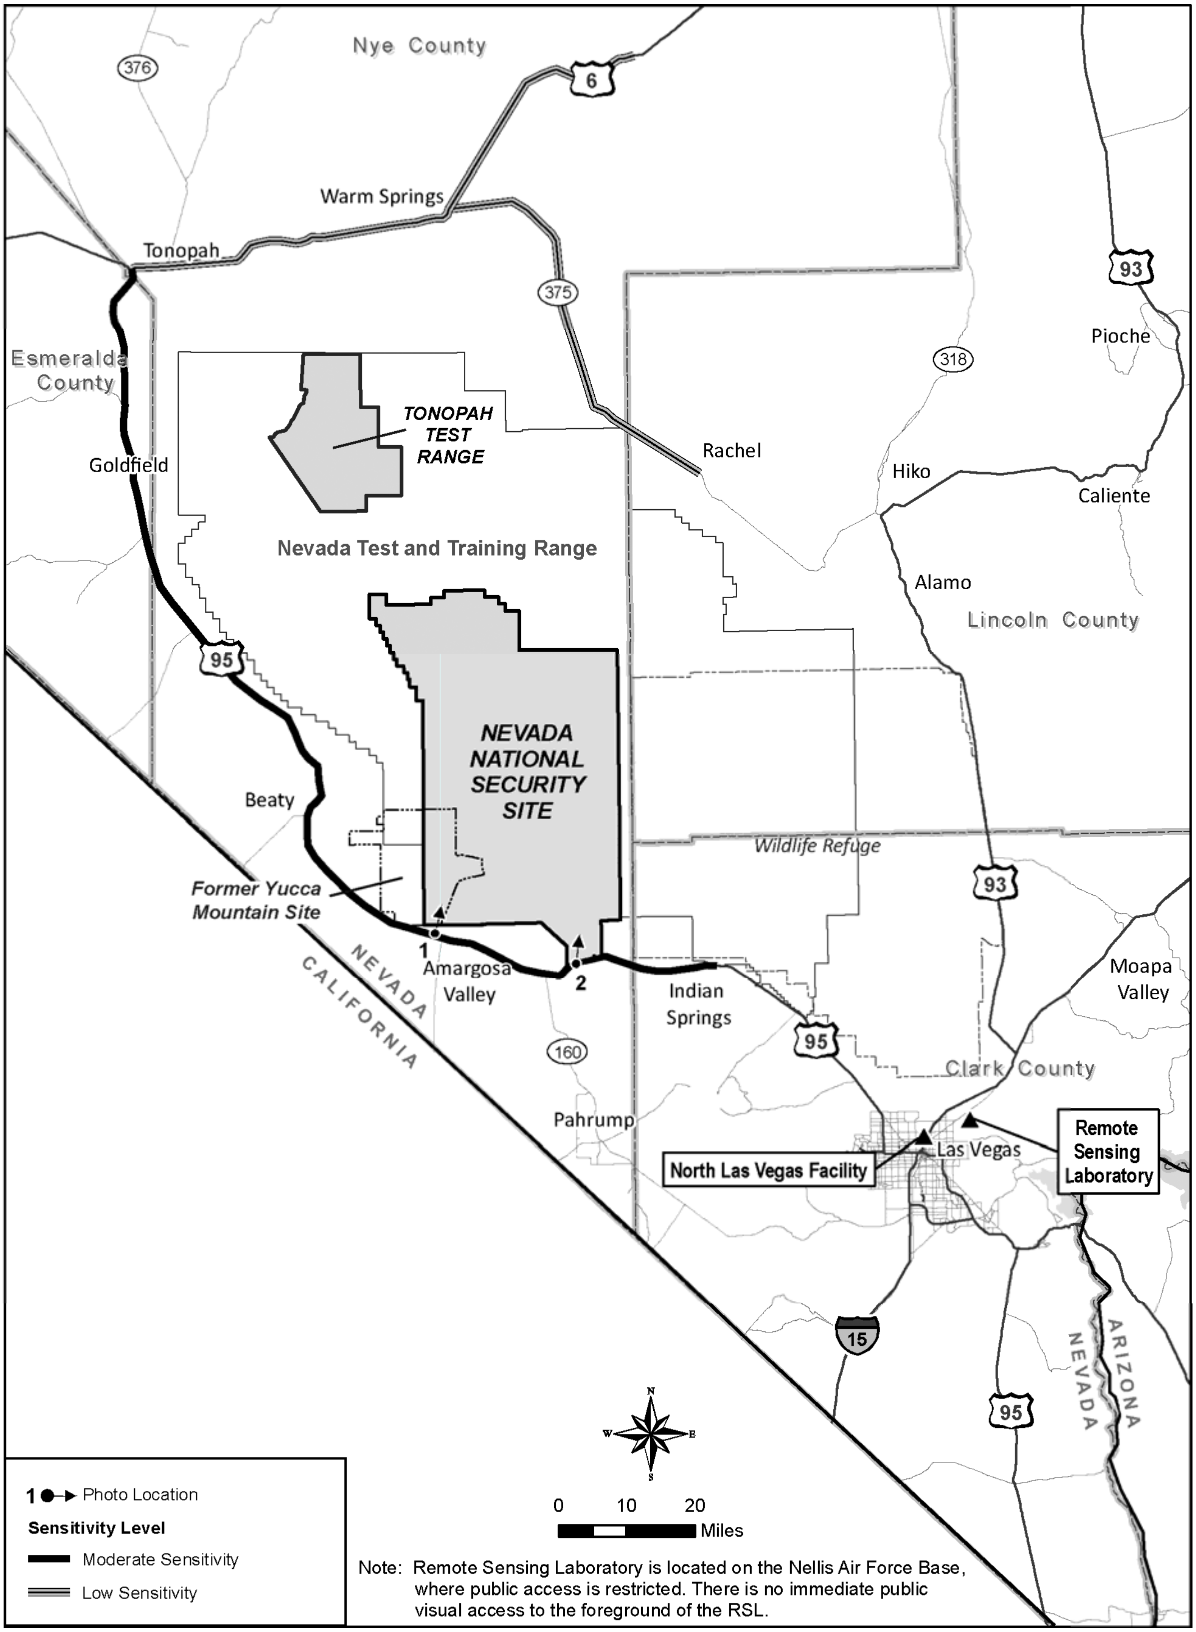

Figure 4–30 Photograph Locations and Sensitivity Levels at the Nevada National Security Site and Other Nevada Locations Managed by the U.S. Department of Energy/National Nuclear Security Administration

The importance of a view is related in part to the position of the viewer to the resource; therefore, visibility and visual dominance of landscape elements depend on their location within the viewshed. A viewshed is defined as all of the surface area visible from a particular location (e.g., an overlook) or sequence of locations (e.g., a roadway or trail) (FHA 1988). To identify the importance of views of a resource, a viewshed must be broken into distance zones of foreground, middleground, and background. Generally, the closer a resource is to the viewer, the more dominant it is and the greater its importance to the viewer. Although distance zones in a viewshed may vary between different geographic regions or types of terrain, the standard foreground zone is up to 0.5 miles from the viewer, the middleground zone is 0.5 miles to 4 miles from the viewer, and the background zone is 4 miles and beyond (USFS 1995).

Visual sensitivity depends on the number and type of viewers and the frequency and duration of views. Visual sensitivity also varies with differences in viewer activity, awareness, and visual expectations in relation to the number of viewers and viewing duration. For example, visual sensitivity is generally higher for views seen by people who are driving for pleasure; people engaging in recreational activities such as hiking, biking, or camping; and homeowners. Sensitivity tends to be lower for views seen by people driving to and from work or as part of their work (USFS 1995; FHA 1988; U.S. Soil Conservation Service 1978). As described above, commuters and nonrecreational travelers have low visual sensitivity. Residential viewers typically have extended viewing periods and are concerned about changes in the views from their homes; therefore, they are generally considered to have high visual sensitivity. Recreational viewers (e.g., those using recreation trails and areas, scenic highways, and scenic overlooks) are usually assessed under the assumption that they have high visual sensitivity.

Visual Resources—American Indian Perspective

CGTO All landforms within the Nevada National Security Site (NNSS) have high sensitivity levels for American Indians. The ability to see the land without the distraction of buildings, towers, cables, roads, and other objects is essential for the spiritual interaction between Indian people and our traditional lands.

Views from places are an important cultural resource that contributes to the location and performance of American Indian ceremonialism. Views combine with other cultural resources to produce special places where power is sought for medicine and other types of ceremony. Views can be of any landscape, but more central viewscapes are experienced from high places, which are often the tops of mountains and the edges of mesas. Indian viewscapes tend to be panoramic and are made special when they contain highly diverse topography. The viewscape panorama is further enhanced by the presence of volcanic cones and lava flows.

Viewscapes are tied with songscapes and storyscapes especially when the vantage point has a panorama composed of multiple locations described by traditional songs or stories. Our traditional songscapes and storyscapes can be compromised if projects like geothermal energy development are pursued. If geothermal resources are altered, our songs and stories will be impacted and will no longer accurately reflect key traditional aspects of the viewscape.

The Consolidated Group of Tribes and Organizations (CGTO) recognizes the cultural significance of viewscapes and have identified a number of these on the NNSS. The Timber Mountain Caldera contains a number of significant vantage points with different panoramas including but not limited to Scrugham Peak, Shoshone Mountain, and Buckboard and Pahute Mesa. The CGTO feels revisiting sites within the viewscapes are essential to Indian people to interact with the land, communicate with the spirits who watch over the land, conduct religious ceremonies with prayers and songs, and monitor each site's condition. Special considerations should be given to tribal elders and youth to provide an educational experience and reinforce positive connections with our culture.

See Appendix C for more details.

Nevada National Security Site Vicinity. The NNSS landscape is typical of the Basin and Range Physiographic Province. Key visual features include the Mercury Valley, on either side of U.S. Route 95, gently sloping upward toward the mountains, mesas, and hills enclosing the valley. Representative locations where photographs were taken and sensitivity levels of the roadways in the area are shown in Figure 4–30. Lower elevations in the valley are vegetated with creosote bush and white bursage shrubland, transitioning to spiny menodora, Nevada jointfir, and white bursage shrubland at higher elevations (DOE/NV 2000d). While this vegetation looks rougher in the foreground, it appears smoother as it recedes into the distance. The coarse, angular terrain of the mountain, mesa, and hill slopes provides visual interest during different times of the day, providing simple-to-complex light and shade patterns (see **Figure 4–31**). These patterns provide visual contrast to the smooth valley floor that does not cast visually dynamic shadows. Light and shade also affect the perceived color of the terrain by saturating or dulling the color hues present in the landscape. Development is limited to the Mercury and Amargosa Valleys. While both of these developed areas are small in scale, the use of light-colored building materials makes these areas more visually apparent against the darker natural landscape (see **Figure 4–32**).

Most of Areas 22 and 23 and portions of Area 25 are the only areas of the NNSS that are visible to the public from U.S. Route 95 and the Amargosa Valley. All other public visual access to the interior of the NNSS is limited by terrain. Portions of the study area visible from U.S. Route 95 are considered to have a Class B scenic quality rating due to the lack of visual intrusions and picturesque views of the natural landscape that vary throughout the day and seasonally, combined with commonality of these views to the region.

Figure 4–32 Landscape Photographs – Developed Areas near the Nevada National Security Site

4.1.10 Cultural Resources

This section discusses the known prehistoric, ethnographic, and historic cultural resources within the boundaries of the NNSS. Unless otherwise noted, the information in this section is derived from the *1996 NTS EIS* (DOE 1996c). Additional information regarding cultural resources on the NNSS was obtained from the Desert Research Institute, which provides cultural resources program support to the DOE/NNSA NSO (DOE 2010a). Information sources provided by the Desert Research Institute include the *Cultural Resources Management Plan for the Nevada Test Site* update (DOE 2010a); short report summaries; lists of recorded sites on the NNSS and their National Register of Historic Places (NRHP) eligibility status; and excerpts from major archaeological, ethnographic, and historical studies conducted on the NNSS for the DOE/NNSA NSO.

Cultural resources include prehistoric and historic archaeological districts, sites, buildings, structures, or objects created or modified by human activity. Cultural resources also include traditional cultural properties, locations of American Indian significance that are important to a community's practices and beliefs and maintain a community's cultural identity. Under Federal regulation, a significant cultural resource, designated as a "historic property," warrants consideration with regard to potential adverse impacts resulting from proposed Federal actions (DOE 2002e). A cultural resource is a historic property if its attributes make it eligible for listing in the NRHP. Federal agencies also are required to consider the effects of their actions on sites, locations, and other resources, such as plants, that are of cultural or religious significance to American Indians, as established under the American Indian Religious Freedom Act (42 U.S.C. 1996). American Indian graves, associated funerary objects, and objects of cultural patrimony are protected by the Native American Graves Protection and Repatriation Act (25 U.S.C. 3001 et seq.).

The area of influence for cultural resources is the geographic area or areas within which an undertaking may directly or indirectly cause alterations in the character or use of historic properties, if any such

properties exist. The area of influence for the NNSS is defined as all ground areas that would be disturbed by construction, maintenance, or operations of program facilities and activities occurring on site. Based on current knowledge of cultural resources on the NNSS, all areas have the potential to contain cultural resources. Therefore, the area of influence for this SWEIS comprises the entire NNSS.

The NNSS lies within the Southern Great Basin physiographic region and possesses a long history of American Indian occupation and more-recent European-American settlement and American military use. The following is a brief outline of prehistoric, ethnographic, and historic cultural chronologies.

Archaeological research has documented 12,000 years of human occupation on the NNSS. Numerous prehistoric chronological sequences have been developed for the Southern Great Basin (Lyneis 1982; Pippin 1995, 1998a; Warren and Crabtree 1986). The chronological periods are defined primarily by major changes in patterns of artifact assemblage composition, subsistence, settlement, and land use characterizing each period. The chronology developed by Pippin is most applicable to the NNSS (Pippin 1998a). These chronologies of cultural adaptations generally fall into periods occurring during the late Pleistocene (12,000–10,000 BP [years before present]); early Holocene (10,000–7,500 BP); middle Holocene (7,500–4,500 BP); and late Holocene (4,500–150 BP) (DOE 2010a).

At the time of historic contact during the mid-nineteenth century, the region in which the NNSS is situated was occupied by Numic-speaking hunter-gatherer groups now known as the Western Shoshone and the Southern Paiute, whose territories were defined by ethnicity, political affiliation, and subsistence and settlement patterns (Drollinger et al. 2009; Pippin 1998b).

The first European Americans known to traverse what is now the NNSS were emigrants on their way to California in 1849 (DOE 2010a). The area remained sparsely populated and served primarily as a transportation corridor. However, short-lived periods of mining and ranching occurred in the region as well. Military use of the area began in 1940; since that time, the NNSS has remained associated with national security missions, military research and training, and nuclear weapons testing.

4.1.10.1 Recorded Cultural Resources

Current knowledge of cultural resources on the NNSS results from numerous cultural resources studies completed over the last 30 years. Many of these studies were completed prior to NNSS activities, but most were completed within the framework of the NNSS Cultural Resources Management Program. Over 600 cultural resources studies have been conducted on the NNSS and almost 2,000 cultural resources sites have been recorded (see **Table 4–47**). Approximately 4 percent of the NNSS has been surveyed for cultural resources. Surveys are generally completed as part of Section 110 inventory requirements or Section 106 compliance for NNSS projects. In the past, projects were frequently conducted at the higher elevations in the northern end of the NNSS; therefore, the amount of acreage surveyed in these areas, along with the number of identified cultural resources, is greater in the north relative to other portions of the NNSS. However, over the past 10 years, most projects and their associated cultural resources studies have occurred at lower elevations. While all areas of the NNSS have the potential to possess cultural resources, the areas with higher numbers of recorded cultural resources are Rainier and Pahute Mesas in the northwest, followed by Jackass Flats in the southwest, and Yucca Flat in the east (DOE 2010a).

Table 4–47 Nevada National Security Site Cultural Resources Sites by Site Type and Hydrographic Basin

	Prehistoric Site Types							*Historic Site Types*		*Untyped Sites*

CA = cache; EL = extractive locality; HI = historic site; LO = locality; NRHP = National Register of Historic Places; NT = nuclear testing; PL = processing locality; RB = residential base; STA = station; TC = temporary camp; UT = untyped.
Note: This table does not include isolated artifacts or features. This table does include sites recorded within environmental restoration sites in the Nevada Test and Training Range adjacent to the NNSS.

Prehistoric archaeological sites make up 90 percent of recorded cultural resources. The remaining 10 percent are historic archaeological sites and structures, more-recent facilities and locations associated with scientific research, or sites of unknown age (DOE 2010a). Numerous evaluations of nuclear weapons testing facilities have been conducted since the *1996 NTS EIS* was completed, resulting in 38 sites and historic districts associated with NNSS activities becoming eligible for listing in the NRHP.

The types of cultural resources found on the NNSS include prehistoric and historic sites, features, and artifacts. These resources provide a range of information about past human activity. The terminology used to describe these resources is derived from site type definitions used by the Desert Research Institute (DOE 2010a) and adapted from the *1996 NTS EIS* (DOE 1996c). Prehistoric sites consist of residential bases, temporary camps, extractive localities, processing localities, uncategorized localities, caches, and stations. Historic site types are presented here in two categories: historic sites reflecting mining, ranching, communications, or transportation activities, and those sites and features associated with nuclear weapons testing of the Cold War era. Untyped sites lack enough information to assign a more specific category. Isolated artifacts consist of single prehistoric or historic artifacts or features that lack context and provide limited information about past human activity.

Residential bases are locations of extended occupation of prehistoric people. Temporary camps are occasional operational centers of prehistoric populations or task-oriented groups. These sites served as bases for resource collection and processing, tool manufacture and maintenance, and living activities. The wide range of artifact categories and features at these sites provides important data reflecting the diverse activities conducted by prehistoric populations. Extractive localities are sites where resources were procured. These sites may consist of quarries, water sources, plant-gathering areas, and hunting blinds. Processing localities are areas where groups brought procured resources, such as plant and animal resources or toolstone material, for processing or manufacture. Uncategorized localities lack sufficient information to determine what type of activity is represented. These three locality site types are areas of focused activity that lack the diverse artifact assemblages that residential bases or temporary camps

possess. Caches are places used for storing tools or plant and animal resources. Stations are areas where information about game movement, travel routes, or ritual activity was shared and may consist of cairns marking travel routes, geoglyphs, rock art, and observation points.

Historic sites reflect broad categories of activities that occurred after European Americans arrived in the area. These activities are reflected in material remains at mining sites and ranching sites, and on transportation and communication routes.

Documents providing further information used to assess cultural resources located on the NNSS include prehistoric overviews (Pippin 1986, 1995; DuBarton and Drollinger 1996; Drollinger et al. 2000; Jones 2001), ethnographic and historical studies (DuBarton and Drollinger 1996; Pippin 1998a; Johnson et al. 1999; Zedeno et al. 1999; Drollinger and Nials 1996; Jones 2001; Drollinger 2003), and studies associated with nuclear testing (Beck et al. 1996; Johnson and Edwards 2000; Johnson et al. 2000; Jones et al. 2005; Drollinger et al. 2009; and others). The following discussion presents a brief description of known cultural resources on the NNSS, most documented as a result of cultural resource compliance studies associated with DOE/NNSA activities. Because the NNSS covers a large geographic area, cultural resources are grouped by the 10 hydrographic basins located within the NNSS boundary (NDWR 2010a) (see Figure 4–15 and Table 4–47). The cultural resources described below consist of archaeological sites and historic NNSS facilities; isolated artifacts and features are not discussed.

4.1.10.1.1 Mercury Valley

Mercury Valley is bounded by the Spotted Range and the Specter Range. Twenty-six cultural resources studies have been conducted within the portion of Mercury Valley that lies within the NNSS. Approximately 338 acres have been surveyed for cultural resources. Only six sites have been recorded as a result of these surveys. Of these, three are prehistoric localities and one is a historic site, none of which is eligible for listing in the NRHP. One historic district associated with nuclear testing, the Camp Desert Rock Historic District, was recorded, evaluated, and determined to be eligible for listing in the NRHP. The Camp Desert Rock Historic District contains building foundations and features associated with the administration and housing of troops who participated in the Desert Rock atmospheric exercises (Edwards 1997).

4.1.10.1.2 Rock Valley

Rock Valley is bounded by the Specter Range to the south and Skull and Little Skull Mountains to the north. The majority of Rock Valley lies within the NNSS boundary. Eleven archaeological reconnaissance surveys have been conducted within Rock Valley and approximately 445 acres have been surveyed for cultural resources. A total of 19 sites have been recorded as a result of these studies, including 1 temporary camp, 1 extractive locality, 1 processing locality, 15 uncategorized localities, and 1 event associated with nuclear testing. Of these 19 sites, 4 are eligible for listing in the NRHP, 1 of which exhibits occupation from the prehistoric, ethnographic, and historic periods (Jones 2001).

4.1.10.1.3 Fortymile Canyon–Jackass Flats

The Fortymile Canyon–Jackass Flats Hydrographic Basin is bounded by Skull and Little Skull Mountains to the south and the Shoshone Mountains to the north. Almost the entire basin falls within the NNSS boundary. A total of 167 cultural resources studies have been conducted within this area, covering approximately 575 acres. The number of cultural resources identified in this basin is high, reflecting the extensive cultural resources studies associated with NNSS activities in the area. A total of 392 cultural resources sites have been recorded as a result of these studies. This number includes 1 residential base, 36 temporary camps, 17 extractive localities, 62 processing localities, 243 uncategorized localities, 7 caches, 1 station, 9 untyped sites, 8 historic sites, and 8 sites related to nuclear testing. To date, 120 sites are eligible for listing in the NRHP.

4.1.10.1.4 Fortymile Canyon–Buckboard Mesa

This hydrographic basin includes Buckboard Mesa and a portion of Pahute Mesa. It is bounded by the Shoshone Mountains to the west and the Eleana Range to the east. Sixty-nine cultural resources studies have been conducted within the portion of Buckboard Mesa that lies within the NNSS boundary. Approximately 6,138 acres have been surveyed for cultural resources. Buckboard Mesa possesses the highest number of recorded archaeological sites on the NNSS. To date, 502 sites have been recorded in the Fortymile Canyon–Buckboard Mesa Hydrographic Basin. This total includes 111 temporary camps, 7 extractive localities, 109 processing localities, 211 uncategorized localities, 6 caches, 1 station, 3 ranching sites, and 54 untyped archaeological sites. Of these resources, 346 sites are eligible for listing in the NRHP. The large number of prehistoric sites, particularly localities and temporary camps, suggests that this region was intensively used by prehistoric hunter-gatherers.

4.1.10.1.5 Oasis Valley

The eastern portion of the Oasis Valley Hydrographic Basin lies within the NNSS boundary and includes portions of Pahute Mesa. A total of 32 cultural resources investigations have been conducted within the portion of Oasis Valley that lies within the NNSS boundary, and 10 studies have been conducted on environmental restoration sites within the Nevada Test and Training Range adjacent to the NNSS. Approximately 3,477 acres have been surveyed for cultural resources. To date, 128 cultural resources have been recorded in this portion of Oasis Valley. These include 14 temporary camps, 1 extractive locality, 20 processing localities, 90 uncategorized localities, 1 historic period site, and 2 untyped sites. Of these, 49 sites are eligible for listing in the NRHP.

4.1.10.1.6 Gold Flat

The southern portion of the Gold Flat Hydrographic Basin lies within the NNSS boundary and includes part of Pahute Mesa. Fifty-two cultural resources studies have been conducted in the portion of Gold Flat that lies within the NNSS. Approximately 6,371 acres have been surveyed for cultural resources. To date, 268 sites have been recorded as a result of these studies. These sites include 25 temporary camps, 1 extractive locality, 97 processing localities, 131 uncategorized localities, 10 caches, 2 historic sites, 1 site associated with a nuclear testing event, and 1 untyped site. Of these, 169 prehistoric sites are eligible for listing in the NRHP.

4.1.10.1.7 Kawich Valley

The southern part of Kawich Valley lies within the NNSS boundary and includes a portion of Pahute Mesa. Twenty-two cultural resources studies have been conducted in the portion of this basin that lies within the NNSS boundary. Approximately 2,635 acres have been surveyed for cultural resources. To date, 82 sites have been recorded as a result of cultural resources studies. These sites include 9 temporary camps, 1 extractive locality, 25 processing localities, 37 uncategorized localities, 2 historic sites, and 8 untyped sites. Of these sites, 58 are eligible for listing in the NRHP.

4.1.10.1.8 Emigrant Valley

A very small portion of the Emigrant Valley Hydrographic Basin lies within the NNSS boundary. This basin includes a portion of the Belted Range. Two cultural resources surveys have been conducted in the portion of the basin that lies within the NNSS boundary and one study has been conducted on an environmental restoration site on the Nevada Test and Training Range just northeast of the NNSS. Approximately 60 acres have been surveyed for cultural resources. Five prehistoric localities have been recorded in this area, none of which is eligible for listing in the NRHP.

4.1.10.1.9 Yucca Flat

Most of the Yucca Flat Hydrographic Basin lies within the NNSS boundary and is bounded by the Eleana Hills to the west and the Halfpint Range to the east. Yucca Dry Lake lies at the southern end of the basin. To date, 150 cultural resources studies have been conducted in Yucca Flat. Approximately 9,030 acres

have been surveyed for cultural resources. To date, 395 sites have been recorded within Yucca Flat. These sites consist of 4 residential bases, 68 temporary camps, 10 extractive localities, 37 processing localities, 132 uncategorized localities, 57 caches, 1 station, 44 historic sites, 25 sites associated with nuclear testing, and 17 untyped sites. Currently, 176 sites are eligible for listing in the NRHP, 18 of which are associated with nuclear testing. One site, Sedan Crater, is already listed in the NRHP. Numerous structures associated with atmospheric nuclear testing are eligible for listing in the NRHP, such as the Yucca Flat Historic District (Jones et al. 2005; Johnson and Edwards 2000; Drollinger et al. 2009).

4.1.10.1.10 Frenchman Flat

Frenchman Flat is bounded by the Spotted Range to the east; Mine Mountain and Massachusetts Mountain to the north; the Shoshone Mountains, Lookout Peak, and the Skull Mountains to the west; and the Ranger Mountains to the south. The western half of the Frenchman Flat Hydrographic Basin lies within the NNSS boundary. Sixty-three cultural resources studies have been completed for the portion of Frenchman Flat that lies within the NNSS boundary. Approximately 9,047 acres have been surveyed for cultural resources. To date, 154 sites have been recorded as a result of these studies. These sites consist of 1 residential base, 3 temporary camps, 2 extractive localities, 43 processing localities, 60 uncategorized localities, 11 historic sites, and 34 sites associated with nuclear testing and research. Of these, 58 sites are eligible for listing in the NRHP, 8 of which are associated with nuclear testing. One of these is the Frenchman Flat Historic District; it includes buildings, structures, and features associated with nuclear atmospheric testing (Johnson et al. 2000).

4.1.10.2 Sites of American Indian Significance

In compliance with Federal laws and DOE policy, the DOE/NNSA NSO conducts an ongoing American Indian consultation program to address American Indian concerns about archaeological sites, plant and animal resources, traditional cultural properties, and sacred sites on the NNSS that hold great cultural value. This program has been in place since 1987 and recognizes the government-to-government relationship between the DOE/NNSA NSO and American Indians. The DOE/NNSA NSO consults with representatives of 16 tribal groups and 1 American Indian organization representing 3 ethnic groups (Western Shoshone, Southern Paiute, and Owens Valley Paiute) who have cultural and historic ties to the NNSS area. These American Indian groups are collectively known as the CGTO. Representatives express their respective tribal concerns and perspectives to DOE/NNSA and provide input regarding the protection and management of sites and resources that hold important cultural values for CGTO (DOE 2010a).

Ongoing consultation with CGTO, consisting of meetings, interviews, and site visits, has resulted in several studies that identify sites and locations throughout the NNSS that possess cultural significance for contemporary American Indians (Stoffle et al. 1989a, 1989b, 1994). These sites and locations consist of numerous ethnoarchaeological, ethnobotanical, and ethnozoological sites; rock art sites; and sites of spiritual significance (DOE 2010a). These consultation efforts have resulted in a better understanding of the cultural significance these sites and locations possess in relation to traditional cultural landscapes (Zedeno et al. 1999; Stoffle et al. 1996; Stoffle et al. 2001).

4.1.10.3 American Indian Cultural Resources

As a part of consultation efforts conducted for this SWEIS, the CGTO American Indian Writers Subgroup documented American Indian perspectives on cultural resources on the NNSS, in relation to the proposed undertaking. This information is presented in the following text box.

Cultural Resources—American Indian Perspective

American Indians consider cultural resources to include not only archaeological remains left by their ancestors but also natural resources and geologic formations in the region, such as plants, animals, water sources, minerals, and natural landforms that mark important locations for keeping their history alive and for teaching their children about their culture. The Consolidated Group of Tribes and Organizations (CGTO) knows, based upon its collective knowledge of Indian culture and past American Indian studies, that American Indian people view cultural resources as being interconnected.

The Nevada National Security Site (NNSS) area and nearby lands were significant to the Western Shoshone, Southern Paiute, and Owens Valley Paiute and Shoshone people. The lands were central in the lives of these people and were mutually shared for religious ceremony, resource use, and social events. When Europeans encroached on these lands, the numbers of Indian people, their relations with one another, and the condition of their traditional lands began to change. European diseases killed many Indian people; European animals replaced Indian animals and disrupted fields of natural plants; Europeans were guided to and then assumed control over Indian minerals; and Europeans took Indian agricultural areas. Indian people believe that the natural state of their traditional lands was what existed before European contact, when Indian people were fully responsible for the continued use and management of these lands.

The withdrawal of Nevada's lands for military purposes in the 1940's, followed by use of the land by the U.S. Department of Energy (DOE) continued the process of Euroamerican encroachment on Indian lands. Land-disturbing activities followed, thus causing some places to become unusable again for Indian people. On the other hand, many places were protected by this land withdrawal because "pothunters" were kept from stealing artifacts from rock shelters and European animals were kept from grazing on Indian plants. The forced removal of Indian people from the land was combined with their involuntary registration and removal to distant reservations in the early 1940s. Indian people were thus removed from lands that had been central to their lives for thousands of years.

DOE has supported several cultural resource studies at the NNSS, most occurring as a result of recommendations made by the CGTO in the 1996 NTS FEIS and commitments made by DOE in the subsequent Record of Decision. Many of these studies are cited throughout Appendix C of the SWEIS. These studies were also designed to comply with various federal laws and executive orders, including the American Indian Religious Freedom Act, Native American Grave Protection and Repatriation Act, and Executive Order 13007, *Indian Sacred Sites*.

Through these studies, the CGTO confirmed that American Indians used traditional sites in the NNSS area to make tools, stone artifacts, and ceremonial objects; many sites are also associated with traditional healing ceremonies and power places. Several areas in the NNSS region are recognized as traditionally or spiritually important. For example, Fortymile Canyon was an important crossroad where trails from such distant places as Owens Valley, Death Valley, and the Avawatz Mountain came together. Black Cone, in Crater Flat, is an important religious site that is considered to be an entry to the underworld. Alice Hill, (refine location with acceptable language) is also regarded as a culturally important place. Prow Pass was an important ceremonial site and, because of this religious significance, tribal representatives have recommended that DOE avoid affecting this area. Oasis Valley was another important area for trade and ceremonies. In 1993, tribal members visited a rockshelter site containing perishable basketry and crookneck staff on the NNSS, and recommended that the items be left in place, with annual monitoring to assess their condition. Gold Meadows is also extremely important to the Indian people. Other areas are considered important based on the abundance of artifacts, traditional-use plants and animals, rock art, and possible burial sites.

See Appendix C for more details.

4.1.11 Waste Management

Introduction

Radioactive and nonradioactive wastes are generated and managed at the NNSS as part of operations in support of National Security/Defense and Nondefense Mission programs; decontamination and demolition of unneeded structures and facilities; and the Environmental Restoration Program, including remediation of soil sites and industrial facilities and, to a small extent, the UGTA Project.[8] Radioactive wastes generated and/or managed at the NNSS include LLW and MLLW, and TRU waste. The Waste Management Program also manages nonradioactive hazardous waste regulated under the Resource Conservation and Recovery Act (RCRA) (42 U.S.C. 6901 et seq.); wastes containing asbestos or polychlorinated biphenyls (PCBs) regulated under the Toxic Substances Control Act (TSCA) (15 U.S.C. 2601 et seq.); explosive wastes; and nonhazardous wastes, including sanitary solid waste, construction and demolition debris, and hydrocarbon-contaminated soil and debris. These wastes are defined in Chapter 12, "Glossary."

LLW and MLLW managed at the NNSS include wastes generated by activities within the NNSS or other in-state locations such as the TTR, as well as wastes received from authorized out-of-state DOE and DoD generators, including classified wastes.[9] The NNSS also accepts for disposal selected nonradioactive classified wastes that result from cleanup of current and former DOE weapons production facilities. Wastes thus generated or received may be disposed within authorized and/or permitted disposal units located at the NNSS Area 5 RWMC and the Area 3 RWMS. (The Area 3 RWMS has been in standby mode since July 1, 2006.)

MLLW received from authorized out-of-state generators must be treated in accordance with EPA land disposal restriction requirements before delivery to the NNSS. MLLW generated at the NNSS or by other authorized in-state generators may be treated at the Area 5 RWMC, then disposed, provided the treated waste meets the acceptance criteria for disposal. In-state-generated MLLW that cannot be properly treated at the NNSS is transferred to offsite treatment, storage, or disposal facilities.[10] In-state-generated LLW containing regulated PCBs in sufficient concentrations, asbestos, or hydrocarbon-contaminated soil and debris may be disposed at the NNSS in state-permitted disposal units, provided the waste meets the NNSS waste acceptance criteria for disposal.[11]

Nevada National Security Site (NNSS) Low-Level and Mixed Low-Level Radioactive Waste Management Programs

The NNSS low-level radioactive waste (LLW) management program addresses waste containing radioactive constituents (LLW as defined in Chapter 12, "Glossary"), as well as LLW containing regulated (friable) asbestos, polychlorinated biphenyls (PCBs) in low concentrations (e.g., radioactive PCB bulk product waste containing PCBs in concentrations less than 50 parts per million), or hydrocarbon-contaminated soil and debris. The NNSS mixed low-level radioactive waste (MLLW) program addresses waste containing both radioactive and hazardous constituents (MLLW as defined in Chapter 12, "Glossary"), as well as radioactive waste containing PCBs in sufficient concentrations (e.g., radioactive PCB remediation waste containing PCBs in large capacitors or fluorescent light ballasts).

[8] *The NNSS Environmental Restoration Program includes compliance with the FFACO, which was entered into in 1996 by DOE, DoD, and the State of Nevada (NDEP 1996). DOE's Office of Legacy Management has responsibility for the Central Nevada Test Area and Project Shoal and became a signatory to the FFACO in August 2006. The FFACO provides a process for identifying sites that have potential historic contamination, implementing state-approved corrective actions, and instituting closure actions for remediated sites.*

[9] *Some LLW or MLLW consists of classified material that has not been sanitized, demilitarized, or declassified. In addition, the NNSS is designated as a Classified Waste Disposal Facility and accepts low-level classified waste (with or without hazardous constituents) for disposal without sanitization.*

[10] *MLLW treated at offsite facilities may be disposed off site or returned to the NNSS for disposal.*

[11] *Hydrocarbon-contaminated LLW received from out-of-state generators may be disposed in any LLW disposal unit.*

TRU waste generated as part of ongoing NNSS operations or from in-state environmental restoration programs is sent to the Area 5 RWMC for temporary storage before shipment off site for further characterization and/or final disposition.

Tritiated liquids generated by environmental restoration or other in-state DOE activities are managed by evaporation.

Hazardous waste (and waste regulated under the TSCA or other statutes) generated at the NNSS may be sent directly from the point of generation to permitted offsite treatment, storage, or disposal facilities. Waste may be temporarily stored in the Area 5 RWMC and consolidated, pending shipment to offsite treatment, storage, or disposal facilities. The waste may also be sent off site for recycle or reuse as part of the NNSS Pollution Prevention and Waste Minimization Program.

Small quantities of explosives or wastes containing explosives may be treated at the Area 11 Explosives Ordnance Disposal Unit in accordance with a RCRA permit.

Nonhazardous waste generated at the NNSS or by other in-state generators may be recycled, reused, or disposed in permitted landfills such as those operating in Areas 6, 9, and 23 of the NNSS.

Waste management construction, storage, treatment, and disposal activities at the NNSS are summarized in **Table 4–48** and discussed in this section. The status column in the table relates the current status of the listed activity with respect to its analyses in the *1996 NTS EIS* (DOE 1996c) and the *Supplement Analysis for the Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (DOE 2002g).

Table 4–48 Current Nevada National Security Site Waste Management Activities

Activity	*Status* [a]	*Remarks*
Area 3 Radioactive Waste Management Site		
Disposal		
DOE/NNSA NSO-generated LLW	On standby	The Area 3 RWMS would be used for specific waste streams for which it would be economically or environmentally advantageous to dispose at that facility.
Other LLW		
Closure		
Disposal Crater Complex U3ax/bl	Complete	Facility closure as a RCRA-regulated MLLW disposal unit was completed in 1999.
Disposal Craters U3ah/at and U3bh	On standby	Additional crater disposal is possible pending final closure in accordance with an integrated closure and monitoring plan.
Construction		
Future LLW disposal units	Not developed	Additional existing subsidence craters would be developed as needed if the Area 3 RWMS is re-opened.
Expanded support facility	Not constructed	This project to double the size of an existing support building by adding a prefabricated structure was not implemented. It may be needed in the future if the Area 3 RWMS is re-opened.
Truck decontamination facility	Not constructed	This facility was not constructed but may be needed in the future if the Area 3 RWMS is re-opened.
Area 5 Radioactive Waste Management Complex		
Disposal		
DOE/NNSA NSO-generated LLW	Ongoing	Disposal is expected to continue for as long as needed by the U.S. Department of Energy complex in a variety of types of disposal units constructed with consideration of the radiological and chemical characteristics of the wastes to be disposed (e.g., deeper disposal for high-activity wastes).
LLW received from other authorized generators		
MLLW	Ongoing	Disposal of in-state- and out-of-state-generated MLLW continues at the Area 5 RWMC in a new NDEP-permitted Mixed Waste Disposal Unit (Cell 18) [b]. Previously used Pit 3 ceased acceptance of MLLW on November 30, 2010, and was closed as part of the existing 92-Acre Area closure.

Activity	***Status*** [a]	***Remarks***
Greater confinement disposal	Complete	The performance assessment for existing greater confinement disposal boreholes was completed, and no new waste has been disposed in them. The boreholes were closed as part of closure of the existing 92-Acre Area.
Regulated asbestos LLW	Ongoing	LLW containing regulated asbestos (also called asbestiform waste) was accepted for disposal in Pit 6, but Pit 6 was closed as part of closure of the existing 92-Acre Area. Disposal of this waste continues in a new Mixed Waste Disposal Unit (Cell 18) at the Area 5 RWMC.
Nonradioactive classified waste	Ongoing	Nonradioactive classified waste is accepted for disposal from current and former DOE weapons production facilities.
Storage		
Mixed waste	Ongoing	DOE/NNSA NSO possesses a RCRA permit for temporary storage of in-state and out-of-state MLLW.
TRU waste	Ongoing	Except for two TRU spheres, all stored legacy TRU wastes were shipped off site for characterization at INL and/or disposal at WIPP. The TRU spheres will be stored pending offsite shipment. Experiments at JASPER generate small annual quantities of TRU waste. Environmental restoration activities may also generate TRU waste. All TRU wastes will be safely stored pending offsite shipment for characterization at INL and/or disposal at WIPP.
Hazardous waste	Ongoing	DOE/NNSA NSO possesses a RCRA permit for temporary storage of hazardous waste before shipment to offsite treatment, storage, or disposal facilities.
Treatment		
Macroencapsulation Microencapsulation	Ongoing	Treatment technologies are currently performed on debris generated by in-state environmental restoration programs to meet disposal requirements such as RCRA land disposal restrictions. Treatment occurs at the TRU Waste Storage Pad.
Facility Construction Activities		
Real-Time Radiography	Complete	A real-time radiography unit is operational for nondestructive examination of LLW and MLLW.
TRU Waste Certification Facility TRU Waste Handling and Loading Facility	Complete	Also known as the Waste Examination Facility. Within the Waste Examination Facility, modifications were made to the Visual Examination and Repackaging Building to support repackaging of TRU waste for offsite shipment, which has been completed. The facility is available for future use for waste treatment projects.
LLW disposal units	Ongoing	New disposal units are typically constructed as needed, based on waste forecasts and baseline operating budgets. The current threshold for new disposal unit construction is when remaining total capacity falls below 3.5 million cubic feet.
MLLW disposal units	Ongoing	DOE/NNSA received an NDEP-issued RCRA permit in December 2010 for a new MLLW disposal unit (Cell 18). Cell 18 is in operation.
Hazardous waste storage unit (expansion)	Not constructed	If needed in the future, increase to 0.138 acres, with a capacity of 55,000 gallons.
Maintenance building	Not constructed	This 3,200-square-foot storage facility for equipment and machinery was not constructed, but may be needed in the future.
LLW Storage Facility	Not constructed	This 3,000-square-foot curbed concrete pad was not constructed, but may be needed in the future.
Closure Activities		
Close LLW disposal units Close MLLW disposal units	Ongoing	Individual disposal units are operationally closed as they are filled to capacity with waste. The existing 92-Acre Area was closed in 2011 under the approved 92-Acre Area closure plan. Closure of current and future disposal units will occur in accordance with a formal plan addressing the entire Area 5 RWMC.
Close greater confinement disposal units	Complete	All existing disposal units were operationally closed, filled to grade as needed, and closed in 2011 as part of closure of the existing 92-Acre Area.

Activity	***Status*** [a]	***Remarks***
Area 6		
Storage Activities		
PCB-contaminated waste	Ongoing	The Area 6 facility operated temporarily as part of an NNSS program to collect and dispose PCB-contaminated waste. Currently, in-state-generated PCB-contaminated waste may be stored at the Hazardous Waste Storage Unit in the Area 5 RWMC before offsite shipment for disposal. LLW and MLLW containing regulated PCBs in concentrations greater than or equal to 50 parts per million are disposed in the Mixed Waste Disposal Unit (Cell 18).
Disposal Activities		
Hydrocarbon landfill	Ongoing	Hydrocarbon-contaminated soils and materials generated at the NNSS are disposed at this NDEP-permitted facility. Small quantities of hydrocarbon waste may also be disposed at the U10c Landfill in Area 9. Hydrocarbon-contaminated LLW is disposed at the Area 5 RWMC.
Area 9		
Disposal Activities		
U10c Landfill	Ongoing	Accepts inert debris and small quantities of hydrocarbon-contaminated soil and debris.
Area 11		
Treatment Activities		
Explosives Ordnance Disposal Unit	Ongoing	This RCRA-permitted treatment unit may detonate up to 100 pounds of approved waste per hour, and up to 4,100 pounds in a year.
Area 23		
Disposal Activities		
Landfill	Ongoing	Accepts less than 20 tons daily of sanitary solid waste.

DOE/NNSA = U.S. Department of Energy/National Nuclear Security Administration; INL = Idaho National Laboratory; JASPER = Joint Actinide Shock Physics Experimental Research Facility; LLW = low-level radioactive waste; MLLW = mixed low-level radioactive waste; NDEP = Nevada Division of Environmental Protection; NNSS = Nevada National Security Site; NSO = Nevada Site Office; PCB = polychlorinated biphenyl; RCRA = Resource Conservation and Recovery Act; RWMC = Area 5 Radioactive Waste Management Complex; RWMS = Area 3 Radioactive Waste Management Site; TRU = transuranic; WIPP = Waste Isolation Pilot Plant.

4.1.11.1 Radioactive Waste Management

This section addresses NNSS management of LLW and MLLW, and TRU waste.

4.1.11.1.1 Low-Level and Mixed Low-Level Radioactive Waste Management and Disposal

LLW management and disposal currently occurs within the Area 5 RWMC. The Area 5 RWMC is also used for management and disposal of MLLW, and for management of TRU and hazardous wastes. The Area 3 RWMS has been used for disposal of LLW, but is currently in standby mode.

The NNSS receives for disposal LLW and MLLW generated within the DOE complex from numerous DOE sites across the United States, including the NNSS, as well as from DoD sites that carry a national security classification[12] (DOE/NV 2009d). In DOE's December 1996 ROD (61 FR 65551) for the *1996 NTS EIS*, DOE selected the Expanded Use Alternative for most activities, but selected the Continue Current Operations (No Action) Alternative for LLW and MLLW management (61 FR 65551) pending a

[12] *A security classification is a category to which national security information and material are assigned to denote the degree of damage that unauthorized disclosure would cause to national defense or foreign relations of the United States and to denote the degree of protection required.*

decision reached through the *Final Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste* (*WM PEIS*) (DOE 1997). On February 25, 2000 (65 FR 10061), in the fourth ROD for the *WM PEIS*, DOE established the NNSS as one of two regional LLW and MLLW disposal sites for the DOE complex. This 2000 ROD also modified DOE's December 1996 ROD (61 FR 65551) for the *1996 NTS EIS* by selecting the Expanded Use Alternative for management of LLW and MLLW (see Chapter 1, Section 1.4).

4.1.11.1.1.1 Area 3 Radioactive Waste Management Site

The Area 3 RWMS is located in the northwestern quadrant of Area 3 (see **Figure 4–33**). It covers about 120 acres and includes two support buildings (an office trailer and a change area), as well as land dedicated to waste disposal. It is an access-controlled facility surrounded by a wire fence and earthen berms to mitigate potential flooding (DOE/NV 2007c). The Area 3 RWMS includes five disposal units configured from seven subsidence craters caused by underground weapons testing (see **Table 4–49**). Opened in the late 1960s, it was used for disposal of bulk and containerized LLW, such as contaminated soil and debris. The facility has been unutilized since July 1, 2006 (Di Sanza and Carilli 2006; DOE/NV 2011). Under the Expanded Operations Alternative, the Area 3 RWMS could be opened to receive LLW generated from environmental restoration and other activities at DOE/NNSA sites within the State of Nevada. Specifically, this action could be triggered by a need for additional disposal space beyond that available in the Area 5 RWMC for disposal of large on-site remediation debris, or soils from clean-up activities on the NTTR. While there is no near-term need to use the Area 3 RWMS, However, should DOE/NNSA need to activate the Area 3 Radioactive Waste Management Site, it would first undergo detailed consultation with the State of Nevada, and would limit disposal to in-state generated LLW.

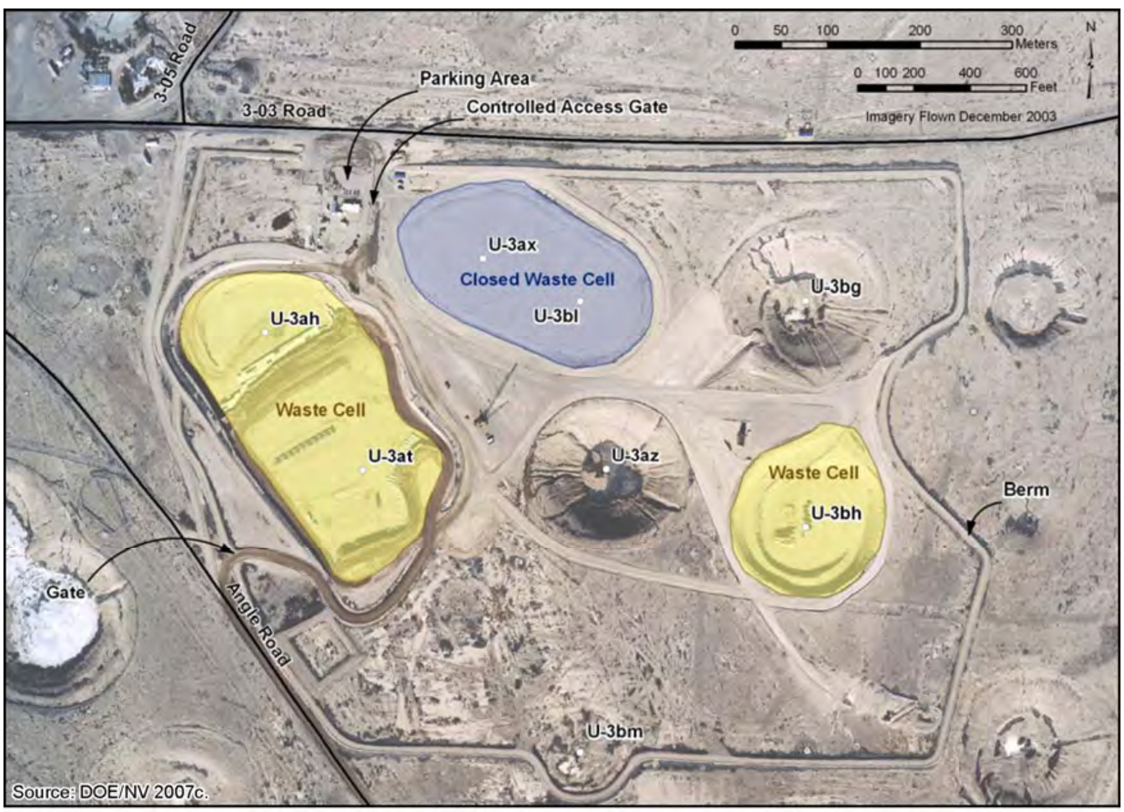

Figure 4–33 Area 3 Radioactive Waste Management Site

Table 4–49 Area 3 Radioactive Waste Management Site Disposal Units

Available Disposal Units [a]	*Closed Disposal Units*	*Undeveloped Disposal Units*
U-3ah/at [b] U-3bh	U-3ax/bl [b]	U-3az U-3bg

[a] As of July 1, 2006, these two disposal units were placed into inactive status.
[b] These disposal units were configured from two subsidence craters.
Source: DOE/NV 2011.

In FY 2001, the U-3ax/bl disposal unit, which contains hazardous constituents regulated under RCRA (CAU 110), was closed in accordance with a closure plan approved by NDEP. In FY 2001, a lysimeter, which measures water content in soil, was constructed at the Area 3 RWMS to gain data to be used to design final closure covers for NNSS disposal areas.

4.1.11.1.1.2 Area 5 Radioactive Waste Management Complex

In 1961, an area northwest of Frenchman Lake was reserved as an LLW disposal site under regulatory provisions derived from the Atomic Energy Act of 1954, as amended. In 1977, the area was designated the Area 5 Radioactive Waste Management Site (DOE 1996c). Since then, activities at the area have been expanded to include management or disposal of other types of waste. The entire complex of waste treatment, storage, management, disposal, and support capacity is termed the Area 5 RWMC (see **Figure 4–34**). Current operations at the Area 5 RWMC include LLW and MLLW examination, repackaging if necessary, and disposal; temporary hazardous and MLLW storage; treatment of some MLLW before disposal; and temporary storage of in-state-generated TRU waste pending offsite shipment.

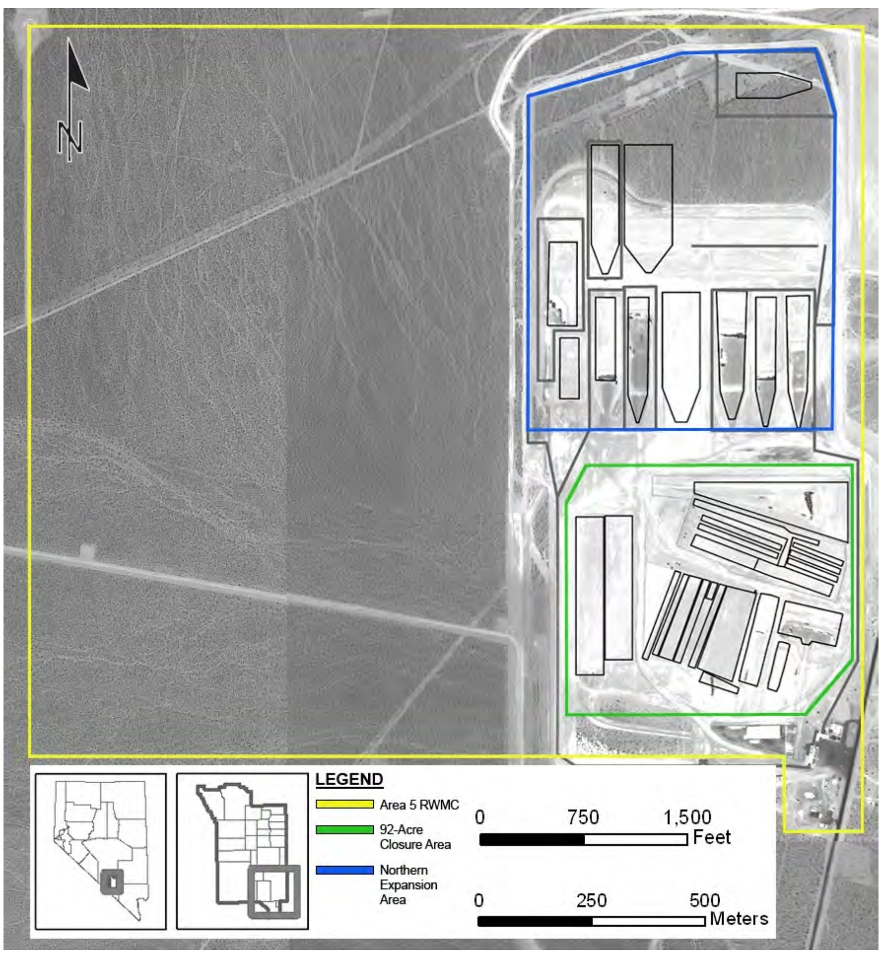

Figure 4–34 Area 5 Radioactive Waste Management Complex

Past and current waste disposal operations are summarized in this section. Additional information about activities at the Area 5 RWMC is provided in the following sections:

- Section 4.1.11.1.1.3, Waste Disposal Support Activities
- Section 4.1.11.1.2, Mixed Low-Level Radioactive Waste Management
- Section 4.1.11.1.3, Transuranic Waste Management
- Section 4.1.11.2.1, Hazardous Waste Management

The Area 5 RWMC covers about 740 acres of DOE/NNSA-owned land[13] and is surrounded by a 1,000-foot-wide buffer zone. The Area 5 RWMC includes several equipment storage yards, as well as structures that are used for offices, laboratories, utilities, and routine operations. Support facilities include:

- Real-Time Radiography Facility (used for verification of MLLW using x-ray technology)
- TRU Waste Storage Pad and Pad Cover Building (used for storage of TRU waste)
- Waste Examination Facility (used to examine and repackage TRU waste for offsite shipment)
- Mixed Waste Storage Units
- Visual Examination and Repackaging Building (located within the Waste Examination Facility)
- Area 5 Hazardous Waste Storage Unit

In addition, a lysimeter facility located southwest of the Area 5 RWMC has been in operation since 1994; data from this facility will be used along with data recorded at the Area 3 RWMS lysimeter to design final disposal covers for NNSS disposal areas.

Waste disposal within the Area 5 RWMC started within a 92-acre area in the southern portion of the site (the "92-Acre Area"), but disposal operations have expanded to the north of this area. The total area used to date for waste disposal, including operational disposal units, covers about 200 acres. The 92-Acre Area consists of 31 pits and trenches and 13 greater confinement disposal (GCD) boreholes. Additional pits have been constructed in the northern expansion area (see **Table 4–50**). The 92-Acre Area was closed under an NDEP-approved Corrective Action Decision Document and Corrective Action Plan that addressed all waste disposed in the 92-Acre Area (see Section 4.1.11.1.1.3).

Table 4–50 Area 5 Radioactive Waste Management Complex Disposal Units [a]

Pits and Trenches	*GCD Boreholes*
Active	
7 cells authorized for LLW 1 cell authorized for MLLW, asbestiform LLW, and LLW containing regulated PCBs in concentrations greater than or equal to 50 ppm (Cell 18)	Not applicable
Permanently Closed	
17 LLW cells 11 LLW and MLLW cells 1 pit permitted for MLLW (Pit 3) 2 cells permitted for asbestiform LLW (Pits 6A and 7)	4 boreholes containing no waste 4 boreholes containing TRU waste 5 boreholes containing LLW

GCD = greater confinement disposal; LLW = low-level radioactive waste; MLLW = mixed low-level radioactive waste; PCB = polychlorinated biphenyl; ppm = parts per million; TRU = transuranic.
[a] As of September 2011.

[13] *In November 2009, permanent ownership of and accountability for the land encompassing the Area 5 RWMC was transferred from BLM to DOE (see Section 4.1.1.3).*

New disposal units will continue to be constructed to the north and west of the 92-Acre Area. It is estimated that the currently unused portion of the Area 5 RWMC could accommodate disposal of several million cubic yards of waste. Disposal services are expected to continue at the Area 5 RWMC for as long as the DOE complex requires them (Di Sanza and Carilli 2006; DOE 2008f; DOE/NV 2008b, 2009d).

Seven disposal units are currently active for LLW, and one disposal unit is active for disposal of MLLW, LLW containing regulated asbestos (also called asbestiform LLW), and LLW containing regulated PCBs in concentrations greater than or equal to 50 parts per million (Cell 18).[14] Thirty-one pits and trenches and all GCD boreholes have been permanently closed with construction of a final closure cover over the 92-Acre Area (see Section 4.1.11.1.1.3).

Of the 31 pits and trenches, 11 pits and trenches contain LLW that also contain constituents that are regulated under RCRA or TSCA. One pit (Pit 3) was operated under RCRA interim status for disposal of MLLW. Two pits contain LLW with regulated asbestos. Seventeen pits and trenches contain LLW that does not include constituents regulated under RCRA or TSCA. One of the trenches, however, is a classified materials trench that contains TRU waste that was inadvertently disposed in 1986. This inadvertent disposal involved two waste shipments containing approximately 102 55-gallon drums (about 1,100 cubic feet) of classified waste originally thought to be LLW (DOE/NV 2006b).

Thirteen GCD boreholes were constructed in the 1980s as an experimental concept for disposal of wastes that were not considered appropriate for near-surface disposal. Of these, nine boreholes were used to dispose TRU waste and some high-activity LLW, and the remaining four boreholes were never used. The boreholes were constructed to depths of about 120 feet. After waste placement, the boreholes containing about 10,350 cubic feet of combined waste were backfilled with at least 60 feet of fill (DOE 1996c; DOE/NV 2001a).

Under current operations, LLW received at the Area 5 RWMC is disposed without further treatment. Some onsite-generated MLLW, however, is repackaged and/or treated at the Area 5 RWMC before disposal (see Section 4.1.11.1.2). Offsite-generated MLLW must be treated to comply with RCRA land disposal restrictions prior to receipt at the NNSS; this waste is disposed without further treatment.

Disposal units are excavated, used, and operationally closed as needed, and are used for disposal of waste typically delivered to the site in drums, soft-sided containers, large cargo containers, and boxes. Currently, one to two new LLW disposal units are excavated each year, as needed. The designs of the waste disposal units vary depending on waste characteristics, as do operational procedures. Some wastes may require special handling or disposal because of size or weight, or because of radiological or chemical characteristics. For example, cover material over wastes in some disposal units may be thicker. In other instances, the disposal unit may be designed for easy offloading of physically large or long wastes, or to safely accommodate high-activity or high-exposure-rate waste packages (e.g., trenches dug within disposal units). Operational practices, such as remote waste placement using large cranes, or placement of waste containers into prepared pockets nested within a dedicated disposal unit, have also been used. Some disposal units may be dedicated for particular types of waste. Examples include Cell 18, used for disposal of MLLW, and pits and trenches used for disposal of classified waste or material (Clark et al. 2005; Di Sanza and Carilli 2006; DOE/NV 2011).

[14] *LLW containing non-regulated PCBs in concentrations less than 50 parts per million can be disposed in any active LLW disposal unit.*

All LLW and MLLW disposed at the NNSS must meet the NNSS waste acceptance criteria for disposal. In addition, all MLLW must meet applicable RCRA land disposal restrictions.[15] The most recent version of the NNSS waste acceptance criteria was issued in February 2012 and requires generators to provide specific information about the characteristics of the wastes, including volume, radionuclide content and quantity, treatment history, and waste form (DOE/NV 2012b). Candidate waste forms for NNSS disposal include (but are not limited to) those listed in the following text box, which illustrates the large variety of different forms in which LLW and MLLW may exist. Some of the listed waste forms (e.g., aqueous liquid) must be processed (e.g., solidified) or specially packaged before receipt and acceptance at the NNSS for disposal. Specific processing and packaging requirements are provided in the NNSS waste acceptance criteria.

Examples of Low-Level and Mixed Low-Level Radioactive Waste Forms Accepted for Nevada National Security Site Disposal[1]

Charcoal	Cation exchange media	Compactable trash
Incinerator ash	Anion exchange media	Noncompactable trash
Soil	Mixed bed ion-exchange media	Animal carcasses
Gas	Contaminated equipment	Biological material (except animal carcasses)
Oil	Organic liquid (except oil)	Activated material (except activated metal)
Aqueous liquid	Glassware or labware	Activated metal
Filter media	Sealed source or device	Other
Mechanical filter	Paint or plating	
EPA hazardous	Evaporator bottoms, sludges, or concentrates	
Demolition rubble		

[1] This list does not include all radioactive waste forms accepted for disposal at the NNSS but provides examples for informational purposes only.
Source: DOE/NV 2009b.

As of 1996, DOE was operating under RCRA interim-status conditions for disposal of MLLW generated by DOE within the state of Nevada (DOE 1996c). By 2002, DOE had applied for a RCRA Part B permit for disposal of MLLW from DOE generators from inside and outside the state of Nevada (DOE 2002g). Pit 3 operated under interim status for disposal of MLLW until it was permanently closed in 2010, and a permit reissued in 2005 removed the restriction on accepting MLLW from outside Nevada. Pursuant to the permit, the NNSS could accept no more than 20,000 cubic meters (about 706,300 cubic feet) of MLLW from outside the state of Nevada and had to permanently close Pit 3 by December 2010, whichever situation occurred first (DOE/NV 2006a).

Waste was received for disposal at Pit 3 through November 30, 2010. Because not all disposal space would have been used by that time, the DOE/NNSA NSO also disposed LLW, as well as MLLW, in Pit 3. After disposal operations in Pit 3 ceased, remaining disposal space was filled with native soil and the disposal unit was closed in 2011 as part of final closure of the 92-Acre Area. Postclosure monitoring started in the same year (DOE/NV 2008b, 2011, 2012a).

On September 29, 2009, DOE submitted an application to NDEP for a new RCRA Part B permit for a new disposal unit for MLLW, including LLW containing PCBs in concentrations greater than or equal to 50 parts per million. The DOE/NNSA NSO received final permit approval from the state in December 2010. The permitted capacity of Cell 18, the new Mixed Waste Disposal Unit, is approximately 900,000 cubic feet. It began operation in January 2011.

[15] *Wastes containing radionuclides and regulated TSCA constituents must also meet any applicable treatment requirements before NNSS disposal.*

The *1996 NTS EIS* projected disposal of about 40,310,000 cubic feet (1,141,422 cubic meters) of LLW and about 10,600,000 cubic feet (300,500 cubic meters) of MLLW over a period of 10 years (DOE 1996c). However, from 1996 through 2008, the NNSS actually disposed about 21,400,000 cubic feet of LLW and about 225,000 cubic feet of MLLW. About 60 percent of this waste was disposed at the Area 5 RWMC and the rest at the Area 3 RWMS. Over these 13 years, annual LLW disposal volumes ranged from about 400,000 cubic feet in 1998 to 3,740,000 cubic feet in 2004, and averaged about 1,540,000 cubic feet; annual MLLW disposal volumes ranged from zero in 1997, 2001, 2003, 2004, and 2005, to about 154,000 cubic feet in 2007, and averaged about 17,300 cubic feet. Since July 1, 2006, all LLW and MLLW disposal has occurred in the Area 5 RWMC. From 2004 through 2008, annual LLW volumes ranged from about 919,000 to 3,630,000 cubic feet, and averaged about 1,698,000 cubic feet; annual MLLW volumes ranged from zero to about 154,000 cubic feet, and averaged about 41,600 cubic feet (Gordon 2009b).

Radioactive Waste Acceptance Program

The U.S. Department of Energy/National Nuclear Security Administration Nevada Site Office Radioactive Waste Acceptance Program (RWAP) ensures that low-level and mixed low-level radioactive wastes (LLW and MLLW) disposed at the Nevada National Security Site (NNSS) meets the NNSS Waste Acceptance Criteria, which includes requirements set forth by the U.S. Department of Energy, the U.S. Department of Transportation, the Resource Conservation and Recovery Act, and other appropriate Federal laws and regulations. The RWAP process consists of two parts: A waste generator evaluation and a waste acceptance process.

4.1.11.1.1.3 Waste Disposal Support Activities

Management and disposal of LLW is regulated by DOE through its authority under the Atomic Energy Act of 1954, as amended. Management and disposal of MLLW containing hazardous constituents is regulated by DOE under the Atomic Energy Act and by EPA and the State of Nevada under RCRA. Management and disposal of LLW containing regulated PCBs in sufficient concentrations, asbestos, or hydrocarbon-contaminated soil and debris is regulated by DOE under the Atomic Energy Act and by EPA and the state under statutes such as TSCA. Safe disposal is assured through operational procedures; compliance with the NNSS waste acceptance criteria; the Radioactive Waste Acceptance Program (RWAP); risk assessments; air, groundwater, and soil monitoring; and disposal unit closure.

Waste Acceptance. Approval to ship waste to the NNSS for disposal may be granted only after a waste generator demonstrates that it has a waste characterization and certification program that meets the requirements stated in the NNSS waste acceptance criteria. These criteria include specific requirements for waste form, characterization, packaging, and transportation. RWAP personnel provide assistance, interpretation, guidance, and technical expertise on the waste acceptance criteria. Through onsite facility evaluations, RWAP personnel are also responsible for verifying that a waste generator has an established program that complies with regulations regarding the characterization, management, and transportation of radioactive waste. Waste is not accepted at the NNSS until the generator meets the prescribed approval process and a specific waste profile has been reviewed and approved (Gordon 2009a).

The waste disposal process begins when a generator (e.g., DOE or DoD) site proposes a specific waste stream for disposal. If initial discussions with the DOE/NNSA NSO indicate that the proposed waste stream may meet NNSS eligibility and waste acceptance criteria, RWAP personnel conduct an evaluation to ensure that the generator has implemented a waste certification program that is compliant with the NNSS waste acceptance criteria. During this evaluation, RWAP personnel complete an onsite examination of the waste generator’s processes and procedures through all stages of waste management, including waste generation, characterization, packaging, and shipment. Potential waste generators must also provide documentation demonstrating the implementation of the NNSS waste acceptance criteria in their program. If issues are identified during the facility evaluations, corrective actions must be approved and implemented prior to waste certification program approval and eventual waste shipment and disposal (Gordon 2009a).

Once a generator has been authorized as an approved generator, it is required to maintain a Quality Assurance Program Plan (QAPP) demonstrating compliance with the current revision of the NNSS waste acceptance criteria; DOE Order 435.1, *Radioactive Waste Management*; DOE Order 414.1D, *Quality Assurance*; and/or 10 CFR 830.122, *Quality Assurance*. Generators are required to submit their current revision of the QAPP to the RWAP manager. Generators must also prepare and submit an NNSS Waste Acceptance Criteria Implementation Crosswalk to the RWAP manager each year. This document references the applicable procedures, processes, or methods affecting quality and personnel directly responsible for implementation of the generator's program. In addition, the generator must submit a written list that identifies key site personnel who certify that the waste meets the NNSS waste acceptance criteria and is safely packaged, marked, and labeled in accordance with U.S. Department of Transportation regulations. RWAP personnel verify the qualifications of these key personnel through the review of training records during the facility evaluations.

Approved waste generators are required to submit documentation (waste profiles) to validate that each proposed waste stream is in compliance with the NNSS waste acceptance criteria. These waste profiles must be in the format prescribed by the DOE/NNSA NSO and include information on waste origin, quantity, composition, and packaging, and the analytical and preparatory methods used to characterize the waste. Waste Acceptance Review Panel personnel review these profiles to ensure that established waste form criteria are met. Copies of the waste profiles are routed to NDEP for concurrent evaluation (Gordon 2009a).

Upon arrival of an LLW or MLLW shipment at the NNSS, the shipment documentation is reviewed to ensure consistency with the pre-approved waste stream profile(s). While this document verification is being conducted, the trucks and trailers carrying the waste are monitored to determine whether external radiation and surface contamination levels are below required limits. As a trailer is unloaded, inspectors verify the physical integrity of the waste packages and check to ensure that container marking and labeling meet NNSS waste acceptance criteria requirements. In addition, onsite real-time radiography (x-ray technology) may be used to visually verify waste package contents, as discussed below.

MLLW requiring treatment prior to disposal may be subject to independent waste verification (real-time radiography examination, visual verification at the generating facility) and chemical screening conducted by RWAP personnel, as determined by the Waste Acceptance Review Panel during the waste profile approval process.[16] At the discretion of the Waste Acceptance Review Panel, LLW may also undergo examination by real-time radiography.

At the Area 5 RWMS, real-time radiography may be performed on pre-selected MLLW and LLW streams, subject to container size and weight limitations associated with the analytical mounting fixture. The procedure is conducted on a predetermined percentage of received containers of waste, based on approved profile specifications, to confirm that the waste form meets the approved profile.

These waste verification activities ensure that the waste form listed on shipment documentation is consistent with the waste form received for disposal. In the unlikely[17] event that any actual waste shipment is deemed not compliant with the NNSS waste acceptance criteria, it is returned to the waste generator for corrective action, consistent with DOE policy (Gordon 2009a).

Disposal Authorization and Performance Assessment

Waste disposal occurs in accordance with authorizations issued by DOE and with permits for MLLW issued by external regulatory agencies. The authorization and permit approval processes are based on formal, quantitative analyses of worker and public health and safety during construction, operation, and closure, as well as consideration of possible long-term (thousands of years) impacts on the public and the

[16] NDEP participates on the Waste Acceptance Review Panel.
[17] For example, during FYs 2004 through 2008, only two shipments were returned to the waste generators (DOE/NV 2005b, 2005g, 2007a, 2007e, 2009a).

environment after the disposal facilities are closed. The results of the analyses must determine that disposal activities would comply with all applicable regulatory requirements.

These analyses include performance assessments and composite analyses prepared in compliance with DOE Order 435.1. The Area 3 RWMS performance assessment and composite analysis were issued in October 2000 (DOE/NV 2000b); the Area 5 RWMC performance assessment, in 1998 (DOE/NV 1998a); and the Area 5 RWMC composite analysis, in September 2001 (DOE/NV 2001a). An addendum to the Area 5 RWMC composite analysis was also issued in November 2001 (DOE/NV 2001d). The scenarios and waste acceptance criteria for the Area 5 RWMC were updated through an April 2000 addendum to the 1998 performance assessment (DOE/NV 2000a). A second addendum to the Area 5 RWMC performance assessment was issued in 2006 and was reviewed by DOE's Low-Level Radioactive Waste Federal Review Group. This review group recommended, without conditions, DOE's approval of the performance assessment, which confirms that it meets the requirements of DOE Order 435.1 (Carilli and Krenzien 2007).

DOE has also conducted analyses of TRU waste disposal to assess compliance with EPA's TRU waste disposal requirements in 40 CFR Part 191. In 2003, DOE approved an analysis addressing disposal of TRU and other waste in the GCD boreholes, concluding that the long-term performance of the boreholes would comply with 40 CFR Part 191 (Colarusso et al. 2003). An additional analysis also concluded compliance with 40 CFR Part 191, as well as with all applicable requirements in DOE Manual 435.1-1 for TRU waste that had been inadvertently disposed in an Area 5 RWMC trench (Colarusso et al. 2003; Shott, Yucel, and Desotell 2008). DOE/NNSA has closed the trench containing the TRU waste as part of permanent closure of the 92-Acre Area (see below).

The performance assessments and composite analyses support the continued operation of the disposal facilities. DOE requires that performance assessments and composite analyses be maintained after their preparation. The maintenance process includes performing annual reviews, carrying out special analyses, and revising the performance assessments and composite analyses as necessary. A maintenance plan for the Area 3 and 5 performance assessments and composite analyses has been issued (DOE/NV 2002a).

Decision Support System

A decision support system has been implemented that allows rapid assessment and documentation of the consequences of waste management decisions using current site characterization information, the radionuclide inventory, and a conceptual model. The core of the decision support system is a probabilistic inventory and performance assessment model that supports multiple graphic capabilities for documentation of data sources, conceptual model, mathematical implementation, and results. The combined models can be used to estimate disposal site inventory, contaminant concentrations in environmental media, and radiological doses to hypothetical members of the public at various locations. The model is routinely used to provide annual updates of site performance, evaluate the consequences of disposal of new waste streams, develop waste concentration limits, optimize the design of new disposal units, and assess the adequacy of environmental monitoring programs (Shott et al. 2006).

The decision support system maintains a database of the inventories of specific radionuclides on both an actual and a projected basis. Generators proposing to dispose waste at the NNSS must submit a waste profile setting forth projected waste volumes and radionuclide distributions. This information is checked through screening analyses, and more-detailed analyses as needed, to enable a determination that proposed disposal of the waste would not result in impacts that would exceed any of the performance objectives or other numerical criteria for the disposal facility.[18] Waste inventory data are routinely updated in the site database as disposal occurs and as new projections of waste inventories are received.

[18] Pursuant to DOE Order 435.1, DOE disposal sites must be operated so that disposal would be in compliance with a number of performance objectives. For example, there are limits on the radiation dose that may be received by a potential future member of the public as determined by performance assessment modeling.

The performance assessment model is updated annually with the latest inventory estimates, and new estimates of the performance measures are calculated. In this way, the DOE/NNSA NSO ensures that final closure of the site when it is filled to capacity will be in compliance with applicable disposal requirements.

Area 3 and 5 Monitoring

DOE/NNSA's environmental monitoring program for the Area 3 and Area 5 disposal sites includes monitoring of radiation exposure, air, groundwater, meteorology, vadose zone, subsidence, and biota. Monitoring data for calendar year (CY) 2008 indicated that the Area 3 and Area 5 disposal sites were performing within the expectations of the model and parameter assumptions for the facility performance assessments (DOE/NV 2009c).

Closure

Final closure of the Area 3 RWMS and Area 5 RWMC will occur in accordance with integrated closure and monitoring plans that are intended to ensure that closure will be in compliance with all applicable standards, including DOE Order 435.1, DOE Manual 435.1-1, 40 CFR Part 191, 40 CFR Part 265, *Nevada Administrative Code* (NAC) 444.743, and RCRA requirements as incorporated into NAC 444.9632. Final closure of the U3ax/bl disposal unit at the Area 3 RWMS has occurred, as has final closure of the 92-Acre Area at the Area 5 RWMC. Current and future disposal units at Area 3 and Area 5 will be operationally closed when appropriate, and their final closure will occur in accordance with the integrated closure and monitoring plans.

Closure plans have been developed and updated over several years, considering schedules, waste inventories, NNSS and facility characterization data, and final cover designs. An integrated closure and monitoring plan for the Area 3 RWMS and Area 5 RWMC was issued in 2001 (DOE/NV 2001b) and updated in 2005 (DOE/NV 2005d). A closure strategy for the Area 5 RWMC was issued in 2007 (DOE/NV 2007b), and updated closure plans for the Area 3 RWMS and Area 5 RWMC were issued in 2007 (DOE/NV 2007c) and 2008 (DOE/NV 2008b), respectively.

The closure plan for the Area 3 RWMS specifically addresses closure of the U-3ah/at and U-3bh disposal units. (A final closure cover has already been placed over unit U-3ax/bl [CAU 110].) The final cover will consist of a monolayer evapotranspiration layer expected to be somewhat less than 10 feet thick. The requirements of postclosure maintenance and monitoring will be determined in the final closure plan, which will address the applicable monitoring requirements prescribed by DOE directives and other Federal regulations and NDEP (DOE/NV 2007c).

The closure plan for the Area 5 RWMC addresses closure of the 92-Acre Area, as well as the remainder of the Area 5 RWMC. As noted in Section 4.1.11.1.1.2, final closure of the 92-Acre Area addressed 31 inactive pits and trenches and all 13 GCD boreholes. The GCD boreholes were filled to grade and the area comprising the pits, trenches, and boreholes was covered with an 8-foot-thick monolayer evapotranspiration cap. This activity was largely completed by May 2011. In October 2011, major portions of the 92-Acre Area were reseeded, and in December, a temporary watering system was installed to sustain germinated vegetation until springtime (DOE/NV 2012a).

The balance of the Area 5 RWMC used for waste disposal will be closed with covers in a fashion similar to the 92-Acre Area, and adjacent areas between the cover systems will be graded for proper drainage. Following final closure of the entire Area 5 RWMC, institutional controls—including control of public access, cover maintenance, and monitoring—will continue thereafter in accordance with applicable Federal and state requirements. Long-term monitoring provisions for the Area 5 RWMC will be developed as part of its final closure plan (DOE/NV 2008b).

4.1.11.1.2 Mixed Low-Level Radioactive Waste Management

MLLW generated at the NNSS may be stored at the Area 5 RWMC. In November 2010, the DOE/NNSA NSO received an NDEP permit for temporary storage of MLLW (Area 5 RWMC) from authorized out-of-state generators.

Onsite treatment of in-state-generated MLLW may occur at the Area 5 RWMC. The treated and/or repackaged waste is then disposed in the Area 5 RWMC (Gordon 2009b).

Disposal of MLLW at the NNSS is described in Section 4.1.11.1.1.2.

4.1.11.1.3 Transuranic Waste Management

For several years, the NNSS stored legacy TRU waste received from Lawrence Livermore National Laboratory, Rocky Flats Environmental Technology Site, Lawrence Berkeley Laboratory, and EG&G, and from environmental restoration at the NNSS and the TTR. In recent years, however, DOE completed a program to repackage, characterize, and ship this legacy waste to WIPP, near Carlsbad, New Mexico, for disposal. Most waste was shipped directly to WIPP, and some waste was shipped to Idaho National Laboratory for final characterization before transfer to WIPP.

Remaining TRU waste consists of two 3-foot-diameter steel spheres that were used in subcritical experiments. The spheres cannot be shipped in their current configuration in approved Transuranic Package Transporter Model 2 (TRUPACT-II) casks because their plutonium content exceeds the current TRUPACT-II limit of 325 grams. The spheres are being stored pending the availability of suitable processing capability.

Currently, small quantities of TRU waste are generated annually from experiments at JASPER and temporarily stored pending offsite shipment. As of December 2010, 25 standard waste boxes (about 1,660 cubic feet) containing this waste were in storage. Environmental restoration at the NNSS or other in-state locations is also expected to occasionally generate small quantities of TRU waste.

The legacy spheres and accumulated TRU waste from JASPER are temporarily stored at the Area 5 RWMC. Most TRU waste at the Area 5 RWMC is stored in a steel-framed, fabric-covered structure known as the TRU Pad Cover Building. This structure rests on a 2.1-acre asphalt pad containing a protective waterproof layer, plus an 8-inch curb to prevent run-on and runoff (DOE/NV 2006c). Classified TRU material is stored in a separate storage building.

4.1.11.1.4 Tritium Waste Disposal by Evaporation

Liquids containing tritium continue to be disposed at the NNSS by evaporation into the air from ponds and open tanks. The sources of the tritium include tritium-containing water removed from tunnels in Area 12 and from onsite wells that were contaminated from past nuclear tests. In recent years, tritiated water to be evaporated has included air conditioning condensate removed from a sump in the basement of a building at NLVF.[19] Some of this tritiated water is evaporated at NLVF, and the remainder is transported to the NNSS for disposal in NNSS sewage lagoons. The tritium inventory for all sources discharged for evaporation at the NNSS ranged from about 9.5 to 130 curies per year from 1996 through 2008, and averaged about 42 curies per year. From 2004 through 2008, the tritium inventory ranged from about 9.5 to 35 curies per year, averaging about 17 curies (DOE/NV 1997b, 1998c, 1999, 2000c, 2001c, 2002b, 2003a, 2004a, 2005f, 2006a, 2007d, 2008a, 2009d).

[19] As addressed in Section 4.3.12, a 1995 accident resulted in a release of tritium within the basement of Building A-1. Although the contamination was cleaned up to the extent practical, some of the tritium penetrated into the concrete floor of the basement. Tritium emanating from the concrete as water vapor is condensed by the building cooling system.

4.1.11.2 Nonradioactive Waste Management

Nonradioactive wastes include hazardous waste, nonhazardous waste, explosive waste, and classified nonradioactive waste from DOE weapons production facilities.

4.1.11.2.1 Hazardous Waste Management

Hazardous and toxic materials used or stored at the NNSS are controlled and managed through the use of a Hazardous Substance Inventory database, which facilitates compliance with the operational and reporting requirements of TSCA; the Federal Insecticide, Fungicide, and Rodenticide Act; the Emergency Planning and Community Right-to-Know Act; and the Nevada Chemical Catastrophe Act. Chemicals to be purchased are subject to a requisition compliance review process.

Hazardous waste (and certain PCB wastes regulated under TSCA as discussed below) generated through NNSS activities may be sent to offsite treatment, storage, or disposal facilities; recycled; or reused. Much of these wastes derives from environmental restoration activities (DOE/NV 2009d). Waste shipped to offsite treatment, storage, or disposal facilities is addressed below; recycle and reuse is addressed in Section 4.1.11.3.

Non-bulk (packaged) hazardous waste generated at the NNSS may be stored temporarily in the RCRA-permitted Hazardous Waste Storage Unit located in proximity to the Area 5 RWMC.[20] NNSS-generated waste containing only PCBs in sufficient amounts, or PCBs mixed with hazardous constituents regulated under RCRA, may also be stored in the Hazardous Waste Storage Unit pending shipment off site for treatment and disposal. PCB-contaminated waste is not routinely generated during operations at the NNSS, but is sometimes generated during environmental restoration and decontamination and decommissioning activities at the NNSS or other in-state locations, and may be received mixed with LLW. Nonradioactive waste containing PCBs in concentrations less than 50 parts per million may generally be disposed as nonhazardous solid waste in a permitted NNSS landfill. Waste quantities shipped off site for treatment and disposal from 2004 through 2008 ranged from 10.8 to 399 tons per year, averaging 111 tons per year (DOE/NV 2005f, 2006a, 2007d, 2008a, 2009d).

4.1.11.2.2 Explosive Ordnance Disposal

Nonradioactive explosive ordnance generated at the NNSS from tunnel operations, the NNSS Security firing range, the resident national laboratories, and other DOE/NNSA activities may be treated by open detonation at the Explosives Ordnance Disposal Unit in Area 11.[21] The Explosives Ordnance Disposal Unit is a detonation pit permitted under RCRA (NEV HW0101) and surrounded by an earthen pad with dimensions of about 25 feet by 100 feet. It includes ancillary equipment such as a bunker, electric shot box, and electric wire. DOE/NNSA is permitted to detonate a maximum of 100 pounds of approved waste at a time, not to exceed one detonation event per hour. The maximum annual treatment capacity is 4,100 pounds.

Annual quantities treated have been much smaller than permitted levels. From 2004 through 2008, the maximum quantity treated was 4.9 pounds in 2004; no wastes were treated in other years (DOE/NV 2005f, 2006a, 2007d, 2008a, 2009d).

[20] Much of the environmental restoration waste is delivered directly as bulk shipments (dump trucks, roll-off boxes) to offsite treatment, storage, or disposal facilities. The Hazardous Waste Storage Unit only manages packaged (non-bulk) hazardous waste.

[21] Explosive waste is not accepted for treatment from offsite sources. Any explosive waste generated at the TTR, for example, is treated at the TTR under Emergency Treatment Permits obtained from NDEP.

4.1.11.2.3 Nonhazardous Waste Management

Nonhazardous wastes annually generated through NNSS activities may be sent to NNSS landfills to be disposed, recycled, or reused. NNSS disposal is addressed below; recycle and reuse is addressed in Section 4.1.11.3.

The NNSS operates three permitted landfills for disposal of nonhazardous wastes: the Area 6 Hydrocarbon Disposal Site (Permit SW-13-097-02), Area 9 U10c Landfill (Permit SW-13-097-03), and Area 23 Landfill (Permit SW-13-097-04).[22] Soils and sludge contaminated with hydrocarbons are disposed in the Area 6 Hydrocarbon Disposal Site, while inert debris, such as construction waste and demolition debris, is disposed in the Area 9 U10c Landfill. The Area 9 U10c Landfill can also accept small quantities of hydrocarbon-contaminated waste, as well as nonfriable asbestos waste. The Area 23 Landfill can accept less than 20 tons daily (based on an annual average) of sanitary solid waste, including friable, nonradioactive asbestos waste. All landfills only accept waste from the NNSS and offsite Nevada locations under DOE/NNSA NSO control (DOE 2002g).

From 2004 through 2008, the Area 6 Hydrocarbon Disposal Site received 19 to 1,166 tons of waste for disposal per year, averaging 548 tons per year. Over this time period, the Area 9 U10c Landfill received 4,569 to 15,446 tons of waste for disposal per year, averaging 8,200 tons per year. The Area 23 Landfill received 573 to 1,819 tons of waste for disposal per year, averaging 963 tons per year (DOE/NV 2005f, 2006a, 2007d, 2008a, 2009d). According to a 2008 survey of remaining landfill capacity, the estimated remaining waste capacities for the landfills are as follows: Area 6 Hydrocarbon Disposal Site, 2.8 million cubic feet; Area 9 U10c Landfill, 15 million cubic feet; and Area 23 Landfill, 13 million cubic feet (Gordon 2009b).

4.1.11.2.4 Nonradioactive Classified Waste

The NNSS accepts for disposal in the Area 5 RWMC select nonradioactive classified wastes resulting from cleanup of current or former DOE weapons production facilities.

4.1.11.3 Pollution Prevention and Waste Minimization

DOE/NNSA's pollution prevention and waste minimization initiatives entail processes to reduce the volume and toxicity of waste generated at the NNSS and its satellite facilities. The processes also ensure that proposed methods of treatment, storage, and disposal minimize potential threats to human health and the environment. These initiatives address the requirements of several Federal and state regulations applicable to operations at the NNSS. The goals are to minimize the generation, release, and disposal of pollutants to the environment by implementing cost-effective pollution protection technologies, practices, and policies. Pollution prevention and waste minimization components include source reduction, recycling, reuse, affirmative procurement, and employee and public awareness. Impetus was given to these initiatives by the October 5, 2009, Executive Order 13514, *Federal Leadership in Environmental, Energy, and Economic Performance*.

The accomplishments of the Pollution Prevention and Waste Minimization Program at the NNSS and satellite facilities are documented in the annual NNSS environmental reports. **Table 4–51** illustrates the types and quantities of hazardous and nonhazardous wastes that were managed by other means than disposal for the years 2006 through 2008.

[22] *An additional permit (SW-13-097-02) is for landfill disposal of LLW containing regulated asbestos in Pit P06UA in the Area 5 RWMC.*

Table 4–51 Waste Reduction Activities, Calendar Years 2006–2008

Activity	*Calendar Year Quantities (tons)*		
	2006	*2007*	*2008*
Hazardous Waste [a]			
Bulk used oil sent to an offsite vendor for recycling	108.2	84.4	84.2
Lead acid batteries shipped to an offsite vendor for recycling	38.0	53.2	196.8
Computer equipment returned to vendor to be refurbished and resold	6.4	42.1	13.3
Spent fluorescent light bulbs and mercury, metal hydride, and sodium lamps sent to an offsite vendor for recycling	3.4	2.3	1.4
Rechargeable batteries sent to an offsite vendor for recycling	1.8	0.3	0.2
Lead scrap metal sold for reuse/recycle	5.7	0.9	b
Lead tire weights reused instead of being disposed as hazardous waste	0.8	0.8	b
Hazardous chemicals relocated to new users through the Material Exchange Program, diverting them from disposal	0.3	b	b
Total:	**164.7**	**184.1**	**296.0**
Nonhazardous Waste			
Scrap ferrous metal sold to a vendor for recycling	593.8	872.8	92.8
Mixed paper and cardboard sent off site for recycling	170.2	668.2	177.5
Food waste from cafeterias sent off site to be reused as pig feed	73.9	52.4	49.2
Shipping materials, including pallets, Styrofoam, bubble wrap, and shipping containers, that were reused	22.8	17.6	9.5
Scrap nonferrous metal sold to a vendor for recycling	19.2	256.1	6.6
Spent toner cartridges sent off site for recycling	2.9	3.2	3.0
Nonhazardous chemicals, equipment, and supplies relocated to new users through the Material Exchange Program, diverting them from disposal	2.0	1.2	3.7
Aluminum cans sent off site for recycling	0.4	0.8	0.8
Total:	**885.1**	**1,872.3**	**343.0**

[a] In accordance with regulations issued pursuant to the Resource Conservation and Recovery Act, the Toxic Substances Control Act, or other applicable Federal or state statutes.

4.1.12 Human Health and Safety

The health and safety of the general public and site workers are discussed in this section. Environmental health risks from NNSS activities include the effects of environmental noise and acute and chronic exposures to ionizing radiation and hazardous chemicals. Regular programs are administered to monitor releases and evaluate associated potential health impacts. Additionally, studies have been conducted to assess the exposure pathways and potential risks of radionuclide and toxic chemical releases during past NNSS operations. These studies focused on the impacts of releases in terms of health risks to site workers and the general public. Results of current assessments and historic studies indicate (1) there is little risk of enhanced carcinogenesis (the production or manifestation of cancer) due to radionuclide and chemical releases during site operations; (2) doses from site radionuclide releases tend to be far lower than those from natural background radiation; and (3) chemical exposures are well within established guidelines. To optimally protect vulnerable populations, DOE maintains a comprehensive Emergency Management Program that features hazard-specific plans, procedures, and controls (DOE Order 151.1C).

4.1.12.1 Public Radiation Exposure and Safety

4.1.12.1.1 General Site Description

Major sources of background radiation and average doses from background radiation exposure to individuals in the NNSS vicinity are shown in **Table 4–52**.[23] The average annual dose from background radiation is approximately 670 millirem. About half of the annual dose is from ubiquitous, natural background sources (355 millirem) that can vary depending on geographic location, individual buildings in a geographic area, and age, but are all essentially from space or naturally occurring in the Earth. About half of the dose is from medical exposure to radiation (300 millirem), including computed tomography, interventional fluoroscopy, x-rays and conventional fluoroscopy, and nuclear medicine (use of unsealed radionuclides for diagnosis and treatment). Another approximately 14 millirem per year are from consumer products and other sources (nuclear power, security, research, and occupational exposure) (NCRP 2009). Average background radiation doses from these sources are expected to remain fairly constant over the period of the proposed actions. Background radiation doses identified in Table 4–52 are unrelated to NNSS operations.

Table 4–52 Sources of Radiation Exposure of Individuals Unrelated to Nevada National Security Site Operations [a]

Source	*Effective Dose (millirem per year) [a]*
Natural Background Radiation	
Cosmic and external terrestrial radiation [b]	98
Internal radiation	29
Radon in homes (inhaled)	228
Other Background Radiation	
Diagnostic x-rays and nuclear medicine	300
Consumer products	13
Industrial, Security, Medical, Educational, and Research	0.3
Occupational	0.5
Total (rounded)	670

[a] Except for cosmic and external terrestrial radiation, values are averages for an individual in the United States.
[b] The dose from cosmic and external terrestrial radiation is based on field readings using a pressurized ion chamber (DOE/NV/2009d).
Source: DOE/NV 2009d; NCRP 2009.

Releases of radionuclides to the environment from NNSS operations provide another potential source of radiation exposure to individuals in the vicinity of the NNSS. Types and estimated quantities of radionuclides released from NNSS operations in 2008 are listed in the *Nevada Test Site Environmental Report, 2008* (DOE/NV 2009d). Estimated doses to the public resulting from these releases are presented in **Table 4–53**. The reported total dose to the maximally exposed individual (MEI) is a conservative estimate. It is based on the concentration of radionuclides at a location on the NNSS (referred to as a "critical receptor station") where a member of the public could not live and includes the assumed consumption of game animals collected on the NNSS (not at offsite locations). MEI doses estimated in a similar manner for the years 2004 through 2008 range from 2 to 2.9 millirem per year. These doses fall within the limits invoked by DOE Order 458.1, Change 2, and are much lower than those due to background radiation.

[23] *Average doses from cosmic and terrestrial sources of background radiation are measured by a pressurized ion chamber in the vicinity of the NNSS. Other background doses are assumed to approximate the average dose to an individual in the U.S. population.*

Table 4–53 Radiation Doses to the Public from Nevada National Security Site Operations in 2008 (Total Effective Dose Equivalent)

Receptor	*Atmospheric Releases* [a]	*Liquid Releases* [b]	*Game Animals*	*Total* [c]
Maximally exposed individual (millirem)	1.9	0	0.5	2.4 [d]
Population within 50 miles (person-rem) [e]	< 1 (0.47)	0	(d)	< 1 (0.47)
Average individual within 50 miles (millirem) [f]	< 0.02	0	(d)	< 0.02

rem = roentgen equivalent man.

[a] DOE Order 458.1, Change 2, invokes the Clean Air Act regulations in 40 CFR Part 61, Subpart H, which establish a compliance limit of 10 millirem per year to a maximally exposed individual.

[b] There is no dose to the public from surface-water or groundwater pathways.

[c] DOE Order 458.1, Change 2, establishes a dose limit of 100 millirem per year to individual members of the public exposed through all pathways.

[d] The dose from the ingestion of contaminated game (cottontail rabbit or doves) is applicable to the maximally exposed individual only.

[e] In 2008, site reports did not present a calculated population dose; however, a population dose exceeding 1 person-rem is very unlikely (DOE 2008b). In 2004, the last year that a specific population dose was reported, the estimated dose to a population of 42,871 living within 50 miles of the Area 6 Control Point was 0.47 person-rem (DOE/NV 2005a).

[f] The average dose to an individual was obtained by dividing the population dose by the number of people living within 50 miles of the site.

Source: DOE 2008b; DOE/NV 2005a, 2009d; Warren 2011.

Using a risk coefficient of 600 cancer deaths per 1 million person-rem (or 0.0006 latent cancer fatalities [LCFs] per rem) (DOE 2003c), the risk of an LCF to the MEI due to radionuclide releases from NNSS operations in 2008 was estimated to be 1.4×10^{-6}. That is, the probability of this person dying of cancer at some time in the future as a result of a radiation dose associated with emissions from 1 year of NNSS operations is about 1 chance in 710,000. The hypothetical MEI is a person whose place of residence and lifestyle make it unlikely that any other member of the public would receive a higher radiation dose from NNSS releases. This person was assumed to be exposed to radionuclides in the air and on the ground from NNSS emissions at the Schooner critical receptor station, a location in the far northwestern corner of the NNSS.

Using the same risk coefficient, the calculated LCF risk to the estimated population for 2004 (the last year in which a population dose was estimated) was 0.00028 (DOE/NV 2005a). This low calculated risk implies that no LCFs are expected as a result of radioactive emissions. For comparison, the annual risk of a cancer in the U.S. population in the year 2000 was about 200 deaths per 100,000 people, or 0.2 percent per year (Weir et al. 2003). At that rate, expected fatalities from all cancers in the population living within 50 miles of the NNSS would be 86.

No members of the public receive direct gamma radiation exposure that is above background levels as a result of past or present NNSS operations. Gamma radiation exposure rates measured at areas accessible to the public are comparable to natural background rates from cosmic and terrestrial radiation. Radioactively contaminated areas on the NNSS are isolated from members of the general public, given the considerable distances between these areas and the site boundary, so members of the public are not exposed to any measurably contaminated soil, either directly or through resuspension (DOE/NV 2009d).

Radiation Basics

What is radiation? Radiation is energy emitted from unstable (radioactive) atoms in the form of atomic particles or electromagnetic waves. This type of radiation is also known as ionizing radiation because it can produce charged particles (ions) in matter.

What is radioactivity? Radioactivity is produced by the process of unstable (radioactive) atoms trying to become stable. Radiation is emitted in the process. In the United States, radioactivity is measured in units of curies (Ci). Smaller fractions of the curie are the millicurie (1 mCi = 1/1,000 Ci), the microcurie (1 µCi = 1/1,000,000 Ci), and the picocurie (1 pCi = 1/1,000,000 µCi).

What is radioactive material? Radioactive material is any material containing unstable atoms that emits radiation.

What are the four basic types of ionizing radiation?

Alpha (α) – Alpha particles consist of two protons and two neutrons. They can travel only a few centimeters in air and can be stopped easily by a sheet of paper or by the skin's surface.

Beta (β) – Beta particles are smaller and lighter than alpha particles and have the mass of a single electron. A high-energy beta particle can travel a few meters in the air. Beta particles can pass through a sheet of paper, but may be stopped by a thin sheet of aluminum foil or glass.

Gamma (γ) – Gamma rays (and x-rays), unlike alpha or beta particles, are waves of pure energy. Gamma radiation is very penetrating and can travel several hundred feet in air. Gamma radiation requires a thick wall of concrete, lead, or steel to stop it.

Neutrons (n) – A neutron is an atomic particle that has about one-quarter the weight of an alpha particle. Like gamma radiation, it can easily travel several hundred feet in air. Neutron radiation is most effectively stopped by materials with high hydrogen content, such as water or plastic.

What are the sources of radiation?

Natural sources of radiation – (1) Cosmic radiation from the sun and outer space; (2) natural radioactive elements in the Earth's crust; (3) natural radioactive elements in the human body; and (4) radon gas from the radioactive decay of uranium naturally present in the soil.

Manmade sources of radiation – Medical radiation (x-rays, medical isotopes), consumer products (TVs, luminous dial watches, smoke detectors), nuclear technology (nuclear power plants, industrial x-ray machines), and worldwide fallout from past nuclear weapons tests or accidents.

What is radiation dose? Radiation dose is the amount of energy of ionizing radiation absorbed per unit mass of any material. For people, radiation dose is the amount of energy absorbed in human tissue. In the United States, radiation dose is measured in units of rad or rem. Smaller fractions of the rem are the millirem (1 millirem = 1/1,000 rem) and the microrem (1 µrem = 1/1,000,000 rem).

Regarding groundwater monitoring programs, annual monitoring has detected tritium-contaminated groundwater in a well beyond the NNSS boundary. The well is a monitoring well that is on federally controlled land (the Nevada Test and Training Range), and there are no indications that contaminated groundwater has migrated to any wells that supply water to members of the public. Consequently, there is no radiation dose incurred by the public from the groundwater pathway. Groundwater monitoring programs are discussed in more detail in Section 4.1.6.2.

Radioactive airborne emissions at the NNSS are monitored on site to ensure compliance with NESHAPs under CAA. A network of 19 air sampling stations and a network of 109 thermoluminescent dosimeters are located throughout the NNSS, primarily within operational areas where historic nuclear testing has occurred or where current radiological operations occur. Air sampling stations monitor tritium, manmade radionuclides, and gross alpha and beta activity in airborne particulates that result either from current site operations or from activities such as environmental restoration that resuspend material at legacy testing locations. Thermoluminescent dosimeters monitor direct gamma radiation exposure.

The total amounts of manmade radionuclides that were emitted to the air from all sources on the NNSS in 2008 were estimated to be 440 curies of tritium, 0.047 curies of americium-241, 0.050 curies of plutonium-238, 0.29 curies of plutonium-239 and -240, and 0.60 curies of depleted uranium. Since the cessation of atmospheric nuclear testing, the annual releases into the air have ranged from 48 to

2,200 curies for tritium, 0.0018 to 0.40 curies for plutonium, and 0.039 to 0.049 curies for americium. These emissions cannot be distinguished from the background airborne radiation measured in communities surrounding the NNSS. Potential radioactive emissions are monitored at stations in selected towns and communities within 240 miles of the NNSS by the independent CEMP. Its purpose is to provide monitoring for radionuclides that may be released beyond the confines of the NNSS boundary. A network of 29 CEMP stations is in use; these stations monitor gross alpha and beta activity, gamma radiation, and meteorological parameters (see Section 4.2.8.3) (DOE/NV 2009d).

4.1.12.2 Occupational Radiation Exposure and Safety

NNSS workers receive the same dose as the general public from background radiation, but they receive an additional dose from working in and near facilities or areas with radioactive material. The average dose to the individual worker and the cumulative dose to all workers at the NNSS from operations in 2008 are presented in **Table 4–54**. Using a risk coefficient of 0.0006 LCFs per person-rem, the projected LCF risk among NNSS workers from normal operations in 2008 was 0.0033. The largest dose received by a worker in 2008 was 451 millirem (Enyeart 2009); the increased risk of an LCF from this dose was 0.00027.

The average dose of 70 millirem in 2008 is comparable to the average doses over the prior 5-year period (2003–2007) of 46 to 81 millirem (DOE 2006a, 2009n).

Table 4–54 Radiation Doses to Workers from Nevada National Security Site Normal Operations in 2008 (Total Effective Dose Equivalent)

Workers	*Onsite Releases and Direct Radiation*	
	Standard [a]	*Actual*
Maximally exposed worker (millirem)	5,000	451
Average radiation worker (millirem)	None	70
Total of all radiation workers (person-rem) [b]	None	5.2

rem = roentgen equivalent man.
[a] No standard is specified for an "average radiation worker"; however, the maximum dose to a worker is limited as follows: The dose limit for an individual worker is 5,000 millirem per year (10 CFR Part 835). However, DOE's goal is to maintain radiation exposure as low as is reasonably achievable (ALARA). DOE has, therefore, established an Administrative Control Level of 2,000 millirem per year; the site contractor sets facility administrative control levels below the DOE level, with 500 millirem per year considered a reasonable goal for trained radiation workers.
[b] There were 75 workers with measurable doses in 2008.
Note: Total radiation worker dose presented in the table slightly differs from that calculated from data shown due to rounding.
Source: 10 CFR 835.202; DOE 1999e, 2009n; Enyeart 2009.

Worker occupational risks are generally associated with activities such as waste handling, construction, environmental restoration, and decontamination and decommissioning. DOE's Computerized Accident/Incident Reporting System provides statistics on worker injury and illness information, including accidents involving government-owned vehicles. Although the total number of hours worked showed an upward trend between 1996 and 2005, the rate of total recorded cases per 200,000 hours worked remained fairly stable, as did the rates of accident cases causing days away from work, restricted work, or job transfer (DART cases). These accident statistics are comparable to those for the DOE complex as a whole. In 2006, the total recorded accident/incident case rate at the NNSS was 2.3, and the DART case rate was 0.9; the comparative rates for 2006 over the entire DOE complex were 1.6 and 0.7, respectively. From 1996 through 2004, accident rates for government vehicles at the NNSS averaged 0.5 accidents per million vehicle miles, while the overall DOE/NNSA accident rates over this period averaged 1.7 accidents per million vehicle miles. In addition, it is noteworthy to mention that a key Lessons Learned (DOE 2002b) implemented in 2002, which consisted of holding a weekly roundtable discussion focused on safety between managers and staff, was responsible for eliminating injury incidents for the better part of the following annual period. This implementation focused on the initiation of regular weekly roundtable discussions between managers and workers during scheduled safety meetings. It is

these types of programs and recognition that are regularly set in place at the NNSS in an effort to keep an accident goal of "zero accidents/incidents" with "zero work-days lost" (DOE 2008f, 2009m).

4.1.12.3 Chemical Exposure and Risk

The background chemical environment important to human health consists of the atmosphere, which may contain hazardous chemicals that can be inhaled; drinking water, which may contain hazardous chemicals that can be ingested; and other environmental media, through which people may come in contact with hazardous chemicals. Hazardous chemicals can cause cancer and non-cancer-related health effects.

Because of the NNSS's remote location and large size, there is no risk of chemical exposure to the surrounding public population resulting from normal site operations. Nevertheless, monitoring efforts and baseline studies are regularly performed. However, certain workers at the NNSS are at risk of chemical exposure depending on their job function and proximity to various sources.

Of key concern at the NNSS is exposure to beryllium. Beryllium can cause acute respiratory disease (for which a workplace air concentration limit has long been in place), and chronic beryllium exposure can cause lung disease. In December 1999, DOE promulgated the Chronic Beryllium Disease Prevention Program (64 FR 68853), and in February 2006, DOE included the program in worker safety and health regulations established to govern contractor activities at DOE sites (71 FR 6857). DOE/NNSA has implemented the program at the NNSS to reduce the number of workers potentially exposed to beryllium and establish a medical surveillance program for early detection of the disease. DOE sponsors and funds a screening program for former DOE workers who may have been exposed to beryllium at the NNSS and other DOE sites.

As discussed in Section 4.1.8, common sources of chemical air pollutants at the NNSS include various particulate matter from construction activities, aggregate production, surface disturbances, fuel-burning equipment, state-authorized open burning, fuel storage facilities, and chemical release tests conducted at NPTEC. An estimated 6.05 tons of criteria air pollutants were released on the NNSS in 2008. The majority of the emissions comprised nitrogen oxides from diesel generators. Total air emissions of lead were 4.56 pounds, and the total quantity of hazardous air pollutants released in 2008 was 0.09 tons. Other emitters included carbon monoxide, sulfur dioxide, and volatile organic compounds, all in quantities well below emission criteria limits (DOE/NV 2009d).

As for monitoring potential chemicals released to drinking water and wastewater systems at the NNSS, six permitted wells on the NNSS serve the drinking water needs of NNSS workers and visitors. The wells are regularly monitored for potability and purity. In 2008, water samples from these wells (in addition to potable-water hauling trucks) met all national primary and secondary drinking water standards. In addition, site operating lagoon systems are tested for biochemical oxygen demand, pH, total suspended solids, and a suite of toxic chemicals; all lagoon water measurements were found to be within permit limits in 2008. Discharge water at the site is also tested for a host of potential contaminants. In 2008, no contaminants were detected at levels that exceeded permit limits (DOE/NV 2009d).

Regarding risks from handling toxic or hazardous chemicals, worker safety programs at the NNSS are enforced via required adherence to Federal and state laws; DOE Orders; Occupational Safety and Health Administration requirements; EPA guidelines; and plans and procedures for performing work, including training, monitoring, use of personal protective equipment, and administrative controls. Although chemical inventories have varied to a limited extent over recent years, administrative controls continually ensure that quantities do not approach levels that pose undue risk due to storage, concentration, bulk quantity, or logistical factors. Any amounts that potentially exceed threshold planning quantities require reporting under Federal regulations (40 CFR Part 355; 40 CFR Part 370).

4.1.12.4 Health Effects Studies

There have been numerous studies conducted over the years examining the potential health effects that U.S. populations may have incurred from exposure to fallout associated with the NNSS atmospheric nuclear tests. Most notable are those discussed below.

A 1979 study reported in the *New England Journal of Medicine* concluded that a significant excess of leukemia deaths occurred in children up to 14 years of age living in Utah between 1959 and 1967. This excess was concentrated in the cohort of children born between 1951 and 1958, and was most pronounced in those residing in Utah counties receiving high fallout. Mortality increased by 2.44 times (95 percent confidence, 1.18 to 5.02) to just slightly above that of the United States in the high-exposure cohort residing in the high-fallout counties, and was greatest in 10- to 14-year-old children. For other childhood cancers, no consistent pattern was found in relation to fallout exposure (NEJM 1979).

In 1994, DOE published a report entitled *Development of the Town Data Base: Estimates of Exposure Rates and Times of Fallout Arrival Near the Nevada Test Site* in an effort to model public radiation exposure rates in populated areas of Nevada, California, Arizona, and Utah at the time of fallout arrival and at 12-hour intervals thereafter. This report only focused on empirical exposure rate data (e.g., intensity isopleths across land areas) and did not convey interpretations of associated resulting health effects on potentially affected populations (DOE/NV 1994). In a 1997 report by the National Cancer Institute, it was determined that 90 atmospheric tests at the NNSS deposited high levels of iodine-131 (149 million curies) across a large portion of the contiguous United States during the 1950s and 1960s, especially in 1952, 1953, 1955, and 1957; the resulting doses were large enough to produce 10,000 to 75,000 cases of thyroid cancer and had the potential of being the causational link for up to 212,000 cases. Results of the study show that, depending on their age at the time of the tests, where they lived, and what foods they consumed, particularly milk, Americans were exposed to varying levels of iodine-131 (which accumulates in the thyroid gland) for about 2 months following each of the 90 tests, after which the isotope decayed to essentially harmless levels. Rain, wind, and the food supply spread iodine-131 from these tests across the United States, with the largest deposits immediately downwind of the NNSS and the lowest on the west coast, upwind of the NNSS. The average cumulative thyroid dose to approximately 160 million people who lived in the United States during the testing era was about 2 rad, about five times the radiation dose emitted by a mammogram. Americans were exposed to varying levels depending on their residence, age, and food consumption. People who lived in the western states to the north and east of the NNSS, such as Colorado, Idaho, Montana, South Dakota, and Utah, had the highest per capita thyroid doses, ranging from 9 to 16 rad. Children between 3 months and 5 years old in these high-fallout areas probably received three to seven times the average dose for the population in their county because they had smaller thyroids and tended to drink more milk than adults (NCI 1997).

Milk was a major exposure vehicle because iodine-131 was deposited on pasture grasses and then consumed by cows. However, an estimated 20,000 people who drank goats' milk during the testing years were at an even greater risk because the iodine-131 was more concentrated in goats' milk than cows' milk. Thyroid doses to the individuals who drank goats' milk could be 10 to 20 times greater than those to residents of the same county who were the same age and gender, and drank an equal amount of cows' milk. Other pathways included inhaling contaminated air or ingesting tainted leafy vegetables, cottage cheese, and eggs. However, the relationship between iodine-131 and thyroid cancer still is not fully known. It makes up less than 1 percent of cancer cases nationwide each year, and cancer registries do not indicate that fallout has caused an epidemic, although record-keeping did not start until the early 1970s (NCI 1997).

A Centers for Disease Control and Prevention report states that fallout from the NNSS, combined with nuclear tests conducted overseas by the United States and other countries, could ultimately be responsible for an additional 17,000 cancer deaths (CDC/NCI 2001).

Studies investigating potential impacts on American Indians from exposure to iodine-131 suggest that doses to this group could have been larger than those calculated for the general population. For the general population, the major exposure pathway was the ingestion of milk; additional exposure pathways considered were inhalation of contaminated air and ingestion of contaminated greens, cheese, and eggs. Evaluations show that exposures via the wild game pathway may have an increased food-chain-related thyroid dose and consequent risk. Therefore, for people eating a diet heavy in small wild game, the major exposure route may be the wild game. The analysis suggests that Duckwater, Nevada (north of the NNSS), residents, who were exposed to contaminated milk in addition to contaminated game, experienced a greater thyroid cancer risk than people whose primary exposure pathway was cows' milk (Russ et al. 2005).

In regard to potential health effects on onsite military and DoD civilian participants during the testing years, the Nuclear Test Personnel Review Program, administered by the U.S. Defense Threat Reduction Agency, was implemented to (1) confirm veteran participation in U.S. atmospheric nuclear tests from 1945 to 1962 and (2) upon confirmation, provide either an actual or estimated radiation dose received by the veteran, leading to potential financial dispensation (via the U.S. Department of Veterans Affairs) associated with a presumptive adverse health condition resulting from this dose. Each dose assessment, thousands of which have been conducted since the program's inception in 1978, can be interpreted as an independent radiation exposure health effects study. Outside of the Nuclear Test Personnel Review Program, there have been numerous other financial claims independently submitted against the Federal Government by employees at the NNSS, alleging similar adverse health effect manifestations resulting from their involvement or presence during the testing era.

There are no studies that indicate adverse health effects in populations near the NNSS as a result of activities or operations supporting the current NNSS missions.

4.1.12.5 Accident History

Nuclear testing began at the NNSS in 1951. There were 100 atmospheric nuclear explosions before the Limited Test Ban Treaty was implemented in 1963. Nuclear tests were conducted underground until October 1992, when the nuclear testing moratorium was implemented. Since 1970, there have been 126 nuclear tests that released approximately 54,000 curies of radioactivity to the atmosphere. Of this amount, 11,500 curies were accidental due to containment failure (massive releases or seeps) and late-time seeps (small releases after a test, when gases diffuse through pore spaces of overlying rock). The remaining 42,500 curies were operational releases. From the perspective of human health risk, if the same person had been standing at the boundary of the NNSS in the area of maximum concentration of radioactivity for every test since 1970, that person's total exposure would be equivalent to 32 extra minutes of normal background exposure, or the equivalent of one-thousandth of a single chest x-ray (OTA 1989).

As with nuclear testing, accidents have occurred in the past that are associated with the unique type of work and experiments performed at the NNSS. Because of the change in the work performed on the NNSS, similar accidents have no or little likelihood of occurring in the future.

- Collapses of the ground surface above underground nuclear tests have resulted in worker injury.
- Explosive accidents have occurred and resulted in injuries to workers; for example, a hydrogen explosion during a post-test re-entry resulted in worker injuries.

In addition to the above accidents that were unique to the NNSS, other accidents similar to those that might occur at a large industrial site have also occurred at the NNSS.

- Vehicle accidents have occurred, ranging from minor accidents resulting only in property damage to more severe accidents resulting hospital treatment of injuries, and in a few cases, fatalities. Inclement weather contributed to difficult driving conditions in some of the accidents.

- Workers have been exposed to hazardous materials during the course of their work. Incidences have included exposure to radioactive materials, for example, during borehole management, and exposure to chemicals, for example, during a training exercise.
- Accidents involving energized electrical systems have occurred, resulting in near misses or worker shock. For example, workers have cut cables or penetrated buried cables that were energized; other instances involved workers performing inspections, maintenance, or repairs on panels or equipment that were not fully secure (loose wires, systems that were thought to be de-energized).
- A variety of industrial accidents have occurred, resulting in employee impacts ranging from mild injuries to severe injuries to fatalities. Examples include sprains, strains, or fractures from accidents associated with lifting or walking over difficult terrain; lacerations or cuts (including a severed fingertip) when equipment that was being worked on moved unexpectedly; hazards from collapse of excavation walls, falls from scaffolding/elevated platforms, and failure of rigging; and injuries from working near or with pressurized systems that fail, impacting workers.
- Natural phenomena have resulted in accidents, some that have threatened or impacted workers. Lightning has caused fires on the NNSS, as well as injuring an employee. High winds have caused damage to buildings, trailers, and utility poles, thereby posing a threat to workers.

4.1.12.6 Emergency Preparedness

Each DOE site has established an Emergency Management Program, developed in accordance with DOE Order 151.1C, *Comprehensive Emergency Management System*, that would be activated in the event of an accident. This program has been developed and maintained to ensure adequate response for postulated accident conditions and to provide response efforts for accidents not specifically considered. The Emergency Management Program incorporates activities associated with emergency planning, preparedness, and response. The DOE/NNSA NSO Consolidated Emergency Plan is designed to document all aspects of the site's Emergency Management Program, including provisions to effectively and efficiently respond to an operational emergency, and minimize the consequences of an emergency event for the health and safety of workers, responders, the public, and the environment. The plan integrates all emergency planning into a single entity to minimize overlap and duplication and to ensure proper responses to emergencies not covered by a plan or directive. DOE/NNSA coordinates emergency response planning and training with local governments. In accordance with the National Incident Management System, the coordination ensures that communications systems and equipment are interoperable and that personnel and equipment can be effectively deployed in the event of an emergency. The DOE/NNSA NSO Site Manager has the responsibility to respond, manage, and recover from an emergency occurring at the NNSS.

The plan provides for identification and notification of personnel for any emergency that may develop during operational and nonoperational hours. DOE/NNSA receives warnings, weather advisories, and any other communications that provide advance warning of a possible emergency. The plan is based upon current DOE/NNSA vulnerability assessments, resources, and capabilities regarding emergency preparedness.

4.1.12.7 Environmental Noise

The acoustic environment in areas adjacent to the NNSS is characteristic of uninhabited desert areas or small rural communities where natural phenomena, such as wind and rain, account for most of the background noise. Manmade noise in some areas of the ROI is caused by vehicles traveling along public highways and an occasional military aircraft. The Creech Air Force Base and the Desert Rock Airstrip are located near the southern border of the NNSS and generate intermittent increases in noise levels in the surrounding area. Although no ambient noise data are available, monitoring measurements from

communities with similar environmental settings show that day–night average noise levels from such communities typically range from 45 to 65 decibels, A-weighted[24] (DOE 2008d).

Major sources of noise at the NNSS include equipment and machines, blasting and explosives experiments, aircraft operations, and vehicles. Explosives at BEEF and other areas in the Nuclear and High Explosives Test Zone (Areas 1, 2, 3, 4, 12, and 16), Areas 5 and 26, and the Explosives Ordnance Disposal Unit in Area 11 occasionally result in increased acute noise levels (less than 10 times per year at each site) (Morris 2009). Because of the NNSS's remote location, large size, access restrictions, and lack of a nearby population, the general public has little to no exposure to noise generated within the NNSS. The closest sensitive receptors to the site boundary are residences located approximately 1 mile to the south, in Amargosa Valley. At the NNSS boundary, away from most facilities, noise from most sources within the NNSS is barely distinguishable above background noise levels. Traffic generated by personnel commuting to and from work and occasional aircraft operations are the main NNSS-related contributors to increased noise levels in nearby communities.

Section 4 of the Noise Control Act of 1972, as amended (42 U.S.C. 4901 et seq.), directs Federal agencies to carry out programs in their jurisdictions "to the fullest extent within their authority" and in a manner that furthers a national policy of promoting an environment free from noise that jeopardizes health and welfare. The Occupational Safety and Health Administration regulations (Occupational Noise Exposure; Hearing Conservation Amendment, 29 CFR 1910.95) require hearing conservation and protection for all employees potentially exposed to criteria noise levels. Standards issued under the authority of the DOE Manual 440.1-1A, *DOE Explosives Safety Manual*, establish safety requirements applicable to operations involving the development, testing, handling, and processing of explosives, including noise protection guidelines during the detonation of explosives (DOE 2006c). High-explosives experiments must be conducted in accordance with this directive. Except for the prohibition of nuisance noise, neither the State of Nevada nor local governments have established specific environmental noise standards. Occupational noise exposure is regulated to the extent required by law.

4.1.13 Environmental Justice

Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*, requires identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental impacts of Federal programs, policies, and activities on minority and low-income populations.

This section presents a summary of the demographic analysis prepared to analyze the potential impacts on low-income and minority populations affected by the programs discussed in this SWEIS. Demographic analysis is the first step in determining disproportionately high and adverse human health or environmental effects on low-income and minority populations. This analysis sets the stage for the impacts analysis presented in Chapter 5. Demographic analysis includes defining the ROI, census block groups, low-income populations, and minority communities.

The ROI for analyzing environmental justice in this SWEIS comprises Nye and Clark Counties, Nevada. DOE/NNSA did not consider areas outside Clark and Nye Counties because any impacts extending beyond this area would impact the population equally and would not have a disproportionately adverse impact on low-income or minority communities.

CGTO has also identified areas and nearby lands as culturally important to American Indian peoples. Although many of the American Indian groups live outside Clark and Nye Counties, American Indian peoples continue to value and recognize traditional ties to the NNSS and surrounding area. In recognition of these traditional ties, DOE/NNSA has established a relationship with CGTO. Specific aspects of the

[24] A decibel is a unit that expresses the relative intensity of sounds on a logarithmic scale where 0 is below human perception and 130 is above the threshold of pain to humans. The A-weighted decibel scale corresponds approximately to the frequency response of the human ear and thus correlates well with loudness.

participation of the group in DOE/NNSA cultural resources management projects are discussed in Section 4.1.10.2. CGTO has also presented additional viewpoints on environmental justice in Chapters 4 and 5 and Appendix C of this SWEIS.

4.1.13.1 Methodology

DOE/NNSA used the Council on Environmental Quality definition of low-income and the annual statistical poverty thresholds from the U.S. Census Bureau in its environmental justice analysis. A low-income community exists when the percentage of low-income people in the area of interest is meaningfully greater than the corresponding percentage in the general population. For purposes of analysis, DOE/NNSA used the state-wide average of 11.2 percent to define the percentage of low-income people in the general population. To identify low-income populations, DOE/NNSA used Census Bureau data for census block groups (USCB 2000, 2008b) where the percentage of low-income people exceeded the state average (sorted into ranges of 11–20, 21–30, and greater than 30 percent). The census block group, which typically consists of between 600 and 3,000 people, with an optimal size of 1,500 people, is the smallest census unit for which the Census Bureau releases income data (to protect confidentiality).

DOE/NNSA followed the Council on Environmental Quality guidance, which considers a minority population to exist where either (1) minority individuals in the affected area exceed 50 percent of the population or (2) the percentage of minority individuals in the affected area is meaningfully greater than the corresponding percentage in the general population or other appropriate unit of geographic analysis. The state-wide percentage of minority individuals (used to represent the general population) is 38.2 percent. For purposes of analysis, DOE/NNSA identified census block groups where the percentage of minority individuals was greater than 50 percent.

4.1.13.2 Low-Income Populations

Poverty thresholds are dollar amounts the Census Bureau uses to determine poverty status. In 2008, the weighted average threshold for households with two people was $14,051; that for households with three people was $17,163.

In 2008, the average household size for Clark County was 2.66; that for Nye County was 3.22. For purposes of analysis, DOE/NNSA rounded the average household size for the counties within the ROI—an average household size of 3 was used for Clark and Nye Counties.

Census data were available for the number of households with an income less than $15,000 and those with an income between $15,000 and $24,999. DOE/NNSA used the combined number of households with incomes less than $24,999 as the poverty threshold for Clark and Nye Counties.

Analysis of the data (see **Figure 4–35**) illustrates that there are numerous census block groups with low-income populations between 11 and 20 percent (that is, at or above the state-wide average) distributed throughout the ROI, including large (but sparsely populated) block groups adjacent to the NNSS. Block groups with low-income populations in the 21–30 and greater-than-30 percent ranges are found further to the east in the Las Vegas metropolitan area, closer to the RSL and NLVF facilities (see Sections 4.2.13 and 4.3.13).

4.1.13.3 Minority Populations

There are no block groups in Nye County (the county the NNSS is located within) with minority populations greater than 50 percent. Within the ROI, the closest block group to the NNSS with a minority population greater than 50 percent is Census Tract 5818, Block Group 1, in Clark County; approximately 2 miles east of the southeastern corner of the NNSS (see **Figure 4–36**). Additional block groups with minority populations greater than 50 percent are found further to the east in the Las Vegas metropolitan area, closer to the RSL and NLVF facilities (see Sections 4.2.13 and 4.3.13).

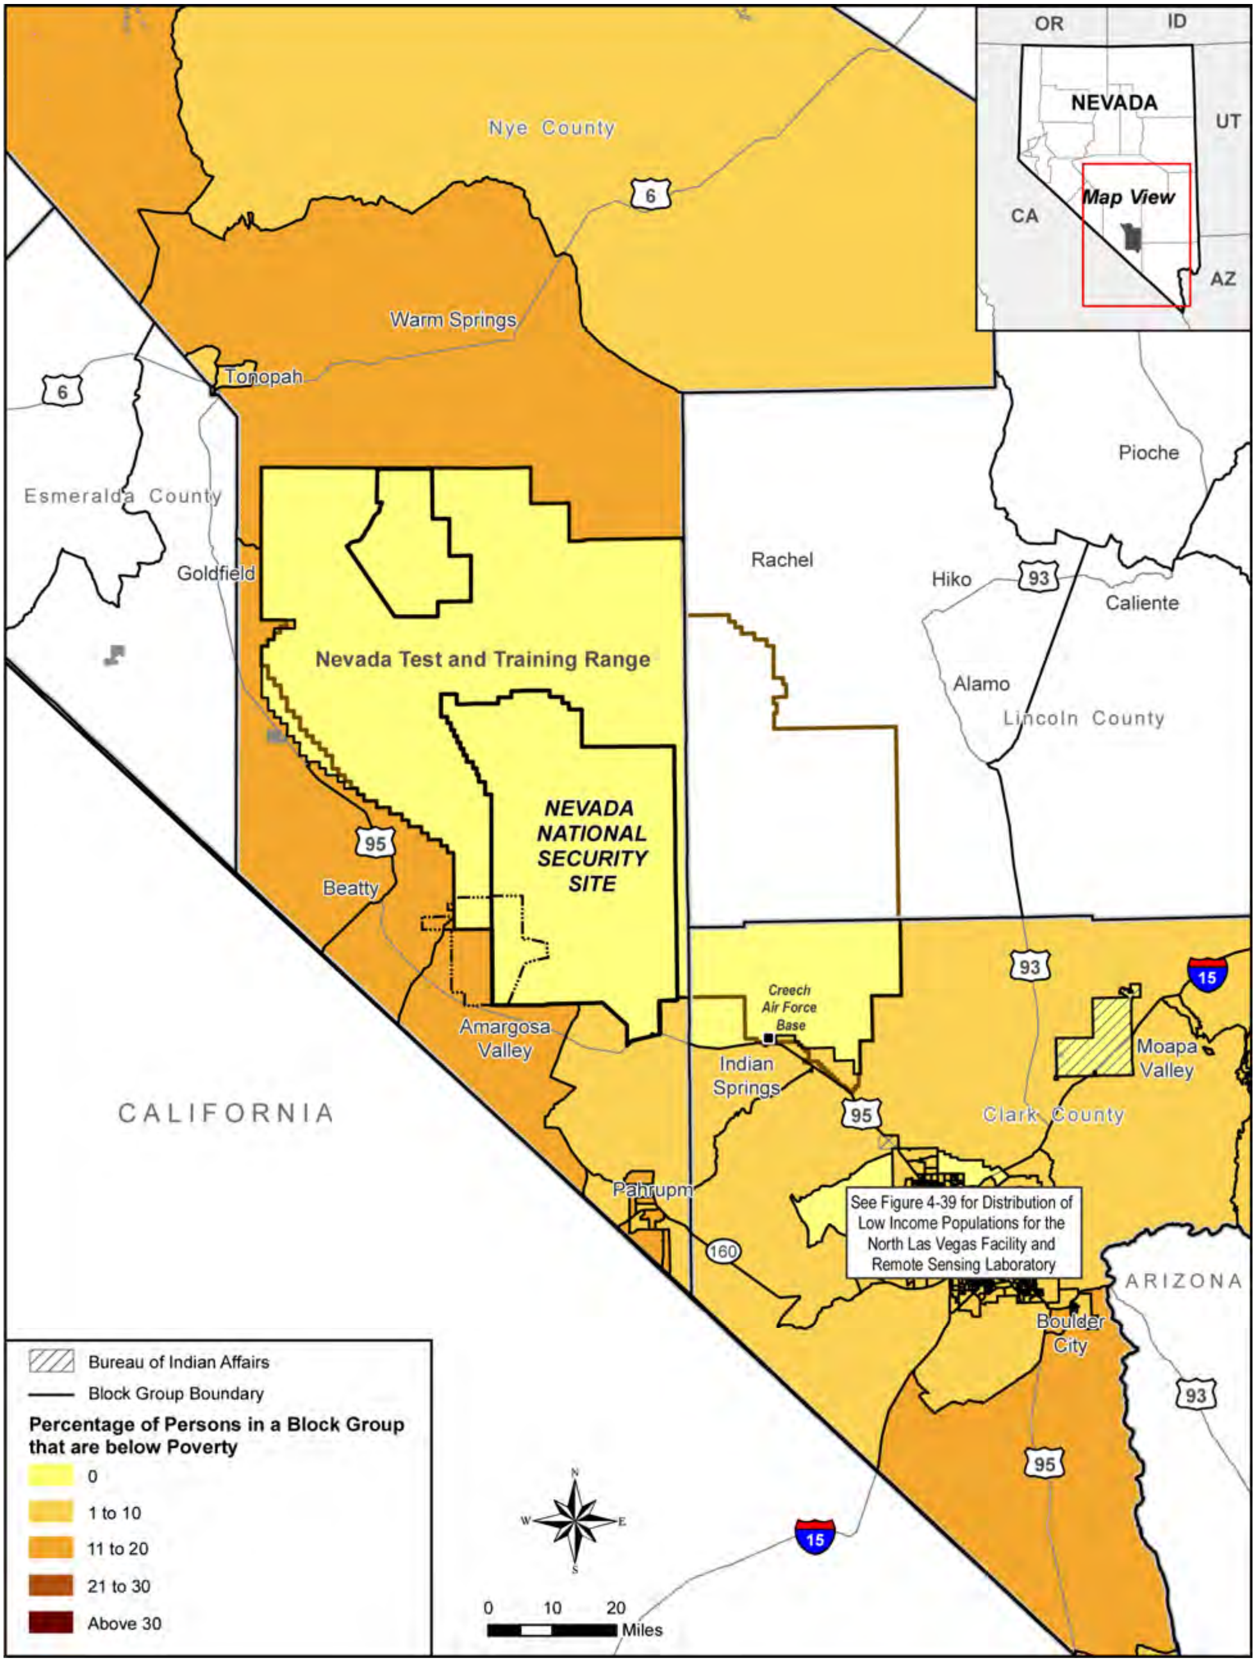

Figure 4–35 Distributions of Low-Income Populations for the Nevada National Security Site and the Tonopah Test Range

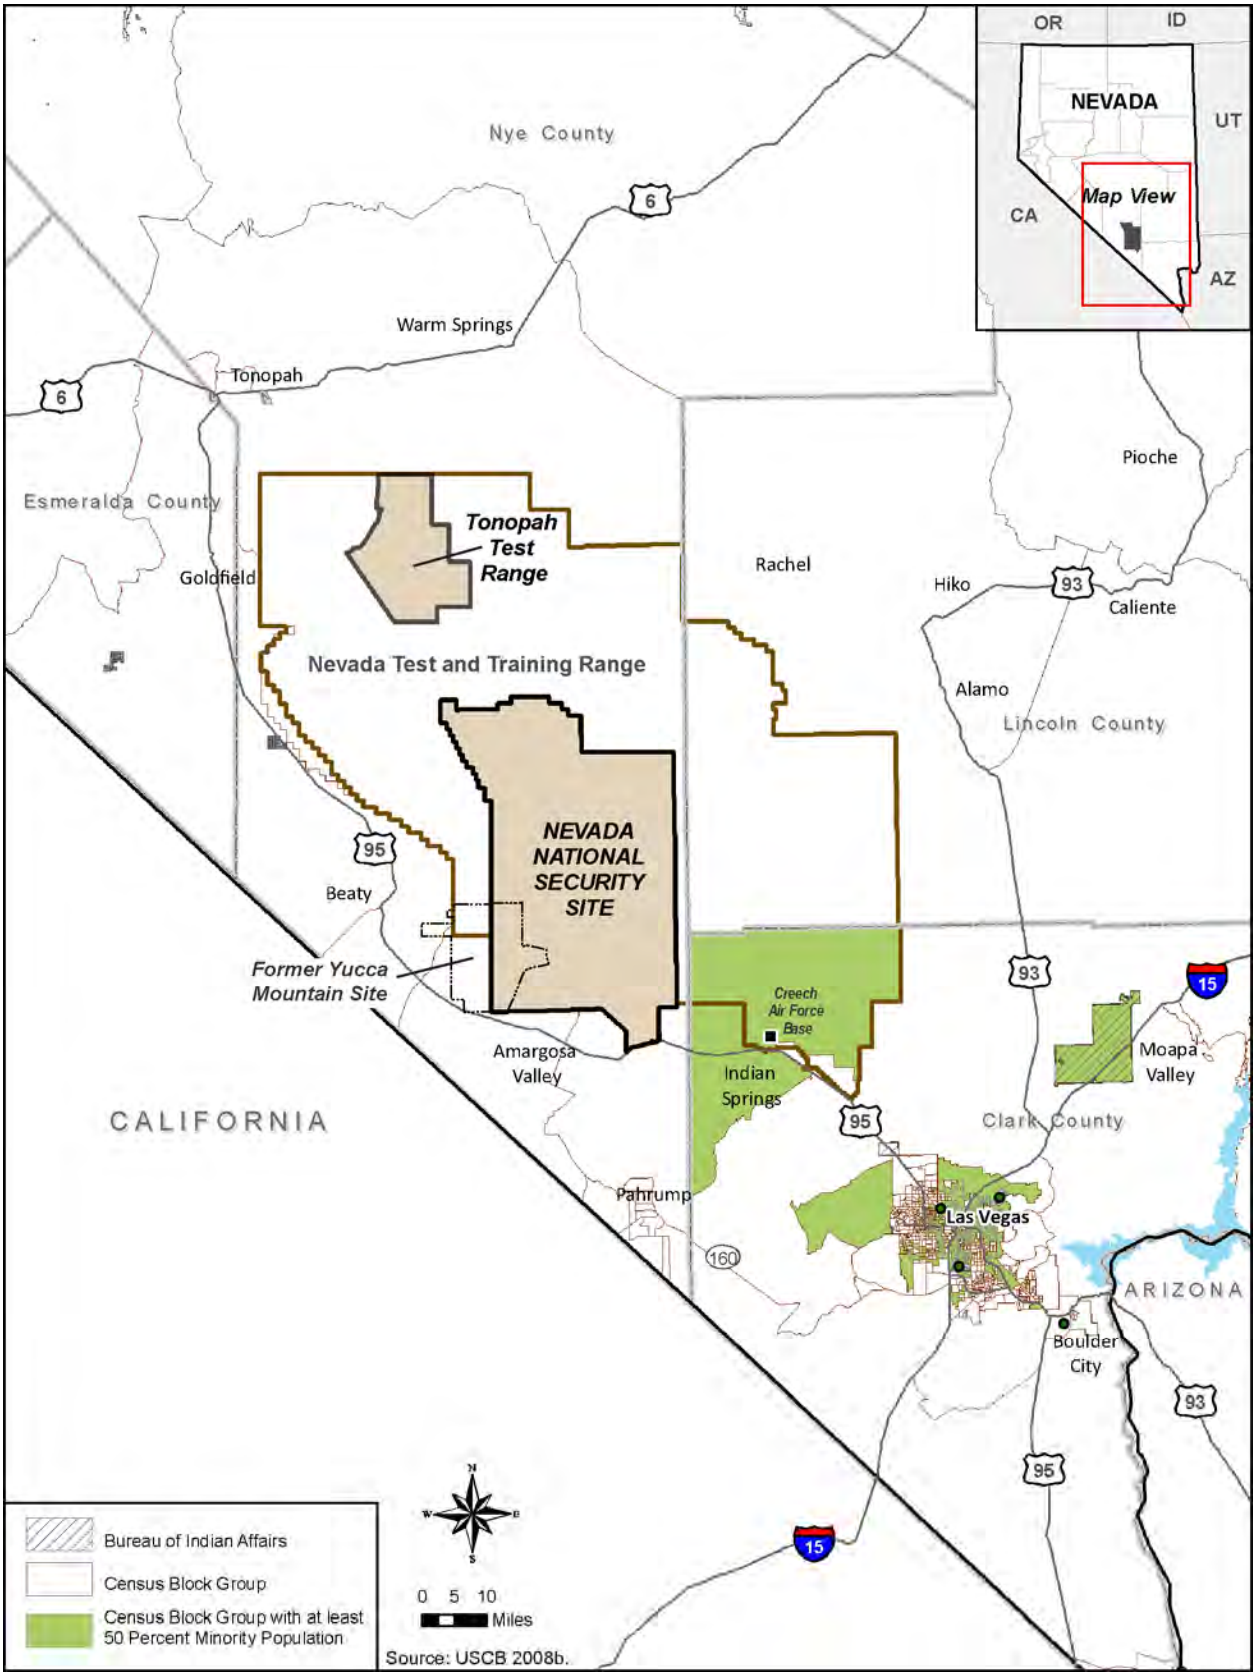

Figure 4–36 Nevada National Security Site and Tonopah Test Range Distributions of Minority Populations Greater than 50 Percent

4.2 Remote Sensing Laboratory

This section describes the existing environmental conditions at RSL. RSL is located adjacent to the main runway on Nellis Air Force Base, in North Las Vegas, Nevada. RSL provides emergency response resources for incidents involving weapons of mass destruction through the development and customization of state-of-the-art instruments and remote sensing technologies.

4.2.1 Land Use

RSL, located on Nellis Air Force Base, is approximately 8.5 miles northeast of the center of Las Vegas. This land is federally owned and withdrawn from the public for military use. Nellis Air Force Base is located adjacent to the city of North Las Vegas to the north and west, the city of Las Vegas to the south and west, and public lands managed by BLM to the east and south. In accordance with a Memorandum of Agreement with the USAF, DOE/NNSA leases the land under a 25-year lease (starting in 1989), with an option for two term extensions (DOE 2009f). The facility, initially occupied in 1989, is located on approximately 35 secured acres and comprises seven buildings used for research, testing, and fabrication laboratories and shops. RSL totals 168,012 gross square feet (DOE 2008f, 2008i). There is no public access to RSL.

Federal regulations and the Integrated Natural Resources Management Plan for Nellis Air Force Base and the Nevada Test and Training Range, developed in May 2007, restrict land use on Nellis Air Force Base. This resource plan was developed to provide guidance for the conservation of natural resources on the installation. The guidelines have been developed within the context of the military mission at Nellis Air Force Base. Private development on the base is not allowed under this mission. Through the guidelines and recommendations in the resources plan, land conservation and natural resource protection is imposed; however, mission needs take precedent (USAF 2007c).

4.2.1.1 Adjacent Land Use

Nellis Air Force Base entirely surrounds RSL. Nellis Air Force Base is a secured military installation and is currently used for aircraft operations and maintenance, weapons storage, rock quarrying, and housing and offices. A large portion of the installation is undeveloped.

The 11,300-acre Nellis Air Force Base is divided into three major functional areas. RSL is within Nellis Air Force Base Area III, which is located just east of Las Vegas Boulevard and adjacent to Nellis Air Force Base Area I. Area III contains housing, a hospital, a runway, and open space (USAF 2010c). The surrounding land to the east and portions to the north of Nellis Air Force Base are managed by BLM's Southern Nevada District Office.

4.2.2 Infrastructure and Energy

4.2.2.1 Infrastructure and Utilities

This section discusses the RSL buildings and transportation infrastructure; potable water, wastewater, and communications utilities; and support services, including law enforcement and security, fire protection, and health care. Further transportation-related information is discussed in Section 4.2.3. Solid waste collection is discussed in Section 4.2.11. Energy systems (electricity, natural gas, and liquid fuels) are discussed in Section 4.2.2.2.

4.2.2.1.1 Infrastructure

Facilities. As stated above, RSL comprises seven DOE/NNSA buildings, all leased from the USAF. The total floor space at RSL is approximately 161,528 square feet, as shown in **Table 4–55**, presented according to building function.

Table 4–55 Remote Sensing Laboratory Building Floor Space by Function

Function	*Floor Space (square feet)*
Administrative	0
Storage	16,454
Industrial/Production/Process	0
Research and Development	144,059
Service Buildings	0
Other	1,015
TOTAL	161,528

Source: NNSA/NSO 2009b.

Transportation Systems. RSL is located on Nellis Air Force Base, adjacent to the runway. There are no railroads at RSL. According to an agreement with the USAF, RSL has access to and use of the runway for mission purposes.

4.2.2.1.2 Utilities

Water Supply. Potable water sources at Nellis Air Force Base include five active government-owned and -operated wells (three wells located off base and two wells located on base) and water purchased from the Southern Nevada Water Authority via bulk-supply pipelines from Lake Mead (NAFB 2005). The base also purchases a small quantity from the City of North Las Vegas Water District. The existing water supply at Nellis Air Force Base is considered adequate.

The water system at RSL suffers from low pressure and limited supply capability. DOE/NNSA is working with Nellis Air Force Base officials to address these issues (DOE 2008f). See Section 4.2.6 for more information on the water supply.

Wastewater Collection and Treatment Systems. RSL wastewater is discharged to existing municipal sewage systems. RSL holds an Industrial Wastewater Discharge Permit (Permit Number CCWRD-080) from the Clark County Water Reclamation District (DOE/NV 2009d).

Communication Systems. RSL has standard communications services (e.g., telephone, internet). RSL has recently undergone extensive fiber optic communications and LAN systems upgrades, bringing the facility up to technological standards, so that it is currently able to function at peak efficiency.

4.2.2.2 Energy

4.2.2.2.1 Electrical Energy

Electrical energy at RSL is supplied by three sources as follows: 65 percent by NV Energy; 10 percent by Western Area Power Administration (Hydropower); and 25 percent by Solar Star, Inc. (the Nellis Air Force Base Solar photovoltaic project). In FY 2009, RSL's electrical usage was 4,850 megawatt-hours (NNSA/NSO 2010b). The existing electrical distribution system at RSL is capable of supporting present demands (DOE 2008f). According to the *FY 2009 NNSA/NSO Ten-Year Site Plan*, the RSL electrical distribution system is slated for improvements in 2014 (DOE 2008i).

As part of energy conservation efforts under Energy Saving Performance Contract funding, buildings at RSL have been retrofitted with low-energy light fixtures (NSTec 2008b).

4.2.2.2.2 Natural Gas

Natural gas at RSL is provided by the Southwest Gas Corporation via 2-inch-high pressure gas lines. Natural gas is regulated to low pressure at three locations. In FY 2009, RSL used 33,673 therms of natural gas (NNSA/NSO 2010b). There is adequate capacity to serve current demands, and the condition of the gas lines is satisfactory (NSTec 2010i).

4.2.2.2.3 Liquid Fuels

RSL maintains liquid-fueled boilers, water heaters, and emergency generators. The underground storage tank program at RSL/Nellis Air Force Base consists of two active permitted tanks (one 550-gallon gasoline tank and one 550-gallon diesel fuel tank), one inactive tank (empty used oil tank), one deferred tank (as per 40 CFR 280.10(d)) for emergency power generation, and three unregulated tanks. The permitted and deferred tanks are located at Building 2211 (DOE/NV 2009d). The two permitted tanks supply RSL with fuel used for the various forklifts, generators, and other onsite needs.

RSL maintains five aircraft that carry out remote sensing operations. These aircraft use approximately 111,030 gallons of JP-8 jet fuel annually (NNSA/NSO 2010b). Nellis Air Force Base provides all JP-8 jet fuel for RSL assets (NSTec 2010i). RSL currently does not use any alternative form of fuel (e.g., E85).

4.2.3 Transportation

4.2.3.1 Onsite Transportation

RSL is located within Nellis Air Force Base, which has several access gates. RSL can be accessed by most of the gates at the base. Hollywood Gate is the gate closest to RSL and may be used by authorized personnel to access the base during designated morning and afternoon hours. As shown in **Figure 4–37**, Access Road provides traffic circulation around RSL facilities and parking areas.

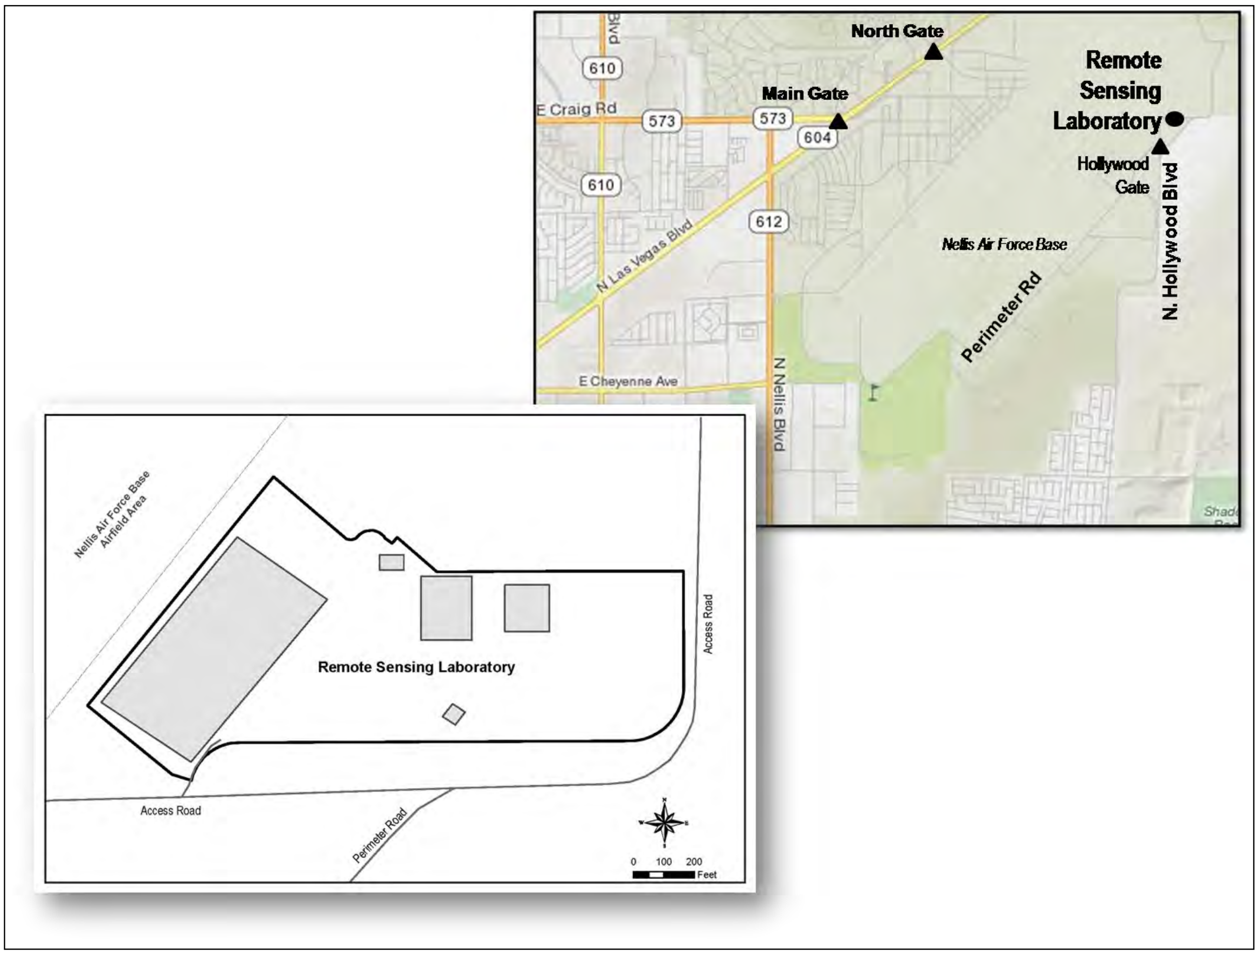

Figure 4–37 Remote Sensing Laboratory Roadways

4.2.3.2 Regional Transportation

The primary access points are the Main Gate and North Gate, which are both located on North Las Vegas Boulevard (see Figure 4–37). The Main Gate is open 24 hours daily, and the North Gate is open from 5:00 A.M. to 5:00 P.M. daily. Access to RSL is provided by Perimeter Road, near Nellis Boulevard (also known as Nevada State Route 612) in the eastern portion of the North Las Vegas region. Traffic volumes and levels of service on roadways in the Las Vegas metropolitan area are discussed in Section 4.1.3.2.2. Traffic volumes near RSL are represented by Las Vegas Boulevard and Nellis Boulevard, presented in Table 4–11; these roadways experience moderate-to-high daily traffic volumes and are operating at levels of service A and B, respectively.

4.2.4 Socioeconomics

General existing socioeconomic conditions within the ROI of RSL (Clark County) are presented in Section 4.1.4.

Police Protection. The USAF provides security services on the wider Nellis Air Force Base, but WSI, a private contractor, provides security services at RSL, following guidelines established by DOE/NNSA NSO Safeguards and Security. Nellis Air Force Base Security Forces respond to RSL when called. The Police Services portion of the current Inter-Service Support Agreement between DOE/NNSA and Nellis Air Force Base, dated January 2006, reads, "In the event of an emergency, Nellis Security Forces response will be limited to securing the exterior of the facility only."

Fire Protection. Fire protection is provided by Nellis Air Force Base.

Health Care. RSL does not have a medical facility. In the event of a medical emergency at RSL, Nellis Air Force Base would dispatch an ambulance from the base hospital (99th Medical Group).

The 99th Medical Group provides medical care for the military community to ensure maximum wartime readiness and combat capability. The group's functions include flight medicine, surgical services, maternal and child care, pharmacy, laboratory, radiology, dental care, medical benefits and information, and diagnostic and therapeutic services.

Emergency calls (9-1-1) reach the Base Fire Department emergency dispatch station directly. Depending on the nature of the emergency, the appropriate response organization is dispatched (e.g., fire department, ambulance).

4.2.5 Geology and Soils

4.2.5.1 Physiography

RSL is located in the northeastern section of the city of Las Vegas on Nellis Air Force Base. Las Vegas is situated in the Las Vegas Valley, a broad northwest–southeast trending basin in the Basin and Range Physiographic Province. The valley was formed during the extensional tectonics and gradually filled with sedimentary deposits that eroded from the surrounding mountain ranges. The deepest sediments are Tertiary in age, and gradually become younger, up to the Quaternary lake bed and stream deposits. The Las Vegas Valley is bounded by the Las Vegas shear zone to the north, by Frenchman Mountain to the east, by the Spring Mountains to the west, and by the McCollough and Bird Spring Ranges to the south (Rodgers et al. 2005).

Nellis Air Force Base is located northwest of Sunrise and Frenchman Mountains, which form the eastern border of the city of Las Vegas. The topography is generally flat at Nellis Air Force Base, although there is a gradual slope to the south. RSL is located approximately 1,850 feet above sea level.

4.2.5.2 Geology

The geologic history for the Las Vegas Valley is described in Section 4.1.5.2. Nellis Air Force Base is located on a series of alluvial fans formed from eroded sediments from the Sunrise, Las Vegas, and Dry

Lake Mountain Ranges. The surrounding mountain ranges are primarily composed of Permian-age limestone, mixed with sandstone, shale, dolomite, and gypsum interbedded with quartzite. Gravity and seismic tests have estimated the maximum thickness of the alluvial deposits in Las Vegas Valley to be up to 3.1 miles thick (Rodgers et al. 2005). The alluvium is approximately 1.86 miles deep beneath RSL (Rodgers et al. 2005).

The alluvial fans around Nellis Air Force Base overlap and are carved by numerous drainage channels. The grain size is largest and poorly sorted closer to the source bedrock, and becomes increasingly finer and well sorted at a farther distance from the mountain range. The deposits found in the alluvium at RSL are pink to pale-brown sand and pebble to cobble conglomerate.

4.2.5.2.1 Structural History

The Las Vegas Valley is bounded to the north by the Las Vegas Valley shear zone, which is a subsidiary zone in the larger Walker Lane shear zone, described in Section 4.1.5.1. The mountain ranges that bound the valley to the east, west, and south are all bounded by normal faults from the extensional tectonics described in Section 4.1.5.2.

The closest normal fault sequence to RSL is the Frenchman Mountain Fault, which creates a structural boundary between Frenchman Mountain and the Las Vegas Valley. The Frenchman Mountain Fault stretches from the northwest to southeast, and gradually curves to the east. The normal fault is typical of the Basin and Range sequence of faults that forms the basin topography. Scarps in the Quaternary-aged alluvium suggest that there has been movement within the last 130,000 years (Anderson 1999b).

In addition to the normal faults at the edge of the Las Vegas Valley, there are several scarp sequences that trend north–south through metropolitan Las Vegas. The scarps can be up to 98.4 feet high and 16.8 miles long. It is unclear if the scarps are related to past tectonic activity or internal basin features (Anderson 1999a). Most of the scarps have been modified by the development of Las Vegas. One prominent scarp in the northwestern section of the Las Vegas Valley is named the Eglington Fault, and may be related to faults within the basin bedrock (Anderson 1999c).

4.2.5.2.2 Faulting and Seismic Activity

An earthquake database search was performed for the area within 30 miles of the center of Las Vegas from 1973 to the present. Because the NNSS is outside of this 30-mile radius, the seismic tests from nuclear testing were not included in the database search. There have been 44 seismic events recorded around Las Vegas since 1973 (USGS 2010c). None of the earthquakes had a magnitude larger than 3.9, and approximately half of the earthquakes had a magnitude of less than 3. Section 4.1.5.2.3 presents a history of the seismic activity in the NNSS area and the greater Basin and Range region, which includes the Las Vegas Valley. Seismic design requirements are discussed in Section 4.1.5.2.3.

Due to the proximity of Las Vegas to the NNSS, seismic effects from nuclear testing have been a concern. Starting in the 1960s, a series of seismic stations were distributed throughout the Las Vegas Valley to measure the shockwaves from earthquakes and nuclear testing at the NNSS. Recordings were taken from 1968 through 1989, when the greatest number of tests occurred at the NNSS. The amount of ground motion recorded at the seismic station network correlated with the size of the nuclear test. The largest explosions at the NNSS (Boxcar, Handley, Muenster, and Fontina) generated the greatest ground motion in Las Vegas. These largest explosions were typically felt as IV or less on the Modified Mercalli Intensity Scale, which is used to measure the felt intensity of an earthquake (Rodgers et al. 2005). At that point, shaking is felt on the ground, but there is generally little to no damage to structures. The Modified Mercalli Intensity IV rating is roughly equivalent to a Richter magnitude of 4.0 (Rodgers et al. 2005). Smaller tests (e.g., Bambwell) generated minimal ground motion in the Las Vegas Valley; typically below 20 square centimeters per second (approximately 2 percent of the coefficient of gravity), which would be felt as weak motion with a low potential for structural damage (Rodgers 2008).

4.2.5.2.3 Geotechnical Hazards

RSL is located on the flat portion of the alluvial fans that fill the Las Vegas Valley. Sunrise Mountain is approximately 1.5 miles to the southeast of the facility. Runoff from Sunrise Mountain and Nellis Air Force Base collects in gullies to the south of RSL, which indicates that RSL would not be affected by landslides.

Section 4.1.5.2.4 describes how soils with shrink-swell properties could affect construction. RSL is located on Glencarb silt loam, which contains moderate amounts of clays and has a moderate shrink-swell potential (USDA 1985).

4.2.5.2.4 Geologic Resources

RSL is located on thick alluvial fans in the Las Vegas Valley. Gravel from alluvial deposits is the only geologic resource in the immediate vicinity of the facility.

4.2.5.3 Soils

The soils at Nellis Air Force Base and RSL have been labeled as Glencarb silt loam by the Natural Resources Conservation Service soil survey. The soil forms on the alluvial deposits from the surrounding mountain ranges and is often eroded and reworked by water. The soil is well drained, with a light, sandy loam with gravel and clay-rich sand in the upper layer. Up to 60 inches beneath the surface is a layer of caliche, which restricts root growth (USDA 1985). Due to the high percentage of clay, the soil does have some shrink-swell properties; however, this does not prevent construction of small commercial buildings. The topsoil is very susceptible to erosion by wind, as the fine-grained silt can be easily stripped from the coarser deposits. This soil is not classified as a prime farmland soil by the U.S. Department of Agriculture.

4.2.5.4 Radiological Sources as a Result of Testing

There has been no nuclear testing at Nellis Air Force Base or RSL; therefore, the soils are not contaminated with radioactive materials.

4.2.6 Hydrology

4.2.6.1 Surface Hydrology

RSL is located on Nellis Air Force Base in the northern portion of the Las Vegas Valley, which extends in a northwest-to-southeast direction and drains through the Las Vegas Wash into Lake Mead (USAF 2007c).

Surface-Water Features. No natural perennial streams, lakes, or springs are found on Nellis Air Force Base due to low precipitation, high evaporation rates, and low humidity. Water erosion is rare in the Las Vegas Valley, but can be somewhat prominent along alluvial fans. Nellis Air Force Base contains several ephemeral streams or washes that eventually flow into the Las Vegas Wash. One ephemeral stream originates near the northeastern corner of the RSL site (USAF 2007c).

Flood Hazards. The Federal Emergency Management Agency Flood Insurance Rate Map covering RSL (Map Number 32003C2200 E) indicates that the facility is located within Zone X. Zone X indicates an area of minimal flood hazard, which is determined to be above the 500-year flood level (FEMA 2002b).

Water Discharges and Regulatory Compliance. RSL holds an Industrial Wastewater Discharge Permit (Permit Number CCWRD-080) from the Clark County Water Reclamation District. The permit includes water chemistry limits and requires quarterly monitoring and reporting (DOE/NV 2011). In 2010, no permit limits were exceeded (see **Table 4–56**).

4.2.6.2 Groundwater

Hydrogeologic Setting. RSL is located on Area 1 of Nellis Air Force Base and is under lease to DOE/NNSA. Nellis Air Force Base is located on the eastern side of the Las Vegas Valley Hydrographic Basin, an intermountain basin within the Basin and Range Physiographic Province of the United States within the Colorado River Basin. The Las Vegas Valley Hydrographic Basin is approximately 1,600 square miles, with an estimated perennial yield of 25,000 acre-feet per year (NDWR 2010b). Groundwater flow within the Las Vegas Valley Hydrographic Basin is generally from west to east (USAF 2007c).

The little precipitation that is captured on site is drawn into the valley's principal basin-fill aquifer, shallow aquifers, and the Colorado River. Nellis Air Force Base is underlain by carbonate rock aquifers of the Colorado aquifer system, which is hydrologically connected to shallower alluvial aquifer systems composed of sand and gravels. The principal aquifer in the Las Vegas Valley Hydrographic Basin is naturally recharged by 30,000 to 35,000 acre-feet per year mostly from the Spring Mountains on the west valley boundary. Recharge of the shallow aquifers also occurs, primarily as a result of irrigation water percolating into the ground (USAF 2008c).

Table 4–56 Water Quality Results for Remote Sensing Laboratory Industrial Wastewater Discharges in 2010

Contaminant	*Permit Limit*	*Outfall*
Ammonia (ppm)	No limit listed	22.1
Cadmium (ppm)	0.35	0.00076
Chromium (total) (ppm)	1.7	0.00209
Copper (ppm)	3.36	0.330
Cyanide (total) (ppm)	1	<0.006
Lead (ppm)	0.99	0.0017
Nickel (ppm)	10.08	0.00426
Oil and Grease (ppm)	100	<5.0
Phosphorus (ppm)	No limit listed	6.2
Silver (ppm)	6.3	0.0011
Total Dissolved Solids (ppm)	No limit listed	1,094
Total Suspended Solids (ppm)	No limit listed	411
Zinc (ppm)	23.06	0.463
pH (Standard Units)	5.0–11.0	8.28
Temperature (degrees Fahrenheit)	140	76.3

pH = a measure of acidity or basicity; ppm = parts per million.
Note: Permit limits are set forth in Clark County Water Reclamation District Industrial Wastewater Discharge Permit (Permit Number CCWRD-080).
Source: DOE/NV 2011, Tables A–7 and A–8.

Groundwater Supply. Sources of groundwater are available from the principal alluvial-fill aquifer underlying the Las Vegas Valley. Approximately 29 percent of the Nellis Air Force Base water supply comes from groundwater, and the base is allotted 7.1 million gallons per day of surface water and groundwater (USAF Air Combat Command 2008). Potable water sources at Nellis Air Force Base include five active government-owned and -operated wells (three wells located off base and two wells located on base) and water purchased from Southern Nevada Water Authority via bulk-supply pipelines from Lake Mead. Virtually all of the water in Lake Mead begins as snowmelt in the Rocky Mountains and arrives via the Colorado River. All the water drawn from Lake Mead is sent to the Alfred Merritt Smith or River Mountains water treatment facilities.

The water supplied by the Southern Nevada Water Authority is supplemented by a small percentage of groundwater from wells located on the base and near the base within the northeastern part of the valley. This groundwater comes from the Las Vegas Valley Aquifer (NAFB 2005). The base also purchases a

small quantity from the City of North Las Vegas Water District. The existing water supply at Nellis Air Force Base is considered adequate.

The raw water from base wells is chlorinated and then mixed with the Southern Nevada Water Authority water prior to use as drinking water. The two on-base wells have arsenic concentrations that exceed the MCL, but, when blended with the Southern Nevada Water Authority water and off-base well water, the resultant arsenic concentration is below the current arsenic MCL of 10 parts per billion. The revised arsenic MCL regulation became effective in January 2006 (NAFB 2005).

The water system supplying RSL, located on Nellis Air Force Base, suffers from low pressure and limited supply capability. DOE/NNSA is working with Nellis Air Force Base officials to address these issues (DOE 2008f). No expansion or addition of water-consuming facilities can be made at RSL until a new water source can be installed.

Nellis Air Force Base announced a water loop project in 2008, which is to take place within 5 years, and invited DOE/NNSA to participate. In the interim, Nellis Air Force Base has offered to allow DOE/NNSA to obtain water from the water line running to Area 2 and to extend the line approximately 4,000 feet from Perimeter Road to the compound. Eventually, this interim line could be capped and the same connection used on the new loop that would be adjacent to the property. The most economical new source for Nellis Air Force Base is approximately 1 mile east of the compound and belongs to the Southern Nevada Water Authority (DOE 2007c).

Groundwater Monitoring and Quality. Technicians collect and analyze water samples monthly from Nellis Air Force Base's drinking water and water treatment facilities. The water is tested more frequently and extensively than the Safe Drinking Water Act and the *Nevada Administrative Code* require (NAFB 2005).

Nellis Air Force Base had two regulatory compliance violations in 2005 (June and September). In June 2005, two samples tested positive for total coliform and one tested positive for *Escherichia coli* bacteria. In September 2005, two samples tested positive for total coliform. Public notifications were issued after both instances, and all subsequent test results were negative for total coliform and *E. coli* bacteria (NAFB 2005).

4.2.7 Biological Resources

RSL is in the Southern Basin and Range Ecoregion. This facility is located in an urban setting that includes buildings, pavement, and landscaping. No original undisturbed native vegetation remains on the site; current vegetation on the site consists of urban landscape. Few wildlife species exist at the site because it is located in an urban area and contains little vegetation.

4.2.7.1 Flora

This facility is located in an urban setting; no native vegetation within a natural setting occurs at this site.

4.2.7.2 Fauna

This facility is located in an urban setting; only urban-adapted wildlife occurs at this site. The only species that exist in this habitat include those that are adapted to urban habitats, which may include small mammals such as the house mouse (*Mus musculus*) and Norway rat (*Rattus norvegicus*), as well as ubiquitous bird species such as the northern mockingbird (*Mimus polyglottos*), European starling (*Sturnus vulgaris*), house finch (*Carpodacus mexicanus*), house sparrow (*Passer domesticus*), ruby-crowned kinglet (*Regulus calendula*), mourning dove (*Zenaida macroura*), and rock dove (*Columba livia*).

4.2.7.3 Threatened and Endangered Species

This facility is located in an urban setting; no threatened, endangered, or rare species are expected to occur at this site. No designated critical habitats for federally listed species exist at RSL. The urban areas of Clark County are not considered tortoise habitat.

4.2.7.4 Other Species of Concern

No other species of concern inhabit RSL.

4.2.7.5 Effects of Past Radiological Tests and Project Activities

This facility is located in an urban setting; no past radiological tests or project activities are anticipated to affect wildlife or vegetation at this site.

4.2.8 Air Quality and Climate

4.2.8.1 Meteorology

Downtown Las Vegas is located in Clark County, Nevada, about 56 miles southeast of the southeastern edge of the NNSS. RSL, at Nellis Air Force Base, is about 14 miles northeast of downtown. RSL is located in the Las Vegas Valley, which is situated in the northeastern corner of the Mojave Desert and in the rain shadow (lee) of the southern Sierra Nevada mountain range.

The Las Vegas Valley has the general climatic characteristics of a mid-latitude desert area, with relatively little precipitation throughout the year and low humidity, large diurnal and seasonal temperature ranges, and intense solar radiation in the summer. The generally dry, desert conditions specific to the area can occasionally be modified by the southwestern monsoon and convective thunderstorms during the summer months and Eastern Pacific tropical storm remnants in the late summer and fall. The dry conditions also tend to be moderated during strong *El Niño* cycles, which generally bring more rainfall to the area.

The average maximum temperatures range from about 95 to 105 °F in the summer and from about 55 to 65 °F in the winter. The average minimum temperatures range from about 70 to 80 °F in the summer and from about 35 to 45 °F in the winter, based on average temperatures recorded from 1971 through 2000 at the Las Vegas Weather Service Office Airport (NCDC 2009).

The Las Vegas Valley ranges in elevation from about 2,300 to 2,620 feet above mean sea level and is bounded by mountains to the north, south, and especially to the west, where the Spring Mountains peak above about 6,560 feet. This terrain causes wind flows in the Las Vegas Valley to be dominated by upslope and downslope conditions. The Clark County Department of Air Quality and Environmental Management (DAQEM) maintains an ambient air monitoring site (the J.D. Smith monitor, at 1301 East Tonopah Road) near RSL. **Figure 4–38** shows the wind roses for the J.D. Smith and E. Craig Road (at 4701 Mitchell Street) Clark County DAQEM sites for 2004 through 2008 (Clark County 2010) and the average wind direction and speed data surrounding both RSL and NVLF for the same time period. For additional information regarding the meteorological characteristics of RSL, see Appendix D, Section D.1.2.1.

The nearest upper-air measurements, used in estimating atmospheric stability, are available from the National Weather Service Desert Rock site located in the southern end of the NNSS about 58 miles northwest of downtown Las Vegas. Based on data recorded from 1978 through 2004 at Desert Rock, stable conditions dominate at night, though stronger windspeeds will tend to mix in the atmosphere, leading to neutral conditions. As greater solar radiation leads to greater instability, unstable conditions dominate the daytime hours and the months with the highest solar radiation (summer). These stability patterns are slightly modified within the Las Vegas Valley because of the lower elevation and slightly higher temperatures, windspeed differences, and potential differences in local cloud cover relative to what occurs at Desert Rock (Soulé 2006). A limited comparison study between Desert Rock and Las Vegas upper-air measurements suggests that differences above the first few tens of meters are minimal (Lehrman et al. 2006).

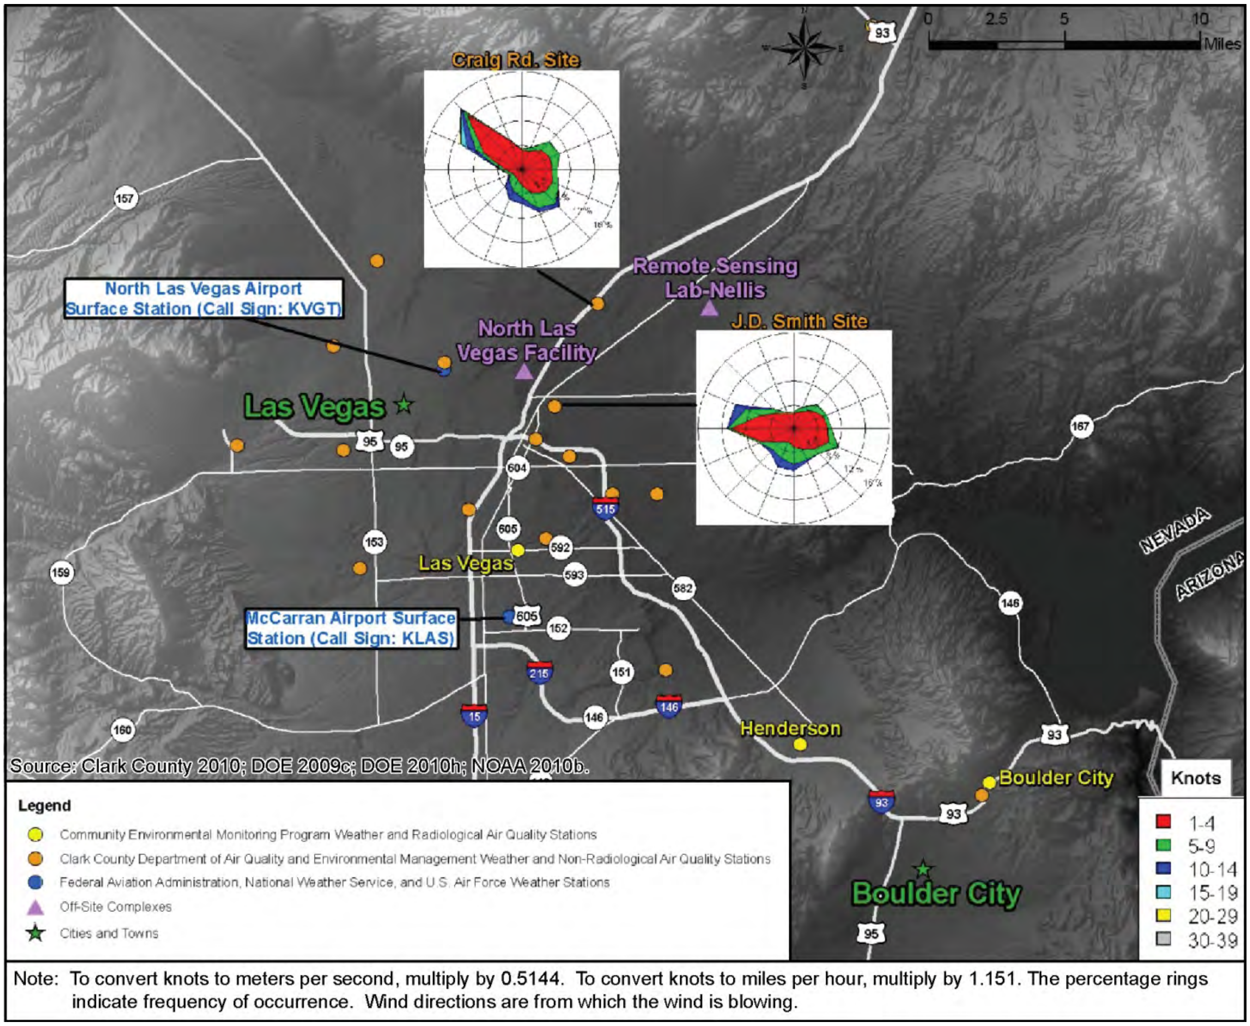

Figure 4–38 Wind Roses for J. D. Smith and E. Craig Road Clark County DAQEM Sites, 2004–2008

4.2.8.2 Ambient Air Quality

4.2.8.2.1 Region of Influence

RSL is located about 60 miles southeast of the southern border of the NNSS. The ROI for air quality and climate for RSL operations comprises northern Clark County. Historic data on pollutant emission inventories and compliance status for the State of Nevada are calculated at the resolution of county or hydrographic areas; these data provide a basis for determining existing air quality in the ROI and a metric for emission comparison assessments.

4.2.8.2.2 Existing Air Quality

Current Ambient Air Quality Standards. See Section 4.1.8.2.2 for a discussion on the current national and Nevada ambient air quality standards.

Air Quality Status. RSL is within Hydrographic Area 212. Clark County is in nonattainment for 8-hour ozone[25] and 24-hour PM_{10}.[26] Clark County is no longer in nonattainment for 8-hour carbon monoxide.[27] All other pollutants are in attainment.

PSD is a regulation incorporated into CAA that limits increases of certain pollutants in clean air areas (attainment areas) to certain increments even though ambient air quality standards are being met. CAA has three classes of areas with different increments. The smallest increments allowed are Class I areas, which are areas of special value (natural, scenic, recreational, or historic). Any degradation of existing air quality in these areas should be minimized. The closest PSD Class I areas are Grand Canyon National Park (about 65 miles to the east) and Sequoia National Park (about 165 miles to the west). RSL currently has no sources of pollution large enough to be subject to PSD requirements. However, because RSL is located in a nonattainment area, it could potentially be subject to nonattainment new source review if the emissions were of sufficient strength; however, they have been determined not to meet the threshold for new source review. Nonattainment new source review requirements are customized for the classification and type of air pollutant nonattainment area.

Emissions Due to RSL Operations. Title V of CAA gives states the authority to use air quality permits to regulate stationary source emissions of criteria pollutants. At RSL, a Facility 348 Authority to Construct/Operating Permit regulates emissions from sources such as boilers, water heaters, cooling towers, emergency generators, a spray paint booth, and a vapor degreaser. Except for 1.3 tons of nitrogen oxides emitted in 2004, emissions of carbon monoxide, nitrogen oxides, PM_{10}, sulfur dioxide, volatile organic compounds, and hazardous air pollutants were each less than 1 ton annually from 2003 through 2008. Total emissions of these pollutants over this 6-year period are about 6 tons (DOE 2004b, 2005b, 2006a, 2007b, 2008j, 2009c).

Table 4–57 shows the onsite emissions due to stationary sources and aircraft-related sources, as well as Clark County emissions due to RSL commuters and commercial vendors. The onsite stationary sources include both permitted sources and natural gas combustion used principally for heating. See Appendix D, Section D.1.2.2.2, for further details and a discussion of the methodology used to determine the stationary source emissions, aircraft emissions, commuter vehicle emissions, and commercial vendor emissions.

---

[25] *Classified as marginal for 8-hour ozone under former Subpart 1 with a nonattainment area that includes those portions of Clark County that lie in Hydrographic Areas 164A, 164B, 165, 166, 167, 212, 213, 214, 216, 217, and 218, but excludes the Moapa River Indian Reservation and the Fort Mojave Indian Reservation. However, on March 29, 2011, EPA made the determination that Clark County is in attainment with 1997 ozone NAAQS (76 FR 17343). EPA is expected to redesignate the area's status to attainment upon approval of the Ozone Redesignation Request and Maintenance Plan submitted to EPA Region 9 in early April 2011.*

[26] *Designated as serious nonattainment for PM_{10}. The nonattainment area covers Hydrographic Area 212. However, on August 3, 2010, EPA made the determination that the Las Vegas Valley is in attainment with the PM_{10} NAAQS based on monitoring data (75 FR 45485). EPA is expected to redesignate the area's status to attainment upon approval of the maintenance plan and request for redesignation that Clark County is expected to submit.*

[27] *A CO Maintenance Plan and formal request for resdesignation to attainment was submitted to the EPA in 2008 and approved on September 7, 2010 (75 FR 59090).*

Table 4–57 Estimated 2008 Air Emissions of Criteria Pollutants and Hazardous Air Pollutants Due to Remote Sensing Laboratory Activities

	Annual Air Emissions (tons per year)

HAPs	0.0071	~0.17	0.0048	0.0076	*~0.18*	*0.012*	***~0.19***

CO = carbon monoxide; HAP = hazardous air pollutant; NO_x = nitrogen oxides; PM_n = particulate matter with an aerodynamic diameter less than or equal to *n* micrometers; RSL = Remote Sensing Laboratory; SO_2 = sulfur dioxide; VOC = volatile organic compound.

Measurements of Ambient Air Concentrations on and near RSL. The Clark County DAQEM maintains an air quality monitoring network. The E. Craig Road monitor (at 4701 Mitchell Street) is about 3 miles west of RSL. It monitors hourly ozone and PM_{10} levels. **Table 4–58** shows (1) maximum 8-hour average concentrations of ozone and (2) maximum 24-hour average and annual average concentrations of PM_{10} measured at the E. Craig Road monitor from 2006 through 2008. Sulfur dioxide, carbon monoxide, and $PM_{2.5}$ values shown are the highest concentrations measured in the Las Vegas Valley. For ozone and PM_{10}, about 25 percent of the 2008 observations were missing, so the maximum concentration numbers for that year could potentially be higher than what is shown; however, the maximum concentration over the past 3 years is likely representative of the current conditions. The ambient air quality standards are also shown in the table. See Table 4–40 for more information on the standards. Note that the E. Craig Road monitor may be moved about 7 miles south in 2010; if that happens, the closest Clark County DAQEM monitor to RSL would be the J.D. Smith monitor (1301 East Tonopah Road), about 5 miles southwest of RSL.

Ozone measurements at the E. Craig Road monitor (at 4701 Mitchell Street) exceeded the 8-hour ozone NAAQS in 2006 and 2007. The largest 8-hour ozone concentration was 0.084 parts per million (ppm) (in 2006), which is 0.009 ppm larger than the current NAAQS (0.075 ppm). Maximum ambient ozone concentration levels have generally remained constant at this and other nearby monitors since at least 1998 (DAQEM 2009). The second-highest 24-hour average PM_{10} concentration at the E. Craig Road monitor (at 4701 Mitchell Street) was 168 micrograms per cubic meter (in 2008), which is 18 micrograms higher than the NAAQS of 150 micrograms per cubic meter. The largest annual average PM_{10} concentration was 35 micrograms per cubic meter (in 2006), well below the Nevada ambient air quality standard of 50 micrograms per cubic meter (there is no national PM_{10} annual average standard). This monitor typically observes the largest PM_{10} concentrations of all the PM_{10} monitors in the Las Vegas Valley.

All other criteria pollutants are well below NAAQS. No lead monitoring data are available in the Las Vegas Valley.

Table 4–58 Ambient Air Quality Monitoring Data in the Vicinity of the Remote Sensing Laboratory, 2006–2008

Year	*2nd Max 1-hour CO (ppm)*	*2nd Max 8-hour CO (ppm)*	*Annual Mean NO_2 (ppm)*	*2nd Max 1-hour NO_2 (ppm)*	*4th Max 8-hour O_3 (ppm)*	*2nd Max 1-hour SO_2 (ppm)*	*2nd Max 24-hour SO_2 (ppm)*	*Annual Mean SO_2 (ppm)*	*98th percentile $PM_{2.5}$ (µg/m^3)*	*Annual Mean $PM_{2.5}$ (µg/m^3)*	*2nd Max 24-hour PM_{10} (µg/m^3)*	*Annual Mean PM_{10} (µg/m^3)*
2006	6.3	5	0.021	0.080	**0.084**	0.015	0.007	0.002	24.3	9.4	124	35
2007	4.6	3.8	0.020	0.066	**0.081**	0.007	0.003	0.001	22.6	10.3	120	34
2008	4.7	3.7	0.016	0.062	**0.080**	0.006	0.001	0.001	22.5	9.1	**168**	33
NAAQS	35.0	9.0	0.053	0.100	0.075	0.075	0.030	0.140	35.0	15.0	150	None

µg/m^3 = micrograms per cubic meter; CO = carbon monoxide; NAAQS = National Ambient Air Quality Standards; NO_2 = nitrogen dioxide; O_3 = ozone; PM_n = particulate matter with an aerodynamic diameter less than or equal to *n* micrometers; ppm = parts per million; SO_2 = sulfur dioxide.

Note: Monitored values are from the E. Craig Road monitor (at 4701 Mitchell Street) for O_3 and PM_{10}; other values are the highest monitored values in the Las Vegas Valley. All exceedances of the NAAQS are shown in **bold** font.

Source: EPA 2010a.

4.2.8.3 Radiological Air Quality

Radiation sources currently used at RSL at Nellis Air Force Base are sealed in locations that prevent the release of radionuclides or any elevated gamma radiation from reaching the public. Therefore, radiation monitoring for public health is not performed (DOE 2009e), and exposure levels are at natural background levels. See Section 4.1.8.3 for more information on radiation sources and radiation monitoring on and near the NNSS.

4.2.8.4 Climate Change

This section describes the affected environment in terms of current and anticipated trends in greenhouse gas emissions and climate. The effects of emissions on the climate involve very complex processes and interact with natural cycles, complicating the measurement and detection of change. Recent advances in the state of the science, however, are contributing to an increasing body of evidence that anthropogenic greenhouse gas emissions affect climate in detectable and quantifiable ways.

For information on greenhouse gas emissions in the United States, please see Section 4.1.8.4.1. Greenhouse gas emissions at RSL are discussed in the next section. Details on the methodology used to determine these emissions are discussed in Appendix D, Section D.2.2.1.1.

4.2.8.4.1 Greenhouse Gas Emissions

Table 4–59 provides greenhouse gas emissions due to RSL-related activities for 2008. The greenhouse gas emissions are presented in carbon-dioxide-equivalent form and are partitioned by various mobile and stationary source types. These emissions were derived from fuel use, vehicle activity, and power consumption data. The greenhouse gas emissions were calculated using the EPA Climate Leaders Simplified Greenhouse Gas Emissions Calculator (EPA 2010b). These emissions were compared with a reference amount of 25,000 metric tons (27,558 tons), which is the threshold for which a quantitative assessment may be meaningful (CEQ 2010).

Table 4–59 Carbon-Dioxide-Equivalent Emissions of Greenhouse Gases from Remote Sensing Laboratory Activities in 2008

Source Type	*Carbon-Dioxide-Equivalent Emissions (tons per year)*	*Fraction of Reference Point of 25,000 Metric Tons* [a]
STATIONARY SOURCES		
Power generation	2,046	0.07
Natural gas heating	203	0.01
All stationary sources, except air conditioning/refrigeration and natural gas heating	11	0.01
All Stationary Sources	*2,260*	*0.08*
MOBILE SOURCES		
Aircraft and ground support equipment	1,184	0.04
Commuting	473	0.02
Commercial vendors	138	0.01
All Mobile Sources	*1,795*	*0.07*
Total	***4,055***	***0.15***

[a] 25,000 metric tons are equal to about 27,558 short tons.

Electricity consumption is by far the largest single source of greenhouse gas emissions related to RSL activities, emitting approximately 2,046 carbon-dioxide-equivalent tons of greenhouse gases, or 50 percent of the RSL-related greenhouse gas emissions total. Stationary sources altogether emitted about 2,260 carbon-dioxide-equivalent tons of greenhouse gases. Mobile sources emitted about 1,795 carbon-dioxide-equivalent tons. Overall, RSL-related activities created about 4,055 carbon-dioxide-equivalent tons of greenhouse gas emissions in 2008, which in itself is well below the threshold reporting level.

4.2.8.4.2 Current Changes in Climate

For a discussion of climate change impacts in the region, please see Section 4.1.8.4.2.

4.2.9 Visual Resources

RSL is located at Nellis Air Force Base, to the east of the northern end of the runways. This area is primarily developed, with the RSL facilities, adjacent runways, and infrastructure such as roadways, fences, and utility lines. The immediate surrounding land is undeveloped desert shrubland of the lower Mojave Desert (USAF 2006c). Public access to the airfield and RSL is restricted.

The area surrounding RSL is Nellis Air Force Base land. Public, middleground views exist from Las Vegas Boulevard North, located over a mile north of RSL, but development along the roadway and infrastructure associated with the airfield are more readily visible. RSL blends with this visual environment. Visible portions of RSL are considered to have a Class C scenic quality rating (see Section 4.1.9 for information on the visual impact rating system) due to the developed nature of the landscape, combined with high intrusion of manmade elements and lack of elements that help to improve aesthetics, such as landscaping. There is no immediate public visual access to the foreground of RSL.

4.2.10 Cultural Resources

For introductory information regarding cultural resources, see Section 4.1.10. Unless otherwise noted, the information in this section is derived from the *1996 NTS EIS* (DOE 1996c).

RSL is situated in the northern Las Vegas Valley, within the Las Vegas Valley Hydrographic Basin, an intermountain basin within the Basin and Range Physiographic Province of the United States (NDWR 2010a). RSL is located in Area III of Nellis Air Force Base, adjacent to the northern end of the Nellis Air Force Base runway. The facility is constructed in a highly built military setting that includes operations buildings, maintenance structures, paved runways, and ornamental landscaping. There is no original undisturbed ground surface on RSL.

The area of influence for cultural resources includes all areas where facilities, operations, and maintenance of DOE/NNSA programs would take place. For the purposes of this SWEIS, the area of influence includes the entire 35-acre RSL facility.

4.2.10.1 Recorded Cultural Resources

There are no recorded cultural resources within the boundary of RSL.

4.2.10.2 Sites of American Indian Significance

There are no known sites of American Indian significance within the boundary of RSL. As part of the preparation of this SWEIS, DOE/NNSA consulted with CGTO to determine whether any sites of American Indian significance exist within RSL.

4.2.11 Waste Management

RSL is a small-quantity generator of hazardous waste that also generates sanitary solid waste and recyclable materials. Hazardous wastes are stored on site at RSL for no more than 90 days before being transferred as needed to an offsite facility. As the landlord for RSL, the USAF provides waste management services, including removal and disposal of miscellaneous laboratory and process equipment wastes. Sanitary solid waste is collected and disposed by a municipal waste service. DOE occasionally ships scrap metal to the NNSS to be combined with other accumulated scrap metal at the NNSS and recycled under the NNSS Pollution Prevention and Waste Minimization Program (see Section 4.1.11.3).

4.2.12 Human Health and Safety

No human health impacts on the public or workers are associated with the regular operation of RSL. Because RSL is located within the Nellis Air Force Base, the greatest contributors to background noise conditions are aircraft operations and vehicular traffic. No environmental noise data are available at RSL; however, because of the surrounding land uses, it is assumed that background noise levels are those typical of an industrial land use area, ranging from 50 to 65 decibels, A-weighted (EPA 1974).

4.2.13 Environmental Justice

As seen in **Figure 4–39**, Nellis Air Force Base (the host installation for the RSL) directly borders several block groups where the low-income population is between 11 and 20 percent, and additional block groups in the 21–30 and greater-than-30 percent range are located further to the southwest. RSL is located in an area where the majority of block groups have minority populations exceeding 50 percent (see **Figure 4–40**).

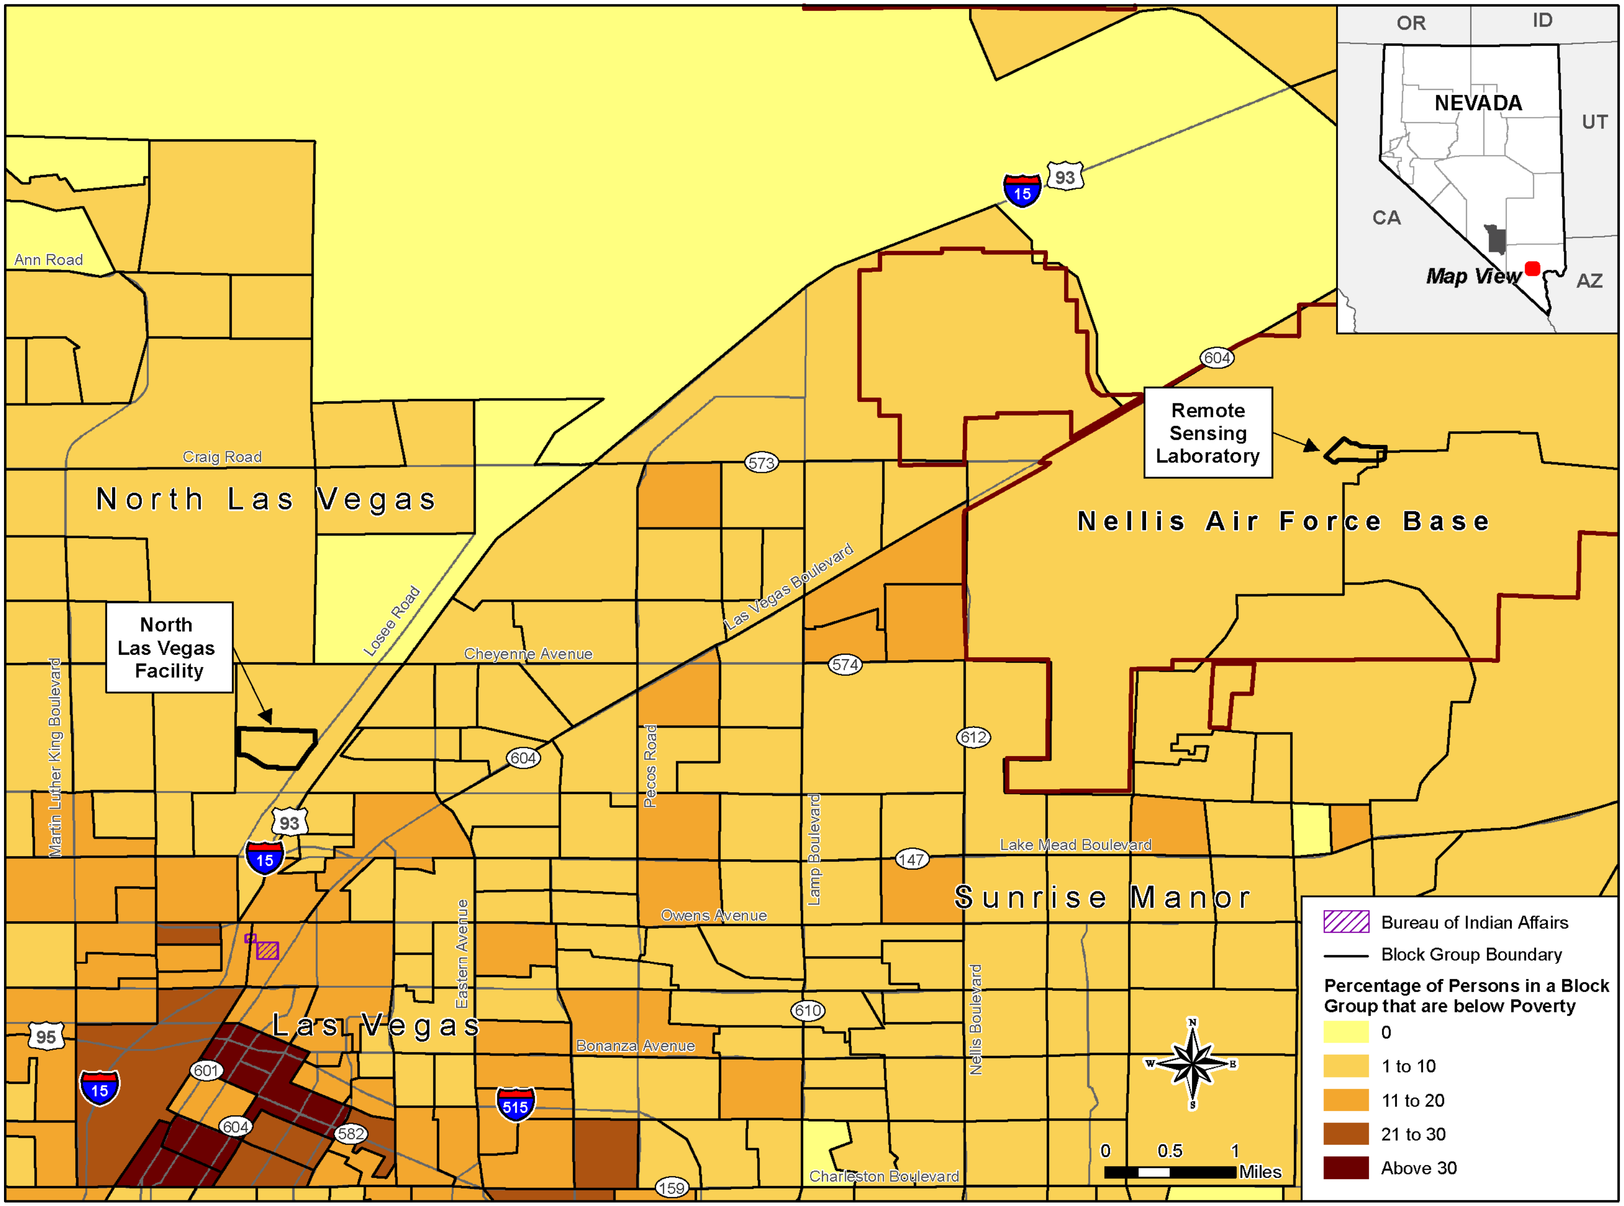

Figure 4–39 Distributions of Low-Income Populations for the North Las Vegas Facility and Remote Sensing Laboratory

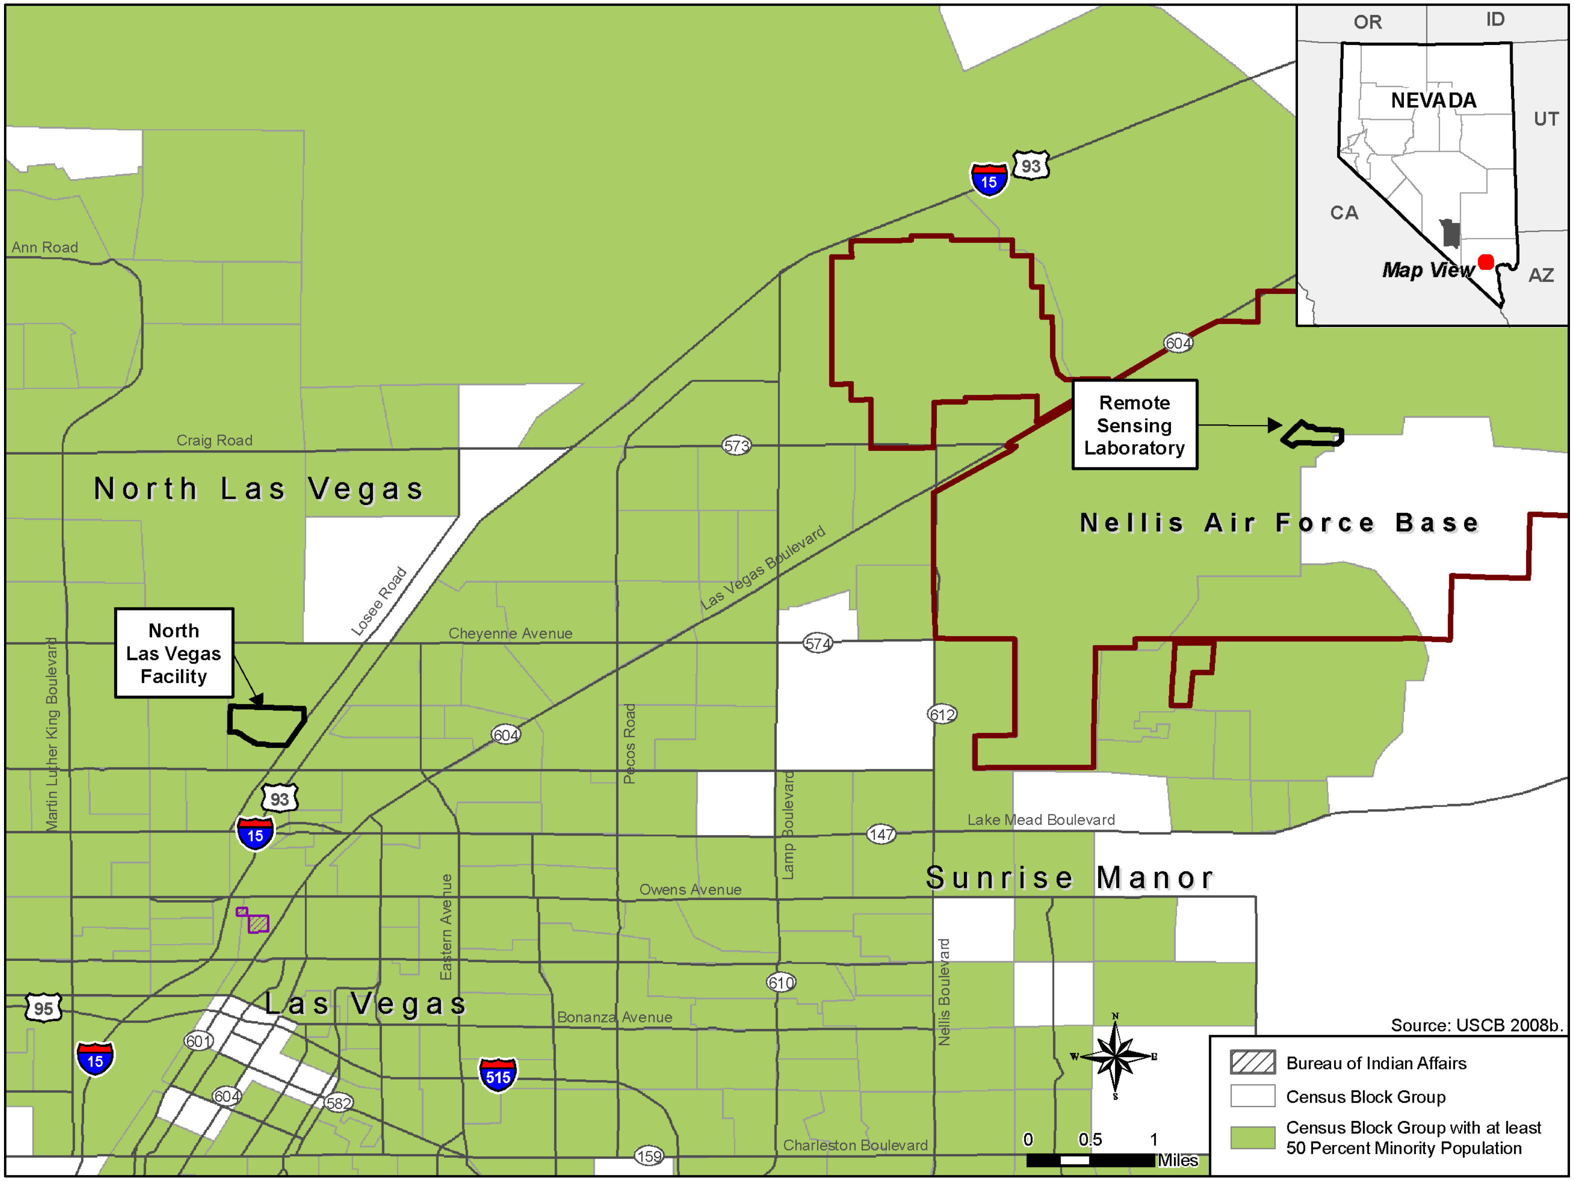

Figure 4–40 North Las Vegas Facility and Remote Sensing Laboratory Distributions of Minority Populations Greater than 50 Percent

4.3 North Las Vegas Facility

This section describes the existing environmental conditions at NLVF. NLVF is located in North Las Vegas, Nevada, and occupies 80 acres along Losee Road, about 0.2 miles west of Interstate 15 (Las Vegas Freeway) and a railroad corridor. Many of the NNSS project management, diagnostic development and testing, designing, engineering, procurement, and environmental compliance activities take place at NLVF. The DOE/NNSA NSO support facility is also located within NLVF. Public access to NLVF is restricted (DOE 2008i).

4.3.1 Land Use

NLVF consists of 30 buildings, parking lots or paved surfaces, and one trailer within the fenced complex. The existing structures account for 665,988 gross square feet of developed space. Buildings A-1 and C-3 provide space for communications, test fabrication and assembly, radiography, and other diagnostics. Building A-1 houses machine shops and overhead cranes that would be essential if nuclear tests were conducted in the future. Building C-3 houses a laboratory, stockpile stewardship experimental facilities, and readiness assets (DOE 2009f). The property is located within a heavy industrial land use area, and the property is zoned for general industry.

4.3.1.1 Adjacent Land Use

The primary land uses adjacent to NLVF are industrial and include manufacturing, processing, warehousing, storage, shipping, and other uses similar in function or intensity. Secondary uses include office uses and commercial uses supporting industrial development.

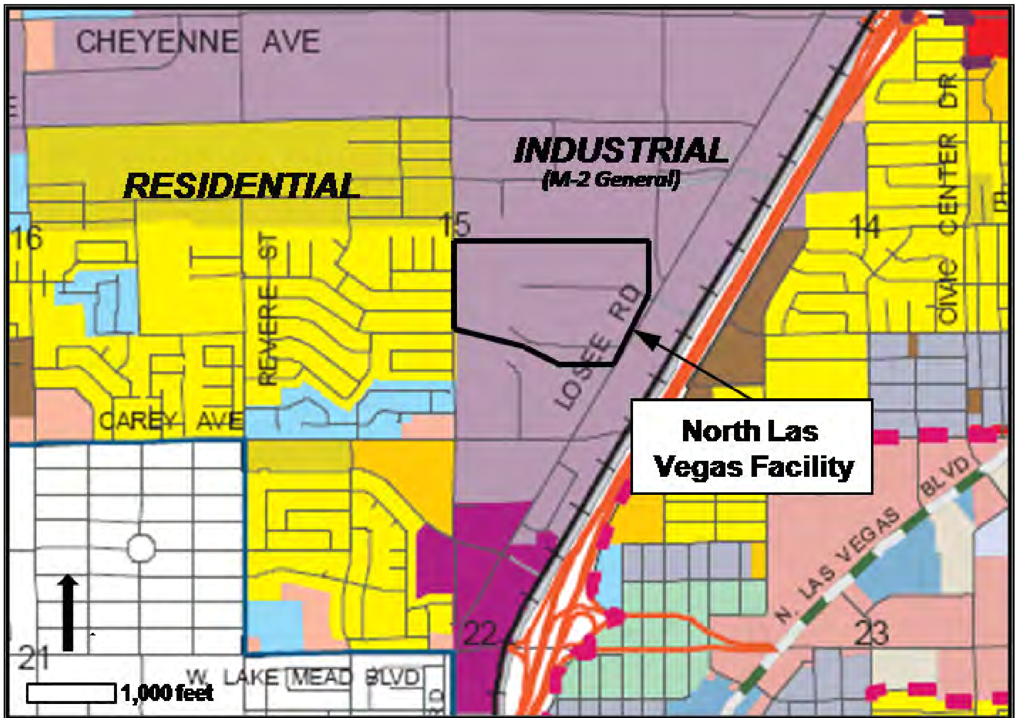
With the exception of the residential area just west of the NLVF western boundary, across North Commerce Street, the land uses adjacent to NLVF consist primarily of businesses in the manufacturing and distribution sectors, with warehouse and office buildings occupying the properties. Products manufactured in this area include automobile engines and transmissions, electrical equipment, and component parts.

The City of North Las Vegas manages land use. Regulations are imposed on the city through the North Las Vegas *2006 Comprehensive Plan*, adopted in 2006. This plan establishes policy and guiding principles for the city for the next 20 years, including a balanced land use mix, a diverse economic base, and thriving and attractive commercial and business centers. Leaders use this plan to help them make decisions about development, programs, and investments in the city. This plan identifies three Specific Planning Areas (SPAs) to help implement and achieve goals of the City of North Las Vegas. The three types of SPAs are as follows (NLV 2006):

- Residential neighborhoods – includes older neighborhoods, areas still under construction and areas yet to be developed
- Activity centers – includes areas planned for mixed-use development, which will serve as key areas of social, commercial, and employment activity for the community
- Employment districts – includes the industrial and primary employment corridors within the city of North Las Vegas and the lands planned for these uses in the future

NLVF is zoned for a general industrial district (M-2) and is within the Employment District SPA, and specifically, within the Industrial District. The M-2 designation provides an area for the development of uses that would not be compatible with those in most other zoning districts because of the nature of the operations, appearance, traffic generation, or emissions associated with industrial activities. These activities are necessary and desirable to the city and are typically located in close proximity to each other (NLV 2010).

Figure 4–41 depicts NLVF and zoning in the city of North Las Vegas.



Source: NLV 2006.

Figure 4–41 Zoning in the City of North Las Vegas and the North Las Vegas Facility

4.3.2 Infrastructure and Energy

4.3.2.1 Infrastructure and Utilities

NLVF facilities are divided into three distinct areas. The first area covers 20 acres and supports the Lawrence Livermore National Laboratory test program. The second area covers 20 acres and supports the Los Alamos National Laboratory test program. The third area covers 38.3 acres and supports a computer center and administrative and engineering support facilities.

4.3.2.1.1 Infrastructure

This section discusses the NLVF buildings and transportation infrastructure; potable water, wastewater, and communications utilities; and support services, including law enforcement and security, fire protection, and health care. Further transportation-related information is discussed in Section 4.3.3. Solid waste collection is discussed in Section 4.3.11. Energy systems (electricity, natural gas, and liquid fuels) are discussed in Section 4.3.2.2.

Facilities. NLVF is a fenced complex composed of 30 buildings (including one trailer), with a total of 665,988 square feet of floor space. **Table 4–60** presents this space according to building function.

Table 4–60 North Las Vegas Facility Building Floor Space by Function

Function	*Floor Space (square feet)*
Administrative	444,090
Storage	22,179
Industrial/Production/Process	58,969
Research and Development	136,079
Service Buildings	4,023
Other	648
Total	665,988

Source: NNSA/NSO 2009b.

Transportation Systems. NLVF consists of a network of approximately 4,000 feet of roadway providing access to the buildings and parking lots. These roads and parking lots are in poor condition and will require replacement or rehabilitation in the near future. There are no railroads or aircraft facilities at NLVF.

4.3.2.1.2 Utilities

Water Supply. Potable water at NLVF is adequately supplied from city services by the Las Vegas Valley Water District (DOE 2008f). NLVF conserves water by using only desert landscaping, which requires minimal use of potable water.

Wastewater Collection and Treatment Systems. NLVF wastewater is discharged to existing municipal sewage systems of the City of North Las Vegas. NLVF holds National Pollutant Discharge Elimination System (NPDES) Permit NV0023507 and Class II Wastewater Contribution Permit VEH-112 (DOE 2008k).

Communication Systems. NLVF has standard communications infrastructure, including telephone, internet, data transmission and storage, radio systems, etc. The telephone communication systems equipment was installed over 20 years ago and is functional but less than adequate; however, some upgrades have been recently installed. Projects are currently under way to modernize NLVF data movement needs.

4.3.2.2 Energy

4.3.2.2.1 Electrical Energy

Electrical energy at NLVF is supplied by NV Energy from the Miller Substation. The main switch is 12.47 kilovolts at 1,200 amperes. The power is distributed throughout the site through an underground distribution system to multiple pad-mounted switches and step-down transformers, where it is transformed to usable 480-volt power (NSTec 2010i). In FY 2009, NLVF's electrical usage was 15,447 megawatt-hours (NNSA/NSO 2010b). The peak demand recorded in 2008 and 2009 was approximately 3,200 kilowatts, recorded in August 2008 during on-peak afternoon hours.

NNSA has met the requirements for installing electrical meters (as set forth in Section 103 of the Energy Policy Act of 2005) for 90 percent of the electricity used by NNSS and NLVF (NSTec 2011c). The metering allows for better tracking of NLVF's use of electricity, water, and gas, thus improving its ability to identify conservation opportunities.

As part of energy conservation efforts under Energy Saving Performance Contract funding, buildings at NLVF have been retrofitted with low-energy light fixtures. All NLVF buildings are equipped with an energy management system that controls lighting and heating, ventilation, and air conditioning 24 hours a day, 7 days a week (NSTec 2008b).

4.3.2.2.2 Natural Gas

Natural gas at NLVF is provided by Southwest Gas Corporation via 2-inch-high pressure gas lines (NSTec 2010i). In FY 2009, the North Las Vegas Complex used 25,947 therms and the Nevada Site Facility (part of the North Las Vegas Complex) used 22,226 therms, for a total natural gas usage of 48,173 therms at NLVF (NNSA/NSO 2010b). There is adequate capacity to serve current demands, and the condition of the gas lines is satisfactory.

4.3.2.2.3 Liquid Fuels

NLVF maintains liquid-fueled boilers and emergency generators. There are currently two liquid fuel storage tanks at NLVF: a diesel tank (267 gallons) and a gasoline tank (391 gallons) (NSTec 2010i; DOE 2008k).

4.3.3 Transportation

4.3.3.1 Onsite Transportation

As shown in **Figure 4–42**, Atlas Drive and Energy Way provide access from Losee Road to NLVF; security gates are located on these roadways. Energy Way provides the main access point for personnel. Paved roads and parking lots at the facility are deteriorating and require replacement or rehabilitation (DOE 2007c).

4.3.3.2 Regional Transportation

NLVF is located on Losee Road, which is adjacent and parallel to Interstate 15 to the east. Traffic volumes and levels of service on roadways in the Las Vegas metropolitan area are discussed in Section 4.1.3.2.2. Traffic volumes on Losee Road are presented in Table 4–11; this roadway experiences moderate levels of daily traffic volumes and is currently operating at level of service B near NLVF.

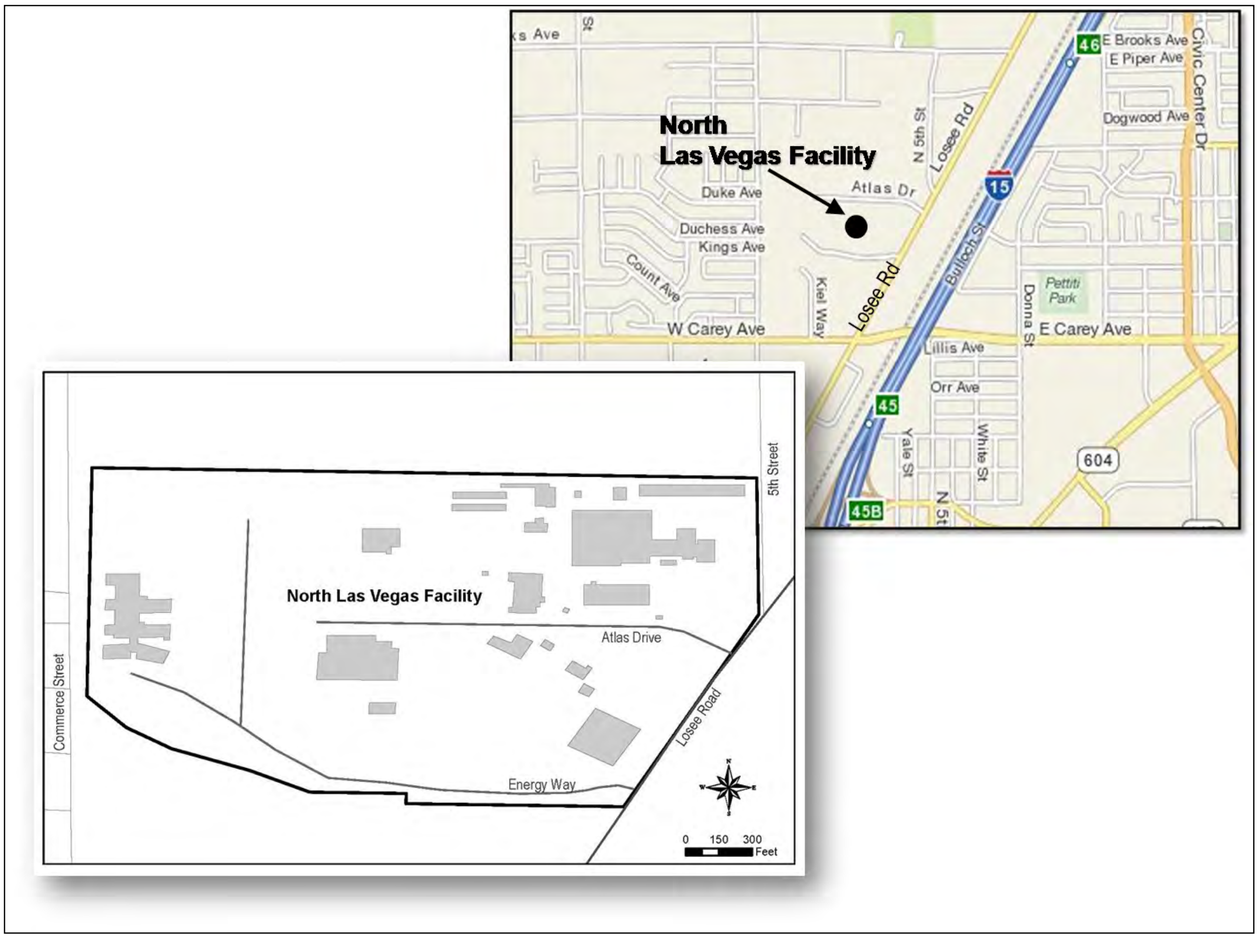


Figure 4–42 North Las Vegas Facility Roadways

4.3.4 Socioeconomics

General existing socioeconomic conditions within the ROI of NLVF (Clark County) are presented in Section 4.1.4.

Police Protection. NLVF is a controlled-access area. WSI, a private contractor, provides security enforcement at NLVF, following guidelines established by DOE/NNSA NSO Safeguards and Security.

Law enforcement at NLVF is provided by the North Las Vegas Police Department.

Fire Protection. Fire protection is provided by the North Las Vegas Fire Department.

Health Care. NLVF has a fully operational occupational medicine center with diagnostic and laboratory support facilities. The center offers a complete array of certification and surveillance exams and has rooms for urgent care, Employee Assistance Program, and ergonomic services. This occupational medicine center can respond to normal and emergency medical situations in North Las Vegas.

4.3.5 Geology and Soils

4.3.5.1 Physiography

NLVF is located in the northern section of the city of Las Vegas. As it is also located in the Las Vegas Valley, the physiography is similar to that described for RSL in Section 4.2.5.1. The facility property has been graded for the construction of its buildings; however, there is a slight grade from west to east. The elevation at the site is approximately 2,000 feet above sea level. The location is surrounded by other urban lands that have also been graded.

4.3.5.2 Geology

NLVF is located on alluvial sediments eroded from the surrounding mountain ranges, as described in Section 4.2.5.2. Although the sediment depth becomes shallower closer to the edges of the valley, the alluvial deposits for most of the valley are at least 0.62 miles deep (Rodgers et al. 2005).

4.3.5.2.1 Structural History

Section 4.2.5.2.1 presents the structural history for the Las Vegas Valley, which includes NLVF. NLVF is located approximately 4.8 miles from the Eglington Fault scarps in northwestern Las Vegas.

4.3.5.2.2 Faulting and Seismic Activity

Section 4.2.5.2.2 presents the faulting and seismic activity for the Las Vegas Valley, which includes NLVF.

4.3.5.2.3 Geotechnical Hazards

The geotechnical hazards would be similar to those discussed in the NNSS and RSL discussions. NLVF is located well within the city boundaries and away from the mountain ranges. Gypsum can generate electrochemical reactions in normal concrete, so foundations for new structures would require concrete resistant to sulfate corrosion (USDA 1985). The presence of several inches of hardpan indicates that heavy machinery would be required for deep excavation.

4.3.5.2.4 Geologic Resources

There are no geologic resources at NLVF.

4.3.5.3 Soils

Soils surveys of the area show that soils at NLVF range from stiff to very stiff, silty and sandy clay, and clay with interbedded medium-dense clayey and silty sand. These soils have been determined acceptable for standard construction (DOE 1996c).

NLVF is located in an urban location, where the soils have previously been disturbed. Two soil associations are found at NLVF. Neither is classified as prime farmland soil. Approximately 60 percent of the site is Las Vegas-McCarran-Grapevine Complex on 0 to 4 percent slopes. The Las Vegas-McCarran-Grapevine Complex is a sandy loam, typically found in basin floor remnants. The soil complex contains three soil associations that are typically too intermingled to define individually. The soil develops in alluvium from limestone, sandstone, and lake bed sediments. The soil profile can be shallow to deep but is generally well drained. The upper section of the soil is typically brown fine, sandy loam that gradually becomes coarser at the bottom. A root-restricting later of hardpan gypsum or lime can be found within approximately 11 inches of the surface (USDA 1985).

The rest of the soils at NLVF constitute Skyhaven very fine sandy loam on 0 to 4 percent slopes. The Skyhaven association is a moderately deep, well-drained soil found on relic alluvial flats. The soil consists of fine, sandy loam over light-brown clay loam that becomes coarser at depth. The soil forms on a variety of rock parent materials, as long as they are rich in lime. A root-constricting layer of lime-cemented materials is found within 15 inches of the surface (USDA 1985).

4.3.5.4 Radiological Sources as a Result of Testing

There has been no nuclear testing at NLVF; therefore, soils are not contaminated with radioactive materials.

4.3.6 Hydrology

4.3.6.1 Surface Hydrology

NLVF is located in the Las Vegas Valley, which has a drainage area of 2,200 square miles in a desert region between sharp, rugged mountain ranges. The lowest point of the valley is the Las Vegas Wash, which drains the area toward Lake Mead (NPS 2001).

Surface-Water Features. There are no surface-water features located at or in close proximity to NLVF.

Flood Hazards. The Federal Emergency Management Agency Flood Insurance Rate Map covering NLVF (Map Number 32003C2160 E) indicates that the facility is located within Zone X. Zone X indicates an area of minimal flood hazard, which is determined to be above the 500-year flood level. There is an area approximately 500 feet north of the facility noted as Zone A, which indicates this location has a 1 percent chance of flooding annually (i.e., a 100-year floodplain) (FEMA 2002a).

Water Discharges and Regulatory Compliance. NLVF has an extensive storm drainage system, consisting of a retention basin, a network of slotted drains, storm drains of reinforced concrete pipe, directed sheetflow, and manmade channels. Stormwater pollution prevention is managed through a variety of measures including, but not limited to, general good housekeeping; spill prevention and response measures (including the implementation of a spill prevention, control, and countermeasures plan); sediment and erosion control measures; and employee training and education (DOE n.d.). NLVF has a "No Exposure Certification" for exclusion from NPDES stormwater permitting, which is afforded to certain facilities where potential contamination sources are protected from exposure to precipitation (Radack 2009).

Wastewater permits for NLVF include a Class II Wastewater Contribution Permit (Permit Number VEH-112) from the City of North Las Vegas for discharges to the city sewer system. This permit specifies concentration limits for contaminants in the wastewater discharges. In 2010, no exceedances of permit limits occurred at either of the two outfalls to the city sewer system (DOE/NV 2011) (see **Table 4–61**).

NLVF also operates under an NPDES permit (Permit Number NV0023507) issued by EPA, which is used for dewatering operations to control rising groundwater levels that surround the facility. Four dewatering wells pump groundwater into a storage tank. The permit allows for the discharge of water from the storage tank to groundwater via percolation, when used for landscape irrigation and dust suppression, and into the Las Vegas Wash via direct discharge into the City of North Las Vegas stormwater drainage system. In accordance with permit requirements, water chemistry analyses are performed quarterly, annually, and biennially for samples collected from the storage tank. In 2010, no permit limits were exceeded (see **Table 4–62**) (DOE/NV 2011).

Table 4–61 Water Quality Results for North Las Vegas Facility Sewer Discharges in 2010

Contaminant	Permit Limit	Outfall A	Outfall B
Ammonia (ppm)	61.0	48.5	22.5
Arsenic (ppm)	2.3	0.00146 [a]	<0.003
Barium (ppm)	13.1	0.140	0.195
Beryllium (ppm)	0.02	<0.00025	0.0000621 [a]
Cadmium (ppm)	0.15	0.000307 [a]	<0.0025
Chromium (hexavalent) (ppm)	0.10	<0.02	0.06
Chromium (total) (ppm)	5.60	<0.001	<0.001
Copper (ppm)	0.60	0.086	0.285
Cyanide (total) (ppm)	19.9	<0.005	<0.005
Lead (ppm)	0.20	<0.0015	<0.0015
Mercury (ppm)	0.001	<0.000066	0.00013
Nickel (ppm)	1.10	0.00301 [a]	0.00348 [a]
Oil and Grease (animal or vegetable) (ppm)	250	<10.0	<10.0
Oil and Grease (mineral or petroleum) (ppm)	100	<10.0	<10.0
Organophosphorous or Carbamate Compounds (ppm)	1.0	0.168	0.168
pH (Standard Units)	5.0–11.0	8.22	7.93
Phenols (ppm)	33.6	<0.05	<0.05
Phosphorus (total) (ppm)	0.50	4.48	4.61
Selenium (ppm)	2.70	<0.0025	<0.0025
Silver (ppm)	8.20	<0.00075	<0.00075
Zinc (ppm)	13.1	0.176	0.264

< = less than; pH = a measure of acidity or basicity; ppm = parts per million.

[a] Estimated concentration; the concentration between the method detection limit and the method reporting limit.

Note: Permit limits set forth in City of North Las Vegas Class II Wastewater Contribution Permit (Permit Number VEH-112).

Source: DOE/NV 2011, Table A-2.

Table 4–62 Water Quality Results for North Las Vegas Facility Dewatering Operations Measured at Water Storage Tank in 2010

Parameter	Sample Frequency	Permit Limit	First Quarter	Second Quarter	Third Quarter	Fourth Quarter
Daily Maximum Flow (MGD)	Continuous	0.005184	0.002486	0.002238	0.002342	0.002401
Total Petroleum Hydrocarbons (ppm)	Annually (4th Quarter)	1.0	NS	NS	NS	ND
Total Suspended Solids (ppm)	Quarterly	135	ND	ND	ND	ND
Total Dissolved Solids (ppm)	Quarterly	1,900	975	985	995	963
Total Inorganic Nitrogen as N (ppm)	Quarterly	20.0	1.38	0.165	0.929	0.965
pH	Quarterly	6.5–9.0	7.81	7.70	8.22	7.64
Tritium (pCi/L)	Annually (4th Quarter)	MR	NS	NS	NS	ND

MGD = million gallons per day; MR = monitor and report; ND = not detected; NS = sample not required that quarter; pCi/L = picocuries per liter; pH = a measure of acidity or basicity; ppm = parts per million.

Note: Permit limits set forth in U.S. Environmental Protection Agency National Pollutant Discharge Elimination System permit (Permit Number NV0023507).

Source: DOE/NV 2011, Table A-3.

4.3.6.2 Groundwater

Hydrogeologic Setting. NLVF is located within the center region of the Las Vegas Valley Hydrographic Basin, an intermountain basin within the Basin and Range Physiographic Province. The Las Vegas Valley Hydrographic Basin is approximately 1,600 square miles, with an estimated perennial yield of 25,000 acre-feet per year (NDWR 2010b). The basin is bordered by Spring Mountains (west), Frenchman Mountains (east), the McCullough Range (south), and the Sheep Range (north). Groundwater flow within the Las Vegas Valley is generally from west to east (USAF 2007c).

Groundwater Supply. All of the utility service lines at the NLVF complex (i.e., power, water, sewage, and natural gas) are owned by DOE/NNSA. NLVF receives its potable water from the Las Vegas Valley Water District, which is a member agency of the Southern Nevada Water Authority (SNWA). Southern Nevada gets nearly 90 percent of its water from the Colorado River. The other 10 percent comes from groundwater that is obtained from production wells in Clark County (LVVWD 2010b). Groundwater comes from three major aquifer zones (underground rock or sediment that is permeable and can conduct water) of the Las Vegas Valley aquifer, generally situated from 300 to 1,500 feet below land surface. Groundwater in the Las Vegas Valley aquifer is naturally recharged from precipitation in the Spring Mountains and the Sheep Range. This drinking water supply is protected from surface contamination by a layer of clay and fine-grained sediments throughout most of the Las Vegas Valley (LVVWD 2010a).

Groundwater Monitoring and Quality. EPA sets national standards for drinking water to protect public health. SNWA requires public drinking water systems to meet these health-based water standards and send customers an annual water quality report. While EPA requires water systems to monitor for approximately 90 regulated contaminants, the Las Vegas Valley Water District monitors for these contaminants as well as about 30 additional unregulated contaminants. Water delivered by the Las Vegas Valley Water District meets or surpasses all Federal and state drinking water standards (LVVWD 2009).

The water table at NLVF occurs at shallow depths ranging from approximately 13 to 50 feet from ground surface. In 1995, a release of tritium occurred in the basement of Building A-1, resulting in the contamination of groundwater that was not discovered until 1999 (Radack 2010b). Remediation was initiated in 2001, when a sump well was installed in the basement of Building A-1. The sump well was used to capture contaminated groundwater until 2002, when remedial operations were completed. All contaminated groundwater was disposed at the NNSS Area 5 sewage lagoon. In early 2003, the sump well was again used intermittently to support NLVF's Dewatering Program. The Dewatering Program was established to control encroaching groundwater beneath Building A-1 (DOE/NV 2011). Although the levels of tritium are now one-tenth of the SNWA limit, water that is pumped from the sump well is disposed at the NNSS Area 5 sewage lagoon in the winter months and is evaporated through swamp coolers located at NLVF during the summer months (DOE/NV 2011; Radack 2010a).

Under the NLVF Dewatering Program, water table elevation monitoring is conducted at 12 monitoring wells, and water levels are monitored continuously at the sump well in Building A-1. In addition, the total volume of groundwater discharged and groundwater chemistry are monitored in accordance with the NPDES permit (NV0023507) (DOE/NV 2011; Radack 2010a).

Groundwater Control. In 1999, groundwater intruded into the elevator pit of Building A-1 (DOE/NV 2008a). As a result of this groundwater intrusion, DOE/NNSA initiated groundwater studies and eventually instituted a Dewatering Program to control rising groundwater levels surrounding the facility. Groundwater studies conducted in 2002 and 2003 revealed a complex hydrogeologic setting. Borehole data from the studies indicate that fine-grained sediments represent a low-energy, mid-valley alluvial and fluvial environment. Individual lithologic units are complexly interbedded, and several normal faults have been mapped in the vicinity.

The hydrogeologic setting suggests that the source of the rising groundwater is water flowing upward along local faults from deeper confined aquifers. This condition is considered a long-term adjustment that

can be attributed to a combination of causes, including a seasonal water injection program conducted by SNWA and shifting of regional pumping centers away from the vicinity of NLVF (Bechtel Nevada 2005).

The Dewatering Program at NLVF is regulated under an NPDES permit (NV0023507), which establishes contaminant and discharge limitations. Dewatering wells (NLVF-13, -15, -16, and -17) pump groundwater into a 10,500-gallon storage tank. The permit allows for the discharge of water from the storage tank to groundwater via percolation, when used for landscape irrigation and dust suppression, and into the Las Vegas Wash via direct discharge into the City of North Las Vegas stormwater drainage system (see Section 4.3.2.1.2 for more information regarding discharges). In accordance with the permit, sampling and analyses of discharge water are performed quarterly, annually, and biennially (DOE/NV 2011).

Discharge rates have not exceeded NPDES permit limits. In 2008, the four dewatering wells produced a total of 2,553 gallons per day (average daily flow) that were directed into the storage tank. The pumping rates varied from 0.72 to 0.24 gallons per minute. The average combined discharge from all four wells was about 78,000 gallons per month (DOE/NV 2009d).

4.3.7 Biological Resources

NLVF is in the Southern Basin and Range Ecoregion. It was built on cleared, previously disturbed land that now consists of an urban setting that includes buildings, pavement, and landscaping. No original undisturbed native vegetation remains on the site. Current vegetation at NLVF consists of urban landscape. Few wildlife species exist at NLVF because it is located in an urban area and contains little vegetation.

4.3.7.1 Flora

This facility is located in an urban setting; no native vegetation within a natural setting occurs at this site.

4.3.7.2 Fauna

This facility is located in an urban setting; only urban-adapted wildlife occurs at this site. Wildlife species would be similar to those described in Section 4.2.7.2 for RSL.

4.3.7.3 Threatened and Endangered Species

NLVF is located in urban Las Vegas, Nevada, on previously disturbed land within a fenced site. No threatened, endangered, or rare species are expected to exist at this site. No designated critical habitats for federally listed species exist at NLVF. The urban areas of Clark County are not considered tortoise habitat.

4.3.7.4 Other Species of Concern

No other species of concern inhabit NLVF.

4.3.7.5 Effects of Past Radiological Tests and Project Activities

This facility is located in an urban setting; no past radiological tests or project activities are anticipated to affect wildlife or vegetation at this site.

4.3.8 Air Quality and Climate

4.3.8.1 Meteorology

Downtown Las Vegas is located in Clark County, Nevada, about 56 miles southeast of the southeastern edge of the NNSS. NLVF is about 10 miles northeast of downtown. The facility is located in the Las Vegas Valley, which is situated in the northeastern corner of the Mojave Desert and in the rain shadow (lee) of the southern Sierra Nevada mountain range.

The Las Vegas Valley has the general climatic characteristics of a mid-latitude desert area, with relatively little precipitation throughout the year and low humidity, large diurnal and seasonal temperature ranges,

and intense solar radiation in the summer. The generally dry desert conditions specific to the area can occasionally be modified by the southwestern monsoon and convective thunderstorms during the summer months and Eastern Pacific tropical storm remnants in the late summer and fall. The dry conditions can also be moderated by strong *El Niño* cycles, which generally bring more rainfall to the area.

The Las Vegas Valley ranges in elevation from about 2,300 to 2,620 feet above mean sea level and is bounded by mountains to the north, south, and especially to the west, where the Spring Mountains peak above about 6,560 feet. This terrain causes wind flows in the Las Vegas Valley to be dominated by upslope and downslope conditions. The Clark County DAQEM maintains an ambient monitoring site (the J.D. Smith monitor, at 1301 East Tonopah Road) near the North Las Vegas Campus. For more information regarding the meteorological characteristics of NLVF, see Appendix D, Section D.1.2.1.

4.3.8.2 Ambient Air Quality

4.3.8.2.1 Region of Influence

NLVF is located about 55 miles southeast of the NNSS. The ROI for air quality and climate for NLVF operations comprises northern Clark County. Historic data on pollutant emissions inventories and compliance status for the State of Nevada are calculated at the resolution of county or hydrographic areas. These data provide a basis for determining existing air quality in the ROI and a metric for emission comparison assessments.

4.3.8.2.2 Existing Air Quality

Ambient Air Quality Standards. See Section 4.1.8.2.2 for a discussion on the current national and Nevada ambient air quality standards.

Air Quality Status. NLVF is within Hydrographic Area 212. Clark County is in nonattainment for 8-hour ozone[28] and 24-hour $PM_{10.}$[29] Clark County is no longer in nonattainment for 8-hour carbon monoxide.[30] All other pollutants are in attainment.

PSD is a regulation incorporated into CAA that limits increases of certain pollutants in clean air areas (attainment areas) to certain increments even though ambient air quality standards are being met. CAA has three classes of areas with different increments. The smallest increments allowed are Class I areas, which are areas of special value (natural, scenic, recreational, or historic). Any degradation of existing air quality in these areas should be minimized. The closest PSD Class I areas are Grand Canyon National Park (about 65 miles to the east) and Sequoia National Park (about 165 miles to the west). NLVF currently has no sources of pollution large enough to be subject to PSD requirements. However, because NLVF is located in a nonattainment area, it could potentially be subject to nonattainment new source review if the emissions were of sufficient strength; however, they have been determined not to meet the threshold for new source review. Nonattainment new source review requirements are customized for the classification and type of air pollutant nonattainment area.

[28] *Classified as marginal for 8-hour ozone under former Subpart 1 with a nonattainment area that includes those portions of Clark County that lie in Hydrographic Areas 164A, 164B, 165, 166, 167, 212, 213, 214, 216, 217, and 218, but excludes the Moapa River Indian Reservation and the Fort Mojave Indian Reservation. However, on March 29, 2011, EPA made the determination that Clark County is in attainment with 1997 ozone NAAQS (76 FR 17343). EPA is expected to redesignate the area's status to attainment upon approval of the Ozone Redesignation Request and Maintenance Plan submitted to EPA Region 9 in early April 2011.*

[29] *Designated as serious nonattainment for $PM_{10.}$ The nonattainment area covers Hydrographic Area 212. However, on August 3, 2010, EPA made the determination that the Las Vegas Valley is in attainment with the PM_{10} NAAQS based on monitoring data (75 FR 45485). EPA is expected to redesignate the area's status to attainment upon approval of the maintenance plan and request for redesignation that Clark County is expected to submit.*

[30] *A CO Maintenance Plan and formal request for resdesignation to attainment was submitted to the EPA in 2008 and approved on September 7, 2010 (75 FR 59090).*

Emissions Due to NLVF Operations. Title V of CAA gives states the authority to use air quality permits to regulate stationary source emissions of criteria pollutants. At NLVF, a Source 657 Authority to Construct/Operating Permit regulates emissions from sources such as an aluminum sander, an abrasive blaster, emergency generators, boilers, cooling towers, and a spray paint booth. The emissions of carbon monoxide, nitrogen oxides, PM_{10}, sulfur dioxide, volatile organic compounds, and hazardous air pollutants were each less than 1 ton annually from 2003 through 2008 for these permitted facilities. Total emissions of these pollutants over this 6-year period are about 4.4 tons (DOE 2004b, 2005b, 2006a, 2007b, 2008j, 2009c).

Table 4–63 shows the onsite emissions due to stationary sources, as well as emissions due to NLVF commuters, commercial vendors, and radioactive waste trucks in Clark County and in Nye County both on the NNSS and off the NNSS, where appropriate. The onsite stationary sources include both permitted sources and natural gas combustion for heating. See Appendix D, Section D.3.2.1, for more information on mobile and stationary source emission methodology.

Measurements of Ambient Air Concentrations on and near NLVF. The Clark County DAQEM maintains an air quality monitoring network throughout Clark County. The J.D. Smith monitor (at 1301 East Tonopah Road) is located about 1 mile northwest of NLVF. It monitors hourly ozone, carbon monoxide, and nitrogen dioxide levels and daily PM_{10}, and $PM_{2.5}$ levels. **Table 4–64** shows these results along with the highest sulfur dioxide value monitored in the Las Vegas Valley. Note that at least 25 percent of the 2008 observations were missing, so the maximum concentrations could potentially be higher than what is shown for that year. The ambient air quality standards are also shown in the table. See Table 4–40 for more information on the standards.

Ozone measurements at the J. D. Smith monitor (at 1301 East Tonopah Road) exceeded the 8-hour ozone NAAQS in 2006 and 2007. The largest 8-hour ozone concentration was 0.081 ppm (in 2006), which is 0.006 ppm larger than the current NAAQS of 0.075 ppm. Maximum ambient ozone concentration levels have generally remained constant at this level and other nearby monitors since at least 1998 (DAQEM 2009).

PM_{10} measurements at the J.D. Smith monitor (at 1301 East Tonopah Road) indicated that the second-highest 24-hour average PM_{10} concentration was 136 micrograms per cubic meter (in 2006), which is 14 micrograms lower than the NAAQS of 150 micrograms per cubic meter. Although this 24-hour PM_{10} concentration is below the NAAQS, other monitoring locations within the Las Vegas Valley exceed the standard and the entire valley has been designated as nonattainment for PM_{10}. The largest annual average PM_{10} concentration was 33 micrograms per cubic meter (in 2006), which is well below the Nevada ambient air quality standard of 50 micrograms per cubic meter (there is no national PM_{10} annual average standard).

All other criteria pollutants are well below NAAQS. No lead monitoring data are available for the Las Vegas Valley.

$\mu g/m^3$ = micrograms per cubic meter; CO = carbon monoxide; NAAQS = National Ambient Air Quality Standards; NO_2 = nitrogen dioxide; O_3 = ozone; PM_n = particulate matter with an aerodynamic diameter less than or equal to *n* micrometers; ppm = parts per million; SO_2 = sulfur dioxide.

Note: Monitored values are from the J.D. Smith monitor (at 1301 East Tonopah Road), except for SO_2, which was the highest monitored value in the Las Vegas Valley.

All exceedances of the NAAQS are shown in bold font.

Source: EPA 2010a.

4.3.8.3 Radiological Air Quality

Direct radiation monitoring is conducted near Buildings A-1 (Source Range Laboratory) and C-3 (High Intensity Source) at NLVF. These are the two locations at NLVF that currently use radioactive sources or are where radiation-producing operations are conducted. These and other historical radiation measurements show that radiological doses to the public from NLVF activities are indistinguishable from background radiation (DOE 2009e). **Table 4–65** presents the total estimated radionuclide emissions from NLVF in 2007 and 2008. Based on the 2008 emission rate of 0.011 curies, the estimated radiation dose to the nearest offsite public access point to NLVF was 0.00006 millirem per year. This is well below the NESHAPs dose limit for the general public of no greater than 10 millirem per year. **Table 4–66** presents statistics on radiation exposure measurements taken once per quarter at the NLVF boundary and control locations. These results both include and are indistinguishable from doses from natural background radiation near NLVF.

Table 4–65 Estimated Annual Air Releases of Radionuclides at the North Las Vegas Facility

	Estimated Annual Emissions (curies)	
	2007	***2008***
Tritium	0.012	0.011
Reference	DOE 2008c	DOE 2009c

Note that parts of the Building A-1 basement were contaminated with tritium in 1995. The release led to a very small potential exposure (less than 0.001 millirem per year) to an offsite person; the NESHAPs dose limit for exposure of the public is 10 millirem per year (40 CFR Part 61, Subpart H). Tritium continues to be emitted at low levels (e.g., 5.3×10^{-4} curies in 2009 [NSTec 2010b]) from the parts of the building that were exposed to the initial release (DOE 2009d).

An accidental release also occurred at NLVF in 2004; this release involved the improper disposal of tritium-contaminated water into a public sewer system. These levels were also well below the level of concern. However, in response to this incident, the DOE/NNSA NSO has developed several procedures to prevent this type of accidental discharge in the future (DOE 2005b).

4.3.8.4 Climate Change

This section describes the affected environment in terms of current and anticipated trends in greenhouse gas emissions and climate. The effects of emissions on the climate involve very complex processes and interact with natural cycles, complicating the measurement and detection of change. Recent advances in the state of the science, however, are contributing to an increasing body of evidence that anthropogenic greenhouse gas emissions affect climate in detectable and quantifiable ways.

For information on greenhouse gas emissions in the United States, please see Section 4.1.8.4.1. Greenhouse gas emissions at NLVF are discussed in the next section. Details on the methodology used to determine these emissions are discussed in Appendix D, Sections D.2.3.1.1, D.2.3.2.1, and D.2.3.3.1.

Table 4–66 Average Annual Average and Maximum Annual Average Radiation Levels Among the North Las Vegas Facility Boundary Monitors and Control Monitors Operating in a Given Year

	Radiation Level (millirem per year)											
	1997	***1998***	***1999***	***2000***	***2001***	***2002***	***2003***	***2004***	***2005***	***2006***	***2007***	***2008***

Note: These radiation measurements are taken once per quarter year (DOE 2009e).

4.3.8.4.1 Greenhouse Gas Emissions

Table 4–67 provides greenhouse gas emissions due to NLVF-related activities for 2008. The greenhouse gas emissions are presented in carbon-dioxide-equivalent form and are partitioned by various mobile and stationary source types. These emissions were derived from fuel use, vehicle activity, and power consumption data. The greenhouse gas emissions were calculated using the EPA Climate Leaders Simplified Greenhouse Gas Emissions Calculator (EPA 2010b). These emissions were compared with a reference amount of 25,000 metric tons (27,558 tons), which is the threshold for which a quantitative assessment may be meaningful (CEQ 2010).

Electricity consumption is by far the largest single source of greenhouse gas emissions related to NLVF activities, emitting approximately 8,392 carbon-dioxide-equivalent tons of greenhouse gases, or 63 percent of the NLVF-related greenhouse gas emissions total. Stationary sources altogether emitted about 8,563 carbon-dioxide-equivalent tons of greenhouse gases. Mobile sources emitted about 4,792 tons, so that overall, NLVF-related activities created about 13,355 carbon-dioxide-equivalent tons of greenhouse gas emissions in 2008, which is about 52 percent below the threshold reporting level.

Table 4–67 Carbon-Dioxide-Equivalent Emissions of Greenhouse Gases from North Las Vegas Facility Activities in 2008

Source Type	***Carbon-Dioxide-Equivalent Emissions (tons per year)***	***Fraction of Reference Point of 25,000 Metric Tons [a]***
STATIONARY SOURCES		
Power generation	8,392	0.30
Natural gas heating	157	0.01
All stationary sources, except air conditioning/refrigeration and natural gas heating	15	0.00
All Stationary Sources	*8,563*	*0.31*
MOBILE SOURCES		
Commuting	3,896	0.14
Hazardous waste transport (nongoverment)	7	<0.01
Commercial vendors	889	0.03
All Mobile Sources	*4,792*	*0.17*
Total	***13,355***	***0.48***

[a] 25,000 metric tons are equal to about 27,558 short tons.

4.3.8.4.2 Current Changes in Climate

For a discussion of climate change impacts in the region, please see Section 4.1.8.4.2.

4.3.9 Visual Resources

The area around NLVF is highly developed, primarily with commercial and warehouse facilities. The visual environment comprises infrastructure, such as buildings, roadways, and utilities. **Figure 4–43** shows the locations from which photographs of the area around NLVF were taken and the sensitivity levels of the roadways in the area (see Section 4.1.9). Vegetation in the area is limited to street landscaping, such as palm and evergreen trees and various shrubs (see **Figure 4–44**, View 1).

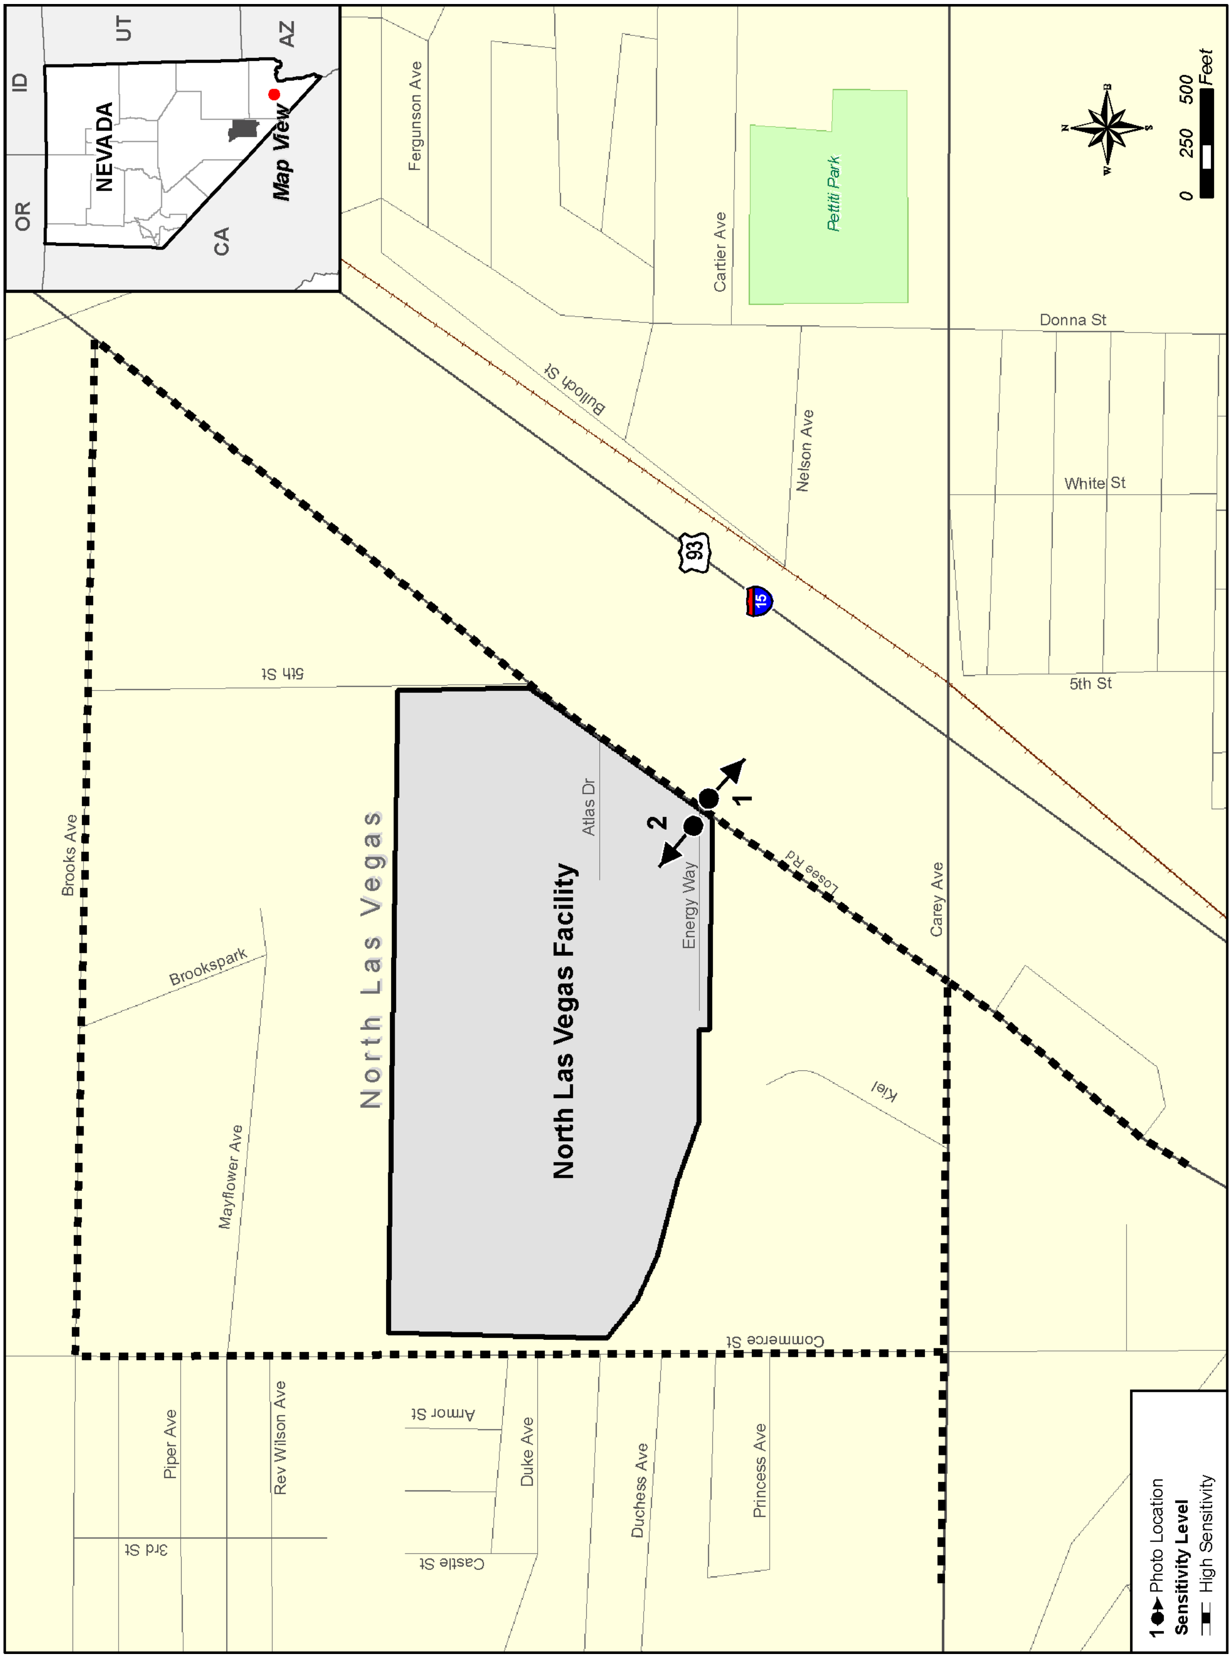

Figure 4–43 Photograph Locations and Sensitivity Levels near the North Las Vegas Facility

View 1

View 2

Figure 4–44 Landscape Photographs near North Las Vegas Facility

The areas surrounding NLVF are developed, with warehouse and commercial facilities; visual access to these areas is limited to views from public roadways and sidewalks in the area. On local streets, such as near NLVF, speed limits are lower, yet surrounding development is dense and there is much more traffic. These elements combine so views are not focused on a specific facility that is visually similar to its surroundings, but on driving and views immediate to the road corridor. There is no public visual access to the interior of NLVF (see Figure 4–44, View 2). The area is primarily visible from Losee Road and may have limited views from Commerce Street, Brooks Avenue, and 5th Street. Visible portions of the area are considered to have a Class C scenic quality rating (see Section 4.1.9 for information on the visual impact rating system) due to the developed nature of the landscape, as described above, combined with high intrusion of manmade elements and lack of elements that help to improve aesthetics, such as landscaping.

4.3.10 Cultural Resources

For introductory information regarding cultural resources, see Section 4.1.10.

NLVF is located in northern Las Vegas Valley, within the center region of the Las Vegas Valley Hydrographic Basin, an intermountain basin within the Basin and Range Physiographic Province of the United States (NDWR 2006). NLVF consists of an 80-acre complex of 30 buildings and 1 trailer located in a highly developed area zoned for generalized industrial activity. It was built on cleared, previously disturbed land that now consists of an urban setting comprising buildings, pavement, and ornamental landscaping. The area of influence at NLVF includes the entire footprint of the facility.

4.3.10.1 Recorded Cultural Resources

There are no recorded cultural resources within the boundary of NLVF.

4.3.10.2 Sites of American Indian Significance

No sites of American Indian significance have been identified within the boundary of NLVF. As part of the preparation of this SWEIS, DOE/NNSA consulted with CGTO to determine whether sites of American Indian significance exist within NLVF.

4.3.11 Waste Management

DOE/NNSA operations do not generate LLW, MLLW, or TRU waste at NLVF. DOE/NNSA does generate, however, water that is slightly contaminated with tritium and collected as air conditioning condensate from the basement sump of one of the buildings. The water is either disposed by evaporation at NLVF or transported in tanker trucks to the NNSS for disposal by evaporation in NNSS sewage lagoons (DOE/NV 2011; NSTec 2009c).

The quantities of hazardous waste that were generated at NLVF and disposed or recycled during CYs 2005 through 2008 are listed in **Table 4–68** (Duke 2009). This waste includes recycled oil and antifreeze, other hazardous waste, such as universal waste, and waste that is regulated under other regulatory authorities, such as TSCA. Hazardous wastes include universal wastes, i.e., materials such as computer equipment, batteries, and fluorescent lamps. (The Regulated Management Program for universal waste is streamlined compared to that for other hazardous wastes and emphasizes material reuse or recycle.) All hazardous and toxic wastes are disposed or recycled at offsite facilities.

Table 4–68 Annual Hazardous and Toxic Waste Disposal or Recycle Quantities for the North Las Vegas Facility (tons)

Waste	*Calendar Year*			
	2005	*2006*	*2007*	*2008*
Recycled oil and antifreeze	a	0.21	a	7.4
Other hazardous waste [b]	0.57	0.98	0.34	1.36
Other waste [c]	a	a	a	0.26

[a] Not reported for this year.
[b] Hazardous waste, including universal wastes such as computer equipment, batteries, and fluorescent lamps that are generated in a wide variety of settings; are not solely industrial; are generated by a large community; and are present in significant volumes in nonhazardous management systems. The Regulated Management Program for universal waste is streamlined compared to that for other hazardous wastes and emphasizes material reuse or recycle.
[c] Waste regulated under the Toxic Substances Control Act or statutory authorities other than the Resource Conservation and Recovery Act.
Source: Duke 2009.

Most hazardous waste comes from the machine shop. Routine hazardous waste streams include lead- and solvent-contaminated rags and lead metal shavings and debris. Nonroutine hazardous waste streams include non-empty aerosol cans; lab-packs of unused, out-of-date chemicals from various locations; and wastes from occasional demolition activities. Universal waste, such as light bulbs and batteries, come from facility maintenance and cleanup activities. Recycled materials include used oil and antifreeze. The used oil is typically generated by draining or replacing quenching or cooling oils at the machine shop and is occasionally generated as part of draining equipment or replacing hydraulic fluid, as well as from facility maintenance projects (Duke 2009).

Finally, NLVF generates sanitary solid waste, which is generally collected and disposed by a municipal waste service. For security reasons, however, some solid waste is collected by the DOE/NNSA NSO and sent for disposal at the NNSS Area 23 Landfill (see Section 4.1.11.2.3).

In the future, waste may be generated as part of decommissioning unneeded structures.

4.3.12 Human Health and Safety

NLVF provides calibration and other services using specialized radiation fields for a variety of instrument packages in support of NNSS operations. The radiation fields are provided by sealed sources containing cobalt-60, cesium-137, or plutonium-239 that are stored in heavily shielded configurations in the below-grade portion of Building A-1. Because these are sealed sources, they do not release radioactive material that could pose a risk to the workers or the public. There is no direct exposure to the public as a result of the shielding provided by the engineered structure and the location below ground level. Worker exposure is managed by the shielding and administrative controls that limit access to the below-grade area where the sealed sources are stored.

An accident in 1995 resulted in the release of more than 1 curie of tritium into the basement area of Building A-1. The release occurred when a container of tritium-aluminum foils was improperly opened in the Atlas Facility in NLVF. The tritium release was cleaned up, but residual tritium continues to emanate from the basement floor. In 2008, the estimated dose to a hypothetical MEI near NLVF was 0.0006 millirem. Since the accident, the highest annual dose to the MEI was 0.0018 millirem in a year; since 2005, the dose has been less than 0.0001 millirem per year. This dose is magnitudes less than the 10 millirem annual limit under NESHAPs (40 CFR Part 61, Subpart H). A detailed discussion of the radiation environment, including radionuclide releases and associated potential doses to an MEI, is presented in the *Nevada Test Site National Emission Standards for Hazardous Air Pollutants – Radioactive Emissions, Calendar Year 2008* (DOE 2009d).

Chemical exposure pathways to NLVF workers during normal operations may include inhaling the workplace atmosphere, drinking NLVF potable water, and possible other contact with hazardous

materials associated with work assignments. The potential for health impacts varies from facility to facility. Workers are protected from hazards specific to the workplace through appropriate training, protective equipment, monitoring, and management controls. NLVF adheres to Occupational Safety and Health Administration and EPA occupational standards (see Chapter 9) that limit atmospheric and drinking water concentrations of potentially hazardous chemicals. Appropriate monitoring, which reflects the frequency and amounts of chemicals utilized in the operational processes, ensures that these standards are not exceeded.

In August 2003, beryllium was found in NLVF Buildings B-1, B-2, and B-3. It was determined that the material was from copper-beryllium alloys milled in Building B-1 during the 1980s. Buildings B-1 and B-2 were demolished in 2004.

The greatest contributor to background noise at NLVF is vehicular traffic, as the facility is located near Interstate 15 (just east of the site) and is buffered on the north, south, and east by general industrial zoning. No environmental noise data are available at NLVF; however, because of its proximity to an interstate and the common occurrence of traffic congestion in the surrounding area, it is estimated that background noise levels range from 60 to 70 decibels, A-weighted (EPA 1974).

4.3.13 Environmental Justice

As seen in Figure 4–39, there are numerous block groups to the south and east of the NLVF where the low-income population is between 11 and 20 percent, and several additional block groups in the 21–30 and greater-than-30 percent range further to the south. The NLVF is located in an area where the majority of block groups have minority populations exceeding 50 percent (see Figure 4–40).

4.4 Tonopah Test Range

This section describes the existing environmental conditions found at the TTR. The TTR comprises approximately 280 square miles (179,200 acres) and is surrounded on three sides by the Nevada Test and Training Range. The Nevada Test and Training Range is located approximately 30 miles from the town of Tonopah, Nevada. The TTR, which is operated by Sandia National Laboratories, offers a unique test bed for DOE and DoD weapons systems. The primary mission of DOE/NNSA at the TTR is to ensure that the Nation's nuclear weapons systems meet the highest standards of safety and reliability.

4.4.1 Land Use

TTR is located in Nye County, Nevada, near the northwestern corner of the Nevada Test and Training Range, approximately 12 miles north of the nearest NNSS boundary. The TTR is 22 miles east of Goldfield and 140 miles north of Las Vegas. The TTR is located in a remote, broad, flat valley with scattered former lake beds between the Cactus Range to the west and Kawich Range to the east.

The main operational area for the TTR is within the Cactus Flat Valley, which has outcrops of low hills in the south and consists of hundreds of buildings, structures, and equipment. Many of these buildings and structures are prefabricated; only a handful are permanent structures or buildings. An airport is located just north of the built-up complex, and an additional airstrip is located just south of the built-up complex. The airport and airstrip are not open for public use.

Adjacent Land Use. The TTR is located within a portion of the 1,302,000-acre Nevada Wild Horse Range, which extends across the northern portions of the Nevada Test and Training Range and southward to the NNSS. The Nevada Test and Training Range is primarily used for weapons development and flight training. BLM manages the wild horses on the Nevada Test and Training Range; management of wild horses is a secondary use of these lands. Visitor access is not permitted due to security reasons.

Sparsely populated public lands north of the TTR boundary are jointly administered by BLM and the U.S. Forest Service and are currently used for cattle grazing, recreation, and other uses. The nearest population to the TTR is approximately 22 miles west of the site, in the town of Goldfield.

Historical Use. The TTR was used extensively between 1956 and 1989. It was one of the primary test facilities during the Cold War era due to its isolation and size. The Atomic Energy Commission began testing weapons systems, research rockets, and artillery on the TTR in 1957. TTR capabilities evolved to include nonnuclear field-testing of nuclear weapons design, stockpile surveillance, and research.

Current Use. Principal DOE/NNSA activities at the TTR include stockpile reliability testing; research and development; and support for a variety of testing, including arming, fusing, and firing systems testing. No nuclear devices are tested at the TTR (DOE 2008k).

DOE/NNSA activities at the TTR are conducted through the DOE/NNSA Sandia Site Office under a land use permit from the USAF. Principal activities are conducted within a smaller area (176,000 acres) known as the "Permitted Premises." Revisions to the TTR boundary and the land use permit area for the Sandia Site Office operations area at the TTR would need to be coordinated with the USAF. The current land use permit granting DOE/NNSA use of this portion of the TTR extends through 2019 (USAF 2002).

Characterization and remediation of industrial sites at the TTR are ongoing, and the majority of the industrial sites have been closed (DOE 2008f).

4.4.1.1 Public Land Orders and Withdrawals

The following Memorandum of Understanding, Withdrawal Act, and land permit are applicable to the TTR.

Memorandum of Understanding. The Memorandum of Understanding, signed in 1956, designated approximately 370,000 acres to support research related to the weapons development program.

Military Lands Withdrawal Act of 1999, Public Law 106-65. Enacted on October 5, 1999, this act extended the withdrawn lands set aside by previous public land orders (about 3 million acres in total) for defense use as part of the Nevada Test and Training Range, including the TTR, for another 20 years. Although no nuclear devices are tested at the TTR, this land is an integral part of DOE/NNSA operations within the Nevada Test and Training Range.

Sandia Land Permit. This permit, effective from April 26, 2002, until October 5, 2019, grants DOE/NNSA permission for use, operation, and occupancy of a portion of the Nevada Test and Training Range at the TTR. This permit is re-evaluated at 5-year intervals to review the requirements that established the need for this permit. This permit does not allow activities that significantly interfere with the Nevada Test and Training Range and requires both entities to work cooperatively to accomplish their respective missions. Activities that occur on this leased land must comply with applicable laws and regulations related to the environment, occupational health and safety, handling and storage of hazardous materials, and disposal of hazardous materials.

4.4.2 Infrastructure and Energy

4.4.2.1 Infrastructure and Utilities

This section discusses the TTR buildings and transportation infrastructure; potable water, wastewater, and communications utilities; and support services, including law enforcement and security, fire protection, and health care. Further transportation-related information is discussed in Section 4.4.3. Solid waste collection is discussed in Section 4.4.11. Energy systems (electricity, natural gas, and liquid fuels) are discussed in Section 4.4.2.2.

4.4.2.1.1 Infrastructure

Facilities. The TTR contains 105 major buildings, providing approximately 161,500 square feet of floor space, and approximately 90 smaller buildings, including towers and small sheds (DOE 1996c).

Transportation Systems. See Section 4.4.3.1 for a discussion of the onsite transportation infrastructure at the TTR.

The USAF maintains an active base and airport on the TTR in support of its missions. This airport building is approximately 10,000 square feet. The existing 12,000-foot runway and navigation aids are open to DOE on an as-needed basis. The Mellan Airstrip is located on the southern portion of the TTR. This airstrip supports DOE and USAF training programs and is used sporadically. There are no support facilities associated with the Mellan Airstrip.

4.4.2.1.2 Utilities

Water Supply. The PWS at the TTR is registered with NDEP as a Nontransient, Noncommunity PWS (see text box in Section 4.1.6.2 for PWS definitions).

The following are three active water wells used by the TTR: (1) Production Well 6, (2) Well 7, and (3) the Roller Coaster Well. The most active are Production Well 6 and the Roller Coaster Well. Production Well 6 supplies drinking water to the TTR Main Compound in Area 3; this well is routinely sampled and analyzed per NDEP requirements to demonstrate conformance with primary drinking water standards. Outlying areas and buildings without potable water service use bottled water (DOE 2009a). Nonpotable wells, particularly the Roller Coaster Well, service the TTR for construction and industrial activities. Some impoundments at the TTR are used to store water during activities. Annual water usage at the TTR is approximately 6 million gallons for the entire range, including water used by the USAF at the TTR (DOE 2008l). See Section 4.4.6 for more information on the water supply.

Wastewater Collection and Treatment Systems. Industrial (primarily discharge from an oil-water separator) and sanitary wastewater generated at the TTR is collected and pumped to a USAF facultative sewage lagoon treatment unit located approximately 1.5 miles southwest of the main gate. The industrial flows are combined with sanitary flows for final treatment using biological processes in two lined aerated ponds, which are permitted by NDEP and operated by the USAF under an NPDES permit (Permit Number NEV20001) (DOE 2009a). Five active septic tank systems are used in remote areas of the TTR for domestic sanitary sewage treatment; there is also one inactive septic tank system in one area (DOE 2009a). Annual wastewater samples are taken at the point where wastewater leaves the TTR property and enters the USAF system (DOE 2009a).

Communication Systems. Communications at the TTR are supported by a regional system. The TTR telecommunication system employs digital telephone switching, fiber optic transmission, microwave, two-way radio, voice privacy, data transmission systems, general- and special-purpose data communications, and teleconferencing services. The TTR also has a ground-to-air communication system that supports all air-to-ground testing programs. The VHF [very-high-frequency] and UHF [ultra-high-frequency] communication capability is reliable within a 200-mile radius of the TTR, depending on the altitude, while high-frequency communication can be reliable for thousands of miles.

4.4.2.2 Electrical Energy

Power to DOE/NNSA facilities at the TTR is supplied by NV Energy. NV Energy has two supply lines to the TTR: the primary line is 120 kilovolts, and a backup line is 60 kilovolts. NV Energy transformers step the voltage down to 13.8 kilovolts for the DOE/NNSA distribution system. The remaining power line supplies the USAF facilities. All remote operations are supplied with electrical power by portable generators.

4.4.2.2.1 Natural Gas

There is no infrastructure for natural gas supply at the TTR.

4.4.2.2.2 Liquid Fuels

The TTR uses various types of liquid fuel for its energy needs, including gasoline, diesel, and propane. There are currently no aboveground storage tanks at the TTR requiring registration with the State of Nevada (DOE 2009a); however, there are a number of fuel storage tanks that are listed as non-permit equipment in the TTR NDEP Class II Air Quality Operating Permit (AP8733-0680.02). The Non-Permit

Equipment List indicates that the TTR maintains diesel-fired generators, gasoline generators, and propane-fired boilers. The TTR has onsite propane storage tanks, as presented in **Table 4–69**, with a permitted collective storage capacity of 23,563 gallons (NDEP 2007).

Table 4–69 Tonopah Test Range Propane Storage Tank Capacities

Equipment	*Quantity*	*Size*
Propane Storage Tanks	22	1 × 119 gallons 1 × 250 gallons 5 × 495 gallons 2 × 500 gallons 5 × 1,000 gallons 1 × 1,050 gallons 3 × 1,150 gallons 1 × 1,500 gallons 1 × 2,000 gallons 1 × 3,000 gallons 1 × 3,219 gallons

Source: NDEP 2007.

4.4.3 Transportation

4.4.3.1 Onsite Transportation

The TTR's onsite roadway network consists of 118 miles of primary paved roads, 23 miles of secondary paved roads, 113 miles of primary compacted dirt roads, and 39 miles of secondary compacted dirt roads (DOE 1996c). The two primary paved roads on the TTR (one traversing north–south and one east–west) support the majority of the daily traffic, as well as traffic during operations. See **Figure 4–45** for primary paved roads. Traffic within the TTR mainly occurs on Main Road South. Dirt roads are used for secondary daily travel, but are primarily used during experimental activities.

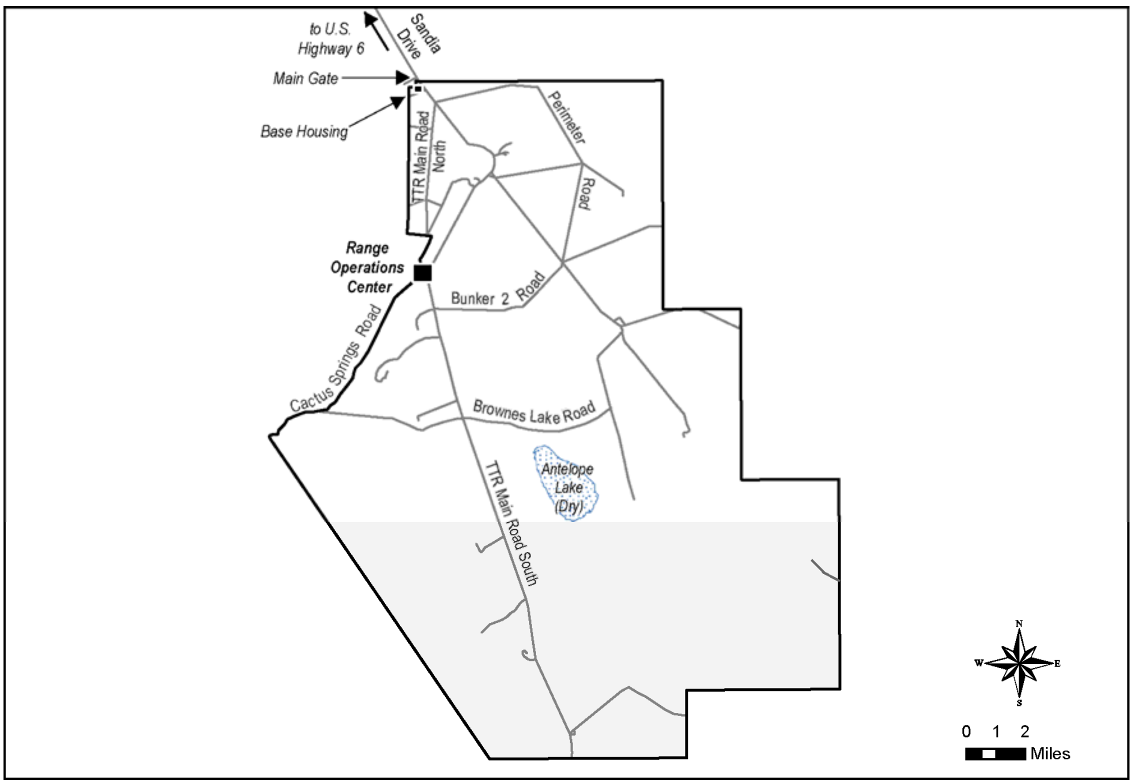

Figure 4–45 Tonopah Test Range Roadways

The roadway system on the TTR is jointly maintained by DOE/NNSA and the USAF. Generally, no privately owned vehicles are permitted on the site; however, privately owned vehicle passes are occasionally issued to offsite personnel and visitors that temporarily reside in the housing area located near the main entrance. Workers either drive government-supplied vehicles from the main entry of the TTR or ride government-supplied bus transportation to the work site. The majority of the onsite traffic is attributed to security support and facility operations (DOE 1996c).

4.4.3.2 Regional Transportation

The TTR is bounded by the Nevada Test and Training Range on the east, west, and south. Although there are access points to areas of the Nevada Test and Training Range through other gates, access to the site is normally through the Main Gate at the northern boundary. North of the Main Gate, Main Road North becomes Sandia Drive (also known as State Route 504), which connects to U.S. Route 6 about 20 miles to the north. Traffic volumes and levels of service on roadways in Nye County, including those near the TTR, are discussed in Section 4.1.3.2.2. Because the TTR is located in an isolated, rural area, traffic volumes on nearby public roadways are low. Daily traffic volumes on U.S. Route 6 are presented in Table 4–11; this roadway is currently operating at level of service B near the TTR.

4.4.4 Socioeconomics

General existing socioeconomic conditions within the ROI of the TTR (Nye County) are presented in Section 4.1.4.

Police Protection. Law enforcement for the TTR is provided by the Nye County Sheriff's Department. Onsite security is provided by Advanced Security, Inc.

Fire Protection. Fire protection services for the TTR are provided by Sandia National Laboratories and the USAF.

Health Care. Currently Sandia National Laboratories provides the TTR with the following emergency operations (fire, rescue, and medical) personnel: 1 registered nurse, 4 emergency medical technicians (intermediate), and 2 emergency medical technicians (basic). If serious care is required, the patient would be either transferred to the town of Tonopah or airlifted to Las Vegas, depending on the medical needs.

4.4.5 Geology and Soils

4.4.5.1 Physiography

The TTR is also located within the southern section of the Great Basin, as described in Section 4.1.5.1. The TTR is located in the lowest sections of Cactus Flat and Stonewall Flat, which are separated by Cactus Range. The TTR is bounded by Stone Cabin Valley to the north, by the Kawich Range to the east and northeast, by Goldfield Hills to the west, and by Stonewall Mountain to the south. Elevations vary dramatically throughout the TTR, from 8,000 feet above sea level at the top peak of the Kawich Range and 8,275 feet above sea level at Stonewall Mountain to 5,400 feet above sea level at the base of Cactus Flat (DOE 1996c). Other features in the area include Gold Flat, which is separated to the south of Cactus Flat by the hills around Gold Mountain.

Within the basins, the topography is flat to gradually sloping. Cactus Flat is a closed basin, so salts and playa deposits form in the deepest sections of the basin. Stonewall Flat is open, so water flows to the west, although playas may form in depressions as well. Because of the high salt concentration in the playa deposits, little vegetation grows in the valleys.

4.4.5.2 Geology

Geologic deposits at the TTR primarily consist of volcanic rocks and alluvium. Alluvial fans composed of eroded volcanic bedrock and ash from the surrounding mountain ranges fill the flats with unconsolidated deposits. Although the total depth of the alluvial deposits is unknown, exploratory wells have determined that basin sediment thickness is at least 1,000 feet (DOE 1996c).

The mountain ranges are primarily composed of Tertiary volcanic rocks, in a sequence of welded and nonwelded ash-flow tuffs and associated basalts, andesites, dacites, and rhyolites. The southern edge of the TTR comprises the Southwestern Volcanic field described in Section 4.1.5.2. The Cactus Range is an exception to the basic volcanic sequences, as it is a fault block bounded by a sequence of elliptical rings, suggesting that it is the center of a major collapsed volcanic cauldron. Basalt dikes and sills have infiltrated the fractures, which cut through Paleozoic sedimentary rocks, granite intrusions, and other Tertiary rocks. The rocks associated with the eruption sequence are approximately 6 million years old. A sequence of small hills to the south and southeast of the range are made up of lavas and tuff valleys and capped by weathered breccias (DOE 1996c).

4.4.5.2.1 Structural History

The Walker Lane shear zone transects the TTR from the northwest to southeast and eventually connects to the Las Vegas Valley shear zone to the southeast (DOE 1996c). The shear zone is a series of transcurrent faults that connect volcanic centers, such as the Cactus Range and Stonewall Mountain.

The main fault sequences at the TTR include the Cactus Flat, Stonewall Mountain, and Gold Flat Faults and a few unnamed Cactus Faults located between Cactus Flat and Gold Flat. The Cactus Flat Fault strikes mostly north, with west-facing scarps. The fault is estimated to have moved within the last 130,000 years (Anderson 1998d). In addition, there are several scattered and unnamed faults in the western section of Cactus Flat (Anderson 1998e).

The Stonewall Mountain Fault forms the structural border between Stonewall Flat and Stonewall Mountain. These faults appear to connect to a fault block sequence and also may have moved within the Late Quaternary period (Anderson 1998f).

4.4.5.2.2 Faulting and Seismic Activity

The TTR is included within the seismic activity review found in Section 4.1.5.2.3, which identified at least 11,988 seismic events within 120 miles of the NNSS. Most of the earthquakes immediately around the TTR have been in the magnitude 2.0 to 3.0 range. Two earthquakes had magnitudes of 4.2 and 4.5. The closest earthquake with a magnitude over 5.0 was the 1992 earthquake near Little Skull Mountain, which is described in Section 4.1.5.2.3. Seismic design requirements are discussed in Section 4.1.5.2.3.

4.4.5.2.3 Geotechnical Hazards

The geologic hazards at the TTR are very similar to those outlined in Section 4.1.5.2.4, specifically surface instability. The geotechnical hazards do not generate extreme constraints on construction in the TTR. In addition, the high concentration of salts in the soils may affect concrete, as discussed in Section 4.3.5.2.3.

4.4.5.2.4 Geologic Resources

Economic geologic resources in and around the TTR include metallic ore and aggregate. Several historic mining districts are located at the TTR, including Silver Bow, Antelope Springs, Cactus Springs, Wilsons, and Mellan (SAIC/DRI 1991). The TTR is also adjacent to a number of other mining districts, most notably the Goldfield Gold Crater, Stonewall, Gold Reed, and Jamestown districts (SAIC/DRI 1991). The Silver Bow district has produced appreciable quantities of silver and gold, while the Antelope Springs district has produced silver and minor amounts of gold. Cactus Springs produced small quantities of silver, although turquoise, gold, and copper are also mined in the area. The Wilsons district produced small quantities of gold and silver in the early 1900s. Minor production of gold and silver came from the Mellan district. Of the mining districts, only the Silver Bow mine is classified as having high potential for economic mineral ores (DOE 1996a).

There is low potential for oil, gas reserves, or other petroleum products at the TTR or adjacent areas on the Nevada Test and Training Range (SAIC/DRI 1991). No geothermal resources have been identified at the TTR (SAIC/DRI 1991). Aggregate used for construction is present at the TTR in the form of sand

and gravels; however, it can be mined from multiple alluvial fans throughout the Basin and Range area; therefore, the resources at the TTR are not considered unique (SAIC/DRI 1991).

4.4.5.3 Soils

Soils at the TTR form in the alluvial fans, ephemeral washes, valley floors, and dry lake beds. The parent material of the soils is the igneous tuff and sedimentary rocks eroded from the surrounding ranges. A major feature of the soils is a silica-cemented duripan, precipitated from the silica-rich igneous parent materials (DOE 1996c).

In 1977, a high-level soil survey was performed at the TTR. Soils were mapped to the soil series throughout the area. Three main soil orders were found at the TTR: (1) mollisols, (2) aridisols, and (3) entisols (DOE 1996c). Mollisols are found in semiarid environments and have well-developed organic horizons. Aridisols are more typical in arid environments, and have little organic matter. Entisols are younger soils that have little or no development in soil horizons. The soils at the TTR would be categorized into three main categories based on their physiographic position in the local topography: (1) playas in valley bottoms and dry lake beds; (2) alluvial fans, the upper alluvial fans; and (3) mountains and hills. **Table 4–70** presents the soil families that were identified at the TTR during the 1977 soil inventory.

Table 4–70 Soil Families Identified in the Tonopah Test Range

Soil Families	*Example Soil Series*	*Physiographic Position*	*General Description of Soils in Physiographic Position*
Typic Salorhids	Saltair	Valley bottom and dry lake beds	Very deep, poorly drained fine-grained soils with concentrated salts and alkali deposits. Shallow groundwater table. Shrink-swell properties from high percentage of clays. Cement corrosion potential from salt concentration.
Typic Haplaquolls	Hutton	Valley bottom and dry lake beds	
Typic Torriorthents	Fang and Cliffdown	Alluvial fan	Deep to very deep, well-drained, sand to sandy loam/loam and gravelly soils on 2 to 4 percent slopes up to 8 to 15 percent slopes. Soils with higher concentrations of gravel are located in ephemeral washes.
Typic Camborthids	Alcorn and Dun Glen	Alluvial fan	
Calciorthids	Puddle	Alluvial fan	
Xerollic Durothids	Ursine	Upper erosional alluvial fan	Very shallow to moderately deep, moderately to well-drained, very coarse to sandy loam/loam and gravelly soils. Some soils may contain an old, rich concentrated clay horizon. Duripan present below the surface. Slopes range from 4 to 8 percent to 15 to 30 percent.
Xerollic Durargids	Ratto, Olson, Indian Creek, and Deer Lodge	Upper erosional alluvial fan	

Source: DOE 1996c.

The upland mountains and hill primarily consist of exposed rock outcrops, cobble or pebble pavement, or steep slopes with thin layers of alluvial deposits. These soils are typically very thin, young, and have little to no horizon definition.

4.4.5.4 Radiological Sources as a Result of Testing

4.4.5.4.1 Soils

Soils have been contaminated by radioactivity from testing at the TTR. Safety tests were performed at the NNSS and the TTR from 1954 to 1963. Section 4.1.5.4 describes the safety tests and the resulting contamination of the soils. Three safety tests were conducted on the TTR as part of the Clean Slate experiments under Project Roller Coaster. The Clean Slate 1, 2, and 3 experiments used open detonation on a concrete pad and detonation in igloo-like structures with varying amounts of earth cover to simulate accidents in open storage and weapon magazines (DOE 1996c). Depleted uranium and plutonium were used as tracers for the tests. Each test location has a concentrated center where the test occurred and a tail

of decreasing contamination to the southeast of each test site. As a result of these tests, approximately 670 acres were contaminated, with an estimated plutonium contamination of 65 curies (DOE 1996c). An initial cleanup of each Clean Slate site was conducted shortly after each test (DOE 2009a). Test-related debris was buried at the test ground zero. Each location where radioactive contamination has exceeded 1,000 micrograms per square meter of plutonium has been fenced off and posted as radioactively contaminated. Although the Clean Slate 1 site is still fenced and posted, contamination above about 400 picocuries per gram of soil or higher was remediated. Further remediation at the Clean Slate sites is pending. Figure 4–13 depicts the areas of the Clean Slate sites that are fenced and posted. Further studies of the ground contamination were performed to determine the extent of the wind-carried contamination (DOE 2009a). Further remediation of the contaminated soil will be completed under the Soils Project. Section 4.1.5.4.1 describes the Soils Project in more detail.

Soils have been routinely tested for pollutants deposited from air or contaminants transported and deposited from moving water. Nonradiological sampling of the soils is periodically conducted at the TTR. In 2010, soil samples were collected from 26 offsite, 10 perimeter, and 13 onsite locations. The soil samples were compared to the Target Analyte List metals with no anomalies identified (DOE 2011b).

4.4.6 Hydrology

4.4.6.1 Surface Hydrology

Five hydrographic basins are within the boundaries of the TTR, including most of Cactus Flat and parts of Stone Cabin Valley, Ralston Valley, Stonewall Flat, and Gold Flat (see **Figure 4–46**). In terms of land area, Cactus Flat is the most extensive hydrographic basin within the TTR. These basins are typically internally drained—runoff collects in playas at the low points of valleys (USAF 1999).

Surface-Water Features. No perennial streams exist on the TTR. There are numerous washes that drain upland areas that occasionally convey ephemeral flow. The ephemeral flows pond in playa areas, which collect and dissipate runoff from these basins. Water typically only exists in the playas for periods of hours following summer storms and weeks following winter storms. Little water is recharged to the groundwater system due to a high rate of evaporation (USAF 1999).

There are three small springs within the TTR's boundaries: (1) Cactus Springs, (2) Antelope Springs, and (3) Silverbow Springs. Water from these springs does not travel more than several tens of yards before it dissipates through evaporation and infiltration (DOE 2009a).

Surface-Water Characteristics. No site-specific water quality data are available for surface waters on the TTR. In general, water quality of the ephemeral waters is poor because of naturally high sediment loads and dissolved solids. The water quality of springs and seeps is primarily controlled by the physical and chemical characteristics of the rocks through which the groundwater flows prior to discharge to the surface. Once the water reaches the surface, other environmental factors affect water quality, such as precipitation, evapotranspiration, erosion, and chemical characteristics of the underlying rock or soil (USAF 1999).

In July 2007, 71 wild horses died at the TTR. The horses were from a herd that frequently drank from a manmade depression on a dry lake bed controlled by DOE/NNSA through Sandia National Laboratories. Initial sampling and necropsy results indicated that high nitrate levels may have caused the deaths. Subsequently, the Desert Research Institute was commissioned by BLM, the USAF, and DOE/NNSA to sample water and soil on the TTR to determine the source of the nitrates that may have caused the deaths. This sampling was conducted in February of 2008. The conclusion of the report reinforced the original theory, specifying that the nitrate most likely came from natural sources concentrated by evaporation of the water within the depression during the heat of the summer (DOE/NV 2008a). In July of 2008, BLM gathered the horses within range of the TTR. During 2008 and 2009, DOE/NNSA drained the manmade depression and filled it with clean soils (SNL 2010b).

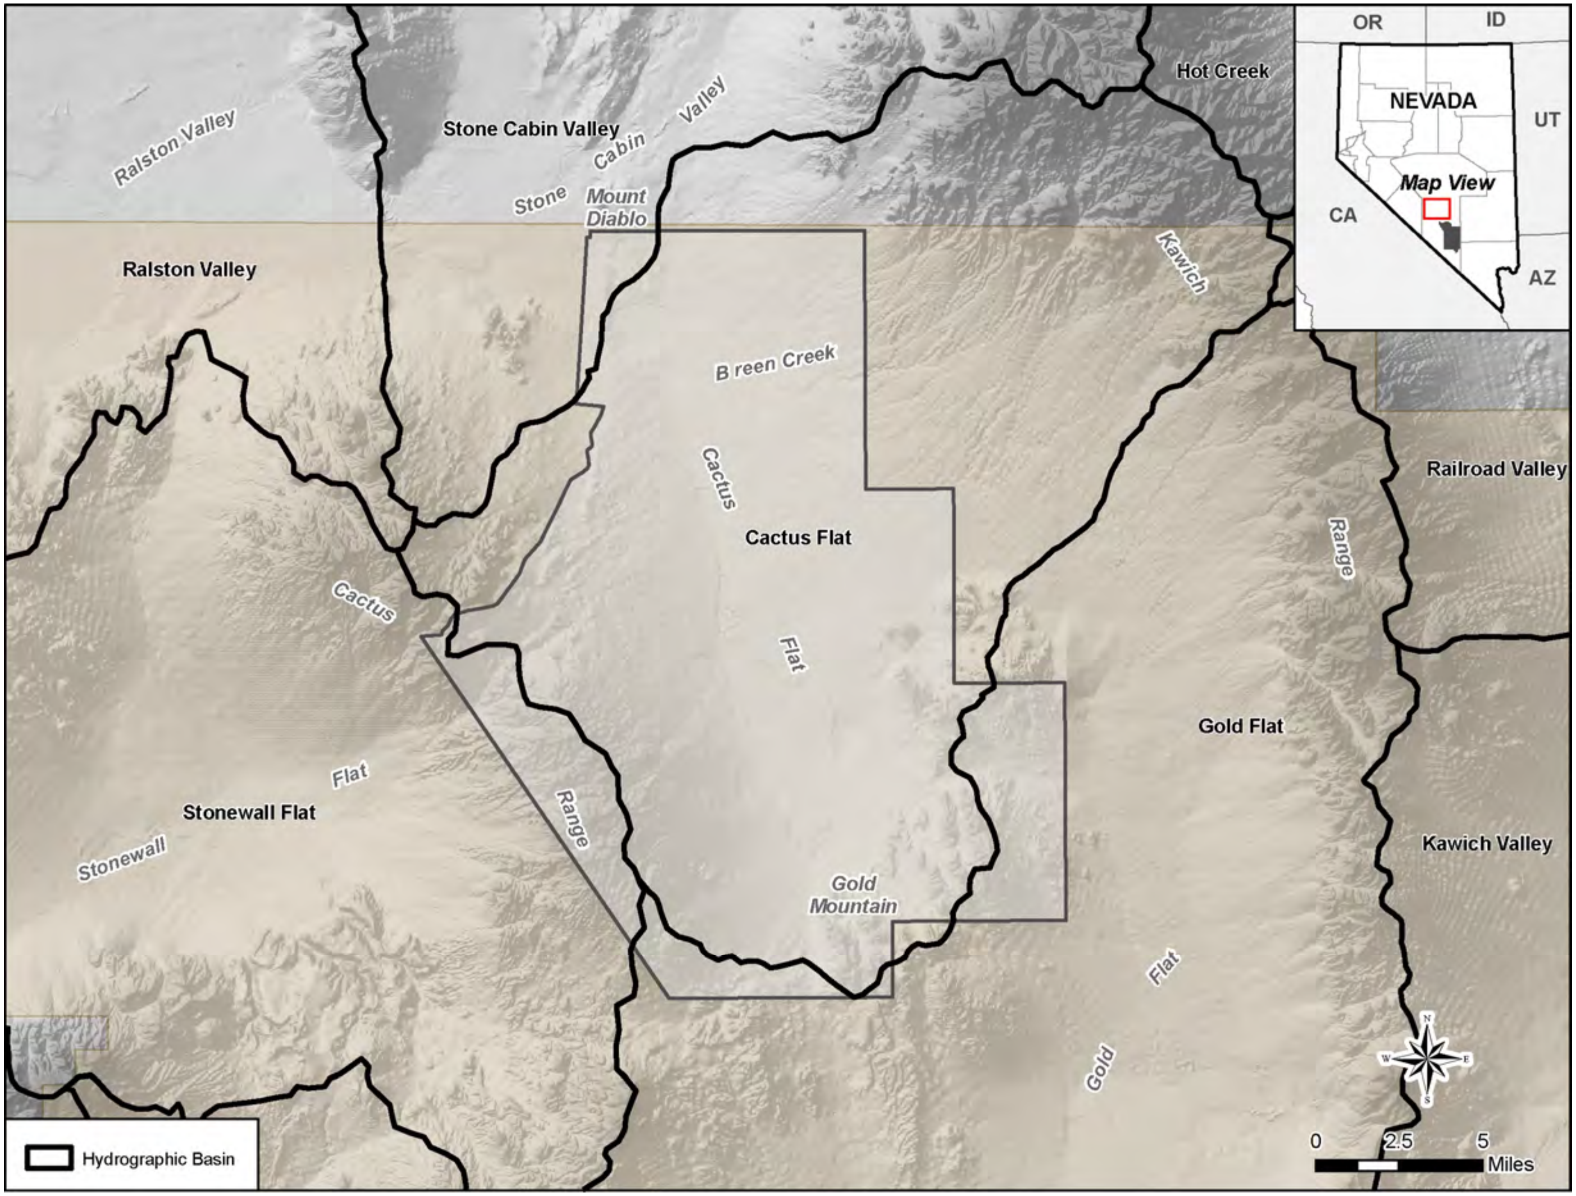

Figure 4–46 Hydrographic Basins on the Tonopah Test Range

Flood Hazards. The USAF has identified and mapped floodplain areas throughout the TTR, thus resulting in the delineation of potential 100-year flood event locations associated with playas, alluvial fans, and valley collectors (i.e., valleys that have relatively large drainage areas or several smaller tributaries that discharge to the main collector). On the TTR, floodplains are associated with two playas near the middle portion of the range (Main Lake and Antelope Lake) and a valley connector running north to south between the two playas, which roughly parallels the main access road on its eastern side. In addition, there are three valley connector floodplains and one alluvial fan floodplain that drain to the Main Lake and Antelope Lake playa system from the east and the south (USAF 1999).

Water Discharges and Regulatory Compliance. Wastewater discharges from TTR activities conducted at facilities in the main compound of Area 3 are conveyed to the USAF facultative sewage lagoon for treatment. The USAF holds an NPDES permit for the facultative sewage lagoon (Permit Number NEV20001) (DOE 2009a). Combined sanitary and pretreated industrial wastewater flows into two lined aerated ponds with treatment by biological processes. This is a zero-discharge treatment facility, by which water is lost through evaporation. For the period from June 2007 through June 2008, effluent water quality was within permitted limits and averaged 33 ppm carbonaceous biochemical oxygen demand, 49 ppm total suspended solids, and 0.4 ppm total petroleum hydrocarbon, and one metal was detected (barium at 0.019 ppm) (Kaminski 2008). All analytical results for wastewater sampled at Area 3 were within regulatory limits from 2008 through 2010 (DOE 2009a; SNL 2010b, 2011). No NPDES stormwater permitting is required at the TTR due to the lack of significant stormwater runoff discharging into waters of the United States (DOE 2009a).

4.4.6.2 Groundwater

Hydrogeologic Setting. The TTR lies between two Great Basin mountain ranges, the Cactus Range to the west and the Kawich Range to the east. The valley is typical of the high desert of the Basin and Range Physiographic Province. The north–south axis of the valley, known as Cactus Flat, consists of a string of playas at an elevation of approximately 5,300 feet above mean sea level. Cactus Flat is a closed basin; surface runoff following precipitation flows toward the playas, with no discharge off of the TTR (SNL 1992). Stonewall Flat is bounded on the south by Stonewall Mountain and on the west by Goldfield Hills. On the valley floors of both Cactus and Stonewall Flat, the dominant features are a number of small playas and the many washes that drain the upland areas (see Section 4.4.6.1 for more information) (DOE 2006d).

The TTR encompasses portions of five hydrographic basins (Cactus Flat, Gold Flat, Stonewall Flat, Ralston Valley, and Stone Cabin Valley) that make up portions of two regional groundwater systems. Past DOE operations have been concentrated in two areas: Stonewall Flat and the lowland portions of Cactus Flat (DOE 2008l).

Groundwater that originates as precipitation over the Kawich Range flows west and then southwest under the TTR, ultimately discharging in Death Valley through springs and evapotranspiration. Some groundwater may flow northwest off the TTR and into the Southern Marshes flow system, with discharge at Mud Lake, Alkali Flat, and Clayton Valley. The generalized directions of regional groundwater flow are shown in **Figure 4–47**. Groundwater in Cactus Flat is derived from precipitation over the upland areas, and there is no subsurface recharge from neighboring basins. The total recharge has been estimated at only 600 acre-feet per year. Depth to groundwater ranges from 90 to 450 feet below the land surface. Groundwater under Stonewall Flat is derived from recharge over the upland areas and is estimated at 100 acre-feet per year. Depth to groundwater ranges from 100 to 275 feet below the land surface (DOE 1996c).

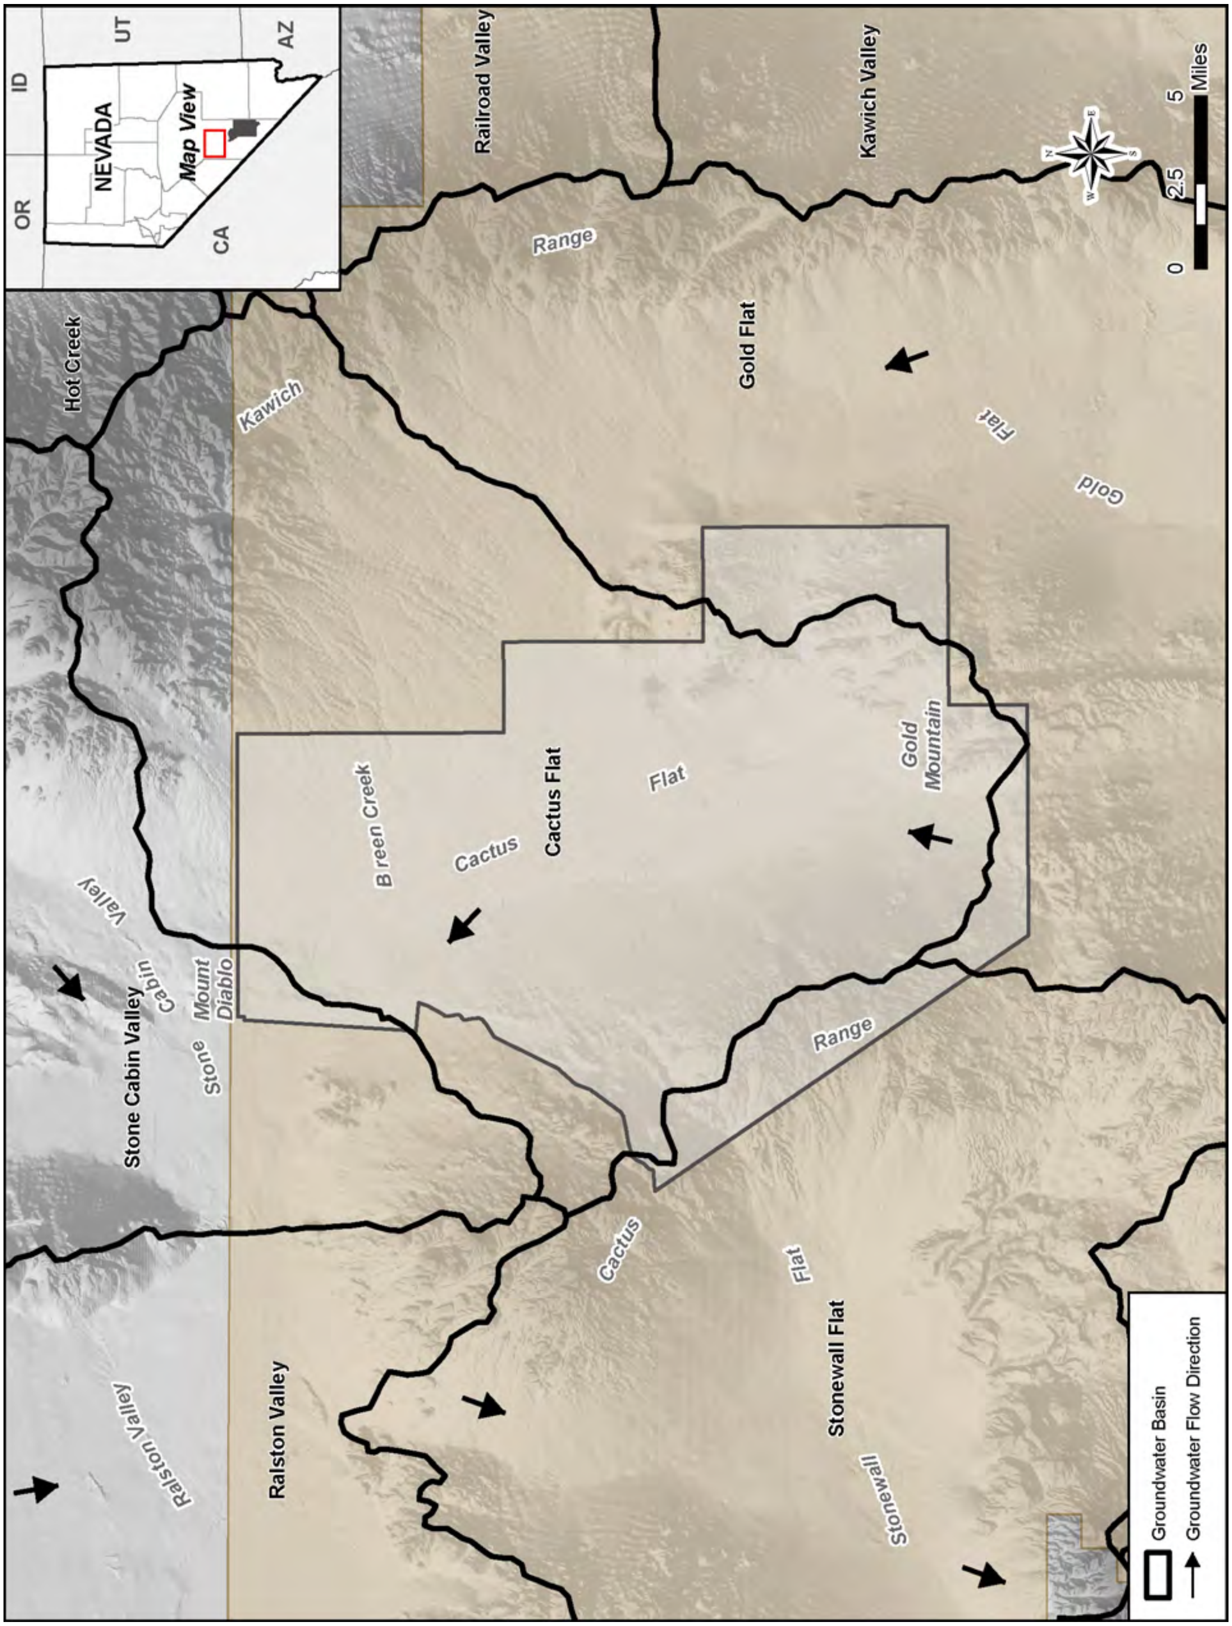

Figure 4–47 Groundwater Basins and Flow at the Tonopah Test Range

Groundwater Supply. Groundwater at the TTR has been used for domestic, industrial, and construction purposes. Groundwater is pumped from a number of wells, depending on the location of range activities and the total demand for water. The following three active wells are used at the TTR: (1) Production Well 6, (2) Production Well 7, and (3) the Roller Coaster Well.

Production Well 6 supplies drinking water and fire water distribution systems at the TTR Main Compound in Area 3 and is the only well that has been sampled for contaminants. It pumps water to an elevated water tank in Area 3 that holds 200,000 gallons (Lacy 2011). In June 2008, a new carbon dioxide (pH) adjusting treatment system for arsenic removal became operational in Area 3 of the TTR (Lacy 2011). Outlying areas and buildings without water service use bottled water. Production Well 7 and Roller Coaster Well are used only for nonpotable purposes (construction and dust suppression), and there is no regulatory sampling requirement. The water use (for the entire TTR, including the USAF) for operations is approximately 6 million gallons per year (DOE 2008l). The static water level at Well 6 is approximately 350 feet (SNL 2010b).

The water conservation plan for the TTR complies with State Water Resources Division regulations requiring a water conservation plan for permitted water systems and major water users in Nevada. An updated Water Conservation Plan for the TTR (SNL 2011) was approved by the Nevada Division of Water Resources in January 2011 and can be found at http://water.nv.gov/programs/planning/plans.cfm.

There are about 15,000 acre-feet per year of water rights in the five hydrographic basins associated with the TTR. Approximately 10,300 acre-feet per year of this total are surface-water rights (see Section 4.4.6.1); the remainder (almost 4,700 acre-feet) represents groundwater rights. Currently, defense-related water appropriations total 1,775 acre-feet per year, 148 acre-feet of which are surface-water rights. **Table 4–71** lists the water yield and resources for each of the basins that encompass portions of the TTR.

Water appropriations are limited to two basins: (1) Cactus Flat and (2) Stone Cabin Valley, and total 200 acre-feet (65,170,200 gallons) per year. Both basins are over-appropriated (i.e., the appropriations exceed the perennial yield in each basin). It is unlikely that additional water rights can be obtained in the area without groundwater mining (the removal of groundwater from storage) (DOE 2008l).

Table 4–71 Water Rights Status for Hydrographic Basins at the Tonopah Test Range

Hydrographic Basin	*Hydrographic Basin Number*	*Perennial Yield (acre-feet per year)*	*Total Committed Groundwater Resources (acre-feet per year)*	*TTR water rights/use (acre-feet per year)*
Cactus Flat	148	300	619	Estimated TTR water rights 160
Gold Flat	147	1,900	95	Estimated TTR water rights 40
Stonewall Flat	145	100	12	No TTR water rights
Ralston Valley	141	6,000	1,917	No TTR water rights
Stone Cabin Valley	149	2,000	2,033	Estimated TTR water rights 240

TTR = Tonopah Test Range.
Source: DOE 2008l; NDWR 2010c.

Groundwater Monitoring and Quality. The lithology of the rocks controls the water chemistry observed in the wells. Potential sources of groundwater contamination existing on the TTR include French drains, septic tanks and leach fields, underground storage tanks, landfills, and sewage lagoons (DOE 2008l). The quality of water at the TTR is generally good and is suitable for domestic purposes, livestock, and wildlife use (DOE 1996c). The nuclear safety tests conducted at the Clean Slate sites on the TTR have resulted in surface soil contamination; however, groundwater contamination has not been detected at the TTR (see Section 4.4.5.4.1 for soil contamination). Infiltration is limited by the depth to groundwater (90 to 150 feet), low rainfall, and high evaporation rate. The small quantities of liquid water that may have been disposed or released will, therefore, attenuate in the soil and are unlikely to affect groundwater. Soil was sampled for explosive residues from unexploded ordnance remedial activities; however, no reference can be found for groundwater sampling for perchlorate (DOE 2008l).

Water analyses are conducted at various times at several locations throughout the TTR to characterize water quality. None of the constituents that have been analyzed have exceeded the recommended health standards set by the Nevada Division of Health, with the exception of pH. Although the pH values slightly exceeded the standard, the waters do not pose health problems. The Roller Coaster Well is classified as a sodium-bicarbonate-chloride-type water, while the remaining wells are classified as sodium-bicarbonate-type waters (DOE and U.S. Air Force 1988).

4.4.7 Biological Resources

The following description of vegetation was taken from EG&G Energy Measurements (1995), unless otherwise stated. The scientific names of plants and animals mentioned in this section are given in Section 4.1.7.

The TTR is within the Great Basin Desert. The lowest elevation on the TTR is approximately 5,250 feet; the highest elevation is approximately 7,550 feet.

The DOE/NNSA Sandia Site Office has an Ecology Program that serves to conserve flora and fauna at the TTR (NNSA/SSO 2010). The primary objectives of the Ecology Program include:

- Collect ecological resource inventory data to support site activities, while preserving ecological resources, and maintaining regulatory compliance
- Collect information on plant and animal species present to further the understanding of ecological resources on site
- Collect biota contaminant data on an as-needed basis in support of site projects and regulatory compliance
- Assist Sandia organizations in complying with regulations and laws
- Provide information to employees regarding ecological resource conservation
- Support Sandia organizations with biological surveys in support of site activities

Enhancement measures that have been utilized in the past include installing artificial nest platforms, boxes, and perches.

In 2010, an Avian Protection Plan was adopted and implemented at the TTR (Lacy 2011). The Avian Protection Plan was developed to describe procedures that would be taken by DOE/NNSA at the TTR to address potential impacts of its associated transmission and distribution lines on avian species that are known to occur in the area (NNSA/SSO 2010).

4.4.7.1 Flora

There are four general vegetation types on the TTR: dwarf shrubland, shrubland, woodland, and bare or disturbed areas (see **Figure 4–48**). The dominant flora of the valley bottoms on the TTR include shadscale, budsage, winterfat, and galleta grass (*Pleuraphis* Torr.). Less-common plant species are horsebrush, greasewood, desert globemallow (*Sphaeralcea ambigua*), and desert prince's plume (*Stanleya pinnata*). Big sagebrush occurs in wash bottoms and near the playa on the southwestern corner of the site. On the bajadas above the valley floor, Nevada jointfir, green rabbitbrush, shadscale, budsage, winterfat, and Indian ricegrass are dominant. At higher elevations, greasewood, wolfberry, hopsage, and desert prince's plume are common. Pinyon-juniper woodlands occur at the highest elevations.

4.4.7.2 Fauna

Animal species on the TTR include all species found in the Great Basin Desert on the NNSS. Some of the most common animal species include side-blotched lizards, desert-horned lizards, horned larks, chisel-toothed kangaroo rats, little pocket mice, and wild horses (Bradley and Moor 1975). State-designated game animals that occur on the TTR include mule deer, bighorn sheep, pronghorn, mountain lions, desert and Nuttall's cottontails, chukar, and mourning dove. The gray fox and bobcat are species known to occur at the TTR that are listed by the state as furbearers (SNL 2010a).

Bird species typically found in the valley floor of the TTR are those associated with the sagebrush community and include sage thrasher (*Oreoscoptes montanus*), sage sparrow (*Amphispiza belli*), horned lark, and common raven. Less-frequently observed species include the green-tailed towhee (*Pipilo chlorurus*), western meadowlark (*Sturnella neglecta*), mourning dove, greater roadrunner (*Geococcyx californianus*), and common nighthawk (*Chordeiles minor*) (NNSA/SSO 2010).

Bird species diversity increases with elevation at the TTR, to include birds such as loggerhead shrike, mourning dove, black-throated sparrow, and juniper titmouse (*Baeolophus ridgwayi*). Scott's orioles (*Icterus spurius*), western kingbirds, and ash-throated flycatchers (*Myiarchus cinerascens*) are occasionally observed nesting in the Joshua trees. In the rocky slopes of the steep terrain, chukars (introduced into the area) and rock wrens (*Salpinctes obsoletus*) are sometimes encountered (NNSA/SSO 2010).

Raptor species are present throughout the TTR and include red-tailed hawk, golden eagle, prairie falcon, American kestrel, common barn owl, great horned owl, Swainson's hawks, and ferruginous hawks (*Buteo regalis*). Known nesting raptors include red-tailed hawk, golden eagle, and great horned owl (NNSA/SSO 2010).

The Nevada Wild Horse Range and other wild horse land use areas constitute a significant portion of the Nevada Test and Training Range, including the TTR, with herds common in Cactus and Gold Flats, Kawich Valley, Goldfield Hills, and the Stonewall Mountains (SNL 2010a). The Nevada Wild Horse Range is managed by BLM, but wild horse and burro management does not affect national security activities at the TTR to a great extent, as the USAF mission still has precedence over BLM management (USAF 2007e). The draft *Integrated Resource Management Plan for Nellis Air Force Base and the Nevada Test and Training Range* (USAF 2007e) recommended that BLM continue annual censuses of the wild horse population and conduct wild horse gathers as necessary to maintain the current appropriate management level for the Nevada Wild Horse Range of 300 to 500 horses. Hundreds of wild horses graze freely throughout the TTR, and activities on site have had little effect on the horse population or their grazing habits. BLM routinely rounds up a portion of the herds for auction through the Wild Horse and Burro Adoption Program (SNL 2010a).

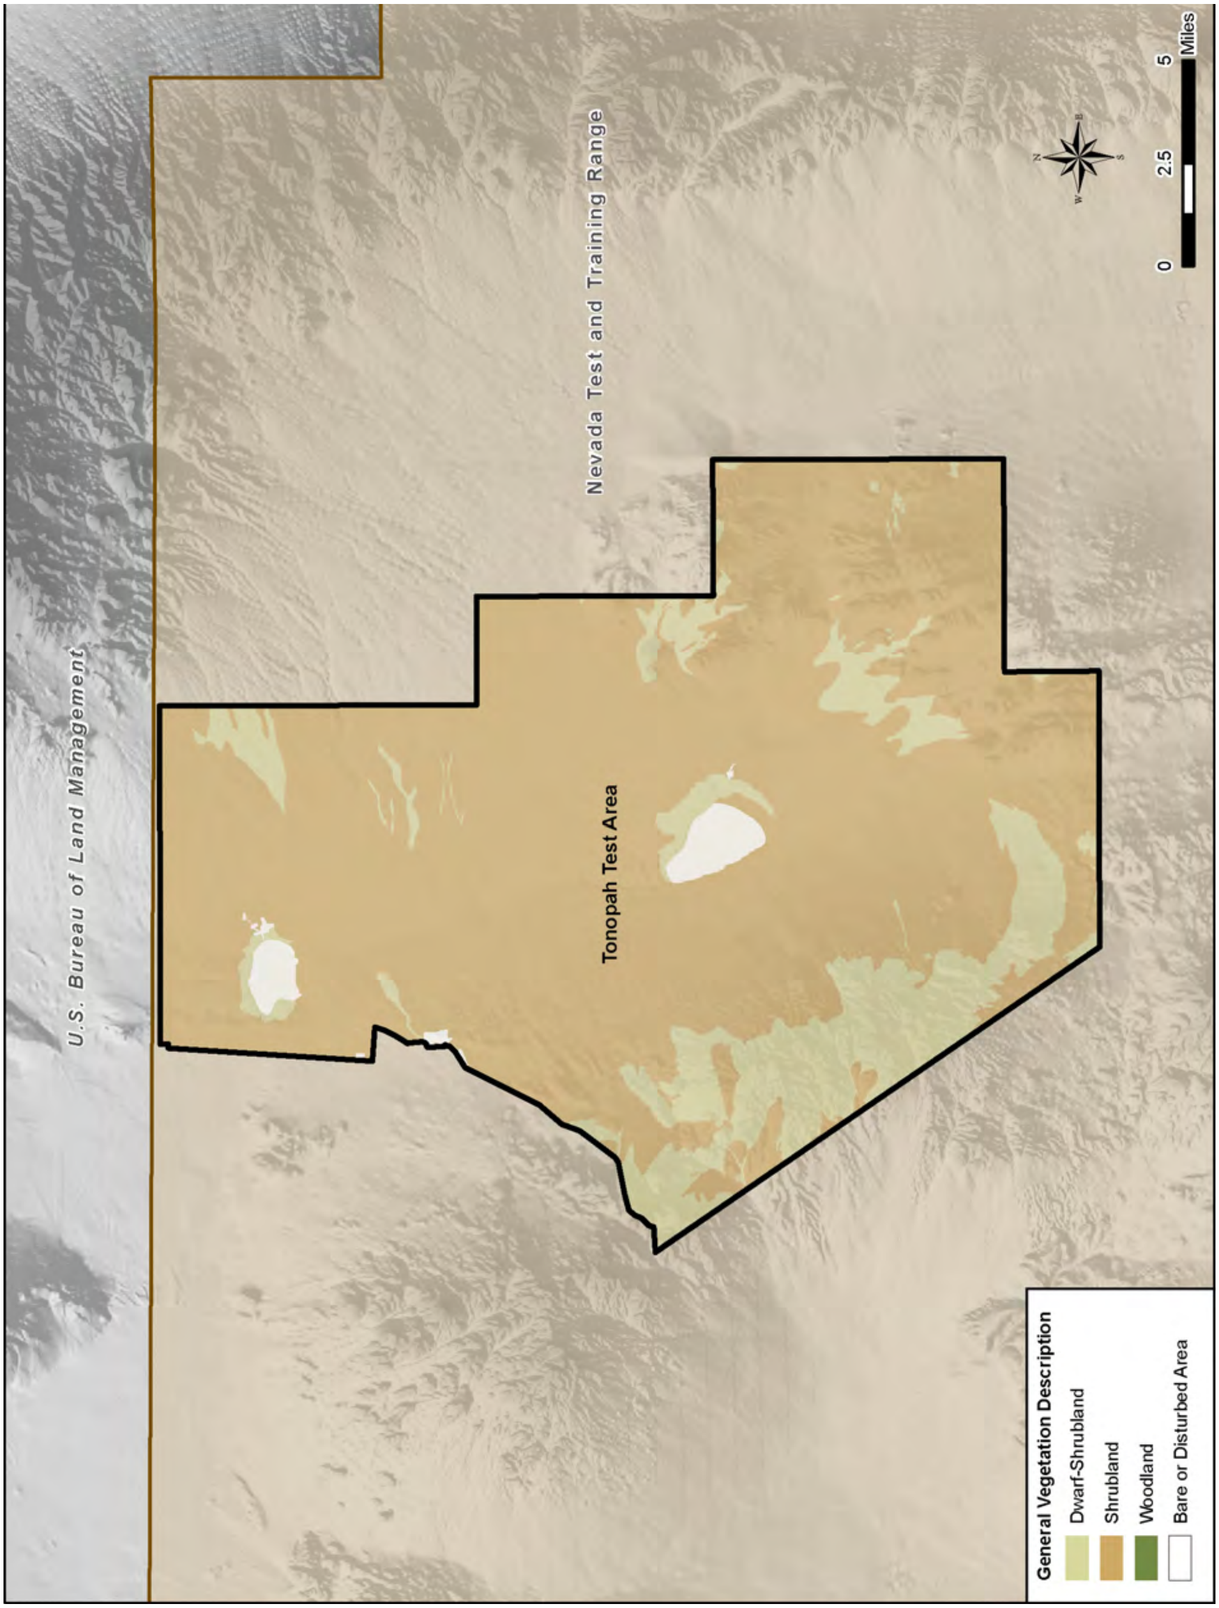

Figure 4–48 Vegetation Types on the Tonopah Test Range

Wild horses have altered the TTR and Nevada Test and Training Range vegetation composition and production where they graze, and compete with native species, such as mule deer, pronghorn, and bighorn sheep, for water and vegetation. An extreme example of the potential negative impacts of wild horse grazing may be seen in the Kawich Valley. Where wild horses are present in this area, the Great Basin scrub vegetation has been uniformly cropped over many acres to less than 8 inches high. It is clear that the closely cropped plants in the Kawich Valley do not represent the condition of the vegetation before the horses were introduced (USAF 2007c). On the TTR, the Clean Slate 1, 2, and 3 environmental remediation sites have been fenced for other purposes, but the fences also serve to prevent grazing by wild horses. These excluded areas have regrown with abundant native vegetation, which is not affected by wild horse grazing (USAF 2007c).

4.4.7.3 Threatened and Endangered Species

No current federally listed threatened, endangered, or candidate plant or animal species are known to occur on the TTR.

4.4.7.4 Other Species of Concern

The western burrowing owl, a state-protected bird, is known to occur on this site. No other species of concern are known to inhabit the TTR.

4.4.7.5 Effects of Past Radiological Tests and Project Activities

Vegetation samples were collected on the TTR in 1973 and again in 1990 and 1991 (EG&G/EM 1993). These studies found that plutonium levels in samples of vegetation ranged from 4.0×10^{-5} to 3.9×10^{-2} nanocuries per gram of dry vegetation, and the plutonium levels had not changed substantially over the past 25 years. Many studies in arid and semiarid environments (Francis 1973; Hakonson 1975; Hanson 1975; Price 1973; Romney and Wallace 1977) have shown that most of the plutonium remains in the soil and is not readily transported. Very little of the contamination is incorporated into the biological components of the ecosystem in similar arid areas (Hakonson and Nyhan 1980). Plutonium contamination of vegetation at the TTR and the NNSS is concentrated mainly on the surface of vegetation and is generally not taken up by the roots and concentrated internally. Small mammals were collected from the TTR for plutonium contamination analyses from 1974 through 1975 (Bradley and Moor 1975) and from other contaminated areas on the NNSS and off site (Gilbert et al. 1988). From these studies, the following general conclusions can be made: very low levels of contamination (from undetectable levels to a few hundred femtocuries [10^{-15} curies] per gram) were found in animals; desert rodents (which represent the primary consumer trophic level) have very low plutonium levels; most of the radioactivity in rodents is associated with the pelt and gastrointestinal tract and not internal organs or carcasses; and the plutonium contamination does not appear to bioaccumulate in the food chain.

4.4.8 Air Quality and Climate

4.4.8.1 Meteorology

As with the NNSS, the TTR is located in the southwestern corner of the Great Basin and in the rain shadow (lee) of the southern Sierra Nevada mountain range. The TTR has the general climatic characteristics of a mid-latitude desert area, with relatively little precipitation and low humidity, large diurnal and seasonal temperature ranges, and intense solar radiation in the summer. The generally dry desert conditions specific to the TTR are occasionally modified by the southwestern monsoon and convective thunderstorms during the summer months and Eastern Pacific tropical storm remnants in the late summer and fall. The dry conditions can be further modified from time to time during strong *El Niño* cycles, which generally bring more rainfall to the area.

Significant climate differences within the TTR stem largely from differences in elevation. The TTR is generally characterized by a broad, flat valley bordered by two north–south mountain ranges: the Cactus Range to the west and the Kawich Range to the east. Elevations range from 5,347 feet above mean sea level in the valley floor to about 7,484 feet above mean sea level at Cactus Peak (DOE 2009a). Wind

flows are strongly affected by the surrounding topographical influences. Temperatures are coolest at the higher elevations and warmest in the valley floor. Precipitation is generally sparse, with about 4 inches of annual average rainfall in the valley floors, though as much as about 12 inches of frozen and liquid precipitation can occur on mountain ridges (SORD 2002).

At the Tonopah Test Range Airport in the north-central portion of the TTR (at an elevation of about 5,548 feet above mean sea level), a long-term meteorological station operates. The average daily maximum temperature typically ranges from about 85 to 90 °F in the summer and from about 40 to 50 °F in the winter; likewise, average minimum temperatures tend to be about 50 to 60 °F in the summer and about 15 to 25 °F in the winter (SORD 2002). The annual average temperature is 52 °F. The Desert Research Institute began operating a meteorological station in July 2008 at the northern edge of the Clean Slate 3 site.

Precipitation falls most often during the spring period (due to passing East Pacific storms) and during the mid- to late-summer period (due to convective thunderstorms, monsoons, and occasional tropical storms). Nevada on the whole has been in a long-term drought for most of the last 100 years, with precipitation amounts below normal. However, much of the 1980s and 1990s were wetter than normal (DOE 2008j). For more information regarding precipitation patterns at the TTR, please see Appendix D, Section D.1.4.1.

Wind conditions are perhaps the most complex of the meteorological conditions on the TTR. The surface winds show strong diurnal variations with distinct drainage in the valley and mountain slopes. The Cactus Range is to the west of the Tonopah Test Range Airport and is closer to the airport than the Kawich Range; as the Cactus Range is oriented north-northwest to south-southeast, these nighttime drainage winds tend to be from the northwest at the airport (DOE 2009a). Localized terrain gradients that are not north to south modify this nighttime wind flow, as do occasional low overcast conditions or conditions with extensive nighttime vertical mixing. **Figure 4–49** shows wind direction and speed data for the TTR. For more information regarding the wind patterns at the TTR, please see Appendix D, Section D.1.4.1.

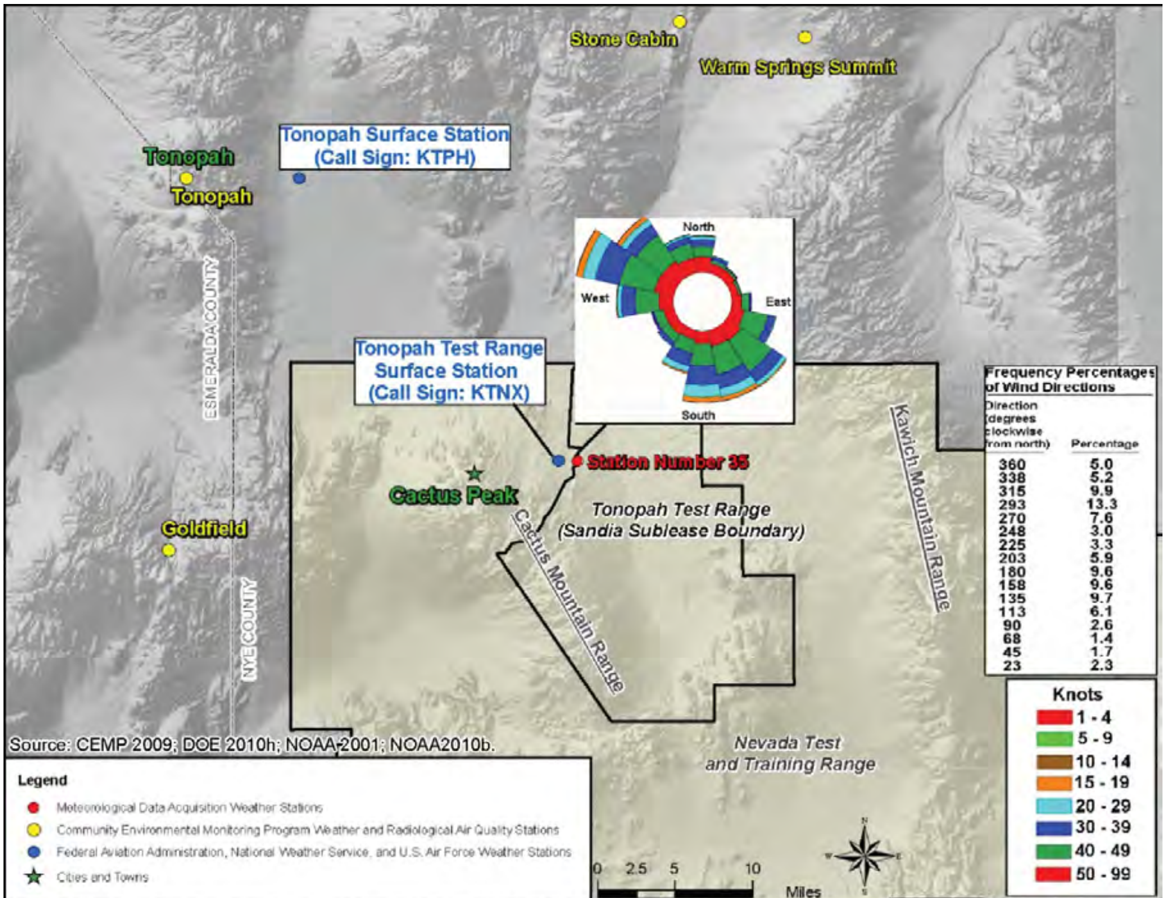
4.4.8.2 Ambient Air Quality

4.4.8.2.1 Region of Influence

The TTR is located about 15 to 40 miles northwest of the NNSS. The ROI for air quality and climate for TTR operations comprises north-central Nye County, with prevailing downwind impacts extending into western Lincoln County. Historic data on pollutant emissions inventories and the compliance status for the State of Nevada are calculated at the county level; these data provide a basis for determining both existing air quality in the ROI and a metric for emission comparison assessments.

4.4.8.2.2 Existing Air Quality

Ambient Air Quality Standards. See Section 4.1.8.2.2 for a discussion on the national and Nevada ambient air quality standards. The TTR is within the Nevada Intrastate Air Quality Region 147. All of the TTR is within Nye County, for which there are insufficient data to determine attainment status, so the TTR is designated as an unclassified area. However, EPA treats unclassified areas as if they are in attainment for regulatory purposes. See Section 4.1.8.2.2 for more information on nearby NAAQS nonattainment areas. No ambient air quality data have been measured on the TTR; however, the ambient air quality characteristics are anticipated to be better than or similar to those of the NNSS, given the lower vehicle and stationary source activity levels.



Note: To convert knots to meters per second, multiply by 0.5144. To convert knots to miles per hour, multiply by 1.151. The percentage rings indicate frequency of occurrence. Wind directions are from which the wind is blowing.

Figure 4–49 Wind Rose for Tonopah Test Range Airport Surface Station, 2004–2008

Emissions Due to TTR Operations. Title V of CAA gives states the authority to use air quality permits to regulate stationary source emissions of criteria pollutants. At the TTR, there is one Class II Air Quality Operating Permit. Class II permits are issued for "minor" sources and limit annual emissions in one of the following ways: (1) annual emissions of any one criteria pollutant must not exceed 100 tons; (2) annual emissions of any one hazardous air pollutant must not exceed 10 tons (including lead); or (3) annual emissions of any combination of hazardous air pollutants must not exceed 25 tons (including lead). The emissions limits associated with the TTR's Class II Air Quality Operating Permit are occasionally re-evaluated and reissued—most recently in 2009. The TTR facilities regulated by this permit include screening plants and maintenance shops (including those for painting, welding, and carpentry).

From 2001 through 2008, the TTR reported total annual emissions of less than 1 ton from permitted facilities (DOE 2002a, 2003a, 2004a, 2005a, 2009a; SNL 2007). In 2008, the TTR reported a total of only 0.21 tons of criteria and hazardous air pollutants. As of 2007, when operating at maximum permitted capacity, stationary sources on the TTR are allowed to emit as much as about 21 tons of emissions (comprising 3 tons from permitted facilities and 18 tons from nonpermitted facilities[31]) (NDEP 2007). For more details on how these maximum allowed emissions were determined, see Appendix D, Section D.1.4.2. The Class II permit also requires that the best practical method be used to limit the resuspension of soil dust into the air during construction, repair, demolition, work, or the use of

[31] *A nonpermitted source is a stationary source that, by regulation, does not require an air operating permit. Examples include emergency stationary generators that operate for less than 500 hours per year and propane storage tanks.*

unpaved or untreated areas without applying the measures described in the dust control plan (NDEP 2007).

Table 4–72 shows the onsite emissions due to the stationary sources, as well as emissions due to government-owned vehicles on the TTR, TTR commuters, and commercial vendors servicing the TTR. These emissions are partitioned into Clark County and Nye County (both on the TTR and off the TTR), where appropriate. See Appendix D, Section D.1.4.2, for further detail on the methodology for determining the emissions from commuter and vendor activities.

4.4.8.3 Radiological Air Quality

Radiation monitoring from 1996 through 1997 indicated a concentration of 1.6×10^{-18} microcuries per milliliter of plutonium-238, 9.5×10^{-19} microcuries per milliliter of plutonium-239 and -240, and 4.10×10^{-18} microcuries per milliliter of americium-241. These radiation levels would cause an MEI (either on site or off site) to receive an effective dose equivalent of 0.024 millirem per year (DOE/NV 1997a, 1997b; DOE 2009a). This dose level is approximately 400 times less than the EPA NESHAPs standard of 10 millirem per year (DOE 2009d). These results are indistinguishable from the natural background radiation level on or near the TTR.

Ambient air quality radiation monitoring had not been performed at the TTR since 1997 because operations at the TTR do not involve activities that release radioactive emissions into the air from point sources or from diffuse sources such as outdoor testing. However, the Desert Research Institute began monitoring air quality for radioactive contaminants at the TTR in July 2008 (DOE 2009c) to address concerns about fugitive radioactive emissions from the possible resuspension of americium and plutonium present at the Clean Slate environmental restoration sites. One site is located near the Range of Operations Center and the other at the northwestern end of the Clean Slate 3 site. Since May 2009, neither site has detected any anthropogenic gamma-emitting radionuclides, which would potentially indicate the presence of americium and/or plutonium. Other environmental restoration sites with minor radioactive contamination, such as depleted uranium, do not produce significant air emission sources from resuspension (DOE 2009a).

4.4.8.4 Climate Change

This section describes the affected environment in terms of current and anticipated trends in greenhouse gas emissions and climate. The effects of emissions and the corresponding processes that affect climate involve very complex processes with considerable variability, complicating the measurement and detection of change. Recent advances in the state of the science, however, are contributing to an increasing body of evidence that anthropogenic greenhouse gas emissions affect climate in detectable and quantifiable ways.

For information on greenhouse gas emissions in the United States, please see Section 4.1.8.4.1. Greenhouse gas emissions at the TTR are discussed in the next section. Details on the methodology used to determine these emissions are discussed in Appendix D, Sections D.2.4.1.1, D.2.4.2.1, and D.2.4.3.1.

Table 4–72 Estimated 2008 Air Emissions of Criteria Pollutants and Hazardous Air Pollutants Due to Tonopah Test Range Activities

CO = carbon monoxide; HAP = hazardous air pollutant; NNSS = Nevada National Security Site; NO_x = nitrogen oxides; PM_n = particulate matter with an aerodynamic diameter less than or equal to *n* micrometers; SO_2 = sulfur dioxide; TTR = Tonopah Test Range; VOC = volatile organic compound.

4.4.8.4.1 Greenhouse Gas Emissions

Table 4–73 provides greenhouse gas emissions due to TTR-related activities for 2008. The greenhouse gas emissions are presented in carbon-dioxide-equivalent form and are partitioned by various mobile and stationary source types. These emissions were derived from fuel use, vehicle activity, and power consumption data. The greenhouse gas emissions were calculated using the EPA Climate Leaders Simplified Greenhouse Gas Emissions Calculator (EPA 2010b). These emissions were compared with a reference amount of 25,000 metric tons (27,558 tons), which is an indicator for when a quantitative assessment may be warranted (CEQ 2010).

Commercial vendors are by far the largest single source of greenhouse gas emissions related to TTR activities, emitting approximately 2,210 carbon-dioxide-equivalent tons of greenhouse gases, or 53 percent of the TTR-related greenhouse gas emissions total. Mobile sources altogether emitted about 3,396 carbon-dioxide-equivalent tons of greenhouse gases, which is 88 percent less than the threshold reporting level. Overall, TTR-related activities created about 4,166 carbon-dioxide-equivalent tons of greenhouse gas emissions in 2008, an amount well below the threshold level.

Table 4–73 Carbon-Dioxide-Equivalent Emissions of Greenhouse Gases Due to Tonopah Test Range Activities in 2008

Source Type	*Carbon-Dioxide-Equivalent Emissions (tons per year)*	*Fraction of Reference Point of 25,000 Metric Tons* [a]
STATIONARY SOURCES		
Power consumption	275	0.01
Natural gas heating	0	0.00
All stationary sources, except air conditioning/refrigeration and natural gas heating	495	0.02
All Stationary Sources	*771*	*0.03*
MOBILE SOURCES		
Onsite government vehicles	454	0.02
Commuting	732	0.03
Commercial vendors	2,210	0.08
All Mobile Sources	*3,396*	*0.12*
Total	***4,166***	***0.15***

[a] 25,000 metric tons are equal to about 27,558 short tons.

4.4.8.4.2 Current Changes in Climate

For a discussion of climate change impacts in the region, please see Section 4.1.8.4.2.

4.4.9 Visual Resources

The TTR is visually similar to areas of the NNSS with higher elevations and is only visible from an access road off U.S. Route 6 (DOE 1996c). The portion of the area visible from U.S. Route 6 is considered to have a Class B scenic quality rating (see Section 4.1.9 for information on the visual impact rating system) due to the lack of visual intrusions and picturesque views of the natural landscape that vary throughout the day and seasonally, combined with the commonality of these views to the region.

4.4.10 Cultural Resources

For introductory information regarding cultural resources, see Section 4.1.10. Unless otherwise noted, the information in this section is derived from the *1996 NTS EIS* (DOE 1996c). Additional information regarding cultural resources on the TTR was obtained from the Desert Research Institute (DOE 2010a), which provides Cultural Resources Program support to the DOE/NNSA NSO and to the USAF. Information sources provided by the Desert Research Institute include short report summaries, lists of recorded sites on the TTR and their NRHP eligibility status, and excerpts from cultural resources studies conducted on the TTR.

The TTR lies within the Southern Great Basin physiographic region and encompasses portions of five hydrographic basins (Cactus Flat, Gold Flat, Stonewall Flat, Ralston Valley, and Stone Cabin Valley) (NDWR 2010a) (see **Figure 4–50**). The TTR area possesses a long history of American Indian occupation and more-recent European-American settlement and American military use. Archaeological research indicates humans have used the area within the TTR for the last 10,000 years. When European-American explorers first entered this area in the mid-nineteenth century, groups of Western Shoshone occupied the region. Historic period activity consisted of mining and ranching; more-recent activity has focused on military use of the TTR area.

The area of influence for the TTR is defined as all ground areas that would experience direct or indirect impacts of construction, maintenance, or operations of program facilities and activities occurring on the TTR. Based on current knowledge of cultural resources within the TTR, all areas have the potential to contain cultural resources. Therefore, the area of influence for this SWEIS includes the entire area within the TTR boundary.

4.4.10.1 Recorded Cultural Resources

Current knowledge about cultural resources on the TTR is largely the result of project-specific cultural resources studies completed for DOE activities. Cultural resources studies that included large portions of the TTR include Bergin et al. 1979 and DuBarton and Johnson 1996. Past DOE operations have been concentrated in two areas: (1) the lowland portions of Cactus Flat and (2) Stonewall Flat (DOE 2008l). As a result, these areas of the TTR have been intensively surveyed for cultural resources (Pippin 2005). One area in particular, along the Breen Creek drainage at the southern end of Cactus Flat, is highly sensitive for prehistoric and historic cultural resources (DuBarton and Johnson 1996). Other areas, however, have undergone little or no cultural resources inventory. Consequently, there is no overarching archaeological cultural resources overview for the TTR (Pippin 2005). Cultural resources sites from all chronological periods and site types have been recorded on the TTR. However, the greatest number of recorded sites consists of prehistoric extractive and processing localities, as well as historic mining and ranching sites. One historic building survey resulted in the development of a comprehensive Cold War era historic context and 59 properties recommended for eligibility for the NRHP as a historic district (Ullrich et al. 2005).

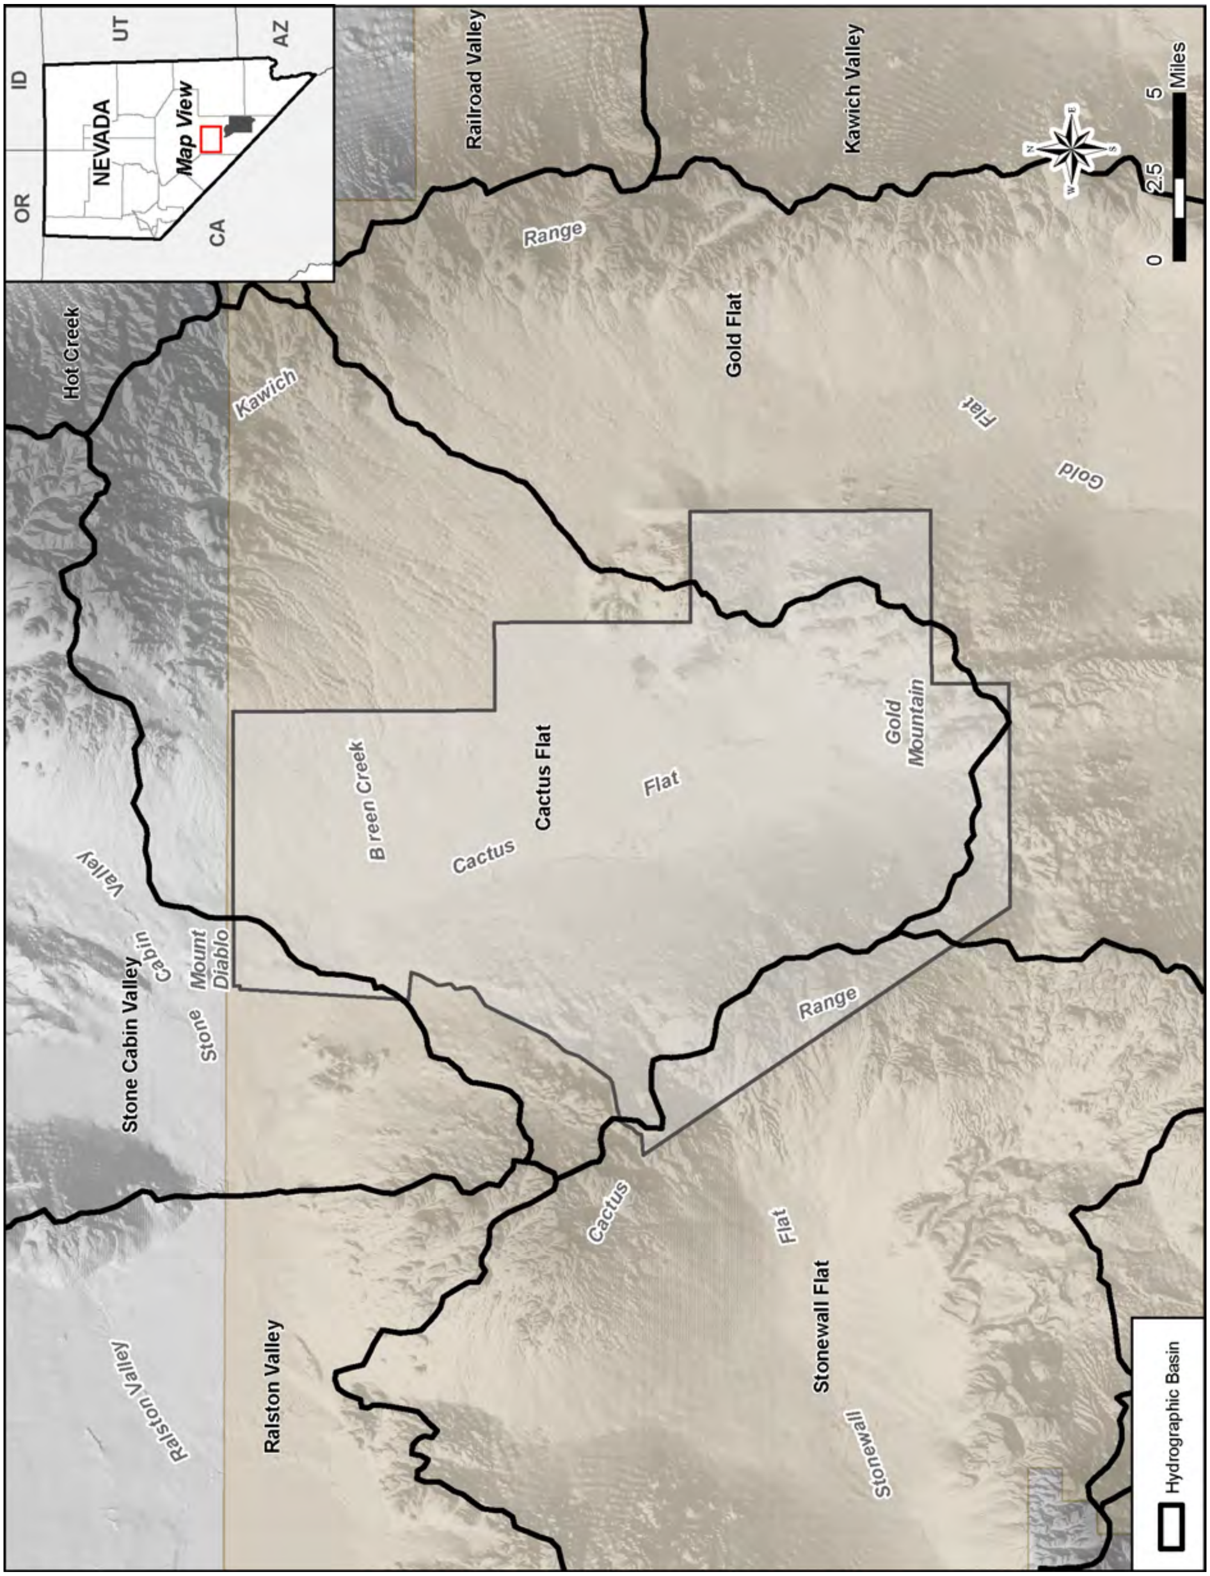

Figure 4–50 Hydrographic Basins Within the Tonopah Test Range Boundary

Less than 4 percent of the TTR has been surveyed for cultural resources. Seventy-one cultural resources studies have been completed on the TTR, and 330 cultural resources sites have been recorded. Prehistoric archaeological sites make up 87 percent, or 288 sites, of recorded sites on the TTR; the remaining 13 percent, or 42 sites, are historic archaeological sites and structures related to mining and ranching, and 1 site associated with military and scientific research (DOE 2010a). Sixty-seven percent, or 222 sites, are eligible for listing in the NRHP. Cultural resources are grouped by the five hydrographic basins located within the TTR (see **Table 4–74**).

Table 4–74 Tonopah Test Range Cultural Resources Sites by Site Type and Hydrographic Basin

Hydrographic Basin	***Prehistoric Site Types***							***Historic Sites***		***Untyped Sites***	***Total Sites***	***NRHP-Eligible***
	RB	***TC***	***EL***	***PL***	***LO***	***CA***	***STA***	***HI***	***NT***	***UT***		
Gold Flat	0	4	0	0	31	0	0	9	0	0	44	40
Stonewall Flat	0	0	0	0	3	0	1	9	0	0	13	13
Ralston Valley	0	2	0	0	36	0	0	2	0	0	40	38
Cactus Flat	0	19	0	3	93	0	0	18	1	0	134	68
Stone Cabin Valley	0	3	0	6	87	0	0	3	0	0	99	63
Total	**0**	**28**	**0**	**9**	**250**	**0**	**1**	**41**	**1**	**0**	**330**	**222**
Total Sites	**330**											**222**

CA = cache; EL = extractive locality; HI = historic site; LO = locality; NRHP = National Register of Historic Places; NT = nuclear testing; PL = processing locality; RB = residential base; STA = station; TC = temporary camp; UT = untyped.
Note: This table does not include isolated artifacts or features.

4.4.10.1.1 Gold Flat

While most of the Gold Flat Hydrographic Basin lies south of the TTR, a portion of Gold Flat lies in the southeastern corner of the TTR. Within the TTR, Gold Flat is divided from the Cactus Flat Hydrographic Basin by the Breen Creek drainage. Seven cultural resources studies have been conducted within the TTR portion of Gold Flat. Approximately 950 acres have been surveyed for cultural resources. To date, 44 cultural resources sites have been recorded, including 4 temporary camps, 31 uncategorized localities, and 9 historic sites associated with mining and ranching. Of these, 40 sites are eligible for listing in the NRHP.

4.4.10.1.2 Stonewall Flat

A small portion of the Stonewall Flat Hydrographic Basin lies within the southwestern TTR area. Stonewall Flat is separated from Cactus Flat by the Cactus Range. One cultural resources survey covering 215 acres has been completed on the TTR portion of Stonewall Flat. A total of 13 sites have been recorded, including 3 uncategorized localities, 1 station, and 9 historic sites associated with mining and ranching. All 13 sites are eligible for listing in the NRHP.

4.4.10.1.3 Ralston Valley

Only the southeastern corner of the Ralston Valley Hydrographic Basin falls within the TTR boundary. The Monitor Hills separate Ralston Valley from the Stone Cabin Valley Hydrographic Basin. One cultural resources survey covering 170 acres has been completed on the TTR portion of Ralston Valley. A total of 40 sites have been recorded, including 2 temporary camps, 36 uncategorized localities, and 2 historic sites. To date, 38 of these sites are eligible for listing in the NRHP.

4.4.10.1.4 Cactus Flat

The majority of the Cactus Flat Hydrographic Basin lies within the TTR boundary. Cactus Flat is bounded by the Cactus Range to the west, the Kawich Range to the east, Gold Mountain to the south, and

Mount Diablo to the north. Cactus Flat is the location of the Tonopah Test Range Airport and support facilities and, therefore, has been intensively surveyed for cultural resources. Fifty-six cultural resources studies have been conducted within Cactus Flat. Approximately 14,057 acres have been surveyed for cultural resources. A total of 134 cultural resources sites have been recorded, including 19 temporary camps, 3 processing localities, 93 uncategorized localities, 18 historic sites associated with mining and ranching, and 1 site associated with nuclear testing. Of these, 68 sites are eligible for listing in the NRHP.

4.4.10.1.5 Stone Cabin Valley

The southern end of Stone Cabin Valley Hydrographic Basin extends into the northern portion of the TTR. The basin is bounded by the Monitor Hills to the west and the Kawich Range to the east. Six cultural resources surveys have been conducted within the TTR portion of Stone Cabin Valley. Approximately 420 acres have been surveyed for cultural resources. To date, 99 cultural resources sites have been recorded, including 3 temporary camps, 6 processing localities, 87 uncategorized localities, and 3 historic sites. Of these, 63 sites are eligible for listing in the NRHP.

4.4.10.2 Sites of American Indian Significance

For a general description of consultation efforts between DOE/NNSA and CGTO, see Section 4.1.10.

DOE/NNSA consultation with CGTO included a site visit to Cactus Flat in 1997 by members of CGTO. The goal of the visit was to provide recommendations for DOE/NNSA site restoration activities in relation to potential sites of American Indian significance (Stoffle et al. 2001). This and other ongoing consultation efforts have resulted in a better understanding of the cultural significance these sites and locations possess in relation to traditional cultural landscapes (Zedeno et al. 1999; Stoffle et al. 2001).

4.4.11 Waste Management

A variety of wastes are generated during TTR operations in support of DOE/NNSA's Weapons Ordnance Program, as well as during environmental restoration activities at the TTR and the Nevada Test and Training Range. Although most wastes so generated are shipped off site for disposal, some sanitary solid waste and construction debris are disposed in onsite landfills.

Waste Generation. Hazardous waste from TTR operations that was disposed or recycled off site during CYs 2006 through 2008 is listed in **Table 4–75** (Schade 2010). Hazardous waste sent off site for disposal includes waste regulated under RCRA; asbestos- and PCB-contaminated waste regulated under TSCA; and waste regulated under other authorities, such as liquids or medical waste. This waste was accumulated and shipped off site for disposal at permitted disposal facilities.[32]

TTR pollution prevention and waste minimization activities include programs to recycle and recover materials such as antifreeze, Freon®, solvents, electronic components, oil, batteries, fluorescent and sodium bulbs, and mercury-containing equipment. Antifreeze is recycled and Freon® is recovered at an onsite unit. Other materials were sent off site for recycling, as shown in Table 4–75.

[32] *The TTR is a small-quantity generator of hazardous waste.*

Table 4–75 Tonopah Test Range Operations Hazardous Waste Disposed or Recycled, Calendar Years 2006–2008 (tons)

Waste Type	*Calendar Year*		
	2006	*2007*	*2008*
Hazardous waste	0.354	1.17	0.765
TSCA waste (asbestos/PCBs)	(a)	0.0353	(a)
Non-RCRA- or TSCA-regulated waste [b]	0.864	3.01	2.01
Recycled waste [c]	3.80	0.465	4.35

PCB = polychlorinated biphenyl; RCRA = Resource Conservation and Recovery Act; TSCA = Toxic Substances Control Act.
Note: Data from the cited source were rounded to three significant figures.
[a] Not reported for this year.
[b] Includes liquids, medical wastes, and other toxic solids that are not regulated under RCRA or TSCA.
[c] Includes materials such as batteries, fluorescent lights, or electronic equipment that are regulated under RCRA or other statutory authorities and were shipped off site for recycling.
Source: Schade 2010.

Solid wastes from TTR operations disposed from 2006 through 2008 are summarized in **Table 4–76**. Construction debris and municipal solid waste may be disposed within TTR landfills operated by the USAF (see Table 4–76). Tires and scrap metal waste generated from cleanup of the TTR Salvage Yard were surveyed by radiation control technicians and disposed by shipment to the Apex Landfill near Las Vegas, Nevada. By disposing this waste at a commercial landfill, possible impacts on TTR or NNSS landfill capacity were avoided.

Table 4–76 Tonopah Test Range Operations Solid Wastes Disposed, Calendar Years 2006–2008 (tons)

Waste Type	*Calendar Year*		
	2006	*2007*	*2008*
Tires and scrap metal	63 [a, b]	47.5 [b]	290.2 [b]
Construction debris	21.5	4.87 [c]	1.6 [c]
Sanitary solid waste	25.6	19.9 [c]	23.9 [c]

[a] Measured in cubic yards.
[b] Generated from cleanup of the TTR Salvage Yard. After being surveyed by radiation control technicians and cleared for release, the waste was shipped to the Apex Landfill near Las Vegas, Nevada, for disposal.
[c] The construction debris was disposed at the USAF Construction Landfill at the TTR, while the sanitary landfill waste was disposed at the USAF Sanitary Landfill at the TTR.
Source: DOE 2009a; SNL 2007, 2008.

Table 4–77 presents a summary of the environmental restoration waste generated at the TTR and disposed during CYs 2006 through 2008 (DOE 2009a; SNL 2007, 2008). During these years, TTR environmental restoration activities generated no RCRA- or TSCA-regulated wastes and no TRU or mixed wastes. In 2006, the TTR generated a small quantity of solid waste, consisting of personal protective equipment, such as paper and plastic, that was transferred to the NNSS for disposal. In addition, in 2005, closure activities for CAU 489 (World War II unexploded ordnance sites) generated 75.5 tons of scrap metal that in 2006 was transported to and disposed at the NNSS. In 2006 and 2007, the TTR disposed materials consisting of unexploded ordnance and debris from an Honest John M-50 rocket. During these years, depleted uranium recovered from the rocket was disposed at the NNSS as LLW and included debris and soil, personal protective equipment, and some material from the rocket. In 2007, 17 tons of inert unexploded ordnance and metal debris were disposed by the USAF (6 tons of inert unexploded ordnance) or shipped to and disposed at a Nevada Test and Training Range unexploded ordnance pile (11 tons of metal debris). Also in 2007, three metal structures were dismantled, and the metal scrap (10.5 tons) was shipped to the NNSS Area 3 Sandia Salvage Yard for reuse or recycle.

In 2008, environmental restoration activities were focused on planning activities for CAU 408 (Bomblet Target Area) and a sampling effort on Main Lake. The sampling effort on Main Lake was conducted to support characterization of approximately 40 soil-filled plastic bags that were ultimately disposed as sanitary solid waste. In 2008, however, the TTR generated 24 tons of hydrocarbon-contaminated soil that was shipped off site for disposal at the NNSS hydrocarbon landfill in Area 6.

Table 4–77 Environmental Restoration Wastes Disposed or Recycled, Calendar Years 2006–2008 (tons)

Waste Type	*Calendar Year*		
	2006	*2007*	*2008*
Scrap metal	75.5	(a)	(a)
Inert UXO and metal rocket debris	142	17.0	(a)
Nonradioactive solid waste	0.244 [c]	(a)	(b)
Recycled metal debris	(a)	10.5	(a)
Hydrocarbon-contaminated soil	(a)	(a)	24.0
Low-level radioactive waste (DU-contaminated)	742	407	(a)

DU = depleted uranium; UXO = unexploded ordnance.

[a] Not reported for this year.

[b] This material consisted of approximately 40 bags of soil that were sampled and ultimately disposed as sanitary solid waste.

[c] Consists of nonimpacted personal protective equipment (plastic, paper, Tyvek®, gloves, etc.) transported to the NNSS for disposal.

Source: DOE 2009a; SNL 2007, 2008.

Landfills. At the TTR, the USAF operates a landfill for disposal of construction debris, as well as an expanded Class II sanitary landfill for disposal of municipal solid waste (DOE 2009a). The original sanitary landfill was transferred from DOE to USAF operation in 1992, and was recently expanded. The landfill is authorized to receive no more than 20 tons of municipal solid waste per day, and is projected to have a total license expectancy of 30 years (USAF 2007a).

4.4.12 Human Health and Safety

The health and safety of the general public and workers at the TTR are discussed in this section. Environmental health risks from TTR activities include the effects of environmental noise and acute and chronic exposures to ionizing radiation and hazardous chemicals. Regular programs are administered to monitor releases and evaluate associated potential health impacts. Additionally, studies have been conducted to assess the exposure pathways and potential risks of radionuclide and toxic chemical releases during past TTR operations. These studies focused on the impacts of releases in terms of health risks to the general public and workers at the TTR. Results of current assessments and historic studies indicate (1) there is little risk of enhanced carcinogenesis due to radionuclide and chemical releases during site operations; (2) exposures to site radionuclide releases tend to be far lower than those due to natural background radiation; and (3) chemical exposures are well within established guidelines. In keeping with the goal of optimal protection of vulnerable populations, DOE maintains a comprehensive Emergency Management Program that features hazard-specific plans, procedures, and controls (DOE Order 151.1C).

4.4.12.1 Public Radiation Exposure and Safety

4.4.12.1.1 General Site Description

Major sources of background radiation and average doses from background radiation exposure to individuals in the TTR vicinity are the same as those for the NNSS (see Table 4–52). The average annual dose from background radiation is approximately 670 millirem. About half of the annual dose is from ubiquitous, natural background sources (355 millirem) that can vary depending on geographic location, individual buildings in a geographic area, and age, but essentially all comes from space or naturally occurring sources in the Earth. About half of the dose is from medical exposure to radiation (300 millirem), including computed tomography, interventional fluoroscopy, x-rays and conventional

fluoroscopy, and nuclear medicine (use of unsealed radionuclides for diagnosis and treatment). Another approximately 14 millirem per year are from consumer products and other sources (nuclear power, security, research, and occupational exposure) (NCRP 2009). Average annual background radiation doses to individuals are expected to remain fairly constant over the time period of the proposed actions. Background radiation doses identified in Table 4–52 are unrelated to TTR operations.

Releases of radionuclides to the environment from TTR operations provide another source of radiation exposure to individuals in the vicinity of the TTR. The only sources of radionuclide emissions from the TTR consist of the resuspension of plutonium and americium from past test activities (DOE 2009a). Doses to the public estimated from historic monitoring at the TTR are presented in **Table 4–78**. These doses fall within the limits established in DOE Order 458.1 and are much lower than those due to background radiation.

Table 4–78 Radiation Doses to the Public from Tonopah Test Range Operations in 2008 (Total Effective Dose Equivalent)

Members of the Public	*Atmospheric Releases* [a]	*Liquid Releases* [b]	*Total* [c]
Maximally exposed individual (millirem)	0.024	0	0.024
Population within 50 miles (person-rem) [d]	<1	0	<1
Average individual within 50 miles (millirem) [e]	<0.024	0	<0.024

rem = roentgen equivalent man.

[a] Clean Air Act regulations in 40 CFR Part 61, Subpart H, establish a compliance limit of 10 millirem per year to a maximally exposed individual.

[b] There is no dose to the public from surface-water or groundwater pathways.

[c] DOE Order 458.1 establishes a dose limit of 100 millirem per year to individual members of the public exposed through all pathways.

[d] A population dose was not reported in the *Calendar Year 2008 Annual Site Environmental Report for Tonopah Test Range, Nevada and Kauai Test Facility, Hawaii* (DOE 2009a). The estimated population within 50 miles of the Tonopah Test Range was only about 5,000 in the year 2008; if every member of that population received the same dose as the Tonopah Test Range maximally exposed individual, the population dose would be much less than 1 person-rem.

[e] The dose to the maximally exposed individual was based on an exposure location at the Tonopah Test Range Airport. Members of the population are further away from the sources of airborne radioactive material and are exposed to lower concentrations; therefore, the average dose to an individual of the 50-mile population is significantly lower than that to the maximally exposed individual.

Source: DOE 2009a; SNL 2009a.

Using a risk coefficient of 600 cancer deaths per 1 million person-rem (0.0006 LCFs per person-rem) (DOE 2003c), the risk of an LCF to the MEI due to radionuclide releases from TTR operations in 2008 was estimated to be 1.4×10^{-8}. That is, the probability of this person dying of cancer at some time in the future as a result of a radiation dose associated with emissions from 1 year of TTR operations is about 1 in 70 million. The hypothetical MEI is a person whose place of residence and lifestyle make it unlikely that any other member of the public would receive a higher radiation dose from TTR releases. This person was assumed to be exposed to radionuclides in the air and on the ground from TTR emissions and was assumed to be located at the Tonopah Test Range Airport (DOE 2009a).

No members of the public receive direct gamma radiation exposure that is above background levels as a result of past or present TTR operations. Gamma radiation exposure rates measured at areas accessible to the public are comparable to natural background rates from cosmic and terrestrial radiation. Radioactively contaminated areas at the TTR are isolated from members of the public, given the considerable distances between these areas and the TTR boundary.

In regard to groundwater monitoring programs, there is no TTR radiation dose incurred by the public from the groundwater pathway. Annual monitoring indicates that no contaminated groundwater has migrated beyond the TTR boundary into surrounding water supplies used by the public (DOE 2009a).

Operations at the TTR do not involve activities that release radioactive emissions from either point sources (stacks/vents) or diffuse sources (outdoor testing). However, diffuse radioactive emissions are produced from the resuspension of americium and plutonium present at sites of previous testing activities. Other locations at the TTR with minor radioactive contamination, such as depleted uranium, are not significant sources of radioactive air emissions from resuspension (DOE 2009a).

4.4.12.2 Occupational Radiation Exposure and Safety

Workers at the TTR receive the same dose as the general public from background radiation, but they potentially receive an additional dose from working in or around areas with radioactive material. No worker dose data have been reported since the year 2002, and no workers received a measurable dose between 1998 and 2002. The average annual worker dose measured between 1991 and 2002 was 12 millirem (DOE 2009i).

Worker occupational risks at the TTR are generally associated with activities such as waste management, environmental restoration, terrestrial surveillance, and environmental monitoring. DOE's Computerized Accident/Incident Reporting System provides statistics on worker injury and illness information, including accidents involving government-owned vehicles. There were no reportable occurrences in 2008 at the TTR. A reportable occurrence is defined as an unanticipated event that leads to a near-miss, injury, or death of an occupational worker.

4.4.12.3 Chemical Exposure and Risk

The background chemical environment important to human health consists of the atmosphere, which may contain hazardous chemicals that can be inhaled; drinking water, which may contain hazardous chemicals that can be ingested; and other environmental media, through which people may come in contact with hazardous chemicals. Hazardous chemicals can cause cancer and non-cancer-related health effects.

Because of the TTR's remote location and large size, there is no risk of chemical exposure to the surrounding public population resulting from normal site operations. Nevertheless, monitoring efforts and baseline studies are regularly performed. However, certain TTR workers may be at risk to chemical exposure depending upon their job function and proximity to various sources.

Common sources of chemical pollutants and RCRA materials at the TTR include solvents, fuels and oil, pesticides, septic sludge, heavy metals, various munitions materiel, lead-acid batteries, and mercury-containing items. Particulate matter from the TTR portable screen and the TTR maintenance shops (which include painting, welding, and carpentry activities) was released in limited quantities in 2008. The portable screen was operated for 220 hours during 2008 and contributed 0.01 tons of particulate matter emissions. Maintenance shops operated for 282 hours or less in 2008 and contributed less than 0.2 tons of emissions (from particulate matter, hazardous air pollutants, and volatile organic compounds) in total (DOE 2009a).

As for monitoring potential chemicals released to TTR drinking water and wastewater systems, a single well (Well 6) supplies the drinking water needs to TTR workers and visitors, and is monitored annually for potability and purity. Water samples from this well continue to meet all national primary and secondary drinking water standards. In addition, the TTR sewage lagoon systems are tested for biochemical oxygen demand, pH, and total suspended solids, as well as for a suite of toxic chemicals. In the two most recent years for which results have been reported, all wastewater measurements were found to be within permit limits (DOE 2009a; SNL 2010b).

To manage risks from handling toxic or hazardous chemicals, TTR worker safety programs are established to comply with Federal and state laws, DOE Orders, Occupational Safety and Health Administration requirements, and EPA guidelines. Sandia National Laboratories plans and procedures for performing work ensure worker protection through training, monitoring, use of personal protective equipment, and administrative controls. Although chemical inventories have varied to a limited extent over recent years, administrative controls continually ensure that quantities do not approach levels that

pose undue risk due to storage, concentration, bulk quantity, or logistical factors. Any amounts that potentially exceed threshold planning quantities require reporting under Federal regulations.

4.4.12.4 Health Effects Studies

To date, apart from the NNSS-related studies described in Section 4.1.12.4, no studies have analyzed potential epidemiological effects resulting from past TTR operations. There are no studies that indicate adverse health effects in populations near the TTR as a result of activities or operations supporting current TTR missions.

4.4.12.5 Accident History

The only significant incident on record to have occurred at the TTR in recent years is the following: Five USAF personnel were killed when a Beechcraft 1900C crashed at the Tonopah Test Range Airport. It was determined that the incident was due to the pilot undergoing cardiac arrest during landing maneuvers (ASN 2004).

4.4.12.6 Emergency Preparedness

Each DOE site has established an Emergency Management Program, developed in accordance with DOE Order 151.1C, *Comprehensive Emergency Management System*, that would be activated in the event of an accident. This program has been developed and maintained to ensure adequate response for postulated accident conditions and to provide response efforts for accidents not specifically considered. The Emergency Management Program incorporates activities associated with emergency planning, preparedness, and response. The TTR Emergency Preparedness Plan is designed to minimize or mitigate the impact of any emergency upon the health and safety of employees and the public. The plan integrates all emergency planning into a single entity to minimize overlap and duplication and to ensure proper responses to emergencies not covered by a plan or directive. DOE/NNSA coordinates emergency response planning and training with local governments. In accordance with the National Incident Management System, the coordination ensures that communications systems and equipment are interoperable and that personnel and equipment can be effectively deployed in the event of an emergency. The DOE/NNSA manager is responsible for managing, countering, and recovering from an emergency occurring at the TTR.

The plan provides for identification and notification of personnel for any emergency that may develop during operational and nonoperational hours. DOE/NNSA receives warnings, weather advisories, and any other communications that provide advance warning of a possible emergency. The plan is based upon current DOE/NNSA vulnerability assessments, resources, and capabilities regarding emergency preparedness.

4.4.12.7 Environmental Noise

The acoustic environment adjacent to the TTR is similar to that described for land areas adjacent to the NNSS. The nearest residents are located in the towns of Goldfield, approximately 22 miles west of the site boundary, and Tonopah, approximately 30 miles northwest of the site. The main sources of noise at the TTR include air- and ground-launched rockets, gun firing, and explosives experiments. An airbase is located within the TTR in support of Nevada Test and Training Range activities. Because of access restrictions and lack of a nearby population, public exposure to these noise sources is limited to occasional sonic booms produced by supersonic overflights of military aircraft. Principal sources of noise to residents of nearby towns include vehicular traffic on U.S. Routes 6 and 95 and aircraft operations.

4.4.13 Environmental Justice

There are no block groups in Nye County (the county the TTR is located within) with minority populations greater than 50 percent. Within the ROI, the closest block group to the NNSS with a minority population greater than 50 percent is more than 60 miles to the southeast of the TTR, near the southeastern corner of the NNSS (see Figure 4–36). Additional block groups with minority populations

greater than 50 percent are found further to the southeast in the Las Vegas metropolitan area, closer to the RSL and NLVF facilities (see Sections 4.2.13 and 4.3.13).

Census data were available for the number of households with an income less than $15,000 and those with an income between $15,000 and $24,999. DOE used the combined number of households with incomes less than $24,999 as the poverty threshold for Nye County. Analysis of the data (see Figure 4–36) illustrates that there are numerous census block groups with low-income populations between 11 and 20 percent (that is, at or above the state-wide average) distributed throughout the ROI, including large (but sparsely populated) block groups adjacent to the TTR.

4.5 Former Yucca Mountain Site Affected Environment

DOE analyzed a proposed action to construct, operate, monitor, and eventually close a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain in Nye County, Nevada, in the *Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (*Yucca Mountain EIS*) (DOE/EIS-0250F) (DOE 2002e), and in the *Final Supplemental Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (DOE/EIS-0250F-S1) (DOE 2008g). The area evaluated for the repository is an approximately 150,000-acre area of land that comprises land administered by DOE (79,000 acres of the NNSS); the USAF (24,000 acres of the Nevada Test and Training Range); and BLM (44,000 acres), as well as private land (a 200-acre Cind-R-Lite Patented Mining Claim). The Nevada Test and Training Range is closed to public access and use. The BLM-administered land outside of the Nevada Test and Training Range is open to public use, with the exception of approximately 4,250 acres. A number of unpatented mining claims are located on the BLM land.

The area evaluated for the repository is in the southern part of the Great Basin, which is characterized by generally north-trending, linear mountain ranges separated by intervening valleys or basins. Within this setting, Yucca Mountain is part of the southwestern Nevada volcanic field, a volcanic plateau that formed between about 14 and 11.5 million years ago. Yucca Mountain is a product of both volcanic activity and faulting. The crest of Yucca Mountain reaches elevations from 4,900 feet to 6,300 feet above sea level. Crater Flat is located on the BLM-administered land to the west of Yucca Mountain and contains four prominent volcanic cinder cones.

Thirty-six species of mammals have been recorded in and around Yucca Mountain. None of these mammals are classified as threatened or endangered by the USFWS. Twenty-seven species of reptiles have been found at and near Yucca Mountain. The desert tortoise (*Gopherus agassizii*) is listed as threatened under the Endangered Species Act. Yucca Mountain is at the northern edge of the range of the desert tortoise. The western chuckwalla (*Sauromalus obesus*) and the western red-tailed skink (*Eumeces gilberti rubricaudatus*) are classified as sensitive species in Nevada by BLM. More than 120 species of birds have been recorded at Yucca Mountain and the surrounding region, including 15 species of raptors. Several bird species are classified as sensitive species in Nevada by BLM. Native plants at Yucca Mountain below an elevation of about 4,000 feet are typical of the Mojave Desert. Above 4,000 feet is a vegetation transition zone between the Mojave Desert and the colder Great Basin Desert. About 30 invasive, nonnative plant species also occur in the Yucca Mountain region.

There are no perennial streams, natural bodies of water, or naturally occurring wetlands in the area evaluated. Solitario Canyon Wash collects drainage from the west side of Yucca Mountain and runs through the Nevada Test and Training Range and BLM-administered lands. Drill Hole Wash and Busted Butte (Dune) Wash collect drainage from the east side of Yucca Mountain and drain into Fortymile Wash on the NNSS. Fortymile Wash drains to the south. The washes only carry water during intense rain and rapid snowmelt. These washes drain into the ephemeral Amargosa River, which terminates in the Badwater Basin in Death Valley.

More than 530 archaeological sites and over 550 isolated artifacts have been discovered at or near Yucca Mountain. Collectively, they indicate that the Yucca Mountain region has been occupied by American Indian populations for at least 12,000 years. According to American Indians, the Yucca Mountain area is part of the holy lands of the Western Shoshone, Southern Paiute, and Owens Valley Paiute and Shoshone people.

BLM assigns visual resource values to the lands it manages on a scale of Class I to Class IV, with Class IV representative of the lowest visual values. DOE has previously determined that the lands to the west and south of Yucca Mountain, which are visible from portions of U.S. Route 95, are Class III and Class IV lands, which are common to the region.

The air quality in the area is characterized as unclassifiable due to limited air quality data. However, data collected by DOE indicate that the air quality is within applicable NAAQS.

CHAPTER 5
ENVIRONMENTAL CONSEQUENCES

5.0 ENVIRONMENTAL CONSEQUENCES

This chapter provides the scientific and analytical basis for the comparison of the alternatives identified in this *Site-Wide Environmental Impact Statement for the Continued Operation of the Department of Energy/National Nuclear Security Administration Nevada National Security Site and Off-Site Locations in the State of Nevada (NNSS SWEIS)*. This discussion addresses the potential direct and indirect effects of each of the alternatives. Within this chapter, the analysis is organized based on the following geographic sites covered within this site-wide environmental impact statement (SWEIS): the Nevada National Security Site (NNSS); the Remote Sensing Laboratory (RSL) at Nellis Air Force Base; the North Las Vegas Facility (NLVF); and the Tonopah Test Range (TTR). For each geographic site, potential environmental consequences are then addressed for the following environmental resource areas:

- Land Use
- Infrastructure and Energy
- Transportation
- Socioeconomics
- Geology and Soils
- Hydrology
- Biological Resources
- Air Quality and Climate
- Visual Resources
- Cultural Resources
- Waste Management
- Human Health
- Environmental Justice

Within each environmental resource area, this SWEIS analyzes the potential environmental consequences associated with the three alternatives (No Action, Reduced Operations, and Expanded Operations) identified in Chapter 3 of this SWEIS. Under each alternative, the potential environmental consequences are also described in relation to the three major missions (National Security/Defense, Environmental Management, and Nondefense) described in Chapter 3 of this SWEIS. For some environmental resource areas, additional technical information used to support the analysis is contained in separate appendices. A summary comparison of the mission-based program activities under each of the proposed alternatives is presented in Chapter 3, Table 3–1, of this *NNSS SWEIS*. Section 5.5 provides the combined impacts of all four U.S. Department of Energy/National Nuclear Security Administration (DOE/NNSA) sites in Nevada for certain resource areas. In Section 3.4, DOE/NNSA identified its Preferred Alternative. DOE/NNSA's Preferred Alternative is a "hybrid" alternative comprising various programs, capabilities, projects, and activities selected from among the three alternatives. Chapter 3, Table 3–3, of this *NNSS SWEIS* provides a comparison of mission-based program activities under the three alternatives and visually identifies which elements of the three alternatives were selected for the Preferred Alternative. Tables 3–4, 3–5, 3–6, and 3–7 also summarize the potential environmental consequences associated with implementing the Preferred Alternative.

Throughout this chapter, the perspectives of American Indian tribes and groups regarding the environmental consequences of DOE/NNSA activities in Nevada are summarized in shaded and marked text boxes identified with a Consolidated Group of Tribes and Organizations (CGTO) feather icon. The full text of American Indian perspectives is contained in Appendix C of this SWEIS, which was prepared by the American Indian Writers Subgroup of the CGTO.

The impact analysis for this SWEIS is based on the best data available, considering current environmental conditions, activities, and facilities. This SWEIS considers ongoing and proposed programs, capabilities, and projects (i.e., activities) at DOE/NNSA facilities in Nevada over the next 10 years. The nature of ongoing activities and their relationship to associated environmental impacts are well understood. In contrast, however, the nature of proposed activities is less well known. In the interest of disclosing potential environmental impacts that could occur at the NNSS and offsite locations over the next 10 years, this SWEIS includes ongoing activities, as well as a number of activities that are in planning and development.

To assess potential environmental impacts from all such activities, it was necessary for DOE/NNSA to estimate at a programmatic level certain aspects of the proposed activities, such as the potential area of land disturbance or the amount of groundwater that may be required. DOE/NNSA incorporated these programmatic-level estimates, along with more-detailed information on ongoing, better-understood activities, into the analysis of impacts. For instance, estimated areas of land disturbance for both proposed and well-defined activities were used to determine the potential impacts on resources such as soils (area of disturbance and erosion), cultural resources (number of sites potentially affected), and biology (vegetation/habitat loss, number of desert tortoises affected).

DOE/NNSA understands that the level of National Environmental Policy Act (NEPA) analysis conducted for some proposed activities may not be sufficient to permit implementation, and such activities could require additional NEPA analysis. These activities are identified in Chapter 3. DOE/NNSA will conduct NEPA reviews for these activities, as appropriate, in the future. DOE/NNSA's NEPA review procedures are described in Chapter 9, Section 9.1.1.

In this SWEIS, DOE/NNSA analyzed potential environmental impacts resulting from proposed activities that may occur within a 10-year planning window, including long-term as well as short-term effects. The durations of impacts vary for individual resource areas, and are dependent upon whether the impacts are due to construction activities, which typically would last no more than a few years, from the operation of facilities, which would last for many years, or from actions for which impacts could last for hundreds of years or longer. For some resource areas, such as biological and cultural resources, potential impacts are primarily dependent on the amount of land that would be newly disturbed due to ongoing or proposed projects and activities; these impacts would occur "one time" and would not change over time. For other resource areas, such as air quality, potential impacts are dependent primarily on the duration of project construction in the short term, and the level of operations in the longer term; such longer-term impacts would occur on an annual basis, and would continue for as long as these projects and activities continue. Although some activities may eventually cease, such as disposal of low-level radioactive waste (LLW), potential impacts would not appear for many decades, but would then last for hundreds or thousands of years. The presentation of potential environmental impacts in this *NNSS SWEIS* reflects these durations for each resource area, as appropriate.

In 2008, DOE/NNSA estimated that approximately 80,000 acres (9 percent) of NNSS land had been disturbed. **Table 5–1** shows the potential amount of additional land disturbance that would result under each of the three alternatives addressed in this SWEIS. Under each alternative in the table, areas of potential land disturbances are noted by mission area, program, and activity. The data used to develop the table were derived from the descriptions in Chapter 3; these data include disturbances associated with ongoing and proposed activities that were used as a basis for an adequate NEPA analysis, as well as disturbances associated with potential activities that are less well developed at this time. In addition, all of these potential land disturbances were assumed to affect previously undisturbed land; however, in some cases, lands that are currently disturbed would be used for proposed and potential activities. For these reasons, the land disturbance areas displayed in Table 5–1 provide one of the bases for a conservative analysis of potential impacts.

D&D = decontamination and decommissioning; IED = Improvised Explosive Device; OST = Office of Secure Transportation; RWMC = Radioactive Waste Management Complex; UGTA = Underground Test Area.

[a] This table includes potential projects and activities that could impact previously undisturbed land but excludes those, such as a new Security Building in Area 23 or Reconfiguration of Mercury, that DOE/NNSA is certain would be located in previously disturbed areas. In addition, some activities, such as explosive experiments and experiments involving releases of chemicals and/or biological simulants, may be conducted in either previously disturbed or undisturbed land. In these cases, a reasonable estimate was made of the number of such experiments that would result in disturbance of previously undisturbed land.

[b] Number of "Events" Over 10 Years is the estimated maximum number of times a proposed or potential project or activity would be conducted over the next 10 years or the number of facilities that would be developed for a type of activity.

[c] Disturbance per "Event" (acres) is the estimated area of land disturbance, in acres, resulting from a single occurrence of a proposed or potential project or activity.

[d] Total Disturbance by Activity equals Disturbance per "Event" × Disturbance per "Event" for a particular proposed project or activity.

[e] Total Disturbance by Program is the aggregated total of acres of potentially disturbed land in the Total Disturbance by Activity column for the specified program.

[f] Total Disturbance by Mission and Alternative is the aggregated total of acres of potentially disturbed land for all programs within a particular mission area and the cumulative total for a specified alternative.

[g] For OST exercises it was conservatively assumed that, for each event, 1 acre of land immediately adjacent to an existing road would be disturbed by overland vehicle movements

[h] UGTA Project characterization and monitoring wells would be located on the NNSS, Nevada Test and Training Range, and possibly on Bureau of Land Management (BLM) land and private property.

[i] Soils Project land disturbance includes sites on the NNSS and Nevada Test and Training Range (except for the TTR).

[j] The acres of disturbance for the commercial solar power generation facility(ies) under each alternative include estimated disturbance to construct the necessary electrical transmission lines to interconnect the facilities to the main transmission grid.

[k] These projects are included in the analysis on a "programmatic" level; however, additional NEPA review would be required as specific projects are developed beyond a conceptual stage.

[l] Disturbance for rebuilding the "backbone" electrical transmission line on the NNSS assumes 100 feet of disturbance along the entire 38.5 miles of the project.

5.1 Nevada National Security Site

The following sections describe the potential environmental consequences associated with the proposed alternatives in this SWEIS, as well as ongoing programs at the NNSS.

5.1.1 Land Use

Land use impacts are considered broadly in this SWEIS to include both land and airspace. The following criteria are used in this analysis of potential impacts on land use and airspace resources resulting from activities of DOE/NNSA in the State of Nevada:

- Compatibility of proposed activities with existing land use and land use designations both on the NNSS and in the surrounding areas
- Availability of sufficient land within the appropriate land use zone for the proposed activities and facilities
- Compatibility of proposed airspace activities with existing airspace use and airspace classifications with both civilian and military airspace use
- Compatibility of proposed activities at RSL, NLVF, and the TTR with surrounding area land uses (determined by the evaluation of existing and future land use or resource management plans)

Impacts on land use were assessed by comparing the compatibility of proposed land uses with existing land uses, current and potential activities within the land use zone designations developed by the DOE/NNSA, and the assessment of land availability. Land use compatibility is defined here as the ability of two or more land uses to coexist without significant conflict. Examples of significant conflicts include interference of proposed activities with existing activities (including airspace activities); insufficient availability of facilities, infrastructure, and/or resources to safely accommodate a proposed activity; and activities resulting in human health and safety issues due to poor siting. Frequently, compatibility between land uses exists in varying degrees based on the frequency, duration, and intensity of a proposed activity. The land use zone designations preclude proposed activities from being located within a designated zone that would be incompatible with the current or proposed uses. However, an activity could be collocated within a land use zone that it is not normally associated with based on evaluation of its compatibility with nearby activities, including consideration of the availability of facilities and infrastructure, safety of personnel, and sensitive environments. All zones are considered compatible with environmental restoration activities. Potential impacts on land use compatibility are based on qualitative assessments and, to the extent possible, quantitative assessments, of the range of activities that could occur under the three missions. Land disturbance within a given land use zone is not considered a land use impact under these criteria unless the disturbance results from a project that is incompatible with the land use designation. Impacts associated with land disturbance that affect resources such as soil, biological resources, and cultural resources, are presented in their respective resource impact sections in this chapter. The following subsections present analyses of the land use impacts under each alternative by mission and program.

Potential development of commercial solar power generation facilities in Area 25 of the NNSS is addressed at varying levels under all three alternatives in this *NNSS SWEIS*. There is no specific schedule for constructing one or more solar power generation facilities at the NNSS, and the analysis of impacts in this *NNSS SWEIS* is included to enable DOE/NNSA to make a decision about whether to make land and infrastructure now under DOE/NNSA control available for another use by a commercial entity.

Impacts on the surrounding land uses near the NNSS, RSL, NLVF, and the TTR were evaluated by assessing existing and future land use and resource management plans to determine whether land uses at these DOE/NNSA site locations are compatible with the surrounding land uses. The primary land uses adjacent to the NNSS and the TTR include additional military training and exercises within the Nevada Test and Training Range lands, as well as grazing, mining, and recreation on the Bureau of Land Management (BLM)-managed lands. The assessment showed that NNSS operations would be compatible with surrounding land uses because NNSS activities would occur within appropriately designated land use zones and existing and proposed experiments and activities would be sited to prevent incompatibility with adjacent land uses. Land use at NLVF would be compatible with surrounding land use because no changes are proposed under any of the alternatives and NLVF is located within an area that is suitably zoned for DOE/NNSA's activities. As RSL is located on Nellis Air Force Base and any activities occurring at this facility would be compatible with the U.S. Air Force's (USAF's) mission and would occur on land withdrawn for the purpose of military training and exercises, no impacts on surrounding land uses would occur. Therefore, discussion of the impacts of each alternative will focus on compatibility with DOE/NNSA land use designations.

Land Use—American Indian Perspective

CGTO During the evaluation of the *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada (1996 NTS EIS)*, the Consolidated Group of Tribes and Organizations (CGTO) noted repeated nuclear testing activities had resulted in severe disturbances to the land on large portions of the Nevada National Security Site (NNSS). This seemingly irreparable damage has made certain areas unfit for human use and inaccessible to American Indians who have relied on it for food, medicine, and ceremonies. Sedan Crater, for example, continues to be a dead site; the spirits of the site and resources on it were destroyed in 1962 and the loss can still be felt by members of the CGTO.

One elder from the Moapa Paiute Tribe in Nevada responded to the potential impacts of radioactive contamination of his traditional land as follows: *"You non-Indians can move if you pollute the land on which you live, but we were created for this place, so we must face whatever happens here. We cannot move and continue to be Paiute people – this is our land – we are this land"*. This view is shared by other culturally-affiliated tribes within the CGTO. The CGTO maintains we have Creation-based rights to protect, use, and have access to lands of the NNSS and the immediate area.

See Appendix C for more details.

Impacts on airspace were assessed by reviewing the existing airspace classifications and users within the region. Potential impacts on airspace are based on qualitative assessments of the range of potential activities under the three missions that could conflict with existing airspace classifications and existing airspace use. Accordingly, the only activities that would affect airspace would be defense-related. Therefore, only the National Security/Defense Mission is discussed and evaluated in this section for airspace impacts resulting from implementation of the alternatives.

The variety of DOE/NNSA programs requiring occasional flights of helicopters and fixed-wing aircraft carrying supplies and personnel would continue to occur under all three alternatives. The NNSS would continue to host the use of aerial platforms (airplanes and helicopters) for research and development, training, and exercises. The inherent constraints of the existing restricted airspace over the NNSS and Nevada Test and Training Range would continue to require nonparticipating civil and military aircraft to be routed around both sites, as necessary. NNSS use of airspace is contingent on joint-use status, operations in progress, and air traffic considerations. DOE/NNSA is required to coordinate scheduling of airspace activities through the Nellis Air Traffic Control Facility, which controls the movement of military aircraft in and out of restricted airspace. While the USAF does not own NNSS airspace, NNSS airspace is controlled by Nellis Air Force Base under agreement between DOE/NNSA and the USAF.

The current level of air traffic control and radar, radio, and navigational aid services would likely be maintained or improved under normal upgrade programs. Based on past trends and improvements in communication, no increased impacts on civilian air traffic are expected.

5.1.1.1 No Action Alternative

Under the No Action Alternative, current activities and operations would continue and the land use zone designations would remain unchanged, except for the Solar Enterprise Zone, which would be redesignated as the Renewable Energy Zone. **Figure 5–1** depicts the land use zone designations on the NNSS under the No Action Alternative. No proposed changes would occur to affect existing and surrounding land use resources associated with the NNSS. Land use impacts resulting from the development of the Renewable Energy Zone in Area 25 are not expected because the facility would be within a land use zone designated for solar power development and would not impact surrounding land use resources.

The impacts on land use for the missions under the No Action Alternative are discussed below.

5.1.1.1.1 National Security/Defense Mission

There would be no land use impacts resulting from the continuation of National Security/Defense Mission activities at the current levels of operations under the No Action Alternative because activities under this alternative would not change. This section further discusses the potential impacts of the No Action Alternative on National Security/Defense Mission programs and use of airspace.

Stockpile Stewardship and Management Program. Activities associated with research, design, development, and testing of nuclear weapons components and the assessment and certification of their safety and reliability would continue within the applicable land use zones. The NNSS would maintain readiness to conduct underground nuclear tests, if directed by the President. The continuation of stockpile stewardship management activities would include disposition of damaged U.S. nuclear weapons, staging of nuclear weapons, and disassembly of nuclear weapons. Drillback operations, which were routinely conducted after an underground nuclear test to obtain samples within the explosive cavity region, would continue for the purposes of exercising and maintaining this capability and obtaining data for groundwater studies. Drillback operations would occur near the site of a former underground nuclear test event.

The No Action Alternative assumes the continuation of Stockpile Stewardship and Management Program operations at current levels, consistent with existing NNSS land use designations; therefore, no overall adverse land use impacts are expected.

Nuclear Emergency Response, Nonproliferation, and Counterterrorism Programs. Because the No Action Alternative assumes the continuation of these programs' current operations and these operations are consistent with existing land use designations, no new impacts on land use are expected.

Work for Others Program. This program is hosted by DOE/NNSA and provides other Federal agencies, state and local government agencies, and nongovernmental organizations with the shared use of certain facilities on the NNSS. Because the No Action Alternative assumes the continuation of this program's current operations and these operations are consistent with existing land use designations, no new impacts are expected.

Airspace. Under the No Action Alternative, activities at the NNSS would continue at the level of current operations; therefore, no new impacts are expected from anticipated airspace activities and requirements. DOE/NNSA would continue to coordinate the use of airspace with the controlling entity responsible for NNSS airspace, the Nellis Air Traffic Control Facility.

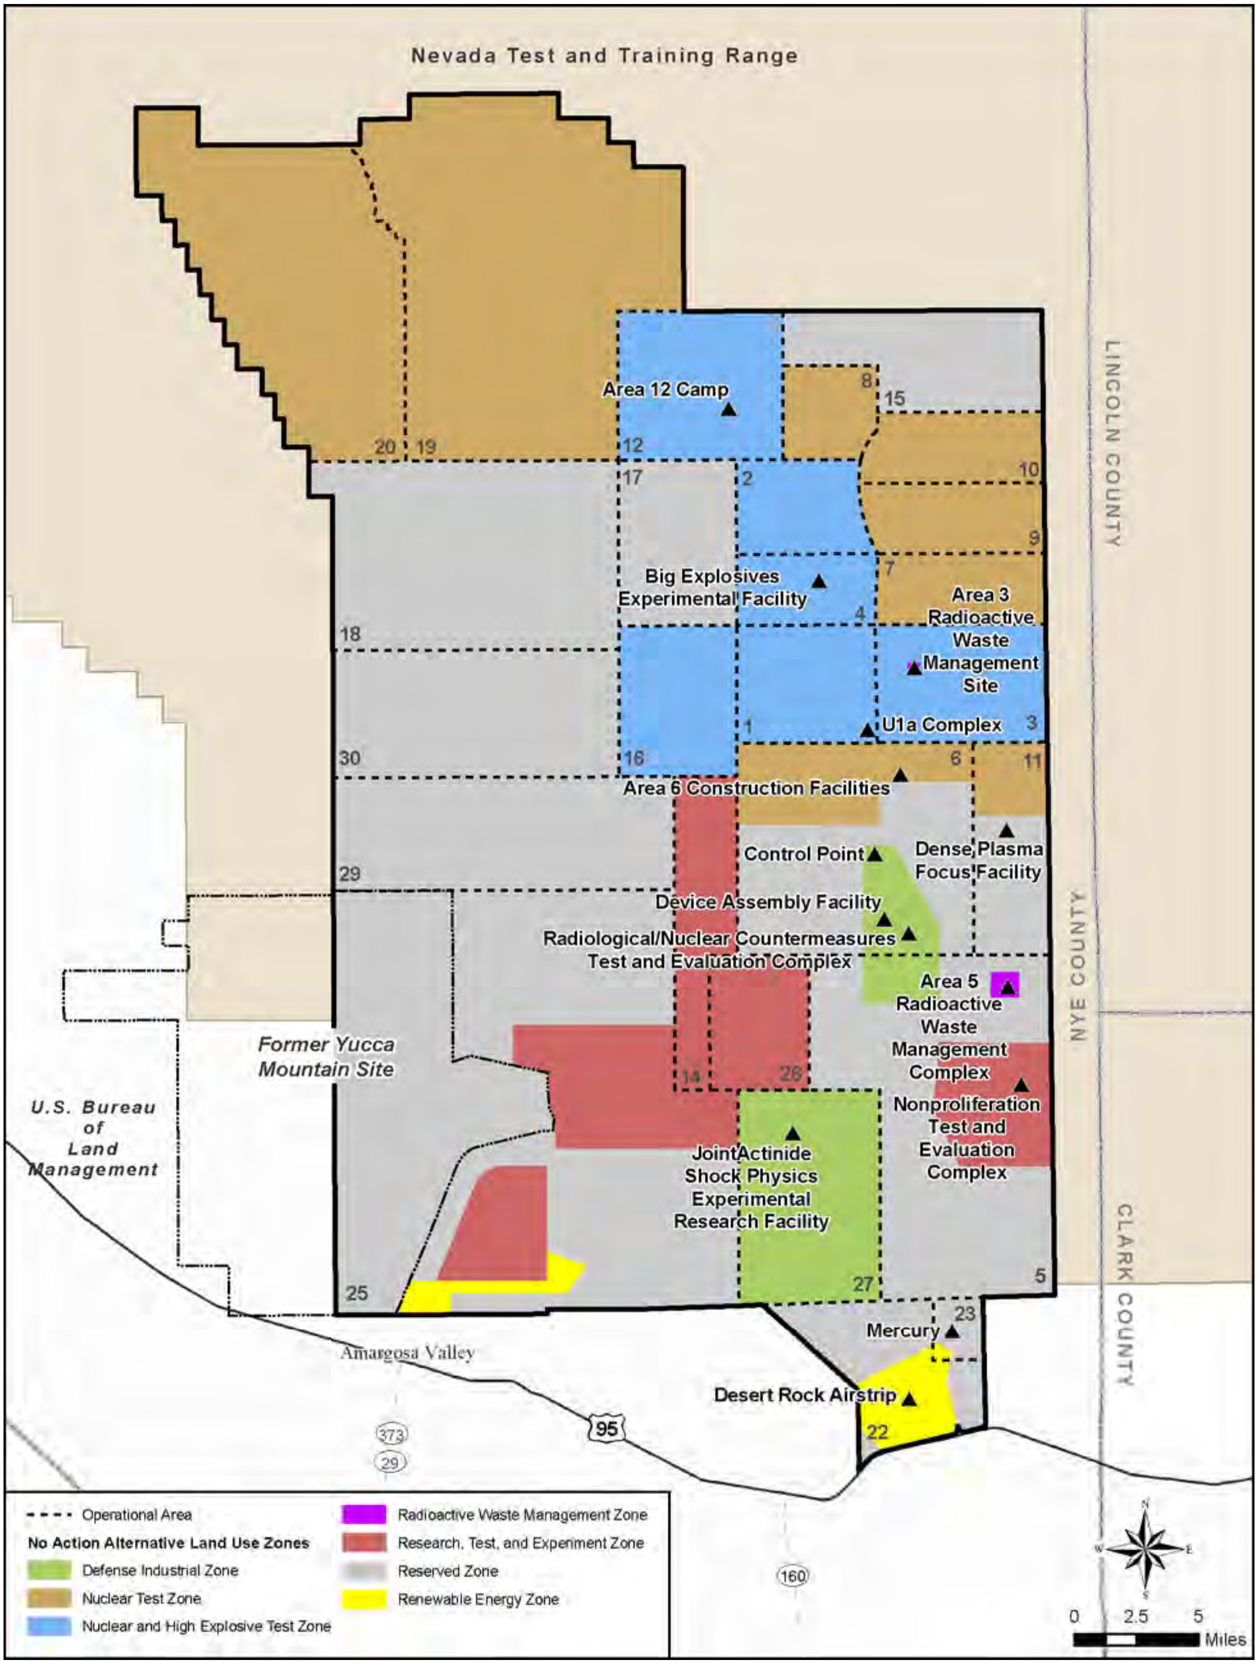

Figure 5–1 Land Use Zones on the Nevada National Security Site Under the No Action Alternative

5.1.1.1.2 Environmental Management Mission

There would be no land use impacts resulting from the continuation of Environmental Management Mission activities at the current levels of operations under the No Action Alternative because activities would not change. This section further discusses the potential impacts of the No Action Alternative on Environmental Management Mission activities.

Waste Management Program. Waste management activities would continue at all existing NNSS facilities in accordance with applicable regulatory requirements.

Environmental Restoration Program. Current Environmental Restoration Program activities would continue. These activities include the identification, characterization, and remediation of contaminated soils and facilities. Additional drilling of characterization and monitoring wells also is expected to continue under this program. Underground Test Area (UGTA) Project activities would occur on the NNSS, the Nevada Test and Training Range, BLM-managed lands, and privately owned land as necessary and as permission is obtained. These activities would not all occur in areas specifically zoned for this type of activity. There could be a temporary impact if restoration activities are carried out in areas that are not consistent with the designated land use identified for that land area; however, coordination with the Nevada Test and Training Range or BLM-managed lands and private landowners prior to the commencement of UGTA Project activities would reduce the impacts resulting from this activity.

5.1.1.1.3 Nondefense Mission

There would be no land use impacts resulting from the continuation of Nondefense Mission activities at the current levels of operations or foreseeable actions under the No Action Alternative because activities under this alternative would not change. This section further discusses the potential impacts of the No Action Alternative on Nondefense Mission activities.

General Site Support and Infrastructure Program. The substantial infrastructure of the NSSS provides all site support activities. This program includes those activities that are necessary to support mission-related programs, such as the construction and maintenance of facilities and warehousing. The infrastructure necessary to support the mission of the NNSS would continue to be maintained, repaired, and replaced as necessary. General Site Support and Infrastructure Program activities would not result in any changes to land use, so no land use impacts are expected.

Conservation and Renewable Energy Program. Under this program, DOE/NNSA would continue to ensure that new construction and renovation projects implement design, construction, maintenance, and operation practices that support high-performance building goals.

Land preparation activities associated with the development of a 240-megawatt commercial solar power generation facility and associated transmission lines within the Renewable Energy Zone in Area 25 would disturb an area of approximately 2,650 acres. Although a portion of Area 22 was identified in the *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada (1996 NTS EIS)* (DOE 1996c) for the Solar Enterprise Zone (now redesignated as the Renewable Energy Zone), with the currently available renewable energy technology, it is no longer considered a viable location to host a solar power generation facility because of the potential impacts that might result from groundwater withdrawal at Devils Hole, a sensitive environmental area that is downgradient from Area 22. Section 5.1.6.2 discusses impacts on groundwater under each alternative. No impacts on land use resulting from this foreseeable action are expected because a solar power generation facility would be located within a compatible land use zone.

Other Research and Development Programs. The NNSS supports scientific research projects conducted by academic entities and other parties under this program, which is currently inactive. Under the No Action Alternative, the NNSS would continue to support this program and, if activated in the future, these activities would occur in locations consistent with NNSS land use zone designations. Therefore, no impacts on land use are expected.

5.1.1.2 Expanded Operations Alternative

Under the Expanded Operations Alternative, the following two changes would occur in the NNSS land use zone designations:

- The designated use for Area 15 would be changed from "Reserved" to "Research, Test, and Experiment."
- Approximately 36,900 acres within Area 25 would be designated as a Renewable Energy Zone, a change that would increase the area available for development of a solar power generation facility by about 32,800 acres.

Figure 5–2 depicts land use zones and major facilities at the NNSS under the Expanded Operations Alternative. The proposed revisions to the total acreage of the land use zones under the Expanded Operations Alternative are shown in **Table 5–2**.

Table 5–2 Changes in Land Use Zones Under the Expanded Operations Alternative

Land Use Zone	*Current Acreage*	*Proposed Acreage*	*Percent Change in Acreage*
Reserved Zone	410,100	387,500	-5.5
Research, Test, and Experiment Zone	76,200	92,200	+21
Renewable Energy Zone [a]	11,900	44,700	+276

[a] The Solar Enterprise Zone was expanded and renamed the Renewable Energy Zone.

Although land use zones under the Expanded Operations Alternative would change, this change is not considered an adverse impact. The NNSS developed the land use zones for internal organizational and functional uses and to group similar uses and activities into specific areas based on the support needs of NNSS missions, as determined by previous and anticipated uses. The Renewable Energy Zone would reserve a larger land area under the Expanded Operations Alternative than under the No Action Alternative.

5.1.1.2.1 National Security/Defense Mission

There would be no land use impacts resulting from the increased National Security/Defense Mission activities under the Expanded Operations Alternative because the changes would be compatible with the land use zones. This section discusses the potential impacts of the Expanded Operations Alternative on National Security/Defense Mission programs and use of airspace.

Stockpile Stewardship and Management Program. This section highlights proposed projects for the Expanded Operations Alternative and provides an analysis of whether the projects are compatible with the land use designations.

As part of the Stockpile Stewardship and Management Program, DOE/NNSA would add additional equipment and ancillary features within the existing Big Explosives Experimental Facility (BEEF) to support activities occurring in the Nuclear and High Explosives Test Zone. Depleted uranium experiment sites would occupy 40 acres per experiment, with up to three experiments conducted during the period of analysis, while high-explosives experiments would occupy 5 acres per experiment, with up to 500 experiments conducted during the period of analysis. The areas for these experiments would be located in appropriately zoned operational areas on the NNSS; however, reserving these areas for the depleted uranium and high-explosives experiments would prevent other activities or uses from occurring within these reserved areas. Because this activity would occur in an already disturbed area at an active facility zoned for this type of activity, no additional impacts on land use are expected.

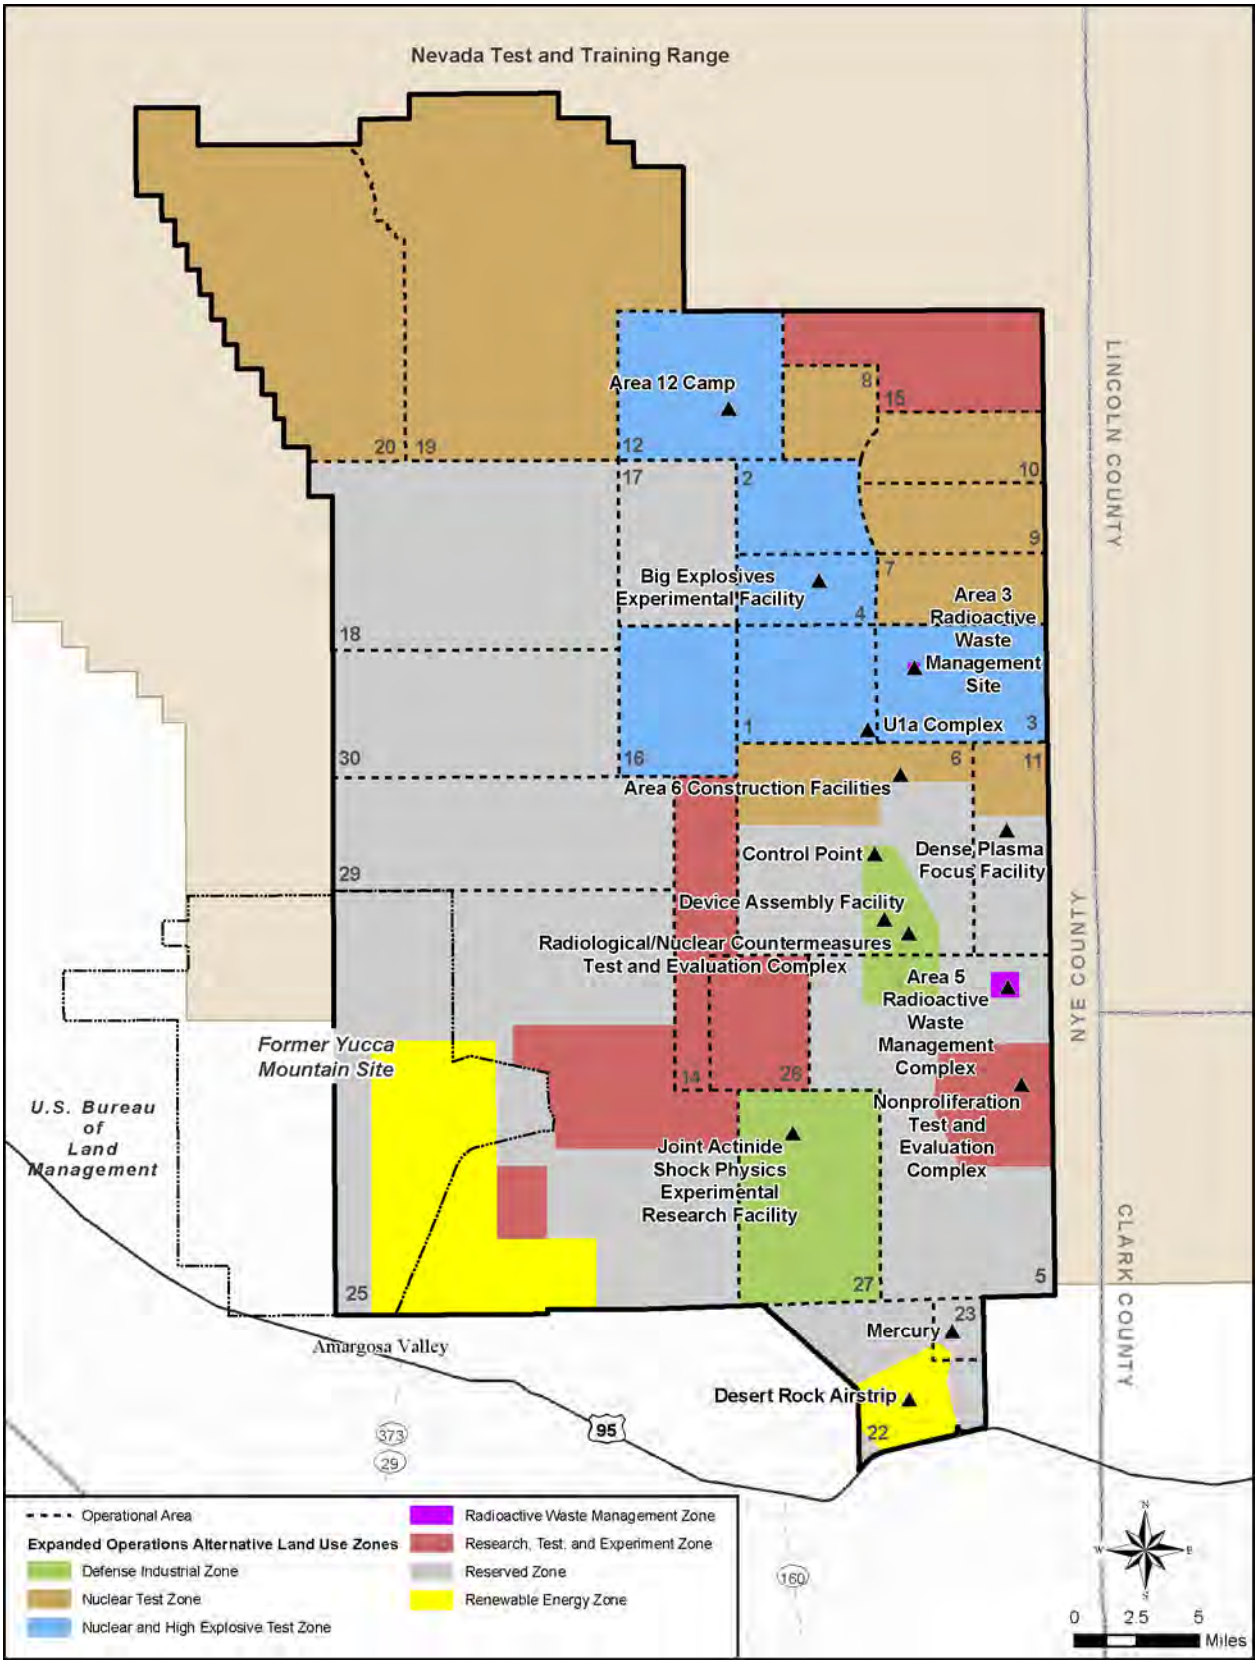

Figure 5–2 Expanded Operations Alternative and Major Facilities

Construction activities for new support facilities for the Office of Secure Transportation training would occur in Area 17. The training area would reserve about 10,000 acres of currently undisturbed land for use as an active training area with development of firing ranges and other training facilities and supporting infrastructure. Additionally, the Office of Secure Transportation would expand facilities in one of the following: Area 12 (12 Camp), Area 6 (Control Point Complex), or Area 23 (Mercury). Because these activities would be located in an area zoned for this type of activity, no land use impacts resulting from construction and utilization are expected.

Nuclear Emergency Response, Nonproliferation, and Counterterrorism Programs. This section highlights proposed projects for the Nuclear Emergency Response, Nonproliferation, and Counterterrorism Programs under the Expanded Operations Alternative and provides an analysis of whether the projects are compatible with the land use designations. The Disposition Forensics Evidence Analysis Team under the multi-agency Disposition and Disposition Forensics Programs would be deployed to the NNSS, as needed for training, exercises, or an actual event. Impacts on land use resulting from disposition activities are not expected because the NNSS already provides facilities for disposition of improvised nuclear devices. Facilities and activities associated with this program would be sited in compatible land use zone designations to minimize land use conflicts.

Additional arms control, nonproliferation, and counterterrorism facilities would be needed to undertake the anticipated enhanced activities. These facilities are still conceptual in nature and their locations are unknown; however, they would be constructed in operational areas within compatible land use zones, which would result in minimal impacts. The land acreage needed for these facilities, to the extent known, are listed below:

- Arms control – Facilities would be sited at various locations at the NNSS and would require approximately 100 acres of land. An additional building encompassing 10,000 square feet (0.2 acres) would be integrated with other buildings.
- Nonproliferation – A new Nonproliferation Test Bed would be developed.
- Counterterrorism – In addition to utilizing existing facilities, an Urban Warfare Complex would be constructed on approximately 100 acres in a remote area on the NNSS.

Work for Others Program. In general, land use impacts would be similar to those described under the No Action Alternative in Section 5.1.1.1.1. This section highlights additional Work for Others Program projects that could have impacts under the Expanded Operations Alternative.

Counterterrorism activities would require the development of new test bed facilities (roads, intersections, small towns, etc.). To support this need, the disturbance of approximately 75 acres of land is expected. Construction of these facilities would require new buildings with about 10,000 square feet (0.2 acres) of new floor space, resulting in approximately 25 acres of land disturbance. These facilities would be constructed in operational areas within compatible land use zones; thus, no land use impacts are expected.

DOE/NNSA would provide support for the National Aeronautics and Space Administration (NASA) deep space propulsion system development. This activity would use existing boreholes for testing nuclear rocket motors; however, it is not expected that testing would occur within the 10-year planning period evaluated in this SWEIS. These facilities would be constructed in operational areas within compatible land use zones; thus, no land use impacts are expected.

Anticipated land disturbance resulting from the construction of additional hangars, shops, and buildings would total approximately 200,000 square feet (4.6 acres) at Desert Rock Airport. A 20,000-square-foot (0.5-acre) hangar would be constructed at the Area 6 Operations Facility. Activities and facilities would be sited in appropriately zoned areas and no land use impacts are anticipated.

Because of the increased activities occurring at the Radiological/Nuclear Countermeasures Test and Evaluation Complex (RNCTEC) by the U.S. Department of Homeland Security (DHS) under this alternative, other Federal agencies performing activities involving active interrogation to detect nuclear

materials would require an additional facility, most likely located in Area 12 or 16. Construction of this new facility would disturb about 100 acres of previously undisturbed land. No impacts on land use are expected because this facility would be sited in a compatible land use zone.

Approximately 200 acres of land would be used to support additional test bed applications. New buildings would occupy approximately 50,000 square feet (1.1 acres). These facilities would be constructed in operational areas within compatible land use zones; thus, no land use impacts are expected.

Airspace. Under the Expanded Operations Alternative, usage of a variety of aerial platforms, such as airplanes and helicopters, would increase for research and development and training purposes. In addition, airspace use would increase, which could result in conflicts with use of airspace over the NNSS by Nellis Air Force Base. However, impacts resulting from the increased use of NNSS airspace would be minimized through scheduling and coordination with the Nellis Air Traffic Control Facility, which manages airspace activities occurring within Nevada Test and Training Range and NNSS airspace.

5.1.1.2.2 Environmental Management Mission

Overall impacts on Environmental Management Mission activities under the Expanded Operations Alternative would be minimal because such activities would occur in specified areas that are compatible with the land use designations and there is sufficient available land within the designated zones. Additionally, an activity could be collocated within a land use zone that is capable of adequately co-hosting the activity. This section further discusses the potential impacts of the Expanded Operations Alternative on Environmental Management Mission activities.

Waste Management Program. In general, potential land use impacts would be similar to those described under the No Action Alternative in Section 5.1.1.1.1. This section highlights additional projects anticipated for the Waste Management Program under the Expanded Operations Alternative that could have land use impacts.

Waste disposal activities would increase, including the storage (pending treatment or disposal) of mixed low-level radioactive waste (MLLW) received from authorized generators. New disposal units would be constructed, filled, and closed to accommodate the waste volumes and types. Because all existing waste management facilities on the NNSS are located within areas designated for their specific uses, there would be no impacts on land use from activities at existing facilities. Development of new sanitary landfills in Area 23 and Area 25 would convert a combined total of 35 acres of currently unused land into waste management facilities and preclude that land from other uses.

Environmental Restoration Program. Impacts would be similar to those described under the No Action Alternative in Section 5.1.1.1.2.

5.1.1.2.3 Nondefense Mission

No land use impacts were identified resulting from the increased Nondefense Mission activities under the Expanded Operations Alternative because the changes would be compatible with the land use zones. This section further discusses the potential impacts of the Expanded Operations Alternative on Nondefense Mission programs.

General Site Support and Infrastructure Program. In general, land use impacts would be similar to those described under the No Action Alternative in Section 5.1.1.1.3. This section highlights additional infrastructure projects anticipated under the Expanded Operations Alternative that were analyzed for land use impacts. Increasing capacities and capabilities or extending the ranges of facilities and/or services to accommodate new operational programs and projects would result in additional infrastructure enhancements under the Expanded Operations Alternative. The following infrastructure enhancements would likely be implemented:

- Rebuild 38.5 miles of the main 138-kilovolt transmission line between Mercury Switchyard in Area 23 and Valley Substation in Area 2.

- Construct an 85,000-square-foot (1.9-acre), two-story security building in Area 23 to consolidate and replace outdated security facilities built in the 1950s and 1960s. The building would include space for administrative offices, computer infrastructure, training, and emergency response to support NNSS operations.
- Expand the cellular telecommunication system through the addition of cell towers.
- Reconfigure Mercury to provide the necessary modern facilities and infrastructure.

These changes would be compatible with the land use zones.

Conservation and Renewable Energy Program. In general, land use impacts would be similar to those described under the No Action Alternative in Section 5.1.1.1.3. DOE/NNSA would pursue renewable energy projects and provide support for demonstration and/or commercial projects using geothermal and solar energy. Under the Expanded Operations Alternative, DOE/NNSA proposes to build a 5-megawatt photovoltaic solar power generation facility, which would require approximately 50 acres of land near the Area 6 Construction Facilities. This solar power generation facility would likely be located within the Nuclear Test Zone and would preclude DOE/NNSA from conducting weapons-related testing or other outdoor experiments in close proximity to this new facility. However, locating this facility within this area would not affect DOE/NNSA's ability to conduct an underground nuclear test or any other weapons-related tests or experiments in other parts of the Nuclear Test Zone or Nuclear and High Explosives Test Zone. Additionally, DOE/NNSA would allow development of one or more commercial solar power generation facilities to be located within the 39,600-acre Renewable Energy Zone, with a maximum combined generating capacity of 1,000 megawatts. These facilities would be constructed in operational areas within compatible land use zones.

A Geothermal Demonstration Project would be developed as a laboratory that would both supply power to the NNSS and conduct research to improve similar systems. The NNSS would evaluate potential locations based on NNSS land use zone compatibility and other factors, including environmental considerations. Approximately 30 to 50 acres of land would be disturbed for construction of the enhanced geothermal power system. No land use impacts are expected because the geothermal power system would be sited in an appropriate land use zone.

5.1.1.3 Reduced Operations Alternative

Under the Reduced Operations Alternative, the following changes to the NNSS land use zone designations would occur: the designated use for Areas 18, 19, 20, 29, and 30 would be changed from "Reserved" to "Limited Use" for military training and exercise use only.

The proposed revisions to the total acreage of the land use zones under the Reduced Operations Alternative are shown in **Table 5–3**. Although land use zones under the Reduced Operations Alternative would change, these changes are not considered adverse impacts. This is not an adverse impact on land use because the NNSS developed the land use zones for internal organizational and functional uses and to group similar uses and activities into specific areas based on the support needs of the NNSS mission, as determined by previous and anticipated uses.

Table 5–3 Changes in Land Use Zones Under the Reduced Operations Alternative

Land Use Zone	*Current Acreage*	*Proposed Acreage*	*Percent Change in Acreage*
Limited Use	0	289,800	Not applicable
Reserved Zone	410,100	120,200	-70.7

Figure 5–3 depicts the NNSS land use zones and major facilities under the Reduced Operations Alternative.

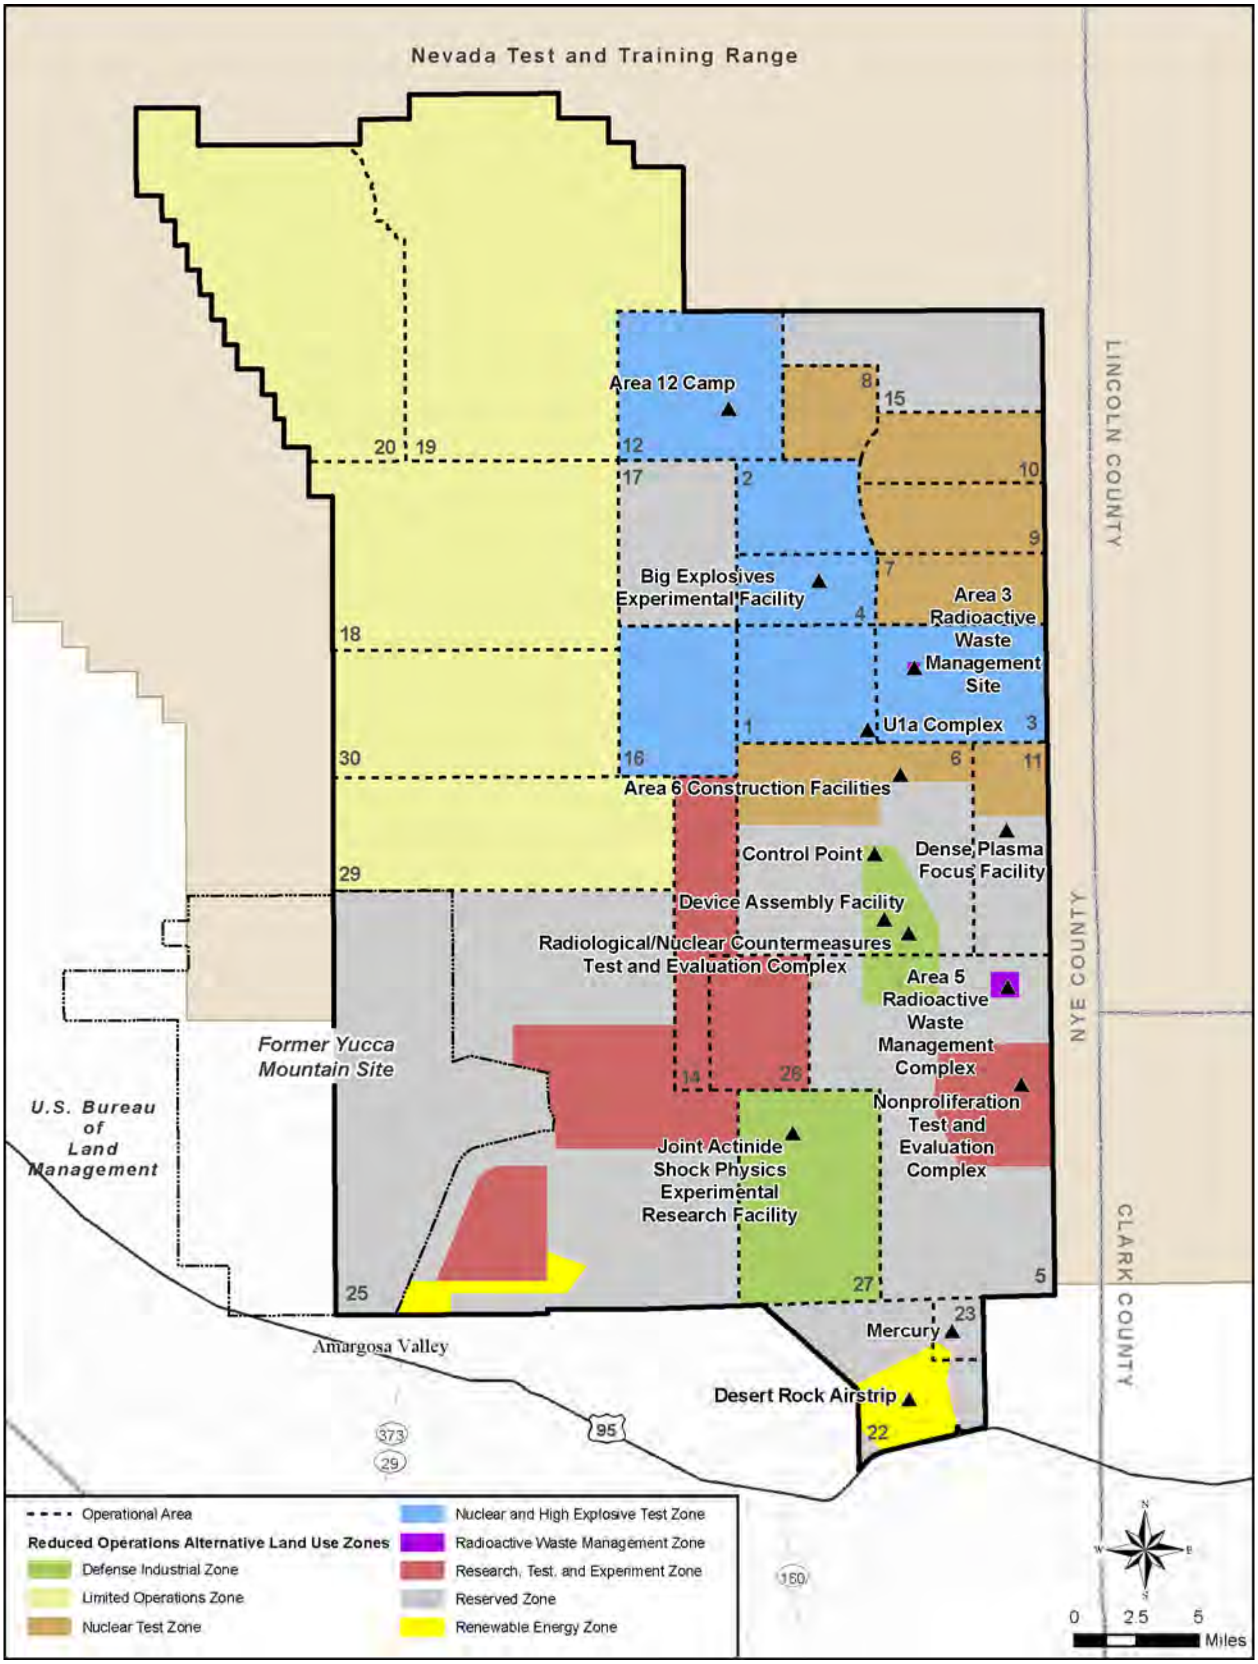

Figure 5–3 Reduced Operations Alternative and Major Facilities

5.1.1.3.1 National Security/Defense Mission

No land use impacts from National Security/Defense Mission activities under the Reduced Operations Alternative are expected because the activities would be compatible with the land use zones and there is sufficient available land within the designated zones. This section further discusses the potential impacts of the Reduced Operations Alternative on National Security/Defense Mission programs and use of airspace.

Stockpile Stewardship and Management Program. Stockpile stewardship and management activities would not be conducted in Areas 18, 19, 20, 29, and 30. There would be an approximately 10 percent decrease in activities relating to maintaining readiness to conduct underground nuclear tests and underground nuclear weapons experiments. Additionally, the Atlas Facility would be decommissioned and dispositioned. These changes would be compatible with the designated land use zones.

Nuclear Emergency Response, Nonproliferation, and Counterterrorism Programs. Land use impacts would be similar to those described under the No Action Alternative in Section 5.1.1.1.1; however, no impacts are expected because activities have been curtailed.

Work for Others Program. Land use impacts would be similar to those described under the No Action Alternative in Section 5.1.1.1.1; however, no impacts are expected because activities have been curtailed.

Airspace. Land use impacts would be similar to those described under the No Action Alternative in Section 5.1.1.1.1.

5.1.1.3.2 Environmental Management Mission

Land use impacts would be similar to those described under the No Action Alternative in Section 5.1.1.1.2 for both the Waste Management Program and the Environmental Restoration Program.

5.1.1.3.3 Nondefense Mission

In general, land use impacts resulting from decreased Nondefense Mission activities under the Reduced Operations Alternative are not expected because the changes would be compatible with the land use zones. This section further discusses the potential impacts of the Reduced Operations Alternative on Nondefense Mission programs.

General Site Support and Infrastructure Program. Land use impacts would be similar to those described under the No Action Alternative in Section 5.1.1.1.1 (i.e., there would be no impacts on land use under the Reduced Operations Alternative).

Conservation and Renewable Energy Program. In general, land use impacts would be similar to those described under the No Action Alternative in Section 5.1.1.1.1. DOE/NNSA would continue to support development of a commercial solar power generation facility in Area 25, which would be sited on 2,400 acres of land; however, the net generating capacity under the Reduced Operations Alternative would be 100 megawatts. No impacts on land use are expected because this facility would be sited within a compatible land use designation zone.

5.1.2 Infrastructure and Energy

5.1.2.1 Infrastructure

This subsection presents the proposed new or expanded facilities and infrastructure projects under each alternative and addresses the potential impacts on the NNSS resulting from increases in personnel, as well as facility and project utility needs. Potential impacts are evaluated for transportation systems infrastructure, water supply infrastructure, wastewater treatment systems, and communication systems. Energy-related impacts are discussed in Section 5.1.2.2. Activities under an alternative would have an adverse impact on infrastructure and utilities if their implementation would result in any of the following effects:

- Projected increases in onsite vehicular and truck traffic, aircraft use, and parking needs would exceed the design capacity of the roads, airports, and parking lots, requiring them to be substantially expanded and improved. (Impacts on transportation system infrastructure are briefly discussed in this subsection and are analyzed in detail in Section 5.1.3, including impacts resulting from increased traffic congestion and delays, road maintenance requirements, and road safety risks.)
- Projected increases in personnel and activities would create a potable water demand exceeding the design capacity of the NNSS water supply system infrastructure, which require substantial unplanned water supply infrastructure improvements. (Impacts on water supply infrastructure are briefly discussed in this subsection and are analyzed in detail in Section 5.1.6, including impacts on groundwater aquifers.)
- Projected personnel increases would generate wastewater amounts exceeding the capacity of existing (or proposed) NNSS wastewater treatment systems, which would require substantial unplanned upgrades of sewer mains, treatment lagoons, or septic tank and leach field systems. Potential impacts on wastewater treatment systems were assessed by comparing projections of wastewater generation under each alternative against onsite treatment capacities.
- Communications infrastructure and capabilities become insufficient to support mission needs and would require substantial unplanned upgrades to resume normal functions.

5.1.2.1.1 No Action Alternative

Potential infrastructure impacts from construction and operation under the No Action Alternative are discussed below in regard to facilities, transportation systems, water supply, wastewater treatment systems, and communication systems.

Facilities. Under the No Action Alternative, DOE/NNSA would continue to maintain, repair, and replace facilities and infrastructure, as needed and within funding limits, as well as conduct small projects to maintain the present capabilities of the DOE/NNSA Nevada Site Office (NSO) facilities. Existing buildings and other facilities would be used and modified as necessary to accommodate the ongoing activities. The only significant new facility considered would be construction and operation of a 240-megawatt solar power generation facility and associated transmission lines by an outside commercial entity. DOE/NNSA estimates this facility would utilize approximately 2,000 acres (disturbing approximately 2,650 acres), including the mirror fields.

The DOE/NNSA NSO is committed to providing a smaller, safer, more-secure, and less-expensive infrastructure that leverages the scientific and technical capabilities of the workforce and meets national security requirements. To this end, ongoing operations at the NNSS aim to eliminate facility redundancies and dramatically improve efficiencies. This is being accomplished by dispositioning excess buildings that are no longer needed to support DOE/NNSA's missions, programs, or support requirements and by consolidating personnel and programs into enduring buildings, thereby optimizing building use at the NNSS. The *Ten-Year Site Plan*, the *Space Management Plan* (NSTec 2009b), and other DOE/NNSA studies delineate recommendation for building disposition and program consolidation. Up to approximately 20 percent of the existing managed building square footage at the NNSS could be dispositioned under the No Action Alternative (NNSA/NSO 2010d).

New or future projects would be reviewed pursuant to requirements in DOE "National Environmental Policy Act Implementing Procedures" (10 CFR Part 1021) and Council on Environmental Quality NEPA regulations (40 CFR Parts 1500–1508).

Furthermore, DOE/NNSA would ensure that existing facilities, as well as all new construction and renovation projects, implement design, construction, maintenance, and operation practices in conformance with the high-performance building goals and statutory requirements of Executive Order 13423 (including those of Executive Order 13514, which expands on Executive Order 13423).

Executive Order 13514 includes a requirement for Federal agencies to prepare an annual Strategic Sustainability Performance Plan. DOE Order 436.1, *Departmental Sustainability*, establishes a requirement for each DOE site to prepare a Site Sustainability Plan. DOE/NNSA's Site Sustainability Plan for the NNSS, RSL, and NLVF includes projected performance (i.e., goals) and reports accomplishment in meeting *High Performance and Sustainable Building Guidance of the Interagency Sustainability Working Group* (ISWG 2008).

Transportation Systems. The transportation infrastructure at the NNSS would be maintained for mission-related uses. Under the No Action Alternative, there would be no changes to the transportation infrastructure; therefore, no infrastructure and energy impacts are expected. The existing transportation infrastructure was designed for a considerably larger workforce and truck traffic than are expected under the No Action Alternative; therefore, it is expected to be sufficient for both present and projected future needs (see Chapter 4, Section 4.1.3, Transportation and Traffic, for further discussion of transportation issues). Transportation infrastructure maintenance expectations under the No Action Alternative are summarized below:

- Roads – DOE/NNSA would continue to maintain mission-essential and other NNSS roadways as resources permit.
- Air facilities – DOE/NNSA would continue to maintain mission-essential NNSS air facilities as resources permit.
- Parking lots – The parking infrastructure at the NNSS would be maintained.

Water Supply Infrastructure. Potable water at the NNSS is supplied through groundwater wells and a network of distribution systems, as described in Chapter 4, Section 4.1.2.1.2, Utilities. Under the No Action Alternative, water system infrastructure may require major recapitalization to meet long-term deterioration issues. Future system upgrades would be undertaken as needed, in accordance with physical infrastructure project needs; these upgrades would be conducted after appropriate NEPA review. (See Section 5.1.6 for a discussion of water supply capacity under the No Action Alternative.)

The impact of the No Action Alternative on water supply resources would be further reduced due to a concerted water conservation effort (see the discussion on water conservation in Chapter 4, Section 4.1.2), in compliance with Executive Order 13423, *Strengthening Federal Environmental, Energy, and Transportation Management*, and DOE Order 436.1, *Departmental Sustainability*. The NNSS expects to reduce water consumption by 16 percent from 2007 levels by 2015, an average reduction in water consumption of approximately 2 percent per year.

Under the No Action Alternative, the NNSS would continue installing water-conserving products (toilets, urinals, faucets, showerheads, boiler systems, and other water-using appliances and fixtures) when existing units require replacement. The NNSS also would continue implementing water conservation practices, including xeric landscaping, water-efficient irrigation, system audits, leak repairs, use of nonpotable water for dust suppression when possible, and the institution of 4-day workweeks (NSTec 2011c).

Wastewater Treatment Systems. Under the No Action Alternative, wastewater treatment needs would typically be maintained at current levels, except for the possible construction and operation of the solar power generation facility. The number of construction workers required for the No Action Alternative, predominantly for construction of the solar power generation facility, would average 500 workers over 35 months, with a peak of 1,000 workers. The sanitary needs of construction workers would be addressed through portable toilets and hand-washing stations, from which the sanitary waste would be transported off site by contracted septic haulers to a permitted sewage treatment facility. The sanitary needs of construction workers for this solar power generation facility would be managed by the commercial entity responsible for the project; the sanitary waste would be transported and disposed off site in accordance with all applicable regulations.

As discussed in Chapter 4, Section 4.1.2, the wastewater treatment systems at the NNSS (which include 2 wastewater treatment lagoons and 23 septic systems) are currently utilized collectively at 17 percent capacity. The existing systems have adequate capacity to handle the workers' wastewater treatment needs. Maintenance of the NNSS sanitary system's lagoons and septic systems would continue to ensure effective operation. Future system upgrades would be undertaken as needed, in accordance with physical infrastructure projects conducted after appropriate NEPA review.

The commercial solar power generation facility would include its own wastewater treatment system, for which the design and potential impacts would be defined in a subsequent NEPA review, should a project proponent come forward.

Communication Systems. The telecommunications information infrastructure is technologically dated and has been degraded in many locations (DOE 2008f). Under the No Action Alternative, the communications systems at the NNSS would be upgraded within existing utility corridors and facilities (i.e., there would be no new land disturbances) to improve the communications network in order to meet ongoing mission requirements.

5.1.2.1.2 Expanded Operations Alternative

The Expanded Operations Alternative includes the proposed new or expanded infrastructure for program support presented in **Table 5–4**. The modifications and improvements proposed to the existing infrastructure under the Expanded Operations Alternative would be adequate to accommodate the increased demand. Additional information on infrastructure demand and impacts during normal operations for the Expanded Operations Alternative is provided below. Please also see Chapter 3, "Description of Alternatives," and Appendix A, "Detailed Description of Alternatives," for further information on the Expanded Operations Alternative, as well as Section 5.1.2.2 for further discussion of energy-related infrastructure improvements. Potential infrastructure and energy impacts from construction and operation under the Expanded Operations Alternative are discussed below in regard to facilities, transportation systems infrastructure, water supply infrastructure, wastewater treatment systems, and communication systems.

In addition to impacts from DOE/NNSA activities under the Expanded Operations Alternative, Section 5.1.2.2 discusses how development of one or more commercial solar power generation facilities within the Fortymile Canyon–Jackass Flats Hydrographic Basin, as well as a Geothermal Demonstration Project that would be sited at a location to be determined, would impact the infrastructure at the NNSS. There is no specific schedule for constructing commercial-scale solar power generation facilities or a Geothermal Demonstration Project at the NNSS. The potential impacts of these projects are addressed in this *NNSS SWEIS* to enable DOE/NNSA to make a decision about whether to make land and infrastructure that is now under DOE/NNSA control available for another use by a commercial entity.

Facilities. Under the Expanded Operations Alternative, infrastructure-related activities would include increasing the capacities and capabilities or extending the ranges of facilities and/or services to accommodate new operational programs, projects, and activities, as well as repairs, replacements, and small projects required to maintain the present capabilities of the NNSS (discussed under the No Action Alternative). DOE/NNSA would also continue its commitment to eliminating facility redundancies and improving operating efficiencies by dispositioning excess buildings and consolidating personnel and programs into enduring buildings, thereby optimizing building use at the NNSS (NSTec 2009b). Up to approximately 28 percent of the existing managed building square footage at the NNSS could be dispositioned under the Expanded Operations Alternative (NNSA/NSO 2010d, 2010e).

Table 5–4 Proposed New Infrastructure for Program Support Under the Expanded Operations Alternative

Stockpile Stewardship and Management Program	
Office of Secure Transportation Complex	
Area 17	
Administrative Offices	5,000 square feet
Mock Town	870,000 square feet
Shooting House	8,000–20,000 square feet
Two Modular Training Facilities with Restrooms	4,000 square feet (2,000 square feet each)
Two Butler Buildings	10,000 square feet (5,000 square feet each)
Electrical Substation	100 square feet
Communications Trailer	300 square feet
Potable Water Tank	10,000–20,000 gallons
Septic System with Leach Field	Size not yet determined – additional NEPA review would be required
Roads (single-lane dirt roads with shoulders, including up to 4 miles of paved asphalt double-lane roads with shoulders) and Firebreaks	25 miles
Electrical Power Line	4.5 miles (approximate)
Potable Water Pipeline	4.5 miles (approximate) from existing well
Area 6, 12, or 23 (Mercury)	
Maintenance Buildings	20,000 square feet
Administrative Buildings	10,000 square feet
Dormitory	20,000 square feet
Nuclear Emergency Response, Nonproliferation, and Counterterrorism Programs	
Arms Control Mission	
Indoor and Outdoor Laboratory Space and Test Ranges	100 acres
New Facility for Data Fusion, Analysis, and Visualization	10,000 square feet
Nonproliferation Mission	
New Facility	Size not yet determined – additional NEPA review would be required
Counterterrorism Mission	
Urban Warfare Complex (located in remote location on the NNSS)	100 acres (approximate)
Work for Others Program	
Counterterrorism	
Test Ranges to Include Roads, Intersections, Small Towns	75 acres
Buildings	10,000 square feet
Future Training Facilities to support U.S. Department of Homeland Security Counterterrorism Operations Support	125 acres
Buildings	10,000 square feet
Miscellaneous Work for Others	
Additional Facilities at Desert Rock Airport: Hangars, Shops, Other Buildings	200,000 square feet
Area 6 Aerial Operations Facility: Hangar	20,000 square feet
Pahute Mesa Airstrip Operations Support Building	Size not yet determined – additional NEPA review would be required
Other Locations to Support Air Operations	5,000 square feet
Active Interrogation to Detect Nuclear Material: Support Facilities in Area 12 or 16	125 acres
Test Bed Applications	200 acres
New Facilities	50,000 square feet

Stockpile Stewardship and Management Program	
Waste Management Program [a]	
Radioactive Waste Management Complex in Area 5	600 acres
Sanitary Landfill in Area 23	15 acres
Construction and Demolition Waste Landfill in Area 25	20 acres
Nondefense Mission	
New Security Building in Area 23	85,000 square feet
Photovoltaic Solar Power Generation Facility (5 megawatts) in Area 6	50 acres
Possible Commercial Energy Projects	
Commercial Solar Power Generation Facilities (1,000 megawatts) in Area 25, [b] including associated on- and offsite transmission lines	10,300 acres
Geothermal Demonstration Project	50 acres

NEPA = National Environmental Policy Act; NNSS = Nevada National Security Site.
[a] See Section 5.1.11 for discussion of waste management impacts.
[b] The commercial solar power generation facilities and Geothermal Demonstration Project would be developed, if at all, by others. Acreages for energy projects are given for land area potentially disturbed. Actual footprints may be up to 15 percent lower.

Additional programs, projects, and activities considered under the Expanded Operations Alternative may require modification and/or expansion of existing facilities and construction of new facilities. As discussed in Chapter 3, "Description of Alternatives," and Appendix A, "Detailed Description of Alternatives," the Expanded Operations Alternative would require implementation of the following facility enhancements:

- **Security building construction** – A new security building in Area 23 would be constructed adjacent to existing security facilities. This project would consolidate security facilities (Buildings 1000, 1001, 1002, 114, 701, 1103, 1106, 1107, and 1108 and portions of Control Points 41, 111, and 525) and their functions into a new, approximately 85,000-square-foot, two-story facility. The facility would include space for administrative offices, computer servers for systems supporting NNSS operations, training, emergency response, locker rooms, restrooms, storage, an armory, technology development, electronic security system engineering and maintenance, and classified work areas. The new building would replace outdated facilities, most of which were built in the 1950s and 1960s, and decrease external exposure to critical security facilities. Buildings that are replaced would be evaluated and either demolished or used for another purpose.
- **Mercury reconfiguration** – Mercury would be reconfigured to provide the modern facilities and infrastructure needed to support advanced experimentation and production at the NNSS. Although undefined at this time, this proposed project would (1) demolish facilities that are no longer needed or are not economically salvageable; (2) identify functional zones to facilitate groupings of similar activities; (3) replace obsolete buildings that are needed to support NNSS activities; and (4) improve selected facilities and infrastructure to extend useful life to accommodate existing and future support requirements. Because the reconfiguration of Mercury is conceptual in nature, an appropriate level of NEPA review and documentation would be required before it may be implemented.

Transportation Systems. Under the Expanded Operations Alternative, the current transportation infrastructure at the NNSS would be maintained for mission-related uses, and new roads and air facilities would be constructed, expanded, or improved, as discussed below. Higher numbers of personnel and activities at the NNSS would generate increased regional traffic from privately owned vehicles and trucks transporting materials and waste (see Section 5.1.3 for a discussion of traffic issues under the Expanded Operations Alternative). Transportation infrastructure maintenance expectations under the Expanded Operations Alternative are summarized below:

- **Roads –** Under the Expanded Operations Alternative, new roadways would be constructed on the NNSS, when necessary, to access newly constructed facilities and accommodate the increased traffic on the roads.

  The proposed training complex for the Office of Secure Transportation would include 25 miles of new road and firebreak construction (as shown in Table 5–4). Most of these roads and firebreaks would be scraped-dirt, single-lane roads with shoulders, with eventually up to 4 miles of paved-asphalt, double-lane roads with shoulders. The main access to the complex would be from Tippipah Highway.

  Overall, the increased traffic at the NNSS under the Expanded Operations Alternative would be acceptably handled within the design capacity of the roadway infrastructure. The existing infrastructure was designed for a much larger workforce and increased program activities. Roads that are currently classified as substandard (DOE 2008f) would require improvements. However, traffic impacts would be mitigated by construction of new roads to the new facilities, as well as maintenance and improvements to the existing roads used most frequently for mission-related purposes. Because the incremental increase in onsite traffic volumes would be moderately high (see Section 5.1.3), the number of repairs and required maintenance on NNSS roadways would increase at a higher rate than currently experienced.

- **Air facilities –** Under the Expanded Operations Alternative, various aircraft facilities potentially would be used, expanded, or improved. The following infrastructure projects associated with these aircraft facilities were described previously under "Facilities" and are shown in Table 5–4:

  - Desert Rock Airport expansion
  - Aerial Operations Facility expansion
  - Pahute Mesa Airstrip improvements
  - New Air Operations Facility construction

  These planned expansions and improvements to the air facilities under the Expanded Operations Alternative would improve aviation operations at the NNSS. These actions would be undertaken after appropriate NEPA review.

- **Parking lots –** Additional parking areas would be provided to accommodate anticipated needs at new facilities or new uses of existing facilities.

Water Supply. Under the Expanded Operations Alternative, the NNSS water supply system would be expanded as necessary to connect to new facilities. Increased potable water demand due to a 25 percent increase in workforce over current levels would affect the existing water supply infrastructure, which is currently in need of repair and upgrade. However, future system upgrades would be undertaken as needed in accordance with physical infrastructure projects conducted after appropriate NEPA review (see Section 5.1.6 for a discussion of water supply capacity under the Expanded Operations Alternative). DOE/NNSA would also continue to implement water conservation efforts under the Expanded Operations Alternative (see the discussion of water conservation in Chapter 4, Section 4.1.2).

Wastewater Treatment Systems. Under the Expanded Operations Alternative, new facilities would be connected to existing permitted wastewater treatment systems when possible, or appropriately sized and permitted wastewater treatment systems would be constructed for the new facilities. The construction phase of the Expanded Operations Alternative would require an average of 750 workers over 42 months, with a peak of 1,500 workers. The sanitary needs of the construction workers would be addressed through portable toilets and hand-washing stations, from which the sanitary waste would be transported off site by contracted septic haulers to a permitted sewage treatment facility. Sanitary waste management required for the construction of one or more commercial solar power generation facilities would be

managed by the commercial entities responsible for the projects, and the sanitary waste would likely be transported and disposed off site in accordance with all applicable regulations.

During operations under the Expanded Operations Alternative, the workforce at the NNSS would increase by approximately 25 percent to about 2,575 persons, including permanent NNSS personnel, employees for solar power generation facilities, and an additional estimated 250 construction workers to implement the various construction projects proposed under the Expanded Operations Alternative.

As discussed in Chapter 4, Section 4.1.2.1, the wastewater treatment systems at the NNSS include two active sewage lagoon systems (the Mercury lagoon in Area 23 and the Yucca Lake lagoon in Area 6) and 23 currently permitted septic tank systems. These lagoons and septic tank systems have an estimated collective capacity of 199,260 gallons per day. To quantify the impact of the Expanded Operations Alternative, the capacity of each of the two lagoon systems was quantified with a projected 25 percent increase in wastewater inflow. As shown in **Table 5–5**, both sewage lagoon systems have adequate capacity to handle the estimated increase, as the Mercury lagoon would be operating at 45 percent of its capacity and the Yucca Lake lagoon at 12 percent of its capacity. New facilities proposed under this alternative are located in areas that currently use septic tank systems and would be either served by their own new septic tanks and leach fields or connected to existing septic tank systems with sufficient capacity if they are located in the vicinity.

The commercial solar power generation facilities would include their own wastewater treatment system, for which the design and potential impacts would be defined in a subsequent NEPA review, should a project proponent come forward.

Table 5–5 also shows the estimated capacity of the collective site-wide NNSS wastewater treatment systems, based on the projected new workforce population under the Expanded Operations Alternative. Given this site-wide scenario, an employee population of 2,575 workers would result in total wastewater generation of approximately 51,500 gallons per day, which amounts to 26 percent of the capacity of the collective existing wastewater treatment systems at the NNSS. Future system upgrades or installation of additional treatment systems would be undertaken as needed, in accordance with physical infrastructure projects conducted after appropriate NEPA review.

Table 5–5 Wastewater Treatment Capacity at the Nevada National Security Site Under the Expanded Operations Alternative

Sewage Lagoon	*Permit Capacity*	*Current Volume Treated (2009) (gallons per day)*	*Projected Volume Treated (25 percent increase) (gallons per day)*	*Percentage of Capacity Used*
Mercury	73,407	26,550	33,188	45
Yucca Lake	10,850	1,049	1,311	12
Workers	***Wastewater Generation (gallons per day)*** [a]	***Capacity of NNSS Wastewater Treatment System (gallons per day)***	***Percentage of Capacity Used***	
2,575	51,500	199,260	26	

NNSS = Nevada National Security Site.

[a] Based on 20 gallons per day per person (see discussion in Chapter 4, Section 4.1.2.1) (CMU 2004, Table 9, p. 58; Lui and Liptak 1997, Tables 7.1.3 and 7.1.4, p. 518).

Communication Systems. Under the Expanded Operations Alternative, the NNSS telecommunication system would be upgraded to replace the existing wired telephone switch with a new one that would seamlessly transition between the older and newer technologies. The wireless elements of the trunked radio infrastructure also would be upgraded to interface with the packet-switched technology. This project would transition the subscriber units (telephones, radios, and cell phones) in a time-phased replacement program to blend all elements of the wired and wireless systems into an integrated telecommunications hierarchy (NNSA/NSO 2010c). These improvements would benefit the

communications network at the NNSS and would have no adverse impact on offsite resources. DOE/NNSA would continue to participate with local governments to ensure that reliable communications interconnectivity and interoperability are achieved in accordance with the National Incident Management System.

5.1.2.1.3 Reduced Operations Alternative

For construction associated with the Reduced Operations Alternative, the facilities, transportation systems infrastructure, water supply infrastructure, wastewater treatment systems, and communication systems are adequate to handle the temporary increased demands. Under the Reduced Operations Alternative, the DOE/NNSA NSO workforce would decline, thereby reducing use of infrastructure compared to the No Action Alternative, as discussed below.

Facilities. Under the Reduced Operations Alternative, DOE/NNSA would continue to maintain, repair, and modify operating facilities and infrastructure, as needed and within funding limits, and conduct small projects to maintain the present capabilities of DOE/NNSA NSO facilities (described under the No Action Alternative). In addition, under the Reduced Operations Alternative, most activities would cease in the northwestern portion of the NNSS within Areas 18, 19, 20, 29, and 30, with the exception of maintenance and operation of the Echo Peak, Motorola, and Shoshone communications facilities; the Echo Peak, Castle Rock, and Stockade Wash Substations, including electrical transmission lines interconnecting these substations; and Well 8. DOE/NNSA would continue environmental restoration, environmental monitoring, site security operations, and military training and exercises within these areas. No infrastructure projects would be conducted in these northwestern areas beyond maintaining the noted mission-essential facilities and critical electrical and communications systems. The only significant new facility considered under the Reduced Operations Alternative would be construction and operation of a 100-megawatt solar power generation facility by an outside commercial entity in Area 25. DOE/NNSA estimates this facility would utilize approximately 1,020 acres (disturbing approximately 1,200 acres), including the mirror fields.

Transportation Systems. Under the Reduced Operations Alternative, transportation-related infrastructure at the NNSS would be maintained only for mission-related uses. Only mission-essential roadways would be maintained, and all other roadways on the NNSS would be allowed to deteriorate. This would have a minor adverse impact on the regional transportation infrastructure; however, under this alternative, the roadways would rarely be used (see Section 5.1.3 for a discussion of traffic issues under the Reduced Operations Alternative). In addition, under the Reduced Operations Alternative, there would be no change compared with the No Action Alternative regarding use of air facilities and parking lots.

Water Supply. Under the Reduced Operations Alternative, the workforce would decrease by approximately 10 percent from current levels. This smaller workforce would reduce the requirement for potable water at the NNSS, which would beneficially impact groundwater resources. The reduced workforce would decrease the requirement for potable water at the NNSS, thus creating an approximate 10 percent reduction in groundwater usage (see Section 5.1.6 for a discussion of water supply capacity under the Reduced Operations Alternative). There would be no change compared with the No Action Alternative regarding water conservation practices.

Wastewater Treatment Systems. The construction phase of the Reduced Operations Alternative would require an average of 400 workers over 32 months, with a peak of 800 workers. The sanitary needs of construction workers would be addressed through portable toilets and hand-washing stations, from which the sanitary waste would be transported off site by contracted septic haulers to a permitted sewage treatment facility. The sanitary needs of construction workers for the solar power generation facility would be managed by the commercial entity responsible for the project, and the sanitary waste would be transported and disposed off site in accordance with all applicable regulations.

During operations under the Reduced Operations Alternative, the workforce would decrease by approximately 10 percent from current levels. This smaller workforce would require less wastewater

treatment at the NNSS than current levels, so there would be more than adequate capacity. As the workforce is reduced and activities and facility use are curtailed, wastewater treatment systems would be deactivated as demand decreases.

The commercial solar power generation facility would include its own wastewater treatment system, for which the design and potential impacts would be defined in a subsequent NEPA review should a project proponent come forward.

Communication Systems. There would be no change in communication systems compared with the No Action Alternative within those areas that continue to operate under the Reduced Operations Alternative. All communication operations would cease in the northwestern portion of the NNSS within Areas 18, 19, 20, 29, and 30, including the Echo Peak, Motorola, and Shoshone communications facilities. DOE/NNSA would maintain only the critical infrastructure for these facilities.

5.1.2.2 Energy

This subsection addresses potential impacts on the energy resources and distribution systems that serve the NNSS. Activities under an alternative would have an adverse impact on energy resources if their implementation would result in any of the following effects:

- Peak electrical power demands would exceed the supply capacity of local or regional distribution systems, resulting in damage to system components, voltage fluctuations, and/or temporary loss of service at frequencies beyond historical averages.
- Growth in average electrical demand would strain the supply capacity of local or regional distribution systems, resulting in the need for unplanned upgrades or diversion of supply from other planned uses.
- Peak demand for liquid fuels would exceed the capacity of onsite fuel storage systems or planned resupply schedules.
- Long-term demand for liquid fuels would strain the capacity of regional or national supply systems.

Potential impacts on energy resources were assessed by comparing projections of utility resource requirements under each alternative against utility system capacities. While some NNSS facilities do not meter utility use, annual site-wide demands are known and were used to make projections for each of the alternatives considered in this SWEIS. Additional information on policies and programs that would beneficially modify energy use patterns (conservation, energy efficiency, renewable energy development, transportation/fleet management, and high-performance, sustainable buildings) are also provided in this subsection. Unless noted otherwise, these impact criteria and methods of analysis apply to all geographic locations and action alternatives within this SWEIS.

5.1.2.2.1 No Action Alternative

Under the No Action Alternative, activities at the NNSS would primarily continue at frequencies and levels consistent with those experienced since 1996. DOE/NNSA would continue to maintain and repair facilities and associated infrastructure as needed to maintain the present capabilities of DOE/NNSA facilities. The only significant new facility considered would be construction of a large solar power generation facility by an outside commercial entity. Specific activities and their potential effects are discussed in the following subsections.

Electrical Energy. Electrical service at the NNSS is supplied by two commercial power sources: NV Energy and the Valley Electric Association (DOE 2008f). Previous studies have suggested that the onsite distribution system can support a theoretical load of approximately 72 megawatts based on the thermal limits of the smallest conductor, but outside utilities could only furnish approximately 36 megawatts because of the NNSS system's voltage constraints (DOE 2007c).

While recent estimates suggest that the maximum operating capacity is closer to 40 megawatts (NNSA/NSO 2010a), capacity at the NNSS is also limited by load demands on commercial power suppliers from other users outside the NNSS, not simply the condition of the NNSS system. Valley Electric Association's line serves additional loads including Pahrump, Lathrop Wells, and Beatty. These outside utility loads have increased at a high rate over the past decade, and the spare capacity of the 138-kilovolt transmission system available for NNSS loads has remained static or effectively decreased, despite reductions in NNSS demand.

From 2003 through 2006, annual electrical energy usage at the NNSS ranged from 57,000 to 95,000 megawatt-hours, averaging 81,000 megawatt-hours (DOE 2008f), while the total electrical usage during fiscal year (FY) 2009 was approximately 84,600 megawatt-hours. Although peak power demand at the NNSS has reached as high as 42 megawatts while nuclear testing programs were active, recent power demand typically averages 20 megawatts, with a peak demand of 27 megawatts (NNSA/NSO 2010a).

Excluding construction and operation of a commercial solar power generation facility (described in subsequent paragraphs), average power demand would likely remain near 20 megawatts, with peak demand of 27 megawatts. However, power demands in any particular year can be affected by unplanned factors, including summer temperatures that would increase power needed for facility air conditioning.

For purposes of analysis, DOE/NNSA estimated that not more than a 10 percent increase in average and peak demand would occur under the No Action Alternative, resulting in average and peak power demands of 22 and 30 megawatts, respectively. Furthermore, a 10 percent increase over DOE/NNSA's 2009 average electrical demand of 84,600 megawatt-hours would amount to approximately 93,000 megawatt-hours. During 2009, NV Energy and Valley Electric Association provided about 21,675,000 megawatt-hours, collectively. Under the No Action Alternative, DOE/NNSA's use of electricity would represent approximately 0.43 percent of the regional electrical demand (NSOE 2010).

Considering the average and peak power demands (22 and 30 megawatts, respectively) and a total NNSS system capacity of 36 megawatts, the NNSS distribution system would be adequate (with 55 to 75 percent of capacity consumed) to support power needs under the No Action Alternative. However, if future demand from offsite users on the commercial power suppliers were to increase rapidly, then the spare capacity of the NNSS distribution could potentially be reduced, resulting in adverse impacts, including voltage fluctuations and blackouts. Such impacts would limit the NNSS's ability to conduct mission-essential experiments while operating support facilities. This impact could be reduced or avoided by negotiating additional power purchases from commercial suppliers. In addition, the physical condition and reliability of the NNSS distribution system would deteriorate over time, although basic maintenance would continue under this alternative. If basic maintenance activities were insufficient to maintain system reliability, DOE/NNSA would pursue more-significant system upgrades (including replacement of some line sections, as described under the Expanded Operations Alternative) based on appropriate NEPA review and decisions.

DOE/NNSA may enter into an agreement with a commercial entity to construct a solar power generation facility within Area 25. Currently, there are no specific proposals from private applicants for construction of a commercial-scale solar power generation facility at the NNSS. To support an NNSS decision allowing commercial-level power production as a land use, DOE/NNSA has analyzed a notional design based on other proposed facilities in southern Nevada. Were a specific design to be proposed by a private applicant, additional project-level NEPA review would be required. Under the No Action Alternative, a proponent would construct a commercial solar power generation facility with a net generating capacity of 240 megawatts and would utilize a "dry" parabolic mirror technology.

This solar power generation facility would result in an additional power demand during the construction phase (estimated to last 35 months); some of this power demand would be met by using portable diesel-fuel-fired generators. This temporary power demand would likely be covered within the estimated

10 percent increase over existing levels assumed for this alternative. When this solar power generation facility is brought on line, it was assumed that it would supply a portion of its generating capacity to support NNSS needs, with the balance supplied to the outside commercial power grid.

The details of any power-sharing arrangements and the need for additional transmission lines to supply the commercial grid are not known at this time, but would be addressed in a project-specific NEPA review. The age and condition of the NNSS power system and the resulting voltage limitations would likely prevent expansion of the NNSS system's power capacity much beyond 40 megawatts, unless significant upgrades were made to the system that are not proposed within this alternative. However, any power supplied to the NNSS from this solar power generation facility would likely offset the potential losses from other commercial providers noted above and avoid adverse impacts on the NNSS distribution system. In addition, use of power from a solar power generation facility would reduce the NNSS's reliance on fossil-fuel-generated power, resulting in an indirect beneficial impact on air quality.

The existing regional electrical transmission system does not have sufficient capacity to accommodate an additional 1,000 megawatts of power. Development of the solar power generation facilities in Area 25 would require construction of additional transmission infrastructure in the region. Independent of and unrelated to the commercial solar power generation facilities considered in this *NNSS SWEIS*, NV Energy, a commercial electrical energy company, and Renewable Energy Transmission Company are planning separate, new large-capacity transmission line projects that would accommodate the additional electrical generation (see Chapter 6, Section 6.2.4.4, for additional information).

Liquid Fuels. **Table 5–6** illustrates liquid fuel consumption at the NNSS for FY 2009, which DOE/NNSA estimates as representative of annual consumption rates under the No Action Alternative. The trend over the last several years has been a decline in petroleum-based fuel usage. The majority of the NNSS fleet currently operates on alternative fuels; E85 fuel is used for Alternative Fuel Vehicles (AFVs) and B-20 biodiesel is used for all diesel vehicles and off-road equipment. Biodiesel is used in all equipment except emergency generators and boilers, representing the maximum foreseeable usage level for the current equipment inventory. As of December 2008, the NNSS has 548 AFVs that are E85-capable, which equates to 94 percent of the NNSS vehicle fleet.

Table 5–6 Estimated Annual Liquid Fuel Usage Under the No Action Alternative

Fuel Type	*Quantity*
#2 Red Dye Fuel Oil for Heating	66,000 gallons
Unleaded Gasoline	427,000 gallons
Ethanol/E85	217,000 gallons
#2 Diesel	65,000 gallons
Biodiesel	343,000 gallons

Source: NNSA/NSO 2010b.

The NNSS has two service stations, each capable of storing 10,000 gallons of unleaded gasoline and 9,500 gallons of biodiesel for vehicle fueling. Each service station is collocated with an E85 fueling station. The bulk storage tanks in Area 6 are capable of storing approximately 100,000 gallons of biodiesel and 40,000 gallons of unleaded gasoline (DOE 2008l). Both bulk storage tanks are filled and maintained to support four weeks of biodiesel consumption and two weeks of unleaded fuel consumption in case of a fuel shortage (NSTec 2009e).

Under the No Action Alternative, the NNSS would not experience significant increases in workforce, fleet vehicles, or the number or size of facilities (excluding the construction and operation of the commercial solar power generation facility). DOE/NNSA has not identified any activities that would result in long-term increases or large peak demands for liquid fuels under the No Action Alternative. Fuel consumption rates are expected to remain similar to the levels seen in FY 2009. Given the volume of existing storage capacity and existing commercial supply arrangements, DOE/NNSA does not foresee

difficulty in obtaining liquid fuels from regional suppliers to meet its needs. The NNSS's annual fuel demands make up a very small proportion of total fuel use in the state for most liquid fuels (e.g., less than 0.05 percent of unleaded gasoline use) and are not expected to strain local and regional fuel supply networks (NSOE 2009). However, the NNSS is a major consumer of biodiesel in Nevada, making up approximately 60 percent of the statewide total demand of 575,000 gallons (NSOE 2009). Although not anticipated, if demand were to exceed regional supply, the NNSS could temporarily switch to petroleum-based diesel for most applications until biodiesel is available again.

Construction of a commercial solar power generation facility would result in large numbers of personal vehicles, construction equipment, and diesel generators operating on the NNSS for up to 35 months. However, these activities are not expected to use NNSS fuel supplies; fuel for this activity would be the responsibility of the commercial entity conducting the construction. Similarly, small quantities of fuel may be needed for the operation of the solar power generation facility (supporting heaters, emergency generators, etc.), but this demand would be met by the commercial operator of the facility.

Energy Conservation. Under all alternatives, DOE/NNSA would continue to identify and implement energy conservation measures and renewable energy projects in compliance with all applicable Executive Orders and DOE Orders and policies. These initiatives would serve to reduce consumption of electrical power and liquid fuels on a per-unit basis, suggesting that the estimates for total consumption under this alternative are conservative in nature, as well as potentially avoid adverse impacts related to energy capacity. These measures would also result in a greater proportion of energy use coming from renewable sources, reducing dependence on fossil fuels, and potentially resulting in indirect beneficial impacts on air quality and other environmental resources. The following are some specific examples of energy conservation measures:

- DOE/NNSA would improve energy efficiency and reduce greenhouse gas emissions through reduction of energy intensity by 3 percent annually and a total of 30 percent through the end of FY 2015, relative to the energy use baseline in FY 2003. Energy intensity is the energy consumption per gross square foot of building space, including industrial and laboratory facilities.
- DOE/NNSA would continue installation of advanced electric metering systems to the extent practicable at all NNSS buildings, as well as implementation of a centralized data collection, reporting, and management system.
- DOE/NNSA would maximize installation of onsite renewable energy projects at the NNSS where technically and economically feasible, with the goal of acquiring at least 7.5 percent of the NNSS's annual electricity and thermal consumption from onsite renewable sources.
- DOE/NNSA would ensure that new construction and renovation projects include design, construction, maintenance, and operation practices in support of the high-performance building goals of Executive Order 13423.

5.1.2.2.2 Expanded Operations Alternative

Under the Expanded Operations Alternative, the NNSS would experience a workforce increase of approximately 25 percent, support several new or expanded facilities, and see an overall increase in the frequency and scope of defense experiments and other activities. These changes have the potential to noticeably increase long-term demands for electrical power and liquid fuels, as well as produce demand peaks during major construction efforts or specific experiment events. However, DOE/NNSA is also proposing upgrades to the electrical distribution system, development of onsite renewable energy sources, consolidation or closure of unused facilities, and measures to improve energy conservation and efficiency that would collectively reduce or avoid adverse impacts on energy capacity or supply. Specific activities and their potential effects are discussed in the following subsections.

Electrical Energy. DOE/NNSA is proposing new or expanded facilities in locations including Areas 6, 12, 16, 17, and 23 (Mercury), as well as the Desert Rock and Pahute Mesa Airstrips. Section 5.1.2.1

provides a detailed description of facility sizes, configurations, and locations. All construction or renovation activities would result in temporary increases in electrical power demand; some of this temporary demand would be met by using portable generators rather than tie-ins to the NNSS electrical distribution system. As noted in Chapter 3 of this SWEIS, some facilities are still in the conceptual planning phase and would be analyzed in future NEPA documents when planning and design have evolved.

Operation of new facilities that would support new mission elements or capabilities would result in a clear increase in electrical power demand on the NNSS. However, these new facilities would likely be more energy-efficient than existing buildings, due to implementation of more energy-efficient components and practices. In cases where new facilities would be constructed to relocate or consolidate existing functions (e.g., consolidation of security functions in Area 23), long-term power demand associated with those functions would likely be lower than previous levels.

Proposals under the Expanded Operations Alternative could result in development of more than 400,000 square feet of building space (added to the approximate 2.45 million square feet currently managed) on the NNSS, or an approximate 16 percent increase. It is reasonably foreseeable that DOE/NNSA would also decommission any existing buildings that are no longer needed, as it has committed to an ongoing reduction of the total building footprint through its Facility and Infrastructure Assessment Process. Up to approximately 28 percent of the existing managed building square footage at the NNSS could be dispositioned under the Expanded Operations Alternative (NNSA/NSO 2010d, 2010e). However, the period between completion of a new construction project and initiation of decommissioning activities is unknown; when dispositioning occurs, it would further reduce the electrical energy demand.

To account for any uncertainties regarding changes in building square footage and associated power demands in any particular year, implementation of energy efficiency measures to new and existing buildings, and an anticipated 25 percent increase in NNSS workforce numbers, DOE/NNSA estimates that average power demand would increase by no more than 25 percent from that analyzed under the No Action Alternative in any year, while peak power demand (including demand associated with construction or renovation activities) would increase by no more than 35 percent. A 35 percent increase over DOE/NNSA's 2009 average electrical demand of 84,600 megawatt-hours would amount to approximately 105,700 megawatt-hours. During 2009, NV Energy and Valley Electric Association provided about 21,675,000 megawatt-hours, collectively. Under the Expanded Operations Alternative, NNSS use of electricity would represent approximately 0.49 percent of the regional electrical demand (NSOE 2010).

The projected increases would result in an average power demand of approximately 28 megawatts, with a peak demand of approximately 41 megawatts. The capacity of the existing NNSS distribution system (estimated at approximately 36 megawatts) would be sufficient to meet average demand, but peak demand periods could exceed the capacity, potentially resulting in voltage fluctuations or blackouts. As noted under the No Action Alternative, any reduction in supply to the NNSS from commercial power suppliers would also reduce the effective supply to the NNSS, making these adverse effects more likely.

Under the Expanded Operations Alternative, DOE/NNSA would propose to upgrade the existing 138-kilovolt electrical distribution system to better provide for this projected demand, increase service reliability, and leave capacity to support any future growth on the NNSS. About 39 miles of the existing system would be replaced between Mercury Switching Center in Area 23 and Valley Substation in Area 2. The replacement transmission line would be constructed on steel towers on a right-of-way generally paralleling the existing system. Sufficient separation between the existing transmission line and the new line would be required to ensure electrical safety during construction of the new line and demolition of the old line.

The transmission line replacement project would occur in three distinct and separately operable stages: (1) Mercury Switching Center to Frenchman Flat Substation, with a loop tap at Mercury Distribution Substation (approximately 15 miles); (2) Frenchman Flat Substation to Tweezer Substation in Area 6 (approximately 9.5 miles); and (3) Tweezer Substation to Valley Substation in Area 2 (approximately 14 miles). DOE/NNSA would coordinate this upgrade, or distinct stages of it, with other proposed activities under this alternative to ensure that additional system capacity and reliability were in place prior to significant additional power demands coming on line.

The new transmission line would increase the capacity of the system from the current level of about 36 megawatts up to approximately 100 megawatts and improve the efficiency of the system (NNSA/NSO 2010c). However, to utilize any capacity above the current level of 36 megawatts, DOE/NNSA would need to purchase additional power from a supplier and could seek to negotiate additional power through an offsite commercial provider, such as NV Energy or Valley Electric Association, if the onsite solar power generation facility is not constructed. If additional power is available from these outside commercial providers, the NNSS's distribution system would be adequate to meet all projected demands, and no adverse impacts are expected. However, it is not known whether these commercial providers would be able to accommodate NNSS's additional power demands at that time.

Under the Expanded Operations Alternative, DOE/NNSA may allow the construction and operation of one or more solar power generation facilities similar to the facility described under the No Action Alternative, but with a net generating capacity of approximately 1,000 megawatts. If these facilities were constructed, DOE/NNSA would likely seek to purchase a portion of the facilities' power, while the balance would be exported to the commercial power grid. This arrangement would allow NNSS's electrical distribution system to meet all projected demands, and no adverse impacts are expected. Such a power-sharing agreement would also enable the NNSS to better meet its goals for use of renewable energy sources, as well as reduce the NNSS's reliance on fossil-fuel-generated power, resulting in an indirect beneficial impact on air quality and other environmental resources.

In addition, under the Expanded Operations Alternative, DOE/NNSA would construct a 5-megawatt photovoltaic solar power generation facility near the Area 6 Construction Facilities. While this project would result in a temporary additional demand for electrical power during construction (covered within the increases estimated under this alternative), it would later provide an additional source of power for the NNSS distribution system and further DOE/NNSA's progress toward reducing dependence on fossil-fuel-based electricity.

DOE/NNSA would also evaluate the feasibility of demonstrating a pilot-scale, enhanced geothermal power system (also referred to as a "Geothermal Demonstration Project"). The primary objective would be to demonstrate the viable recovery of a practical operating level energy (5 to 50 megawatts) from rock that is hot (greater than 180 degrees Celsius [ºC]), but does not contain mobile water. The size of the pilot-scale geothermal power system would be unique to each site's geothermal characteristics and based on the optimal balance of temperature, rock reservoir size, heat exchange rate, water pressure, and flow rate, among other factors. If this pilot-scale Geothermal Demonstration Project were found to be technically feasible, it would then serve as a testing facility for improvements applicable to similar systems elsewhere, as well as supply some additional electrical power to the NNSS. A decision on the best location for a geothermal power system would depend on a combination of the system's power generation potential, environmental constraints, and economic considerations. Because there are no location-specific proposals for development of a geothermal power system on the NNSS at this time, additional NEPA review would be required before such work could be conducted.

Liquid Fuels. DOE/NNSA is proposing new or expanded facilities in locations including Areas 6, 12, 16, 17, and 23 (Mercury), as well as Desert Rock and Pahute Mesa Airstrips. Section 5.1.2.1 provides a detailed description of facility sizes, configurations, and locations. All construction or renovation activities would result in temporary increases in liquid fuel demand. In some cases, long-term increases

in total fuel usage may be required to operate additional buildings and equipment and meet the greater vehicle fuel needs associated with the increased frequency of certain experiments and training activities.

However, the planned consolidation of certain functions (e.g., consolidation of security functions in Area 23) would reduce the need to travel between locations, thereby reducing associated vehicle requirements and fuel consumption. All new buildings are also expected to be more fuel-efficient on a square-foot basis due to the inclusion of "green" technologies in building design. As noted in Chapter 3 of this SWEIS, some other facilities are still in the conceptual planning phase and would be analyzed in future NEPA documents when planning and design have evolved further.

To account for changes in building square footage, the timing of construction projects, implementation of energy efficiency measures, and an anticipated 25 percent increase in NNSS workforce numbers, DOE/NNSA estimates that annual liquid fuel demand would increase by no more than 25 percent from that analyzed under the No Action Alternative in any year. While additional demand associated with vehicles would likely be associated with nonpetroleum fuels (E85 and biodiesel), it is reasonably foreseeable that other uses (boilers, emergency generators) would increase the use of petroleum-based fuels (heating oil, #2 diesel, unleaded gasoline) if they could not be configured for alternative fuels. **Table 5–7** presents estimated annual liquid fuel demand under the Expanded Operations Alternative.

Table 5–7 Estimated Annual Liquid Fuel Usage Under the Expanded Operations Alternative

Fuel Type	*Quantity*
#2 Red Dye Fuel Oil for Heating	83,000 gallons
Unleaded Gasoline	534,000 gallons
Ethanol/E85	271,000 gallons
#2 Diesel	81,000 gallons
Biodiesel	429,000 gallons

New facilities with boilers or liquid-fuel-fired heating units would include adjacent fuel storage tanks in their designs. DOE/NNSA would also retain the vehicle service stations and the Area 6 bulk storage tanks (kept filled to 80 percent capacity) described under the No Action Alternative. Given the volume of existing storage tanks and existing commercial supply arrangements, DOE/NNSA does not foresee difficulty in obtaining liquid fuels from regional suppliers to meet its needs. The NNSS's projected annual fuel demands would make up a very small proportion of the current, total fuel use in the state for most liquid fuels (e.g., approximately 0.05 percent of unleaded gasoline use) and are not expected to strain local and regional fuel supply networks (NSOE 2009). However, the NNSS is a major consumer of biodiesel in Nevada, making up approximately 60 percent of the statewide total demand of 575,000 gallons (NSOE 2009); under this alternative, DOE/NNSA would increase consumption of biodiesel to about 75 percent. Although not anticipated, if demand were to exceed regional supply, the NNSS could temporarily switch to petroleum-based diesel for most applications until biodiesel is available again.

Construction of one or more commercial solar power generation facilities with a 1,000-megawatt combined capacity would result in large numbers of personal vehicles, construction equipment, and diesel generators operating on the NNSS for up to 42 months. However, these activities are not expected to use NNSS fuel supplies; fuel for this activity would be the responsibility of the commercial entity conducting the construction. Similarly, small quantities of fuel may be needed for operation of the commercial solar power generation facilities (supporting heaters, emergency generators, etc.), but this demand would be met by the commercial operator of the facility.

Construction and operation of the 5-megawatt photovoltaic solar power generation facility in Area 6 and the Geothermal Demonstration Project (no specific location proposed at this time) would also use small quantities of liquid fuel to supply emergency generators, heaters, and/or boilers. DOE/NNSA estimates

that the fuel demand from these activities would be captured within the 25 percent overall demand increase associated with this alternative.

Energy Conservation. DOE/NNSA would continue to identify and implement the energy conservation measures and renewable energy projects described under the No Action Alternative. These initiatives would serve to reduce consumption of electrical power and liquid fuels on a per-unit basis, suggesting that the estimates for total consumption under this alternative are conservative in nature and would potentially avoid adverse impacts related to energy capacity. These measures would also result in a greater proportion of energy use coming from renewable sources, reducing dependence on fossil fuels, and potentially resulting in indirect beneficial impacts on air quality and other environmental resources.

5.1.2.2.3 Reduced Operations Alternative

Under the Reduced Operations Alternative, the NNSS would operate below current levels, and a number of facilities would be decommissioned, thereby reducing energy needs. Conservation and renewable energy goals would continue to be pursued, further reducing energy demand.

DOE/NNSA would continue to maintain, repair, and modify operating facilities and infrastructure, as needed and within funding limits, and would conduct small projects to maintain the present capabilities of DOE/NNSA NSO facilities (described under the No Action Alternative). Under the Reduced Operations Alternative, however, all activities would cease in the northwestern portion of the NNSS within Areas 18, 19, 20, 29, and 30, with the exception of maintenance and operation of the Echo Peak, Motorola, and Shoshone communications facilities; the Echo Peak, Castle Rock, and Stockade Wash Substations, including electrical transmission lines interconnecting these substations; and Well 8. DOE/NNSA would continue environmental restoration, environmental monitoring, site security operations, and military training and exercises within these areas. No infrastructure projects would be conducted in these northwestern areas beyond maintaining mission-essential facilities and critical electrical and communication systems. The Reduced Operations Alternative also includes a 100-megawatt commercial solar power generation facility in Area 25.

Additional information on energy use (electrical and liquid fuels) and energy conservation and efficiency is provided below.

Electrical Energy. Under the Reduced Operations Alternative, net NNSS power demand would be reduced as numerous activities across the NNSS were scaled back or eliminated. Based on a projected 10 percent decrease in staffing at the NNSS and the eventual closure of several facilities, DOE/NNSA estimated that average power demand would decrease by 10 percent (to 20 megawatts) compared to demand under the No Action Alternative, and peak demand would decrease by 10 percent (to 27 megawatts). A 10 percent decrease from DOE/NNSA's 2009 average electrical demand of 85,600 megawatt-hours would reduce demand to approximately 76,140 megawatt-hours. During 2009, NV Energy and Valley Electric Association provided about 21,675,000 megawatt-hours, collectively. Under the Reduced Operations Alternative, use of electricity would represent approximately 0.35 percent of the regional electrical demand (NSOE 2010). These projected demand reductions, along with ongoing implementation of energy efficiency measures, would make the current distribution system capacity of 36 megawatts adequate for both average and peak power demands.

As noted under other alternatives, any reduction in power to the NNSS from commercial suppliers would reduce the effective power supply on the NNSS, which would make adverse effects (e.g., voltage fluctuations and temporary loss of service) possible, but still unlikely. In addition, the physical condition and reliability of the NNSS distribution system would deteriorate over time, although basic maintenance would continue under this alternative. If basic maintenance activities were insufficient to maintain system reliability, DOE/NNSA would pursue the more significant system upgrades (including replacement of some line sections) as described under the Expanded Operations Alternative, based on a future NEPA review and decision.

Under the Reduced Operations Alternative, DOE/NNSA may allow construction and operation of a solar power generation facility similar to that described under the No Action Alternative. However, the size of this facility would be reduced, resulting in a net generating capacity of approximately 100 megawatts. If this facility were constructed, DOE/NNSA would likely seek to purchase a portion of this facility's power, and the balance would be exported to the commercial power grid. This arrangement would allow NNSS's distribution system to meet all projected demands with more confidence, and no adverse impacts are expected. Such a power-sharing agreement would also enable the NNSS to better meet its goals for use of renewable energy sources by reducing the NNSS's reliance on fossil fuel-generated power, resulting in an indirect beneficial impact on air quality and other environmental resources.

Liquid Fuels. Under the Reduced Operations Alternative, liquid fuel demand from all uses would decrease as activity and staffing levels were reduced. DOE/NNSA estimates that demand for all fuel types would decrease by approximately 10 percent from the levels seen in the No Action Alternative. **Table 5–8** presents estimated annual fuel demand under the Reduced Operations Alternative.

Table 5–8 Estimated Annual Liquid Fuel Usage Under the Reduced Operations Alternative

Fuel Type	*Quantity*
#2 Red Dye Fuel Oil for Heating	59,000 gallons
Unleaded Gasoline	384,000 gallons
Ethanol/E85	195,000 gallons
#2 Diesel	59,000 gallons
Biodiesel	309,000 gallons

Given the volume of existing storage tanks (described under the No Action Alternative) and existing commercial supply arrangements, DOE/NNSA does not foresee difficulty in obtaining liquid fuels from regional suppliers to meet its needs. The NNSS's projected annual fuel demands would make up a very small proportion of current, total fuel use in the state for most liquid fuels (for example, less than 0.04 percent of unleaded gasoline use) and are not expected to strain local and regional fuel supply networks (NSOE 2009). However, the NNSS is a major consumer of biodiesel in Nevada, making up approximately 60 percent of the statewide total demand of 575,000 gallons (NSOE 2009); under this alternative, DOE/NNSA would decrease consumption of biodiesel to about 54 percent. Although not anticipated, if demand were to exceed regional supply, the NNSS could temporarily switch to petroleum-based diesel for most applications until biodiesel is available again.

Construction of a commercial 100-megawatt solar power generation facility would result in large numbers of personal vehicles, construction equipment, and diesel generators operating on the NNSS for up to 32 months. However, these activities are not expected to use NNSS fuel supplies; fuel for this activity would be the responsibility of the commercial entity conducting the construction. Similarly, small quantities of fuel may be needed for operation of the solar power generation facility (supporting heaters, emergency generators, etc.), but this demand would be met by the commercial operator of the facility.

Energy Conservation. DOE/NNSA would continue to identify and implement the energy conservation measures and renewable energy projects described under the No Action Alternative. These initiatives would reduce consumption of electrical power and liquid fuels on a per-unit basis, suggesting that the estimates for total consumption under this alternative are conservative in nature, and would potentially avoid adverse impacts related to energy capacity. These measures would also result in a greater proportion of energy use coming from renewable sources, reducing dependence on fossil fuels, and potentially resulting in indirect beneficial impacts on air quality and other environmental resources.

5.1.3 Transportation and Traffic

Section 5.1.3.1 evaluates both radiological and nonradiological impacts from shipment of radioactive waste to the NNSS, onsite shipment of radioactive waste, and shipment of other radioactive materials to and from the NNSS; only nonradiological impacts would result from shipment of nonradioactive materials. Radiological impacts are those associated with the effects of low levels of radiation emitted during incident-free transportation and those resulting from the accidental release of radioactive materials; radiological impacts are expressed as additional latent cancer fatalities (LCFs). Nonradiological impacts are independent of the nature of the cargo being transported and are expressed as traffic accident fatalities when there is no release of radioactive material. Note that all shipments must meet U.S. Department of Transportation (DOT) regulations, and the packaging of radioactive materials must meet U.S. Nuclear Regulatory Commission regulations, as discussed in Appendix E, Sections E.3.1 and E.3.2. NNSS shipments have never exceeded regulatory requirements for transportation radiation limits.

Section 5.1.3.2 discusses the traffic impacts that would result from changes in the current numbers of personnel trips and trucks transporting radioactive and nonradioactive materials due to the differing activity levels among alternatives. Traffic impacts are expressed as the percent change in the number of onsite and regional (i.e., offsite) daily vehicle trips and changes in roadway levels of service associated with transporting personnel, materials, and waste.

Transportation—American Indian Perspective

Indian reservations within the region of influence are located in remote areas with limited access by standard and substandard roads. Should an emergency situation arise resulting from Nevada National Security Site (NNSS)-related activities, including the transportation of hazardous and radioactive waste, it could result in the closure of the main transportation artery to that land. If a major (only) road into a reservation closes, numerous adverse social and economic impacts could occur. For example, Indian students who have to travel an unusually high number of miles to or from school could realize delays or separation from their families or support systems. Delays could also occur for regular deliveries of necessary supplies for inventories needed by tribal enterprises and personal use or medical supplies. Emergency medical services en route to or from the reservation, and purchases by patrons of tribal enterprises could be dramatically impeded. Potential investors interested in expanding tribal enterprises, as well as on-going considerations by tribal governments for future or current tribal enterprises, may significantly diminish because of the real and perceived risks from the transportation of hazardous and radioactive waste associated with NNSS-related activities.

Because of these potential transportation impacts relating directly to NNSS activities, the Consolidated Group of Tribes and Organizations (CGTO) recommends the U.S. Department of Energy (DOE) collaborate with potentially affected tribes to develop emergency response measures regarding transportation.

See Appendix C for more details.

The following criteria are used to analyze the risks of potential transportation activities during incident-free operations and accidents:

- Radiation dose and risk to the public, including cumulative effects on the population and effects on maximally exposed individuals (MEIs)
- Radiation dose and risk to workers, including cumulative effects on the worker population and effects on MEIs
- Number of traffic fatalities resulting from traffic accidents (not related to the radioactive cargo)

These criteria are used to evaluate potential impacts on onsite and regional traffic conditions:

- Percent change in average daily traffic for onsite and regional traffic conditions
- Degree of change in the volume-to-capacity and resulting level of service for key roadways under regional traffic conditions

Increases in nonradioactive pollutants from traffic emissions are discussed in Section 5.1.8. Appendix E contains a more detailed description of the transportation analysis and results.

5.1.3.1 Transportation

Methodology and Assumptions. Shipping packages containing radioactive materials emit low levels of radiation; the amount of radiation depends on the kind and amount of transported materials. DOT regulations (49 CFR Part 173 Subpart I) require shipping packages containing radioactive materials to have sufficient radiation shielding to limit the radiation to 10 millirem per hour at a distance of 6.6 feet from the transporter. For incident-free transportation, the potential human health impacts of the radiation field surrounding the transportation packages were estimated for transportation workers and the general population along the route (off-traffic, or off-link), as well as for people sharing the route (in-traffic or on-link) and at rest areas and other stops along the route. The Radioactive Material Transportation Risk Assessment Code 6 (RADTRAN) computer program (SNL 2009b) was used to estimate the impacts on transportation workers, the public, and an MEI (e.g., a person stuck in traffic, a gas station attendant, an inspector).

Transportation accidents involving radioactive materials present both nonradiological and radiological risks to workers and the public. Nonradiological impacts of transportation accidents include traffic accident fatalities. Radioactive material would be released during transportation accidents only when the package carrying the material is subjected to forces that exceed the package design standard. Only a severe fire and/or a powerful collision, both events of extremely low probability, could damage a transportation package of the type used to transport radioactive material to the extent that radioactivity would be released to the environment with significant consequences.

The radiological impact of a specific accident is expressed in terms of probabilistic risk (i.e., dose-risk), which is defined as the accident probability (accident frequency) multiplied by the accident consequences (dose). The overall radiological risk estimate is obtained by summing the individual radiological risks from all reasonably conceivable accidents. Analysis of accident risks accounts for a spectrum of accident severities, ranging from high-probability accidents of low severity (e.g., fender benders) to hypothetical high-severity accidents that have a low probability of occurrence. In addition to calculating the radiological risks that would result from all reasonably conceivable accidents during transportation of radioactive materials, this SWEIS assesses the highest consequences of a maximum reasonably foreseeable accident with a radioactive release frequency greater than 1×10^{-7} (1 chance in 10 million) per year in an urban or suburban population area along the route. This latter analysis used the

Waste Transportation through the Las Vegas Valley

Historically, the U.S. Department of Energy (DOE) committed to the State of Nevada that it would avoid shipping low-level radioactive waste (LLW) through the Interstate 15/U.S. Route 95 interchange in Las Vegas, Nevada. This commitment was made when major highways, such as Interstate 15 and U.S. Route 95, were unable to accommodate increased traffic volumes. The commitment, as stated in the Waste Acceptance Criteria (WAC) for the Nevada National Security Site (NNSS), avoided Hoover Dam and Las Vegas. In compliance with this requirement, commercial carriers of LLW used alternate shipping routes, such as Nevada State Route 160.

Now, the transportation infrastructure throughout metropolitan Las Vegas, such as Interstate 15 and U.S. Route 95, has been expanded and improved. In addition, the 215 Beltway was built to take traffic around the center of Las Vegas. Moreover, highways that continue to be used to transport waste, such as Nevada State Route 160, have experienced increased traffic as the population has grown in that area of the valley.

The National Nuclear Security Administration (NNSA) has analyzed two transportation cases: one that reflects the existing commitment (Constrained Case) and one that permits shipments through the greater metropolitan Las Vegas area (Unconstrained Case). This analysis was undertaken to develop a greater understanding of the potential environmental consequences of shipping such waste through and around metropolitan Las Vegas and to provide information relevant to consideration of potential highway routing-related revisions to NNSS's WAC. Although an analysis of LLW/mixed low-level radioactive waste (MLLW) shipping routes is included in this site-wide environmental impact statement, individual decisions on routing will not be made as part of this National Environmental Policy Act process. Such decisions are developed in accordance with NNSA's standard practices, which include consultation with the State of Nevada, and, when finalized, become publicly available through publication on the NNSS website.

After consultation with the Nevada Division of Environmental Protection as part of the WAC revision process, DOE/NNSA announced in September 2012 (www.nv.doe.gov) that it would retain the current highway routing restrictions for shipments of LLW/MLLW in the greater Las Vegas metropolitan area and, therefore, there would be no need to revise the WAC in this regard (DOE 2012).

Risks and Consequences of Radioactive Material Transport (RISKIND) computer program to estimate doses to individuals and populations (Yuan et al. 1995).

Incident-free radiological health impacts are expressed in terms of additional LCFs. Radiological health impacts from accidents are also expressed as additional LCFs. Nonradiological accident impacts are expressed as additional immediate (traffic accident) fatalities. LCFs associated with radiological exposure were estimated by multiplying the occupational (worker) and public dose by a dose conversion factor of 0.0006 LCFs per rem or person-rem of exposure (DOE 2003d). The health impacts associated with the shipment of radioactive wastes were calculated assuming that all wastes would be transported using either truck or rail transport. Health impacts associated with the shipment of special nuclear material (SNM) and nuclear weapons were calculated assuming these materials would be transported by DOE safeguards transporters.

In determining transportation risks, per-shipment risk factors were calculated for incident-free and accident conditions using the RADTRAN 6 computer program (SNL 2009b) in conjunction with the Transportation Routing Analysis Geographic Information System (TRAGIS) computer program (Johnson and Michelhaugh 2003) to choose transportation routes in accordance with DOT regulations. The TRAGIS program provides population density estimates for rural, suburban, and urban areas along the routes based on the 2000 U.S. census. The population density estimates were escalated to 2016 population density estimates using state-level 2000 and 2010 census data and assuming population growth between 2000 and 2010 would continue through 2016. The region of influence for this analysis is the affected population, including individuals living within 0.5 miles of each side of the road or rail line for incident-free operations and, for accident conditions, individuals living within 50 miles of the accident. The MEI was assumed to be a receptor located 330 feet directly downwind from the accident. Additional details on the analytical approach and on modeling and parameter selections are provided in Appendix E of this SWEIS.

Route-specific accident and fatality rates for commercial truck transports and rail shipments were used to determine the risk of traffic accident fatalities (Saricks and Tompkins 1999) after being adjusted for possible under-reporting (UMTRI 2003). Statistics specific to DOE safeguards transporters are used for safeguards transporters shipments (Phillips, Clauss, and Blower 1994). The methodology for obtaining and using accident and fatality rates is provided in Appendix E, Section E.6.2.

This *NNSS SWEIS* presents transportation analyses of two cases: a Constrained Case and an Unconstrained Case.

Maximally Exposed Individual (MEI) – A hypothetical individual whose location and habits result in the highest total radiological exposure (and thus dose) from a particular source for all relevant exposure routes (e.g., inhalation, ingestion, direct exposure).

Rem – A unit of radiation dose used to measure the biological effects of different types of radiation on humans. The dose in rem is estimated using a formula that accounts for the type of radiation, the total absorbed dose, and the tissues involved. One thousandth of a rem is a millirem. The average dose to an individual in the United States received primarily from natural background sources of radiation is about 310 millirem per year; the national average, including medical sources, is about 620 millirem per year.

Person-rem – A unit of collective radiation dose applied to a population or group of individuals. It is calculated as the sum of the estimated doses, in rem, received by each individual of the specified population. For example, if 1,000 people each received a dose of 1 millirem, the collective dose would be 1 person-rem (1,000 persons × 0.001 rem).

Latent cancer fatalities (LCFs) – Deaths from cancer resulting from, and occurring sometime after, exposure to ionizing radiation or other carcinogens. This site-wide environmental impact statement focuses on LCFs as the primary means of evaluating health risk from radiation exposure. The values reported for LCFs are the increased risk of a fatal cancer for an MEI or noninvolved worker or the increased risk of a single fatal cancer occurring in an identified population.

Constrained Case

For the Constrained Case, DOE/NNSA was assumed to maintain current operational practices by avoiding transporting waste and materials across the Colorado River near the Hoover Dam and on the interstate system within Las Vegas. It was further assumed that shipments approaching the NNSS from the south (via Interstate 40 [I-40]) would use U.S. Route 95 to Nevada State Route 164, to I-15, to Nevada State Route 160, to U.S. Route 95. Shipments approaching the NNSS from the north would use U.S. Routes 50, 6, and 95. Shipments from the TTR would use U.S. Routes 6 and 95. The Constrained Case is analyzed for all alternatives and addresses both radioactive waste and other radioactive material transports.

As appropriate, for each SWEIS alternative, transportation impacts were evaluated for transport of (1) LLW and MLLW to the NNSS for disposal and from the NNSS to a treatment facility and then returned; (2) transuranic (TRU) waste from the NNSS to Idaho National Laboratory (INL) for treatment and certification; (3) SNM to and from the NNSS; (4) nuclear weapons to and from the NNSS for exchange of limited life components; (5) nuclear weapons to the NNSS for dismantlement and subsequent transport of plutonium to Pantex, canned subassemblies to the Y-12 Plant, and milliwatt generators to Los Alamos National Laboratory; (6) sealed sources from San Antonio, Texas, to the NNSS; and (7) nonradioactive hazardous and sanitary waste and recyclables from the NNSS. The numbers of transports of LLW and MLLW to the NNSS were based on DOE/NNSA projections as estimated by waste generators (see Appendix E, Table E–3). The numbers of transports for other wastes and materials were based on programmatic needs as described in Appendix A.

For the Expanded Operations Alternative, LLW and MLLW volumes from waste generators were determined using data from the Waste Management Information System. These waste volumes were apportioned to containers and number of shipments using historical data regarding the types of containers typically received (note that containers may be used to transport waste to the NNSS that were not assumed as part of this analysis, as described in Appendix E, Table E–4). These volumes were apportioned to regions of the United States (see Appendix E, Figure E–2) based on the locations of the waste generators. The following regions were used for analyzing radioactive waste shipments: Northeast, South, Southeast, Upper Midwest, Southwest, Mountain West, West, and Northwest (see Appendix E, Figure E–2, for a depiction of the regions). The transportation analysis was based on the regional waste volume totals so that waste generators would not be limited to those obtained from the Waste Management Information System. The waste volume from each region was assumed to be received from a regional location that would provide a conservative estimate of the impacts from transporting from that region based on distance traveled and population density along the route. This approach was used because not all potential waste generators may be identified in the Waste Management Information System and to account for the amount of uncertainty in the magnitude of waste volume projections.

For the No Action Alternative and Reduced Operations Alternative, it was assumed that the total amount of LLW to be received over a 10-year period, 15,000,000 cubic feet, would be based on the average annual volumes received between FY 1997 and the end of FY 2010. The volume of MLLW analyzed under the No Action and Reduced Operations Alternatives is 900,000 cubic feet, which was based on the permitted volume of Cell 18 at the Area 5 Radioactive Waste Management Complex (RWMC) (the actual permitted volume is 899,996 cubic feet). This volume was apportioned to the waste generators shown in Appendix E, Table E–3, using the percentage of the total volume each waste generator contributed to the waste projections under the Expanded Operations Alternative.

DOE has completed NEPA documentation for other projects in the DOE Complex in which waste was projected to be transported to the NNSS; these documents have not yet been included in the Waste Management Information System. These waste streams are included under the Expanded Operations Alternative with their transportation impacts shown separately. These waste streams include conversion products from Portsmouth, Ohio, and Paducah, Kentucky (DOE 2004e, 2004d), decommissioning waste from the West Valley Demonstration Project (DOE 2010c), and uranium-233 downblending waste from Oak Ridge National Laboratory (DOE 2010b).

To assess incident-free and transportation accident impacts related to radioactive waste shipments, radioactive waste shipments were assumed to be conducted by truck or by a combination of rail and truck. Rail transport to the NNSS is not possible; therefore, rail cargo must be transferred to trucks at a transfer station. DOE/NNSA is not proposing to construct or procure construction of any new rail-to-truck transfer facilities to accommodate shipments of radioactive waste or materials under any of the alternatives considered in this SWEIS. For purposes of analysis only for the Constrained Case, two transfer station sites were assumed: Parker, Arizona, and West Wendover, Nevada. These stations are those outside of Las Vegas, but nearest to the NNSS, at which transfers have occurred in the past. The overall transportation impacts associated with using transfer stations at Parker and West Wendover would be comparable to other locations in the vicinity of the NNSS. For instance, use of a transfer station at Arden, south of Las Vegas, would yield comparable results because it is located along the truck route between Parker and the NNSS. For LLW and MLLW waste shipments, Appendix E, Figure E–3, depicts the analyzed truck and rail routes from each region of the United States while Appendix E, Figure E–4, depicts the analyzed truck routes from the transfer stations at Parker, Arizona, and West Wendover, Nevada, to the NNSS.

The NNSS would send TRU waste to INL for treatment and certification before shipping it to the Waste Isolation Pilot Plant (WIPP) in New Mexico. Rail transport was not analyzed for TRU waste. The INL contractor would assume responsibility for treating, certifying, and transporting the TRU waste to WIPP.

Nuclear weapons and SNM would be transported to and from the NNSS by safeguards transporters. Types of SNM are identified in Appendix A, Section A.2.1.1. Truck routes between specific origination and destination sites were analyzed for the transportation of SNM. For nuclear weapons, routes from different regions of the United States were analyzed, and the route that yielded the highest impacts was used for the analysis.

Unconstrained Case. In the Unconstrained Case, both all truck and combined rail-truck transportation were analyzed to consider all routes within the bounds of the existing regulatory parameters and legal constraints, as well as to reflect major changes and upgrades made to the Las Vegas Valley highway infrastructure over the past 15 years.

(a) All truck: Impacts were analyzed for two route segments. The first segment is from the originating regional site to an entry point to Las Vegas (see Appendix E, Figure E–5). These entry points are Henderson (at the intersection of I-515 and U.S. Route 95), Apex (on I-15 north of Las Vegas), and Arden (on I-15 just south of the junction of I-15 and I-215). Only some of the offsite shipments were analyzed to each entry point, with the sum entering all three points being 100 percent of the shipments. This provides a more realistic analysis such that truck shipments would only enter the Las Vegas area from a direction that makes the most sense (for example, shipments from the West region would not go to Henderson, but would enter the Las Vegas area at Arden). The second segment consists of different routes from these entry points to the NNSS. It was assumed there would be no route limitations in the Las Vegas area; shipments could proceed through or around Las Vegas on several different possible routes, as depicted in **Figure 5–4**. Truck routes were analyzed in segments to make it easier to analyze multiple routes (different segments can be added together).

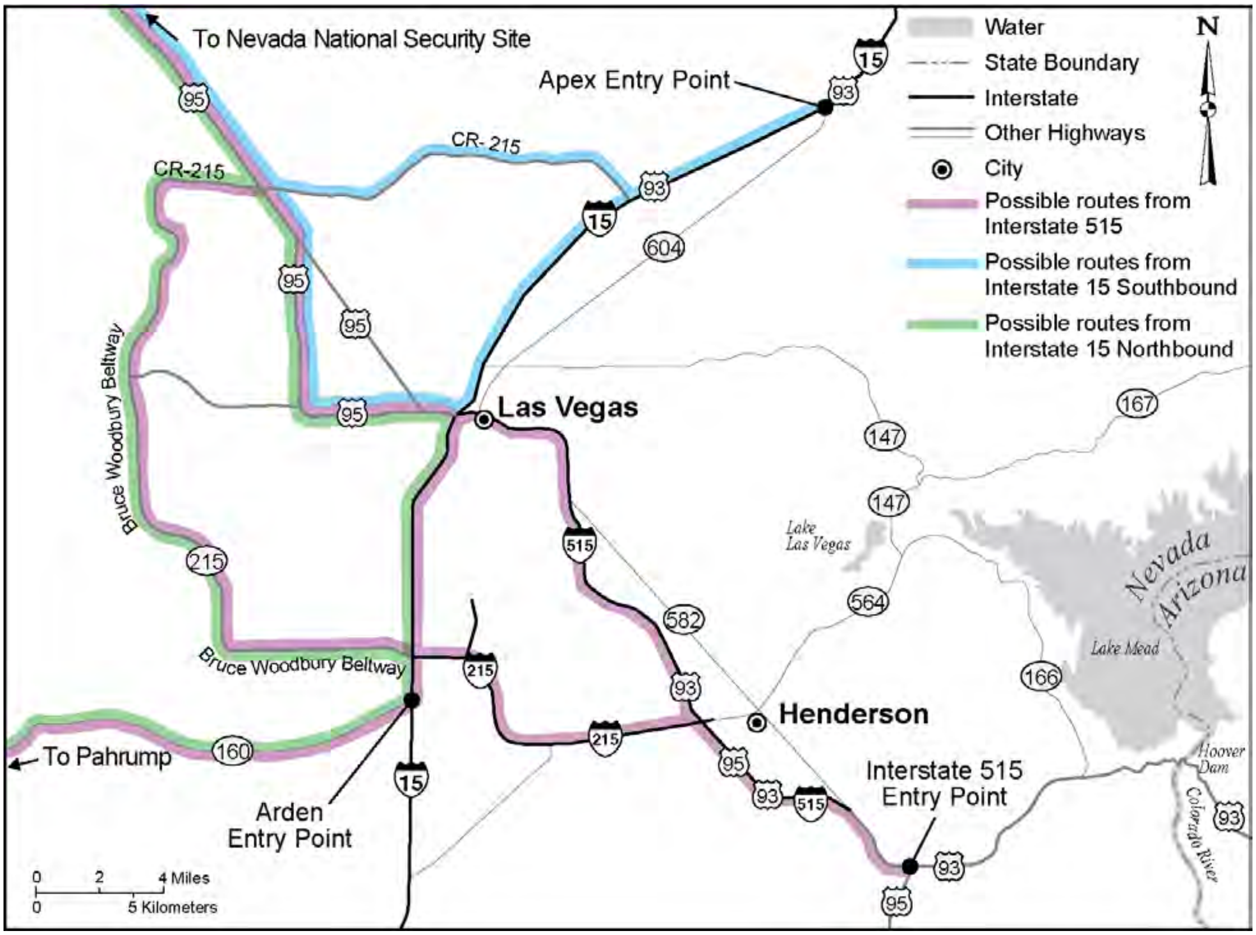

Figure 5–4 Transportation Routes Analyzed in Las Vegas for the Transport of Low-Level and Mixed Low-Level Radioactive Waste for the Unconstrained Case

- Rail-Truck: Rail-truck transportation impacts were also analyzed by route segment. The first segment is rail transport from each region of the United States to a transfer station location in the Las Vegas region. All of the rail shipments were assumed to be transported to five different transfer station locations, where they would be transferred to truck. As depicted in **Figure 5–5**, these five locations are West Wendover, Apex, and Arden, Nevada; and Parker and Kingman, Arizona. [Note: In practice, the location at which shipments would be received would be dependent on arrangements made by the shipper. The actual impacts would fall within the range of results determined in this analysis. In addition, as noted above, DOE/NNSA is not proposing to construct or procure construction of any new rail-to-truck transfer facilities to accommodate shipments of radioactive waste or materials under any of the alternatives considered in this SWEIS.] Appendix E, Figures E–7 and E–8, show the rail routes to each transfer station location. When analyzing rail-to-truck transportation, truck transport from an analyzed transfer station to a Las Vegas entry point (identified in (a) above) was evaluated as a segment, as depicted in Appendix E, Figure E–9. Note that the truck segment from the transfer station to the entry point is only applicable to West Wendover, Parker, and Kingman because the transfer stations at Apex and Arden are already located at an entry point to Las Vegas. Truck transport from West Wendover would proceed to the Apex entry point; truck transport from Parker would proceed to Henderson via U.S. Route 95; and truck transport from Kingman would proceed to Henderson via U.S. Route 93 over the bridge downstream of the Hoover Dam. The final segment is truck travel from a Las Vegas entry point to the NNSS as described in (a) above and depicted in Figure 5–4.

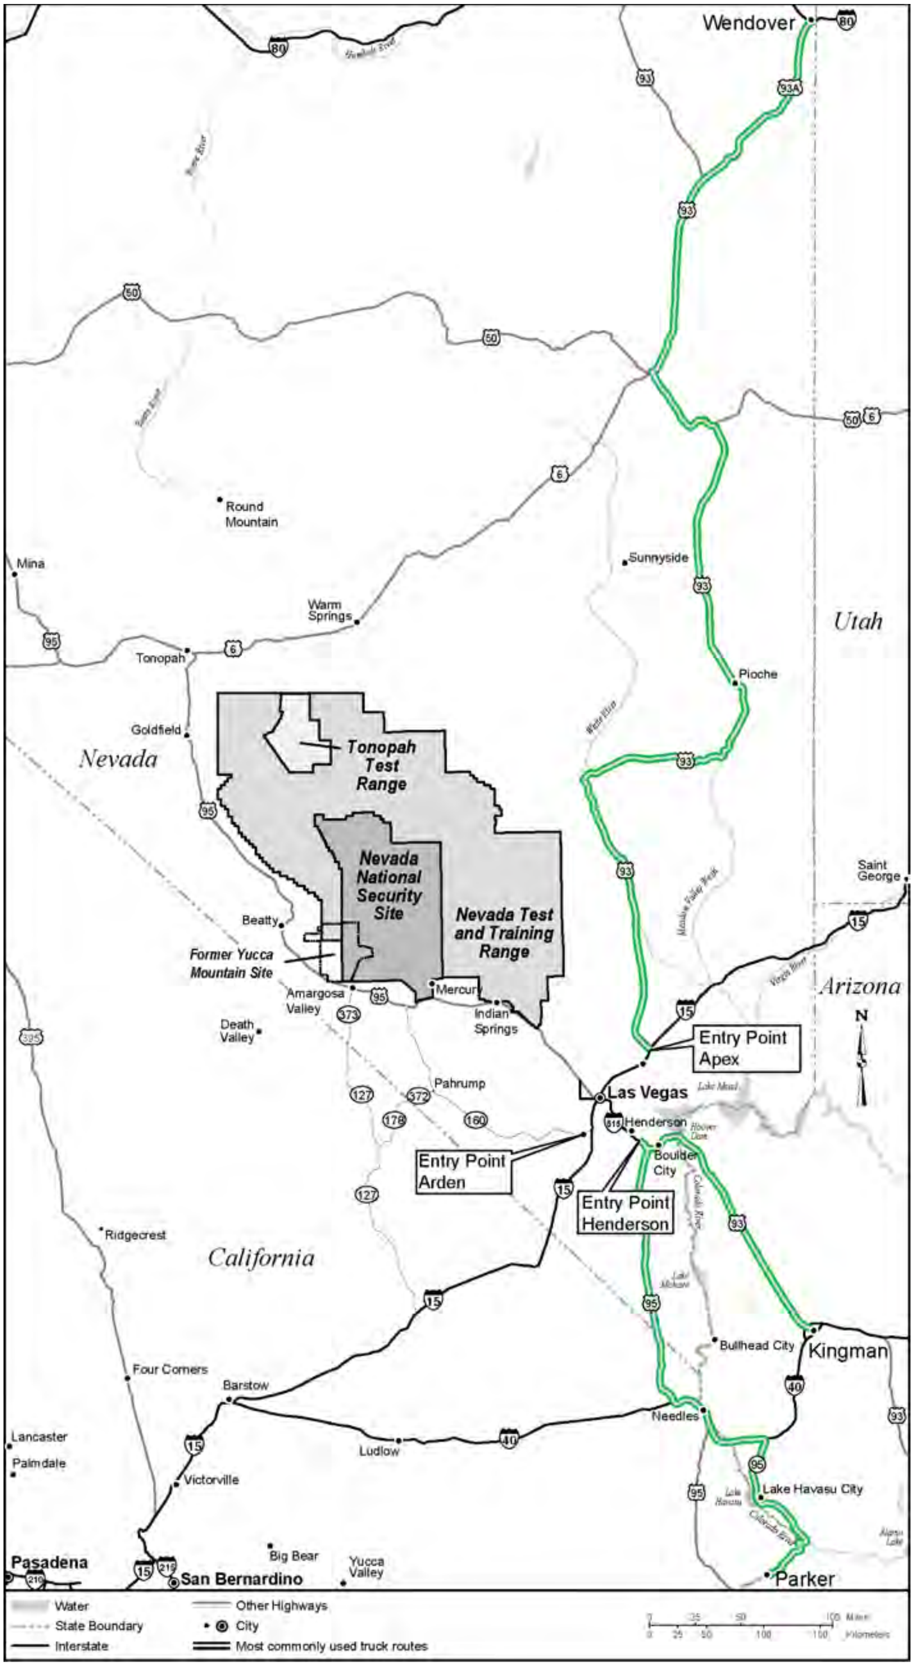

Figure 5–5 Transfer Station Locations and Analyzed Routes from These Locations to Las Vegas for the Unconstrained Case

In addition to analyzing the use of transfer stations in the Las Vegas region, truck-to-rail transfer station locations were analyzed for three different regions of the United States: Southwest region, Northeast region, and West region (see Appendix E, Figure E–2, for a depiction of the regions). This analysis was performed to provide representative impacts associated with transporting LLW/MLLW from generating sites in these regions to a regional transfer station. These regions were selected because there are known possible LLW and/or MLLW generating sites in these regions that do not have direct access to rail.

Comparison of Impacts. Table 5–9 provides the estimated number of waste truck shipments under each alternative from each region, by container type for LLW and MLLW. A shipment is defined as the amount of waste transported on a single truck or a single railcar. The number of rail shipments would be half of the number of truck shipments. The different types of containers shown in the table are described in Appendix E, Section E.4.2.

TRU waste would be generated at the NNSS under all alternatives. Projected TRU waste shipments would include waste in storage, TRU waste generated by the Joint Actinide Shock Physics Experimental Research Facility (JASPER) operations from 2011 through 2020, and waste from environmental restoration activities at the TTR and the Nevada Test and Training Range. **Table 5–10** shows the number of shipments of TRU waste, radioisotopic thermoelectric generators, sealed sources, SNM, and nuclear weapons under each alternative.

Impacts are presented for the Constrained Case for the No Action, Reduced Operations, and Expanded Operations Alternatives for transport of all radioactive waste and materials. **Tables 5–11** and **5–12** present the estimated impacts associated with the Constrained Case for each alternative for radioactive waste and radioactive materials, respectively. Section 5.1.3.1.2.2 presents the estimated impacts associated with the Unconstrained Case.

Table 5–9 Estimated Numbers of Truck Shipments of Low-Level and Mixed Low-Level Radioactive Waste Under Each Alternative Over a 10-Year Period [a]

In-State/Out-of-State Source	*Total Number of Shipments*	*Container Type*				
		Drums	*B-25 Box*	*Sealand* [b]	*B-12 Box*	*Type B Container* [c]

Total – All [g]	**95,000**	**15,000**	**10,000**	**36,000**	**990**	**8,400**

N/A = not applicable.

[a] Number of rail shipments was assumed to be one-half of the number of truck shipments, except for the number of rail shipments for transporting depleted uranium conversion products (see footnote g).

[b] For purposes of analysis, it was assumed that bulk bags would be transported in International Organization for Standardization (Sealand) containers.

[c] A Type B container is used to transport remote-handled LLW or MLLW.

[d] Includes shipment of MLLW from the NNSS to the Oak Ridge, Tennessee, area for treatment, as well as return of the treated waste to the NNSS.

[e] Includes shipments analyzed in other NEPA documents, such as 1,026 truck shipments from Paducah, Kentucky, in the South region (DOE 2002e, 2004d) and 553 truck shipments from Portsmouth, Ohio, in the Upper Midwest region (DOE 2002e, 2004e). These shipments were assumed to consist of Sealand containers transporting depleted uranium conversion products.

[f] Includes radioactive waste generated by environmental restoration activities at the Nevada Test and Training Range and Tonopah Test Range (230 shipments of Sealand containers for the No Action and Reduced Operations Alternatives and 13,000 shipments of Sealand containers for the Expanded Operations Alternative).

[g] Total may not equal the sum of contributions due to rounding.

[h] In addition to shipments estimated from the DOE Waste Management Information System, these numbers include estimated shipments of waste from operation and decontamination and decommissioning of the U.S. Enrichment Corporation lead cascade fuel enrichment facility and operation of the U.S. Enrichment Corporation fuel enrichment full-scale facility.

[i] Includes shipments analyzed in other NEPA documents as follows: 12,243 truck shipments from the West Valley Demonstration Project in the Northeast region (DOE 2010c); 367 shipments of uranium-233 downblending waste from Oak Ridge National Laboratory in the South region (DOE 2010b); and uranium oxide conversion product consisting of 7,240 truck shipments from Paducah, Kentucky, in the South region (DOE 2004d) and 5,834 truck shipments from Portsmouth, Ohio, in the Upper Midwest region (DOE 2004e). For the uranium oxide conversion products, the number of truck shipments is based on depleted uranium hexafluoride cylinders being filled with uranium oxide conversion product, two cylinders per truck. The numbers of rail shipments required for shipment of uranium oxide conversion products are 5,963 from Paducah (DOE 2004d) and 3,216 from Portsmouth (DOE 2004e). This does not include shipments that would occur after 2020.

[j] The total values provided for each container type include 26,000 'Other Out-of-State Shipments.' See footnote i for details.

Table 5–10 Estimated Numbers of Shipments of Transuranic Waste, Radioisotopic Thermoelectric Generators, Sealed Sources, and Special Nuclear Material Over a 10-Year Period [a]

Origin or Activity	*Number of Shipments No Action*	*Number of Shipments Expanded Operations*	*Number of Shipments Reduced Operations*
Transuranic Waste			
JASPER [b]	16	36	11
Environmental Restoration	6	6	6
Radioisotopic Thermoelectric Generators			
Norfolk, Virginia	3	10	3
Sealed Sources			
San Antonio, Texas	120	240	120
Special Nuclear Material			
LLNL (Global Security SNM)	3	3	3
LLNL (HEU)	1	1	1
LANL (Uranium-233)	0	1	0
INL (ZPPR)	0	7	0
INL (ZPPR) – plutonium material	0	8	0
ORNL (Uranium-233)	0	32	0
LLNL (target material for JASPER)	120	240	60
Nuclear Weapons			
Transport to/from the NNSS	0	8,200 [c]	0
Weapon Component Disposition [d]	0	2,010	0

HEU = highly enriched uranium; INL = Idaho National Laboratory; JASPER = Joint Actinide Shock Physics Experimental Research Facility; LANL = Los Alamos National Laboratory; LLNL = Lawrence Livermore National Laboratory; NNSS = Nevada National Security Site; ORNL = Oak Ridge National Laboratory; SNM = special nuclear material; ZPPR = zero power plutonium reactor.

[a] Number of shipments are for one-way transport. The analysis accounts for any return trips or if material is forwarded to another site.

[b] Includes number of shipments related to transuranic waste in storage.

[c] Includes 100 shipments per year for transporting nuclear weapons to the NNSS for disassembly and 360 shipments per year of nuclear weapons to the NNSS to support component exchange, as well as return shipments of refurbished weapons.

[d] Includes 100 shipments per year of canned subassemblies to the Y-12 National Security Complex and plutonium to the Pantex Plant, as well as 1 shipment per year of milliwatt generators to LANL.

Table 5–11 Risks of Transporting Radioactive Waste Under Each Alternative – Constrained Case [a]

Region	Transport Mode	Number of Shipments	One-Way Kilometers Traveled (million)	One-Way Miles Traveled (million)	Incident-Free Conditions: Crew Dose (person-rem)	Incident-Free Conditions: Crew Risk [b]	Incident-Free Conditions: Population Dose (person-rem)	Incident-Free Conditions: Population Risk [b]	Accident Conditions: Radiological Risk [b]	Accident Conditions: Roundtrip Nonradiological Risk [b]

< = less than; DUF_6 = depleted uranium hexafluoride; EA = environmental assessment; ER = Environmental Restoration; LLW = low-level radioactive waste; MLLW = mixed low-level radioactive waste; ORNL = Oak Ridge National Laboratory; rem = roentgen equivalent man; RTG = radioisotope thermoelectric generator; TRU = transuranic; TTR = Tonopah Test Range.

[a] LLW and MLLW were assumed to be transported in 55-gallon drums, B-25 boxes, B-12 boxes, and 20-foot International Organization for Standardization (Sealand) containers based on historical information regarding prevalence of use.

[b] Risk is expressed in terms of LCFs, except for nonradiological risk, where it refers to the number of traffic accident fatalities. Accident dose risk can be calculated by dividing the risk values by 0.0006 (DOE 2003d).

[c] These values reflect only the portion of the routes traveled by railcar.

[d] These values reflect the combined use of rail and truck after rail transporting radioactive waste to the NNSS vicinity.

[e] Transuranic waste is first transported to Idaho National Laboratory for characterization and then transported back to the NNSS with final disposal at WIPP.

[f] The cited risk values are representative of the portion of the routes used for transporting LLW and MLLW within Nevada to the NNSS, excluding shipments identified in other National Environmental Policy Act documentation. The stated risks for travel within Nevada are included in the risks for the regional routes shown in the table. The values for the Reduced Operations Alternative are similar to those for the No Action Alternative.

[g] The risks from transporting Paducah, Kentucky, and Portsmouth DUF_6 conversion wastes and the West Valley Demonstration Project wastes to the NNSS are cited directly from their respective site EISs (DOE 2004d, 2004e, 2010c), proportionally adjusted for a 10-year period. The rail transport risk values for these analyses consider direct transport to the NNSS; therefore, the risks do not include truck transport from a transfer station. If rail-truck transport were used for these shipments, the incident-free risk would be lower, but the accident risk would be slightly higher, given the results of transporting LLW and MLLW. Transportation risks from transporting wastes associated with these waste streams generated beyond this 10-year period are included in the cumulative impacts (see Chapter 6 of this *NNSS SWEIS*).

[h] DOE 2010b.

Note: To convert kilometers to miles, multiply by 0.62137. Total may not equal the sum of the contributions due to rounding. Also due to rounding, the cited risk values are different from multiplication of dose by a dose risk factor of 0.0006 LCFs per person-rem.

rem = roentgen equivalent man.

[a] Risk is expressed in terms of latent cancer fatalities, except for the nonradiological risk, where it refers to the number of traffic accident fatalities. Accident dose risk can be calculated by dividing the risk values by 0.0006 (DOE 2003d).

Table 5–13 provides the estimated dose and risk to an individual and population from a maximum foreseeable truck or rail transportation accident with the highest consequences under each alternative. The highest consequences for the maximum foreseeable accident would be from accidents involving a severe collision with a truck or railcar carrying LLW or MLLW in a 20-foot International Organization for Standardization (ISO) container in conjunction with a long-lasting fire. The calculated population doses shown are based on the maximum population density.

Table 5–13 Estimated Dose to the Population and to Maximally Exposed Individuals Under Most Severe Accident Conditions [a]

Alternative/ Transport Mode [b]		*Waste Material in the Accident With the Highest Consequences*	*Likelihood of the Accident (per year)*	*Population* [c]		*MEI* [d]	
				Dose (person-rem)	*Risk (LCF)*	*Dose (rem)*	*Risk (LCF)*
No Action and Reduced Operations	Truck	LLW/MLLW in 20-foot ISO container	3.2×10^{-7}	180	0.1	0.034	2×10^{-5}
Expanded Operations	Truck	LLW/MLLW in 20-foot ISO container	6.1×10^{-7}	180	0.1	0.034	2×10^{-5}
Transport within Nevada [e]		LLW/MLLW in 20-foot ISO container	3.7×10^{-6}	27	0.02	0.034	2×10^{-5}

ISO = International Organization for Standardization; LCF = latent cancer fatality; LLW = low-level radioactive waste; MEI = maximally exposed individual; MLLW = mixed low-level radioactive waste; rem = roentgen equivalent man.

[a] The likelihood of accidents is based on the annual estimated number of transports from each region to the NNSS. The cited likelihood of accidents is the highest calculated value among all transports. Note that the likelihood of rail accidents is less than 10^{-7} per year; therefore, rail accident impacts are not shown.

[b] The maximum probability for a rail accident is less than 1 in 10 million per year; therefore, no consequences are presented for rail transportation in this table.

[c] Population extends at a uniform density to a radius of 50 miles. The weather condition was assumed to be Pasquill Stability Class D with a wind speed of 8.8 miles per hour. Unless otherwise noted, the population doses and risks are presented for an urban area on the transportation route.

[d] The MEI was assumed to be 330 feet downwind from the accident and exposed to the entire plume of the radioactive release. The weather condition was assumed to be Pasquill Stability Class F, with a wind speed of 2.2 miles per hour.

[e] Population dose and risk are for a suburban area along the route. The probability of a maximum foreseeable accident in an urban area along the transportation route is less than 10^{-7} per year. The cited likelihood of an accident is for the Expanded Operations Alternative. The likelihood of accidents under the No Action and Reduced Operations Alternatives is 1.2×10^{-6} per year.

5.1.3.1.1 No Action Alternative (Constrained Case)

Under the No Action Alternative, approximately 27,400 truck shipments of LLW and MLLW over a 10-year period would be transported to disposal facilities at the NNSS, 25,100 of which would come from outside Nevada. Approximately 20 shipments of TRU waste would be made to INL; after treatment, this waste would be transported to WIPP. About 240 shipments associated with radioisotopic thermoelectric generators and sealed sources would be made.

Impacts of Incident-Free Transportation. Under this alternative, the impacts of transporting LLW and MLLW by truck would be about double the impacts of rail-truck transport (rail-truck transport is the use of rail to move waste and materials to a transfer station in the Nevada region where it is transferred to trucks to complete the trip to the NNSS), as discussed below. Transportation of LLW or MLLW from outside of Nevada would be the primary contributor to the total radiological and nonradiological impacts of transportation activities. The following sections discuss the impacts of incident-free transportation on transportation crewmembers, intermodal workers, and the public.

- Crew – The transport of LLW and MLLW by truck from out of state would incur about 2,100 person-rem of exposure, resulting in approximately 1 (1.3) LCF to a crewmember, assuming no administrative controls were implemented. The contributions from transporting TRU waste

and radioisotopic thermoelectric generators are minimal (about 1.5 person-rem). If rail-truck transport were used, the cumulative dose to rail and truck crewmembers during the transportation of waste under this alternative would be about 860 person-rem (500 person-rem to rail crew and 360 person-rem to truck crew), resulting in 1 (0.5) additional LCF.

Transport of sealed sources and SNM would contribute only a very small additional increment to the total crew exposures (about 20 person-rem, resulting in less than 1 [0.01] LCF) compared to transport of LLW and MLLW because there would be fewer shipments.

Impacts on individual crewmembers would be managed through the implementation of administrative controls to minimize radiation exposure. A transportation worker would be restricted to an exposure level of 100 millirem per year unless that individual were a trained radiation worker subject to administrative procedures that would limit his or her annual dose to 2 rem (DOE 1999e). The potential risk of a trained radiation worker developing an LCF from the maximum annual exposure is 0.0012. Therefore, an individual transportation worker is not expected to develop a lifetime LCF from radiation exposure during these activities.

- Transfer station workers – Workers at transfer stations would be exposed to external radiation fields surrounding the waste shipping containers. The dose estimates per unit handling (person-rem per container) for transferring LLW or MLLW containers from railcars to trucks were based on the estimates provided in the *NTS Intermodal Study* (DOE 1999d). For waste containers with an exposure rate of 1 millirem per hour at 3.3 feet, the worker dose per transfer was estimated to be 3.4×10^{-4} person-rem. The number of container transfers under the No Action Alternative would be 25,100, leading to a total transfer station worker population dose of about 8.5 person-rem, or a risk of less than 1 (0.005) LCF.
- Public – The cumulative dose to the general population during transportation of LLW and MLLW by truck from out of state would be about 400 person-rem, resulting in less than 1 (0.2) additional LCF. If rail-truck transport were used, the cumulative dose to the general population would be about 230 person-rem (160 person-rem to the population along the rail route and 70 person-rem to the population along the truck route), resulting in less than 1 (0.1) additional LCF. The contributions from transporting TRU waste and radioisotopic thermoelectric generators are minimal (about 1 person-rem). Rail-truck transport would lead to lower doses to the general population because (1) the number of rail shipments would be about half of the shipments using all trucks, and (2) truck transports would occur primarily in areas of low population density and over shorter distances.

  Transport of sealed sources, SNM, and nuclear weapons would contribute only a very small additional amount of population dose (about 5 person-rem, resulting in less than 1 [0.003] LCF) compared to transport of LLW and MLLW from out of state.

Impacts of Transportation Accidents. As described previously, two sets of radiological transportation accident impacts were analyzed: (1) impacts of maximum reasonably foreseeable accidents (accidents with radioactive release probabilities greater than 1×10^{-7} [1 chance in 10 million] per year) and (2) impacts of all conceivable accidents (total transportation accidents).

For waste shipped under any of the alternatives, the maximum reasonably foreseeable offsite truck or rail transportation accident with the highest consequences would be a severe collision involving a truck or railcar carrying LLW or MLLW in a 20-foot ISO container (Sealand container) in conjunction with a long-lasting fire. The calculated population doses are based on the maximum population density.

The probabilities of a truck or railcar accident involving this type of waste shipment are slightly different. Transportation accident probabilities were calculated for all route segments (rural, suburban, urban), and maximum consequences were determined for those route segments with a likelihood of release frequency exceeding 1 in 10 million per year. The maximum reasonably foreseeable probability of a truck accident

involving this waste type would be 3.2×10^{-7} per year in an urban area, while the maximum probability for a rail accident would be 8.4×10^{-8} per year in an urban area. Because the maximum probability for a rail accident is less than 1 in 10 million per year, no consequences are presented for rail in Table 5–13. The consequences of the truck transport accident in terms of population dose would be about 180 person-rem. Such exposures could result in less than 1 (0.1) additional LCF among the exposed population. The maximum dose from a truck accident to an MEI located 330 feet from the accident and exposed to the accident plume for 2 hours would be about 0.034 rem, with a risk of 0.00002 LCFs.

Under the No Action Alternative, estimates of the total transportation accident risks for all projected accidents are as follows: a radiological dose risk[1] to the general population of 0.33 person-rem if all trucks are used to transport all radioactive waste and materials, and 0.13 person-rem if a combination of rail and truck are used. This would result in less than 1 LCF (0.0002 LCFs for all trucks and 0.00008 LCFs for a combination of rail and truck). The accident dose risk to the general population if a combination of rail and truck is used is therefore about half of the dose risk associated with using only trucks. Nonradiological accident risks for transporting LLW and MLLW would range from 2 to 6 fatalities to the general population for all truck transport and a combination of rail and truck transport, respectively. Nonradiological risks for all radioactive shipments other than LLW and MLLW would be less than 1 (0.01) fatality.

Accidents at transfer stations have also been considered. Railcars or trucks carrying LLW or MLLW while on the property of a transfer station would have the potential for some of the same accidents that could occur outside of transfer stations. The low speeds at which they would be traveling would result in impacts much less severe than those possible while traveling at higher speeds outside the transfer station. However, transfer station activities introduce an additional accident scenario associated with the transfer of containers between railcars and trucks. Shipments and transfer of LLW or MLLW would not present unique nonradiological risks to workers at a transfer station as containers are moved between trucks and railcars. Transfer facilities routinely receive materials shipped in large containers (for example, ISO containers) and have established procedures for safely transferring them between transport vehicles. In the course of transferring containers, there is the possibility of a mechanical or human error that could result in a dropped container. This presents a physical hazard to workers involved in the transfer, but use of safe working practices should prevent workers from being in locations where they could be hit by a falling container.

There would be a small possibility of an environmental release of radioactive material resulting from a dropped container. In order to cause a release to the environment, the drop would have to cause a breach of the outer container, as well as a failure of the packaging within the container (for example, 55-gallon drums or soft-sided containers). Assuming that such a release did occur, however, the released material would result only in localized contamination; the drop of a container would not have sufficient energy to eject material and cause widespread contamination. There would be a potential for a dose to workers in the immediate vicinity of such an accident, but the magnitude of the dose could vary widely depending on the size of the breach, proximity of workers, and air currents. No impact on a noninvolved worker or a member of the public is expected due to the expected small release amount and distance to these receptors. A more severe accident with enough energy to spread radioactive material beyond the immediate vicinity (e.g., a drop and breach followed by a fire) could result in impacts beyond the immediate vicinity of the accident; impacts would be comparable to or less than those calculated above for the maximum reasonably foreseeable truck accident.

Impacts of Nonradioactive Waste Transport. The impacts of transporting sanitary waste, hazardous waste, and other wastes and recyclables generated at NNSS facilities to onsite or offsite disposal or reuse facilities were also evaluated (including impacts from construction and operation of a commercial solar

[1] *The term "dose risk" is used because the value includes both the likelihood of the accident and the consequence of that accident. The likelihood arises from the accident rate and the probability of container failure along with the potential for the quantities being released and becoming airborne.*

power generation facility), with results shown in Appendix E, Table E–19. The estimated transportation impacts under this alternative would be 2 (1.5) traffic accidents and less than 1 (0.06) traffic accident fatality in 2.0 million two-way miles traveled.

Impacts within the State of Nevada. For both truck and rail-truck transport, crewmembers transporting radioactive materials and waste in Nevada would receive a cumulative dose of about 210 person-rem, resulting in less than 1 (0.1) LCF; this dose would be managed and minimized using administrative controls, as discussed in the previous paragraphs. The public in Nevada would receive a cumulative population dose of about 38 person-rem, resulting in less than 1 (0.02) LCF.

Estimates of the total transportation accident risks that would occur in Nevada under this alternative for all projected accidents involving radioactive materials and waste shipments, regardless of waste type, are as follows: a maximum radiological dose risk to the general population of 0.007 person-rem over the life of expected shipments, resulting in less than 1 (0.000004) LCF, and a maximum nonradiological accident risk of less than 1 (0.2) fatality in the general population over 5.0 million one-way miles traveled.

5.1.3.1.2 Expanded Operations Alternative

5.1.3.1.2.1 Constrained Case

Under the Expanded Operations Alternative, a total of about 94,800 truck shipments of LLW and MLLW would be made to disposal facilities at the NNSS, about 79,300 of which would come from offsite locations. About 42 shipments of TRU waste would be made to INL for treatment; after treatment, this waste would be transported to WIPP. There would be 290 shipments of SNM, 8,200 shipments of nuclear weapons to and from the NNSS for either component replacement or disassembly, and about 2,000 shipments of disassembled parts from weapon dismantlement. There would also be 240 shipments of sealed sources.

Impacts of Incident-Free Transportation

Under this alternative, the radiological impacts of transporting LLW and MLLW by truck would be greater than the impacts of rail-truck transport. Transportation of LLW and MLLW from offsite locations would be the primary contributor to the total radiological and nonradiological impacts of transportation activities. Impacts on crewmembers, transfer station workers, and the public are discussed below.

- Crew – Transport of LLW and MLLW by truck would incur about 5,300 person-rem of exposure, resulting in approximately 3 (3.1) additional LCFs to crewmembers, assuming no administrative controls were implemented. The contributions from transporting TRU waste and radioisotopic thermoelectric generators are minimal (about 3.3 person-rem). If rail-truck transport were used, the cumulative dose to crewmembers during the transportation of waste under this alternative would be about 2,500 person-rem, resulting in about 2 (1.5) additional LCFs.

  The transportation of sealed sources, SNM, and nuclear weapons would contribute only a very small additional amount to total crew exposures (about 250 person-rem, resulting in less than 1 [0.2] LCF) compared to the transport of LLW and MLLW because there would be fewer shipments.

- Transfer station worker – Workers at transfer facilities would be exposed to external radiation fields surrounding the waste shipping containers. As stated under the No Action Alternative, a dose rate of 3.4×10^{-4} person-rem per container transfer from railcar to truck was used. The number of container transfers under the Expanded Operations Alternative would be about 54,000, leading to a total transfer station worker dose of about 18 person-rem.

- Public – The cumulative dose to the general population during transportation of LLW and MLLW by truck would be about 1,100 person-rem, resulting in about 1 (0.7) additional LCF. If rail-truck transport were used, the cumulative dose to the general population would be about 530 person-rem (about 370 person-rem to the population along the rail route and 160 person-rem to the population

along the truck route), resulting in less than 1 (0.3) additional LCF. The contributions from transporting TRU waste and radioisotopic thermoelectric generators are minimal (about 2.4 person-rem). Rail-truck transport would lead to lower doses to the general population because (1) such shipments would be fewer and (2) truck transports would occur primarily in areas of low population density and over shorter distances. Transportation of SNM, sealed sources, and nuclear weapons would contribute about an additional 260 person-rem to the dose to the general population, resulting in less than 1 (0.2) LCF.

Impacts of Transportation Accidents. As described previously, the maximum reasonably foreseeable offsite truck or rail transportation accident with the highest consequences would be a severe collision involving a truck or railcar carrying LLW or MLLW in a 20-foot ISO container in conjunction with a long-lasting fire. The calculated population doses are based on the maximum population density. These waste shipments are expected to occur over the 10-year period. The impacts in terms of dose and risks to the public and individuals are the same as those provided under the No Action Alternative in Section 5.1.3.1.1, although with a greater foreseeable probability of 6.1×10^{-7} per year in an urban area (about twice the probability as compared to the No Action Alternative).

Under the Expanded Operations Alternative, estimates of the total transportation accident risks for all projected accidents are as follows: a radiological dose risk to the general population of 17 person-rem if all trucks are used to transport LLW and MLLW and 8 person-rem if a combination of rail and truck are used. This would resulting in less than 1 LCF (0.01 LCFs for all trucks and 0.005 LCFs for a combination of rail and truck). The dose risk to the general population for transporting wastes and materials other than LLW and MLLW would be about 0.035 person-rem, resulting in less than 1 (0.00002) LCF if all trucks are used. Nonradiological accident risks for transporting LLW and MLLW would range from 7 to 16 fatalities to the general population for all truck transport and a combination of rail and truck transport, respectively. Nonradiological risks for all radioactive wastes and materials other than LLW and MLLW would cause less than 1 (0.2) fatality.

Impacts of Nonradioactive Waste Transport. The impacts of transporting sanitary waste, hazardous waste, and other wastes and recyclables generated at NNSS facilities to onsite or offsite disposal or reuse facilities were also evaluated (including impacts from concentration and operation of one or more commercial solar power generation facilities), with results shown in Appendix E, Table E–19. The estimated transportation impacts under this alternative would be 3 (2.8) traffic accidents and less than 1 (0.11) traffic accident fatality in 3.8 million two-way miles traveled.

Impacts within the State of Nevada. Transport of all radioactive materials and waste through Nevada would incur less than one-tenth of the total incident-free radiological impacts. For both truck and rail-truck transport, crewmembers transporting wastes and radioactive materials in Nevada would receive a cumulative dose of about 450 person-rem, resulting in less than 1 (0.3) LCF; this dose would be managed using administrative controls, as discussed in the previous paragraphs. The public in Nevada would receive a cumulative population dose of about 100 person-rem, resulting in less than 1 (0.06) LCF.

Under the Expanded Operations Alternative, estimates of the total transportation accident risks that would occur in Nevada for all projected accidents involving radioactive materials and waste shipments, regardless of waste type, would be a maximum radiological dose risk to the general population of 0.013 person-rem over the life of expected shipments, resulting in less than 1 (0.000008) LCF for rail-truck transport, and a maximum nonradiological accident risk of about 1 (0.5) fatality to the general population for rail-truck transport over 12 million one-way miles traveled.

5.1.3.1.2.2 Unconstrained Case

The Unconstrained Case addresses the transportation of offsite LLW/MLLW from regions of the United States to the NNSS by (a) all truck, and (b) a combination of rail-truck, as described in Section 5.1.3.1. Appendix E provides more-detailed data regarding the analysis of the Unconstrained Case. While DOE/NNSA is not making any decisions for specific waste transportation routes through this NEPA

process, DOE/NNSA sought to understand the differences in potential environmental effects between different routing options, communicate those differences to the public, and seek stakeholder comments on the range of transportation routes. Subsequently, DOE/NNSA determined that it would retain the current highway routing restrictions for shipments of LLW/MLLW in the greater Las Vegas metropolitan area and, therefore, there would be no need to revise the waste acceptance criteria in this regard (DOE 2012).

All Truck: Table 5–14 summarizes the range of impacts for transporting offsite LLW/MLLW to the NNSS and compares these impacts to the comparable impacts from the Constrained Case (from Table 5–11). The range of impacts reflects multiple routes that could be taken from the Las Vegas entry point to the NNSS. A range is only shown where there is a measurable difference due to using different routes. Based on Table 5–14, if routes are unconstrained, the incident-free risks and accident-related radiological and nonradiological risks would be about the same as those for the Constrained Case.

Table 5–14 Range of Risks for Unconstrained Truck Transport from U.S. Regions to the Nevada National Security Site [a]

From Regions Through Entry Points Below to the NNSS	*Number of Shipments*	*Incident-Free*				*Accident*	
		Crew		*Population*			
		Dose (person-rem)	*Risk (LCF)*	*Dose (person-rem)*	*Risk (LCF)*	*Radiological Risk (LCF)*	*Nonradiological Risk (fatalities)*
Apex [b]	23,500	960 – 970	0.6	230 – 240	0.1	0.0002	2
Arden [b]	3,040	38 – 39	0.2 – 0.3	14	0.008 – 0.009	5×10^{-6} – 7×10^{-6}	0.07
Henderson [b]	27,400	3,000 – 3,100	2	530	0.3	0.0002	2
Total (unconstrained)	**54,000**	**4,000 – 4,100**	**2 – 3**	**770 – 780**	**0.5**	**0.0003 – 0.0004**	**4**
Total (constrained) [c]	**54,000**	**4,900**	**3**	**850**	**0.5**	**0.0003**	**5**

LCF = latent cancer fatality; NNSS = Nevada National Security Site; rem = roentgen equivalent man.

[a] Ranges are shown only where there are differences in results among the routes, assuming three significant figures for shipments, two significant figures for dose, and one significant figure for risk.

[b] There would be two possible routes from Apex, Nevada, three possible routes from Arden, Nevada, and four possible routes from Henderson, Nevada, to the NNSS, as analyzed in this *NNSS SWEIS*.

[c] Results are from Table 5–11. The results do not reflect shipments of LLW/MLLW analyzed in other NEPA documents.

Note: Totals may not sum due to rounding.

Rail-Truck: Rail transport of offsite LLW/MLLW to five possible transfer station locations in the Las Vegas region were analyzed: Apex, Arden, and West Wendover in Nevada; and Kingman and Parker in Arizona. This analysis assumed all rail shipments would go to each of these transfer stations. **Table 5–15** summarizes the range of impacts for transporting offsite LLW/MLLW to each of these transfer stations, trucking the waste from each transfer station to Las Vegas, and subsequently traveling through Las Vegas to the NNSS using different routes, as shown in Figure 5–4. Based on the results in Table 5–15, the incident-free dose to the rail and truck crews would be highest if a transfer station were located at West Wendover because of the longer distance traveled by truck, as compared to other transfer station locations. The risk to the crews, however, would be about the same (1 LCF) for all locations analyzed. While the incident-free population dose and risk can vary somewhat, these differences are small. There would be small differences in radiological accident risks among the different transfer station alternatives. The risk for traffic fatalities would range from 12 to 14, with the use of a transfer station at Parker incurring the highest risk.

Table 5–15 Range of Risks for Unconstrained Rail-Truck Transport from U.S. Regions to the Nevada National Security Site [a]

From Regions to Transfer Stations Below to the NNSS	Number of Shipments	Incident-Free: Crew Dose (person-rem)	Incident-Free: Crew Risk (LCF)	Incident-Free: Population Dose (person-rem)	Incident-Free: Population Risk (LCF)	Accident: Radiological Risk (LCF)	Accident: Non-radiological Risk (fatalities)
Apex	81,000	1,300	0.8	360 – 380	0.2	0.0001 – 0.0002	13
Arden	81,000	1,300	0.8	380 – 390	0.2	0.0001 – 0.0002	13
Kingman [b]	81,000	1,400 – 1,500	0.8 – 0.9	440 – 450	0.3	0.0002	12
Parker [c]	81,000	1,700 – 1,800	1	490 – 500	0.3	0.0002	14
West Wendover [d]	81,000	1,900	1	430 – 450	0.3 – 0.4	0.0001 – 0.0002	12
Constrained Case [e]	81,000	1,800	1	480	0.3	0.0002	13

LCF = latent cancer fatality; NNSS = Nevada National Security Site; rem = roentgen equivalent man.
[a] Ranges are shown only where there are differences in results among the routes, assuming three significant figures for shipments, two significant figures for dose, and one significant figure for risk.
[b] Truck transports from Kingman, Arizona, would use U.S. Route 93 (across the bridge downstream of the Hoover Dam) and enter the Las Vegas area through Henderson, Nevada, from which there would be four possible routes to the NNSS.
[c] Truck transports from Parker, Arizona, would use U.S. Route 95 and enter the Las Vegas area through Henderson, from which there would be four possible routes to the NNSS.
[d] Truck transports from West Wendover, Nevada, would enter the Las Vegas area through Apex, Nevada, from which there would be two possible routes to the NNSS.
[e] Results are from Table 5–11 and represent the combined use of a transfer station at Parker and one at West Wendover. The results do not reflect shipments of LLW/MLLW analyzed in other NEPA documents.
Note: Totals may not sum due to rounding.

Regional Transfer Stations: It is possible that a waste generator may want to transport LLW/MLLW to the NNSS for disposal by rail, but does not have onsite access to rail. In this case, the waste generator would transport waste by truck to a rail-truck transfer station in the generator's region. At least one known waste generator without direct rail access within the Southwest, Northeast, and West regions exists. There would be transportation impacts associated with transport of wastes from these waste generators to a regional transfer station. Because of the uncertainty in whether currently known or unknown waste generators would use a regional transfer station, impacts were estimated for the Southwest, Northeast, and West regions in such a way that would be generally representative of use of a regional transfer station located within a given distance of a generator. **Table 5–16** shows these impacts, assuming a number of shipments that are forecasted to be received from a known generator. Note that these impacts can be proportionally adjusted for other numbers of shipments.

Table 5–16 Transport to Regional Transfer Stations – Impacts

Region	One-way Distance [a] (km/miles)	Number of Shipments	One-way Travel (million km/million miles)	Incident Free [b]: Crew Dose (rem)	Incident Free [b]: Crew Risk (LCF)	Incident Free [b]: Population Dose (person-rem)	Incident Free [b]: Population Risk (LCF)	Accident [b]: Radiological Risk (LCF)	Accident [b]: Traffic Fatality (roundtrip)
Southwest	155/96	7750	1.20/0.75	15	8×10^{-3}	6.7	4×10^{-3}	4×10^{-6}	3×10^{-5}
Northeast	54/34	25	0.0014/0.00087	0.014	8×10^{-6}	0.0071	4×10^{-6}	2×10^{-8}	7×10^{-6}
West	104/65	360	0.037/0.023	0.66	4×10^{-4}	0.28	2×10^{-4}	9×10^{-7}	1×10^{-5}

km = kilometers; LCF = latent cancer fatality; rem = roentgen equivalent man.
[a] It was assumed that the one-way distance for each region encompasses a reasonable distance from a waste generator to a regional transfer station.
[b] The incident-free and accident impacts were calculated using rural, suburban, and urban population densities considered to be representative of the region.

5.1.3.1.3 Reduced Operations Alternative (Constrained Case)

Under the Reduced Operations Alternative, the same number of shipments of LLW and MLLW, and radioisotopic thermoelectric generators would occur as that projected under the No Action Alternative. There would be a reduction in the number of shipments of TRU waste (17 shipments under the Reduced Operations Alternative versus 20 under the No Action Alternative) and SNM (60 shipments under the Reduced Operations Alternative versus 120 under the No Action Alternative). Because the total number of shipments for all waste and materials under these two alternatives is essentially the same, the potential radiological and nonradiological impacts under the Reduced Operations Alternative would be equivalent to the risks under the No Action Alternative.

The impacts of transporting sanitary waste, hazardous waste, and other wastes and recyclables generated at NNSS facilities to onsite or remote disposal or reuse facilities would be slightly less than those under the No Action Alternative, with results shown in Appendix E, Table E–19. The potential impacts under this alternative would be 1 (1.4) traffic accident and less than 1 (0.05) traffic accident fatality in 1.8 million two-way miles traveled.

5.1.3.2 Traffic

5.1.3.2.1 Methodology and Assumptions

Onsite traffic. Onsite traffic impacts at the NNSS were analyzed by evaluating changes in the traffic volume of privately owned vehicles, trucks transporting radioactive waste and nonradioactive waste, and miscellaneous service vehicles. The estimated changes in daily onsite traffic volumes are presented in **Table 5–17**. It was assumed that rates of bus usage by employees under all alternatives would be similar to current conditions; that is, 50 percent of personnel would commute to and from the NNSS using the bus service (see Chapter 4, Section 4.1.3.1). The majority of the truck trips were assumed to transport wastes, based on waste projections. Daily truck shipments of radioactive wastes and materials were estimated based on projections presented in Section 5.1.3.1.

Table 5–17 Incremental Change in Onsite Daily Vehicle Trips on Mercury Highway at the Nevada National Security Site

Segment of Mercury Highway	*No Action*		*Expanded Operations*		*Reduced Operations*	
	POVs	***Trucks***	***POVs***	***Trucks***	***POVs***	***Trucks***
Between U.S. Route 95 and Mercury	+0	+20	+670	+130	-170	+20
Between Mercury and Tippipah Highway	+0	+20	+410	+140	-100	+10
North of Tippipah Highway	+0	+10	+270	+100	-70	+5

POVs = privately owned vehicles.
Note: These estimates do not include traffic volumes associated with the construction and operation of any solar power generation facilities because this traffic would access facilities from a gate located on Lathrop Wells Road and would not likely contribute to traffic volumes on Mercury Highway.

The only available onsite traffic data come from a 1999 traffic study of Mercury Highway (PBS&J 1999); therefore, the onsite traffic impacts in this section are discussed in terms of impacts on Mercury Highway. The study recorded daily traffic volumes on three segments of Mercury Highway. Because Mercury Highway is the main roadway at the NNSS, it was assumed that impacts on this highway represent an upper bound to potential traffic impacts that could occur on other key roadways at the NNSS.

For this analysis, the percent change in the number of daily vehicle trips associated with personnel vehicles and truck transport of miscellaneous wastes and materials reflects the degree of impact on baseline traffic conditions at the NNSS. A "trip" is defined as a one-way vehicle movement from an origin to a destination. Current traffic conditions on Mercury Highway were estimated based on the 1999 onsite traffic study, as discussed in Chapter 4, Section 4.1.3.1. Approximately 90 percent of vehicles currently accessing the NNSS on a daily basis are privately owned vehicles used by commuting workers.

The remaining 10 percent of vehicles are trucks (PBS&J 1999). The number of trips made per day and per peak morning and evening hours were estimated for each alternative and compared with current traffic volumes. To evaluate potential impacts on other principal roadways within the NNSS, the total daily vehicle trips projected to occur on Mercury Highway under each alternative were compared with the capacities of these roadways (main roadways throughout the NNSS were estimated to have capacities exceeding 2,000 vehicles per hour for both directions combined).

Regional traffic. The impacts analysis of regional (i.e., offsite) traffic was based on a determination of the number of personnel and truck trips that would occur under each alternative. Offsite traffic impacts in the region were assessed by estimating the changes in the numbers of daily vehicle trips made under each alternative and applying the changes to baseline traffic volumes on key roadways (for comparison to future baseline conditions, see Chapter 4, Table 4–11, for projected traffic volumes to the year 2020). The estimated changes in daily traffic volumes that were used for the regional traffic analysis are the same as those listed for "Between U.S. Route 95 and Mercury" in Table 5–17, as they reflect the incremental increase in daily traffic volumes that could occur off site. In addition, under the No Action, Expanded Operations, and Reduced Operations Alternatives, vehicles associated with one or more solar power generation facilities were added to these estimates (1,000; 1,500; and 800 daily vehicle trips were respectively added to represent peak construction traffic for conservative estimates). Current traffic volumes, or "average daily traffic," for 2008 were obtained from the Nevada Department of Transportation (NDOT 2008a, 2008b) (see Chapter 4, Table 4–9, for the 2008 average daily traffic volumes).

> The *2000 Highway Capacity Manual* defines six categories of **level of service** that reflect the level of traffic congestion and qualify the operating conditions of a roadway or intersection. The six levels are given letter designations ranging from *A* to *F*, with "*A*" representing the best operating conditions (free flow, little delay) and "*F*" the worst (congestion, long delays) (TRB 2000).

The region of influence (ROI) for the regional traffic analysis includes the principal roadways leading to the NNSS and offsite project locations, with emphasis on the areas surrounding each site; the ROI is limited to Nye and Clark Counties. The geographic distribution of additional vehicle trips is based on the location of main entry points for each of the locations (the NNSS, NLVF, RSL, and TTR) and travel patterns. To determine the travel patterns of future personnel, it was assumed that residential choices for new personnel would correspond to the ratio of current personnel (NSTec 2009d). The geographic distribution of vehicle trips from trucks transporting radioactive waste was based on routes described in Chapter 4, Section 4.1.3.2. Routes for miscellaneous trucks (such as vendors) were assumed to originate and end in the Las Vegas metropolitan area.

To account for increases in traffic from population growth, baseline traffic volumes were projected to the year 2020, assuming an annual increase in traffic volumes of 5 percent for Nye County and Clark County (NV State Demographer's Office 2008). To better reflect operating conditions of the roadways, volume-to-capacity ratios and levels of service on key roadways were determined for the peak hour (see Chapter 4, Table 4–10, for the level of service designations for associated ratio values).

5.1.3.2.2 Summary of Impacts (Nevada National Security Site)

Onsite traffic. Onsite potential impacts from increased daily vehicle trips would include increased traffic congestion and delays, increased need for road maintenance and improvements, and increased risks regarding road safety. Table 5–17 summarizes the incremental changes in daily vehicle trips projected under each alternative that would result from trips made by privately owned vehicles and trucks along the three analyzed segments of Mercury Highway. **Table 5–18** presents the total daily traffic volumes projected under each alternative along the three analyzed segments of Mercury Highway.

Table 5–18 Projected Traffic Volumes on Mercury Highway

Traffic Volume Component	*Segment of Mercury Highway*		
	Between U.S. Route 95 and Mercury Highway	*Between Mercury Highway and Tippipah Highway*	*North of Tippipah Highway*
Baseline Conditions			
Average Daily Traffic	1,748	1,151	764
A.M. Peak Hour	349	172	75
P.M. Peak Hour	349	172	152
No Action Alternative			
Average Daily Traffic	1,768	1,171	774
A.M. Peak Hour	354	176	78
P.M. Peak Hour	354	176	155
Expanded Operations Alternative			
Average Daily Traffic	2,548	1,701	1,134
A.M. Peak Hour	511	255	113
P.M. Peak Hour	511	255	226
Reduced Operations Alternative			
Average Daily Traffic	1,598	1,061	699
A.M. Peak Hour	319	159	70
P.M. Peak Hour	319	159	140

Regional traffic. For regional traffic impacts, increases in traffic volumes could potentially result in traffic congestion and delays, degradation of operating capacities on roadways, degradation of road surfaces and increased frequency in road maintenance, and increased traffic accidents. For each of the alternatives, **Tables 5–19** and **5–20**, located at the end of this section, summarize the projected average daily traffic volumes for 2020, the percent of traffic volume change expected to occur, the volume-to-capacity ratios, and the levels of service for key roadways in Nye and Clark Counties, respectively.

Under future baseline conditions (i.e., traffic conditions in the year 2020 without the NNSS activities proposed under the alternatives), it is predicted that the majority of roadways analyzed would remain similar to current levels of service (see Chapter 4, Table 4–11). As noted in Tables 5–19 and 5–20, the contribution of additional vehicle volumes associated with NNSS activities is considered relatively low (under the No Action and Reduced Operations Alternatives) to moderately high (under the Expanded Operations Alternative) when compared to projected traffic volumes in the region. Only Mercury Highway, which provides direct access to the NNSS from U.S. Route 95, is predicted to experience a degradation of level of service—from level A to B under the Expanded Operation Alternative—as a result of new NNSS activities. Potential impacts on the regional traffic system resulting from construction and operation of renewable energy projects and other development in the area are discussed in Chapter 6, Section 6.3.3.

5.1.3.2.3 No Action Alternative

Onsite traffic. The total daily vehicle trips projected for Mercury Highway under the No Action Alternative would increase by approximately 2 percent from current conditions. The additional traffic volumes on Mercury Highway would be attributable to trucks transporting wastes and materials; minimal incremental traffic increases are expected from privately owned vehicles because the only personnel increase would occur from the proposed solar power generation facility in Area 25, which is not expected to use Mercury Highway at the NNSS. Based on the traffic volumes during peak hours, it is expected that Mercury Highway would operate at a level of service of A. It was assumed that peak traffic volumes on key onsite roadways throughout the NNSS would not exceed the levels projected for Mercury Highway;

therefore, no capacity issues are expected on other key roadways, except possibly for those serving the commercial solar power generation facility in Area 25.

The projected traffic volumes presented in Tables 5–19 and 5–20 do not include potential increases in traffic volumes from construction and operation of the solar power generation facility because personnel and trucks associated with the facility would access the facility from a gate located on Lathrop Wells Road and would not likely contribute to traffic volumes on Mercury Highway. Approximately 500 and 1,000 workers were estimated to be required for construction of this facility during average and peak construction conditions, respectively. Assuming that 50 percent of the construction workers would carpool to the site, approximately 250 (average) and 500 (peak) additional vehicle trips could occur during the peak commute hours (or a total of 500 and 1,000 additional vehicle trips could occur on a daily basis during average and peak construction activities, respectively) on roads leading up to the project site in Area 25. The addition of these vehicles and associated construction trucks on a daily basis (estimated to occur over a 35-month period) would increase the rate of pavement deterioration and degrade levels of service and could require increased road maintenance and upgrades for roads in the project area.

Regional traffic. U.S. Route 95, State Route 160, and State Route 372 would experience the greatest percent increases in daily traffic volumes because these roadways serve an area that is considered characteristically rural and generally experiences relatively low daily traffic volumes. The volume-to-capacity ratios would remain similar for all roadways analyzed, and levels of service are predicted to be the same as those under future baseline traffic volumes (see Chapter 4, Table 4–11). The similarity of traffic conditions under the No Action Alternative and future baseline conditions reflect the minor contribution of NNSS-related activities to overall traffic volumes in the region. The increase in daily trips under this alternative would have minor impacts on traffic congestion in the ROI. Coordination with public safety and maintenance agencies would aid in planning for and mitigating delays resulting from the anticipated increase in traffic volumes.

5.1.3.2.4 Expanded Operations Alternative

Onsite traffic. The total daily vehicle trips projected for the three segments of Mercury Highway analyzed under the Expanded Operations Alternative would increase by approximately 50 percent above current traffic levels, mainly due to the 25 percent increase in NNSS personnel and traffic from construction-related vehicles. Based on the traffic volumes during peak hours, it is expected that Mercury Highway would operate at a level of service of B or better and other key roadways would not have any capacity issues. Drivers accessing the main entry gate would experience longer delays during the peak morning and evening traffic hours, and increased traffic congestion would occur throughout Mercury due to the increase in privately owned vehicles. Drivers on Mercury Highway could experience longer delays or reduced travel speeds due to the high increase in daily truck traffic. Because the incremental increase in onsite traffic volumes would be moderately high, the number of repairs and required maintenance on NNSS roadways would increase at a greater rate than currently experienced.

The projected traffic volumes presented in Tables 5–19 and 5–20 do not include potential increases in traffic volumes from the construction of one or more solar power generation facilities. Personnel and trucks associated with the solar power generation facilities would access the facility from a gate located on Lathrop Wells Road. Approximately 750 and 1,500 workers were estimated to be required for construction of this facility during average and peak construction conditions, respectively. Assuming that 50 percent of the workers would carpool to the site, approximately 375 (average) and 750 (peak) additional vehicle trips could occur during the peak commute hours (or a total of 750 and 1,500 additional vehicle trips could occur on a daily basis during average and peak construction activities, respectively) on roads leading up to the project site in Area 25. The addition of these vehicles and associated construction trucks on a daily basis (estimated to occur over a 42-month period) would increase the rate of pavement deterioration, degrade levels of service, and could require increased road maintenance and upgrades for roads in the project area.

Regional traffic. Roadways in Nye and Clark Counties would generally experience higher increases in traffic volumes. When compared to the No Action Alternative, Mercury Highway and segments of Nevada State Route 372, State Route 160, U.S. Route 95, and State Route 164 would experience moderately high percent increases in daily traffic; however, the operating capacities would remain similar to those under future baseline traffic volumes (see Chapter 4, Table 4–11). Only Mercury Highway would experience a substantially high increase in traffic (an approximately 80 percent increase) and degrade in level of service (from a Level A to a Level B). As most of the increases in daily traffic volumes during the peak hours would be attributable to workers commuting to the NNSS, any detectable changes in traffic volumes would primarily occur during the main commuting hours and at the entry gates of the NNSS (the main entrance gate for regular NNSS employees and Gate 510 for those associated with the construction and operation of the commercial solar power generation facilities in Area 25). Coordination with public safety and maintenance agencies would aid in planning for and mitigating delays resulting from the anticipated increase in traffic volumes.

Table 5–19 includes traffic volumes from the truck transport of radioactive waste and materials under the Unconstrained Case (as discussed in Section 5.1.3.1). Under the Constrained Case, it was assumed that DOE/NNSA would maintain its current operational practice of avoiding transporting waste and materials on the interstate system within Las Vegas. Table 5–20 denotes which study locations would not experience these additional truck volumes under the Constrained Case.

5.1.3.2.5 Reduced Operations Alternative

Onsite traffic. The total daily vehicle trips projected for Mercury Highway under the Reduced Operations Alternative would decrease by approximately 10 percent from current conditions mainly because the number of NNSS workers is expected to decrease by 10 percent. Compared with current conditions, the number of daily trips from privately owned vehicles would decline. Impacts under this alternative would be similar or slightly reduced compared to those under the No Action Alternative; key roadways, including Mercury Highway, would operate well below maximum capacities.

The projected traffic volumes presented in Tables 5–19 and 5–20 do not include potential increases in traffic volumes from the construction and operation of the solar power generation facility because personnel and trucks associated with the facility would enter from a gate located on Lathrop Wells Road and would not likely contribute to traffic volumes on Mercury Highway. Approximately 400 and 800 workers were estimated to be required for construction of this facility during average and peak construction conditions, respectively. Assuming that 50 percent of the workers would carpool to the site, approximately 200 (average) and 400 (peak) additional vehicle trips could occur during the peak commute hours (or a total of 400 and 800 additional vehicle trips could occur on a daily basis during average and peak construction activities, respectively) on roads leading up to the project site in Area 25. The addition of these vehicles and associated construction trucks on a daily basis (estimated to occur over a 32-month period) would increase the rate of pavement deterioration, degrade levels of service, and could require increased road maintenance and upgrades for roads in the project area.

Regional traffic. Under the Reduced Operations Alternative, traffic volumes would increase slightly during peak hours on almost all of the roadways analyzed because the number of personnel at the NNSS would be reduced and most of the additional traffic volumes would be attributable to vehicles associated with the construction and operation of the commercial solar power generation facility. Impacts on regional traffic under this alternative would therefore be slightly less or similar to those described under the No Action Alternative; volume-to-capacity ratios and levels of service would remain unchanged from future baseline conditions (see Chapter 4, Table 4–11).

AADT = annual average daily traffic; LOS = level of service; NLVF = North Las Vegas Facility; RSL = Remote Sensing Laboratory; V/C = volume-to-capacity ratio.
Note: See Chapter 4, Table 4–11, for future (i.e., 2020 without new NNSS activities) baseline traffic volumes, volume-to-capacity ratios, and levels of service.

[a] Source: NDOT 2008b, Clark County.

[b] Percent change in annual average daily traffic under future conditions (i.e., in the year 2020) due to the change in the number of vehicle trips predicted under an alternative.

[c] Under the Constrained Case for the Expanded Operations Alternative, trucks transporting radioactive waste and material would not pass through this location. Therefore, the daily traffic volumes shown for this alternative could be reduced by up to 30 trips.

5.1.4 Socioeconomics

This section addresses potential impacts on the region's socioeconomic conditions. The discussion focuses on the region's economic activity, population, and housing, public finances, and public services. DOE/NNSA assessed the potential for impacts, both beneficial and adverse, based on whether the proposed activities would directly or indirectly result in any of the following:

- Alterations in the projected rates of population growth
- Effects on the housing market
- Effects on local businesses and the economy
- Displacement of existing jobs
- Effects on local employment or the workforce

5.1.4.1 No Action Alternative

5.1.4.1.1 Economic Activity, Population, and Housing

Under the No Action Alternative, a 240-megawatt solar power generation facility would be constructed. Operation of this solar power generation facility would be the sole source of new permanent employment at the NNSS, adding 150 full-time equivalent (FTE) positions to the current employment level of 1,699 (see **Table 5–21** and **Table 5–22**).

Table 5–21 Onsite Employment

Alternative	*NNSS*		*NLVF*	*RSL*	*TTR*	*Total*
	NNSS Only	*Including Solar Power Generation Facility Employees*				
No Action	1,699	1,849	1,442	132	106	3,379
Expanded Operations	2,124 [a]	2,324	1,803 [a]	132	43	4,102
Reduced Operations	1,529 [b]	1,654	1,298 [b]	132	39 [c]	2,998

NLVF = North Las Vegas Facility; NNSS = Nevada National Security Site; RSL = Remote Sensing Laboratory; TTR = Tonopah Test Range.
[a] Current employment number plus 25 percent.
[b] Current employment number minus 10 percent.
[c] Number from the *Complex Transformation Supplemental Programmatic Environmental Impact Statement* minus 10 percent.

Table 5–22 Construction Employment

Alternative	*NNSS* [a]	*NLVF*	*RSL*	*TTR*
No Action	For commercial solar facility, average of 500 FTE positions over 35 months, peak of 1,000 FTE positions.	0	0	0
Expanded Operations	For commercial solar facilities, average of 750 FTE positions over 42 months, peak of 1,500 FTE positions. 250 additional FTE positions from other projects.	0	0	0
Reduced Operations	For commercial solar facility, average of 400 FTE positions over 32 months, peak of 800 FTE positions.	0	0	0

FTE = full-time equivalent; NLVF = North Las Vegas Facility; NNSS = Nevada National Security Site; RSL = Remote Sensing Laboratory; TTR = Tonopah Test Range.
[a] NNSA Plant Construction Numbers based on Amargosa Farm Road Solar Energy Project.

Approximately 10 percent of the 150 FTE positions, or 15 individuals, are expected to relocate as a result of the No Action Alternative. It was assumed that 77 percent would live in Clark County (12 workers) and 23 percent in Nye County (3 workers), consistent with current workforce demographics (NSTec 2009d). Projected rates of population growth would not be altered as a result of the No Action Alternative. Sufficient housing exists in the area (208,275 and 3,202 housing vacancies in Clark and Nye Counties, respectively) to support an increase in population of 15 people. This would result in a

0.01 percent reduction in housing vacancy rates in Clark County and a 0.1 percent reduction in Nye County.

The remaining 135 individuals filling the new jobs are expected to be already living in Clark and Nye counties. Of the 135 individuals, it was assumed that 77 percent would live in Clark County (104 workers) and 23 percent in Nye County (31 workers), consistent with current workforce demographics (NSTec 2009d). This would decrease unemployment in Clark County by 0.07 percent (a total of 142,137 Clark County residents were unemployed as of August 2010). It also would decrease unemployment in Nye County by about 0.99 percent (a total of 3,133 Nye County residents were unemployed as of August 2010).

Daily spending by these new employees would positively affect the immediate area of the NNSS. Purchases made would typically include gasoline, automobile servicing, food and beverages, laundry services, and other retail items. Therefore, a minor beneficial impact on economic activity would occur under the No Action Alternative due to the increase in employment.

The Regional Input-Output Modeling System II (RIMS II) developed for the U.S. Department of Commerce, Bureau of Economic Analysis, was used to evaluate the indirect economic impact on employment of constructing the solar power generation facility. RIMS II provides two types of multipliers, final-demand and direct-effect, for estimating the impacts of changes on employment. An estimate of the change in the total number of jobs in a region's economy was calculated by multiplying the initial change in jobs by a direct-effect employment multiplier. By adding 150 FTE positions to support the solar power generation facility, the analysis showed that approximately 394 secondary jobs would be created. The combined effect of direct and indirect employment would result in a decrease in unemployment in Clark County of about 0.3 percent and about 3.9 percent in Nye County.

Approximately 500 FTE positions over 35 months, with a peak of 1,000 FTE positions, would be filled for construction of the solar power generation facility. Given the high unemployment rates in Clark and Nye Counties (14.7 and 17.2 percent, respectively, as of August 2010), it was assumed that the majority of construction workers hired for construction of the solar power generation facility would currently be living in the area. Between January 2009 and January 2010, 29,800 construction jobs were lost in the State of Nevada (LVRJ 2010). Because relocation of construction workers is unlikely, an increase in population and a decrease in housing availability are not anticipated; only negligible impacts on population and housing are anticipated during construction.

The addition of construction jobs would have a direct economic impact on employment in the region. As construction firms are hired to support the solar power generation facility, regional economic activity (purchases of building materials, construction supplies, and equipment, as well as spending by the construction workers) would also increase. Therefore, construction would have a minor beneficial impact on employment and the local economy.

As described previously, RIMS II was used to calculate the indirect economic impact of the project on employment. An estimate of the change in the total number of jobs in a region's economy was calculated by multiplying the initial change in jobs by a direct-effect employment multiplier. By adding 500 to 1,000 FTE positions, the analysis showed that approximately 930 to 1,860 secondary jobs would be created as a result of construction of the solar power generation facility (DOC 2010). This would reduce the unemployment rate in the region and temporarily benefit the economy and employment in the region.

Public finance. Increased sales transactions for the purchase of materials and supplies for construction of the solar power generation facility would generate some additional revenues for local governments. These impacts would be minor, but beneficial. In addition, revenues for Clark and Nye Counties would increase due to increases in personal income and total employment, which could lead to increased spending.

5.1.4.1.2 Public Services

Public education. For the 2009 to 2010 school year, the Clark County School District student–teacher ratio was 21:1. The student–teacher ratio for the Nye County School District was 18.6:1. Under the No Action Alternative, a total of 28 children could relocate to the area based on a state average of 1.89 children per family (USCB 2000). This represents an increase of 22 children in the Clark County School District (77 percent of the children would reside in Clark County, consistent with current NNSS workforce demographics [NSTec 2009d]) and an increase of 6 children in the Nye County School District (23 percent of the children would reside in Nye County). It is unlikely that all students relocating to the area would be the same age and living in the same neighborhood. However, based on an increase of 22 children to the Clark County School District, one additional teacher may be required in Clark County to maintain the 21:1 student-teacher ratio. No new teachers would be required in Nye County as a result of the No Action Alternative.

Police protection. Under the No Action Alternative, the number of daytime occupants on the NNSS would increase, which could result in more calls for police services. Civilian law enforcement at the NNSS is provided under a contract with the Nye County Sheriff's Department. To maintain the existing level of service, the NNSS would need to increase the number of civilian law enforcement officers under contract due to the increase of 150 permanent employees. Because the increase in number of employees that would relocate to Clark and Nye Counties is only 15 total, there would be no effect on levels of service at the Las Vegas Metropolitan Police Department, the North Las Vegas Police Department, or the Nye County Sheriff's Department. In addition, law enforcement is not provided by the Las Vegas Metropolitan Police Department or the North Las Vegas Police Department.

Fire protection. Construction and operation of the solar power generation facility would increase building density on the NNSS, which could result in additional calls for fire protection. NNSS Fire and Rescue operates out of two fire stations: one in Mercury and a newly constructed station in Area 6 that provides rapid response to emergencies in the forward areas of the NNSS. This impact is expected to be minor and would not affect levels of service at the Clark County Fire Department, the Las Vegas Fire Department, or the Nye County volunteer fire departments.

Health care. It was assumed that the majority of the 150 employees hired to operate the solar power generation facility would be currently living within the ROI. Therefore, the current person-to-hospital-bed ratio within the ROI would remain the same. Construction and operation of the solar power generation facility under the No Action Alternative would not displace any health care facilities or conflict with local and regional plans for health care or emergency services. Therefore, construction and operation of the solar power generation facility would not increase the need for hospital personnel.

5.1.4.2 Expanded Operations Alternative

5.1.4.2.1 Economic Activity, Population, and Housing

Under the Expanded Operations Alternative, it was assumed that operation of commercial solar power facilities, as well as other permanent positions created at the NNSS, would increase employment from 1,699 to 2,324, which would be an increase of 625 jobs (see Table 5–21).

Approximately 10 percent, or 63 individuals, are expected to relocate as a result of the Expanded Operations Alternative. It was assumed that 77 percent would live in Clark County (49 workers) and 23 percent in Nye County (14 workers), consistent with current workforce demographics (NSTec 2009). Projected rates of population growth would not be altered as a result of the Expanded Operations Alternative. Sufficient housing exists in the area (208,275 and 3,202 housing vacancies in Clark and Nye Counties, respectively) to support an increase in population of 63 people. This would result in a 0.02 percent reduction in housing vacancy rates in Clark County and a 0.4 percent reduction in Nye County.

The remaining 563 individuals filling the jobs are expected to be already living in the region. Of these 563 jobs, it was assumed that 77 percent (a total of 434) would live in Clark County and 23 percent (a total of 130) in Nye County, consistent with current workforce demographics (NSTec 2009d).

The 434 jobs added in Clark County would decrease unemployment by 0.31 percent (a total of 142,137 Clark County residents were unemployed as of August 2010). In Nye County, the 130 new jobs would decrease unemployment by about 4.2 percent (a total of 3,133 Nye County residents were unemployed as of August 2010). These additional jobs would represent a minor beneficial impact on employment in Clark County and a moderately beneficial impact on Nye County.

As described under the No Action Alternative, RIMS II was used to calculate the indirect economic impact of the project on employment. By adding 625 direct jobs under the Expanded Operations Alternative, approximately 920 indirect jobs would be created in the ROI. The combined effect of direct and indirect employment would result in a decrease in unemployment in Clark County of about 0.8 percent and about 11.0 percent in Nye County.

Daily spending by new employees would positively affect the immediate area of the NNSS. Purchases made would typically include gasoline, automobile servicing, food and beverages, laundry, and other retail items. Therefore, a minor beneficial impact on economic activity would occur under the Expanded Operations Alternative due to the increase in employment.

Approximately 750 FTE positions over 42 months, with a peak of 1,500 FTE positions, would need to be filled for construction of one or more solar power generation facilities. Other construction projects at the NNSS would require approximately 250 FTE positions over the next 10 years. Given the high unemployment rates in Clark and Nye Counties (14.72 and 17.2 percent, respectively, as of August 2010), it was estimated that the majority of the construction workers would come from within the region. This would temporarily reduce the unemployment rate in the region and would have a short-term beneficial impact on the economy and employment in the region.

RIMS II was used to calculate the indirect economic impact on employment resulting from solar power generation facility construction and other construction projects at the NNSS. An estimate of the change in the total number of jobs in a region’s economy was calculated by multiplying the initial change in jobs by a direct-effect employment multiplier. By adding 750 to 1,500 FTE positions, approximately 1,400 to 2,790 jobs would be created as a result of solar power generation facility construction. The other construction projects would add 250 FTE positions, which would create approximately 466 jobs in the ROI. This would have a moderately beneficial impact on the economy and employment in the region during the period of construction.

As described under the No Action Alternative, regional economic activity would increase as construction firms are hired to support the solar power generation facilities due to the purchase of building materials and construction supplies and equipment, as well as spending by the construction workers. Therefore, construction would have a minor beneficial impact on employment and the economy under the Expanded Operations Alternative due to the increase in employment.

Public finance. As described under the No Action Alternative, increased sales transactions from purchases of materials and supplies for construction of the solar power generation facilities would generate additional revenues for local governments. These impacts would be minor but beneficial. In addition, property taxes collected as a result of the relocation of 49 households in Clark County and 14 in Nye County would increase revenue for local governments.

5.1.4.2.2 Public Services

Public education. As described under the No Action Alternative, for the 2009 to 2010 school year, the Clark County School District student–teacher ratio was 21:1. The student–teacher ratio for the Nye County School District was 18.6:1. Under the Expanded Operations Alternative, a total of 119 children could relocate to the area based on an average of 1.89 children per family (USCB 2008b). This represents an increase of 92 children in the Clark County School District (77 percent of the children would reside in Clark County) and an increase of 27 children in the Nye County School District (23 percent of the children would reside in Nye County). Four additional teachers would be needed in Clark County to maintain the current student–teacher ratio. One new teacher would be required in Nye County under the Expanded Operations Alternative.

Police protection. Under the Expanded Operations Alternative, the number of daytime occupants on the NNSS would increase by 625 employees, which could result in more calls for police services. To maintain the existing level of service, the NNSS would need to increase the number of civilian law enforcement officers under contract due to the increase of 625 permanent employees. As described under the No Action Alternative, this impact on police and public safety is expected to be negligible. It would not affect levels of service at the Las Vegas Metropolitan Police Department, the North Las Vegas Police Department, or the Nye County Sheriff's Department because law enforcement is handled under a separate contract.

Fire protection. Activities under the Expanded Operations Alternative could result in additional calls for fire protection. NNSS Fire and Rescue operates out of two fire stations: one in Mercury and a newly constructed station in Area 6, which provides rapid response to emergencies in the forward areas of the NNSS. This impact is expected to be minor and would not impact levels of service at the Clark County Fire Department, the Las Vegas Fire Department, or the Nye County volunteer fire departments.

Health care. The addition of 625 employees would have only a minor impact on area hospitals and hospital personnel. An eight-bed dispensary in Mercury serves as a clinic for the NNSS. The activities associated with the Expanded Operations Alternative are not anticipated to increase the need for hospital care or personnel within the ROI. However, due to the increase in the number of employees at the NNSS, the clinic in Mercury may need to expand its number of beds.

5.1.4.3 Reduced Operations Alternative

5.1.4.3.1 Economic Activity, Population, and Housing

Under the Reduced Operations Alternative, it was assumed that total employment at the NNSS would decrease from the current level of 1,699 to 1,654, with employment from the operation of the solar power generation facility offsetting most losses associated with a reduction in activity associated with other NNSS programs. This decrease would be equal to about 45 jobs lost: 35 in Clark County and 10 in Nye County. In Clark County, this would increase unemployment by about 0.02 percent (a total of 142,137 Clark County residents were unemployed as of August 2010). In Nye County, the increase in unemployment would be about 0.32 percent (a total of 3,133 Nye County residents were unemployed as of August 2010). Daily spending in the immediate area of the NNSS would decrease correspondingly, which would have a minor adverse impact on economic activity. Housing vacancies would increase and demand for public services would decrease due to the reduction in the permanent workforce.

Approximately 400 FTE positions over 32 months, with a peak of 800 positions, would need to be filled for construction of the commercial solar power generation facility. As described under the No Action Alternative, RIMS II was used to calculate the indirect economic impact of the project on employment. An estimate of the change in the total number of jobs in a region's economy was calculated by multiplying the initial change in jobs by a direct-effect employment multiplier. By adding 400 to 800 FTE positions, approximately 745 to 1,490 jobs would be created as a result of the solar power generation facility construction (DOC 2010), which would have a moderately beneficial impact on the economy and employment in the region.

As described under the No Action Alternative, regional economic activity would increase as construction firms are hired by the commercial sponsor of the solar power generation facility due to purchases of building materials and construction supplies and equipment, as well as spending by construction workers. Therefore, construction would have a minor beneficial impact on employment and the economy under the Reduced Operations Alternative due to the increase in employment.

Public finance. As described under the No Action Alternative, increased sales transactions from purchases of materials and supplies for construction of the solar power generation facility would generate some additional revenues for local governments under the Reduced Operations Alternative. These impacts would be minor, but beneficial.

5.1.4.3.2 Public Services

Public education. For the 2009 to 2010 school year, the Clark County School District student–teacher ratio was 21:1. The student–teacher ratio for the Nye County School District was 18.6:1. Under the Reduced Operations Alternative, no individuals are expected to relocate to these counties; therefore, no new students would enroll in Clark County or Nye County schools and no new teachers would be required as a result of the Reduced Operations Alternative.

Police protection. Under the Reduced Operations Alternative, the number of daytime occupants on the NNSS would decrease, which could result in fewer calls for police services, which would be a minor beneficial impact on police protection resources.

Fire protection. Construction and operation of the solar power generation facility would result in increased building density on the NNSS, which could result in additional calls for fire protection. NNSS Fire and Rescue operates out of two fire stations, one in Mercury and a newly constructed station in Area 6, which provides rapid response to emergencies in the forward areas of the NNSS. This impact is expected to be minor and would not impact levels of service at the Clark County Fire Department, the Las Vegas Fire Department, or the Nye County volunteer fire departments.

Health care. Under the Reduced Operations Alternative, a small staff reduction of 45 people is anticipated, but would not result in any impact on health care in the region. Existing levels of services would be maintained.

Socioeconomics—American Indian Perspective

CGTO

Indian people prefer to live in our traditional homelands. One primary reason for this is because Indian people have special ties to our traditional lands and a unique relationship with each other. When Indian people receive employment near our reservations, we can remain on the reservations while commuting to work. This pattern of employment tends to have positive benefits for both the Indian community and tribal enterprises like housing. The reservation Indian community has the participation of the individual and his (her) financial contribution. The individual payment for housing is tied to income level, so the more a person earns with the job, the more they pay to the tribal housing office, and thus making tribally sponsored housing more economically sustainable and attractive for tribal governments.

When employment opportunities decline on reservations, however, Indian families must often move away from our reservations to seek employment elsewhere. As Indian people move away, Indian culture is threatened because the number of families living on reservations declines. Tribal members who choose to relocate from their reservations impact reservation economies, school, housing, and emergency services. Both schools and economies are impacted because federal funding available to tribes is based on population statistics.

With local employment opportunities such as those offered by the Nevada National Security Site (NNSS) for eligible tribal representatives, prices of tribal housing rise because they are based on income. If a positive balance between increased income and increased cost of living in tribal reservations is achieved, then both individual members and the tribe benefit from employment opportunities.

Tribal housing programs become jeopardized if vacancies occur in rental properties and dwellings remain unoccupied. If vacancies occur, tribal revenues and federal funding are adversely impacted and making it more difficult to expand housing programs in future years.

Additionally, vacant units require more maintenance. If tribal members are unavailable to occupy a tribal housing unit, then tribes make units available to non-Indians, and this, too, potentially impacts Indian culture. The increased presence of non-Indians on a reservation or in an Indian community reduces the privacy needed for the conduct of certain ceremonies and traditional practices. When non-Indian children are in constant interaction with Indian children, it creates a situation that potentially disrupts the perpetuation of cultural learning opportunities that occur in everyday life.

When Indian people move away from our reservations several dilemmas occur. Typically, Indian people experience a feeling of isolation from their tribe, culture, and family. When an Indian person relocates to an off-reservation area, the individual finds that there are fewer people of their tribe and culture around them. As a result, Indian people must decide on the appropriateness of practicing traditional ceremonies in the presence of non-Indian people. Indian people are continually torn between the decision to stay in the city or return to the reservation to participate in traditional ceremonies and interact with other tribal members. This dilemma occurs on a regular basis and potentially impacts the livelihood and cultural well-being of off-reservation employees and their families. When off-reservation individuals choose to return to our homelands to participate in traditional ceremonies or renew familial ties, they risk losing their jobs or being subjected to disciplinary actions against their children who attend public schools due to excessive absenteeism.

Under federal and tribal law, American Indian children can be educated in tribally-controlled and federally-certified schools located on Indian reservations (also known as Indian Trust Land). Federal funds are available through the Indian Education Act for the education of Indian children. Compensation from the federal government is provided to any school district that has entered into a cooperative agreement with federally-recognized tribes, whether it be public, private, or an Indian-controlled school.

Small rural Indian reservations must have a sufficient number of people to generate an emergency response capability. The need for emergency services will decline as people move away from the reservation. Tribal members employed in these emergency service occupations may move away because of their marketable skills. Tribal revenues for administration, school, housing, and emergency services will be reduced accordingly, due to a decline in population size.

Indian reservations within the region of influence are located in remote areas with limited access by standard and substandard roads. Should an emergency situation occur resulting from NNSS-related activities, including the transportation of hazardous and radioactive waste, it could result in the closure of the main or only transportation artery to our land. If a major (only) road into a reservation closes, numerous adverse social and economic impacts could occur. For example, Indian students who have to travel an unusually high number of miles to or from school could realize delays. Delays also could occur for regular deliveries of necessary supplies for inventories needed by tribal enterprises and personal use. Emergency medical services en route to or from the reservation, and purchases by patrons of tribal enterprises could be dramatically impeded. Potential investors interested in expanding tribal enterprises, as well as on-going considerations by tribal governments for future tribal enterprises, may significantly diminish because of the real and perceived risks from the transportation of hazardous and radioactive waste associated with NNSS-related activities.

See Appendix C for more details.

5.1.5 Geology and Soils

This section addresses the impacts on geology and soils under the No Action, Expanded Operations, and Reduced Operations Alternatives. Under each alternative, the impact discussion is broken down into the missions and associated programs. The physical setting under review in this section includes the topography, physiography, economic mineral resources, unique geologic features, soils, and local geologic hazards.

Impact Assessment Criteria. Activities under an alternative would have an adverse impact on the geology or soils if they result in any of the following effects:

- Substantial soil erosion or loss of topsoil
- Direct conversion of prime and unique farmland to nonagricultural uses
- Loss of availability of a known mineral resource that would be of value to the region and/or the residents of the state
- Increased instability of a geologic unit or soil due to project activities, potentially leading to an onsite or offsite landslide, subsidence, or collapse
- Exposure of people or structures to substantial adverse effects from seismic activity
- Contamination of soil or mineral resources

Maps, past studies, and regional models were used to determine the impacts from the alternatives on the physical setting based on the criteria described above. Activities that would occur in already established facilities, tunnels, or laboratories generally would not have an impact on the geologic resources. Mitigation measures used to minimize adverse impacts on the physical setting are presented in Chapter 7.

5.1.5.1 No Action Alternative

Chapter 3 describes the activities that would occur under the No Action Alternative. Many of the activities are similar to those described in the ROD for the *1996 NTS EIS* (and subsequent amendments) and other completed NEPA documents. The NNSS was withdrawn from public access and entry. This withdrawn status prevents exploration for economic minerals at the NNSS. The existence of past mines prior to the land withdrawal suggests that metallic and other economic minerals are present at the NNSS. However, the activities outlined under the No Action Alternative are not expected to affect the presence of economic mineral deposits, which would allow their extraction in the future. The unavailability of the minerals and other economic materials from the NNSS has had little effect on Nevada's mining, manufacturing, and construction industries and would probably have little effect on those industries in the future.

Open borrow pits at the NNSS may continue to be used to supply the NNSS with fill for construction or operations purposes. No new borrow pits would be opened under the No Action Alternative. Removing alluvial materials for fill would not substantially reduce the aggregate resources in the region. The NNSS has a low potential for oil and gas resources, so there would be no impact on the regional energy mineral resources.

The Natural Resources Conservation Service has not characterized soils at the NNSS, and the presence of prime farmland is not known. As agriculture production in Nevada requires irrigation, the best potential for prime farmland soils would be located in the deepest sections of Yucca Flat, Frenchman Flat, and Plutonium Valley (see Chapter 4, Section 4.1.5.3). However, as there are no plans for irrigating the valley floors, the presence of prime farmland soils at the NNSS is extremely unlikely. Therefore, the actions under all of the alternatives would not have an impact on regional prime farmland soil availability.

The following discussion presents the potential for impacts from the programs and activities proposed under the No Action Alternative that could affect geologic or soil resources.

5.1.5.1.1 National Security/Defense Mission

Stockpile Stewardship and Management Program. Under the No Action Alternative, DOE/NNSA would maintain the capability to conduct underground nuclear weapons testing. As maintenance of the facilities and utilities would occur at already disturbed outdoor or enclosed locations, maintaining this capability and the nuclear weapons stockpile would not impact geologic or soil resources.

There would be no impact on the physical setting from conducting dynamic experiments at the U1a Complex, or in unused vertical emplacement holes or other locations within the Nuclear Test and Nuclear and High Explosives Test Zones. These experiments would occur within areas previously excavated for facility construction or past tests. Some alluvial materials may need to be excavated if the U1a Complex needs additional experiment alcoves. However, the excavated material could be used for construction or as fill at the NNSS, which would reduce the overall need for alluvial materials from other borrow pits.

Conducting conventional high-explosives experiments would impact soils and geology. Activities would consist of up to 20 conventional high-explosives experiments per year at BEEF and up to 10 per year at other locations at the NNSS. Open-air high-explosives experiments at BEEF would occur on a constructed firing table in locations previously disturbed through construction and past tests, which would preclude impacts on the soil and alluvial geologic deposits. However, surface soils would be disturbed if an open-air detonation were to occur at previously undisturbed locations. This would increase the potential for soil erosion by wind and water at the experiment location. Depending on the type of experiments and composition of the high-explosive material that would be used, soils could be contaminated with chemicals, heavy metals, hydrocarbons, or small amounts of radiological isotopes. Additional impacts would be seen through the alteration of natural drainage paths, which would result in a potential for preferential erosion of alluvial deposits and increased sediment deposition in the valleys. However, the potential experiment locations (Areas 1, 2, 3, 4, 12, and 16) have been previously disturbed, so the surface disturbance would be minor. If soils were significantly contaminated by explosives experiments, they would be identified as a corrective action site and would be remediated as necessary.

There would be no impact on the physical setting from DOE/NNSA's conduct of shock physics experiments under the No Action Alternative. The experiments would occur within existing facilities at JASPER in Area 27 and the U1a Complex in Area 1. Any additional construction required at the U1a Complex to accommodate the Large-Bore Powder Gun would occur in areas that were previously disturbed by surface construction and would likely use alluvial materials previously excavated from the complex.

The physical setting would not be impacted by conducting criticality experiments, training, and other activities or pulsed-power and plasma physics and fusion experiments because these tests would occur within current facilities. Stockpile management activities at the NNSS would also occur within existing facilities and would not require additional surface or subsurface disturbance.

Some localized impacts on the surface soil structure would occur in off-road locations from DOE/NNSA and the U.S. Department of Defense (DoD) conducting training activities for the Office of Secure Transportation in off-road locations. Driving vehicles through undisturbed soils and vegetation would disturb the soil structures and increase soil erosion by wind.

DOE/NNSA would perform up to five drillback operations during the next 10 years. Each operation would disturb approximately 5 acres for the construction laydown area, borehole, and temporary storage of excavated material. The drillback sites would be located adjacent to an existing UGTA, so the surface disturbance would be minimal compared to the original test area.

Nuclear Emergency Response, Nonproliferation, and Counterterrorism Programs. Most of the activities under these programs would be located at existing disturbed areas and developed facilities at the NNSS and, therefore, would not impact the physical setting. Support for the following activities would

not impact the physical setting: consequence management through the Federal Radiological Monitoring and Assessment Center, Accident Response Group, and Radiological Assistance Program, as well as weapons of mass destruction emergency responder training. The disposition of improvised nuclear and radiological dispersion devices would also occur within existing facilities and would not result in land disturbance.

Some nonproliferation- and counterterrorism-related activities would use existing facilities at the NNSS, so they would not impact the physical setting. An Arms Control Treaty Verification Test Bed would use existing capabilities, such as the Nonproliferation Test and Evaluation Complex (NPTEC), BEEF, various tunnels, laboratories, and training facilities, to support design and certification of treaty verification technology, training of inspectors, and development of arms control confidence-building measures. An existing building at Mercury would be retrofitted for uses not supplied by the other facilities. No impacts on the physical setting would occur because the activities would occur at existing structures at the NNSS.

Nonproliferation programs would use several areas and facilities at the NNSS as a base of operations for collaboration and experiments. Unique facilities at the NNSS, including NPTEC, previously contaminated surface locations, and tunnels, would be used to support training and exercises. Although some exercises would likely cause minor soil disturbance, it would be in areas already disturbed by historical testing. Nuclear forensics activities would occur in previously disturbed areas and existing facilities and would not impact soils or geologic media.

The NNSS would also be used for a counterterrorism training program with various U.S. agencies and possibly international participants. This program would be conducted at BEEF, NPTEC, and other locations at the NNSS. Some high explosives would be used as part of the training, so the impacts would be similar to those described for the high-explosion experiments under the Stockpile Stewardship and Management Program. There would be a potential for increased soil erosion and surface instability where training occurs in the rugged terrain and previously undisturbed areas of the NNSS.

Work for Others Program. Several projects are included in the Work for Others Program. Some of the activities would use existing facilities and would not impact the physical setting. Others may require construction or experiments that would introduce additional surface disturbances at the NNSS.

No impacts would occur from DOE/NNSA hosting activities for treaty verification, including research and development, because the activities would occur within the existing facilities.

Conventional weapons effect tests (including live drop and static high-explosive detonations) using up to 30,000-pound-class weapon systems with up to 20,000 pounds of TNT [2,4,6-trinitrotoluene]-equivalent explosives would be performed within the Nuclear and High Explosives Test Zone. Other types of explosives experiments would occur in various locations at the NNSS, as described in Chapter 3, Section 3.1.1.3. Surface soils would be disturbed if an open-air explosive experiment were to occur at a previously undisturbed location. This would increase the potential for soil erosion by wind and water at the testing location. Surface drainage may be altered, which would increase the potential for erosion from increased gullying. Many locations in Areas 1, 2, 3, 4, 12, and 16 have been disturbed by past tests, so the surface disturbance would not be unique to these areas.

Other activities, such as development and demonstration of capabilities and technologies against deeply buried hardened targets, would be based primarily in the U16b Tunnel of Area 16, but could also be conducted at other existing locations at the NNSS. Elsewhere, up to 20 controlled chemical and biological simulant release experiments would be conducted annually to test sensors and train first responders. The location of these experiments has not been determined. The release of simulants would not affect the physical setting.

Joint counterterrorism training between DoD, DHS, and other Federal agencies would occur in the remote areas of the NNSS. Small arms live-fire and small explosions would be used as part of the training; however, the impacts would be similar to those described for the high-explosion experiments under the

Stockpile Stewardship and Management Program. There would be a potential for increased soil erosion and surface instability where training occurs in the rugged terrain and previously undisturbed areas of the NNSS. Other training would include overland navigation techniques, which would introduce more soil disturbance to locations that may not be previously disturbed. This would generate minor soil impacts by increasing the potential for erosion and introducing some surface instability to the area.

The criticality experiments for NASA and the miscellaneous Work for Others Program activities would not introduce impacts because they would use existing facilities.

5.1.5.1.2 Environmental Management Mission

Waste Management Program. DOE/NNSA operates facilities at the NNSS to manage radioactive waste generated both within Nevada and out of state by DOE/NNSA and other authorized generators. The Area 5 RWMC evaluates, processes, stores, and disposes LLW and MLLW. The facility uses excavated trenches, pits, and boreholes in an approximately 740-acre area.

On December 1, 2010, the Nevada Division of Environmental Protection (NDEP) issued a permit to the DOE/NNSA NSO for a new MLLW Disposal Unit at the Area 5 RWMC. The new MLLW Disposal Unit consists of a single lined cell (Cell 18) with a capacity of about 900,000 cubic feet (actual permitted disposal volume is 899,996 cubic feet). Construction of Cell 18 is complete and it began accepting MLLW for disposal in January 2011.

Under the No Action Alternative, less than 50 percent of the approximately 740-acre Area 5 RWMC would be used for LLW and MLLW disposal cells over the next 10 years. Once filled, disposal cells would be operationally capped, pending final closure. Preshipment storage of TRU waste, mixed TRU waste, MLLW, and hazardous wastes at the NNSS would not generate impacts on soils because the wastes would be stored on existing storage pads.

The Area 3 Radioactive Waste Management Site (RWMS) was constructed by excavating underground nuclear test subsidence craters that met specific design criteria and would be closed with an engineered cap. The Area 3 RWMS is not active, although it would be reactivated, if necessary, and its existing craters would be used for disposal of onsite LLW or nonhazardous solid waste.

Open-air detonation of old or unusable explosives would continue at the Explosives Ordnance Disposal Unit in Area 11 and would not result in additional soil disturbance.

The hydrocarbon-contaminated waste disposal sites (Area 6 Hydrocarbon Solid Waste and U10c Solid Waste Disposal sites) would continue to operate under their respective permits issued by NDEP and would not create any additional impacts on geologic resources or soils.

Environmental Restoration Program. The Soils Project under the Environmental Restoration Program would continue to investigate, characterize, and close contaminated soil sites previously identified in the corrective action units. Under the Environmental Restoration Program, each contaminated site is prioritized and evaluated to determine the appropriate corrective action. Depending on the nature and extent of the contamination, either a streamlined or complex corrective action process would be used. Some soil sites may be closed in place with appropriate controls; others may be closed with other actions, such as stabilization and/or excavation of contaminated soil and disposal (FFACO 2008). Closure of these sites is conducted under the Federal Facility Agreement and Consent Order (FFACO) with approval by NDEP. If the appropriate corrective action includes contaminated soil removal, there would be a temporary increase in erosion from the disturbance of the soil. This would increase the potential that soil could be moved by wind and water processes.

Under the Soils Project outlined in the *1996 NTS EIS* (DOE 1996c), approximately 3,257 acres of plutonium-contaminated soils would be dispositioned at the NNSS, the TTR, and the Nevada Test and Training Range (formerly the Nellis Air Force Range Complex) (DOE 1996d). As of 2009, several corrective action sites in Frenchman Flat, Oak Spring, Yucca Flat, and Buckboard Mesa were declared

closed by a corrective action document (FFACO 2009). DOE/NNSA anticipates that all identified Soils Project sites would be closed under the Environmental Restoration Program by the end of 2022.

Drilling additional monitoring wells under the UGTA Project would result in localized erosion around the drilling locations. Similar impacts would result from the decontamination and demolition of industrial sites, remediation of Defense Threat Reduction Agency (DTRA) sites, and the Borehole Management Program.

Because petroleum fuels, lubricants, and a variety of chemicals are used and stored at the NNSS, there is a chance that an accidental spill could contaminate the soil surface. If an accidental release of hydrocarbons were to occur, the soils contaminated with hydrocarbons would be removed and disposed in permitted and approved landfills. With spill prevention and mitigation measures in place, the potential for soil contamination would be reduced.

5.1.5.1.3 Nondefense Mission

General Site Support and Infrastructure Program. Under the No Action Alternative, infrastructure-associated activities would be primarily limited to projects that maintain the present facility capabilities, such as repairs and replacements. There would be no increasing of the capabilities or extending the ranges of the existing infrastructure. Although repairs may require some surface disturbance around the existing facilities, it would be limited to areas that were previously disturbed, and would not significantly increase surface erosion around at the NNSS.

Conservation and Renewable Energy Program. Under the No Action Alternative, implementing efficiency and conservation for energy and water, continuing transportation and fleet management, and upgrading the facilities at the NNSS to high-performance, sustainable buildings under the NNSS Conservation and Renewable Energy Program would result in no impacts on the local geology or soils.

A 240-megawatt commercial solar power generation facility would be constructed in Area 25 under the No Action Alternative. Construction of the commercial solar power generation facility and associated transmission lines could disturb up to 2,650 acres. Most of the soils in Area 25 have not been modified through construction or other uses, so construction of the solar power generation facility would affect topsoil and increase the potential for erosion in Jackass Flats.

Other Research and Development Programs. DOE/NNSA would continue to host environmental research projects at the NNSS, but would not actively promote the National Environmental Research Park Program. Each research project would be reviewed by DOE/NNSA on a case-by-case basis. Although minor amounts of soil may be disturbed during the data-gathering or research procedures, the effects would be temporary.

5.1.5.2 Expanded Operations Alternative

The potential impacts of implementing the Expanded Operations Alternative would largely be similar to those discussed above under the No Action Alternative. However, some additional facilities and activities are proposed, and some activities would be expanded or increased, which could magnify the impacts of the No Action Alternative. The sections below present the alternative activities that have different impacts from those described in Section 5.1.5.1.

5.1.5.2.1 National Security/Defense Mission

Stockpile Stewardship and Management Program. There would be no additional impacts from DOE/NNSA's maintenance of the potential to conduct underground nuclear weapons testing under the Expanded Operations Alternative. Several activities under the Stockpile Stewardship and Management Program would remain the same as those under the No Action Alternative, including disposition of damaged U.S. nuclear weapons, criticality experiments, and drillback operations. The potential impacts would be the same as those described under the No Action Alternative.

Under the Expanded Operations Alternative, the number of dynamic experiments would increase to 20 per year, all within the Nuclear Test and Nuclear and High Explosives Test Zones at the NNSS. The increase would not impact the physical setting because the experiments would occur within existing facilities. At BEEF, up to 100 conventional explosives experiments would occur every year. A new firing table and ancillary facilities would also be constructed to support the additional experimental needs. These features would be constructed within the existing developed BEEF facility area. Therefore, the potential for erosion would likely be minor. DOE/NNSA would increase the size and number of high explosives at the Nuclear and High Explosives Test Zone. The impacts are described further in the Work for Others Program section below.

DOE/NNSA would establish up to three areas dedicated to conducting explosive experiments with depleted uranium in Areas 2, 4, 12, or 16. Up to 20 experiments would be performed each year using a cumulative maximum of 4,000 pounds of depleted uranium and 12,000 pounds (TNT-equivalent) of high explosives. These detonations would impact soils in the area because the explosions would remove the topsoil and increase the potential for erosion by wind. The use of depleted uranium in the experiments would increase the radioactivity in the soils at the experiment locations. These experiments would be located in research areas that have previously hosted extensive underground and atmospheric testing. Some of the experiment sites would likely be located on areas (e.g., Yucca Flat, Rainier Mesa, and Shoshone Mountain) that had undergone previous underground nuclear testing. After the experiments and cleanup, radiation monitoring would determine whether a site would need to be included in the Soils Project of the Environmental Restoration Program.

There would be no impact on the physical setting from DOE/NNSA's increasing the number of shock physics experiments under the Expanded Operations Alternative. The experiments would occur within existing facilities, and opening the facilities to academic and other research would not require constructing new buildings. There would be no impacts on the physical setting from increasing the number of pulsed-power experiments at the Atlas Facility. There would be no impact from the staging of SNM under the stockpile management activities because it also would occur within existing facilities on NNSS property.

No impact on the physical setting would occur by expanding the use of the NNSS Dense Plasma Focus machine. There is no indication that moving the machine to another building in Area 6 would require the construction of additional facilities, so moving the equipment to a new location would not disturb soils or affect unique geologic resources. The old building in Area 11 would be placed on standby.

Under the Expanded Operations Alternative, DOE/NNSA would construct new support facilities near Eleana Ridge in Area 17 to support the Office of Secure Transportation training programs. The new facilities, consisting of buildings and training areas, would occupy approximately 10,000 acres, including about 25 miles of internal roads and firebreaks around the active training areas. A 4.5-mile utility corridor for electrical lines and a water pipeline would be built to support the new facility. As a result, there would be temporary impacts on soils from construction surface disturbance. Additionally, facilities would be expanded in the Area 12 Camp, Area 6 Control Point, or in Mercury (Area 23), which would temporarily increase the soil erosion around the construction site.

Soils would be disturbed from grading the facilities' location, developing roads, and excavating the pipeline trench, as well as from construction equipment moving across the desert surface. Soils disturbed during construction would have a potential for increased erosion from wind and water, and some soils would be permanently disturbed underneath the new structures and roads. The utility corridor would be restored by replacing topsoil and encouraging native vegetation growth. Some of the roads would not be paved; the existing soil structure would be compacted for stability. The facilities would be sited and designed to minimize the geotechnical hazards (e.g., shrink-swell soils, slope instability) that could affect the new structures.

Nuclear Emergency Response, Nonproliferation, and Counterterrorism Programs. Under the Expanded Operations Alternative, there would be no changes compared with the No Action Alternative for the following projects and activities under the Nuclear Emergency Response, Nonproliferation, and Counterterrorism Programs: consequence management support for the Federal Radiological Monitoring and Assessment Center, the Accident Response Group, and the Radiological Assistance Program; weapons of mass destruction emergency responder training; assistance for the Emergency Communications Network; and improvised nuclear device dispositioning and forensics.

Some of the nonproliferation- and counterterrorism-related activities would remain similar to those under the No Action Alternative; however, new facilities would be constructed to support program requirements. These new facilities, described below, are still conceptual in nature, so additional NEPA review may be required once locations and plans are finalized. The Arms Control Treaty Verification Test Bed project would need both indoor and outdoor laboratory and test areas, which would require a total of 100 acres of land. The facilities would be sited at various locations within the NNSS. Approximately 0.23 acres would be needed to construct a new facility for data fusion analysis and visualization. This facility would be located near the other Arms Control Treaty Verification facilities. Construction of the new facilities would increase the potential for erosion of the soils and permanently disturb about 100 acres of soils. This would result in minor impacts on soils.

A new facility would be constructed to contain a nonproliferation test bed, which would simulate clandestine chemical and radiological releases. The impacts on the soils would be similar to the impacts of the Arms Control Treaty Verification facilities, i.e., about 100 acres of land disturbance.

In addition to conducting counterterrorism training at existing facilities, an Urban Warfare Complex would be constructed at the NNSS. This complex would include full-scale, modular replicas of the types of urban areas where terrorists and insurgents typically seek refuge. The Urban Warfare Complex would be constructed on about 100 acres in a remote area on the NNSS. The impacts on the soils would be similar to the Arms Control Treaty Verification facilities. Further NEPA review would be required once more information about the proposed facilities and locations becomes available.

Work for Others Program. The treaty verification activities under the Work for Others Program would be the same as those described under the No Action Alternative; as a result, they would have no impact on the physical setting. The Nonproliferation Projects and Counterproliferation Research and Development would add additional sensor technologies and active interrogation programs to detect nuclear material. The impacts would be the same as those described under the No Action Alternative.

New facilities would be constructed to support counterterrorism activities. Approximately 75 acres of land would be disturbed to build test beds (roads, intersections, small towns, etc.) and support facilities for research and development of improvised explosive device sensors. Additional DHS counterterrorism operations support facilities would disturb 25 acres of land. As a result, there would be minor, temporary impacts on soils from construction activities. Further NEPA review would be required after more information about the proposed facilities and locations becomes available.

DOE/NNSA would support NASA nuclear rocket motor development by allowing the use of an existing borehole for tests of a prototype nuclear rocket motor. As an existing borehole would be used, impacts would be limited to surface disturbance around the test site. Although it is not likely that NASA would test an actual nuclear rocket motor, spiked xenon may be used for proof-of-concept tests. As a result, soils would be contaminated with short-lived xenon isotopes with half-lives of a few hours to days.

Several new facilities would be constructed to support the increased use of aerial platforms at the NNSS. Approximately 4.6 acres would be disturbed at Desert Rock Airport for support hangars and other buildings. Another 4.6 acres would be disturbed at the Area 6 Aerial Operations Facility, and minor improvements would be made to the Pahute Mesa Airstrip. Other aerial platform facilities at other locations at the NNSS would disturb up to a total of 0.11 acres. In addition, 100 acres of previously undisturbed land in Area 6 would be needed for expansion of the RNCTEC facility for DHS.

Construction would disturb soils and increase the potential for erosion, especially in previously disturbed locations.

Radioactive tracer experiments would be conducted under the Expanded Operations Alternative. Underground releases of radioactive noble gases with noncritical detonations would temporarily contaminate the subsurface with radiological isotopes. However, these isotopes have short half-lives, typically 5 to 36 days. Up to 12 experiments involving open-air releases would be conducted each year. There would be temporary impacts on soils from contamination by these short-half-life radioisotopes.

New research and development test beds supporting national security initiatives would be constructed on 200 acres of previously undisturbed land throughout the NNSS. The test beds would be used by several agencies and for a variety of uses. Construction would disturb soils and increase the potential for their erosion, especially in previously disturbed locations. This would cause a minor impact on the soils, as surface disturbance would increase the potential for erosion.

5.1.5.2.2 Environmental Management Mission

Waste Management Program. Under the Expanded Operations Alternative, the greatest impact on geologic media and soils would result from the increased volumes of LLW and MLLW that would be disposed at the Area 5 RWMC (and potentially the Area 3 RWMS). New disposal cell construction for the increased volumes of LLW and MLLW, combined with previously constructed cells, would use essentially all of the available land within the Area 5 RWMC. To handle the increased volumes and increased shipment rates of LLW and/or MLLW, a waste off-loading and a container staging area would be built at the Area 5 RWMC. Construction of the new waste off-loading and a container staging area would increase surface disturbance and increase soil erosion; it would be located within the approximately 740-acre area of the Area 5 RWMC. The Area 3 RWMS would be reopened, which may result in additional surface disturbance.

DOE/NNSA would construct a new sanitary waste landfill in Area 23. Fifteen acres of land would be required for construction and operation of the new landfill. A construction and demolition debris landfill would be constructed in Area 25, which would require 20 acres of surface disturbance. These landfills would not impact the subsurface geology, although the surface disturbance would increase the potential for soil erosion around the construction site. Once the landfills are operational, soil erosion would be negligible.

Environmental Restoration Program. Under the Expanded Operations Alternative, the Environmental Restoration Program would continue, in compliance with the FFACO. Therefore, the impacts would be the same as those described under the No Action Alternative. The UGTA, Soils, and Industrial Sites Projects; remediation of DTRA sites; and Borehole Management Program would also continue.

5.1.5.2.3 Nondefense Mission

General Site Support and Infrastructure Program. The Expanded Operations Alternative would implement the same small projects to maintain the present capabilities at the NNSS; as a result, these projects would have similar impacts on soils as those described under the No Action Alternative. In addition to these maintenance activities, new infrastructure enhancements, which could affect soils by disturbing the topsoil during construction and demolition activities, would be implemented. Outdated facilities in Area 23 would be replaced with a new security building. Construction of this security building would disturb up to an acre of soils, which would increase the potential for erosion. The outdated structures would be demolished or used for other purposes. Other projects would include replacing about 35 miles of the existing 138-kilovolt electrical transmission system, increasing the number of cell towers at the NNSS, and constructing/demolishing buildings in Mercury. Each of these projects would disturb topsoil and increase the potential for erosion during construction and demolition. In remote locations with fewer structures and more previously undisturbed land, such as the cell-tower locations, the potential for erosion and soil disturbance would be higher.

Conservation and Renewable Energy Program. DOE/NNSA would implement energy efficiency conservation and water measures, continue transportation and fleet management efforts, and upgrade the facilities at the NNSS under the NNSS Conservation and Renewable Energy Program. These activities would not affect the local geology or soils.

Under the Expanded Operations Alternative, DOE/NNSA would build a 5-megawatt photovoltaic solar power generation facility near the Area 6 Construction Facilities. Based on a similar project on Nellis Air Force Base, construction and operation of this solar power generation facility would disturb 50 acres of land (USAF 2006c). DOE/NNSA would also permit one or more commercial solar power generation facilities with a generating capacity of up to 1,000 megawatts in Area 25. These commercial solar power facilities would disturb approximately 10,300 acres of land. Additional construction would be needed to update and add electrical transmission capacity off the NNSS. As there are no specific designs or private-sector proponents for the commercial solar power generation facilities, additional NEPA review would be required prior to its construction.

A geothermal laboratory could be developed on NNSS property. Exploratory studies at the NNSS would evaluate the feasibility of implementing such a project. The location of the facility would vary depending on the geothermal potential, zone use restrictions, environmental and economic considerations, and other factors. If an appropriate location on the NNSS were identified, the facility would be used to test an enhanced Geothermal Demonstration Project. Approximately 30 to 50 acres of land would be disturbed during construction of the facility. An excavated, lined sump to hold drilling water would be built adjacent to the main structures. Drilling the geothermal wells would remove some of the bedrock within the construction disturbance area. However, the drilling would not impact geologic features unique to the area. Operating the facility would not impact the geology or soils. The data gained during construction and operation of the Geothermal Demonstration Project may be considered a beneficial impact. A separate, but related facility, a Geothermal Research Center, would not affect the soils because it would be built in a previously disturbed area at Mercury.

Other Research and Development Programs. Additional research projects would be performed at the NNSS as part of the National Environmental Research Park Program. Each research project would be reviewed by DOE/NNSA on a case-by-case basis. Although minor amounts of soil may be disturbed during the data gathering or research procedures, the effects would be temporary.

5.1.5.3 Reduced Operations Alternative

The Reduced Operations Alternative includes all of the activities actually conducted at the NNSS since 1996. For most of the programs, the activity levels and frequencies would be limited to those ongoing since 1996. The Reduced Operations Alternative would also curtail all activities other than environmental restoration, environmental monitoring, site security operations, military training and exercises, and maintenance of Well 8 and critical communications and electrical transmission systems in Areas 18, 19, 20, 29, and 30 in the northwestern NNSS.

Soils would experience a general beneficial impact from the cessation of all activities except for Environmental Restoration Program activities, environmental monitoring, and other site maintenance activities. Maintenance of old roads would be discontinued, allowing previously disturbed soils to reform their structure. There would be no impacts on economic minerals or energy resources, although public access would continue to be restricted at the NNSS. The following discussion presents the programs and activities that would have different impacts than those under the No Action Alternative.

5.1.5.3.1 National Security/Defense Mission

DOE/NNSA would continue its readiness to conduct an underground nuclear test, so the impacts would be similar to those described under the No Action Alternative. There would be no change compared with the No Action Alternative for the following activities: shock physics experiments, disposition of damaged

nuclear weapons, criticality experiments, training support for the Office of Secure Transportation, staging of SNM, and readiness-related training and exercises using various kinds of nuclear weapon simulators.

The conventional high-explosives experiments at BEEF and other locations in the Nuclear and High Explosives Test Zone, including hydrodynamic and explosively driven pulsed-power experiments that directly support the Stockpile Stewardship and Management Program, would continue; however, all other high-explosives experiments would be curtailed. The high-explosives experiments at BEEF would have similar impacts on the soils to those under the No Action Alternative; however, the effects would be less because there would be fewer experiments overall. The other experiments would not affect the physical setting because they would be located in already existing facilities.

No impacts would result from conducting up to 10 dynamic experiments at the NNSS. Dynamic experiments would not be conducted in the Limited Use Zone on the NNSS.

There would be minor impacts on the soils from the conventional high-explosives experiments under the Reduced Operations Alternative. Up to 10 experiments per year would be conducted to directly support the Stockpile Stewardship and Management Program, less than the number under the No Action Alternative. The experiment locations would primarily be at BEEF. Minor soil impacts would result from decommissioning and dispositioning the Atlas Facility. Construction equipment used to dismantle the facility would disturb soils directly around the facility. This would increase the potential for erosion; however, the cleared facility location would allow the soils to redevelop.

There would be no impact on the physical setting from DOE/NNSA's conduct of shock physics experiments under the Reduced Operations Alternative. No more than 12 shock physics experiments would occur within existing facilities at JASPER, and 10 would be conducted at the Large-Bore Powder Gun at the U1a Complex.

Nuclear Emergency Response, Nonproliferation, and Counterterrorism Programs. There would be no change in programmatic activities compared with the No Action Alternative, so the impacts would be the same.

Work for Others Program. Under the Work for Others Program, DOE/NNSA would still host the projects of other Federal agencies, state and local governments, and nongovernmental organizations; however, certain activities, primarily those requiring high-explosives testing or involvement, would not be conducted. No Work for Others Program activities, except military training and exercises, would be conducted in Areas 18, 19, 20, 29, and 30. This would reduce impacts on soils and geologic media at the NNSS, compared to those under the No Action Alternative.

5.1.5.3.2 Environmental Management Mission

The Waste Management and Environmental Restoration Programs under the Reduced Operations Alternative would function the same as under the No Action Alternative. Therefore, the impacts would be the same as those described in the Environmental Management Mission section in Section 5.1.5.1.

5.1.5.3.3 Nondefense Mission

General Site Support and Infrastructure Program. Under the Reduced Operations Alternative, fewer repair and replacement activities would occur at the NNSS. Only critical infrastructure within Areas 18, 19, 20, 29 and 30 would be maintained. Roads within these areas would only be maintained to provide access necessary to maintain the noted infrastructure (maintenance and operation of the Echo Peak, Motorola, and Shoshone communications facilities; the Echo Peak, Castle Rock, and Stockade Wash Substations, including electrical transmission lines interconnecting these substations; and Well 8). Because of fewer enhancements and maintenance activities, the soils would be affected to a lesser degree than under the No Action Alternative.

Conservation and Renewable Energy Program. DOE/NNSA would permit the construction of a 100-megawatt commercial solar power generation facility in Area 25, disturbing approximately

1,200 acres of soils. Construction would temporarily increase the potential for erosion of the topsoil, and additional NEPA review would be required after site selection occurs.

Other Research and Development Programs. DOE/NNSA would continue to host environmental research projects at the NNSS, but would not actively promote the National Environmental Research Park Program. Each research project would be reviewed by DOE/NNSA on a case-by-case basis. Although minor amounts of soil may be disturbed during the data-gathering or research procedures, the effects would be temporary.

Geology and Soils

CGTO During the evaluation of the *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada (1996 NTS EIS)*, the Consolidated Group of Tribes and Organizations (CGTO) noted repeated nuclear testing activities had resulted in severe disturbances to the geology and soils, or minerals, in large portions of the Nevada National Security Site (NNSS). This seemingly irreparable damage has made certain areas unfit for human use and inaccessible to American Indians who have relied on the earth and rocks for medicine and religious purposes. Sedan Crater, for example, continues to be a dead site; the spirits of the site and resources on it were destroyed in 1962 and the loss can still be felt by members of the CGTO.

The CGTO visited the NNSS in February 2010 and believes the geology and soils are in even poorer condition than they were during the *1996 NTS EIS* due to the continued drought. Drought conditions, ground disturbing site activities, and damage to the soil from previous underground nuclear testing are significantly enhancing erosion. Negative impacts to these resources are long-lasting.

Activities that alter geologic structure also alter hydrologic systems. Such actions result in changes to important geologic and soil features that directly connect the tribes to their homelands in specific, spiritual ways. These changes require spiritual and cultural intervention necessary for restoring balance.

According to tribal elders, *"Bombs have melted the soil. It turned to glass…Severe disturbances are still out there. Everything is still suffering from it. …All Tribes are in agreement that they want to be here to do what they can to help stop this terrible pressure put on the earth and to sing the songs to help the site and to say prayers. The land has its own songs and when you sing the songs to the land, it'll sing back to you. These songs must be sung to help heal the earth and to restore harmony and balance."*

See Appendix C for more details.

5.1.6 Hydrology

5.1.6.1 Surface-Water Hydrology

Impacts on surface hydrology were assessed by reviewing the proposed activities described in Chapter 3 to determine whether they have the potential to directly or indirectly affect surface-water resources. Impacts are based on qualitative assessments of the range of potential activities that may occur under the three missions for the three alternatives. Activities under an alternative would have an adverse impact on surface-water resources if they result in any the following effects:

- Alteration of natural drainage pathways (pools, channels, or the ground surface)
- Contamination of surface waters with chemical and/or biological agents
- Sedimentation to surface waters
- Conflict with the provisions of approved water discharge permits
- Alteration of 100-year or 500-year floodplains or other flood hazard areas in a manner that would endanger lives and property

It is important to note that, as described in Chapter 4, Section 4.1.6.1, springs are the only perennial sources of surface water at the NNSS; therefore, the only perennial surface waters occur as pools at some large springs. Springs are located outside of locations used for testing and training events and are generally upgradient. In addition, onsite springs are fed by locally derived or "perched" groundwater (Hansen et al. 1997; Moore 1961) (i.e., groundwater in a saturated zone of material separated from other groundwater bodies by a relatively impervious zone) that is not hydrologically connected to any of the

aquifers that may be affected by underground nuclear tests (Bechtel Nevada 1998a; DOE/NV 1999); therefore, no potential impacts are anticipated to occur to perennial surface waters at the NNSS under any of the alternatives.

As described in Chapter 4, Section 4.1.6.1, ephemeral flows in surface-water features on the NNSS occur rarely, with no flow occurring in some years. During infrequent heavy precipitation events, runoff is typically of short duration; however, large peak discharge rates can result. Flooding events on site have the potential to affect offsite locations downgradient. The primary hydrographic basin on site with the potential to affect offsite areas is the Fortymile Canyon; a storm event in 1995 resulted in the temporary closing of U.S. Route 95 due to flooding in Fortymile Wash. Ephemeral features in the Rock Valley and Mercury Valley basins also have the potential to flow off site.

Overall, sites containing nonradiological or both radiological and nonradiological contamination total approximately 2,580 acres of land, or about 0.3 percent of the total area of the NNSS. Currently, a total of 14 sites contain nonradiological soil contamination within the Fortymile Canyon Hydrographic Basin and 7 contain both radiological and nonradiological contamination. The majority (10) of the nonradiological sites consist of landfill locations that either are known to contain contamination or could possibly contain it. The four non-landfill sites are all located in the Jackass Flats subdivision of Fortymile Canyon and contain total petroleum hydrocarbons (TPH), tetrachloroethene (TCE), or hydraulic oil. The two TPH and TCE sites contain subsurface contamination below the ground surface, while the hydraulic oil contamination is within underground tunnels. The radiological sites, which are also contaminated by lead, include five locations in Area 18 (Buckboard Mesa subdivision of Fortymile Canyon), where nuclear weapons tests occurred; one in Area 30 (Buckboard Mesa subdivision of Fortymile Canyon), where Project Buggy (a Plowshare Program experiment) was conducted; and one in Area 25 (Jackass Flats subdivision of Fortymile Canyon), where nuclear reactor research was conducted for the space program.

None of these sites is particularly close to Fortymile Wash, the primary pathway for which surface water may exit the NNSS. The closest is the radiologically contaminated site in Area 30, which is approximately 1 mile from Fortymile Wash. Topopah Wash lies to the east of Fortymile Wash in the Jackass Flats subdivision of Fortymile Canyon and has the potential for flow off site, though flow rates and frequencies are typically considerably lower. Eight sites are located in the general vicinity of Topopah Wash or its tributaries, one of which is the radiologically contaminated site in Area 25.

There are five sites containing nonradiological contamination in the Mercury Valley Hydrographic Basin. Two of these contain TPH contamination below the ground surface; two are landfill locations that are either known to contain contamination or could possibly contain it; and one is an area with subsurface contamination by TPH, benzo(a)pyrene, dibenz(a,h)anthracene, and TCE. Each of these sites is in the general area of ephemeral features that flow off site to the south. There are no radiologically contaminated sites in the Mercury Valley Hydrographic Basin and no contaminated sites within the Rock Valley Hydrographic Basin.

Each of the aforementioned contaminated sites has been closed with restrictions on its use. When a contaminated site is closed in place, a risk-based assessment is conducted to determine the potential for spread of contamination from the site. The level of contamination that remains, the stability of each site, and location of each site preclude the potential for release of contaminants at levels that would pose a risk. Most of the sites contain subsurface contamination, which does not have the potential to be spread via surface water. In addition, precipitation events generating flows large enough to make onsite ephemeral water flow off site are rare occurrences. Thus, there is a negligible potential for existing onsite contamination to be transported off site via surface water or through flood events. The following sections address the potential for surface-water transport of contaminants under the three alternatives.

Overall, impacts would be minimized through use of the mitigation measures described in Chapter 7. For example, impacts related to surface disturbances (e.g., sedimentation to ephemeral waters) would be

mitigated on a site-specific basis depending on several factors (e.g., soil characteristics); erosion and sediment controls would include a variety of measures, such as use of filter or silt berms or fences and timely revegetation of exposed surfaces. Where practicable, DOE/NNSA would use areas disturbed by past activities to minimize erosion.

5.1.6.1.1 No Action Alternative

The following sections describe impacts associated with the various activities that may potentially occur under the three missions. With respect to the aforementioned impact criteria, no activities are expected to conflict with the provisions of approved water discharge permits or cause alteration to 100- or 500-year floodplains or other flood hazard areas in a manner that would endanger lives and property.

The following activities are not expected to alter natural drainage pathways: dynamic experiments, drillback operations, and training activities for the Office of Secure Transportation under the Stockpile Stewardship and Management Program; counterterrorism activities under the Work for Others Program; UGTA, Soils, and Industrial Sites Projects activities, remediation of the DTRA sites, and Borehole Management under the Environmental Restoration Program; and activities under the General Site Support and Infrastructure Program.

The following activities are not expected to contaminate surface waters with radioactive materials, chemicals, and/or biological simulants: dynamic experiments, drillback operations, and training activities for the Office of Secure Transportation under the Stockpile Stewardship and Management Program; counterterrorism activities under the Work for Others Program; LLW, MLLW, and sanitary solid waste management activities under the Waste Management Program; Industrial Sites Project and Borehole Management Program activities under the Environmental Restoration Program; activities under the General Site Support and Infrastructure Program; and activities under the Other Research and Development Programs.

The following activities are not expected to deposit sediment in surface waters: dynamic experiments and conventional high-explosives experiments under the Stockpile Stewardship and Management Program; nonproliferation projects and counterproliferation research and development under the Work for Others Program; LLW and MLLW management activities and explosives waste treatment under the Waste Management Program; remediation of DTRA sites and Borehole Management Program activities under the Environmental Restoration Program; and activities under the General Site Support and Infrastructure Program.

5.1.6.1.1.1 National Security/Defense Mission

Stockpile Stewardship and Management Program – Dynamic Experiments. Up to 10 dynamic experiments would be conducted per year at locations within the Nuclear Test and Nuclear and High Explosives Test Zones. Experiments using SNM coupled with conventional explosives would be conducted underground and/or in confinement vessels and would not cause surface disturbances that could alter natural drainage pathways or contaminate ephemeral waters.

Stockpile Stewardship and Management Program – Conventional High-Explosives Experiments. Up to 20 conventional high-explosives experiments per year would be conducted at BEEF, and up to 10 per year would be conducted at other locations within the Nuclear and High Explosives Test Zone. Experiments at BEEF would be conducted on the firing table and are not expected to cause surface contamination or significant changes in natural drainage pathways. Detonations would be contained within the firing table, which generally consists of a 66-foot by 66-foot gravel area 6 to 8 feet deep, though it can be extended or deepened if an experiment warrants it. Materials dispersed during experiments would consist of solid debris that is recovered following the experiment or contained within the gravel, which would be periodically removed and replaced. For experiments at other locations within the Nuclear and High Explosives Test Zone, some minor alteration of natural drainage pathways for storm-generated sheetflow and flows in ephemeral waters (if located in close proximity to the experiment

location) could occur due to surface disturbances resulting from detonations. In addition, experiments conducted at or above the ground surface could cause surface contamination and, ultimately, some contamination of ephemeral waters. Any potential surface contamination would be located within hydrographic basins that drain internally within the NNSS and would not affect offsite areas during rare flooding events.

Stockpile Stewardship and Management Program – Drillback Operations. Up to five drillback operations may take place during the 10-year planning period. Drillback operations would occur within the area of a former underground nuclear test event and would require approximately 5 acres of land. Earth-disturbing activities during site preparation and drilling (e.g., vehicle and equipment movements) could result in a small degree of sedimentation in nearby ephemeral waters.

Stockpile Stewardship and Management Program – Training for Office of Secure Transportation. Training for the Office of Secure Transportation would occur on existing roads and nearby off-road areas on the NNSS. Should off-road training activities occur in areas near ephemeral waters, particularly those involving vehicle maneuvers, a small degree of sedimentation may occur in those waters from nearby land surface disturbances.

Nuclear Emergency Response, Nonproliferation, and Counterterrorism Programs – Nonproliferation and Counterterrorism-Related Activities. Under the No Action Alternative, a Nonproliferation and Counterterrorism Training Program would be established. Experiments and training events using explosives may cause surface disturbances that could alter natural drainage pathways in terms of storm-generated sheetflow and flows in ephemeral waters. Overall, no permanent change in surface-water quality is expected because springs are located outside of experiment and training areas and are generally upgradient. Ephemeral flows could experience decreases in water quality from the introduction of chemical contaminants; however, these impacts would be localized to the experiment or training area and would occur only when local surface-water features contain water (e.g., after a storm event). Any potential surface contamination would be located within hydrographic basins that drain internally within the NNSS and would not affect offsite areas during rare flooding events. Should off-road training activities, particularly those involving vehicle maneuvers, occur in areas near ephemeral waters, a small degree of sedimentation may occur in those waters from nearby land surface disturbances.

Work for Others Program – Nonproliferation Projects and Counterproliferation Research and Development. Under this program, DOE/NNSA would support other agencies on nonproliferation projects and counterproliferation research and development. These projects would include high-explosives detonations, which may cause surface disturbances that could alter natural drainage pathways in terms of storm-generated sheetflow and flows in ephemeral waters. Overall, no permanent change in surface-water quality is expected because springs are located outside of experiment areas and are generally upgradient. Ephemeral flows could experience decreases in water quality from the introduction of chemical contaminants; however, these impacts would be localized to the experiment area and would occur only when local surface-water features contain water (e.g., after a storm event). Any potential surface contamination would be located within hydrographic basins that drain internally within the NNSS and would not affect offsite areas during rare flooding events.

Up to 20 controlled chemical and biological simulant releases would occur per year. These releases would have no impact on natural water bodies. Chemicals would not be released to any surface-water bodies. Biological simulants could be released into Cambric Ditch, an existing manmade ditch; however, most liquid releases would be to lined sewage lagoons or ponds. No releases to natural springs or ephemeral waters would occur (DOE 2004c).

Work for Others Program – Counterterrorism. Under this program, DOE/NNSA would support other agencies on counterterrorism projects. These could include training for engaging and neutralizing adversaries. Off-road activities (e.g., training exercises, ordnance development, and vehicle testing) could

cause a small degree of sedimentation to ephemeral waters located near training areas from nearby land surface disturbances.

5.1.6.1.1.2 Environmental Management Mission

Waste Management Program – Low-Level Radioactive Waste and Mixed Low-Level Radioactive Waste Management. Waste management operations would continue to include LLW and MLLW management, including the development of new disposal cells at the Area 5 RWMC and, potentially, a new MLLW facility. Chapter 4, Section 4.1.6.1, describes potential flood hazards on the NNSS. Flood protection is an important issue when siting waste management facilities; thus, consideration of flood potential would be necessary when siting and designing new disposal cells in the Area 5 RWMC (estimated to occur at a rate of two to three new cells per year) or a new MLLW storage facility. There is a 100-year flood hazard area along the southwest corner of the Area 5 RWMC associated with Barren Wash (Schmeltzer et al. 1993) that would be avoided. Continued operation of the Area 5 RWMC would continue to alter natural drainage pathways due to engineered berms designed to prevent run-on to the site, though this would not significantly alter the overall drainage of the area. Should the Area 3 RWMS become operational in the future, it would likely have a minimal beneficial impact on local drainage patterns because craters developed during past underground nuclear tests would continue to be used to dispose materials. Continued filling of craters and their engineered closure would restore the natural topography and drainage patterns in the affected portions of Area 3.

Waste Management Program – Explosives Waste Treatment. DOE/NNSA would treat old and/or unusable explosives by open-air detonation at the Explosives Ordnance Disposal Unit in Area 11. Open-air detonations could cause surface contamination through deposition of explosive residues and, ultimately, some contamination of ephemeral waters. Any potential surface contamination would be located within hydrographic basins that drain internally within the NNSS and would not affect offsite areas during rare flooding events.

Waste Management Program – Manage Sanitary Solid Waste. DOE/NNSA would continue to operate existing waste disposal sites, with no additional land disturbance expected and therefore no impact on drainage pathways.

Environmental Restoration Program – Underground Test Area Project. This project would monitor groundwater quality and evaluate closure strategies in areas of groundwater contamination. The UGTA Project would produce water from characterization and monitoring wells, which could only be discharged to the surface if the water complies with the requirements of the NDEP-approved UGTA Fluid Management Plan (DOE 2009k). The water would be monitored and sediment erosion would be reduced through the use of onsite sumps and designated infiltration areas as needed, thereby eliminating most impacts on natural drainage pathways or downgradient springs and surface impoundments. Accidental discharges of water contaminated with radionuclides or other hazardous substances could occur, potentially contaminating the surface. This is considered unlikely, however, because the standard practice is to contain discharged water from near-field wells in lined sumps. Continued strict adherence to the UGTA Fluid Management Plan requirements would ensure no surface contamination would affect offsite areas during rare flooding events.

Environmental Restoration Program – Soils Project. This project would continue to investigate soil sites to determine whether contamination exists and to perform corrective actions as needed. Land-disturbing activities associated with these corrective actions (e.g., vehicular and equipment movements) could cause some minor sedimentation to ephemeral waters. During corrective action activities, excavated or exposed contaminated materials could potentially be transported to downgradient land surfaces during storm events that generate runoff. Appropriate site-specific dust and drainage controls would be implemented for each corrective action (e.g., establishing temporary diversion berms), which would minimize the potential for impacts to occur; however, it is possible that moderate impacts on the water quality of ephemeral surface waters could occur if contaminants were transported to such

features. As described in Appendix A, Section A.1.2.2, the Soils Project employs surface-water contaminant transport studies while investigating soils sites and plans accordingly. Thus, any movement of contaminated soils could possibly affect ephemeral surface waters locally; however, drainage control measures would be employed that would ensure no offsite impacts would occur during rare flooding events.

Environmental Restoration Program – Industrial Sites Project. This project would continue to identify, characterize, and remediate industrial sites. Following the remediation of industrial sites, the facilities would be demolished with foundations normally left in place. Land-disturbing activities associated with demolition (e.g., vehicular and equipment movements) could cause some minor sedimentation to ephemeral waters.

Environmental Restoration Program – Defense Threat Reduction Agency Sites. Surface disturbing activities for the DTRA sites have been completed, and only environmental monitoring, such as water sampling, would continue. Monitoring would not result in any changes to the physical environment.

Environmental Restoration Program – Borehole Management Program. Unneeded boreholes would continue to be plugged; it was estimated that 183 would be plugged from 2010 through 2013. Open boreholes may capture a small proportion of the surface water that would otherwise continue to flow across the surface as sheetflow. Therefore, plugging of these unneeded boreholes is expected to have a minor beneficial impact in terms of restoring the natural hydrology of these locations.

5.1.6.1.1.3 Nondefense Mission

General Site Support and Infrastructure Program. Infrastructure-associated activities would continue to maintain facilities' present capabilities. Continued wastewater discharges to the Area 6 Yucca Lake and Area 23 Mercury sewage lagoon systems, as well as the E-Tunnel Waste Water Disposal System ponds, are not expected to affect natural surface-water resources. Wastewater would be contained within the lagoons and ponds and would not be released to the ground surface or any natural water bodies. In 2009, all contaminant concentrations in discharged effluent were within permitted levels.

Conservation and Renewable Energy Program – Renewable Energy. A large-scale commercial solar power generation facility covering approximately 2,400 acres could be established in Area 25. It was assumed that, if developed, this facility would be sited to avoid disturbing larger ephemeral waters located in Area 25, such as Fortymile Wash, Topopah Wash, and Rock Valley Wash.

Land preparation associated with the development of solar power generation facility (e.g., land grading) could cause sedimentation in ephemeral waters, as well as long-term alteration of natural drainage pathways. Considering the relatively large land area that the facility would cover, it is likely that some smaller ephemeral waters would be altered; however, as previously stated, it was assumed that larger surface-water features would not be disturbed.

Stormwater runoff from an operational solar power generation facility would be diverted to an appropriately sized detention basin, as well as to appropriate conveyance features (e.g., ditches and culverts), to contain flows from storm events on site. The potential for surface contamination resulting from the use of process chemicals would be minimized through the use of standard best management practices and standard operating procedures (e.g., providing secondary containment around petroleum storage areas and responding to spills as soon as possible), as well as establishment of a bioremediation area to manage any soils contaminated with toxic materials. Onsite stormwater detention would preclude the possibility for any onsite surface contamination to impact offsite areas during rare flooding events.

Other Research and Development Programs. The DOE National Environmental Research Park Program would continue to perform environmental research activities. It is possible that ground-disturbing activities associated with developing and performing experiments could result in sedimentation to ephemeral waters and alterations of natural drainage pathways; however, assuming

research projects are conducted in an environmentally responsible manner, these impacts could be minimized.

5.1.6.1.2 Expanded Operations Alternative

The following sections describe impacts associated with the various activities that may potentially occur under the three missions. With respect to the aforementioned impact criteria, no activities are expected to conflict with the provisions of approved water discharge permits or cause alteration to 100- or 500-year floodplains or other flood hazard areas in a manner that would endanger lives and property.

The following activities are not expected to alter natural drainage pathways: dynamic experiments and drillback operations under the Stockpile Stewardship and Management Program; NASA support under the Work for Others Program; and UGTA, Soils, and Industrial Sites Projects activities, remediation of DTRA sites, and Borehole Management under the Environmental Restoration Program.

The following activities are not expected to contaminate surface waters with radioactive materials, chemicals, and/or biological simulants: dynamic experiments, drillback operations, and training activities for the Office of Secure Transportation under the Stockpile Stewardship and Management Program; counterterrorism and miscellaneous activities under the Work for Others Program; LLW, MLLW, and sanitary solid waste management activities under the Waste Management Program; Industrial Sites Project and Borehole Management Program activities under the Environmental Restoration Program; activities under the General Site Support and Infrastructure Program; and activities under the Other Research and Development Programs.

The following activities are not expected to deposit sediment in surface waters: dynamic experiments under the Stockpile Stewardship and Management Program; nonproliferation projects, counterproliferation research and development, and NASA support under the Work for Others Program; LLW and MLLW management and explosives waste treatment under the Waste Management Program; and remediation of DTRA sites and Borehole Management Program activities under the Environmental Restoration Program.

5.1.6.1.2.1 National Security/Defense Mission

Stockpile Stewardship and Management Program – Dynamic Experiments. Up to 20 dynamic experiments could be conducted per year. Impacts would be the same as those described under the No Action Alternative in Section 5.1.6.1.1.1; therefore, no impacts on surface hydrology are expected.

Stockpile Stewardship and Management Program – Conventional High-Explosives Experiments. DOE/NNSA would conduct up to 100 high-explosives experiments per year at BEEF and various locations in the Nuclear and High Explosives Test Zone and would develop new facilities and features within the already developed areas of BEEF. Impacts of these experiments would be similar to those described under the No Action Alternative (see Section 5.1.6.1.1.1), but would be intensified because the number of experiments would increase. Therefore, no impacts are expected as a result of experiments conducted at BEEF; however, experiments at other locations within the Nuclear and High Explosives Test Zone could cause impacts. In comparison to the impacts described under the No Action Alternative, the additional tests would likely result in increased amounts of sedimentation to ephemeral waters, alterations of natural drainage pathways, and instances of surface contamination and other impacts that could occur over a larger land area as a result of the greater number of experiments. New facility construction activities at BEEF could cause some minor sedimentation in ephemeral waters and alteration of natural drainage pathways by introducing structures that would impede natural flows.

DOE/NNSA would establish up to three 40-acre sites within Areas 2, 4, 12, or 16 to conduct explosives experiments using depleted uranium. These experiments could cause surface disturbances that could alter natural drainage pathways in terms of storm-generated sheetflow and flows in ephemeral waters. Overall, no permanent change in surface-water quality is expected because springs are located outside of the experiment areas and are generally upgradient. Ephemeral flows could experience decreases in water

quality resulting from the introduction of pollutants (e.g., sedimentation and chemicals); however, these impacts would be localized to the experiment area and would occur only when local surface-water features contain water (e.g., after a storm event). However, depending on their size and location, these experiments could cause more significant surface contamination (lead and depleted uranium primarily). Any potential surface contamination would be located within hydrographic basins that drain internally within the NNSS and would not affect offsite areas during rare flooding events.

Stockpile Stewardship and Management Program – Drillback Operations. Impacts of drillback operations would be the same as those described under the No Action Alternative in Section 5.1.6.1.1.1.

Stockpile Stewardship and Management Program – Training for Office of Secure Transportation. Activities associated with training for the Office of Secure Transportation would include development of several new facilities and expansions of existing facilities. Construction of new facilities and support infrastructure (e.g., roads, utility lines, and a firing range) to support training activities in Area 17 could cause sedimentation in ephemeral waters and short-term alterations of natural drainage pathways because it is likely that ephemeral waters would be crossed by linear features (e.g., pipelines), thus causing short-term disturbances to local surface-water features. Natural topographies would be restored following construction, to the extent practicable. Operation of the training areas could also result in a small degree of sedimentation in ephemeral waters, primarily from vehicular movement. New construction proposed for Area 17 (37,400 square feet of facilities) could cause long-term alterations of natural drainage pathways by introducing structures that would impede natural flows. In addition, construction of the support infrastructure would likely cause long-term alterations of natural drainage pathways, primarily due to new roads and land-grading associated with development of the firing range. Expansion of facilities in Areas 6, 12, 17, or 23 could also cause long-term alterations of natural drainage pathways by introducing structures that would impede natural flows.

Nuclear Emergency Response, Nonproliferation, and Counterterrorism Programs – Nonproliferation and Counterterrorism-Related Activities. Impacts of nonproliferation and counterterrorism-related activities would be similar to those described under the No Action Alternative (see Section 5.1.6.1.1.1). Impacts of experiments and training events also would be the same as those described under the No Action Alternative (alterations of natural drainage pathways, sedimentation to ephemeral waters, and surface chemical contamination); however, in addition, new construction of nonproliferation and counterterrorism facilities would occur in additional locations (more than 200 acres). Construction of the facilities could cause sedimentation in ephemeral waters, and the presence of the new facilities could cause long-term alterations of natural drainage pathways by impeding natural flows.

Work for Others Program – Nonproliferation Projects and Counterproliferation Research and Development. Impacts of nonproliferation projects and counterproliferation research and development would be the same as those described under the No Action Alternative in Section 5.1.6.1.1.1.

Work for Others Program – Counterterrorism. Impacts of counterterrorism activities would be similar to those described under the No Action Alternative in Section 5.1.6.1.1.1 (sedimentation to ephemeral waters). However, in addition, new facility construction activities would disturb approximately 100 acres of land, which could cause localized sedimentation in ephemeral waters and long-term alteration of natural drainage pathways by introducing structures that would impede natural flows.

Work for Others Program – Support for the National Aeronautics and Space Administration. DOE/NNSA would provide support to NASA on nuclear rocket motor development. The use of boreholes to sequester the emissions of a prototype nuclear rocket motor could result in minimal amounts of localized surface contamination, which could be introduced to ephemeral waters; however, because this activity would likely occur in the Yucca Flat area, any surface contamination would be confined to the NNSS.

Work for Others Program – Miscellaneous Work for Others. Activities would include increased research, development, and use of aerial platforms, as well as construction of additional facilities at Desert Rock Airport, the Area 6 Aerial Operations Facility, Pahute Mesa, and other locations. Additional construction could cause localized sedimentation in ephemeral waters from construction-related land disturbing activities and long-term alteration of natural drainage pathways by introducing structures that would impede natural flows. Minimal impacts are expected. Experiments using releases of biological simulants into water are expected to have no impact on natural water bodies because releases would be contained in manmade features (i.e., Cambric Ditch or sewer and septic systems).

5.1.6.1.2.2 Environmental Management Mission

Waste Management Program – Low-Level Radioactive Waste and Mixed Low-Level Radioactive Waste Management. Impacts would be similar to those described under the No Action Alternative in Section 5.1.6.1.1.2; however, these impacts would increase somewhat because waste disposal volumes would increase, so more disposal cells would be developed. In addition, the Area 3 RWMS would be reactivated, as opposed to its possible reactivation under the No Action Alternative. Therefore, impacts at the Area 5 RWMC under the Expanded Operations Alternative would likely be the same as those under the No Action Alternative because engineered berms would continue to alter natural drainage pathways; no flood hazard impacts are expected because flood hazard areas would be avoided. Increased use of the Area 3 RWMS would have a greater beneficial impact on natural drainage pathways compared to the impact under the No Action Alternative because additional craters would be filled to manage greater waste volumes, thus restoring natural surface topographies and drainage patterns over a larger area.

Waste Management Program – Explosives Waste Treatment. Impacts would be the same as those described under the No Action Alternative in Section 5.1.6.1.1.2.

Waste Management Program – Manage Sanitary Solid Waste. DOE/NNSA would continue to operate existing waste disposal sites and develop a new landfill on approximately 15 acres of land. In addition, a 20-acre construction/demolition debris landfill would be established in Area 25. Chapter 4, Section 4.1.6.1, describes potential flood hazards on the NNSS. Flood protection is an important issue when siting waste management facilities. DOE/NNSA would consider flood potential when siting and designing new landfills. Land preparation activities associated with the development of new landfills (e.g., land grading) could alter natural drainage pathways and cause sedimentation in ephemeral waters.

Environmental Restoration Program – Underground Test Area Project. Impacts would be the same as those described under the No Action Alternative in Section 5.1.6.1.1.2.

Environmental Restoration Program – Soils Project. Impacts would be similar to those described under the No Action Alternative in Section 5.1.6.1.1.2; however, these impacts could be greater because activities could occur at an accelerated rate. Therefore, compared to the No Action Alternative, an increased potential for surface contamination would occur, as well as increased sedimentation to ephemeral waters under the Expanded Operations Alternative. No water-quality impacts on offsite areas are expected during rare flooding events.

Environmental Restoration Program – Industrial Sites Project. Impacts would be similar to those described under the No Action Alternative in Section 5.1.6.1.1.2; however, these impacts could be greater because activities could occur at an accelerated rate. Therefore, compared to the No Action Alternative, more work would be done to restore natural topographies and drainage patterns in areas where remediated facilities are demolished and increased sedimentation to ephemeral waters would occur.

Environmental Restoration Program – DTRA Sites. Impacts would be the same as those described under the No Action Alternative in Section 5.1.6.1.1.2.

Environmental Restoration Program – Borehole Management Program. Impacts would be the same as those described under the No Action Alternative in Section 5.1.6.1.1.2.

5.1.6.1.2.3 Nondefense Mission

General Site Support and Infrastructure Program. Infrastructure-related activities would cause impacts similar to those described under the No Action Alternative in Section 5.1.6.1.1.3. Therefore, continued wastewater discharges are not expected to cause any impacts on surface hydrology. However, there would be additional impacts associated with several new facility construction projects and expansion of some existing facilities. Demolition and construction of facilities and infrastructure could cause short-term sedimentation and increased loads of inorganic compounds in ephemeral waters, as well as long-term alteration of natural drainage pathways. Improvements within and adjacent to existing developed areas would likely have lower impacts compared to those resulting from improvements in more pristine areas.

Conservation and Renewable Energy Program. Impacts resulting from construction and operation of one or more commercial solar power generation facilities with up to 1,000 megawatts of combined capacity in Area 25 would be similar to the impacts described under the No Action Alternative in Section 5.1.6.1.1.3; however, these impacts would occur to a larger area of land because the facilities would be considerably larger, occupying a land area of approximately 10,300 acres. Therefore, compared to the No Action Alternative, increased amounts of long-term alterations to natural drainage pathways would occur over a larger land area, as well as sedimentation to ephemeral waters. In addition, the potential for surface contamination would apply to a larger land area. Onsite stormwater detention would preclude the possibility of onsite surface contamination affecting offsite areas during rare flooding events.

In addition to the large-scale solar power generation facilities, a 5-megawatt photovoltaic solar power generation facility would be developed near the Area 6 Construction Facilities on 50 acres of land. Geothermal energy production would also be explored. Development of a Geothermal Demonstration Project would require approximately 30 to 50 acres of land and would include an excavated, lined sump to store water during drilling and reservoir development. Land preparation activities associated with development of the photovoltaic solar power generation facility and construction of geothermal power system facilities (e.g., land grading) could cause sedimentation and increased loads of inorganic compounds in ephemeral waters, as well as long-term alteration of natural drainage pathways.

Other Research and Development Programs. Operation of the Nevada National Environmental Research Park would continue and could include new research and development projects. Impacts would be similar to those described under the No Action Alternative in Section 5.1.6.1.1.3; however, the development of additional research projects could result in somewhat greater impacts or could generate additional ones. Therefore, compared to the No Action Alternative, increased amounts of alterations of natural drainage pathways, as well as sedimentation to ephemeral waters, could occur under the Expanded Operations Alternative.

5.1.6.1.3 Reduced Operations Alternative

The following sections describe impacts associated with the various activities that may potentially occur under the three missions. With respect to the aforementioned impact criteria, no activities are expected to conflict with the provisions of approved water discharge permits or cause alteration to 100- or 500-year floodplains or other flood hazard areas in a manner that would endanger lives and property.

The following activities are not expected to alter natural drainage pathways: dynamic experiments, drillback operations, and training activities for the Office of Secure Transportation under the Stockpile Stewardship and Management Program; counterterrorism activities under the Work for Others Program; UGTA, Soils, and Industrial Sites Projects activities, remediation of DTRA sites, and Borehole Management Program activities under the Environmental Restoration Program; and activities under the General Site Support and Infrastructure Program.

The following activities are not expected to contaminate surface waters with radioactive materials, chemicals, and/or biological simulants: dynamic experiments, pulsed-power experiments, drillback

operations, and training activities for the Office of Secure Transportation under the Stockpile Stewardship and Management Program; counterterrorism activities under the Work for Others Program; LLW, MLLW, and solid waste management activities under the Waste Management Program; Industrial Sites Project and Borehole Management Program activities under the Environmental Restoration Program; activities under the General Site Support and Infrastructure Program; and activities under the Other Research and Development Programs.

The following activities are not expected to deposit sediment in surface waters: dynamic and conventional high-explosives experiments under the Stockpile Stewardship and Management Program; nonproliferation projects and counterproliferation research and development under the Work for Others Program; LLW and MLLW management and explosives waste treatment under the Waste Management Program; remediation of DTRA sites and Borehole Management Program activities under the Environmental Restoration Program; and activities under the General Site Support and Infrastructure Program.

5.1.6.1.3.1 National Security/Defense Mission

Stockpile Stewardship and Management Program – Dynamic Experiments. Up to six dynamic experiments could be conducted per year. Impacts would be the same as those described under the No Action Alternative in Section 5.1.6.1.1.1; therefore, no impacts on surface hydrology are expected.

Stockpile Stewardship and Management Program – Conventional High-Explosives Experiments. Up to 10 conventional high-explosives experiments could be conducted per year. Impacts would be similar to those described under the No Action Alternative in Section 5.1.6.1.1.1; however, these impacts would generally be reduced because the number of experiments conducted would be lower. Therefore, no impacts are expected for experiments conducted at BEEF; however, experiments at other locations within the Nuclear and High Explosives Test Zone could cause impacts. In comparison to the impacts described under the No Action Alternative, the additional tests would likely result in decreased amounts of sedimentation to ephemeral waters and alterations of natural drainage pathways; instances of surface contamination and impacts could occur over a smaller land area (if possible) if fewer experiments are conducted. Any potential surface contamination would be located within hydrographic basins that drain internally within the NNSS and would not affect offsite areas during rare flooding events.

Stockpile Stewardship and Management Program – Pulsed-Power Experiments. Pulsed-power experiments at the Atlas Facility would be discontinued and the facility would be decommissioned. Earth-disturbing activities during decommissioning (e.g., facility demolition) could cause a small degree of sedimentation in ephemeral waters; however, should the facility be demolished to ground level, decommissioning could restore the natural topography and drainage patterns at location of the Atlas Facility.

Stockpile Stewardship and Management Program – Drillback Operations. Impacts would be the same as those described under the No Action Alternative in Section 5.1.6.1.1.1.

Stockpile Stewardship and Management Program – Training for Office of Secure Transportation. Impacts would be the same as those described under the No Action Alternative in Section 5.1.6.1.1.1.

Nuclear Emergency Response, Nonproliferation, and Counterterrorism Programs – Nonproliferation and Counterterrorism-Related Activities. Impacts would be the same as those described under the No Action Alternative in Section 5.1.6.1.1.1.

Work for Others Program – Counterterrorism. Impacts would be the same as those described under the No Action Alternative in Section 5.1.6.1.1.1.

5.1.6.1.3.2 Environmental Management Mission

Waste Management Program – Low-Level Radioactive Waste and Mixed Low-Level Radioactive Waste Management. Impacts would be the same as those described under the No Action Alternative in Section 5.1.6.1.1.2.

Waste Management Program – Explosives Waste Treatment. Impacts would be the same as those described under the No Action Alternative in Section 5.1.6.1.1.2.

Waste Management Program – Manage Sanitary Solid Waste. Impacts would be the same as those described under the No Action Alternative in Section 5.1.6.1.1.2.

Environmental Restoration Program – Underground Test Area Project. Impacts would be the same as those described under the No Action Alternative in Section 5.1.6.1.1.2.

Environmental Restoration Program – Soils Project. Impacts would be the same as those described under the No Action Alternative in Section 5.1.6.1.1.2.

Environmental Restoration Program – Industrial Sites Project. Impacts would be the same as those described under the No Action Alternative in Section 5.1.6.1.1.2.

Environmental Restoration Program – DTRA Sites. Impacts would be the same as those described under the No Action Alternative in Section 5.1.6.1.1.2.

Environmental Restoration Program – Borehole Management Program. Impacts would be the same as those described under the No Action Alternative in Section 5.1.6.1.1.2.

5.1.6.1.3.3 Nondefense Mission

General Site Support and Infrastructure Program. Impacts would be the same as those described under the No Action Alternative in Section 5.1.6.1.1.3; therefore, no impacts on continued wastewater discharges are expected.

Conservation and Renewable Energy Program. Impacts of the commercial solar power generation facility in Area 25 would be similar to those described for a similar facility under the No Action Alternative in Section 5.1.6.1.1.3. However, these impacts would generally be reduced because the facility would have less than one-half the generating capacity and occupy a smaller land area of approximately 1,200 acres. In addition, due to the smaller overall facility size, about 12 acres would be devoted to stormwater detention ponds. Therefore, compared to the No Action Alternative, decreased amounts of long-term alterations to natural drainage pathways would occur over a smaller land area, as well as sedimentation to ephemeral waters. In addition, the potential for surface contamination would occur over a smaller land area, and onsite stormwater detention would preclude the possibility of onsite surface contamination affecting offsite areas during rare flooding events.

Other Research and Development Programs. DOE/NNSA would continue to host existing environmental research projects at the NNSS, but would not actively promote the Nevada National Environmental Research Park. Impacts would be similar to those described under the No Action Alternative in Section 5.1.6.1.1.3; however, these impacts would generally be reduced because fewer research projects would be performed overall. Therefore, compared to the No Action Alternative, alterations of natural drainage pathways and sedimentation to ephemeral waters could decrease.

5.1.6.2 Groundwater

Groundwater impacts were assessed by reviewing the proposed activities described in Chapter 3 to determine whether they have the potential to directly or indirectly affect groundwater resources. Activities under an alternative would have an adverse impact on groundwater resources if they result in any the following effects:

- Noncompliance with applicable water quality standards
- Water level declines in areas adjacent to operating wells that adversely affect other uses in that aquifer
- Alteration of groundwater recharge to another downgradient aquifer to the degree that it reduces that aquifer's sustainable yield or adversely affects current uses of that aquifer
- Exceedance of the sustainable withdrawal capacity of an aquifer

Impacts on groundwater availability were analyzed by comparing current groundwater demand for each individual basin found throughout the NNSS, as discussed in Chapter 4, Section 4.1.6, to the sustainable yield of each individual basin, under each alternative. Chapter 4, Table 4–24, presents the sustainable yield (the perennial yield of the basin minus any rights already committed to other users by the State Engineer) of each basin, and Table 4–30 presents the percentage of total NNSS water demand historically met by withdrawals from each basin. DOE/NNSA has made the following assumptions for purposes of analysis of the impacts on groundwater supply:

- Future groundwater withdrawals at the NNSS would continue to occur in the four basins that are currently developed (Frenchman Flat, Yucca Flat, and the Buckboard Mesa and Jackass Flats subdivisions of Fortymile Canyon). Of the remaining six basins underlying the NNSS, most only slightly overlap the NNSS near its borders and are not likely to be developed in the future due to their remote location relative to existing and proposed facilities. Any future project requiring water withdrawals from a new basin would require NEPA review. The Mercury Valley Basin is not considered viable for new withdrawals under any alternative at this time.
- Recent patterns of water use distribution among the four developed basins (i.e., the percent of the NNSS's total demand met from each basin) would be representative of future water withdrawal patterns under each alternative, with the exception of a commercial solar power generation facility, whose additional demand would be met solely through withdrawals from the Jackass Flats subdivision of Fortymile Canyon (Basin 227a).
- The sustainable yield used for each basin is based only on the recharge from precipitation within that basin and does not include recharge associated with subsurface inflow from upgradient basins. Annual water withdrawals from a basin that are below the sustainable yield of that basin were generally assumed not to reduce outflow (recharge) to other downgradient basins. In cases where withdrawals approach sustainable yield, or where other site-specific aspects affect the potential for reduction of recharge to other basins, DOE/NNSA would consider flow modeling efforts and studies to reach determinations about the potential for adverse impacts.

Potential impacts on water quality (e.g., contamination resulting in exceedance of water quality standards) were assessed qualitatively by examining a project or activity's potential for release of hazardous constituents and the likely pathways for contaminants to reach groundwater resources.

5.1.6.2.1 No Action Alternative

Under the No Action Alternative, activities at the NNSS would primarily continue at frequencies and levels consistent with those experienced since 1996. DOE/NNSA would continue to maintain and repair facilities and associated infrastructure as needed to maintain the present capabilities of DOE/NNSA

facilities. The only significant new facility considered would be construction of a large solar power generation facility by an outside commercial entity.

From 2005 through 2009, measured annual water usage at the NNSS from the active wells ranged from approximately 173 million to 225 million gallons per year, with an average of approximately 198 million gallons per year. DOE/NNSA estimates that total water withdrawals across all programs (excluding construction or operation of a commercial solar power generation facility) would not exceed 225 million gallons per year, the highest measured value since 2005. However, the implementation of water conservation efforts in support of the NNSS Energy Executable Plan (see Section 5.1.6.1.3) would result in a downward trend in potable water consumption. Therefore, an amount of 225 million gallons per year (691 acre-feet per year) is viewed as a conservative estimate of total water consumption for activities excluding construction or operation of a solar power generation facility. As an acre-foot is the conventional unit of measurement for capacity of an aquifer, acre-feet are used in the remainder of this analysis in lieu of gallons per year.

Annual water withdrawals from each basin on the NNSS between 2005 and 2009 are presented in Chapter 4, Table 4–27. For purposes of analysis, the 5-year average of the percentage of total water demand met by each basin (e.g., 68.6 percent of total demand on Frenchman Flat) was used to estimate the future demand on each basin. **Table 5–23** presents the individual demands on each basin to support a total demand of 691 acre-feet per year, as well as additional demands associated with a commercial solar power generation facility (discussed in subsequent paragraphs), and compares these demands to the sustainable yield of each basin.

Table 5–23 Impacts on Groundwater Supply Under the No Action Alternative

Basin	***Water Demand, Excluding Solar Power Generation Facility (acre-feet per year)***	***Water Demand, Including Construction Demand from Solar Power Generation Facility (acre-feet per year)***	***Water Demand, Including Operational Demand from Solar Power Generation Facility (acre-feet per year)***	***Sustainable Yield of Basin (acre-feet per year)***	***Maximum Percentage of Sustainable Yield Consumed During Construction***	***Maximum Percentage of Sustainable Yield Consumed During Operation***
Frenchman Flat (160)	474	474	474	100	474%	474%
Fortymile Canyon, Buckboard Mesa subdivision (227b)	42	42	42	3,600	1%	1%
Fortymile Canyon, Jackass Flats subdivision (227a)	47	397	297	4,000	10%	7%
Yucca Flat (159)	128	128	128	350	37%	37%

Source: Derived from Chapter 4, Tables 4–24, 4–27, and 4–30.

A commercial solar power generation facility was analyzed in the *1996 NTS EIS*, but was never implemented. In the *1996 NTS EIS*, both Areas 25 and 22 were analyzed as potential facility sites. A sensitive environmental area, Devils Hole, exists downgradient from Area 22; therefore, potential groundwater impacts from large-scale pumping would be much higher in Area 22 compared to Area 25. For that reason, Area 22 is no longer considered a viable option for siting a commercial solar power generation facility.

Currently, there are no specific proposals from private applicants for a commercial-scale solar power generation project at the NNSS. To support an NNSS decision regarding allowing commercial-level power production as a land use, DOE/NNSA has analyzed a notional design based on other proposed facilities in southern Nevada. Were a specific design to be proposed by a private applicant, additional

project-level NEPA review would be required. The existing NNSS water system may be used to convey water from the point of extraction.

Construction and operation of a 240-megawatt commercial solar power generation facility would represent the largest water demand from any single activity or project on the NNSS. Operation of a 240-megawatt solar power generation facility in Area 25 would add an additional demand of approximately 250 acre-feet per year. During construction of the solar power generation facility, there would be a temporary demand of approximately 350 acre-feet per year for 35 months to support dust suppression, soil compaction, and other facility construction needs. This analysis assumes that all water demand for the solar power generation facility would be withdrawn from the Jackass Flats subdivision of Fortymile Canyon (Basin 227a).

As illustrated in Table 5–23, annual withdrawals from each basin under the No Action Alternative would be below the sustainable yield of each basin, with the exception of Frenchman Flat. The greatest demand would likely be placed on Frenchman Flat, with approximately 474 percent of the basin's sustainable yield consumed on an annual basis. As discussed in Chapter 4, Section 4.1.6.2, the Nevada State Engineer estimated a perennial yield of only 100 acre-feet per year for Frenchman Flat (NDWR 2010a), based on previous assumptions that little or no groundwater recharge from precipitation occurred in Basin 160. More-recent studies suggest that in-basin recharge does occur in Basin 160 and perennial yield values are much higher than 100 acre-feet per year. DOE/NNSA has extensively studied the groundwater recharge in Frenchman Flat using a model from the UGTA Project, two U.S. Geological Survey (USGS) models (Hevesi et al. 2003), and two Desert Research Institute models (Russell and Minor 2002). All of these models provide revised estimates of precipitation-driven recharge (and thus perennial yield) of Frenchman Flat using more-rigorous analytical methods and more-recent data. For example, the UGTA Project model estimates a perennial yield of 1,070 acre-feet per year for Frenchman Flat, and the USGS and Desert Research Institute models estimate perennial yields of 1,830 and 1,920 acre-feet per year, respectively. As it stands now, the NNSS appears to be overdrawing water from Frenchman Flat by a large percentage; however, water levels have remained static and have not shown a downward trend of water drawdown, even during peak water usage of 3,375 acre-feet per year in 1989 at the NNSS. This suggests that the perennial yield of Frenchman Flat is significantly higher than 100 acre-feet per year, and more likely in the range of the yields calculated by other DOE and USGS models.

Construction and operation of a commercial solar power generation facility would result in a marked increase in water consumption in Basin 227a (and likely the single largest use of water on the NNSS), resulting in a demand of 10 percent of the sustainable yield of Basin 227a. While the Nevada State Engineer lists the perennial yield of the Jackass Flats Subdivision of Fortymile Canyon as 4,000 acre-feet per year, this value actually represents an aggregation of yield values for several basins adjacent to Basin 227a (i.e., a regional yield value). Studies conducted by DOE/NNSA show a range of values as low as 880 acre-feet per year (DOE 2008d). However, for purposes of this analysis, the perennial yields listed by the Nevada State Engineer were used for all basins.

These demands on each basin would be unlikely to reduce groundwater recharge to another downgradient aquifer to the degree that it reduces that aquifer's sustainable yield or adversely affects current uses of that aquifer. However, DOE/NNSA would still continue to monitor groundwater levels and flow patterns across the NNSS, would employ site-specific modeling to estimate specific impacts of future projects, and would modify the points of diversion and pumping rates if needed to avoid adversely impacting any single aquifer. Therefore, no adverse effects on groundwater supply are expected under the No Action Alternative.

No proposed activities under the No Action Alternative are expected to result in violations of water quality standards, water level drawdowns precluding other uses of an aquifer, or alterations of groundwater recharge adversely affecting downgradient aquifers. Ongoing maintenance of the quality of waters that are currently clean will continue to be managed by the NNSS through implementation of the Groundwater Management Protection Plan. The Groundwater Management Protection Plan includes

measures such as ensuring the continued sustainable use of groundwater through the installation, closing, or buffering of wells to prevent groundwater contamination from testing activities; locating equipment maintenance and fueling areas away from groundwater wells; and conducting periodic groundwater sampling to identify adverse impacts on groundwater during current operations. Aspects of specific projects and activities under the NNSS missions, particularly water quality effects, are discussed in the remainder of Section 5.1.6.2.

5.1.6.2.1.1 National Security/Defense Mission

Past underground nuclear testing has contaminated some groundwater resources at the NNSS, as discussed in Chapter 4, Section 4.1.6. The NNSS must maintain the capability to conduct nuclear tests under the Stockpile Stewardship and Management Program.

Under the Stockpile Stewardship and Management Program, the NNSS would conduct up to 10 dynamic experiments per year in Areas 1–4, 6–12, 16, 19, and 20 and would perform up to 30 conventional high-explosives experiments per year at BEEF and other locations in Areas 1–4, 12, and 16. While these types of experiments can release hazardous materials at or below ground surface, the NNSS operates under standard operating procedures that ensure no experiments are conducted within approximately 300 feet of the groundwater table. Given these operational restrictions and the depth of groundwater at the NNSS (up to 2,000 feet below the ground surface), these experiments are not expected to result in any adverse impacts on groundwater quality.

The NNSS would conduct five "post-shot" drillback operations over the next 10 years under the Stockpile Stewardship and Management Program. Drillback operations provide essential data on the results and post-shot underground environment of areas previously used for an underground nuclear test. Drillback activities have been conducted since the end of underground nuclear testing as a means of exercising the capability to do such drilling (maintenance of capability) and to obtain data for groundwater studies. There is the potential for small quantities of drilling fluids to be introduced to groundwater during drillback operations. However, the drillback operations are conducted in former underground nuclear test sites that are already contaminated, and any contamination resulting from the drillback activities would not result in any new violation of water quality standards.

DOE/NNSA's Office of Secure Transportation conducts exercises on the NNSS to maintain the skills of personnel transporting nuclear weapons. Convoy exercises may be conducted up to six times annually and could include activities such as refueling of vehicles in off-road areas. Any potential impacts associated with substances (i.e., fuels, oils, and other lubricants) leaking into soils and entering groundwater aquifers would be avoided through the use of best management practices (BMPs) to prevent spills or leaks, as well as the extreme depth to groundwater at most locations. Such BMPs would include regular inspection of vehicles and routine maintenance checks to limit adverse impacts.

Under the Work for Others Program, the DOE/NNSA NSO would support DoD in unmanned aerial system field-testing and training activities. Should unmanned aerial system operations encounter complications (e.g., an emergency landing), there is the possibility that aircraft fuel or other hazardous materials could leak and result in localized soil contamination. However, the depth to groundwater and existing procedures for emergency response and site remediation make it highly unlikely that contaminants would impact groundwater resources.

While other activities under the National Security/Defense Mission require the use of hazardous materials, or would generate hazardous or radioactive wastes, these activities are performed in contained locations and use operational procedures that preclude the release of contaminants to groundwater.

5.1.6.2.1.2 Environmental Management Mission

Groundwater monitoring at the Area 5 RWMC indicates that no contamination of groundwater resources has occurred as a result of waste management activities. Annual modeling exercises used to support the performance assessment for the Area 5 RWMC conclude that no groundwater pathway exists for this

disposal facility (NSTec 2010f). Given the depth to groundwater at waste disposal facilities at Area 3 and the stringent operating controls and monitoring programs, LLW and MLLW disposal operations are not expected to adversely affect groundwater resources.

Hazardous waste generated at the NNSS would be stored up to 1 year prior to shipment for offsite treatment. Additionally, JASPER would generate approximately 24 cubic meters of TRU waste per year that would be stored at the TRU Storage Pad pending characterization and shipment off site. While small releases of hazardous or TRU waste are possible during storage or transportation, stringent operating procedures would reduce the likelihood of such an event. The depth to groundwater in most areas of the NNSS and the stringent operating controls and inspection programs in place would preclude contamination of groundwater resources from a release.

Environmental Restoration Program activities at the NNSS include the UGTA Project, which monitors groundwater in the interest of developing groundwater flow and transport models to assist in remediation strategies. Groundwater use during environmental activities under the UGTA Project would be limited to dust control, drilling and testing of wells, decontamination of sampling materials, and purging of wells prior to sampling. The greatest demand for nonpotable water would be during drilling of a new well. It was estimated that water demand for drilling of a new well would be approximately 6 acre-feet. Through 2020, it is expected that a maximum of 5 new wells a year would be drilled throughout the NNSS, totaling an annual nonpotable demand of approximately 30 acre-feet per year. This demand is included with the estimate of total demand across the NNSS for this alternative.

The Industrial Sites Project would continue decontaminating and decommissioning facilities through 2012. Decommissioning of facilities is unlikely to affect groundwater due to the short duration of these activities, the small quantity of contaminants that could be released, and the extreme depth of the groundwater. Nonpotable water demands for dust suppression during decontamination and decommissioning (D&D) would be temporary and minor (estimated at less than 1 percent of total water use).

The Borehole Management Program plugs unneeded boreholes that exist throughout the NNSS. Based on the current schedule, DOE/NNSA would complete plugging by 2013 (see Table A–3). This activity would serve to eliminate potential pathways for contaminants to reach groundwater resources.

5.1.6.2.1.3 Nondefense Mission

DOE/NNSA may enter into an agreement with a commercial entity to construct a solar power generation facility within Area 25. The additional water demand associated with this project is presented in the previous overview subsection for this alternative, and is not expected to result in adverse impacts related to groundwater supply. While numerous hazardous materials (e.g., fuel, lubricants, heat transfer fluid) would be stored and used during both construction and operation of the commercial solar power generation facility, any releases are not expected to adversely impact groundwater quality. These materials would be handled and stored in accordance with established spill prevention and response procedures, and any releases would be promptly contained, and contaminated soil managed appropriately.

DOE/NNSA would continue to employ water conservation measures at the NNSS as described in annual Site Sustainability Plans prepared in accordance with DOE Order 436.1, *Departmental Sustainability*. Goals under the fiscal year 2012 plan include achieving by fiscal year 2020 a 26 percent reduction in water use intensity and a 20 percent reduction in water consumption for industrial landscaping.

As per the DOE/NNSA NSO Energy Executable Plan of December 2008, the goal is to reduce potable water production by at least 16 percent from the 2007 level. This reflects an average reduction in water consumption of approximately 2 percent per year (see **Table 5–24**). To accomplish this positive effect on groundwater resources, the NNSS began saving water through several water conservation measures and BMPs for water efficiency. Examples include the installation of water-conserving products (more-efficient toilets, urinals, faucets, showerheads, boiler systems, and other items), xeric landscaping,

water-efficient irrigation, system audits and repairs of leaks, use of nonpotable water for dust suppression when possible, and institution of 4-day workweeks.

Table 5–24 Potable Water Production Goals

Year	*Potable Water Production Goals (millions of gallons)*	*Cumulative Percent Reduction*	*Actual Water Production (millions of gallons)*
2007	210.6	Base Year	225.2
2008	206	2	172.6
2009	202	4	190
2010	198	6	N/A
2011	194	8	N/A
2012	190	10	N/A
2013	185	12	N/A
2014	181	14	N/A
2015	177	16	N/A

Source: NSTec 2009e.

5.1.6.2.2 Expanded Operations Alternative

This section describes the proposed changes to activities under the Expanded Operations Alternative and their associated impacts on groundwater resources.

Under the Expanded Operations Alternative, the NNSS workforce would increase by approximately 25 percent from the No Action Alternative, activity levels of existing programs would increase, and some new facilities and operations would be phased in over the 10-year planning period. The NNSS water supply system would also be expanded as necessary to connect to new facilities that would be constructed.

As potable water uses would likely continue to represent the majority of total water demand (see Chapter 4, Section 4.1.6.2), it was estimated that total water use (i.e., potable and nonpotable) (excluding construction and operation of one or more solar power generation facilities) would increase by approximately 25 percent from the value analyzed under the No Action Alternative. This results in an estimate of approximately 862 acre-feet per year for all activities excluding construction or operation of commercial solar power generation facilities. However, the implementation of water conservation efforts in support of the NNSS Energy Executable Plan would likely result in more efficient potable and nonpotable water uses, making this a conservative estimate.

Under the Expanded Operations Alternative, one or more commercial solar power generation facilities with a combined capacity of up to 1,000 megawatts would add an additional demand of approximately 700 acre-feet per year. During construction of the solar power generation facilities, there would be a temporary demand of approximately 1,000 acre-feet per year for 42 months to support dust suppression, soil compaction, and other facility construction needs.

Table 5–25 summarizes the demand on each basin associated with a withdrawal of 862 acre-feet per year, as well as additional demands associated with commercial solar power generation facilities (discussed in subsequent paragraphs), and compares these demands to the sustainable yield of each basin.

As illustrated in Table 5–25, annual withdrawals from each basin under the Expanded Operations Alternative would be well below the sustainable yield of each basin, with the exception of Frenchman Flat. The greatest demand from DOE/NNSA activities would be placed on Frenchman Flat, with approximately 591 percent of the basin's sustainable yield consumed on an annual basis. As discussed in Section 5.1.6.2.1, although the Frenchman Flat basin appears to be overdrawn, there is no evidence of a downward trend of water drawdown in the basin, and the perennial yield is believed to be much higher when groundwater recharge into the basin is considered. The UGTA Project has the most conservative estimate of perennial yield for Basin 160 (1,070 acre-feet per year), compared to those of the USGS and

the Desert Research Institute models (1,830 and 1,920 acre-feet per year, respectively). Construction of one or more commercial solar power generation facilities would result in a temporary marked increase in water consumption in Basin 227a (with construction demand exceeding all other uses of water on the NNSS), resulting in a demand of 27 percent of the sustainable yield of Basin 227a. Operation of the commercial solar power generation facilities would also result in a marked increase in water consumption in Basin 227a, resulting in a demand of 19 percent of the sustainable yield of Basin 227a.

Table 5–25 Impacts on Groundwater Supply Under the Expanded Operations Alternative

Basin	*Water Demand, Excluding Solar Power Generation Facilities (acre-feet per year)*	*Water Demand, Including Construction Demand from Solar Power Generation Facilities (acre-feet per year)*	*Water Demand, Including Operational Demand from Solar Power Generation Facilities (acre-feet per year)*	*Sustainable Yield of Basin (acre-feet per year)*	*Maximum Percentage of Sustainable Yield Consumed During Construction*	*Maximum Percentage of Sustainable Yield Consumed During Operation*
Frenchman Flat (160)	591	591	591	100	591%	591%

Source: Derived from Chapter 4, Tables 4–24, 4–27, and 4–30.

The demands on each basin would be unlikely to reduce groundwater recharge to another downgradient aquifer to the degree that it reduces that aquifer's sustainable yield or adversely affects current uses of that aquifer because the flow out of each basin would be less than the flow into each basin. However, DOE/NNSA would continue to monitor groundwater levels and flow patterns across the NNSS, would employ site-specific modeling to estimate specific impacts of future projects, and would modify the points of diversion and pumping rates if needed to avoid adversely impacting any single aquifer.

No proposed activities under the Expanded Operations Alternative are expected to result in violations of water quality standards, water-level drawdowns precluding other uses of an aquifer, or alterations of groundwater recharge adversely affecting downgradient aquifers. Aspects of specific projects and activities under the NNSS missions, particularly water quality effects, are discussed in the remainder of Section 5.1.6.2.2.

5.1.6.2.2.1 National Security/Defense Mission

New facilities. DOE/NNSA is proposing 39,000 square feet of permanent facilities for the Office of Secure Transportation in Area 17 to support training activities, as well as a mock town and live-fire training area. The Office of Secure Transportation also proposes to construct 30,000 square feet of maintenance and administrative buildings and a 20,000-square-foot dormitory in Area 6, 12, or 23. Approximately 85,000 square feet of new facilities are also proposed under the Nuclear Emergency Response, Nonproliferation, Counterterrorism, and Work for Others Programs, collectively disturbing an additional 500 acres of land, although locations for these facilities are not yet known. Depending on the exact location and final design of these facilities, additional water supply infrastructure, such as distribution pipelines and water storage tanks would also be constructed. It is not known at this time whether additional water supply wells would be required to support these facilities.

Various types and quantities of hazardous materials (e.g., fuel, lubricants, and paints) would be stored and used at construction sites, and small spills or leaks could possibly occur. Adherence to established spill control procedures would reduce the likelihood of such an event, and the depth to groundwater across

most of the NNSS would generally preclude such spills from reaching groundwater sources. Additionally, the location of the permanent facilities and construction sites would also be evaluated for their proximity to water supply wells to avoid wellhead contamination. Therefore, impacts on groundwater quality are not expected to occur from facility construction activities.

Construction would require water for activities such as mixing concrete, washing equipment, dust control and soil compaction, and meeting the sanitary needs of construction employees. It is anticipated that this water would be obtained from the NNSS's groundwater distribution system via a temporary service connection or would be trucked to the point-of-use, especially during the early stages of construction. Although the timing and intensity of individual construction activities are not known at this time, it was estimated that approximately 250 construction employees (excluding those associated with one or more proposed commercial solar power generation facilities) would be present at the NNSS at any given time (see Section 5.1.4). Assuming that construction workers would each use approximately 30 gallons of potable water per day, total potable water demand for these workers was estimated at approximately 1.8 million gallons (5.5 acre-feet) annually. However, use of portable toilets by construction personnel could greatly reduce this demand.

Annual nonpotable water demands from these construction projects would vary greatly, depending on the type of facility and the construction phase of each project, and are not well known at this time. However, the assumption of a 25 percent increase in all water uses (including nonpotable uses) from the No Action Alternative provides a conservative estimate of demand associated with these and other nonpotable uses in any given year. Given the remaining sustainable capacity of the water supply system at the NNSS, no adverse impacts are expected on aquifer supply and recharge from these construction activities.

The design of new facilities would include more-efficient water conservation design and measures (e.g., installation of WaterSense™ products [toilets, urinals, faucets, showerheads, boiler systems, and other items] and xeric landscaping) combined with demolition of existing facilities under the Environmental Management Mission, which would help offset water use once these facilities become operational. The estimate of a 25 percent increase in total annual water consumption noted in the introduction to Section 5.1.6.2.2 incorporates the demand from personal and nonpersonal uses of water once new facilities are occupied.

Experiments and activities. Under the Expanded Operations Alternative, DOE/NNSA proposes increases in both the frequency and intensity of ongoing activities described under the No Action Alternative. For example, within the Stockpile Stewardship and Management Program, the number of conventional high-explosive detonations would increase to as high as 100 per year (from 20), and the size of the charges would increase to up to 120,000 pounds (from 70,000 pounds) of TNT-equivalent explosives. This increase in operational tempo would also result in increased levels of waste generation (e.g., a three-fold increase in TRU waste from experiments at JASPER) throughout the NNSS. However, the same factors that preclude impacts on groundwater quality (e.g., contained and/or aboveground nature of experiments, depth to groundwater, operational controls, and groundwater monitoring programs) under the No Action Alternative would continue to all ongoing activities in the Expanded Operations Alternative. DOE/NNSA does not estimate any additional impacts on groundwater quality from activities under the Expanded Operations Alternative.

Several new or significantly revised activities are also proposed under the Expanded Operations Alternative. Within the Stockpile Stewardship and Management Program, DOE/NNSA would establish up to three areas at the NNSS for conducting explosive experiments with depleted uranium. While the locations and operational parameters of these experiments have not been fully defined, DOE/NNSA would consider site- and project-specific criteria (e.g., local groundwater depth and movement rates, solubility of potential contaminants) in the planning process to ensure that depleted uranium or other chemical contaminants would not adversely affect groundwater resources.

Under the Work for Others Program, DOE/NNSA would support NASA nuclear rocket motor development, including the use of existing boreholes to test their suitability for sequestering of emissions. Although testing of an actual nuclear rocket is not planned at this time, NASA may conduct a proof-of-concept experiment using a surrogate, such as xenon, in a borehole. Any radioactive materials released in the subsurface in this or other related experiments (such as radioactive tracer experiments) would have short half-lives and would be used well above the groundwater table; as such, they are not expected to adversely affect groundwater quality.

As noted in Chapter 3 of this SWEIS, there are several activities and facilities considered for the NNSS that are still conceptual in nature; no detailed design or siting information is available at this time. These include construction of test beds and support facilities for nonproliferation and counterterrorism activities; new counterterrorism training facilities and reconfiguration of the RNCTEC facility for DHS; and additional facilities for nuclear material detection training for DHS and other Federal agencies. These types of conceptual facilities and activities would undergo an appropriate level of NEPA review and documentation before they would be implemented.

5.1.6.2.2.2 Environmental Management Mission

Waste management activities on the NNSS would increase under the Expanded Operations Alternative, with up to 44,498,253 cubic feet of LLW and 2,790,583 cubic feet of MLLW disposed at the Area 5 RWMC and Area 3 RWMS. TRU waste amounts stored at the TRU Storage Pad pending characterization and shipment off site would increase to approximately 1,766 cubic feet. Annual modeling exercises used to support performance assessments for the Area 5 RWMC and Area 3 RWMS conclude that no groundwater pathway exists for these disposal facilities (NSTec 2010f). Although the waste management activities would increase, the absence of a groundwater pathway, the depth to groundwater at waste disposal facilities at Areas 3 and 5, and the stringent operating controls and monitoring programs, LLW and MLLW disposal operations are not expected to adversely affect groundwater resources.

DOE/NNSA would construct sanitary solid waste disposal facilities as needed in Area 23, and develop a new sanitary solid waste disposal site in Area 25 to support environmental restoration activities, as well as the construction associated with potential solar energy projects in Area 25. These facilities would incorporate contaminant containment strategies in their design, and are not expected to result in adverse impacts on groundwater quality during their construction or operational phases.

No changes to environmental restoration activities are proposed under the Expanded Operations Alternative.

5.1.6.2.2.3 Nondefense Mission

Infrastructure-related activities, including repairs and replacements, would include increasing the capacities, capabilities, and ranges of facilities to accommodate expanded operations. Approximately 300,000 square feet of new facilities would be constructed to support air operations, Desert Rock Airport, and security requirements. Similar to the construction activities described in Section 5.1.6.1.2, these activities are not expected to result in any adverse impacts on groundwater quality or supply.

Any facilities that are no longer required and economically salvageable would be decommissioned. Decommissioning activities are unlikely to affect groundwater quality due to their short durations, operational controls applied, and the depth of the groundwater. Nonpotable water demands for dust suppression during decommissioning would be smaller than those required for construction activities, and would not strain the sustainable capacity of the NNSS. The estimated 25 percent increase in total water use under the Expanded Operations Alternative incorporates any water demand that would occur as a result of decommissioning facilities.

DOE/NNSA may enter into an agreement with a commercial entity to construct one or more solar power generation facilities within Area 25. Under the Expanded Operations Alternative, the generating capacity

of the commercial solar power generation facilities would increase to 1,000 megawatts. While numerous hazardous materials (e.g., fuel, lubricants, heat transfer fluid) would be stored and used during both construction and operation of the commercial solar power generation facilities, any releases are not expected to adversely impact groundwater quality. These materials would be handled and stored in accordance with established spill prevention and response procedures, and any releases would be promptly contained, and contaminated soil managed appropriately. The notional design for this solar power generation facility includes a bioremediation cell for the segregation and remediation of contaminated soil.

Additionally, DOE/NNSA proposes to construct a 5-megawatt photovoltaic solar power generation facility near the Area 6 Construction Facilities. It was estimated that annual nonpotable water use would total approximately 165,000 gallons (0.5 acre-feet) per year, which is only a small fraction of the total water use on the NNSS.

DOE/NNSA would additionally explore the NNSS for geothermal energy to evaluate the feasibility of developing a Geothermal Demonstration Project. There are seven locations on the NNSS that have enhanced geothermal potential, as depicted in Appendix A, Figure A–3. Several boreholes may be drilled up to 20,000 feet in depth, and the development of a reservoir would be necessary to store water during drilling. Minor quantities of drilling fluids may be introduced to groundwater during drilling operations, but are not expected to result in violation of any water quality standards or otherwise threaten potable water sources. The nonpotable water demand to prime the system initially (which includes the boreholes and reservoir) would be approximately 20 acre-feet on a one-time basis, or about 2 percent of the NNSS's water use in any year. Once a geothermal power plant is continuously operating, it was estimated that 50 acre-feet of water would be required annually (about 6 percent of the NNSS average annual water use). The seven locations on the NNSS to be possibly explored for enhanced geothermal potential are located within six separate hydrographic basins. Of the six basins, Yucca Flat, with 350 acre-feet available for withdrawal, has the lowest remaining yield for groundwater withdrawals (see Chapter 4, Table 4–24). An annual operational use of 50 acre-feet per year would represent 14 percent of this basin's available yield, resulting in a minor impact. Impacts on the remaining five hydrographic basins would be lower as the remaining yield for withdrawals are greater. Therefore, construction, initial priming, and operational water demands from this project would not significantly affect groundwater supply in any of the six basins to be possibly explored.

5.1.6.2.3 Reduced Operations Alternative

This section describes the proposed changes to activities under the Reduced Operations Alternative and their associated impacts on groundwater resources. Under the Reduced Operations Alternative, the frequency and scope of most ongoing activities at the NNSS would be reduced, and no new activities and facilities (even if selected in a previous NEPA decision) would be implemented. Several activities would be more geographically restricted than under the other alternatives in this SWEIS, and a 10 percent reduction in workforce from the No Action Alternative is expected.

As potable water uses would likely continue to represent the majority of total water demand (see Chapter 4, Section 4.1.6.2), it was estimated that total water use (excluding construction and operation of a solar power generation facility) would also decrease by 10 percent from that projected for the No Action Alternative, to approximately 622 acre-feet per year. However, the implementation of water conservation efforts in support of the NNSS Energy Executable Plan would likely result in more efficient potable and nonpotable water uses, making this a conservative estimate.

Under the Reduced Operations Alternative, the size of the commercial solar power generation facility would decrease to 100 megawatts in generating capacity. This facility would add an additional demand of approximately 175 acre-feet per year. During construction of the solar power generation facility, there would be a temporary demand of approximately 200 acre-feet per year for 32 months to support dust suppression, soil compaction, and other facility construction needs.

Table 5–26 summarizes the demand on each basin associated with a withdrawal of 622 acre-feet per year, as well as additional demands associated with a commercial solar power generation facility (discussed in subsequent paragraphs), and compares these demands to the sustainable yield of each basin.

As illustrated in Table 5–26, annual withdrawals from each basin under the Reduced Operations Alternative would be well below the sustainable yield of each basin, with the exception of Frenchman Flat. The greatest demand would be placed on Frenchman Flat, with approximately 427 percent of the basin's sustainable yield consumed on an annual basis. As discussed in Sections 5.1.6.2.1 and 5.1.6.2.2, the Frenchman Flat basin appears to be overdrawn, however, there is no evidence of a downward trend of water drawdown in the basin, and the perennial yield is believed to be much higher when groundwater recharge into the basin is considered. The UGTA Project has the most conservative estimate of perennial yield for Basin 160 (1,070 acre feet per year) compared to those of the USGS and the Desert Research Institute models (1,830 and 1,920 acre-feet per year, respectively). While construction and operation of a commercial solar power generation facility would result in a marked increase in water consumption in Basin 227a (construction demand would likely be the single largest use of water on the NNSS), the resulting demand would be 6 percent of the sustainable yield of Basin 227a.

Table 5–26 Impacts on Groundwater Supply Under the Reduced Operations Alternative

Basin	***Water Demand, Excluding Solar Power Generation Facility (acre-feet per year)***	***Water Demand, Including Construction Demand from Solar Power Generation Facility (acre-feet per year)***	***Water Demand, Including Operational Demand from Solar Power Generation Facility (acre-feet per year)***	***Sustainable Yield of Basin (acre-feet per year)***	***Maximum Percentage of Sustainable Yield Consumed During Construction***	***Maximum Percentage of Sustainable Yield Consumed During Operation***
Frenchman Flat (160)	427	427	427	100	427%	427%
Fortymile Canyon, Buckboard Mesa subdivision (227b)	38	38	38	3,600	1%	1%
Fortymile Canyon, Jackass Flats subdivision (227a)	42	242	217	4,000	6%	5%
Yucca Flat (159)	115	115	115	350	33%	33%

Source: Derived from Chapter 4, Tables 4–24, 4–27, and 4–30.

These demands on each basin would be unlikely to reduce groundwater recharge to another downgradient aquifer to the degree that it would reduce that aquifer's sustainable yield or adversely affect current uses of that aquifer. However, DOE/NNSA would continue to monitor groundwater levels and flow patterns across the NNSS, employ site-specific modeling to estimate specific impacts of future projects, and modify the points of diversion and pumping rates if needed to avoid adversely impacting any single aquifer. Therefore, no adverse effects on groundwater supply are expected under the Reduced Operations Alternative.

No proposed activities under the Reduced Operations Alternative are expected to result in violations of water quality standards, water level drawdowns precluding other uses of an aquifer, or alterations of groundwater recharge adversely affecting downgradient aquifers. Aspects of specific projects and activities under the NNSS missions, particularly water quality effects, are discussed in the remainder of Section 5.1.6.2.3.

5.1.6.2.3.1 National Security/Defense Mission

Under the Reduced Operations Alternative, DOE/NNSA would reduce the frequency and scope of experiments and activities and place additional geographic restrictions on ongoing activities. Specifically, Areas 12, 18, 19, and 20 would not support most activities within the National Security/Defense Mission.

This would effectively curtail most activities (other than environmental restoration) in the northwest portion of the NNSS. DOE/NNSA does not anticipate any adverse impacts on groundwater quality from National Security/Defense Mission activities under the Reduced Operations Alternative.

5.1.6.2.3.2 Environmental Management Mission

Under the Reduced Operations Alternative, LLW and MLLW waste disposal would remain the same as under the No Action Alternative. Onsite generation of hazardous, nonhazardous, and TRU waste would decrease relative to the No Action Alternative. DOE/NNSA does not anticipate any adverse impacts on groundwater quality from waste management activities under the Reduced Operations Alternative.

No change in Environmental Restoration Program activities is proposed under this alternative. Although most defense-related activities would cease in the northwest portion of the NNSS, environmental restoration and environmental monitoring activities would continue as described under the No Action Alternative. Therefore, impacts would remain the same as those under the No Action Alternative.

5.1.6.2.3.3 Nondefense Mission

Under the Reduced Operations Alternative, the only new infrastructure considered would be a solar power generation facility, whose net generating capacity would be reduced to 100 megawatts. The additional water demand associated with this project is presented in the previous introductory subsection for this alternative and is not expected to result in adverse impacts related to groundwater supply. While numerous hazardous materials (e.g., fuel, lubricants, heat transfer fluid) would be stored and used during both construction and operation of the commercial solar power generation facility, any releases are not expected to adversely impact groundwater quality. These materials would be handled and stored in accordance with established spill prevention and response procedures; any releases would be promptly contained, and contaminated soil would be managed appropriately. The notional design for this solar power generation facility includes a bioremediation cell for the segregation and remediation of contaminated soil.

Hydrology—American Indian Perspective

CGTO The Consolidated Group of Tribes and Organizations (CGTO) knows we are in a drought because humans have disrespected the earth. It is affecting the balance of our earth's climate. One inevitable implication of the current 100-year drought is that the surface water[1] on the Nevada National Security Site (NNSS) and immediate areas have diminished and become more sporadic. The modification and availability of surface water has the ability to affect all trophic levels on the NNSS.

Other tribal elders noted, *"Water has been disrespected and therefore it is disappearing. It is a medicine—used to heal and used for healing. It is used for ceremonial purposes in prayer. It is alive and must be awakened. It is spiritual--an essential component to begin religious ceremonies, and part of sweat ceremonies. Historically, water was pure and available to those who respected it. Bathing was a ritual. Now we do not trust the purity of the water because it has been disrespected. Hot springs have been affected and are no longer at the temperatures they used to be."*

When humans respect water, it sustains them and life-forms on the surface, but when water is not treated well, it withdraws its life-giving support and returns to the underworld. The CGTO knows that the springs on Pahute and Rainier mesas and near Buckboard Mesa have dried up. Water has returned to the underworld because it has not been treated correctly by the U.S. Department of Energy (DOE) activities. There are places on the NNSS where the rain falls but does not nurture the plants and animals. The CGTO wants to be involved in DOE hydrology studies because if the water continues to be treated in inappropriate ways, it will totally remove itself from the NNSS.

See Appendix C for more details.

[1] *Surface water is defined here as water available for shallow rooted plants during rainfall, water available during post-rain ponding, runoff, and absorption, and water recharged into near-surface aquifers.*

5.1.7 Biological Resources

Biological resources addressed in this impact analysis include native and nonnative vegetation and wildlife that inhabit or otherwise use DOE/NNSA sites in Nevada. Nonnative invasive or introduced species are generally considered deleterious. Both RSL and NLVF are located within developed urban settings that are devoid of natural habitat and are maintained with ornamental plant species. For this reason, detailed analysis of impacts on biological resources is limited to the NNSS and the TTR in this *NNSS SWEIS*.

Adverse impacts on wildlife include damage to or loss of habitat, direct mortality, and disturbance. Adverse impacts on vegetation include direct removal and reduction in suitable growing area. Loss of habitat and reduction in growing area are directly related to acres of land disturbed. Adverse impacts on soils, wells, and springs would also result in adverse impacts on vegetation and wildlife. DOE/NNSA is subject to, and complies with, existing laws, regulations, and policies regarding protection of sensitive and otherwise regulated plant and animal species and has established practices to minimize or avoid potential adverse effects on biological resources.

The following criteria are used in this analysis of potential impacts on biological resources resulting from activities of DOE/NNSA in Nevada:

- Area of land disturbance, i.e., habitat loss, particularly important habitats, and potential damage to biologically important habitat features, such as wells, springs, wetlands, and other resources that support biological resources. Impacts on habitats by land disturbance could affect both wildlife and native vegetation.
- The potential of proposed activities to cause damage to any species protected by applicable statutes, including exceeding the terms and conditions in the *Final Programmatic Biological Opinion for Implementation of Actions Proposed on the Nevada Test Site, Nye County, Nevada* (*2009 Biological Opinion*) (USFWS 2009a). It is important to note that the analyses of potential impacts on biological resources in this SWEIS are conservative and are not intended to represent a biological assessment within the meaning of the U.S. Fish and Wildlife Service (USFWS) in its regulations implementing the Endangered Species Act. For this reason, where the take of desert tortoises may appear to exceed the tems and conditions of the *2009 Biological Opinion*, this is only for purposes of comparing the relative impacts of the alternatives addressed in this SWEIS.

Table 5–27 shows the potential area of land that would be disturbed for each mission and program area under each of the three alternatives. Potential land disturbance related to UGTA and Soils Projects activities on the Nevada Test and Training Range (except the TTR) are included in the analysis of potential impacts on biological resources at the NNSS. In 2008, the DOE/NNSA NSO estimated that about 790,400 acres, or about 91 percent of the total area of the NNSS, were considered undisturbed land based on implementation of the Expanded Use Alternative from the *1996 NTS EIS* (DOE 2008f). Although some projects envisioned in 1996 were not implemented, such as construction of a large defense industrial complex or a commercial solar power generation facility, there have been other land-disturbing projects, such as the RNCTEC and various security improvements in the areas around some facilities. For purposes of this analysis, it was assumed that about 790,400 acres of the NNSS would remain undisturbed and that all undisturbed land would continue to provide habitat for wildlife.

NERNC = Nuclear Emergency Response, Nonproliferation, and Counterterrorism; NNSS = Nevada National Security Site.

[a] Percentages may not sum due to rounding.

[b] Land disturbance for Environmental Restoration activities includes 500 acres for new Underground Test Area Project groundwater characterization and monitoring wells and 420 acres for Soils Project sites. About one-half (250 acres) of the disturbance for new characterization and monitoring wells was assumed to occur on land owned or managed by others adjacent to the NNSS on the Nevada Test and Training Range, Bureau of Land Management (BLM) land, and privately owned land. Almost all of the 420 acres of land disturbance for the Soils Projects sites would occur on the Nevada Test and Training Range. For purposes of analysis and because of the close proximity of the portions of the Nevada Test and Training Range, BLM land, and privately owned land that would be disturbed, all land disturbances associated with these Environmental Restoration Program activities are included with NNSS land disturbances.

Disturbance impacts on vegetation are considered permanent when there is no evidence to indicate that predisturbance levels of biomass, cover, density, soils, and plant community structure could be achieved within approximately 5 years of the disturbance or of conducting reclamation efforts. Based on this, all vegetation disturbances under each of the alternatives would be considered permanent because reclamation is not required for all land disturbances at the NNSS; therefore, reclamation was not assumed for any land disturbances.

Under all alternatives, disturbance of native vegetation either by direct removal or by mechanical damage from off-road vehicular or pedestrian traffic could promote the proliferation of nonnative invasive weeds, such as Russian thistle. This species is currently not listed on the Nevada noxious weed list, but is considered aggressive and opportunistic, and often portrays weed-like trends. Other weed species that could invade the disturbed areas over the long term include puncture vine (*Tribulus terrestris*), perennial pepperweed (*Lepidium latifolium*), gumweed (*Grindelia* spp.), yellow star thistle (*Centaurea solstitialis*), and Russian knapweed (*Acroptilon repens*). Other impacts on vegetation include soil compaction, spread of weeds already present in the disturbance footprint to areas not currently infested, and accidental introduction of new weed species from contaminated equipment brought in from other regions. DOE/NNSA takes positive steps to prevent the introduction and/or spread of noxious weeds at the NNSS, as described in Chapter 7, Section 7.7.

Endangered Species Act Definitions

Endangered Species – Any species that is in danger of extinction throughout all or a significant portion of its range.
